## USE IN LIFE SUPPORT DEVICES OR SYSTEMS MUST BE EXPRESSLY AUTHORIZED

## 555

SGS-THOMSON PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF SGS-THOMSON Microelectronics. As used herein:

1. Life support devices or systems are those which (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided with the product, can be reasonably expected to result in significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can reasonably be expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

SGS-THOMSON's dedicated video product range is now so extensive that it has been necessary to divide the databook into two volumes: one for power devices and graphic circuits and one for signal devices. Application notes for video products have been gathered together in the video products Application Manual.

Volume 1, Signal Processing Products, covers chroma and video ICs, single-chip processors, video switch matrices and other signal level parts. In this area the company specializes in offering complete solutions all of the ICs needed for a specific TV or monitor chassis type and gives special attention to the basic solutions. Much of the knowhow in this field has been gained in the demanding Asia/Pacific market for the cost effective aspect, and in western Europe for PAL/SECAM multistandard design, placing SGS-THOMSON in a very strong position in the emergent East European market the new frontier in consumer electronics.

Volume 2, Power \& Graphics Products, covers power ICs such as deflection boosters and sound channels, plus other ICs for graphics monitor deflection applications. In the monitor market SGS-THOMSON is the recognized world leader; in fact today 7 out of 10 monitors produced in the world include SGS-THOMSON ICs. Power ICs in general are a traditional specialty of the company, which began producing monolithic power amplifiers in the 60's and has remained at the forefront of power technology development ever since.

With these two volumes SGS-THOMSON Microelectronics proposes a dedicated video product range that satisfies virtually every need in television, monitor, VCR and related applications. And if you don't find the product you are looking for in these volumes contact the nearest SGS-THOMSON office; it may be that the product you want is included in other books covering micros, memories, standard ICs or discretes.

The Video Products Application Manual is part of the comprehensive technical support offered by SGS-THOMSON's Video Division to make application design fast and productive. This support also includes PC design aids and evaluation boards.

* Darlington
- Typical Value
- Also Ideal for SMPS

The Fastswitching BUH Series is a new family of high voltage Bipolar Transistors fully dedicated to TV and Monitor application. Their switching performance coupled with a new style of characterization make then ideal for horizontal deflection in most standard and high definition displays.

## DEFLECTION DIODE

## SELECTION GUIDE

## CHROMA

## CHROMA VIDEO CIRCUITS

| Type <br> Number | Description | Packages | Page/DB |
| :--- | :--- | :--- | :---: |
| TDA3562A | PAL/NTSC One-Chip Decoder \& Video Processor | DIP28 | 901 |
| TDA8217 | PAL Decoder \& Video Processor | DIP20 | 1107 |
| TEA5040 | Bus-controlled Video Processor | DIP40 | 1187 |
| TEA5640E | PAL/SECAM/NTSC 3.58/NTSC 4.53 Decoder | DIP28 | 1227 |
| TEA5640F | PAL/SECAM Decoder | DIP28 | 1241 |
| TEA5652 | Wide Band Video Processor | DIP28 | 1255 |

RGB HIGH Voltage output stage

| Type <br> Number | Description | Packages | Page/DB |
| :--- | :--- | :--- | :---: |
| TDA8153 | RGB Video Output Amplifier | MULTIWATT15 | ao |
| TEA5101A | RGB Video Output Amplifier | MULTIWATT15 | ao |

VIDEO CHROMA \& DEFLECTION PROCESSOR

| Type <br> Number | Description | Packages | Page/DB |
| :---: | :---: | :---: | :---: |
| STV2100 | PAL Luma-Chroma \& Deflection Processor | SDIP30 | 397 |

## INTERMEDIATE FREQUENCY (IF)

## VIDEO IF CIRCUITS

| Type <br> Number | Description | Packages | Page/DB |
| :--- | :--- | :--- | :---: |
| TDA2540/41 | Video IF System With AFC | DIP16 | 875 |
| TDA4443 | Multistandard Video IF | DIP16 | 927 |
| TDA8123A | Multistandard Video IF System | DIP16 | 1015 |

SOUND IF CIRCUITS

| Type <br> Number | Description | Packages | Page/DB |
| :--- | :--- | :--- | :---: |
| TDA1190Z | TV Sound Channel | FINDIP | 865 |
| TDA3190 | TV Sound Channel | DIP16 | $891, \mathrm{~d}$ |
| TDA4190 | TV Sound Channel | DIP20 | $909, \mathrm{~d}$ |
| TDA4445A/B | Multistandard Sound IF | DIP16 | 935 |

| STI3220 | 20 | PLCC44 | $61, \mathrm{~m}$ |  |

## IMAGE PRE-POST PROCESSING DEVICES

| Type <br> Number | Description | Data Rate <br> $(\mathbf{M H z})$ | Package | Page/DB |
| :---: | :--- | :---: | :---: | :---: |
| IMSA110 | 2 Dimensional Filter / Convolver <br> 21 x 1 or 7 x 3 Kermel <br> 3 Delay Lines <br> Back-end Processor | 20 | PGA100 | m |
| STV3300 | Filter and Dematrixing Chip <br> Y, U, V to R, G, B Converter | 27 | PLCC52 | $399, \mathrm{~m}$ |
|  | Triple 8-Bit D/A Converter <br> Voltage Outputs | 70 | SHRINK/ <br> SDIP42 | $441, \mathrm{~m}$ |
|  | Internal Voltage Reference <br> External Analog Inputs With Switching Capability |  |  |  |

AUDIO POWER AMPLIFIERS

| Type <br> Number | Description | Packages | Page/DB |
| :--- | :--- | :--- | :--- |
| TDA1904 | 4W Audio Amplifier | POWERDIP (8+8) | ao,d |
| TDA1905 | 5W Audio Amplifier + Mute | POWERDIP (8+8) | ao,d |
| TDA2006 | 12W Audio Amplifier | PENTAWATT | ao,d |
| TDA2007 | 6+6W Stereo Amplifier | SIP9 | ao,d |
| TDA2007A | 6+6W Stereo Amplifier | SIP9 | ao,d |
| TDA2009 | 10+10W Quality Stereo Amplifier | MULTIWATT 11 | ao,d |
| TDA2009A | 10+10W Quality Stereo Amplifier | MULTIWATT 11 | ao,d |
| TDA2030 | 14W Hi-Fi Audio Amplifier | PENTAWATT | ao,d |
| TDA2030A | 18W Hi-FI Audio Amplifier | PENTAWATT | ao,d |
| TDA2040 | 20W Hi-Fi Audio Amplifier | PENTAWATT | ao,d |
| TDA2050 | 28W Hi-Fi Audio Amplifier | PENTAWATT | ao,d |
| TDA2051 | 40W Hi-Fi Audio Amplifier | PENTAWATT | ao,d |
| TDA2052 | 65W Hi-Fi Audio Amplifier With Mute/Stand-By | HEPTAWATT | ao,d |
| TDA2822 | Dual 1.7W Amplifier | DIP16 | ao,d |
| TDA2822D | Dual 1 W Amplifier | SO-8 | ao,d |
| TDA2822M | Dual 1W Amplifier | DIP8/MINIDIP | ao,d |
| TDA2824 | Dual 1.7W Amplifier | POWERDIP (12+2+2) | ao,d |
| TDA2824S | Dual 1.7W Amplifier | SIP9 | ao,d |
| TDA7231A | 1.6W Audio Amplifier | DIP8/MINIDIP | ao,d |
| TDA7233/D | 1W Audio Amplifier + Mute | ao,d |  |
| TDA7233S | 1W Audio Amplifier + Mute | MINIDIP, SO-8 | ao,d |
| TDA7245 | $5 W$ Audio Amplifier | SIP9 | ao,d |
| TDA7246 | 10W Audio Amplifier + Mute and Stand-By | POWER DIP (9+9) | ao,d |
| TDA7250 | Hi-Fi Dual Driver | HEPTAWATT | ao,d |
| TDA7262 | 20+20W High-Quality TV Amplifier | DIP20 | ao,d |

## PREAMPLIFIERS AND AUDIO PROCESSORS

| Type <br> Number | Description | Packages | Page/DB |
| :--- | :--- | :--- | :--- |
| TDA7273 | Stereo Cassette Playback System | SO-16 | $941, \mathrm{~d}$ |
| TDA7300 | Digital Control Stereo Audio Processor | DIP28, SO-28 | $947, \mathrm{~d}$ |
| TDA7302 | Digital Control Stereo Audio Processor | DIP28 | $961, \mathrm{~d}$ |
| TDA7306 | Digital Control Stereo Audio Processor | DIP28 | $973, \mathrm{~d}$ |
| TDA7318 | S-Bus Controlled Audio Processor | DIP28, SO-28 | $785, \mathrm{~d}$ |

## SELECTION GUIDE

## VOLTAGE REGULATORS

| Type Number | Description | Packages | Page/DB |
| :---: | :---: | :---: | :---: |
| L4901A | Dual 5V Regulator With Reset | HEPTAWATT | ao,d |
| L4902A | Dual 5V Regulator With Reset and Disable | HEPTAWATT | ao,d |
| L4903 | Dual 5V Regulator With Reset and Disable | DIP8/MINIDIP | ao,d |
| L4904A | Dual 5V Regulator With Reset | DIP8/MINIDIP | ao,d |
| L4905 | Dual 5V Regulator With Reset and Disable | HEPTAWATT | ao,d |
| TDA8134 | Dual Voltage Regulator With Disable ( $+5.1 \mathrm{~V},+12 \mathrm{~V}$ ) | HEPTAWATT | ao |
| TDA8135 | Dual Voltage Regulator With Disable ( +5 V , Adjustable) | HEPTAWATT | ao |
| TDA8136 | Dual Voltage Regulator With Disable (+12V) | HEPTAWATT | ao |
| TDA8137 | Dual Voltage Regulator With Disable \& Reset ( +5.1 T ) | HEPTAWATT | ao |
| TDA8138 | Dual Voltage Regulator With Disable \& Reset ( +5.1 V ) | SIP9, <br> HEPTAWATT | ao |
| TDA8139 | Dual Voltage Regulator With Disable \& Reset ( +5.1 V ) | SIP9 | ao |
| TEA7605 | Low Dropout Voltage Regulator ( +5 V ) | TO -220 | ao |
| TEA7610 | Low Dropout Voltage Regulator (+10) | TO-220 | ao |
| TEA7685 | Low Dropout Voltage Regulator (+8.5) | TO-220 | ao |

## AUTOMATIC VOLTAGE SWITCH

| Type <br> Number | Description | Packages | Page/DB |
| :--- | :---: | :---: | :---: |
| AVS08 | Automatic Mains Selector (110/220V AC) for SMPS <200W | TO -220AB | 43, ao |
| AVS10 | Automatic Mains Selector (110/220V AC) for SMPS <300W | TO -220AB | 49, ao |
| AVS12 | Automatic Mains Selector (110/220V AC) for SMPS <500W | TO -220AB | 55, ao |

## HIGH CURRENT SWITCHING REGULATORS

| Type <br> Number | Description | Packages | Page/DB |
| :--- | :--- | :--- | :---: |
| L4960 | 2.5A Power Switching Regulator | HEPTAWATT | ao |
| L4962 | 1.5A Power Switching Regulator | HEPTAWATT,(12+2+2) | ao |
| L4963 | 1.5A Power Switching Regulator | DIP18,(12+3+3) | ao |
| L4972A | 2A Power Switching Regulator | POWERDIP (16+2+2), | ao |

## MOTOR CONTROLLERS

| Type <br> Number | Description | Packages | Page/DB |
| :--- | :--- | :--- | :---: |
| L272D | Dual Power Operational Amplifier | SO -16 | $79, \mathrm{~d}$ |
| L272/M | Dual Power Operational Amplifier | DIP8/MINIDIP | $73, \mathrm{~d}$ |
| L2720/2/4 | Low Drop Dual Power Operational Amplifier | POWERDIP (8+8), | $83, \mathrm{~d}$ |
| MINIDIP, SIP9 |  |  |  |
| L2726 | Low Drop Dual Power Operational Amplifier | SO -20 | $91, \mathrm{~d}$ |
| L6232A | Brushless Motor Drivers | PLCC28, PLCC44 | 95 |
| L6243/D | Voice Coil Motor Drivers | SO -20, PLCC44 | 103 |

## LED DISPLAY DRIVERS

| Type <br> Number | Description | Packages | Page/DB |
| :--- | :--- | :--- | :---: |
| M5450/51 | LED Display Driver | DIP40, PLCC44 | ao |
| M5480 | LED Display Driver | DIP28 | ao |
| M5481 | LED Display Driver | DIP20 | ao |
| M5482 | LED Display Driver | DIP20 | ao |

## SPECIAL FUNCTIONS

| Type <br> Number | Description | Packages | Page/DB |
| :--- | :--- | :--- | :---: |
| L6603/04 | Smart Card Interface | DIP28, PLCC28 | 113 |
| L6605 | Smart Card Interface | POWERDIP (12+2+2) | 121 |
| L6720/21 | Minitel Interface | POWERDIP (16+2+2) | ao |
| STV1389AQ | Cable Driver for Digital Transfer | QFP32 | 349 |
| STV1601A | Serial Interface Transmission Encoder | PGA37 | 357 |
| STV1602A | Serial Interface Transmission Decoder | PGA37 | 375 |

PROTECTION DEVICES

## POWER-ON AND POWER-OFF RESET BEHAVIOUR

SGS-THOMSON

TYPICAL APPLICATION

ORDERING INFORMATION

## AVS12

## PROGRAMMABLE - LENGTH DIGITAL DELAY LINE

## FEATURES

Variable length 5-1317 cycles (latencies of 6-1318)
Fully cascadable in width and length
Auto-zeroing of data on length change
Up to 20 MHz data rate
Fully static high speed CMOS implementation
TTL compatible
Single $+5 \mathrm{~V} \pm 10 \%$ Supply
Power dissipation < 250mWatts
44 pin PLCC package

## APPLICATIONS

Image processing
Audio processing
Enhancment of A100/A110/A121 applications
Ghost/echo cancellation
Radar/Sonar Beamforming
Digital TV line buffer
Latency equaliser

## DESCRIPTION

The IMS A113 is a digital Delay line of programmable length. The device can be set up to delay input data from 5 clock cycles up to 1317 clock cycles. The delay line can be viewed as a data queue of prespecified length. On the rising edge of each clock pulse the data word on the $\operatorname{Din}[8-0]$ bus is placed onto the back of the queue and the data word at the front of the queue is placed onto the Dout[8-0] bus. Data is thus delayed by a number of clock cycles equal to the value present on the pins Length[10-0].

## System services

| Pin | In/out | Function |
| :--- | :---: | :--- |
| VCC, GND <br> CLK | In | Power supply and return <br> Input clock |

## Synchronous input/output

| Pin | In/out | Function |
| :--- | :--- | :--- |
| Din[8-0] | In | Data input port |
| Dout[8-0] | Out | Data output port |
| notClkEn | In | Enable internal clock |
| Length[10-0] | In | Delay line length input port |

## Asynchronous input

| Pin | In/out | Function |
| :---: | :---: | :--- |
| notOE | In | Output port tristate control |

### 1.1 System services

Power
Power is supplied to the device via the VCC and GND pins. All supply pins must be connected. The supply must be decoupled close to the chip by at least one 100 nF low inductance (e.g. ceramic) capacitor between VCC and GND. Four layer boards are recommended; if two layer boards are used, extra care should be taken in decoupling.

Input voltages must not exceed specification with respect to VCC and GND.
CLK
The clock input signal CLK controls the timing of input and the output on the three dedicated interfaces, and controls the progress of data through the line delay. Since the IMS A113 is fully static, the clock can be stopped in either phase without corrupting data.

## Resetting the device

The IMS A113 does not have a reset pin. A reset is initiated automatically when power is first applied to the device. This reset will be completed once four cycles of CLK have occurred after VCC is valid.

### 1.2 Synchronous input/output

## Din[8-0]

The data input port is sampled on every clock cycle. Data must be valid on the rising edge of CLK.

## Dout[8-0]

The data output port is driven on the rising edge of CLK.

## notClkEn

The notClkEn pin is sampled on the rising edge of CLK. The signal is active low. When it is inactive the device's internal clock is stopped, thus stopping the progress of data through the line delay.

## Length[10-0]

The length of the delay line is specified by the binary number present on Length[10-0]. Length[0] is the least signifigant bit. The length set will give a latency of Length +1 after the output data has been clocked on the following rising clock edge. For example to achieve a latency of 6 cycles Length[10-0] must be set to 5. Since Din[8-0] is latched on the rising clock edge when cascading devices for increased length the overall latency is the sum of the individual latencies.

For a fixed delay Length[10-0] are simply wired to Vdd or Gnd as appropriate. In order to accomodate variable delay lengths the Length[10-0] bus is sampled on the rising edge of CLK. When a delay length change is detected the line delay is reset. The value on the Din[8-0] bus at the time of the delay length change will appear at the Dout[8-0] bus after a period equal to the new delay length.

When the delay length on Length[10-0] is changed the contents of the delay line are zeroed, excepting the three data samples at the front of the queue. At power on the delay length on Length[10-0] is treated as a new length.

The exception to this is changing to the minimum delay length of five cycles, when no zeroing takes place.
When an illegal delay length (less than 5 or greater than 1317) is programmed no data is taken from the Din[8-0] bus. So effectively the Dout[8-0] bus will continue to be zero. The delay lengths from 1984 to 2015 are used for testing purposes and therefore should not be set.

## Example of a length Change

If the delay length is changed for example to an $x$ cycles delay, the status of the delay line immediately after the change is shown in the diagram below.

Thus the order of data pushed from the front of the queue immediately following the length change will be :-

- 3 cycles of original data (including data output as new length latched)
- $x-3$ cycles of zeroed data
- Valid data, beginning with that sampled at the time of the length change

Refer to the tıming diagram, Figure 1, for an example of changing the length to 6.

Figure 1 Example of length change

### 1.3 Asynchronous input/output

notOE
This pin is asynchronous to CLK. The signal is active low. When it is inactive the Dout[8-0] pins are high impedance.

## ELECTRICAL SPECIFICATION

### 2.1 DC electrical characteristics

## Absolute maximum ratings

| Symbol | Parameter | Min | Max | Units | Notes (1) |
| :--- | :--- | :---: | :---: | :---: | :---: |
| VCC | DC supply voltage | 0 | 7.0 | V | 2 |
| VI, VO | Voltage on input and output pins | -1.0 | VCC +0.5 | V | 2 |
| TA | Temperature under bias | -40 | 85 | ${ }^{\circ} \mathrm{C}$ | 2 |
| TS | Storage temperature | -65 | 150 | ${ }^{\circ} \mathrm{C}$ | 2 |
| PDmax | Power dissipation |  | 250 | mW |  |

1 All voltages are with respect to GND.
2 This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Stresses greater than those listed may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

## DC operating conditions

| Symbol | Parameter | Min. | Nom. | Max. | Units | Notes (1) |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: |
| VCC | DC supply Voltage | 4.5 | 5.0 | 5.5 | V |  |
| VIH | Input Logic '1' Voltage | 2.0 |  | VCC +0.5 | V | 2 |
| VIL | Input Logic '0' Voltage | -0.5 |  | 0.8 | V | 2 |
| TA | Ambient Operatıng Temperature | 0 |  | 70 | ${ }^{\circ} \mathrm{C}$ | 3 |

## Notes

1 All voltages are with respect to GND. All GND pins must be connected to GND.
2 Input signal transients 10 ns wide, are permitted in the voltage ranges GND -0.5 V to $\mathrm{GND}-1.0 \mathrm{~V}$ and $\mathrm{VCC}+0.5 \mathrm{~V}$ to $\mathrm{VCC}+1.0 \mathrm{~V}$.

3400 linear ft/min transverse air flow.

DC characteristics

| Symbol | Parameter | Min. | Max. | Units | Notes (1,2) |
| :--- | :--- | :---: | :---: | :---: | :---: |
| VOH | Output Logic '1' Voltage | 2.4 | VCC | V | $\mathrm{IO} \leq-4.4 \mathrm{~mA}$ |
| VOL | Output Logic '0' Voltage | 0 | 0.4 | V | $\mathrm{IO} \leq 4.4 \mathrm{~mA}$ |
| IIN | Input leakage current (any input) |  | $\pm 10$ | $\mu \mathrm{~A}$ | 3 |
| ICC | Average power supply current |  | 55 | mA | 4 |

## Notes

1 All voltages are with respect to GND. All GND pins must be connected to GND.
2 Under the conditions specified by the DC operating conditions.
$3 \mathrm{VCC}=\mathrm{VCC}(\max ), \mathrm{GND} \leq \mathrm{VIN} \leq \mathrm{VCC}$
4 This applies with no DC loading on the output pins at 20 MHz and it will be less at slower clock rates

### 2.2 A.C. timing characteristics

All timings are given for a load of 30 pF unless otherwise stated.

## Clock requirements

| Symbol | Parameter | Min | Max | Units | Notes |
| :---: | :--- | :---: | :---: | :---: | :---: |
| t CHCL | Clock Pulse High Width | 20 |  | ns |  |
| t clCH | Clock Pulse Low Width | 20 |  | ns |  |
| tchCH | Clock Perıod | 50 |  | ns |  |
| tR | Clock rise time | 0 | 50 | ns | 1 |
| tF | Clock fall time | 0 | 50 | ns | 1 |

## Notes

1 The clock edges should be monotonic between VIL and VIH.

Synchronous input and output (Din, Dout)

| Symbol | Parameter | Min | Max | Units | Notes |
| :---: | :--- | :---: | :---: | :---: | :---: |
| t CHQV | CLK high to Dout Valid |  | 38 | ns |  |
| t CHQx | Dout hold time after CLK | 2 |  | ns |  |
| tovCH | Din setup time to CLK high | 10 |  | ns |  |
| tchDx | Din hold time to CLK high | 0 |  | ns |  |

Synchronous control (notClkEn, Length[10-0])

| Symbol | Parameter | Min | Max | Units | Notes |
| :---: | :--- | :---: | :---: | :---: | :---: |
| t GHCH | notClkEn/Length hold to clock <br> high | 0 |  | ns |  |
| t GSCH | notClkEn/Length setup to clock <br> high | 10 |  | ns |  |

Asynchronous control (notOE)

| Symbol | Parameter | Min | Max | Units | Notes |
| :---: | :--- | :---: | :---: | :---: | :---: |
| toEON | notOE to Dout enabled |  | 15 | ns |  |
| toEOFF | notOE to Dout high impedance |  | 15 | ns |  |

Output load (output turn-off tests)

3 PACKAGE SPECIFICATIONS
3.144 pin PLCC package

Figure 2 IMS A113 44 pin PLCC J-bend package pinout

## Note

All VCC pins must be connected to the 5 Volt power supply. All GND pins must be connected to ground. N/C indicates pin not connected.

## APPLICATION SUGGESTION

## NOTE

In order to avoid possible instability occurring into final stage the usual suggestions for the linear power stages are useful, as for instance:

- layout accuracy;
- A 100 nF capacitor corrected between supply pins and ground;
- boucherot cell ( 0.1 to $0.2 \mu \mathrm{~F}+1 \Omega$ series) between outputs and ground or across the load.

Fig. 9 - Bidirectional DC motor control with $\mu \mathrm{P}$ compatible inputs

Fig. 10 - Servocontrol for compact-disc

Fig. 11 - Capstan motor control in video recorders

Fig. 12 - Motor current control circuit

Note: The input voltage level is compatible with L291 (5-BIT D/A converter)

Fig. 13 - Bidirectional speed control of DC motors.
For circuit stability ensure that $R_{X}>\frac{2 R 3 \circ R 1}{R_{M}}$ where $R_{M}=$ internal resistance of motor. The voltage available at the terminals of the motor is $V_{M}=2\left(V_{1}-\frac{V_{s}}{2}\right)+\left|R_{o}\right| . I_{M}$ where $\left|R_{0}\right|=\frac{2 R 3 \circ R 1}{R_{X}}$ and $I_{M}$ is the motor current.

## DUAL POWER OPERATIONAL AMPLIFIER

- OUTPUT CURRENT TO 1A
- OPERATES AT LOW VOLTAGES
- SINGLE OR SPLIT SUPPLY
- LARGE COMMON-MODE AND DIFFERENTIAL MODE RANGE
- GROUND COMPATIBLE INPUTS
- LOW SATURATION VOLTAGE
- THERMAL SHUTDOWN

The L272D is a monolithic integrated circuit in SO-16 packages intended for use as power operational amplifier in a wide range of appli-
cations including servo amplifiers and power supplies, compact disc, VCR, etc. The high gain and high output power capability provide superior performance wheatever an operational amplifier/power booster combination is required.

## APPLICATION SUGGESTION

In order to avoid possible instability occurring into final stage the usual suggestions for the linear power stages are useful, as for instance:

- layout accuracy;
- A 100 nF capacitor connected between supply pins and ground;
- boucherot cell ( 0.1 to $0.2 \mu \mathrm{~F}+1 \Omega$ series) between outputs and ground or across the load. With single supply operation, a resistor ( $1 \mathrm{~K} \Omega$ ) between the output and supply pin can be necessary for stability.

Fig. 8 - Bidirectional DC motor control with $\mu \mathrm{P}$ compatible inputs

Fig. 9 - Servocontrol for compact-disc

Fig. 10 - Capstan motor control in video recorders

Fig. 11 - Motor current control circuit

Note: The input voltage level is compatible with L291 (5-BIT D/A converter)

Fig. 12 - Bidirectional speed control of DC motors.
For circuit stability ensure that $R_{x}>\frac{2 R 3 \circ R 1}{R_{M}}$ where $R_{M}=$ internal resistance of motor. The voltage available at the terminals of the motor is $V_{M}=2\left(V_{1}-\frac{V_{s}}{2}\right)+\left|R_{0}\right| . I_{M}$ where $\left|R_{0}\right|=\frac{2 R 3 \circ R 1}{R_{X}}$ and $I_{M}$ is the motor current.

## LOW DROP DUAL POWER OPERATIONAL AMPLIFIER

- OUTPUT CURRENT TO 1A
- OPERATES AT LOW VOLTAGES
- SINGLE OR SPLIT SUPPLY
- LARGE COMMON-MODE AND DIFFERENTIAL MODE RANGE
- LOW INPUT OFFSET VOLTAGE
- GROUND COMPATIBLE INPUTS
- LOW SATURATION VOLTAGE
- THERMAL SHUTDOWN
- CLAMP DIODE
- ESD PROTECTICN
- DUMP PROTECTION

The L2726 is a monolithic integrated circuit in SO-20 package intended for use as power operational amplifiers in a wide range of applications including servo amplifiers and power supplies.

It is particularly indicated for driving inductive loads, as motor and finds applications in com-pact-disc VCR automotive, etc.
The high gain and high output power capability provide superior performance whatever an operational amplifier/power booster combination is required.

## DESCRIPTION

The L6232A is a triple half bridge driver intended for use in brushless DC motor applications. This part can be used to form the power stage of a three-phase, brushless DC motor control loop, and is especially useful for disk drive applications. Power drivers are Integrated DMOS transistors and feature fast recirculating diodes as an integral

part of their structure. The logic inputs are TTLlevel compatible, with internal pull-up, allowing interfacing to open collector outputs. All necessary circuitry to perform PWM and linear motor speed control is included. A central charge pump is utilized to drive the upper DMOS transistors, and also to power the braking function. The L6232A is packaged in PLCC44.

## BLOCK DIAGRAM

## PIN DESCRIPTION

| Pin | Name | Function |
| :---: | :---: | :---: |
| 1 to 6 | GND | Common Ground. Also provides heat-sink to PCB. |
| 7 | COMP | External compensation for error amplifier. |
| 8 | LIN Vref | Input for Reference Control voltage in LIN mode. |
| 9 | PWM Vref | Input for Reference Control in PWM mode. |
| 10 | OUTA | DMOS Half-bridge A Out. |
| 13 | OUTB | DMOS Half-bridge B Out. |
| 17 | OUTC | DMOS Half-bridge C Out. |
| 11 | BRK | Active LOW logic input that triggers the delayed brake. |
| 12 | BRK DLY | External RC network for the brake delay. |
| 14 | INUA |  |
| 15 | INUB | Logic Inputs to turn on the upper drivers (Active Low). |
| 16 | INUC |  |
| 18 to 28 | GND | Common Ground. Also provides heat-sink to PCB. |
| 29,34 | SENSE | Output for current sense resistors. |
| 30 | INLC |  |
| 31 | INLB | Logic inputs to turn on the lower drivers (Active High). |
| 33 | INLA |  |
| 32,38 | $V_{S}$ | Supply Voltage. |
| 35,36 | $\mathrm{C}_{\text {s }}$ | External Charge Pump Capacitor. |
| 37 | RC | Cutoff Time RC Network in PWM mode. The Resistor value is also used to define the slew-rate in linear mode (LIN). |
| 39 | $\mathrm{C}_{P}$ | External Main Charge Pump capacitor. |
| 40 to 44 | GND | Common Ground. Also provides heat-sink to PCB. |

Figure 1: Brake Delay and Braking timing of the L6232A. At the time t1 a VP Powerdown threshold detector drives low the BRK input; at time t2 the Charge Pump voltage becomes inadequate to maintain ON the lower DMOS.

FUNCTIONAL DESCRIPTION (Refer to the Block Diagram)
The commutation sequence is provided by the user via six inputs. INUA, INUB,INUC turn on the three upper DMOS drivers when held at logic LOW, and inputs $\operatorname{INLA}$, INLB,INLC turn on the three lower DMOS drivers when held at logic HIGH.
The BRK and BRK DLY inputs offer flexibility to the system designer in the implementation of the braking function. The BRK logic input, when pulled low will turn-off all upper and lower Dmos drivers. The low transition at BRK will produce a delayed negative transition at the BRK DLY input, configurable by connection of a capacitor Cd and a resistor Rd from the BRK DLY pin to ground. The negative transition at BRK DLY will initiate the braking of the motor by turning on all lower Dmos, while keeping all upper DMOS turned-off. This feature provides a time interval where the motor BEMF can be used to power the head parking function before the braking procedure is iniziated. External detection of the supply(VP) drop-off is necessary to provide the appropriate logic signal to the BRK input. (see Fig. 1)
The brake function utilizes the energy stored in the central charge pump capacitor (Cp) to turn-on or turn-off the DMOS drivers. This allows for completion of the braking procedure after the VP supply has powered down.
The L6232A is capable of driving the motor in either pulse width modulation (PWM) or linear (LIN)
mode. The driving mode is determined by the smaller of two analog voltages inputs, LIN Vref and PWM Vref. The motor current is controlled by LIN Vref and PWM Vref and the current sense resistor Rs connected to the SENSE output. The SENSE output provides for connection of a resistor in series with the source of all lower DMOS drivers. The voltage at this pin provides the error signal wich is utilized internally to regulate the motor current Im. The current in both PWM and linear mode is determined by the expression :

$$
I_{\mathrm{m}}=\frac{\mathrm{V}_{\text {ref }}}{\mathrm{GV} \cdot \mathrm{R}_{\mathrm{S}}}
$$

in wich Gv is the voltage gain of the sense amplifier. In linear mode, the current is regulated by a linear control loop wich drives the lower DMOS. Compensation of the linear control loop is achieved by connection of a series network (Rc,Cc) from the transconductance amplifier output (Gm) and ground. Control is passed to each lower DMOS in succession during the commutation sequence(MPX).
The rate at which the upper and lower drivers turns-off during linear mode operation is configurable externally by the value of the resistor $R$ used at the RC pin. This defines a current which is utilized internally to limit the voltage slew-rate at the outputs during transitions. The output slewrate is internally adjusted for fast slewing during PWM operation to reduce losses, and a relatively slower rate during linear mode operation to minimize noise effects(EMI). LIN Vref and PWM Vref are connected to a comparator whose output is
fed to the logic. The upper and lower DMOS driver slew-rates are controlled by the internal logic.
In PWM mode, the upper driver is turned-off when the motor current reaches the intended value. An internal One-Shot pulse determines the lenght of time the upper driver stays off before turning on again. The pulse width, and thus the cutoff time (toff), is configurable by means of the external RC network connected to the RC pin. (see Fig. 2). The resistor at the RC pin, therefore determines both the driver output slew-rate during linear mode and the off-time constant during PWM. The lower driver is always on during PWM mode of operation; an on-chip $2 \mu$ s mask can prevent the beginning of a new cutoff time because of transient current spikes caused by the upper drivers turn-on.
The driving mode is determined by the smaller of the two controlling input voltages. In a typical application the motor start-up would occur in PWM mode to limit power dissipation, with on-speed control then performed in linear mode.
Thermal protection circuitry will shut-off all drivers when the chip junction temperature exceeds the threshold temperature. A small amount of hysteresis is included to prevent rapid on/off cycling of the power stages.
Additional protection is provided against driver input combinations where the upper and lower drivers of a half bridge are turned on simultaneusly, resulting in a short from supply to ground. The chip logic will cause both the upper and lower drivers involved to turn-off. (see Table 1)

## APPLICATION INFORMATION

A typical application configuration of the L6232A driving a three-phase brushless DC motor is shown in Fig.3. The spindle motor is a 4 ohm2 mH per phase, star connected. This load requires a suitable compensation of the linear control loop that can be achieved by $\mathrm{Rc}=10 \mathrm{Kohm}$ and $\mathrm{Cc}=10 \mathrm{nF}(\mathrm{R3} ; \mathrm{C} 8)$. Changing the motor characteristics, the RcCc network would be modified for the best performances of the system. At the start-up the spindle is driven in PWM mode fixed toff time.

The off-time is calculated by the formula :

$$
\text { toff }=1.8 \mathrm{R} 2 \mathrm{C} 7+6 \cdot 10-^{6}
$$

See fig. 2 for a quick choice of the needed capacitor, after the resistor has been fixed. The value of the resistor defines the rate at which the upper and lower drivers turn-off during linear mode operation to avoid EMI effects. The PWM to linear mode of operation is switched by decreasing the LIN Vref level under the PWM Vref value that could be fixed and calculated by:

$$
\text { PWM Vref = } 4 \text { Rs lp }
$$

where Ip is the peak chopping current in the motor windings. Of course, when the required

Figure 2: Typical toff vs. Capacity of C

RPM is reached, it become of no need a strong torque and the LIN Vref starting from a value higher than the calculated PWM Vref, decreases to the value :

$$
\text { LIN Vref }=4 \text { Rs Im }
$$

where Im , smaller than lp , is the needed motor current to keep constant spin. This last reference voltage is generally a PLL output driven by speed transducers coupled to the spindle (like Hall effect sensors or BEMF processors). To drive the upper DMOS and during the brake function a voltage higher than the supply Vs is needed. The charge pump integrated in the L6232A keeps C3 at the correct voltage. To guarantee efficient braking of the motor, C3 must be chosen of adeguate quality (very high equivalent parallel resistance). C4 can be a ceramic disk capacitor. The typical application od the L6232A is in HDD systems on which there is the need to park the Read-Write Heads before the motor braking. This behavior is possible with the circuit of Fig.3. At Power Supply switch-off (see Fig. 1), VP falls down and drives down the BRK input (Active Low). D1 insulates the L6232A from the power suppy output while the power output stage is switched in a high impedance state. The spindle motor acting as a three-phase alternator supplies the Heads voice coil motor driven through integrated diodes that rectrfie the EMF. After a delay longer than the parking time, the lower output DMOS are switched-on and the spindle motor is braked. The brake delay time is tipically 150 msec and it is defined by:

$$
\operatorname{td}(B R K)=R 1 C 6
$$

The sensing resistor value is generally lower than 1ohm, but a wire wounded type must be avoided. In Fig. 3 the 0.33 ohm sensing resistor is shown as three parallel 1ohm metal film resistors. Care must be taken in the PC Board design particularly about ground loops and ground copper area. The typical Thermal Resistance junction to ambient versus PC Board copper area (Fig.5) is shown in Fig 6. For Transient Thermal Resistance see Fig. 7.

## DESCRIPTION

The L6243/D is a Bipolar IC developed for use in Hard Disk Head Actuator positioning applications. The Power Op-Amp Output Bridge, Differential Amplifier, and Error Amplifier, are controlled by TTL/CMOS, input compatible, Digital Logic, and an Analog Current Control Voltage. A simple RC compensation network, tied to the output of the Error Amp, will configure the system to work

as a Transconductance Amplifier to drive a Voice Coil Motor in Linear Mode.
Additional features include Power On Reset Delay, Enable and Park, as well as a general purpose Operational Amplifier. A logic low at the Park input activates the parking function. Holding the Enable input low will disable the device by forcing the outputs into a tristate mode. Power Fail Monitors for the logic and power supplies initiate an automatic parking sequence during a power failure. A resistor programmed parking voltage enables a constant velocity head retract.

## FUNCTIONAL DESCRIPTION

The VCM Driver is controlled via three control signals, ENABLE, POWER ON RESET, and WRITE DISABLE. An analog input voltage, ERROR AMP IN, controls the polarity and amplitude of the VCM driving current.
Refer to figure two. This diagram is a representation of the function of the VCM System. Note that the signals with the bars represent the "not true", or "non asserted" condition. From initial power up, the system is held in the Park Mode. Upon completion of the POWER UP RESET DELAY the machine moves to Tristate Mode or Run Mode, depending upon the condition of the ENABLE input. If ENABLE is asserted, the machine moves directly to Run Mode. If ENABLE is not asserted, the machine moves to Tristate Mode.

POWER ON RESET is an asynchronous output. Additionally it affects the internal logic as a hard wired reset and therefore if a supply failure occurs during Tristate or Run state, the machine moves directly back to a few the Park Mode. A WRITE DISABLE occurs five to ten microseconds prior to the POWER ON RESET in order for the system to halt any read/write activity before a head retract begins.
While in Tristate Mode, the assertion of ENABLE will move the machine to the Run Mode. Run Mode will typically be the steady running state. The deassertion of the ENABLE signal causes the machine to move into Tristate. If it is desired to perform an active Parking function, the PARK input must be driven low by the external hardware, or the the VCM can be driven to the Park position via the ERROR AMP IN control voltage

## FUNCTIONAL DESCRIPTION (continued)

| Function | Description |
| :---: | :---: |
| $V_{C C}$ input | This is the Power Supply input. An internal sense is done monitor this supply. A POWER ON RESET is asserted if the Vcc supply drops below the programmed threshold. |
| POWER FAIL THRESH | Input for the $\mathrm{V}_{\text {cc }}$ supply monitor. The Threshold can be externally set via a voltage divider. |
| $\begin{gathered} V_{C C} \text { SENSE OUT } \\ \text { Output } \end{gathered}$ | TTL compatible signal indicating the $\mathrm{V}_{C C}$ supply has dropped below the POWER FAIL THRESHOLD. |
| LOGIC SUPPLY SENSE input | This input is used to monitor the Five Volt LOGIC SUPPLY SENSE Logic Supply for the external control and other support IC's. The LOGIC SUPPLY SENSE operates independently of the 12 V Power Supply. When a 5 V supply failure is detected a POWER ON RESET is generated. |
| 5V FILTER input | This pin allows for the application of filter circuitry in order to avoid false triggering. |
| PARK POWER input | This input is used during the Power Down/Power Fail Parking operation. When the supply goes down, a typical Spindle Driver Circuit automatically tristates its output stages. During this time the spindle motor spins freely and the stored energy is used to drive the VCM to the park position. The generated BEMF is rectified and filtered across an external PARKING CAPACITOR. |
| PROGRAMMABLE <br> PARK VOLTAGE input | Used to set the voltage applied to the VCM during an Automatic Parking Operation. |
| PARK input | Logic signal asserted low, activates parking. |
| POWER ON RESET output | Indicates an error condition to the external control and support circuitry. A Logic Supply Fail condition automatically initiates a POWER ON RESET. |
| POWER ON RESET DELAY input | The intent of this input is to provide a time delay at power up. During this time, the POWER ON RESET line will be asserted (low). A POWER ON RESET, will hold the system in the PARK mode. Once the delay has timed out, the POWER ON RESET will be removed to allow the external system to assume control. When applied in a Disk Drive Application, the POWER ON RESET DELAY will be required to have a minimum duration which will ensure that the Read/Write Heads can be fully parked. |
| WRITE DISABLE output | Becomes asserted five to ten microseconds prior to the assertion of POWER ON RESET. |
| ENABLE input | This signal originates at the external controller and, when asserted, allows the VCM Drivers to operate. When deasserted the VCM Driver is forced into Tristate mode. During a POWER ON RESET condition however, the parking operation is automatic and takes priority over the ENABLE function. Only at the end of the POWER ON RESET DELAY will the ENABLE input become active. If active parking is desired, it will be accomplished under control of the $\mathrm{V}_{\text {IN }}$ signal, otherwise it is an automatic function at power down. |
| $V_{\text {REF }}$ input | The reference voltage input is basically that voltage, at which the output current is zero. |
| ERROR AMP IN input | Inverting input of error amplifier. The non inverting one is internally tied to $\mathrm{V}_{\text {ref }}$. |
| ERROR AMP OUT output | Error amplifier output pin. |
| OUTPUT A power output | Voice Coil power output. |
| OUTPUT B power output | Voice Coil power output. |
| SENSE AMP IN $A / B$ signal input | Sense amplifier input pins. The sense resistor is connected across these pins. |
| SENSE AMP OUT signal output | Output pin of sense amplifier. |
| AMPOUT output | Output of an internal op-amp for general application. |
| AMP+ input | Non inverting general purpose op-amp input. |
| AMP- input | Inverting input general purpose op-amp input. |

## BLOCK DESCRIPTION

## OUTPUT STAGE

It consists of two Power Op Amps connected in bridge configuration.

## CURRENT SENSE ÁMPLIFIER

Differential amplifier whose inputs are connected to the sense lines and whose output is accessible externally. Closing the loop will transform the differential voltage signal from the sense lines into a current signal for the Error Amplifier.

## ERROR AMPLIFIER

Error amplifier which drives the output stage. The input and the output pins are accessible externally.

## POWER SUPPLY MONITOR OPERATION

The circuit monitors the logic supply voltage input (typ 5V) and activates Power on Reset and Write Disable output when such a supply drops below the safe operating limit. After the logic supply voltage reaches its nominal value a delay capacitor has to be charged [Tdelay $=3 \times 10 \mathrm{e} 5 \times \mathrm{C}$ sec] before Power on Reset and Write Disable outputs change from low to high level. Falling edges of

Write Disable and Power on Reset are delayed (typ $4 \mu \mathrm{~s}$ ) in order to disable the writing on the disk before the Power on Reset is activated. An additional supervisor circuit is present in the IC with a programmable threshold, which is set by an external resistive divider. The TTL compatible output can be used separately or connected to Park input in order to park the head.
The Vcc sense output pin can also be connected to 5 V filter input in order to implement a POWER ON RESET function sensitive both to 5 V and V Cc.

## PARKING CIRCUIT OPERATIONT

The voice coil driver is switched into the parking condition when Power on Reset output or Park input are low. In such a condition a fixed voltage is superimposed on the load and the value of such a voltage is set by connecting an external resistor between Park Voltage Program input and ground: (Vpark=Rext x Iref, Iref=100 $\mu \mathrm{A}$ typ). Connecting ENABLE input to GND the driver will be disabled (outputs in high impedance mode).

## THERMAL SHUTDOWN

It will disable the IC when the junction temperature exceeds the threshold value above which the device could be damaged.

## APPLICATION INFORMATION

## Operation of Programming Supply Vpvs

The output voltage VPVS can be programmed from 5 V to 25.5 V by steps of 0.1 V and can be expressed as follows:
$V_{\text {VPS }}=\frac{\text { Decimal value of code DACO }-7}{10}$
Writing mode (Decimal value of code 51 to 255 ): VPVS $=5.1$ to 25.5 V
In the latter case, the voltage drop between output of converter DC/DC (PVSI) and VPVs is constant and typically of 3 V .

The Decimal Value of an 8bit word is computed as it follws:

| $X$ | $X$ | $x$ | $x$ | $x$ | $x$ | $x$ | $x$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | | Word |
| :--- |
| (DAC0-7) |

| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 128 | 64 | 32 | 16 | 8 | 4 | 2 | 1 |
| If <br> $X$$=L^{(*)}$ |  |  |  |  |  |  |  |
| $2^{n}$ |  |  |  |  |  |  |  |
| if |  |  |  |  |  |  |  |
|  | (*) |  |  |  |  |  |  |

(*) Corresponding Decımal Value
When Vpvs is requested to be of 21 V the Decimal Value of Code DAC 0to7 is 210, that is obtained by:

```
128+64+ 0+ 16+ 0+ 0+ 2+ 0
```

Then the word is the following:

| $H$ | $H$ | $L$ | $H$ | $L$ | $L$ | $H$ | $L$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

The throuth table of Ckout is the following:

| Strobe (pin 3) | CKenable (pin 4) | $\mathrm{C}_{\text {Kout ( }}$ (pin 24) |
| :---: | :---: | :---: |
| $H$ $L$ $X$ | $\begin{aligned} & L \\ & L \\ & H \end{aligned}$ | L H Clock |

## SMART CARD INTERFACE

PRODUCT PREVIEW

- 8 DIFFERENT VPp OUTPUT VOLTAGE LEVELS
- Vpp, VCs RISE AND FALL TIME FULL SPEC WITH ISO/IEC 7816-3
- POWER SUPPLY OUTPUT FOR MEMORY CARD ( $5 \mathrm{~V} / 80 \mathrm{~mA}$ )
- POWER ON/OFF RESET
- VPp, Vcs SHORT CIRCUIT PROTECTIONS
- INTERNAL STATUS FAILURE CODING
- SHORT CIRCUIT CODE
- INSERTION FAILURE CODE
- OVERTEMPERATURE FAILURE
- ANTI-BOUNCING SYSTEM
- INPUT/OUTPUT LOGIC TTL COMPATIBLE
- THERMAL PROTECTION

## DESCRIPTION

The L6605 is an IC dedicated as intelligent interface between different types of smart cards and microprocessors. The internal architecture can be shared in a power supply section and in a diagnostic parts.
The power supply section can deliver in output $5 \mathrm{~V} / 80 \mathrm{~mA}$ to supply the card and $\mathrm{V}_{\mathrm{PP}} / 50 \mathrm{~mA}$ to

## Multipower BCD Technology

Powerdip 12+3+3
write the memory inside the card; the VPP voltage can be programmed by means of the 3 serial input bit (see TAB, 1).

Table 1: 3 bit DAC CODE

| CODE | V PP |
| :---: | :---: |
| 0000 | 5 V |
| 0001 | 10 V |
| 010 | 12.5 V |
| 011 | 13.5 V |
| 100 | 15 V |
| 101 | 18 V |
| 11 | 0 |
| 1 | 11 |

## BLOCK DIAGRAM

DESCRIPTION (continued)
The diagnostic part allows to monitor failures due to overcurrent, overtemperature or wrong card positioning. The fallures are internally coded and readable inside the STATUS REGISTER through
the bidirectional pin DATA configurated in output. The antibouncing circuitry, active during card insertion only, rejects ripetitive switching-on of the power supply sections.

## PIN FUNCTION

| Pin | Description |
| :---: | :---: |
| Vs | Input Power Supply voltage for V ${ }_{\text {cs }}$ regulated output and for device supply |
| $V_{\text {cso }}$ | Output regulated voltage for card supply; $\mathrm{lcSmax}^{\text {max }}=80 \mathrm{~mA}$; overload protected ( 81 to 200 mA ) |
| Voprin | Input power supply for Vop regulated voltage |
| $V_{\text {PPoLt }}$ | Programmable output regulated voltage for memory card writing; 8 voltage levels are allowed by means of 3 bit DAC. lpp $_{\text {max }}=50 \mathrm{~mA}$ |
| VOSEN | Active Low) VCS supply input enable; Its value is fixed from the $\mu \mathrm{P}$ allowing or not the normal R/W operations on the card |
| SWITCH | Input signal produced by the reader system indicating that a card has been inserted. Internally, an antibounding system is provided to avoid multiple switching. |
| CS | Chip select (active low) $\overline{\mathrm{CS}}$ low level indicates an I O operation request from $\mu \mathrm{P}$ |
| IRQ | Interrupt Request (Active low). <br> An IRQ iow :evel indicates that a card insertion extraction or Failure has occured. |
| $\overline{\mathrm{PRG}}$ | Program Active low). <br> PRG low evel enables L66כ5 to deliver in output the $V_{\text {Ppo }}$ level set by 3 bit DAC. |
| DATA | $1 O$ pin for data exchange between $\mu \mathrm{P}$ and the device. Through this pin flow 3 bit input DAC or 2 bit STATUS REGISTER code. |
| CK | External clock |
| $\mathrm{C}_{\text {EX }}$ - | Pin to connect an external capacitor for antibouncing delay time. |
| GND | 4 pins to ground |

## CIRCUIT OPERATION

## CARD POWER SUPPLY

Regulated voltage to supply the card（ $5 \mathrm{~V} / 80 \mathrm{~mA}$ ）． During nominal condition（ $\mathrm{V}_{\mathrm{S}}=12 \mathrm{~V}$ ， $\mathrm{I} \mathrm{Cs}=80 \mathrm{~mA}$ ） the Vcs range variation is equal to $\pm 3 \%$ ．
While during line／load variation（ $\mathrm{V}_{\mathrm{S}}=10 \mathrm{~V}$ to 15 V ； $I_{c s}=1 \mathrm{~mA}$ to 80 mA ）the VCS range is $\pm 5 \%$ ．
An internal circuitry checks the Ics level；the pro－ tection block activates an IRQ with the proper failure code when the output current is in 81 mA to 200 mA range．

PROGRAMMING POWER SUPPLY
L6605 works in step－down mode by means of the
programmed output voltage Vpp．
8 V pp levels can be selected programming the 3 bit DAC as per Table 1．During nominal condi－ tions（lpp $=50 \mathrm{~mA}$ ； $\mathrm{V}_{\mathrm{PPI}}=30 \mathrm{~V}$ ）the $\mathrm{V}_{\mathrm{PP}}$ range vari－ ation is equal to $\pm 2.5 \%$ ：while during line／load variation（ $\mathrm{IPP}=1 \mathrm{~mA}$ to 50 mA ； $\mathrm{V}_{\mathrm{PPI}}=\mathrm{max} .33 \mathrm{~V}$ ） the $V_{P P}$ range is $\pm 5 \%$ ．An internal circuitry checks the IPP level；the protection block activates an IRQ with the proper failure code when the output current is in 51 mA to 150 mA range．Under the power ON／OFF threshold value the logic section and the power supply regulators are disabled．

## LOGIC SECTION

L6605 includes a logic circuitry in order to protect，
both card and itself.
If a failure occours an asynchronous IRQ is sent to the $\mu \mathrm{P}$; consequently the $\mu \mathrm{P}$ forces low CS signal as $1 / O$ request.
After CS variation the $\mu \mathrm{P}$ sends also one "data direction bit" into DATA DIRECTION REGISTER.

- Direction bit = "0"

Pin DATA is configurated in output and the $\mu \mathrm{P}$ reads the 2 bit STATUS REGISTER content

| Code | 1st bit | 2nd bit |
| :---: | :--- | :--- |
| 0 | No insertıon | No Failure |
| 1 | Card Inserted | Failure |

Failure could be overtemperature or short circuit over the 2 regulators (VPP, VCS).

- $\quad$ Direction bit $=" 1 "$

Pin DATA is configurated in input to allow the 3 bit DAC loading and than the programming of VPPo output level voltage. (see Table 1).
During card insertion only resing edge of switch signal is detected, while during card extraction switch level is detected

## PLL TV MICROCOMPUTER INTERFACE

- HIGHLY INTEGRATED SOLUTION INCLUDING PLL SYNTHESIZER, NV MEMORY, D/A CONVERTERS, BAND SELECT OUTPUTS, CLOCK OSCILLATOR, IR SIGNAL PRE-PROCESSOR AND SERIAL BUS INTERFACE
- $32 \times 16$ BITS OF NV MEMORY WITH LIFETIMES OF $10^{4}$ CYCLES/WORD AND MINIMUM 10 YEARS RETENTION STORES TUNING DATA FOR 30 CHANNELS PLUS PRESET VALUES FOR THE SIX ANALOG OUTPUTS
- PRE-PROCESSOR FOR INFRARED REMOTE CONTROL SIGNALS REDUCES COMPONENT COUNT
- SIX PWM D/A CONVERTERS WITH 64-STEP RESOLUTION
- FOUR OPEN-DRAIN BAND SELECT OUTPUTS RATED TO 13.2 V
- ON-CHIP 4 MHz CLOCK OSCILLATOR WITH BUFFERED OUTPUT
- INTEGRATED DIGITAL POWER-ON RESET
- 3-WIRE SERIAL BUS TO LOAD/READ INTERNAL REGISTERS

## DESCRIPTION

The M206 is a highly integrated, programmable LSI integrated circuit for microcomputer controlled TV applications, realized using an advanced N -channel double polysilicon gate technology (NVMOS) that allows the integration of non-volatile memory and standard logic on the same chip.
It contains a phase-locked loop (PLL) synthesizer, six pulse-width modulation (PWM) digital/analog converters, a four-bit parallel output buffer, clock oscillator with buffered output, pre-processor for infrared remote control signals and a 3-wire serial bus interface.
The M206 interfaces with a microcomputer through the three-wire serial bus and is programmed by loading thirteen internal registers - twelve of which are readable to simplify programming.
The PLL synthesizer requires an external $64+15 / 16$ prescaler and divider and works with a phase comparator reference frequency of 0.9765 kHz . Outputs are provided to control the division ratio of the prescaler and to signal the out-of-lock condition to the microcomputer.

The infrared remote control signal pre-processor consists of a preamplifier, a squarer and a digital filter to separate noise from signals transmitted by the M708, M709 and M710 remote control transmitters. The output of this pre-processor is connected to the interrupt input of a microcomputer programmed to receive and decode the signal.
The M206 is supplied with two separate 5 V supply inputs, each provided with internal power-on reset circuits. The first, $\mathrm{V}_{\mathrm{DD} 1}$, supplies the remote control and clock circuits in both standby and TV set operation. The second, $\mathrm{V}_{\mathrm{DD} 2}$, supplies the rest of the circuits and is only active during TV operation.
The M206 is packaged in a 28 -pin dual in-line plastic package.

PIN CONNECTIONS

## PIN DESCRIPTION

DA1-DA6 - Digital/Analog converter outputs (opendrain outputs)
Output from the six pulse-width modulation D.'A converters.

B0-B3 - Band drive outputs (open-drain outputs) Outputs from the four-bit buffer used for band selection.

SBD - Serial Bus Data (bidirectional) Data line for serial communication with a microcomputer.

SBE - Serial Bus Enable (bidirectional. active low) Enables serial bus transmissions.
$\overline{\text { SBC }}$ - Serial Bus Clock (input. active low) Clock for serial bus transmissions.

RCIN - Remote Control signal Input (analog input) Input to the infrared remote control signal preprocessor. Connected to the output of the IR preamplifier. Minimum input level 0.5 V peak-to-peak.

RCOUT - Remote Control signal Output Output from the infrared remote control signal preprocessor. To be connected to the interrupt input of a microcomputer.

PDI - Programmable Divider Input (input) This pin is the input of the programmable divider and is connected to the output of the prescaler.

PCM - Prescaler Modulo Control (output) Control signal to set the prescaler division ratio (15 if high, 16 if low).
$\overline{\mathrm{OL}}$ - Out of Lock (output. active low)
Signals an out of lock condition. This output is also active during the power on reset sequence.

## PCO - Phase Comparator Output

The output of the phase comparator. Connected to the input of a low pass filter used to generate the tuning voltage.

TEST - Test pin (input)
The test pin is used only to test the device and is not specified for customer use. It must be connected to ground.

CLIN, CLOUT - Clock oscillator connections A 4 MHz quartz crystal is connected between these pins.

VDD1, VDD2, GND - Power Supply Connections $V_{D D 1}$ is the $+5 V$ standby supply input ; $V_{D D 2}$ is the main +5 V supply input.

MS - Memory Supply Input (input)
Programming pulses for the NV memory are supplied to this pin during store cycles.
$\overline{\text { MT }}$ - Memory Timing (output. active low)
This output supplies the timing for the memory write pulses supplied to the MS input during store cycles.

## CLBUF - Clock Buffer (output)

This is a buffered output from the on-chip clock oscillator and can be used to drive other components (for example the microcomputer).

BLOCK DIAGRAM

## FUNCTIONAL DESCRIPTION

## CLOCK

To use the internal oscillator a 4 MHz quartz crystal is connected between the pins CLIN and CLOUT. If an external clock is used this must be connected to CLIN and CLOUT left unconnected or, if required as
a clock output, loaded by a capacitor up to 15 pF . The minimum external clock amplitude is 2 V peak-to-peak. A buffered clock output, CLBUF, is provided which can drive up to three $\pm 100 \mu \mathrm{~A}$ loads.

## LOADING AND READING INTERNAL REGISTERS

The M206 is programmed by loading a set of internal registers through a 3 -wire serial bus. The functions of these registers are summarised in table 1.
TABLE 1 : Summary of Internal Registers

| Register Number | Address |  |  |  | Number of Bits | Function |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | A3 | A2 | A1 | AO |  |  |
| 0 | L | L | L | L | 6 | D/A Converter $\mathrm{n}^{\circ} 1$ |
| 1 | L | L | L | H | 6 | D/A Converter n ${ }^{\circ} 2$ |
| 2 | L | L | H | L | 6 | D/A Converter $\mathrm{n}^{\circ} 3$ |
| 3 | L | L | H | H | 6 | D/A Converter $\mathrm{n}^{\circ} 4$ |
| 4 | L | H | L | L | 6 | D/A Converter $\mathrm{n}^{\circ} 5$ |
| 5 | L | H | L | H | 6 | D/A Converter $\mathrm{n}^{\circ} 6$ |
| 6 | L | H | H | L | 7 | PLL Counter (MSB) |
| 7 | L | H | H | H | 8 | PLL Counter (LSB) |
| 8 | H | L | L | L | 7 | Buffer Outputs/Phase Comp. Output Control |
| 9 | H | L | L | H | 5 | NV Memory Address |
| 10 | H | L | H | H | 8 | NV Memory DATA |
| 11 | H | L | H | H | 8 | NV Memory DATA |
| 12 | H | H | L | L | 2 | NV Memory Modify Control/Reset Control |

The 3-wire serial bus consists of the signals SBD (Serial Bus Data), SBE (Serial Bus Enable) and SBC (Serial Bus Clock). The enable and data pins, SBD and SBE, are bidirectional.

Data is accepted when the clock is low (active) and latched into the M206 on the low-high transition of the clock. All bus transfers are controlled by $\overline{\text { SBE }}$.

REGISTER LOADING. Serial data transferred from the microprocessor to the M206 has the following format :

| Bit | +Description |
| :---: | :--- |
| CS | Chip Select (always low) |
| PARITY | Parity bit (the number of " H " bits transmitted is odd) |
| R/W | Read/Write. High for Register Load ; Low for Register Read |
| A0-A3 | Register Address (see table 1) |
| D0-D7 | Data to be loaded into register (load operation only) |

The received data word is checked - length, CS and parity - immediately after the low-high transition of SBE. If the received word is valid this is signalled to
the microprocessor by forcing the SBE line low for $20-24 \mu \mathrm{~s}$.

REGISTER READING. M206 registers are read by transmitting a 15 bit word as shown in fig. 4 with $\overline{\mathrm{R}} / W$ low and the address of the register to be read in A0, A1, A2, A3. Bits D0-D7 can be high or low except when register 9 is addressed.
If this word is received correctly the $\overline{\text { SBE }}$ line is im-
mediately pulled low by the M206 and after $24 \mu$ s the contents of the addressed register will be available to be read. The microprocessor reads this data by sending eight clock pulses. Data is output on the low-high transition of SBC and the first data bit is available before the first clock pulse.

LOADING THE NON-VOLATILE MEMORY. Data is stored in the $32 \times 16$-bit NV memory by loading the new contents into registers 10 and 11 then the address into register 9 . The memory modify cycle begins when the address has been loaded and successful completion is indicated by a logic "1" in bit zero of register 12.

The time for a modify cycle varies from a few milliseconds to several hundred milliseconds during the device lifetime and is not internally limited. The storage operation should be aborted after one second if it proves unsuccessful. This is done by setting bit zero of register 12.

READING THE NON-VOLATILE MEMORY. The NV memory is read by loading the address into register 9 . The contents of the addressed word are automatically loaded into registers 10 and 11 and can be read by two register read operations. The data is ready $200 \mu \mathrm{~s}$ after the address load.

## PLL COUNTER

The PLL counter consists of a single counter that acts as the program counter ( 11 bit ) and is swallow counter ( 4 bit) alternately. Data for the PLL counter is loaded into registers 6 and 7. Register 6 must be loaded first because the register 7 load operation initiates the data transfer to the PLL counter.
The reference frequency is produced by dividing the clock frequency by 4096 . With a 4 MHz clock this gives a reference frequency of 976.5 Hz .
An out-of-lock signal is generated (output $\overline{\mathrm{OL}}$ ) when the phase error between the reference frequency and the input frequency exceeds $0.72(2 \mu \mathrm{~s})$.
The phase comparator output, PCO, has a threestate push pull configuration with a high level of 5 V and a low level of 0 V (with zero current sink or pump). The output impedance (both states) is typically $200 \Omega$ ( $400 \Omega$ maximum). The phase comparator output can be set to a high impedance state (both
sink and pump transistors off) by setting bit 4 of register 8 . The output is held in the high impedance state until this bit is reset. The phase comparator output should be set to high impedance when changing band.

RECOVERING LOCK. The phase comparator output can also be set to high and low levels to restore normal operation when the oscillator stops or the prescaler functions incorrectly at high frequency.
In the first condition (oscillator off) the prescaler sometimes oscillates, at high frequency. The loop reacts by reducing the varicap voltage in an attempt to reduce the frequency, thus worsening the situation. This out-of-lock condition is signalled to the microprocessor (by the OL output) which can set the phase comparator output to low level, forcing the varicap voltage up and restarting the oscillator. The phase comparator output is forced low by setting bit 5 of register 8. After about 1 ms this bit is automatically reset and the loop should lock again.
When the out-of-lock condition is caused by a failure of the prescaler to operate correctly at high frequencies the loop reacts by increasing the voltage, hence the frequency, again worsening the situation. To recover from this condition the phase comparator output is set high. This is done by setting bit 6 of register 8 which, as in the previous case, resets itself after 1 ms .

The out-of-lock condition could also be caused by unwanted changes in band or PLL counter contents provoked by external interference (spikes on supply etc.). For this reason it is always advisable to reload the band and PLL counter registers before attempting to recover lock as described above. If the phase comparator output is in the high impedance state, the OL output signals the reset condition but not the out-of-lock condition.

## CALCULATING PLL COUNTER VALUES

a) $\mathrm{F}=$ video carrier
b) $\mathrm{IF}=38.9 \mathrm{MHz}$
c) The frequency to be synthesized is $\mathrm{Fs}=\mathrm{F}+\mathrm{IF}$
d) The Ref. frequency of the phase comparator is
$F_{\text {ref }}=\frac{4.000 \mathrm{MHz}}{4096}=0.97656 \mathrm{kHz}$
e) Using the prescaler $64+15 / 16$ the minimum frequency steps is

$$
F_{\text {ref }} \times 64=62.5 \mathrm{kHz}
$$

f) The modulo of division $N$ is given by the ratio
between the frequency to be synthesized and the reference frequency multiplied by 64 . The result has to be rounded.
$N S=$ integer rounded $\left[\frac{F_{S}}{F_{\text {ref }} \cdot 64}\right]$
g) With the $64+15 / 16$ prescaler and the particular counter of the M206 the division by N is given by

$$
N_{S}=\left(I_{S}+1\right) \cdot 15+(R s+1) \cdot 16
$$

where I (integer part) controls the division by 15 (program counter) and R (rest) controls the division by 16 (swallow counter). For ease of calculation we decrement $\mathrm{N}_{\mathrm{S}}$ by one getting $\mathrm{N}_{\mathrm{C}}=$ $\mathrm{N}_{\mathrm{s}}-1$.
The numbers Ic and $\mathrm{Rc}_{\mathrm{c}}$ are given by :

$$
\begin{gathered}
\mathrm{N}_{\mathrm{C}}=\left(\mathrm{I}_{\mathrm{C}}+1\right) \cdot 15+\left(\mathrm{R}_{\mathrm{C}}+1\right) \cdot 16 \\
\mathrm{~N}_{\mathrm{C}}-31=\mathrm{I}_{\mathrm{c}} \cdot 15+\mathrm{Rc}_{\mathrm{C}} \cdot 16
\end{gathered}
$$

using the formulas :
$R_{C}=N_{C}-31-15 \cdot$ Integer $\left[\frac{N_{C}-31}{15}\right]$
$I C=\frac{N_{C}-31-R_{C} \cdot 16}{15}$
$R_{s}=R_{c}+1$
IS $=$ Ic 1

## Example :

Channel 21, $F=471.25 \mathrm{MHz}$
Fs $=F+I F, F s=471.25+38.9=510.15 \mathrm{MHz}$

$$
\begin{aligned}
N_{S} & =\text { Integer rounded }\left[\frac{510.15 \cdot 10^{6}}{62.5 \cdot 10^{3}}\right] \\
& =\text { Integer rounded }[8162.4]=8162
\end{aligned}
$$

$N_{C}=N_{S}-1=8161$
$R_{c}=N_{C}-31-15 \cdot$ Integer $\left[\frac{N_{C}-31}{15}\right]$

$$
=8161-31-15 \cdot \text { Integer }\left[\frac{8161-31}{15}\right]
$$

$$
=8130-15 \cdot \text { Integer [542] }
$$

$$
=8130-15 \cdot 542=8130-8130=0
$$

$\mathrm{I}_{\mathrm{C}}=\frac{\mathrm{N}_{\mathrm{C}}-31-\mathrm{R}_{\mathrm{C}} \cdot 16}{15}=\frac{8161-31}{15}=542$
$R_{s}=R_{c}+1=0+1=1$
Is $=\mathrm{lc}-1=542-1=541$
$R$ and I have to be translated into binary code.

## DIGITAL/ANALOG CONVERTERS

The six pulse-width modulation (PWM) D/A converters have a resolution of 64 steps and an output frequency of 16 kHz (with 4 MHz clock). At power on reset they are set to a duty cycle of zero.

## POWER ON RESET

The VDD1 and $V_{D D 2}$ supplies have an integrated digital power on reset with a duration of 250 ms .
The reset condition is signalled by a low level on the out-of-lock output, OL. The microprocessor can test this condition by reading bit 1 of register 12. This bit is zero during power on reset and the OL output remains active until it is read. Reading this bit automatically restores it to a high state.
During power on reset time commands from the micoprocessor are not acknowledged. Power on reset also sets the phase comparator output to a high impedance, state. It is restored by resetting bit 4 of register 8.

## REMOTE CONTROL SIGNAL PRE-PROCESSOR

This section contains a preamplifier, squarer, digital filter and a pulse generator. The digital filter enables the pulse generator only if three successive negative going pulses ( 4 edges) are detected. The distance between these pulses must be in the range $24-27 \mu \mathrm{~s}$ (about $37-41 \mathrm{kHz}$ with a 4 MHz clock). The input is not tested for the duration of the output pulse (192-256 $\mu \mathrm{s}$ ).
If this pre-processor is used in conjunction with M709 or M710 remote control transmitters valid signals can be recognized in the presence of extreme noise conditions. Separating the signals from the noise externally in this way reduces the number of interrupts that the microcomputer has to handle thus allowing it to concentrate on other takes. To take advantage of this section the M708, 709, 710 transmitters must operate with a clock frequency in the range $492-508 \mathrm{kHz}$.
The input can be DC or AC compled to the I.R. preamplifier.
In case of DC coupling the quiescent input level is suggested to be 1.5 V .

Response of the Digital Filter as a Function of the Input Frequency (in kHz ).

## TYPICAL APPLICATIONS

Remote Controlled TV Frequency Synthetizer.

88DSM206-20

- Remote Control Decoding by Microprocessor.
- 32 Station Non-Volatile Memory or 30 Station
- Memory + Normalized D/A Positions
- Flexible System Operation
- Frequency Synthesis of all Standard and CATV Channels
- Direct Channel Selection
- $\pm 4 \mathrm{MHz}$ Fine Tuning ( 62.5 kHz per Step)
- Automatic Search within Channel (using TDA4433)
- AFC Operation (using TDA4433)
- 6D/A Converters
- Teletext and Viewdata Data Bus Conversion

Remote Controlled TV Frequency Synthetizer and Clock Timer.

Frequency Synthesis as described in the Basic Configuration with the addition of :

- Further Station Memory, using M120, 1 K NV MEMORY
- Clock and programmable timer for automatic switch ON/OFF, using M755.

## PACKAGE MECHANICAL DATA

28 PINS - PLASTIC DIP

## SINGLE-CHIP VOLTAGE SYNTHESIS TUNING SYSTEM WITH 1 ANALOG CONTROL

- 16-STATION MEMORY - 7-SEGMENT LED DISPLAY
- VOLTAGE SYNTHESIZER : 13 BITS
- 4-BAND PRESET CAPABILITY
- NON-VOLATILE MEMORY : 304 BITS
- 16 WORDS OF 19 BITS FOR TUNING VOLTAGE (13 bits) - BAND (2 bits) - FINE DETUNING (4 bits)
- $10^{4}$ MODIFY CYCLES PER WORD
- MIN 10 YEARS DATA RETENTION
- PCM REMOTE CONTROL RECEIVER : DECODES SIGNAL TRANSMITTED BY M708
- VOLUME D/A : 6-BIT RESOLUTION / 8kHz
- MEMORY SKIP FUNCTION
- AUTOMATIC SEARCH WITH DIGITAL AFT CONTROL
- FINE DETUNING D/A ACTING ON AFT DISCRIMINATOR ( 16 steps) WITH SEPARATE STORAGE FOR EACH MEMORY POSITION. ALTERNATIVELY IT CAN BE USED TO CONTROL BRIGHTNESS OR COLOUR SATURATION
- MANUAL SEARCH WITH DIGITAL AFT CONTROL
- MANUAL SEARCH WITH LINEAR AFT
- SWEEP SEARCH DISPLAY OUTPUT
- SUPPLY VOLTAGES : VDD $=+5 \mathrm{~V}$, $V_{P P}=+25 \mathrm{~V}$ FOR THE MEMORY
- CLOCK OSCILLATOR : 445 TO 510kHz
- INTEGRATED DIGITAL POWER ON RESET (no external initialization circuitry required)

## DESCRIPTION

The M491B is a monolithic N-MOS LSI circuit including a Floating-gate Non-Volatile Memory for storage of up to 16 stations. Tuning of the station is performed with a 8192 step D/A converter, using the principle of voltage synthesis.
It is designed for 7 -segment LED displays. Direct memory selection is possible only from remote control while Up/Down memory scanning is possible on the set and also from remote control. An option input for 8 or 16 stations is available.
The circuit also includes a PCM remote control receiver operating in conjunction with the transmitter M708. The highly reliable transmission code en-
sures error-free signal detection even in presence of high noise conditions.
Search of the station is possible in automatic or manual modes. The circuit can operate with a Digital or Linear AFT control.
The Digital AFT mode is necessary for automatic search and requires an external circuit (TDA4433 or equivalent, e.g. dual comparator plus TV station detector) to convert the AFC-S-curve into an Up/Down command.
Fine tuning (detuning) is also possible with different modes of operation.
The circuit is assembled in 40-pin dual in-line plastic package.

## DESCRIPTION (All timings at $\mathrm{f}_{\text {clock }}=500 \mathrm{kHz}$ )

PIN 1 : VSS
The substrate of the IC is connected to this pin. This is the reference pin for all parameters of the IC.

## PIN 2 : MEMORY SUPPLY VOLTAGE

A supply voltage of $25 \pm 1 \mathrm{~V}$ has to be applied to this pin during the modify and read cycles.

## MODIFY CYCLE

A modify cycle consists of three steps :

1. All "1"s are written in the bits of the selected word.
2. All bits of the selected word are erased (all "0"s)
3. The new content is written.

Thus a constant aging of all the bits of the word is obtained.
During both write and erase cycles the memory status is checked continuously ; therefore after each write or erase pulse a read operation is carried out. The write or the erase operations are stopped as soon as the result of the read operation is valid.

WRITE CYCLE. The peak of the current flowing through pin 2 during a write operation is shown in fig. 1 , while fig. 2 shows the envelope of the same current.
The typical write time is $3-4 \mathrm{~ms}$ for the first cycles and increases to about 30 ms after 1000 cycles.

Figure 1

Figure 2

ERASE CYCLE. Fig. 3 shows the timing and the waveform of the current flowing through pin 2 during the erase operation. The peak current is 7 mA (max) during the erase cycle and 6 mA (max) during the
read cycle. The typical erase time is 10 ms for a new device and increases with the number of modify operations up to 200 ms after 1000 cycles.

Figure 3
(
In order to protect the memory in case of failure of some bits the modify operation is stopped after 1 sec .

NIGROEMECTRONICS

READ CYCLE
Fig. 4 shows the waveform of the current during a read operation.

## Figure 4

PIN 3 : MEMORY TIMING OUTPUT
This output gives the timing for the pulses to be applied at pin 2 during the modify and read cycles. The output consists of an open drain transistor.

PIN 4 : FINE TUNING D/A
A D/A converter with 16-step resolution and a fre-
quency of 15 kHz can be used to generate a voltage which, if fed to a varicap diode in parallel to the AFC discriminator, will detune the receiver by a small $\Delta f$ while maintaining the action of the Digital AFT. This output can be used in conjunction with both Linear and Digital AFT modes of operations.

Figure 5

The Fine tuning function operates as follows:

- At the start of any automatic or manual search, the output is set at the mid range.
- When the search has been completed it is possible to operate on $\mathrm{FT} \pm$ commands.
The store command memorizes this information
together with the 13 tuning voltage bits and 2 information bits.
- Modification time of FT D/A is of 1 step every 200 ms if issued locally or every 2 received signals from Remote control transmitter.

## PIN 5 : TUNING D/A

$\mathrm{A} 2^{13}=8192$ step pulse modulated signal for the tuning voltage is available on this pin.
Pulse modulation is implemented by combination of a rate multiplier and pulse width principle.
With a tuning voltage increasing from zero, the num-
ber of pulses increases continuously up to $2^{8}=256$; starting from this point the number of pulses remains the same but the pulses get larger until they reach the maximum content of the internal counter. The output consists of an open drain transistor which offers a low impedance to ground when in the ON state.

Figure 6

## PIN 6 : DIGITAL AFT STATUS OUTPUT

This output shows the status of the digital AFT. It is low when the digital AFT is enabled and it can directly drive a LED.
The output consists of an open drain transistor.
Figure 7

## PINS 7 \& 8 : OSCILLATOR INPUT/OUTPUT

The frequency of the clock oscillator should be between 445 and 510 kHz using a low-cost ceramic resonator. In these conditions the value of the reference frequency of the transmitter can be in the same range. In other words the transmitter and the
receiver can operate with different reference frequencies.

Figure 8

PIN 9 : VDD
The supply voltage has to be comprised in the range 4.75 to 5.25 V . When it is applied an internal power on reset of 0.5 s is generated.
The memory position 1 is automatically read if the mains on option input (pin 25) is grounded.

PIN 10 : TEST
This pin is used for testing and has to be connected to Vss.

PIN 11 : I.R. SIGNAL INPUT
The integrated receiver decodes signals transmitted by M708, address 9 .

The minimum signal to be applied is 0.5 V peak-topeak. (AC-coupled).
The receiver input section performs the following tests on the incoming signal to achieve the necessary noise immunity :

- measurement of the pulse distance (time base synchronization)
- check of the position of the received bits opening window at the time bases
- check of the parity bit
- check of the absence of pulses between the parity bit and the stop pulse
- check of noise level ; the receiver checks parasitic transients inside and outside the time windows.

If the above test conditions are not fulfilled, the received word is rejected and not decoded. If the received signal is acknowledged as a valid word it is stored an decoded.

The end of transmission will be acknowledged by receiving the end of transmission code or by means of an internal timer if the transmission remains interrupted for more than about 550 ms .

## PINS $12 \& 13$ : AFT1-AFT2 (STOP AFT INPUTS)

These pins are enabled during the automatic search and during normal operation. when the digital AFT is enabled (see description of pin 17).

The STOP/AFT inputs are also disabled internally during any program or band change for the duration of the Mute signal.

These pins work according to the truth table given below :

| M491B Pin 12 <br> TDA4433 Pin 2 | M491 B Pin 13 <br> TDA4433 Pin 6 | Function <br> H |
| :---: | :---: | :---: |
| L | L | Up |
| L | H | Down |
| H | H | Middle |

These inputs have two different functions depending on whether the system is in the search or in normal operation (AFT control).

The inputs have internal pull-up resistors of $30 \mathrm{k} \Omega$ typ.
A) Search mode : after depressing the Automatic search or preset keys, the levels of the signals coming from the TDA4433. applied to these pins, control the search function and determine when the search must stop. i.e. a TV station has been recognized.
The circuit operates in the following sequence (see fig. 10 for reference) :
1 - after pressing the search start key the search occurs in the FAST UP mode.
2 - eventual transitions available on these inputs are ignored during the first 15 search steps if the system is in the UHF or CATV bands.
If the system operates in VHF I and III bands, the first 60 search steps are ignored. The acceptance delay of 15 (60) search steps has been introduced to prevent the system from stopping at the previous station.
After this time the FAST UP speed is automatically reduced to half during each UP signal (MEDIUM UP = FAST UP/2).
A DOWN signal preceded by at least an UP signal will set the search to MEDIUM DOWN mode (FAST UP;4).
3 - the next UP signal will switch the search to SLOW UP speed ( 61 Hz ).
At this point the systems is in normal AFT operation.
B) Digital AFT operation : when a station is perfectly tuned, the input signals coming from TDA4433 are at middle condition.

If the tuning moves lower than the threshold below 38.9 MHz , the pin 12 is put H and pin 13 is put $L$; the 13 bit internal counter is moved SLOW UP speed to increase the varicap voltage.
When a detuning occurs in the opposite direction the input 12 goes Low and 13 goes High and the tuning voltage falls at VERY SLOW DOWN speed ( 7.6 Hz ).
The increase or decrease of the tuning voltage is stopped as soon as the input returns to middle conditions.

Therefore during normal operation pins 12 and 13 act as digital AFT control commands.
C) Recall from memory : when the digital AFT is enabled and data is recalled from Memory, a fixed value of 8 steps $(\approx 31.2 \mathrm{mV})$ is subtracted from the tuning voltage.
This corresponds to a detuning of 0.6 MHz (UHF) and of 0.3 MHz in VHF III into that part of the IF response curve which corresponds to the fully transmitted sideband.
At this point the AFT operation takes over as described in point $B$ above and the exact tuning is achieved in about 0.2 sec .
This feature increases the AFT capture range and fullfills the stability requirements of the tuner, voltage references and the D/A converter.
If the Digital AFT is disabled (pin 17 at $\mathrm{V}_{\mathrm{SS}}$ ), the memory content is read without any change.

Figure 10

## PIN 14 : SWEEP SEARCH DISPLAY OUTPUT

This output, which is normally Low, goes High during automatic search automatic preset et intervals of 160 ms for about 40 ms to blank the LED of band display.

Figure 11

## PIN 15 : VOLUME D/A OUTPUT

This output delivers a square wave signal of 7.8 kHz and duty cycle variable in 63 steps. In case of a continuous command for varying the volume, the duty cycle is changed at the rate of the transmitted signal
(approximately every 102 ms with $\mathrm{f}_{\text {ref }}=500 \mathrm{kHz}$ ) or every 112 ms if issued locally.
Overflow and underflow protection are provided.
The volume output can be switched to $\mathrm{V}_{S S}$ and reset to the previous level by means of the Mute On/Off command. It is also reset by the Volume Up/Down and the Mains On/Off commands.
The volume is muted for about 1 s at each mains on and off command during the power on reset time and program change ( 0.5 s ).
At the first power on reset of $V_{D D}$ the volume $D / A$ is set at the level 21/64. The last level is preserved until $V_{D D}$ is not removed.

## PIN 16 : LINEAR AFT DEFEAT OUTPUT

This output is normally High and goes Low when a Manual Up/Down command is issued.
It returns High with a 1 second delay from the release of the key, in order to give the user the possibility of the tuning adjustment without the AFT intervention. It goes Low for 0.5 s during program change.

Figure 12

88DSM491B-14

## PIN 17 : DIGITAL AFT ENABLE INPUT

If this input is connected to $V_{S S}$ (GND), the digital AFT loop is always disabled. If pin 17 is left open or is connected to $V_{D D}$, the digital AFT is automatically enabled at power on. When a manual up/down
search command is issued, the digital AFT loop is disabled and the digital AFT status output is inhibited.
The digital AFT loop is restored by the commands: Digital AFT on/Automatic search/Automatic preset.

PINS 18-19-20-21-22-23-24 : KEYBOARD MATRIX
Figure 13

A command is accepted if the corresponding contact has been closed for a minimum time of 30 ms .

Local input commands and I.R. commands have the same priority.

If a complete I.R. command has been received, the local inputs are blocked until the command has been executed and the "end of transmission code" generated.

Viceversa an I.R. signal cannot be decoded until an
issued local command has been executed.

## MEMORY UP/DOWN

Depressing one of these two commands, the memory position is stepped in the UP or DOWN direction.
If the key is kept closed, the channels are stepped UP/DOWN every 0.5 second or every 5 commands from the transmitter.
The memory locations 9 to 16 are jumped if pin 31 is at GND level.

## BAND SELECTION

The bands can be selected either directly or with a step-by-step command in the following sequence :

```
VHFI
CATV
VHF III
UHF
VHF I and so on
```

Only one band change is performed at each accepted command.
Disabled bands are automatically skipped. A band can be disabled connecting the corresponding output to $\mathrm{V}_{\mathrm{ss}}$.

## SEARCH MODES

4 modes are available :
a) Automatic search
b) Automatic preset
(digital AFT)
c) Manual up/down (digital and linear AFT)
d) Manual up/down (linear AFT)
a) AUTOMATIC SEARCH. The search starts from the actual tuning and band position. During the search the tuning voltage is always changing from lower to higher voltage levels. When the end of the band is reached the search restarts from the beginning of the next band after a 480 ms interruption with the sequence of step-by-step band selection. Disabled bands are automatically skipped.
The search is stopped when the first station is found or if a channel selection command is given.
Stop of the automatic search is determined by the STOP/AFT inputs controlled by the TDA4433 which converts the AFC-S-curve into an up/down command.
At the end of the search the up/down command controls the correct tuning acting on the counter of the voltage synthesizer (Digital AFT).
It is important to call the attention to the Digital AFT capture range which is larger than the normal linear AFT as shown in fig. 14.

Figure 14

Additionally the use of the Digital AFT allows storage of the tuning information corresponding to the zero point of the AFC-S-curve. This cannot be guaranteed using the Linear AFT method only. The latter is a cheaper system, because it does not require the use of the TDA4433 but it cannot guarantee what described above.
As a result of the use of the Digital AFT, the requirements for stability of the tuner, of the reference voltage source and of stability of the D/A converter are less critical.

Tuning speed in automatic search, if no station is found is:

| VHF I | 8 second |
| :--- | :--- |
| VHF III | 8 second |
| UHF | 32 second |
| CATV | 32 second |

The tuning and band information can be stored using the store/memory addressing command.
The search can be stopped by a memory selection command.
b) AUTOMATIC PRESET. The search starts from the lowest memory address, tuning voltage and VHF I band as described in automatic search mode.
When an active station is encountered, the corresponding tuning and band information is automatically stored in the Non-Volatile Memory.
Afterwards the system starts to search for the next station. The cycle is repeated until all bands have been scanned or the tuning information has been stored into all address locations. After completing this cycle the system reads out the tuning information of the lowest address.
c) MANUAL UP/DOWN WITH DIGITAL AND LINEAR AFT (pin 17 at $V_{D D}$ ). Holding one of these commands pressed, the tuning voltage is increased or decreased.
During this operation, the Digital AFT is automatically defeated and can only be reconnected with the "AFT on" command or by an Automatic search or preset command.
The search speed is kept at minimum (there is no increment with the time)

| Band | Sweep Time <br> for the <br> Complete Band | Number of Tuning <br> Steps/Second |
| :---: | :---: | :---: |
| VHFI | 128 seconds | 64 |
| VHF III | 128 seconds | 64 |
| UHF | 512 seconds | 16 |
| CATV | 512 seconds | 16 |

In case of command received from remote control, the counter is increased/decreased every two received commands.

No band switching is provided at the upper or lower tuning positions.
The volume is automatically muted 3 second after the key pressure is immediately restored at the release of the key.
d) MANUAL UP/DOWN WITH LINEAR AFT (pin 17 at $\mathrm{V}_{\mathrm{SS}}$ ). When this control is used the Digital AFT is disabled.
The Linear AFT output goes low after an up or down command is issued and remains Low for 1 second after the release of the key.
The volume is automatically muted for 3 seconds after the key pressure and is immediately restored at the release of the key.
Tuning speeds are as follows:
FINE TUNING UP/DOWN
See description of pin 4.
DIGITAL AFT ON
See description of pin 17.
VOLUME UP/DOWN
See description of pin 15.
MAINS ON/OFF
See description of pins 25 and 26.

| Band | Number of Tuning Steps Second |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Time 0 | After 1 s | After 2 s | After 3 s |
| VHF I | 64 | 128 | 256 | 512 |
| VHF III | 64 | 128 | 256 | 512 |
| UHF | 16 | 32 | 64 | 128 |
| CATV | 16 | 32 | 64 | 128 |

## STORE COMMANDS

2 modes of operations are available.
a) store
b) memory addressing

In order to protect the memory, the store function is internally disabled after one store cycle.
It is enabled after a program change or a tuning operation (it is not disabled by the Digital AFT control).
a) STORE. The tuning information (Tuning D/A, Fine tuning D/A and band) is stored in a previously selected memory address when this command is issued.
b) MEMORY ADDRESSING. The tuning information can also be stored with this command followed by the memory position selection.
When this command is accepted all the memory LEDs are blanked.

Selection of the memory position initiates the store operations and restores the display.

## MUTE ON/OFF

See description of pin 15.

## PIN 25 : MAINS ON OPTION INPUT

If connected to $\mathrm{V}_{S S}$ (GND) the Mains output is automatically switched on when $V_{D D}$ is applied and memory 1 is read.
If it is connected to $V_{D D}$ the circuit goes in stand by condition.

## PIN 26 : MAINS ON/OFF OUTPUT

Switch on of the set is controlled by the Mains on command issued for more than 0.3 s . The output transistor is set in the off condition to drive through an integrated pull-up resistor, an external NPN transistor.

Figure 15

© At each Mains on command a memory read out occurs. $A$ VPP (+ 25 V ) is required for this operation, a 1 second delay starts when the mains output is switched off. For a correct reading of the memory the VPP supply voltage must reach the value of 25 V within 1 second after a Mains on command.
In case of automatic switch on at power on caused by pin 25 at GND, the total delay is of 1.13 second ( 0.13 s for $V_{D D}$ power on reset plus 1 second for mains on).
The Mains on/off command, if repeated, will switch the output on (set off).
The last address information is preserved until $V_{D D}$ is present.
Next Mains on command will switch the set at the previously selected memory address and a read operation will be performed.

PINS 27-28-29-30-33-34-35-36 : MEMORY ADDRESS OUTPUT
These pins operate as output only for display of the selected memory location. Max drive capability is of
$15 \mathrm{~mA} / 1.2 \mathrm{~V}$ with the exception of pin 36 that is of $30 \mathrm{~mA} / 1.5 \mathrm{~V}$.
Direct memory selection is only possible by remote control. A local memory up/down command is available in case of emergency.
Pin 32 must be grounded.
If pin 31 is grounded, the memory position 9 to 16 are skipped in case of memory up/down commands.
For normal operation pin 31 can be left open or, better, connected to VDD.

PINS 31-32
See description of pins 27 to 30 and 33 to 36 .
PINS 37-38-39-40 : BAND INPUT/OUTPUT
These outputs are provided to select up to 4 bands via external PNPs.
If one or more bands have to be skipped, the corresponding outputs have to be short-circuited to Vss.

Figure 16

The relation between pins and bands are as follows :
pin $37=$ UHF
pin $38=$ CATV
pin $39=$ VHF III
$\operatorname{pin} 40=\mathrm{VHF} \mathrm{I}$

## INPUT/OUTPUT CONFIGURATION

## SINGLE-CHIP VOLTAGE TUNING SYSTEM WITH 4 ANALOG CONTROLS AND $\mu$ P INTERFACE

- NON-VOLATILE MEMORY FOR20 PROGRAM WORDS
(17 BIT x 20)
- TUNING VOLTAGE 12 BITS
- BAND 2 BITS
- MULTI STANDARD 2 BITS
- PROGRAM SKIP BIT 1 BIT
- 10,000 MODIFY CYCLES PER WORD
- MIN. 10 YEARS DATA RETENTION
- 13 BIT VOLTAGE SYNTHESIZER (BRM + PWM)
- NV MEMORY FOR 4 ANALOG CONTROLS (6 BIT x 4)
- 4 BAND SWITCH OUTPUTS (VHF I \& III, UHF, CATV)
- $5 \times 7$ KEYBOARD
- 2 AUDIO VISUAL OUTPUTS (VCR \& PC)
- 2 CODED MULTI STANDARD OUTPUTS (e.g. PAL, SECAM, NTSC etc.)
- DIRECT 11/2 DIGIT 7 SEGMENT COMMON ANODE LED DISPLAY DRIVING
- PCM REMOTE CONTROL RECEIVER (M708 transmitter)
- 5-BIT DATA INPUT + CONTROL LINE FOR P INTERFACE
- LINEAR AFC DEFEAT OUTPUT
- FLYBACKSYNC. COINCIDENCE INPUT FOR SEMIAUTOMATIC SEARCH
- STANDBY OUTPUT
- OPTION SELECT:
- 16 OR 20 PROGRAMS
- POWER UP MODE
- PROGRAM SKIP DEFEAT
- AV OPTIONS
- 1 * OR DECADE MODE OPTION IN 20 PROGRAM OPTION
- TEMPORARY ANALOG UP/DOWN INDICATOR ON LED DISPLAY
- BAND SKIP OPTION
- 455 TO 510 KHz CHEAP CERAMIC RESONATOR
- $V_{D D}=5 \mathrm{~V} \pm 5 \% . V_{P P}=25 \mathrm{~V} \pm 1 \mathrm{~V}$

## DESCRIPTION

The M494 is a monolithic LSI integrated circuit fabricated in SGS-THOMSON's EPM2 process ; an Nchannel, Planox, double poly MOS process capable
of including a floating gate NV memory cell (EEPROM).
The i.c. has been designed as a complete digital TV tuning system based on the voltage synthesis principle and as a replacement for all the conventional potentiometers and band switches particularly in low cost TV sets. It also provides some functions normally only associated with higher cost sets. NV memory is integrated on the chip together with all the necessary control circuitry to provide the program memory. Separate NV memory is also integrated to provide the memory for four analog controls. A seven segment LED display can be directly driven by the chip to display the program selected, and the direction of movement of the analog controls. Provision is made for a remote control receiver both on and off chip, the latter is interfaced via a data input and single control line. (This enables control by a microprocessor). A local keyboard can be used with the device in a variety of configurations. An option select pin provides for different program number options, power up options and skip associated functions. This device is another significant step towards the complete integration of TV control circuitry.
The device is packaged in a 40 pin DIL plastic package.

DIP40
(Plastic Package)
ORDER CODE : M494B1

Stresses above those under "Absolute Maxımum Ratıngs" may causes permanent damage to the device This is a stress ratıng only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specıfication is not implied. Exposure to absolute maximum ratıng conditıons for extended perıods may affect device relıability.

## DEFINITION OF TERMS

The M494 has four conditions or states that it can be in which are defined below. Logic LOOV and logic $\mathrm{HI} \equiv 5 \mathrm{~V}$.

## POWERED DOWN

$V_{D D}=0 V . V_{P P}=0 V$

## ON

$V_{D D}=5 \mathrm{~V} . \mathrm{V}_{\mathrm{PP}}=25 \mathrm{~V}$. Device driving display normally. Data Handshake pin configured as RTS i/p. Standby $\mathrm{o} / \mathrm{p}=\mathrm{HI}$. All other functions operating normally.

## STANBDBY

$V_{D D}=5 \mathrm{~V} . \mathrm{V}_{\mathrm{PP}}=0 \mathrm{~V}$. Device driving display to show a single static bar (g segment). Data Handshake pin configured as RTS $\mathrm{i} / \mathrm{p}$. Standby $\mathrm{o} / \mathrm{p}=$ LO. All key-
board commands are disabled except any program command On/Off. On/Standby. Memory sequence up or down, $1^{*}$ and $\pm 10$ (decade) commands. All RC and Data commands are disabled except any program command, On/Standby, Memory sequence up or down, $1^{*}$ and $\pm 10$ (decade) commands. Analog controls. Tuning, AV, MS and AFC defeat o/p's = LO. Band o/p's = HI (externally pulled up). See Standby section for more detail.

OFF
$V_{D D}=5 \mathrm{~V} . \mathrm{V}_{\mathrm{PP}}=0 \mathrm{~V}$. Device not driving display. Data Handshake pin configured as OFF o/p. Standby o/p $=$ LO. Display disabled and Display drive $0 / \mathrm{p}=\mathrm{HI}$ (externally pulled up). All keyboard commands disabled except ON/OFF. Remote and data command sources disabled. Analog controls, Tuning, AV, MS and AFC defeat $0 / \mathrm{p}$ 's $=\mathrm{HI}$ (externally pulled up).

## STATIC ELECTRICAL CHARACTERISTICS

( $\mathrm{T}_{\mathrm{amb}}=0$ to $70^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}$ unless otherwise specified)

## FUNCTIONAL DESCRIPTION

(clock frequency $=500 \mathrm{kHz}$ )

## VDD \& VSS

$V_{D D}=+5 \mathrm{~V} \pm 5 \%$. When applied, an internal power on reset of 110 ms is generated. The voltage threshold for the reset is in the range 3 to 3.5 V but is in fact the point at which the internal clock phases start.
$\mathrm{V}_{\mathrm{SS}}=0 \mathrm{~V}$. This pin is connected to the substrate of the i.c. and is the reference for all parameters of the device.

## OSCILLATOR I/O

The frequency of the oscillator should be between 445 and 510 kHz using a cheap ceramic resonator. The reference frequency of the remote control transmitter must also be in the same range i.e. if the oscillator frequency is 455 kHz then the transmitter frequency could be 510 kHz or vice versa.

## TEST

This pin is normally used for post fabrication testing purposes only and should be tied to Vss. However this pin can be used by SGS-THOMSON Microelectronics or the OEM to enable external loading of the memory. Details of how to achieve this can be furnished by SGS-THOMSON.

## REMOTE CONTROL INPUT

The integrated RC receiver decodes signals transmitted by the M708 (address 10). The minimum signal amplitude should be 0.5 V peak to peak at the input pin. The minimum pulse width should be $8 \mu \mathrm{~s}$. The signal from the preamplifier (TDA8160) is brought to the RC signal input via an $A C$ coupling network (see fig. 1).

| $\mathrm{V}_{\text {DD }}$ (TDA8160) | $\mathbf{R}$ | $\mathbf{C}$ |
| :---: | :---: | :---: |
| 5 V | $2.2 \mathrm{k} \Omega$ | 4.7 nF |
| 12 V | $10 \mathrm{k} \Omega$ | 4.7 nF |

Figure 1.

The input is self biased to approx. 1.5 V . When a large signal is applied to the input a level shift will take place predominantly due to the coupling network. However another time constant is also visible due to the coupling $C$ and the internal resistor $R_{1}$. (see figs. 2 \& 3).

Figure 2.

Figure 3.

Several tests are performed on the signal :
a) Measurement of the pulse distance $T$ (time base synchronization).
b) Check of the bit positions relative to the time base windows.
c) Check of the parity bit.
d) Check of the absence of pulses between parity and stop pulses.
e) Check of the noise level. The receiver checks the noise level for a time $T$ after each pulse detected.
If all these tests are successful the received word is stored and decoded. If not it is rejected. The transmission is terminated on reception of the end of
transmission (EOT) code or if the internal timer measures a transmission interruption of more than 550 ms . For more detail concerning the operation of the RC receiver refer to SGS-THOMSON Technical Note No. 155 pp11-12.
The RC receiver and the local keyboard have the same command source priority i.e. a local command is not accepted until a previously accepted RC command has been completely executed and the EOT code transmitted. Similarly if a local command is under execution then an RC command will not be accepted. The RC truth table and commands are shown on the next page.

## ANALOG CONTROL OUTPUTS

Four analog control outputs are implemented to provide for Volume, Brightness, Saturation and Contrast from four 6 bit D/A's. These D/A's use the Pulse Width Modulation technique to synthesize a pulse train of constant frequency but variable pulse width (PWM). Each output delivers a 7.8 kHz square wave whose duty cycle is variable in 63 steps. External RC filtering and level shifting is required to realise a static DC voltage from the pulse train. If the analog outputs are continuously varied by command from the keyboard or data command sources the outputs will change approx. every 112 ms (fck $=500 \mathrm{kHz}$ ) or approx. every 102 ms if the command is issued from the RC command source. One analog control is specifically designed as a volume control as mute circuitry is built in.
On start up reset the analog control outputs except volume are enabled after a period of approx. 1.1 seconds. In the Standby and Off states'all the analog control outputs are pulled to logic LO.
The normalise command reads the contents of each analog memory sequentially to its corresponding counter and D/A output.

## TUNING OUTPUT

The tuning voltage is generated from a 13 bit counter. The program memory stores the 12 MSB's of the tuning word. The range of the AFC circuitry is
at least 3 bits so the LSB of the tuning counter does not affect the resolution of tuning.
The contents of the counter are converted using a PWM and a Bit Rate Multiplier (BRM) technique. 13 bits gives 8192 steps which yields a resolution of approximately 3.9 mV with a max. tuning voltage of 32 V . This corresponds to a resolution of about 75 kHz in the UHF band. The 5 MSB 's of the tuning word are converted using PWM and the remaining 8 bits using BRM. Thus as the tuning word increases from all zeroes the number of pulses in one period increases to 256 with all the pulses being the same length ( $t_{0}=2 \mu \mathrm{~s}$ ). For values larger then 256 PWM conversion takes place where the number of pulses in one period stays constant at 256 but the width changes. When the pulse width reaches $15 t_{0}$ two successive pulses "link" together and the number of pulses decreases. (see fig. 4).
Figure 4.

The pulse train is fed to an external low pass filter to realise a DC voltage. The temperature dependence of this system is predominantly the switching times of the output pulses and as there are only a maximum of 256 pulses in one period the temperature stability is very good.
In Standby and Off states the tuning output is pulled to logic LO.

M494 REMOTE CONTROL COMMANDS (address 10, code = 1010)

| M708 Command Number | Function |  | Code |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

The above table showns the difference between the 16 and 20 program options with respect to the remote control commands. Commands 16, 17, 18 \& 21 change function between the two options. Commands $22,23 \& 24$ should not be used in the 20 program option, as they have no function. NOP $=$ No operation

SGS-THOMSON

## PROGRAM MEMORY

NV memory (EEPROM) is integrated on the chip to provide storage for up to 20 stations. Each memory location is 17 bits in length providing 12 bits for tuning voltage, 2 bits for band, 2 bits for two coded multistandard outputs and 1 bit program skip flag. Individual program words can be read on command from the keyboard, remote or data command sources but can only be written on command from the keyboard. There are two methods for storing a program (writing the memory) : pre and post tuning selection of the program number. See Commands, section 7. Reading each memory location in sequence (up or down) can also be achieved from all the command sources.

All memory timing functions are provided on chip and only one external transistor is required to switch the external memory supply (25V). There are essentially two operations carried out on the memory : Write/Modify and Read. The Write/Modify cycle consists of 3 steps :
a) All " 1 s " are written to the bits of the addressed word.
b) All bits of the word are erased.
c) The new contents are written.

Using this method all the bits of the addressed word are aged the same. For more detail concerning the write, erase and read current waveforms at the Memory Supply pin see M491 datasheet.

## MEMORY FOR ANALOG CONTROLS

The memory for the analog controls is electrically identical to the main program memory but is organised as four 6 bit words located in two sequentially addressed words at the memory. Each word
corresponds to the Volume, Brightness, Saturation and Contrast outputs. At power on reset and normalise command each memory word is read out to its corresponding counter and D/A in sequence.

## DISPLAY, KEYBOARD AND DATA MULTIPLEXING

Logic is integrated on the chip to provide the multiplexing between the display, keyboard and data inputs. In the On state and with the Data Handshake pin at logic HI as an input the display and keyboard are muxed together. See fig. 5 . Each column output goes to logic LO in sequence and the row inputs are scanned for a key closure. In chronological order across the total mux. period there is : initialisation, scan, decision and display periods.
The Data Handshake pin has a complex logical function. It has two modes of operation : as a hand shake I/O line to a $\mu \mathrm{P}$ and as an output line to the $P$ to signal that the M494 is in the Off state. In order to achieve this function careful signal timing is required both internally and externally to the chip. See fig. 6. When the device is in the OFF state the Data Handshake pin is used to signal this condition to the $\mu \mathrm{P}$ by being pulled LO .

Figure 5.

Figure 6 : Data-input-timing.

## DISPLAY

The M494 is capable of directly driving a 1 digit common anode LED display at the max. sink current of 15 mA per segment. The $\mathrm{h}+\mathrm{i}$ pin is capable of sinking a max. current of 30 mA so that these two segments can be driven from the same pin and be the same brightness as the other segments.
On instruction from the internal command decoder the display shows programme number, direction of analog control movement, decade change or Memory Addressing function active. Analog controls in this context are defined as Tuning, Volume, Contrast, Saturation \& Brightness. The formats of the display for analog control direction, decade change and Memory Addressing are shown below respectively :

For the analog controls the above condition is displayed with an "overrun" time of 300 ms . i.e. the display will show the "arrows" for a period of 300 ms after the release of any analog control up or down key. The Memory Addressing function display flashes at 5 Hz after the Memory Addressing function is commanded and continues to flash until a pro-
gramme is selected or any other command is given.
In $1^{*}$ the g segment only flashes at 5 Hz and continues to flash until a programme number is selected or any other command is given. If in Memory Addressing and $1^{*}$ is pressed then the display above is shown with segments $\mathrm{g} \& \mathrm{~d}$ only flashing at 5 Hz until a programme number is selected or any other commands is given. When Store or Set Skip Flag commands are executed the whole display is flashed at 5 Hz for 1 second.

## KEYBOARD

It is possible to implement a keyboard with a max. size of 35 keys as a $5 \times 7$ array. Fig. 8 shows the arrangement of the key matrix. Each key connects a row ( $\mathrm{a}-\mathrm{g}$ ) with a column (D0-D4) with a max. re sistance of $10 \mathrm{~K} \Omega$. De-bounce logic is integrated on the chip that only allows acceptance of a command if the key is closed for longer than 40ms except for the On/Standby and On/Off commands where the relevant keys must be closed for approximately 100 ms . This is equivalent to 2 received RC commands).
For the main keyboard matrix (a-g x D0-D4), if the logic detects two keys closed simultaneously the display is blanked to indicate this condition to the user and no command is executed. When the logic detects only one key pressed the display will re-illuminate and the command be executed.

This avoids confusion as to which command should be executed and provides feed back to the user. For the Option select line all options/commands can be active simultaneously.
$1^{*}$ mode or decade mode can be selected on the option select line by the presence of a diode or not respectively. These two modes are only active for the 20 program option and are described below:
In $1^{*}$ mode the display will toggle in \& out of the condition shown in the Display Section. Access to programs in the first decade is made by simply pressing any 0-9 program key and access to programs in the second decade, whatever the current program is made by pressing $1^{*}$ followed by any 0-9 program key.
In decade mode on pressing either $\pm 10$ (decade) keys the display will light or extinguish the half digit respectively and simultaneously effect the tuning information. e.g. if the device is in program 3 pressing +10 (decade) key will give program 13 and then pressing - 10 (decade) key will give program 3. Pressing - 10 (decade) again will have no effect.

Figure 7 : Keyboard 16 Programs.

The 20 program option select acts like an enable for the $1^{*}$ or decade modes. i.e. the $1^{*}$ or decade modes are only selectable in the 20 program option. In 16 program option the function of the $1^{*}$ key, program key 0, -10 (decade) $\&+10$ (decade) are changed to no function, programme 10, 11 \& 12 respectively. i.e. The difference between fig. 7 \& 8 for those keys that change function.
If the $1^{*}$ key is pressed followed by brightness up for example the device will increase the brightness only and reset the 1 * command i.e. the last command from any command source will always be executed if it is a single keystroke command and the 1 * command will be reset by it. It is possible to press the $1^{*}$ key on the keyboard and then a program 0-9 command from RC or Data command sources or vice versa. Thus there are 2 methods of selecting a program from the keyboard for the 16 program option : direct access (only up to 12 programs) or Memory sequence up/down. And there are 3 methods of selecting a program from the keyboard for the 20 program option: $1^{*}$ mode, decade mode and Memory sequence up/down.
Figure 8 : Keyboard 20 Programs.

DATA INPUT
Shown below are the codes for the commands:

## M494 DATA COMMANDS

| Command Number | Function |  | Code |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 16 Programs | 20 Porgrams | D0 | D1 | D2 | D3 | D4 |
| 0 | EOT | EOT | 0 | 0 | 0 | 0 | 0 |
| 1 | Program 1 | Program 1 | 1 | 0 | 0 | 0 | 0 |
| 2 | Program 2 | Program 2 | 1 | 0 | 0 | 0 | 0 |

| 12 | Program 12 | + 10 (decade) | 0 | 0 | 1 | 1 | 0 |
| 13 | Program 13 | 1* | 1 | 0 | 1 | 1 | 0 |
| 14 | Program 14 | NOP | 0 | 1 | 1 | 1 | 0 |
| 15 | Program 15 | NOP | 1 |  | 1 | 1 | 0 |
| 16 | Program 16 | NOP | 0 | 0 | 0 | 0 | 1 |
| 17 | Normalise | Normalise | 1 | 0 | 0 | 0 | 1 |
| 18 | Volume up | Volume up | 0 | 1 | 0 | 0 | 1 |
| 19 | Volume down | Volume down | 1 | 1 | 0 | 0 | 1 |
| 20 | Contrast up | Contrast up | 0 | 0 | , | 0 | 1 |
| 21 | Contrast down | Contrast down | 1 | 0 | 1 | 0 | 1 |
| 22 | Brightness up | Brightness up | 0 | 1 | 1 | 0 | 1 |
| 23 | Brightness down | Brightness down | 1 |  | 1 | 0 | 1 |
| 24 | Saturation up | Saturation up | 0 | 0 | 0 | 1 | 1 |
| 25 | Saturation down | Saturation down | 1 | 0 | 0 | 1 | 0 |
| 26 | Memory Seq. up. | Memory Seq. up. | 0 | 1 | 0 | 1 | 1 |
| 27 | Memory Seq. down | Memory Seq. down | 1 | 1 | 0 | 1 | 1 |
| 28 | On/standby (toggle) | On/standby (toggle) | 0 | 0 | 1 | 1 | 1 |
| 29 | Standby | Standby | 1 | 0 | 1 | 1 | 1 |
| 30 | Mute (toggle) | Mute (toggle) | 0 | 1 | 1 | 1 | 1 |
|  | NO TRANSMISSION (pulled up) |  | 1 | 1 | 1 | 1 | 1 |

The above table shown the difference between the 16 and 20 program options with respect to the Data input commands. Commands 10, 11, 12 \& 13 change function between the two options. Commands $14,15 \& 16$ should not be used in the 20 program option, as they have no function.
NOP = No Operation

The Data input will accept signals whose timing is defined in fig. 6 and electrical characteristics defined in the table of static electrical characteristics. The EOT code must be transmitted after each command after a min. period of 112 ms .

## BAND OUTPUTS

Four band outputs are provided for selection of the signal band: VHF I \& III, UHF and CATV. Band skip logic is implemented so that by tieing the relevant pin to $V_{s s}$ a band can be skipped in regions of no transmission in that band. The bands can be selected only in a rolling sequence by the band sequence keyboard command. The sequence is as follows:
VHF III, UHF, VHF I, CATV

## MULTI STANDARD OUTPUTS

Two coded multi standard outputs (or general purpose TV system flags) are provided so that the TV set can be designed for use in areas of more than one transmission standard. This function requires an external decoder to realise 4 different standards e.g. PAL 1, PAL 2, NTSC, SECAM etc. The multi standard sequence command available from the keyboard gives a simple binary count at the two outputs : 00, 01, 10, 11, 00 etc. In Standby and Off states the multistandard outputs are pulled to logic LO.

## AUDIO VISUAL OUTPUTS

Two audio visual outputs are provided for automatic selection of a VCR and/or personal computer. The logic state of the pins depends on the AV option selected, the program option and the program number selected according to the truth tables below

| AV Option 1 |  |  |  | AV Option 2 |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 16/20 Programs |  |  |  | 16/20 Programs |  |  |
| Program | AV0 | AV1 |  | Program | AV0 | AV1 |
| 16/0 | 1 | 0 |  | 8/8 | 1 | 0 |
| 15/19 | 0 | 1 |  | $7 / 7$ | 0 | 1 |
| Others | 0 | 0 | ¢ | 6/6 | 1 | 1 |
|  |  |  | § | Others | 0 | 0 |

External pull up resistors must be used to realise a logic Hl as the outputs are open drain transistors. See I/O Configuration.

## AFC DEFEAT OUTPUT

The AFC defeat output is a TTL compatible signal that is capable of switching the AFC circuitry in and out. The AFC defeat output is pulled LO on any program change including memory sequence up and down and is held LO for 500 ms after execution of the command. When tune up or down are commanded the AFC defeat output is taken to logic LO. After the tuning operation the AFC defeat is held LO for $1 \mathrm{sec}-$ ond after the key is released. See fig. 8. On power on \& start up resets it is taken to logic LO for approx. 1.1 seconds.

Figure 9.

## STANDBY

The standby output is a push pull output capable of directly driving an NPN transistor for switching a relay. The states of this pin are defined in the definition of terms. When standby is commanded, available from all command sources as Standby or $\mathrm{On} /$ Standby commands, the standby output is enabled.
If the device goes into Standby from On then any program command will bring the device On with that program selected. On/Off command from keyboard only will execute the Off function. On/Standby, Memory sequence up or down, 1 * and $\pm 10$ (decade) commands from any command source will bring the device On in the program selected before Standby with the display showing that program only, i.e. the device executes an On command only.

If the device goes into Standby from Powered down then the On/Off command from keyboard only and any program command, On/Standby, Memory sequence up or down, $1^{*}$ and $\pm 10$ (decade) commands from any command source will bring the device $O n$ in program 1. i.e. the device executes an On command only.

## OPTION SELECT

The Option select pin provides an extra line that performs a "hard wired keyboard function" in conjunction with the keyboard scanning lines D0-D4. This line has integrated logic associated with it that enables one or many of the functions to be active simultaneously. In contrast, the keyboard inputs a-g will allow one key active at any given time. See keyboard section.

Various options can be selected by the connection or not of a diode as shown in figs. 7 \& 8. From left to right along the Option select line column 1 selects the number of programs. A diode connected here selects 20 programs (full complement) and no diode (default) selects 16 programs only that can be accessed. The 20 program option only enables selection of $1^{*}$ or decade modes in column 4. In column 2 the AV option defines the state of the AV outputs for two protocols. These are described in section Audio visual output. Column 3 defines the state the M494 powers up in. If no connection of a diode (default) is made here the device powers up in the Off state. If a diode is present then the device powers up in the Standby state. In column 4, activated by the 20 program option only, the presence of a diode places the device in $1^{*}$ mode and the absence of a diode selects decade mode. The diode and switch in column 5 defeats the skip condition and enables program memory words to be read with the skip flag set. This allows programming (or reprogramming) of previously skipped words.

## SKIP FUNCTION

Program skip is implemented in the M494 by a single memory bit associated with each program word. The bit acts as a flag to the device to indicate that the program word should be skipped and the next program word read from the memory in ascending or descending order if the skip flag is set. Programs are skipped only when accessed using the memory sequence up/down commands. Direct access to a program from the keyboard, RC or data command sources will always override the skip function. e.g. if skip is set on prog. 7 and prog. 7 is commanded from RC then prog. 7 will be tuned even if there is nc prog. stored in that memory location.
In order to program the skip bit and to defeat its function when required two commands are available : set skip flag and skip defeat. The skip defeat switch is designed to be activated by a facia panel on the TV set under which are infrequently used controls.
On the set skip flag command the M494 stores the current contents of the tuning, band and MS counters and sets the skip bit. After the set skip flag operation the contents of the tuning, band and

MS counters will not change and the device continues to output these values. The operation is transparent to the user in terms of function but is indicated on the display by the program number flashing at 5 Hz for 1 second. In order to reset the skip bit for any program word the desired program should be selected with skip defeated. A station should then be tuned, if required, and then the store command issued. The store command automatically resets the skip flag.
The skip defeat command enables the reading and writing (plus resetting of skip flag) of memory words whose skip flag is set. If skip is defeated the device will only access the number of programs selected by the option select i.e. If 16 programs only are selected then skip defeat will NOT enable access to all 20 programs.

## RESET

There are two conditions under which the M494 is reset : power on and start up (On command). Power on reset is triggered whenever $V_{D D}$ falls below about 3 V . The duration of this reset is 110 ms after $\mathrm{V}_{\mathrm{DD}}$ has been restored.

POWER ON RESET (Powered down to Off or Standby states)
After the reset period of 110 ms :
a) The program counter is set to program 1.
b) The outputs are disabled as defined in the Off and Standby states. See Standby \& Off definitions.
c) The option selection, keyboard, momentary on switch and, when in standby, the display, RC and data inputs become active. For the "activity level" of the keyboard in Off and standby states. See Standby \& Off definitions.
d) An internal register is set to indicate that the device has powered up from the powered down state.

Start up reset (Standby or Off states to On state) A start up reset is instigated by the reception of the commands given in the definition of terms or the Standby section. The following then occurs :
a).The internal register indicating that the device has powered up from the powered down state is read:
I) If the register is set than the memory word addres sed by the program counter is loaded into the tu ning counter and then the analog values are read rom the memory.
II) If the register is reset then the previously selec ted tuning and analog values are left unchanged.
b) The AFC is defeated and the volume muted for a period of approx 1.7 seconds or 0.6 seconds lon ger than the other analog outputs.
c) The tuning and analogue outputs, except volume, are enabled after approx. 1.1 seconds.
d) The volume output is enabled after 1.7 seconds
e) The standby output is pulled up internally to logic HI
f) The internal register is reset.

If the device has either of the power up options (power up in Off or standby states) selected then it will perform a power up reset but all the outputs and command sources will remain disabled, then on the On command, a start up reset will be performed. If the device is required to power up in the On state using the momentary mechanical switch connected to the $h+i$ pin then it will perform an ordinary power on reset followed immediately by a start up reset. The outputs and command sources will be enabled after the periods defined above.

## MANUAL TUNING

Manual tuning commands tune up or down, are available from keyboard only and are provided to allow both manual station search and tuning adjustments. If a continuous tuning up or down command is made from the keyboard the speed of movement of the tuning counter is as shown in fig. 10 for the UHF and CATV bands. Time $t_{o}$ is the
start time for the key being pressed. When the $\mathrm{FB} /$ sync. coincidence input is a logic HI the tuning speed is reduced to 16 steps $/ \mathrm{sec}$. If, at time to the $\mathrm{FB} /$ sync. coincidence input is at logic LO than the tuning.sweep speed jumps immediately to 512 steps/sec.

For VHF III \& I all these levels are shifted up by a factor of $2 \& 4$ respectively giving slowest speeds of 8 steps $/ \mathrm{sec}$. and $16 \mathrm{steps} / \mathrm{sec}$. and highest speeds of 1024 steps/sec and 2048 steps/sec. If the continuity of command is broken by releasing the keyboard for example then the tuning speed returns to its slowest speed when the $\mathrm{FB} /$ sync. coincidence input is at logic HI . If the upper or lower limit of a band is reached during manual tuning then tuning will continue in the same direction from the opposite limit after a 480 ms delay to allow for the discharge of the external network.

The tuning counter is 13 bits in length giving a range of 8192 steps. The UHF band has a bandwidth of approx. 400 MHz . Thus in the UHF band the slowest speed of 4 steps/sec. gives a tuning speed of about $200 \mathrm{KHz} / \mathrm{sec}$. The fastest speed of 512 step/sec. corresponds to a total band sweep time of 16 seconds.

Figure 10 : Tuning Sweep Speed (UHF \& CATV BANDS).

## PROGRAM MEMORY SEQUENCE

A continuous up/down program memory command from keyboard produces a program change every 500 ms . From remote control and data command sources a continuous program memory sequence command produces a program change approx. every 500 ms or every 5 received commands. A
memory sequence up or down command issued from any source will bring the device out of standby to the program selected before standby was commanded. The memory sequence up or down will not then commence until the command is stopped and reissued from any source (until an EOT has been received or internally generated).

## MUTE

The sound mute function is available as a toggle command from all command sources. There are other commands and functions during which the sound is muted:

- FB/sync. coincidence - If there is no FB/sync. coincidence under any conditions the sound is muted.
- Start up reset - the sound is muted for approx. 1.7 seconds.
- Program change - the sound is muted for 0.6 seconds on any program change ; direct, $1^{*}$ $+0-9$ program (only after the second keystroke), $\pm 10$ (decade) \& Memory sequence up/down continuous or single keystrokes.
- Standby \& Off states - the sound is muted.
- Band sequence - same as program change.
- The sound is demuted under the following conditions:
- When the mute command is received from any source.
- When the device is commanded On from standby of Off, i.e. if the device was muted
when the standby command was issued then when On is commanded it will always start up with the sound demuted after the reset and settling period of approx. 17 seconds.
- Volume up - if volume up is commanded whilst the sound is muted then the volume will increase from zero.
- Volume down-if volume downis commanded whilst the sound is muted then there is no effect.
- Any program change - the sound is NOT demuted.

## MOMENTARY ON SWITCH

Provision is made for a momentary switch connected between the $\mathrm{h}+\mathrm{i}$ pin and ground to force the M494 to make Power on and Start up resets automatically so that the device attains the On state immediately.
The condition of the $h+i$ pin is latched after the reset period of 110 ms . Therefore the period of switch contact closure should be a min. of 120 ms .

## INPUT/OUTPUT PINS

COMMANDS

| Command | Source | Function |
| :---: | :---: | :---: |
| Programs 1-12 | KB, D,RC <br> (16 opt.) | Reads the contents of the memory location: 2MSB's to the MS counter, next 2 MSB's to the band counter next 12 MSB's to the tuning counter and D/A and LSB to skip flag register. Initiates an on command only after standby. |
| Programs 0-9 | $\begin{aligned} & \text { KB, D, RC } \\ & \text { (20 opt.) } \end{aligned}$ | Reads the contents of the memory location : 2MSB's to the MS counter, next 2 MSB's to the band counter next 12 MSB's to the tuning counter and D/A and LSB to skip flag register. Initiates an on command only after standby. |
| Programs 13-16 | D, RC <br> (16 opt.) | Reads the contents of the memory location : 2 MSB's to the MS counter, next 2 MSB's to the band counter next 12 MSB's to the tuning counter and D/A and LSB to skip flag register. Initiates an on command only after standby. |
| -10 (decade) | KB, D, RC <br> (20 opt.) | Sustracts 10 from the current program (if possible). Initiates an on command only after standby. |
| + 10 (decade) | $\mathrm{KB}, \mathrm{D}, \mathrm{RC}$ <br> (20 opt.) | Adds 10 to the current program (if possible). Initiates an on command only after standby. |
| 1* | KB, D, RC <br> (20 opt.) | Commands the M494 to wait for a 0-9 program command or to reset on any other command. Display shows static half digit and g segment flashing at 5 Hz . Initiates an on command only after standby. |
| Vol. up/down Bri. up/down Sat. up/down Con. up/down | KB, D, RC | Increments up or down the relevant analog control counter every keystroke or continuously every 112 ms from KB and every 102 ms from the RC and data inputs. The display shows an up/down arrow for 300 ms min. |
| Tune up/down | KB | Increments up or down the tuning counter. The speed or increment/decrement is defined by Fig. 10. The display shows an up/down arrow for 300 ms min. |
| Mem. up/down | KB, D, RC | The program number (memory location) is incremented/decremented. |
| Mute (toggle) | KB, D, RC | Volume Mute. See mute section. |
| Standby | D, RC | Commands the standby state. |
| On/standby (toggle) | KB, D, RC | Commands the standby state from the on state and the on state from the standby state. |
| ON/OFF | KB | Commands the on state when in the off state and commands the off state when in the on state. See standby section. |
| Store Program | KB | The currently addressed memory location is written from the tuning, band and MS counters and the skip flag is reset. See fig. 11. Execution of this command is indicated by the display flashing at 5 Hz for 1 second. |
| Store analog Controls | KB | The analog control memories are written in sequence from the analog control counters. Execution of this command is indicated by the display flashing at 5 Hz for 1 second. |
| Band Sequence | KB | Command the next band in the sequence as defined in bands outputs section. One step for each key stroke. |
| MS Sequence | KB | Increments the MS counter by binary one. One step for each key stroke. |
| Normalise Analog | KB, D, RC | Reads the analog memories in sequence to their corresponding D/A's. The analog control outputs are disabled during the read sequence. |
| Memory addressing | KB | Strokes the program selected immediately after the memory addressing command (post tuning program selection). See fig. 12. |
| Set Skip Flag | KB | Sets the skip flag on the currently selected program. Execution of this command is indicated by the display flashing at 5 Hz for 1 second. |
| Skip Defeat | OS | Defeats the function of the skip bit to allow reading and writing of the currently selected program. |

KB = Keyboard; D = Data; RC = Remove Control; OS = Optıon Select.

Figs. $11 \& 12$ respectively show in flow diagram form the two methods for storing a station : pretuning program selection and post tuning program selection. Figs. 13, $14 \& 15$ show the select programme sub-
routine for figs. 11 \& 12 for either 16 program option or 20 program option with $1^{*}$ or $\pm 10$ (decade modes).

M708/A

## PCM REMOTE CONTROL TRANSMITTER

- 30 CHANNELS/4 ADDRESSES
- SELECTABLE FLASH/CARRIER TRANSMISSION MODE
- END OF TRANSMISSION CODE
- VERY LOW POWER DISSIPATION DURING TRANSMISSION : DUTY CYCLE $0.15 \%$ (flash mode), $0.7 \%$ (carrier mode)
- SINGLE CONTACT MATRIX KEYBOARD
- INTEGRATED ANTIBOUNCE AND INTERLOCK
- WIDE SUPPLY RANGE (M708 4.5 to 10.5 V)/(M708A 3 to 10.5 V )
- WIDE REFERENCE FREQUENCY RANGE ( 445 to 510 kHz ceramic resonator)
- 20 PIN PLASTIC PACKAGE
- TO BE USED IN CONJUNCTION WITH M491/M494 SINGLE CHIP STATION MEMORY AND R.C. RECEIVER (flash mode) OR WITH MICROPROCESSOR CONTROLLED SYSTEM (carrier mode)

## DESCRIPTION

This IC has been developed for remote control in consumer applications. It uses a highly reliable transmission code which has the capacity of 1024 channels. Each transmitted word is structured into 4 bits which constitute the address and 6 bits which constitute the command. However only 2 address bits and 30 commands are available in this IC. An additional command (000000) is used to transmit the "end of transmission code" when the key is released.
Additional bits are transmitted for synchronization of transmitter and receiver clocks and for security checks. The address organization provides simultaneous applications without interference among each system.
The receiver accepts the decoded command only if the transmitted address matches the address selected at the receiver. Four addresses are available for this purpose. The reference oscillator is controlled by a cheap ceramic resonator.
When the M708 works in conjunction with M491/M494 single chip Station Memory and R.C. receiver the oscillator frequency can be in the range 445 to 510 kHz and no synchronization is required with the receiver clock.

The M708 is produced with CMOS Si-gate technology and is available in a 20 pin dual in-line plastic package.

## PIN CONNECTIONS

Note : The test pin must be connected to $\mathrm{V}_{\text {ss }}$

## BLOCK DIAGRAM

## ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter | Value | Unit |
| :---: | :--- | :---: | :---: |

## DESCRIPTION

The signals are transmitted with infrared light using a Pulse Code Modulation. Each word consists of 12 bits. The binary information of a bit is determined by the time interval between two pulses. If "T" is the time base, the bits are coded as follows :

Odd bits (1, 3, etc)
$0=T$
$1=2 T$
Even bits (2, 4, etc.)
$0=T$
$1=3 T$

The different code introduced for the even and odd "1s" improves the capability to recognize false codes at the receiver end. For example the double error which can cause the exchange "10" with "01" is easily detected. A Parity bit is also added in order to further increase the reliability of the transmission. This bit is " 1 " if the number of transmitted " 1 " is even while it is " 0 " if the number of transmitted " 1 " is odd. In addition, every word contains a preliminary pulse, a start pulse and a stop pulse. The spacing between the preliminary and the start pulse is 4 T . This is followed after 1 T by 11 data pulses (one parity bit), and terminated after a 4T interval by a stop pulse. Consequently, a word in which the binary digit 0 occurs ten times has a total duration of 21T. A word containing ten "1s" has a duration of 36 T .

Example:

## SYNCHRONIZATION BETWEEN TRANSMITTER AND RECEIVER

The transmitter and the receiver can operate with different reference frequencies. Typical values suitable for correct operation of the system should be comprised between 445 and 510 kHz , using a cheap ceramic resonator.
Synchronization between the transmitter and the receiver, necessary to obtain the above described wide range of frequency tolerance is achieved by measuring in the receiver the interval between the start pulse and the first data pulse, storing this value and using it as time base T .

## KEYBOARD/CODE REPETITION

One column, input (pins IMNOPQ) has to be connected to one row (pins ACEGH) input to activate
the transmitter. The contact must be continuously closed for a minimum of 25 ms .

Double and multiple contact operations are not accepted. The command information is repeatedly transmitted at intervals of 102 ms ( $\mathrm{fref}=500 \mathrm{kHz}$ ) as long as the push button remains operated. When the contact is interrupted the circuit transmits, after a pause of 18 ms , the "end of transmission code" and returns to stand-by mode. If the contact is interrupted while a command is being transmitted the circuit carries on with the transmission to the end. After a pause of about 18 ms it transmits the end of transmission code.

No command is accepted until the "end of transmission code" is over.

## TRANSMISSION MODE (pin T)

The M708 can operate in Flash (pin $T=V_{D D}$ ) or
Carrier (pin $\mathrm{T}=\mathrm{V}_{\mathrm{SS}}$ ) transmission modes. Using a
referance frequency of 500 kHz the output signal has these formats respectively :

| Flash Mode |  | Transmission time $\mathrm{min} .=2.1 \mathrm{~ms}$ max. $=3.6 \mathrm{~ms}$ duty cycle $=0.15 \%$ |
| :---: | :---: | :---: |

Carrier Mode

Transmission time
$\mathrm{min} .=32.76 \mathrm{~ms}$
$\max =56.16 \mathrm{~ms}$
duty cycle $=0.7 \%$

## ADDRESS (pins X, Z)

The address information is coded and transmitted as follows.

| Address <br> Number | Transmitted Code |  |  | Address Input Code |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | A1 | A2 | A3 | A4 | $\mathbf{X}$ | Z |
| 1 | 0 | 0 | 0 | 0 | L | L |
| 2 | 1 | 0 | 0 | H | L |  |
| 9 | 0 | 0 | 0 | 1 | H |  |
| 10 | 1 | 0 | 1 | H |  |  |

The Address inputs have internal pull-downs which are disabled during stand-by.

Single address selection

Multiple address selection

Note : Unused inputs can be left open or connected to $\mathrm{V}_{\text {SS }}$

## TYPICAL APPLICATIONS

## FLASH MODE

Infrared Diode Peak Current $=1.8 \mathrm{~A}$
Total Average Consumption $=6.5 \mathrm{~mA}$

CARRIER MODE

Infrared Diode Peak Current $=1.25 \mathrm{~A}$
Total Average Consumption $=13 \mathrm{~mA}$

## PACKAGE MECHANICAL DATA

- 20 PIN PLASTIC PACKAGE
- TO BE USED IN CONJUNCTION WITH M491/M494 SINGLE CHIP STATION MEMORY AND R.C. RECEIVER (flash mode)

## DESCRIPTION

This IC has been developed for remote control in consumer applications. It uses a highly reliable transmission code wich has the capacity of 1024 channels. Each transmitted word is structured into 4 bits which constitute the address and 6 bits which constitute the command. However only 2 bits of addresses and 30 commands are available in this IC. An additional command ( 000000 ) is used to transmit the "end of transmission code" when the key is released.

Additional bits are transmitted for synchronization of transmitter and receiver clock and for security checks. The address organization provides simultaneous applications without interference among each system.
The receiver accepts the decoded command only if the transmitted address matches the address selected at the receiver. Two address are available for this purpose. The reference oscillator is controlled by a cheap ceramic resonator.
When the M708L works in conjunction with M491/M494 single chip Station Memory and R.C. receiver the oscillator frequency can be in the range 445 to 510 KHz and no synchronization is required with the receiver clock.

The M708L is produced with CMOS Si-gate technology and is available in a 20 pin dual in-line plastic package.

## DESCRIPTION

The signals are transmitted with infrared light using a Pulse Code Modulation. Each word consists of 12 bits. The binary information of a bit is determined by the time interval between two pulses. If "T" is the time base, the bits are coded as follows :

| Odd bits (1, 3, etc.)$\begin{aligned} & 0=T \\ & 1=2 T \end{aligned}$ | T | 2 T |
| :---: | :---: | :---: |
|  | " 0 " | " 1" |
|  | S-5561 |  |
|  | 89DSM708L-04 |  |
| T | 3 T |  |
| " 0 " | * 1 " |  |
| S-55 52 |  |  |
| Even bits (2, 4, etc.) $0=T$ | 89DSM708L-05 |  |
| $\begin{aligned} & 0=T \\ & 1=3 T \end{aligned}$ |  |  |

The different code introduced for the even and odd "1s" improves the capability to recognize false codes at the receiver end. For example the double error which can cause the exchange " 10 " with "01" is easily detected. A Parity bit is also added in order to further increase the reliability of the transmission. This bit is " 1 " if the number of transmitted " 1 " is even while it is " 0 " if the number of transmitted " 1 " is odd. In addition, every word contains a preliminary pulse, a start pulse and a stop pulse. The spacing between the preliminary and the start pulse is 4 T . This is followed after 1T by 11 data pulses (one parity bit), and terminated after a 4T interval by a stop pulse. Con-
sequently, a word in which the ninary digit 0 occurs ten times has a total duration of 21T. A word containing ten "1s" has a duration of 36 T .(see Example)

## SYNCHRONIZATION BETWEEN TRANSMITTER AND RECEIVER.

The transmitter and the receiver can operate with different reference frequencies. Typical values suitable for correct operation of the system should be comprised between 445 and 510 KHz , using a cheap ceramic resonator.
Synchronization between the transmitter and the receiver necessary to obtain the above described wide range of frequency tolerance is achieved by measuring in the receiver the interval between the start pulse and the first data pulse, storing this value and using it as time base T .

## KEYBOARD/CODE RECEPTION.

One column input (pins IMNOPQ) has to be connected to one row (pins ACEGH) input to activate the transmitter. The contact must be continuously closed for a minimum of 25 ms .
Double and multiple contact operations are not accepted. The command information is repatedly transmitted at intervals of 102 ms ( $\mathrm{fref}=500 \mathrm{KHz}$ ) as long as the push button remains operated.
When the contact is interrupted the circuit transmits, after a pause of 18 ms , the "end of transmission code" and returns to stand-by mode. If the contact is interrupted while a command is being transmitted the circuit carries on with the transmission to the end. After a pause of about 18 ms it transmits the end of transmission code.
No command is accepted until the "end of transmission code" is over.

Example

TRANSMISSION MODE (Pin T).
The M708 can operate in Flash (pin $T=V_{D D}$ ) or Carrier (pin $T=V_{S S}$ ) transmission modes. Using a reference frequency of 500 KHz the output signal has these formats respectively :
Flash mode

Carrier mode

ADDRESS (Pin $X, Z$ ).
The address information is coded and transmitted as follows :

| Address <br> Number | Transmitted Code |  |  | Address <br> Input Code |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | A1 | A2 | A3 | A4 | X | Z |
| 1 | 0 | 0 | 0 | 0 | L | L |
| 2 | 1 | 0 | 0 | 0 | H | L |
| 9 | 0 | 0 | 0 | 1 | L | H |
| 10 | 1 | 0 | 0 | 1 | H | H |
|  |  |  |  |  |  |  |

The Address inputs have internal pull-downs which are disabled during stand-by.
Note : Unused inputs can be left open or connected to $V_{\text {ss }}$

TYPICAL APPLICATION (flash mode)
STANDARD

VOLTAGE DUPLICATOR

## PCM REMOTE CONTROL TRANSMITTERS

- M 709 : 40 COMMANDS x 16 ADDRESSES
- M 710 : 64 COMMANDS x 16 ADDRESSES
- ADDRESS ORGANIZATION PROVIDES WIDE RANGE OF SIMULTANEOUS APPLICATIONS WITHOUT INTERFERENCE BETWEEN SYSTEMS
- IMPROVED PCM TRANSMISSION CODE PROVIDES EASY RECOGNITION OF FALSE SIGNALS
- "FLASH" OR "CARRIER" PIN SELECTABLE TRANSMISSION MODES
- END OF TRANSMISSION CODE
- SINGLE CONTACT MATRIX KEYBOARD
- INTEGRATED ANTIBOUNCE AND INTERLOCK
- WIDE SUPPLY RANGE (M709 - M710 4.5 to 10.5V) / (M709A - M710A 3 to 10.5V)
- WIDE REFERENCE FREQUENCY RANGE ( 445 to 510 kHz ceramic resonator)
- VERY LOW POWER CONSUMPTION DURING TRANSMISSION. OUTPUT DUTY CYCLE $0.15 \%$ (flash mode), $0.7 \%$ (carrier mode)
- FULLY COMPATIBLE WITH M491 AND M494 (In flash mode)

## DESCRIPTION

These ICs have been developed for remote control in consumer applications (TV, radio, videorecorders) or in the industrial field and use a highly reliable transmission code which has a capacity of 1024 channels. Each transmitted word is structured into 4 bits which constitute the address and 6 bits which constitute the command ( 64 commands available). One command ( $1 \mathrm{st}=000000$ ) is used to transmit the "end of transmission code " when the key is released. Additional bits are transmitted for synchronization of transmitter and receiver clocks and for security checks. The address organization provides a wide range of simultaneous applications without interference between systems. The receiver accepts the decoded command only if the transmitted address matches the address selected at the receiver. 16 addresses are available for this purpose.

The reference oscillator is controlled by a cheap ceramic or LC resonator. Two types of transmission mode are available : "Flash" or "Carrier" mode.
The M709 is a simplified version of the M710 which can only transmit 40 commands with 16 possible addresses. The M710 on the other hand has the full system capacity : it can transmit 64 commands with 16 addresses.
The M709 and M710 are produced with CMOS Si-gate technology and are available in 24 and 28 -pin dual in-line plastic packages respectively.

ORDER CODES : M709B1/M709AB1

## DESCRIPTION

The signals are transmitted with infrared light using pulse code modulation. Each word consists of 12 bits. The binary information of a bit is determined by the time interval between two pulses.
If " $T$ " is the time base, the bits are coded as follows :
Odd bits (1, 3, etc)
$0=T$
$1=2 T$

Even bits (2, 4, etc)
$0=T$
$1=3 T$

The different code introduced for the even and odd "1s" improves the capability to recognize false
codes at the receiver end. For example the double error which can cause the exchange "10" with "01" is easily detected.

A parity bit is also added in order to further increase the reliability of the transmission. This bits is "1" if the number of transmitted " 1 s " is even while it is " 0 " if the number of transmitted "1s" is odd.
In addition, every word contains a preliminary pulse, a start pulse and a stop pulse. The spacing between the preliminary and the start pulse is 4 T . This is followed after 1T by 11 data pulses (one parity bit), and terminated after 4T interval by a stop pulse.
Consequently, a word in which the binary digit 0 occurs ten times has a total duration of 21 T .
A word containing ten "1s" has a duration of 36 T .
Example :

## SYNCHRONIZATION BETWEEN TRANSMITTER AND RECEIVER

The transmitter and the receiver can operate with different reference frequencies.
Typical values suitable for correct operation of the system should be between 445 and 510 kHz , using a cheap ceramic resonator.
Synchronization between the transmitter and the receiver, necessary to obtain the wide range of frequency tolerance described above is achieved by measuring in the receiver the interval between the start pulse and the first data pulse, storing this value and using it as time base $T$.
KEYBOARD (pins A to Q) / CODE REPETITION
One column input ( $K$ to $Q$ ) has to be connected to one row ( A to H ) input to activate the transmitter. The
contact must be continuously closed for a minimum of 25 ms .

Double and multiple contact operations are not accepted.
The command information is repeatedly transmitted at intervals of 102 ms (fref $=500 \mathrm{kHz}$ ) as long as the push button remains operated.
When the contact is interrupted the circuit transmits, after a pause of about 18 ms , the "end of transmission code" and returns to stand-by mode.
If the contact is interrupted while a command is being transmitted the circuit carries on with the transmission to the end. After a pause of about 18 ms it transmits the end of transmission code.
No command is accepted until the "end of transmission code" is over.

## TRANSMISSION MODE (pin 1)

The M709/M710 can operate in Flash (pin $1=V_{D D}$ ) or Carrier (pin $1=\mathrm{V}_{\mathrm{ss}}$ ) transmission modes. Using
a reference frequency of 500 kHz the output signal has these formats :

SGS-THOMSON

ADDRESS (pins $X, Y, W, Z$ )
The Address information is coded and transmitted as follows :

|  | ADDRESS BITS |  |  |  | COMMAND BITS |  |  |  |  |  | PARITY BIT | STOP PULSE |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| PRELIMINARY PULSE AND START PULSE | A1 | A2 | A3 | A4 | C1 | C2 | C3 | C4 | C5 | C6 |  |  |
| t |  |  |  |  |  |  |  |  |  |  |  |  |
| 88DSM709A-12 |  |  |  |  |  |  |  |  |  |  |  |  |

| Address <br> Number | Transmitted Code |  |  |  | Address Input Code |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | A1 | A2 | A3 | A4 | $\mathbf{X}$ | $\mathbf{Y}$ | W | Z |
| 1 | 0 | 0 | 0 | 0 | L | L | L | L |
| 2 | 1 | 0 | 0 | 0 | H | L | L | L |
| 3 | 0 | 1 | 0 | 0 | L | H | L | L |
| 4 | 1 | 1 | 0 | 0 | H | H | L | L |
| 5 | 0 | 0 | 1 | 0 | L | L | H | L |
| 6 | 1 | 0 | 1 | 0 | H | L | H | L |
| 7 | 0 | 1 | 1 | 0 | L | H | H | L |
| 8 | 1 | 1 | 1 | 0 | H | H | H | L |
| 9 | 0 | 0 | 0 | 1 | L | L | L | H |
| 10 | 1 | 0 | 0 | 1 | H | L | L | H |
| 11 | 0 | 1 | 0 | 1 | L | H | L | H |
| 12 | 1 | 1 | 0 | 1 | H | H | H |  |
| 13 | 0 | 0 | 1 | L | L | H | H |  |
| 14 | 1 | 0 | 1 | H | L | H | H |  |
| 15 | 0 | 1 | 1 | H | H | H | H |  |
| 16 | 1 | 1 | 1 | H | H | H | H |  |

The address inputs have internal pull-downs which are disabled during stand-by.

Single address selection

Multiple address selection

Note : unused inputs can be left open or connected to $\mathrm{V}_{\mathrm{SS}}$

## TYPICAL APPLICATIONS

FLASH MODE

## CARRIER MODE

88DSM709A-16

INFRARED DIODE PEAK CURRENT $=1.25 \mathrm{~A}$
TOTAL AVERAGE CONSUMPTION $=13 \mathrm{~mA}$

## PACKAGE MECHANICAL DATA

## 24 PINS - PLASTIC DIP

28 PINS - PLASTIC DIP

M709L M710L

## PCM REMOTE CONTROL TRANSMITTERS (LOW VOLTAGE)

- 2.2V TO 5V OPERATING SUPPLY VOLTAGE RANGE
- M 709L : 40 COMMANDS $\times 16$ ADDRESSES
- M 710L : 64 COMMANDS x 16 ADDRESSES
- ADDRESS ORGANIZATION PROVIDES WIDE RANGE OF SIMULTANEOUS APPLICATIONS WITHOUT INTERFERENCE BETWEEN SYSTEMS
- IMPROVED PCM TRANSMISSION CODE PROVIDES EASY RECOGNITION OF FALSE SIGNALS
- "FLASH" OR "CARRIER" PIN SELECTABLE TRANSMISSION MODES
- END OF TRANSMISSION CODE
- SINGLE CONTACT MATRIX KEYBOARD
- INTEGRATED ANTIBOUNCE AND INTERLOCK
- WIDE REFERENCE FREQUENCY RANGE ( 445 to 510 kHz ceramic resonator)
- VERY LOW POWER CONSUMPTION DURING TRANSMISSION. OUTPUT DUTY CYCLE 0.15 \% (flash mode), 0.7 \% (carrier mode)
- FULLY COMPATIBLE WITH M491 AND M494 (In flash mode)

The reference oscillator is controlled by a cheap ceramic or LC resonator. Two types of transmission mode are available : "Flash" or "Carrier" mode.
The M709L is a simplified version of the M710L which can only transmit 40 commands with 16 possible addresses. The M710L on the other hand has the full system capacity : it can transmit 64 commands with 16 addresses.
The M709L and M710L are produced with CMOS Si-gate technology and are available in 24 and 28 -pin dual in-line plastic packages respectively.

PIN CONNECTIONS

Note : The test pın must be connected to $\mathrm{V}_{\text {ss }}$.

## BLOCK DIAGRAM

## ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter | Value | Unit |
| :---: | :--- | :---: | :---: |
| $\mathrm{V}_{\mathrm{DD}}$ | Supply Voltage Range | -0.3 to 5.5 | V |
| $\mathrm{~V}_{\mathrm{I}}$ | Input Voltage Range | -0.3 to $\mathrm{V}_{\mathrm{DD}}+0.3$ | V |
| $\mid \mathrm{Iol}$ | IR Output Current ( $\mathrm{t}<50 \mu \mathrm{~s}$ ) | 10 | mA |
| $\mathrm{P}_{\text {tot }}$ | Total Package Power Dissipation | 200 | mW |
| $\mathrm{~T}_{\text {oper }}$ | Operating Temperature Range | 0 to 70 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\text {stg }}$ | Storage Temperature Range | -55 to +125 | ${ }^{\circ} \mathrm{C}$ |

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability

## RECOMMENDED OPERATING CONDITIONS

| Symbol | Parameter | Value | Unit |
| :---: | :--- | :---: | :---: |
| $V_{D D}$ | Supply Voltage Range | 2.2 to 5 | V |
| $\mathrm{~V}_{\mathrm{I}}$ | Input Voltage Range | 0 to $\mathrm{V}_{\mathrm{DD}}$ | V |
| $\mid \mathrm{l}_{\mathrm{l}}$ | IR Output Current $(\mathrm{t}<50 \mu \mathrm{~s})$ | max. 2.5 | mA |
| $\mathrm{f}_{\text {ref }}$ | Reference Frequency Range | 445 to 510 | kHz |
| $\mathrm{T}_{\text {oper }}$ | Operating Temperature Range | 0 to 70 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{r}_{\mathrm{s}}$ | Serial Resistance of a Closed Key Contact | $\max .2 .5$ | $\mathrm{k} \Omega$ |
| $\mathrm{r}_{\mathrm{p}}$ | Parallel Resistance of Open Key Contact | min. 2.2 | $\mathrm{M} \Omega$ |
| $\mathrm{R}_{\mathrm{s}}$ | Serial Resistance of the Ceramic Resonator | max. 20 | $\Omega$ |

STATIC ELECTRICAL CHARACTERISTICS (over recommended operating conditions)
Typical values are at 9 V and $\mathrm{T}_{\text {AMB }}=25^{\circ} \mathrm{C}$

## DESCRIPTION

The signals are transmitted with infrared light using pulse code modulation. Each word consists of 12 bits. The binary information of a bit is determined by the time interval between two pulses.
If " T " is the time base, the bits are coded as follows :
Odd bits (1, 3, etc)
$0=T$
$1=2 T$

Even bits (2, 4, etc)
$0=T$
$1=3 T$

The different code introduced for the even and odd "1s" improves the capability to recognize false
codes at the receiver end. For example the double error which can cause the exchange "10" with "01" is easily detected.
A parity bit is also added in order to further increase the reliability of the transmission. This bits is " 1 " if the number of transmitted "1s" is even while it is "0" if the number of transmitted " 1 s " is odd.
In addition, every word contains a preliminary pulse, a start pulse and a stop pulse. The spacing between the preliminary and the start pulse is 4 T . This is followed after 1 T by 11 data pulses (one parity bit), and terminated after 4T interval by a stop pulse.

Consequently, a word in which the binary digit 0 occurs ten times has a total duration of 21 T .

A word containing ten "1s" has a duration of 36 T .
Example :

## SYNCHRONIZATION BETWEEN TRANSMIT-

 TER AND RECEIVERThe transmitter and the receiver can operate with different reference frequencies.
Typical values suitable for correct operation of the system should be between 445 and 510 kHz , using a cheap ceramic resonator.
Synchronization between the transmitter and the receiver, necessary to obtain the wide range of frequency tolerance described above is achieved by measuring in the receiver the interval between the start pulse and the first data pulse, storing this value and using it as time base $T$.

## KEYBOARD (pins A to Q) / CODE REPETITION

One column input ( $K$ to $Q$ ) has to be connected to one row ( A to H ) input to activate the transmitter. The
contact must be continuously closed for a minimum of 25 ms .

Double and multiple contact operations are not accepted.
The command information is repeatedly transmitted at intervals of 102 ms (fref $=500 \mathrm{kHz}$ ) as long as the push button remains operated.
When the contact is interrupted the circuit transmits, after a pause of about 18 ms , the "end of transmission code" and returns to stand-by mode.
If the contact is interrupted while a command is being transmitted the circuit carries on with the transmission to the end. After a pause of about 18 ms it transmits the end of transmission code.
No command is accepted until the "end of transmission code" is over.

## TRANSMISSION MODE (pin 7)

The M709L/M710L can operate in Flash (pin $\mathrm{T}=$ $V_{D D}$ ) or Carrier (pin $T=V_{S S}$ ) transmission modes.

Using a reference frequency of 500 kHz the output signal has these formats :

Flash mode

88DSM709L-10

## Carrier mode

88DSM709L-11

## Transmission time

min . $=2.1 \mathrm{~ms}$
max. $=3.6 \mathrm{~ms}$
duty cycle $=0.15 \%$

## Transmission time

$\mathrm{min} .=32.76 \mathrm{~ms}$
max. $=56.16 \mathrm{~ms}$
duty cycle $=0.7 \%$

ADDRESS (pins X, Y, W, Z)
The Address information is coded and transmitted as follows :

|  | ADDRESS BITS |  |  |  | COMMAND BITS |  |  |  |  |  | PARITY BIT | STOP PULSE |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## REMOTE CONTROL TRANSMITTER

- FLASHED OR MODULATED TRANSMISSION
- 7 SUB-SYSTEM ADDRESSES
- UP TO 64 COMMANDS PER SUB-SYSTEM ADDRESS
- HIGH-CURRENT REMOTE OUTPUT AT $\mathrm{V}_{\mathrm{DD}}=6 \mathrm{~V}(-\mathrm{loH}=80 \mathrm{~mA})$
- LOW NUMBER OF ADDITIONAL COMPONENTS
- KEY RELEASE DETECTION BY TOGGLE BITS
- VERY LOW STAND-BY CURRENT ( < $2 \mu \mathrm{~A}$ )
- OPERATIONAL CURRENT < 1mA AT 6V SUPPLY
- SUPPLY VOLTAGE RANGE 4 TO 11V
- CERAMIC RESONATOR CONTROLLED FREQUENCY (typ. 450kHz)

## DESCRIPTION

The M3004AB1 transmitter IC is designed for infrared remote control systems. It has a total of 448 commands which are divided into 7 sub-system groups with 64 commands each. The sub-system code may be selected by a press button, a slider switch or hard wired.
The M3004AB1 generates the pattern for driving the output stage. These patterns are pulse distance coded. The pulses are infrared flashes or modulated. The transmission mode is defined in conjunction with the sub-system address. Modulated pulses allow receivers with narrow-band preamplifiers for improved noise rejection to be used. Flashed pulses require a wide-band preamplifier within the receiver.

PIN CONNECTIONS

BLOCK DIAGRAM

## INPUTS AND OUTPUTS

Key matrix inputs and outputs (DRVON to DRV6N and SEN0N to SEN6N).
The transmitter keyboard is arranged as a scanned matrix. The matrix consists of 7 driver outputs and 7 sense inputs as shown in fig. 1. The driver outputs DRV0N to DRV6N are open drain N-channel transistors and they are conductive in the stand-by mode. The 7 sense inputs (SENON to SEN6N) enable the generation of 56 command codes. With 2 external diodes all 64 commands are addressable. The sense inputs have P-channel pull-up transistors so that they are HIGH until they are pulled LOW by connecting them to an output via a key depression to initiate a code transmission.

## ADDRESS MODE INPUT (ADRM)

The sub-system address and the transmission mode are defined by connecting the ADRM input to one or more driver outputs (DRV0N to DRV6N) of the key matrix. If more than one driver is connected to ADRM, they must be decoupled by diodes. This allows the definition of seven sub-system addresses as shown in table 3. If driver DRV6N is connected to ADRM, the data output
format of REMO is modulated or if not connected, flashed.
The ADRM input has switched pull-up and pulldown loads. In the stand-by mode only the pulldown device is active. Whether ADRM is open (sub-system address 0 , flashed mode) or connected to the driver outputs, this input is LOW and will not cause unwanted dissipation. When the transmitter becomes active by pressing a key, the pull-down device is switched off and the pull-up device is switched on, so that the applied driver signals are sensed for the decoding of the sub-system address and the mode of transmission.
The arrangement of the sub-system address coding is such that only the driver DRVnM with the highest number ( n ) defines the sub-system address, e.g. if drivers DRV2N and DRV4N are connected to ADRM, only DRV4N will define the sub-system address. This option can be used in systems requiring more than one sub-system address. The transmitter may be hard-wired for subsystem address 2 by connecting DRV1N to ADRM. If now DRV3N is added to ADRM by a key or a switch, the transmitted sub-system address changes to 4 . A change of the sub-system address will not start a transmision.

## REMOTE CONTROL SIGNAL OUTPUT (REMO)

The REMO signal output stage is a push-pull type. In the HIGH state, a bipolar emitter-follower allows a high output current. The timing of the data output format is listed in tables 1 and 2. The information is defined by the distance to between the leading edges of the flashed pulses or the first edge of the modulated pulses (see fig. 3). The format of the output data is given in fig. 2 and 3. The data word starts with two toggle bits T1 and T0, followed by three bits for defining the sub-system address S 2 , S1 and S0, and six bits F, E, D, C, B and A which are defined by the selected key.
In the modulated transmission mode the first toggle bit is replaced by a constant reference time bit (REF). This can be used as a reference time for the decoding sequence. The toggle bits function is an indication for the decoder that the next instruction has to be considered as a new command. The codes for the sub-system address and the selected key are given in tables 3 and 4.
The REMO output is protected against "Lock-up", i.e. the length of an output pulse is limited to $<1 \mathrm{~ms}$, even if the oscillator stops during an output pulse. This avoids the rapid discharge of the battery that would otherwise be caused by the continuous activation of the LED.

## OSCILLATOR INPUT / OUTPUT (osci and osco)

The external components must be connected to these pins when using an oscillator with a ceramic resonator. The oscillator frequency may vary between 350 kHz and 600 kHz as defined by the resonator.

## FUNCTIONAL DESCRIPTION

## Keyboard operation.

In the stand-by mode all drivers (DRVON to DRV6N) are on (low impedance to $\mathrm{V}_{\mathrm{ss}}$ ). Whenever a key is pressed, one or more of the sense inputs (SENnN) are tied to ground. This will start the power-up sequence. First the oscillator is activated and after the debounce time tDB (see fig. 4) the output drivers (DRV0N to DRV6N) become active successively.
Within the first scan cycle the transmission mode, the applied sub-system address and the selected
command code are sensed and loaded into an internal data latch.
In contrast to the command code, the sub-system is sensed only within the first scan cycle. If the applied sub-system address is changed while the command key is pressed, the transmitted sub-system address is not altered.
In a multiple key stroke sequence (see fig. 5) the command code is always altered in accordance with the sensed key.

## MULTIPLE KEY-STROKE PROTECTION

The keyboard is protected against multiple keystrokes. If more than one key is pressed at the same time, the circuit will not generate a new output at REMO (see fig. 5). In case of a multiple key-stroke, the scan repetition rate is increased to detect the release of a key as soon as possible.
There are two restrictions caused by the special structure of the keyboard matrix :

- The keys switching to ground (code numbers 7, $15,23,31,39,47,55$ and 63) and the keys connected to SEN5N and SEN6N are not covered completely by the multiple key protection. If one sense input is switched to ground, further keys on the same sense line are ignored, i.e. the command code corresponding to "key to ground" is transmitted.
- SEN5N and SEN6N are not protected against multiple keystroke on the same driver line, because this condition has been used for the definition of additional codes (code number 56 to $63)$.

## OUTPUT SEQUENCE (data format)

The output operation will start when the selected code is found. A burst of pulses, including the latched address and command codes, is generated at the output REMO as long as a key is pressed. The format of the output pulse train is given in fig. 2 and 3. The operation is terminated by releasing the key or if more than one key is pressed at the same time. Once a sequence is started, the transmitted data words will always be completed after the key is released.
The toggle bits T0 and T1 are incremented if the key is released for a minimum time trel (see fig. 4). The toggle bits remain unchanged within a multiple key-stroke sequence.

PIN CONNECTIONS

BLOCK DIAGRAM

## INPUTS AND OUTPUTS

Key matrix inputs and outputs (DRVON to DRV6N and SENON to SEN6N).
The transmitter keyboard is arranged as a scanned matrix. The matrix consists of 7 driver outputs and 7 sense inputs as shown in fig. 1. The driver outputs DRV0N to DRV6N are open drain N-channel transistors and they are conductive in the stand-by mode. The 7 sense inputs (SENON to SEN6N) enable the generation of 56 command codes. With 2 external diodes all 64 commands are addressable. The sense inputs have P-channel pull-up transistors so that they are HIGH until they are pulled LOW by connecting them to an output via a key depression to initiate a code transmission.

## ADDRESS MODE INPUT (ADRM)

The sub-system address and the transmission mode are defined by connecting the ADRM input to one or more driver outputs (DRVON to DRV6N) of the key matrix. If more than one driver is connected to ADRM, they must be decoupled by diodes. This allows the definition of seven sub-system addresses as shown in table 3. If driver DRV6N is connected to ADRM, the data output
format of REMO is modulated or if not connected, flashed.
The ADRM input has switched pull-up and pulldown loads. In the stand-by mode only the pulldown device is active. Whether ADRM is open (sub-system address 0 , flashed mode) or connected to the driver outputs, this input is LOW and will not cause unwanted dissipation. When the transmitter becomes active by pressing a key, the pull-down device is switched off and the pull-up device is switched on, so that the applied driver signals are sensed for the decoding of the sub-system address and the mode of transmission.
The arrangement of the sub-system address coding is such that only the driver DRVnM with the highest number ( n ) defines the sub-system address, e.g. if drivers DRV2N and DRV4N are connected to ADRM, only DRV4N will define the sub-system address. This option can be used in systems requiring more than one sub-system address. The transmitter may be hard-wired for subsystem address 2 by connecting DRV1N to ADRM. If now DRV3N is added to ADRM by a key or a switch, the transmitted sub-system address changes to 4. A change of the sub-system address will not start a transmision.

## REMOTE CONTROL SIGNAL OUTPUT (REMO)

The REMO signal output stage is a push-pull type. In the HIGH state, a bipolar emitter-follower allows a high output current. The timing of the data output format is listed in tables 1 and 2. The information is defined by the distance $t_{b}$ between the leading edges of the flashed pulses or the first edge of the modulated pulses (see fig. 3). The format of the output data is given in fig. 2 and 3. The data word starts with two toggle bits T1 and T0, followed by three bits for defining the sub-system address S2, S1 and S0, and six bits F, E, D, C, B and A which are defined by the selected key.
In the modulated transmission mode the first toggle bit is replaced by a constant reference time bit (REF). This can be used as a reference time for the decoding sequence. The toggle bits function is an indication for the decoder that the next instruction has to be considered as a new command. The codes for the sub-system address and the selected key are given in tables 3 and 4 .
The REMO output is protected against "Lock-up", i.e. the length of an output pulse is limited to $<1 \mathrm{~ms}$, even if the oscillator stops during an output pulse. This avoids the rapid discharge of the battery that would otherwise be caused by the continuous activation of the LED.

## OSCILLATOR INPUT / OUTPUT (osci and osco)

The external components must be connected to these pins when using an oscillator with a ceramic resonator. The oscillator frequency may vary between 350 kHz and 600 kHz as defined by the resonator.

## FUNCTIONAL DESCRIPTION

## Keyboard operation.

In the stand-by mode all drivers (DRVON to DRV6N) are on (low impedance to $\mathrm{V}_{\mathrm{SS}}$ ). Whenever a key is pressed, one or more of the sense inputs (SENnN) are tied to ground. This will start the power-up sequence. First the oscillator is activated and after the debounce time tDb (see fig. 4) the output drivers (DRV0N to DRV6N) become active successively.
Within the first scan cycle the transmission mode, the applied sub-system address and the selected
command code are sensed and loaded into an internal data latch.
In contrast to the command code, the sub-system is sensed only within the first scan cycle. If the applied sub-system address is changed while the command key is pressed, the transmitted sub-system address is not altered.
In a multiple key stroke sequence (see fig. 5) the command code is always altered in accordance with the sensed key.

## MULTIPLE KEY-STROKE PROTECTION

The keyboard is protected against multiple keystrokes. If more than one key is pressed at the same time, the circuit will not generate a new output at REMO (see fig. 5). In case of a multiple key-stroke, the scan repetition rate is increased to detect the release of a key as soon as possible.
There are two restrictions caused by the special structure of the keyboard matrix :

- The keys switching to ground (code numbers 7, $15,23,31,39,47,55$ and 63) and the keys connected to SEN5N and SEN6N are not covered completely by the multiple key protection. If one sense input is switched to ground, further keys on the same sense line are ignored, i.e. the command code corresponding to "key to ground" is transmitted.
- SEN5N and SEN6N are not protected against multiple keystroke on the same driver line, because this condition has been used for the definition of additional codes (code number 56 to 63).

## OUTPUT SEQUENCE (data format)

The output operation will start when the selected code is found. A burst of pulses, including the latched address and command codes, is generated at the output REMO as long as a key is pressed. The format of the output pulse train is given in fig. 2 and 3. The operation is terminated by releasing the key or if more than one key is pressed at the same time. Once a sequence is started, the transmitted data words will always be completed after the key is released.
The toggle bits T0 and T1 are incremented if the key is released for a minimum time trel (see fig. 4). The toggle bits remain unchanged within a multiple key-stroke sequence.

## REMOTE CONTROL TRANSMITTER

- FLASHED OR MODULATED TRANSMISSION
- 7 SUB-SYSTEM ADDRESSES
-UP TO 64 COMMANDS PER SUB-SYSTEM ADDRESS
- HIGH-CURRENT REMOTE OUTPUT AT $\mathrm{V}_{\mathrm{DD}}=6 \mathrm{~V}\left(-\mathrm{l}_{\mathrm{OH}}=80 \mathrm{~mA}\right)$
- LOW NUMBER OF ADDITIONAL COMPONENTS
- KEY RELEASE DETECTION BY TOGGLE BITS
- VERY LOW STAND-BY CURRENT (< $2 \mu \mathrm{~A}$ )
- OPERATIONAL CURRENT < 1mA AT 6V SUPPLY
- SUPPLY VOLTAGE RANGE 4 TO 11V
- CERAMIC RESONATOR CONTROLLED FREQUENCY (typ. 450kHz)

## DESCRIPTION

The M3005AB1 transmitter IC is designed for infrared remote control systems. It has a total of 448 commands which are divided into 7 sub-system groups with 64 commands each. The sub-system code may be selected by a press button, a slider switch or hard wired.
The M3005AB1 generates the pattern for driving the output stage. These patterns are pulse distance coded. The pulses are infrared flashes or modulated. The transmission mode is defined in conjunction with the sub-system address. Modulated pulses allow receivers with narrow-band preamplifiers for improved noise rejection to be used. Flashed pulses require a wide-band preamplifier within the receiver.

PIN CONNECTIONS

## BLOCK DIAGRAM

## INPUTS AND OUTPUTS

Key matrix inputs and outputs (DRVON to DRV6N and SEN0N to SEN6N).
The transmitter keyboard is arranged as a scanned matrix. The matrix consists of 7 driver outputs and 7 sense inputs as shown in fig. 1. The driver outputs DRV0N to DRV6N are open drain N-channel transistors and they are conductive in the stand-by mode. The 7 sense inputs (SENON to SEN6N) enable the generation of 56 command codes. With 2 external diodes all 64 commands are addressable. The sense inputs have P-channel pull-up transistors so that they are HIGH until they are pulled LOW by connecting them to an output via a key depression to initiate a code transmission.

## ADDRESS MODE INPUT (ADRM)

The sub-system address and the transmission mode are defined by connecting the ADRM input to one or more driver outputs (DRV0N to DRV6N) of the key matrix. If more than one driver is connected to ADRM, they must be decoupled by diodes. This allows the definition of seven sub-system addresses as shown in table 3. If driver DRV6N is connected to ADRM, the data output
format of REMO is modulated or if not connected, flashed.
The ADRM input has switched pull-up and pulldown loads. In the stand-by mode only the pulldown device is active. Whether ADRM is open (sub-system address 0 , flashed mode) or connected to the driver outputs, this input is LOW and will not cause unwanted dissipation. When the transmitter becomes active by pressing a key, the pull-down device is switched off and the pull-up device is switched on, so that the applied driver signals are sensed for the decoding of the sub-system address and the mode of transmission.
The arrangement of the sub-system address coding is such that only the driver DRVnM with the highest number ( $n$ ) defines the sub-system address, e.g. if drivers DRV2N and DRV4N are connected to ADRM, only DRV4N will define the sub-system address. This option can be used in systems requiring more than one sub-system address. The transmitter may be hard-wired for subsystem address 2 by connecting DRV1N to ADRM. If now DRV3N is added to ADRM by a key or a switch, the transmitted sub-system address changes to 4 . A change of the sub-system address will not start a transmision.

SGS-THOMSON
MICROELECURONUCS

## REMOTE CONTROL SIGNAL OUTPUT (REMO)

The REMO signal output stage is a push-pull type. In the HIGH state, a bipolar emitter-follower allows a high output current. The timing of the data output format is listed in tables 1 and 2. The information is defined by the distance $t_{b}$ between the leading edges of the flashed pulses or the first edge of the modulated pulses (see fig. 3). The format of the output data is given in fig. 2 and 3. The data word starts with two toggle bits T1 and T0, followed by three bits for defining the sub-system address S 2 , S1 and S0, and six bits F, E, D, C, B and A which are defined by the selected key.
In the modulated transmission mode the first toggle bit is replaced by a constant reference time bit (REF). This can be used as a reference time for the decoding sequence. The toggle bits function is an indication for the decoder that the next instruction has to be considered as a new command. The codes for the sub-system address and the selected key are given in tables 3 and 4.
The REMO output is protected against "Lock-up", i.e. the length of an output pulse is limited to $<1 \mathrm{~ms}$, even if the oscillator stops during an output pulse. This avoids the rapid discharge of the battery that would otherwise be caused by the continuous activation of the LED.

## OSCILLATOR INPUT / OUTPUT (osci and osco)

The external components must be connected to these pins when using an oscillator with a ceramic resonator. The oscillator frequency may vary between 350 kHz and 600 kHz as defined by the resonator.

## FUNCTIONAL DESCRIPTION

## Keyboard operation.

In the stand-by mode all drivers (DRVON to DRV6N) are on (low impedance to $\mathrm{V}_{\mathrm{ss}}$ ). Whenever a key is pressed, one or more of the sense inputs (SENnN) are tied to ground. This will start the power-up sequence. First the oscillator is activated and after the debounce time tob (see fig. 4) the output drivers (DRV0N to DRV6N) become active successively.
Within the first scan cycle the transmission mode, the applied sub-system address and the selected
command code are sensed and loaded into an internal data latch.
In contrast to the command code, the sub-system is sensed only within the first scan cycle. If the applied sub-system address is changed while the command key is pressed, the transmitted sub-system address is not altered.
In a multiple key stroke sequence (see fig. 5) the command code is always altered in accordance with the sensed key.

## MULTIPLE KEY-STROKE PROTECTION

The keyboard is protected against multiple keystrokes. If more than one key is pressed at the same time, the circuit will not generate a new output at REMO (see fig. 5). In case of a multiple key-stroke, the scan repetition rate is increased to detect the release of a key as soon as possible. There are two restrictions caused by the special structure of the keyboard matrix :

- The keys switching to ground (code numbers 7, $15,23,31,39,47,55$ and 63 ) and the keys connected to SEN5N and SEN6N are not covered completely by the multiple key protection. If one sense input is switched to ground, further keys on the same sense line are ignored, i.e. the command code corresponding to "key to ground" is transmitted.
- SEN5N and SEN6N are not protected against multiple keystroke on the same driver line, because this condition has been used for the definition of additional codes (code number 56 to 63).

## OUTPUT SEQUENCE (data format)

The output operation will start when the selected code is found. A burst of pulses, including the latched address and command codes, is generated at the output REMO as long as a key is pressed. The format of the output pulse train is given in fig. 2 and 3 . The operation is terminated by releasing the key or if more than one key is pressed at the same time. Once a sequence is started, the transmitted data words will always be completed after the key is released.
The toggle bits T0 and T1 are incremented if the key is released for a minimum time trel (see fig. 4). The toggle bits remain unchanged within a multiple key-stroke sequence.

Table 1 : Pulse Train Timing.

| Mode | $\mathrm{T}_{\mathrm{O}}(\mathrm{ms})$ | $\mathrm{t}_{\mathrm{P}}(\mu \mathbf{s})$ | $\mathrm{t}_{\mathrm{M}}(\mu \mathbf{s})$ | $\mathrm{t}_{\mathrm{w}}(\mathbf{m s})$ |
| :--- | :---: | :---: | :---: | :---: |
| Flashed | 2.53 | 8.8 | - | 121 |
| Modulated | 2.53 | - | tosc | 121 |

|  | Flash Mode | Carrier Mode |  |
| :---: | :---: | :---: | :--- |
| fosc | 455 kHz | 600 kHz |  |
| $\mathrm{t}_{\mathrm{p}}$ | $4 \times$ tosc |  | Flashed Pulse Width |
| $\mathrm{t}_{\mathrm{M}}$ |  | tosc | Modulation Perıod |
| N |  | $8^{\star}$ | Number of Modulation Pulses |
| $\mathrm{To}_{\mathrm{o}}$ | $1152 \times$ tosc | $1536 \times$ tOSC | Basic Unit of Pulse Distance |
| tw | $55296 \times$ tosc | $73728 \times$ tOSC | Word Distance |

The following number of pulses may be selected by Metal optıon: $N=8,12,16$
Note: The different dividıng ratıo for To and tw between flash mode and carrier mode is obtained by changıng the modulo of a partıcular divider from divide by 3 during flash mode to divide by 4 during carrier mode This allows the use of a 600 kHz ceramic resonator during carrier mode to obtain a better noise immunity for the receiver without a significant change in To and tw. For first samples, the correct divider ratıon is obtained by a metal mask optıon For final parts, this is automatıcally done together with the selection of flash-/carrier mode.

Table 2 : Pulse Train Separation (tb).

| Code | $\boldsymbol{t}_{\mathrm{b}}$ |

## REMOTE CONTROL TRANSMITTER

- FLASHED OR MODULATED TRANSMISSION
- 7 SUB-SYSTEM ADDRESSES
- UP TO 64 COMMANDS PER SUB-SYSTEM ADDRESS
- HIGH-CURRENT REMOTE OUTPUT AT $V_{D D}=6 \mathrm{~V}(-\mathrm{loH}=80 \mathrm{~mA})$
- LOW NUMBER OF ADDITIONAL COMPONENTS
- KEY RELEASE DETECTION BY TOGGLE BITS
- VERY LOW STAND-BY CURRENT ( < $2 \mu \mathrm{~A}$ )
- OPERATIONAL CURRENT < 1mA AT 6V SUPPLY
- SUPPLY VOLTAGE RANGE 2 TO 6.5V
- CERAMIC RESONATOR CONTROLLED FREQUENCY (typ. 450kHz)

## DESCRIPTION

The M3005LAB1 transmitter IC is designed for infrared remote control systems. It has a total of 448 commands which are divided into 7 sub-system groups with 64 commands each. The sub-system code may be selected by a press button, a slider switch or hard wired.
The M3005LAB1 generates the pattern for driving the output stage. These patterns are pulse distance coded. The pulses are infrared flashes or modulated. The transmission mode is defined in conjunction with the sub-system address. Modulated pulses allow receivers with narrow-band preamplifiers for improved noise rejection to be used. Flashed pulses require a wide-band preamplifier within the receiver.

## PIN CONNECTIONS

91DS3005LAB1-01

BLOCK DIAGRAM

## INPUTS AND OUTPUTS

Key matrix inputs and outputs (DRVON to DRV6N and SENON to SEN6N).
The transmitter keyboard is arranged as a scanned matrix. The matrix consists of 7 driver outputs and 7 sense inputs as shown in fig. 1. The driver outputs DRVON to DRV6N are open drain N -channel transistors and they are conductive in the stand-by mode. The 7 sense inputs (SENON to SEN6N) enable the generation of 56 command codes. With 2 external diodes all 64 commands are addressable. The sense inputs have P-channel pull-up transistors so that they are HIGH until they are pulled LOW by connecting them to an output via a key depression to initiate a code transmission.

## ADDRESS MODE INPUT (ADRM)

The sub-system address and the transmission mode are defined by connecting the ADRM input to one or more driver outputs (DRV0N to DRV6N) of the key matrix. If more than one driver is connected to ADRM, they must be decoupled by diodes. This allows the definition of seven sub-system addresses as shown in table 3. If driver DRV6N is connected to ADRM, the data output
format of REMO is modulated or if not connected, flashed.
The ADRM input has switched pull-up and pulldown loads. In the stand-by mode only the pulldown device is active. Whether ADRM is open (sub-system address 0 , flashed mode) or connected to the driver outputs, this input is LOW and will not cause unwanted dissipation. When the transmitter becomes active by pressing a key, the pull-down device is switched off and the pull-up device is switched on, so that the applied driver signals are sensed for the decoding of the sub-system address and the mode of transmission.
The arrangement of the sub-system address coding is such that only the driver DRVnM with the highest number ( n ) defines the sub-system address. e.g. if drivers DRV2N and DRV4N are connected to ADRM, only DRV4N will define the sub-system address. This option can be used in systems requiring more than one sub-system address. The transmitter may be hard-wired for subsystem address 2 by connecting DRV1N to ADRM. If now DRV3N is added to ADRM by a key or a switch, the transmitted sub-system address changes to 4 . A change of the sub-system address will not start a transmision.

## REMOTE CONTROL SIGNAL OUTPUT (REMO)

The REMO signal output stage is a push-pull type. In the HIGH state, a bipolar emitter-follower allows a high output current. The timing of the data output format is listed in tables 1 and 2. The information is defined by the distance to between the leading edges of the flashed pulses or the first edge of the modulated pulses (see fig. 3). The format of the output data is given in fig. 2 and 3 . The data word starts with two toggle bits T1 and T0, followed by three bits for defining the sub-system address S 2 , S1 and S0, and six bits F, E, D, C, B and A which are defined by the selected key.
In the modulated transmission mode the first toggle bit is replaced by a constant reference time bit (REF). This can be used as a reference time for the decoding sequence. The toggle bits function is an indication for the decoder that the next instruction has to be considered as a new command. The codes for the sub-system address and the selected key are given in tables 3 and 4.
The REMO output is protected against "Lock-up", i.e. the length of an output pulse is limited to $<1 \mathrm{~ms}$, even if the oscillator stops during an output pulse. This avoids the rapid discharge of the battery that would otherwise be caused by the continuous activation of the LED.

## OSCILLATOR INPUT / OUTPUT (osci and osco)

The external components must be connected to these pins when using an oscillator with a ceramic resonator. The oscillator frequency may vary between 350 kHz and 600 kHz as defined by the resonator.

## FUNCTIONAL DESCRIPTION

## Keyboard operation.

In the stand-by mode all drivers (DRVON to DRV6N) are on (low impedance to Vss ). Whenever a key is pressed, one or more of the sense inputs (SENnN) are tied to ground. This will start the power-up sequence. First the oscillator is activated and after the debounce time tDb (see fig. 4) the output drivers (DRV0N to DRV6N) become active successively.
Within the first scan cycle the transmission mode, the applied sub-system address and the selected
command code are sensed and loaded into an internal data latch.
In contrast to the command code, the sub-system is sensed only within the first scan cycle. If the applied sub-system address is changed while the command key is pressed, the transmitted sub-system address is not altered.
In a multiple key stroke sequence (see fig. 5) the command code is always altered in accordance with the sensed key.

## MULTIPLE KEY-STROKE PROTECTION

The keyboard is protected against multiple keystrokes. If more than one key is pressed at the same time, the circuit will not generate a new output at REMO (see fig. 5). In case of a multiple key-stroke, the scan repetition rate is increased to detect the release of a key as soon as possible.
There are two restrictions caused by the special structure of the keyboard matrix :

- The keys switching to ground (code numbers 7, $15,23,31,39,47,55$ and 63) and the keys connected to SEN5N and SEN6N are not covered completely by the multiple key protection. If one sense input is switched to ground, further keys on the same sense line are ignored, i.e. the command code corresponding to "key to ground" is transmitted.
- SEN5N and SEN6N are not protected against multiple keystroke on the same driver line, because this condition has been used for the definition of additional codes (code number 56 to $63)$.

## OUTPUT SEQUENCE (data format)

The output operation will start when the selected code is found. A burst of pulses, including the latched address and command codes, is generated at the output REMO as long as a key is pressed. The format of the output pulse train is given in fig. 2 and 3. The operation is terminated by releasing the key or if more than one key is pressed at the same time. Once a sequence is started, the transmitted data words will always be completed after the key is released.
The toggle bits T0 and T1 are incremented if the key is released for a minimum time trel (see fig. 4). The toggle bits remain unchanged within a multiple key-stroke sequence.

Table 1 : Pulse Train Timing.

| Mode | $\mathrm{T}_{\mathrm{O}}(\mathrm{ms})$ | $\mathbf{t p}_{\mathrm{P}}(\mu \mathbf{s})$ | $\mathrm{t}_{\mathrm{M}}(\mu \mathbf{s})$ | $\mathbf{t}_{\mathrm{W}}(\mathrm{ms})$ |
| :--- | :---: | :---: | :---: | :---: |
| Flashed | 2.53 | 8.8 | - | 121 |
| Modulated | 2.53 | - | tosc | 121 |

|  | Flash Mode | Carrier Mode |  |
| :---: | :---: | :---: | :---: |
| fosc | 455 kHz | 600 kHz | - • |
| $t_{p}$ | $4 \times$ tosc |  | Flashed Pulse Width |
| $\mathrm{t}_{\mathrm{M}}$ | $12 \times$ tosc | tOSC | Modulation Period |
| N |  | 8* | Number of Modulatıon Pulses |
| To | $1152 \times$ tosc | $1536 \times$ tOSC | Basıc Unit of Pulse Distance |
| tw | $55296 \times$ tosc | $73728 \times$ tOSC $\therefore$ | Word Distance |

The following number of pulses may be selected by Metal option $\cdot N=8,12,16$
Note : The different dividing ratıo for To and tw between flash mode and carrier mode is obtained by changing the modulo of a partıcular divider from divide by 3 during flash mode to divide by 4 during carrier mode This allows the use of a 600 kHz ceramic resonator during carrier mode to obtain a better noise immunity for the receiver without a significant change in To and tw For first samples, the correct divider ration is obtained by a metal mask option. For final parts, this is automatically done together with the selection of flash-/carrier mode.

Table 2 : Pulse Train Separation ( tb ).

| Code | $\mathbf{t}_{\mathbf{b}}$ |
| :--- | :---: |
| Logic "0" | $2 \times \mathrm{T}_{0}$ |
| Logic "1" | $3 \times \mathrm{T}_{0}$ |
| Toggle Bit Time | $2 \times \mathrm{T}_{0}$ or $3 \times \mathrm{T}_{0}$ |

Table 3 : Transmission Mode and Sub-system Adress Selection.
The sub-system address and the transmission mode are defined by connecting the ADRM input
to one or more driver outputs (DRV0N To DRV6N) of the key matrix. If more than one driver is connected to ADRM, they must be decoupled by diodes.

## REMOTE CONTROL TRANSMITTER

- FLASHED OR MODULATED TRANSMISSION
- 5 SUB-SYSTEM ADDRESSES
-UP TO 36 COMMANDS PER SUB-SYSTEM ADDRESS
- HIGH-CURRENT REMOTE OUTPUT AT VDD = $6 \mathrm{~V}(-\mathrm{loH}=120 \mathrm{~mA})$
: LOW NUMBER OF ADDITIONAL COMPONENTS
- KEY RELEASE DETECTION BY TOGGLE BITS
- VERY LOW STAND-BY CURRENT ( $<2 \mu \mathrm{~A}$ )
- OPERATIONAL CURRENT < 1mA AT 6V SUPPLY
- SUPPLY VOLTAGE RANGE 2 TO 6.5V
- CERAMIC RESONATOR CONTROLLED FREQUENCY (typ. 450kHz)
- ENCAPSULATION : 16-LEAD PLASTIC DIL

## DESCRIPTION

The M3006LAB1 transmitter IC is designed for infrared remote control systems. It has a total of 180 commands which are divided into 5 sub-system groups with 36 commands each. The sub-system code may be selected by a press button, a slider switch or hard wired.
The M3006LAB1 generates the pattern for driving the output stage. These patterns are pulse distance coded. The pulses are infrared flashes or modulated. The transmission mode is defined in conjunction with the sub-system address. Modulated pulses allow receivers with narrow-band preamplifiers for improved noise rejection to be used. Flashed pulses require a wide-band preamplifier within the receiver.

ADVANCE DATA

PIN CONNECTIONS

## BLOCK DIAGRAM

## INPUTS AND OUTPUTS

Key matrix inputs and outputs (DRVON to DRV6N and SENON to SEN6N).
The transmitter keyboard is arranged as a scanned matrix. The matrix consists of 5 driver outputs and 5 sense inputs as shown in fig. 1. The driver outputs DRV0N to DRV6N are open drain N-channel transistors and they are conductive in the stand-by mode. The 5 sense inputs (SENON to SEN6N) enable the generation of 30 command codes. With 2 external diodes all 36 commands are addressable. The sense inputs have P-channel pull-up transistors so that they are HIGH until they are pulled LOW by connecting them to an output via a key depression to initiate a code transmission.

## ADRESS MODE INPUT (ADRM)

The sub-system address and the transmission mode are defined by connecting the ADRM input to one or more driver outputs (DRVON to DRV6N) of the key matrix. If more than one driver is connected to ADRM, they must be decoupled by diodes. This allows the definition of five sub-system addresses as shown in table 3 . If driver DRV6N is
connected to ADRM, the data output format of REMO is modulated or if not connected, flashed.
The ADRM input has switched pull-up and pulldown loads. In the stand-by mode, only the pulldown device is active. Whether ADRM is open (sub-system address 0 , flashed mode) or connected to the driver outputs, this input is LOW and will not cause unwanted dissipation. When the transmitter becomes active by pressing a key, the pull-down device is switched off and the pull-up device is switched on, so that the applied driver signals are sensed for the decoding of the sub-system address and the mode of transmission.
The arrangement of the sub-system address coding is such that only the driver DRVnN with the highest number ( n ) defines the sub-system address, e.g. if drivers DRV1N and DRV4N are connected to ADRM, only DRV4N will define the sub-system address. This option can be used in systems requiring more than one sub-system address. The transmitter may be hard-wired for subsystem address 2 by connecting DRV1N to ADRM. If now DRV4N is added to ADRM by a key or a switch, the transmitted sub-system address changes to 5 . A change of the sub-system address will not start a transmission.

## REMOTE CONTROL SIGNAL OUTPUT (REMO)

The REMO signal output stage is a push-pull type. In the HIGH state, a bipolar emitter-follower allows a high output current. The timing of the data output format is listed in tables 1 and 2. The information is defined by the distance to between the leading edges of the flashed pulses or the first edge of the modulated pulses (see fig. 3). The format of the output data is given in fig. 2 and 3. The data word starts with two toggle bits T1 and T0, followed by three bits for defining the sub-system address S 2 , S1 and SO, and six bits F, E, D, C, B and A which are defined by the selected key.
In the modulated transmission mode the first toggle bit is replaced by a constant reference time bit (REF). This can be used as a reference time for the decoding sequence. The toggle bits function as an indication for the decoder that the next instruction has to be considered as a new command. The codes for the sub-system address and the selected key are given in tables 3 and 4 .
The REMO output is protected against "Lock-up", i.e. the length of an output pulse is limited to $<1 \mathrm{msec}$, even if the oscillator stops during an output pulse. This avoids the rapid discharge of the battery that would otherwise be caused by the continuous activation of the LED.

## OSCILLATOR INPUT/OUTPUT (osci and osco)

The external components must be connected to these pins when using an oscillator with a ceramic resonator. The oscillator frequency may vary between 350 kHz and 600 kHz as defined by the resonator.

## FUNCTIONAL DESCRIPTION

Keyboard operation.
In the stand-by mode all drivers (DRVON to DRV6N) are on (low impedance to $\mathrm{V}_{\text {ss }}$ ). Whenever a key is pressed, one or more of the sense inputs (SENnN) are tied to ground. This will start the power-up sequence. First the oscillator is activated and after the debounce time tbb (see fig. 4) the output drivers (DRVON to DRV6N) become active successively).
Within the first scan cycle the transmission mode, the applied sub-system address and the selected command code are sensed and loaded into an internal data latch.

In contrast to the command code, the sub-system is sensed only within the first scan cycle. If the applied sub-system address is changed while the command key is pressed, the transmitted sub-system address is not altered.
In a multiple key stroke sequence (see fig. 5) the command code is always altered in accordance with the sensed key.

## MULTIPLE KEY-STROKE PROTECTION

The keyboard is protected against multiple keystrokes. If more than one key is pressed at the same time, the circuit will not generate a new output at REMO (see fig. 5). In case of a multiple key-stroke, the scan repetition rate is increased to detect the release of a key as soon as possible. There are two restrictions caused by the special structure of the keyboard matrix :

- The keys switching to ground (code numbers 5 , 11, 17, 23, 29 and 35) and the keys connected to SEN5N and SEN6N are not covered completely by the multiple key protection. If one sense input is switched to ground, further keys on the same sense line are ignored, i.e. the command code corresponding to "key to ground" is transmitted.
- SEN5N and SEN6N are not protected against multiple keystroke on the same driver line, because this condition has been used for the definition of additional codes (code number 30 to 35).

## OUTPUT SEQUENCE (data format)

The output operation will start when the selected code is found. A burst of pulses, including the latched address and command codes, is generated at the output REMO as long as a key is pressed. The format of the output pulse train is given in fig. 2 and 3. The operation is terminated by releasing the key or if more than one key is pressed at the same time. Once a sequence is started, the transmitted data words will always be completed after the key is released.
The toggle bits T0 and T1 are incremented if the key is released for a minimum time trel (see fig. 4). The toggle bits remain unchanged within a multiple key-stroke sequence.

Table 1 : Pulse Train Timing.

| Mode | $\mathbf{T}_{\mathbf{O}}(\mathbf{m s})$ | $\mathbf{t}_{\mathbf{p}}(\mu \mathbf{s})$ | $\mathbf{t}_{\mathbf{M}}(\mu \mathbf{s})$ | $\mathbf{t}_{\mathbf{M L}}(\mu \mathbf{s})$ | $\mathbf{t}_{\mathbf{M H}}(\mu \mathbf{s})$ | $\mathbf{t}_{\mathbf{W}}(\mathbf{m s})$ |

## GENERAL DESCRIPTION

The integrated circuit M8716B contains a digital clock counting seconds, minutes, hours, days and months or seconds, minutes, hours and days of the week as an option. A 32.768 kHz quartz oscillator serves as time-base. This circuit is intended for use within a microcomputer system.
Writing (time setting) and reading of the counters is done via a serial interface ( ${ }^{2} \mathrm{C}$ Bus). The micro-computer is used for controlling the data transfer and for generating the signals to drive a ( 7 segment) display. If a data transfer takes place between the M8716B and the microprocessor, a 5 V supply voltage has to be provided. During standby the circuit is supplied by two NiCd-cells at a very low power consumption.

## FUNCTIONAL DESCRIPTION

## DIVIDERS AND COUNTERS

The oscillator frequency of 32.768 kHz is first divided by 256 and then again by 128 . The resulting output frequency of 1 Hz then serves as clock pulse for the time counters.
The content of the counters for sec, min, hr, day and month of sec, min, hr, and day of week can be read or modified (written) via the $I^{2} \mathrm{C}$ Bus interface. During a "write" cycle only the content of the counters starting from the minutes counter is modified: the seconds counter and the seconds divider block are reset to zero.
Selection between "calendar" operation (display of day and month) and "day of week" operation (display of day of week 1 to 7 ) is done as follows:
If the second bit in the first data byte is " 1 " during a "write" operation, the counters are set for the mode "day of week".
If this bit remains at "0" during a "write" operation the calendar mode is selected. In this case, carry of the "day" counter is performed automatically at positions 28, 30 or 31, depending on the month. In case of a leap year the day 29 (of February) can be set by a "write" operation.
In this case, carry takes place on 3-1 (March 1st).

## $I^{2} \mathrm{C}$ BUS INTERFACE GENERAL DESCRIPTION

Data transfer from the circuit M8716B to the microcomputer (reading) and vice versa (writing) takes place via the two lines SDA and SCL. Address and data are transmitted on SDA while at the same time clock pulses have to be provided on SCL for synchronization by the microcomputer.

## $1^{2} \mathrm{C}$ BUS INTERFACE ADDRESSING

(see fig. 1...3)
A data transfer (reading or writing) is initiated by a start condition ("1" - > "0" transition on SDA while SCL remains at "1") and a subsequent address byte. By assigning a unique address to each circuit. several circuits may be connected to the $I^{2} \mathrm{C}$ Bus without interfering each other.
If the M8716B recognizes an address transmitted on the bus as its own address, the data transfer starts. The least significant bit of the address word controls the direction of data transfer ( $R / \bar{W}$-control). If it is set to " 0 ", data is transferred from the microcomputer to the circuit, i.e. the content of the time counters is modified. If it is set to " 1 " the time information is read out by the microcomputer. A data transmission between the microprocessor and M8716B must always be completed otherwise the clock content may be lost. This means that the "master" can't use the possibility to stop the transmission after a certain byte by not sending the acknowledge bit.
Even $2 f$ M8716B can work at the frequency four DC UP to 100 kHz , it is tested at a frequency of 30 kHz . If a carry of the time counter should take place during a data transfer, the carry will be stored and made after the data transfer. As only one carry can be stored, the whole data transfer must not take a time longer than one second.

## SYNCHRONIZATION

For easy of synchronization with an external time reference in case of small deviations ( $< \pm 30 \mathrm{sec}$ ). only the address (with $\mathrm{R} / \overline{\mathrm{W}}=$ " 0 ") has to be transmitted. followed immediately by a stop condition. No data is transmitted (see fig. 4). The second divider block ( 128 Hz to 1 Hz ) and the seconds counter are reset. If the seconds counter was at position 30 ... 59, a carry to the minutes counter takes place in addition to the reset.

## POWER FAIL

In case of total power fail an internal register is set to "0". This register disables the data of the watch. So in a read cycle the $\mu \mathrm{P}$ recognizes " 0 " of the watch content. This is a unique situation appearing only in case of a power fail. The power fall register is automatically reset by the first "write" command.

## PULSE OUTPUTS Fout, SEC

The output frequency of the first divider block ( 128 Hz ) is provided on the pin Fout and facilitates adjustment of the oscillator frequency without loading (and detuning) the oscillator.

The output SEC ( 1 Hz ) may be utilized for a blinking second indication.
Both pins Fout and SEC can also be used as input during the functional test. A Low impedance ( 50 to
$100 \Omega$ ) external signal source which overrides the internal output buffer can drive the circuit at a frequency higher than the normal rate. This allows to reduce test time.

## REMOTE CONTROL ENCODER/DECODER CIRCUITS

- M145026 ENCODER
- M145027/M145028 DECODERS
- MAY BE ADDRESSED IN EITHER BINARY OR TRINARY
- TRINARY ADDRESSING MAXIMIZES NUMBER OF CODES
- INTERFACES WITH RF, ULTRASONIC, OR INFRARED TRANSMISSION MEDIAS
- DOUBLE TRANSMISSIONS FOR ERROR CHECKING
- 4.5V TO 18V OPERATION
- ON-CHIP R/C OSCILLATOR, NO CRYSTAL REQUIRED
- HIGH EXTERNAL COMPONENT TOLERANCE, CAN USE 5\% COMPONENTS
- STANDARD CMOS B-SERIES INPUT AND OUTPUT CHARACTERISTICS
- APPLICATIONS INCLUDE GARAGE DOOR OPENERS, REMOTE CONTROLLED TOYS, SECURITY MONITORING, ANTITHEFT SYSTEMS, LOW END DATA TRANSMISSIONS WIRE LESS TELEPHONES

## DESCRIPTION

The M145026 encodes nine bits of information and serially transmits this information upon receipt of a transmit enable, TE, (active low) signal. Nine inputs may be encoded with trinary data ( 0,1 , open) to allow $3^{9}$ (19.683) different codes.
Two decoders are presently available. Both use the same transmitter - the M145026. The decoders will receive the 9-bit word and will interpret some of the bits as address codes and some as data. The M145027 interprets the first five transmitted bits as address and the last four bits as data. The M145028 treats all nine bits as address. If no errors are received, the M145027 outputs the four data bits when the transmitter sends address codes that match that of the receiver. A valid transmission output goes high on both decoders when they recognize an address that matches that of the decoder. Other receivers can be produced with different address/data ratios.
All the devices are available in 16 lead plastic package. The M145026 is available in SO16 plastic package (narrow) and the M145028 is available in SO16 plastic package (large).

## OPERATING CHARACTERISTICS

## M145026

The encoder will serially transmit nine bits of trinary data as defined by the state of the A1/D1-A9/D9 input pins. These pins can be in either of three states ( 0,1 , open) allowing $3^{9}=19683$ possible codes. The transmit sequence will be initiated by a low level of the TE inputpin. Each time the TE input is forced low the encoder will output two identical data words. This redundant information is used by the receiver to reduce errors. If the TE input is kept low, the encoder will continuously transmit the data words. The transmitted words are self-completing (two words will be transmitted for each $\overline{\mathrm{TE}}$ pulse).
Each transmitted data bit is encoded into two data pulses. A logic zero will be encoded as two consecutive short pulses, a logic one by two consecutive long pulses, and an open as a long pulse followed by a short pulse. The input state is determined by using a weak output device to try to force each input first low, then high. If only a high state results from the two tests, the input is assumed to be hard wired to $\mathrm{V}_{\mathrm{DD}}$. If only a low state is obtained, the input is assumed to be hard wired to $\mathrm{V}_{\mathrm{ss}}$. If both a high and a low can be forced at an input, it is assumed to be open and is encoded as such.
The transmit sequence is enabled by a logic zero on the TE input. This input has an internal pullup device so that a simple switch may be used to force the input low. While TE is high the encoder is completely disabled, the oscillator is inhibited and the current drain is reduced to quiescent current. When TE is brought low, the oscillator is started, and an internal reset is generated to initialize the transmit sequence. Each input is then sequentially selected and a determination is made as to input logic state. This information is serially transmitted via the Data Out output pin.

## M145027

The decoder will receive the serial data from the encoder, check it for errors and output data if valid. The transmitted data consisting of two identical data words is examined bit by bit as it is received. The first five bits are assumed to be address bits and must
be encoded to match the address inputs at the receiver. If the address bits match, the next four (data) bits are stored and compared to the last valid data stored. if this data matches, the VT pin will go high on the 2nd rising edge of the 9th bit of the first word. Between the two data words no signal is sent for three data bit times. As the second encoded word is received, the address must again match, and if it does, the data bits are checked against the previously stored data bits. If the two words of data (four bits each) match, the data is transferred to the output data latches and will remain until new data replaces it. At the same time, the Valid Transmission output pin is brought high and will remain high until an error is received or until no input signal is received for four data bit times.
Although the address information is encoded in trinary fashion, the data information must be either a one or a zero. A trinary (open) will be decoded as a logic one.

M145028
This receiver operates in the same manner as the M145027 except that nine address bits are used and no data output is available. The Valid Transmission output is used to indicate that a valid signal has been received.
Although address information normally is encoded in trinary, the designer should be aware that, for the M145028, the ninth address bit (A9) must be either a one or a zero. This part, therefore, can accept only $2 \times 3^{8}=13.122$ different codes. A trinary (open) A9 will be interpreted as a logic 1 . However if the transmitter sends a trinary (or logic 1) and the receiver address is a logic 1 (or trinary) respectively, the valid transmission output will be shortened to the $\mathrm{R} 1 \times \mathrm{C} 1$ time constant.

## DOUBLE TRANSMISSION DECODING

Although the encoder sends two words fo error checking, a decoder does not necessarily wait for two transmitted words to be received before issuing a valid transmission output. Refer to the flowcharts in Figure 7 and 8.

Figure 1: Encoder Block Diagram M145026.

88DSM145026/27/28-02

Figure 2 : Decoder Block Diagram M145027.

Figure 3 : Decoder Block Diagram M145028.

## PIN DESCRIPTION

## M145026 ENCODER

A1/D1-A9/D9. These inputs will be encoded and the data serially output form the encoder.
Vss. The most negative supply (usually ground).
RS, CTC, RTC. These pins are part of the oscillator section of the encoder. If an external signal source is used instead of the internal oscillator it should be connected to the RS input and the RTC and CTC pins should be left open.
$\overline{\mathrm{TE}}$. This Transmit-Enable (active low) input will initiate transmission when forced low. A pullup device will keep this input high normally.
DATA OUT. This is the output of the encoder that will present the serially encoded signals.
VDD. The most positive supply.

## M145027/M145028 DECODERS

A1-A5 (M145027) / A1-A9 (M145028). These are the address inputs that must match the encoder inputs A1/D1-A5/D5 in the case of M145027 or A1/D1A0/D9 in the case of M145028, in order for the decoder to output data.
D6-D9 (M145027). These outputs will give the information that is presented to the encoder inputs A6/D6-A9/D9.
Note: Only binary data will be acknowledged, a trinary open will be decoded as logic one.

R1, C1. These pins accept a resistor and capacitor that are used to determine whether a narrow pulse or a wide pulse has been encoded. The time constant R1 x C1 should be set to 1.72 transmit clock periods. R1C1 $=3.95$ RTC $\times$ CTC .
R2/C2. This pin accepts a resistor to $V_{S S}$ and a capacitor to $V_{s s}$ that are used to detect both the end of an encoded word and the end of transmission. The time constant R2 $\times$ C2 should be 33.5 transmit clock periods (four data bit periods). This time constant is used to determine that the Data In input has remained low for four data bit times (end of transmission). A separate comparator looks at a voltage equivalent two data bit times (0.4 R2C2) to detect the dead time between transmitted words. R2C2 = $77 \times$ RTC $\times$ CTC.
VALID TRANSMISSION, VT. This output will go high when the following conditions are satisfied:

1. the transmitted address matches the receiver address, and
2. the transmitted data matches the last valid data received (M145028 only).
VT will remain high until either a mismatch is received, or no input signal is received for four data data bit times.
$V_{D D}$. The most positive supply.
Vss. The most negative supply (usually ground).

Figure 4 : Encoder Oscillator Information.

The value for RS should be chosen to be about 2 times RTC. This range will ensure that current through RS is insignificant compared to current through RTC. The upper limit for RS must ensure that RS $\times 5 \mathrm{pF}$ (input capacitance) is small compared

This oscillator will operate at a frequency determined by the external RC network; i.e..
$f \approx \frac{1}{2.3 \cdot \text { RTC } \cdot \text { CTC }}(\mathrm{Hz})$
for $1 \mathrm{kHz} \leq \mathrm{f} \leq 400 \mathrm{kHz}$
where: $C T C=C T C+C$ layout +12 pF
RS $\approx 2$ RTC
$R S \geq 20 k$
RTC $\geq 10 \mathrm{k}$
$400 \mathrm{pF}<\mathrm{CTC}<\mu \mathrm{F}$
to RTC $\times$ CTC. For frequencies outside the indicated range, the formula will be less accurate. The actual oscillation range of this circuit is from less than 1 Hz to over 1 MHz .

- EXTERNAL OSCILLATOR GENERATING 6MHz SIGNAL SYNCHRONIZED TO A MULTIPLE OF THE LINE FREQUENCY BY PLL
- A 6.9375 MHz CLOCK GENERATED FROM AN EXTERNAL QUARTZ CRYSTAL
- "AFTER-HOURS" SYNCHRONIZATION OPTION
- PROGRAMMABLE LEVELS FOR THE INPUT COMPOSITE VIDEO SIGNAL (1V OR 2.5V)
- PROCESSING OF EXTERNAL TELETEXT DATA
- OUTPUT OF POSITIVE OR NEGATIVE SYNCHRONIZING SIGNALS
- 28 PIN DIP PACKAGE
- HDS2P2 TECHNOLOGY

## DESCRIPTION

The SAA5231 is a monolithic integrated circuit in 28 Pin DIP package designed to separate Teletext signals from TV signal.

## PIN CONNECTIONS

## PIN DESCRIPTION

| Pin | Function | Description |
| :---: | :---: | :---: |
| 1 | Display Synchronization Output | Synchronization signal output available as positive or negative |
| 2 | Input Video Signal Level | Input level selected as 1 V (pin 2 low) or 2.5 V (pin 2 not connected) |
| 3 | H.F. Filter | Video signal filtering using an external capacitor of 15pF |
| 4-5-6 | "HF STORE" <br> "Amplitude STORE" <br> "Zero Level STORE" | Three external capacitors used to store : <br> 1/ HF amplitude <br> 2/ Amplitude of adaptive data slicer <br> 3/ Zero level |
| 7 | External Data Input | "Teletext data slice" input from external source |
| 8 | Data Timing | Connection of an external 270pF capacitor for the timing of the adaptive data slicer |
| 9 | Store Phase | Storage on an external capacitor of the output signal "Clock phase detector" |
| 10 | "Video Tape Recorder" Mode (VCR) | Control signal for the PLL in the low-time constant mode |
| 11 | Crystal | External connection for a 13.875 MHz crystal. This frequency, divided by 2 , yields the 6.9375 MHz clock |
| 12 | Clock Filter | Filter for 6.9375 MHz clock |
| 13 | Ground |  |
| 14 | Teletext Clock Output | Clock output for the SDA5243 |
| 15 | Teletext Data Output | Output of Teletext data for the SDA5243 |
| 16 | Supply V CC |  |
| 17 | 6 MHz Clock Output | 6 MHz clock output for the SDA5243 |
| 18/20 | Oscillator Output/lnput | An external resonant circuit between pins 18 and 20 is connected to the 6 MHz internal VCO |
| 19 | Filter 2 | Low time constant filter for phase detection of the horizontal signal |
| 21 | Filter 1 | High time constant filter for phase detection of the horizontal signal |
| 22 | "Sandcastle" Input Pulse | Input of the sandcastle signal produced by the SDA5243 from the PL and CBB signals |
| 23 | Pulse Timing Resistor | External resistor of $68 \mathrm{k} \Omega$ used to define the current for the pulse generator |
| 24 | Pulse Timing Capacitor | External capacitor of 270 pF to define the timing of the pulse generator |
| 25 | Composite Video Synchronizing Output (Vcs) | Synchronizing output for the SDA5243 |
| 26 | Black level | Storage of the black level for the adaptive sync. separator on an external 68nF capacitor |
| 27 | Composite Video Input | Composite video signal input for the adaptive sync. separator via an external capacitor of $2.2 \mu \mathrm{~F}$ |
| 28 | Teletext Composite Sync. Input ( $\overline{\mathrm{TCS}}$ ) or Scan Composite Sync. Input (SCS) | $\overline{T C S}$ input from the SDA5243 or $\overline{\text { SCS }}$ input from an alternative synchronizing circuit. |

## ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter | Value | Unit |
| :---: | :--- | :---: | :---: |
| $\mathrm{V}_{16}$ | Supply Voltage | 13.2 | V |
| $-\mathrm{I}_{25}$ | Output Current $\mathrm{V}_{\mathrm{Cs}}$ | 5 | mA |
| $-\mathrm{I}_{15}$ | Output Current TTD | 10 | mA |
| $-I_{14}$ | Output Current TTC | 10 | mA |
| $-\mathrm{I}_{17}$ | Output Current F6 | 10 | mA |
| $\mathrm{I}_{1}$ | Output Current Sync. | 5 | mA |
| $\mathrm{~T}_{\text {stg }}$ | Storage Temperature | -40 to +150 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\mathrm{J}}$ | Junction Temperature | 0 to +150 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\mathrm{A}}$ | Ambient Temperature | 0 to +70 | ${ }^{\circ} \mathrm{C}$ |

THERMAL DATA

| Symbol | Parameter | Value | Unit |
| :---: | :---: | :---: | :---: |
| $R_{\text {th(f(-a) }}$ | Junction-Ambient Thermal Resistance | Max. | 70 |
| ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |  |  |  |

## ELECTRICAL CHARACTERISTICS

$\mathrm{V}_{\mathrm{S}}=12 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ (unless otherwise specified)

| Symbol | Parameter | Min | Typ | Max | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | | POWER SUPPLY (pin 16) |  |  |  |  |  |
| :---: | :--- | :---: | :---: | :---: | :---: |
| V $_{\mathrm{S}}$ | Supply Voltage | Supply Current | - | 10.8 | 12 |
| Is |  |  |  |  |  |

CVBS INPUT (pin 27)

| $\mathrm{V}_{27}$ | Input Signal Level : |  |  |  | V |
| :--- | :--- | :---: | :---: | :---: | :---: |
|  | Pin 2 to ground | 1.7 | 1 | 1.4 | V |
|  | Pin 2 open | 1.75 | 2.5 | 3.5 |  |
| $\mathrm{~V}_{27(\rho-\mathrm{P})}$ | Synchronous Signal Amplitude | 0.1 | - | 1 | V |
| $\mathrm{~V}_{27(\mathrm{Xx})}$ | Teletext Data Level : |  |  |  | V |
|  | Pin 2 to ground | 0.3 | 0.46 | 0.7 |  |
|  | Pin 2 open | 0.75 | 1.15 | 1.75 |  |
| $\mathrm{R}_{\mathrm{G} 27}$ | Generator Resistance | - | - | 250 | $\Omega$ |

VIDEO INPUT LEVEL SELECT (pin 2)

|  | Voltage : |  |  |  |  |
| :--- | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{2 \mathrm{~L}}$ | Low $\left(\mathrm{V}_{27}=1 \mathrm{~V}\right)$ |  |  |  |  |
| $\mathrm{V}_{2 \mathrm{H}}$ | High $\left(\mathrm{V}_{27}=2.5 \mathrm{~V}\right)$ | 0 | - | 0.8 | V |
|  | Current : | 2 | - | 5.5 | V |
| $-\mathrm{I}_{2 \mathrm{~L}}$ | Low |  |  |  |  |
| $\mathrm{I}_{2 \mathrm{H}}$ | High | 0 | - | 150 | $\mu \mathrm{~A}$ |

TELETEXT DATA (pin 15)

| $\mathrm{V}_{15(\mathrm{p}-\mathrm{p})}$ | Signal TTD Output | 2.5 | 3.5 | 4.5 | V |
| :---: | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{t}_{\mathrm{r}}, \mathrm{t}_{\mathrm{f}}$ | Transition Times | 20 | 30 | 45 | ns |
| $\mathrm{C}_{15}$ | Load Capacitance | - | - | 40 | pF |
| $\mathrm{V}_{15 \mathrm{DC}}$ | DC Voltage at Output | - | 4 | - | V |

DATA CLOCK (pin 15)

| $\mathrm{V}_{14(\rho-\mathrm{p})}$ | Signal TTC Output | 2.5 | 3.5 | 4.5 | V |
| :---: | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{t}_{\mathrm{r}}, \mathrm{t}_{\mathrm{f}}$ | Transiton Times | 20 | 30 | 45 | ns |
| $\mathrm{C}_{14}$ | Load Capacitance | - | - | 40 | pF |
| $\mathrm{t}_{\mathrm{d}}$ | Time Deviation with Respect to TTD | -20 | 0 | +20 | ns |
| $\mathrm{~V}_{14 \mathrm{DC}}$ | DC Voltage at Output | - | 4 | - | V |

SYNC. PULSE SEPARATION VCS (to SDA5243) (pin 25)

|  | Output Voltage: |  |  |  | V |
| :---: | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{25 \mathrm{~L}}$ | Low |  |  |  |  |
| $\mathrm{V}_{25 \mathrm{H}}$ | High | 0 | - | 0.4 |  |
|  | Output Current: | - | 5.5 |  |  |
| $\mathrm{I}_{25 \mathrm{~L}}$ | Low | - | - | 0.5 | mA |
| $-\mathrm{I}_{25 \mathrm{H}}$ | High | - | - | 1.5 |  |
| $\mathrm{t}_{\mathrm{d}}$ | Delay with Respect to CVBS Sync. | - | 0.5 | - | $\mu \mathrm{s}$ |

ELECTRICAL CHARACTERISTICS (continued)
$V_{S}=12 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ (unless otherwise specified)

| Symbol | Parameter | Min | Typ | Max | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: |

SYNC. OUTPUT DRIVER (to TV set) (pin 1)

| $V_{1(p-p)}$ | Output Voltage : <br> TCS Operation <br> CVBS Operation | - | 0.45 | V |  |
| :---: | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{~V}_{1 D C}$ | DC Voltage with Load Resistor to Ground <br> (positve synchronous signal) | - | 1.4 | - | V |
| $-I_{1}$ | Output Current | - | - | 3 | mA |
| $\mathrm{~V}_{10 \mathrm{D}}$ | DC Voltage with Load Resistor to $\mathrm{V}_{\mathrm{S}}$ <br> (negative synchronous signal) |  | 10.1 |  | V |
| $\mathrm{I}_{1}$ | Output Current | - | - | 3 | mA |

6MHz CLOCK F6 (pın 17)

| $V_{17(p-p)}$ | F6 Output Signal (neglıgible harmonic content) | 1 | 2 | 3 | $V$ |
| :---: | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{t}_{\mathrm{r}}, \mathrm{t}_{\mathrm{f}}$ | Transition Times | 20 | - | 40 | ns |
| $\mathrm{C}_{17}$ | Load Capacitance | - | - | 40 | pF |
| $\mathrm{V}_{17 \mathrm{DC}}$ | DC Voltage | 4 | - | 8.5 | V |

SYNCHRONIZATION SELECTION (pin 28)

| $\begin{gathered} -1_{28} \\ \mathrm{I}_{28} \end{gathered}$ | Input Current: <br> TCS Operation ( $\mathrm{V}_{28}=0$ to 7 V ) <br> CVBS Operation ( $\mathrm{V}_{28}=10 \mathrm{~V}$ to $\mathrm{V}_{\mathrm{S}}$ ) | $\begin{aligned} & 40 \\ & -5 \end{aligned}$ | $\begin{gathered} 70 \\ 0 \end{gathered}$ | $\begin{gathered} 100 \\ 5 \end{gathered}$ | $\mu \mathrm{A}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \mathrm{V}_{28 \mathrm{~L}} \\ & \mathrm{~V}_{28 \mathrm{H}} \end{aligned}$ | TCS Operation : Input Voltage (load resistor at pin 1) <br> Low <br> High | $\begin{aligned} & 0 \\ & 2 \end{aligned}$ | - | $\begin{aligned} & 0.8 \\ & 6.1 \end{aligned}$ | V |
| $\begin{aligned} & \mathrm{V}_{28 \mathrm{~L}} \\ & \mathrm{~V}_{28 \mathrm{H}} \end{aligned}$ | $\overline{\text { SCS Operation : }}$ <br> Input Voltage (pin 1 open) <br> Low <br> High | $\begin{gathered} 0 \\ 3.5 \end{gathered}$ | - | $\begin{aligned} & 1.5 \\ & 6.1 \end{aligned}$ | V |
| $t_{p}$ | Line Synchronous Pulse Width : TCS Operation SCS Operation | - | $\begin{aligned} & 2 \\ & 3 \end{aligned}$ |  | $\mu \mathrm{s}$ |

VCR OPERATION (pin 10)

|  | Input Voltage: | 0 |  |  | V |
| :---: | :--- | :---: | :---: | :---: | :---: |
| $V_{10 L}$ | VCR Operation | 2 | - | 0.8 |  |
| $V_{10 \mathrm{H}}$ | Standard Operation | -10 | 0 | 10 | $\mu \mathrm{~A}$ |
| $\mathrm{I}_{10}$ | Input Current | -10 |  |  |  |

ELECTRICAL CHARACTERISTICS (continued)
$\mathrm{V}_{\mathrm{S}}=12 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ (unless otherwise specified)

| Symbol | Parameter | Min | Typ | Max | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: |

SANDCASTLE PULSE INPUT (pin 22)

|  | Phase Locked Mode Input Voltage PL: <br> $V_{22 L}$ <br> Low <br> $V_{22 \mathrm{H}}$ | High | 0 | - | 3 |
| :---: | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{t}_{\mathrm{pl}}$ | PL - Low Time For Free-Wheeling Oscillator | 3.9 | - | 5.5 |  |
|  | Reset Pulse for Data Separation | 100 | - | - | ms |
|  | Input Voltage CBB : |  |  |  |  |
| $V_{22 L}$ | Low | 0 | - | 0.5 | V |
| $V_{22 \mathrm{H}}$ | High | 1 | - | 5.5 |  |
| $\mathrm{I}_{22}$ | Input Current | -10 | - | 10 | $\mu \mathrm{~A}$ |

EXTERNAL DATA INPUT (CURRENT SOURCE DRIVING) (pin 7)

|  | Internal Data Processing Input : |  |  |  |  |
| :--- | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{I}_{7}$ | Current | -10 | 0 | 100 | $\mu \mathrm{~A}$ |
| $\mathrm{~V}_{7}$ | Voltage $\left(\mathrm{I}_{7}=-10\right.$ to $\left.100 \mu \mathrm{~A}\right)$ | - | 10 | - | V |
|  | External data processing input: |  |  |  |  |
| $\mathrm{I}_{7 \mathrm{~L}}$ | Current for Low Level | -175 | -40 | -25 | $\mu \mathrm{~A}$ |
| $\mathrm{I}_{7 \mathrm{H}}$ | Current for High Level | -1000 | -500 | -325 | $\mu \mathrm{~A}$ |
| $\mathrm{~V}_{7}$ | Voltage ( $\mathrm{I}_{7}=-1000$ to $\left.-25 \mu \mathrm{~A}\right)$ | 7 | 8 | - | V |

28 pns

## SDA5243 SDA5243/H

## COMPUTER-CONTROLLED TELETEXT DECODER

- AUTOMATIC SELECTION OF UP TO SEVEN NATIONAL LANGUAGES
- FOUR SIMULTANEOUS PAGE REQUESTS
- DISPLAY OF THE 25TH STATUS ROW
- MICROPROCESSOR CONTROL VIA AN I2C BUS (SLAVE ADDRESS 0010001 R/W)
- DATA ACQUISITION AVAILABLE FROM LINES 2 TO 22 OR FROM A COMPLETE FIELD.
- DIRECT INTERFACE TO A STATIC RAM OF UP TO 8kBYTES
- HIGH QUALITY DISPLAY USING A CHARACTER MATRIX OF $12 \times 10$ DOTS.
- SINGLE + 5V SUPPLY VOLTAGE
- ON-CHIP MASK PROGRAMMABLE ROM CHARACTER GENERATORS
- NMOSH2 PROCESS

## DESCRIPTION

The SDA5243 is a NMOSH2 integrated circuit which performs all the processing of logical data within a 625 line system teletext decoder. It is designed to operate in conjunction with at least two chips : the SAA5231 integrated chip which extracts Teletext information embedded in a composite video signal and up to eight kilobytes of static RAM memory which can be used to store a maximum of 8 pages of display data. A complete system also comprises a microprocessor controling the SDA5243 via a 2-wire serial bus. An on-chip ROM memory contains the character sets. The SDA5243 performs automatic selection of one of up to seven natural languages. Data bytes may be decoded in either 7-Bit plus parity or in full 8-Bit formats. The chip set also supports facilities for reception and display of higher-level protocol data.

PIN CONNECTIONS

## PIN DESCRIPTION

| Pin | Symbol | Function | Description |
| :---: | :---: | :---: | :--- |
| 1 | V | +5D | Positive supply voltage |
| $2,3,40$ | A11, A12, A10 | Chapter address | Address selection outputs for 1 of 8 static RAM <br> chapters each of 1 kBytes. |
| 4 | $\overline{\text { OE }}$ | Output enable | Active-low RAM output enable control signal. |
| 5 | $\overline{\text { WE }}$ | Write enable | Active-low RAM write enable control signal. It <br> supports write-cycles interleaved with read-cycles. |
| 6 | TTD | Teletext data input | An A.C. coupled teletext data input supplied by the <br> SAA5231 chip is latched to VSs between 4 and 8 $\mu \mathrm{S}$ |
| after each TV line. |  |  |  |

## ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter | Value | Unit |
| :---: | :---: | :---: | :---: |
| $V_{D D}$ | Power Supply Range | -0.3 to +7.5 | V |

INPUT VOLTAGE RANGE :

| $V_{1}$ | VCS,SDA,SCL,D0-D7 | -0.3 to +7.5 | V |
| :---: | :--- | :--- | :--- |
|  | TTD,F6,TCS/SCS,TTC | -0.3 to +10 | V |

OUTPUT VOLTAGE RANGE :

| Vo | $\frac{\text { SAND,AO-A12 }}{\text { TCS } / \mathrm{OE}}, \overline{\mathrm{WE}}, \mathrm{DO}-\mathrm{D} 7, \mathrm{SDA}, \overline{\mathrm{ODD} / E V E N}, \mathrm{R}, \mathrm{G}, \mathrm{B}, \mathrm{BLAN}, \overline{\mathrm{COR}}, \mathrm{Y}$ | $\begin{aligned} & -0.3 \text { to }+7.5 \\ & -0.3 \text { to }+10 \end{aligned}$ | V |
| :---: | :---: | :---: | :---: |
| $\mathrm{T}_{\text {stg }}$ | Storage Temperature Range | -20 to +125 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\mathrm{A}}$ | Operating Ambient Temperature Range | -20 to +70 | ${ }^{\circ} \mathrm{C}$ |

## ELECTRICAL CHARACTERISTICS

$\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}, \mathrm{~V}_{\mathrm{SS}}=0 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=-20$ to $+70^{\circ} \mathrm{C}$

| Symbol | Parameter | Min | Typ | Max | Unit |
| :---: | :--- | :---: | :---: | :---: | :---: |
| $V_{D D}$ | Supply Voltage (pin 1) | 4.5 | 5 | 5.5 | V |
| IDD | Supply Current | - | 140 | 200 | mA |

INPUTS

| TTD (pin 6) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Cext | Ext. Coupling Capacitor | - | - | 50 | nF |

F6, TTC, TTD INPUT INTERNAL CONNECTIONS

## TELETEXT DATA INPUT TIMING

Data Stable : 1 if $\geq 2 \mathrm{~V}$, 0 if $\leq 0.8 \mathrm{~V}$

## SYNCHRONIZATION TIMING

Figure 5

COMPOSITE SYNC. WAVEFORMS
Figure 6

The number positions indicate the end of lines.
The Teletext composite synchronization signal (TCS), whether interlacing is present or not, comprises three components.
a) The line-synchronization pulses (LSP).
b) the equalisation pulses (EP)
c) the frame-synchronization pulses (BP).

The timing reference is specified by the descending edge of the signal LSP, with a tolerance spread of $\pm 100 \mathrm{~ns}$.

Figure 9

## APPLICATION NOTES

## ORGANIZATION OF A PAGE-MEMORY

The organization of a page-memory is shown in Figure 11. In contrast with the first generation of Teletext Decoders the new CCT (Computer Controlled Teletext) chip provides a display format of 25 rows of 40 characters per row.
Row number twenty-four is used by the microprocessor for the display of information.
Row zero contains the page header.
The organization is as follows:
The first seven characters $(0-6)$ are used for messages regarding the operational status.
The eighth character is an alphanumeric control character either "white" or "green" defining the
"search" status of the page. When it is "white" the operational state is normal and the header appears white ; when it is "green" the operational state corresponds to "search mode" and the header appears green. The following twenty-four characters give the header of the requested page when the system is in search mode. The last eight characters display the time of day.
Row twenty-five comprises ten bytes of control data concerning the received page (see Table 1) and fourteen free bytes which can be used by the microprocessor.

## PAGE MEMORY ORGANISATION

Figure 11

Table 1 : Row 25 received control data format.

| Do | PU0 | PTO | MUO | MTO | HUO | HTO | C7 | C11 | MAGO | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| D1 | PU1 | PT1 | MU1 | MT1 | HU1 | HT1 | C8 | C12 | MAG1 | 0 |
| D2 | PU2 | PT2 | MU2 | MT2 | HU2 | C5 | C9 | C13 | MAG2 | 0 |
| D3 | PU3 | PT3 | MU3 | C4 | HU3 | C6 | C10 | C14 | 0 | 0 |

| D7 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| COLUMN | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |

Page number : - MAG = magazine, PU = page units, PT = page tens.
Page sub-code : - $\mathrm{MU}=$ minutes units, $\mathrm{MT}=$ mınutes tens, $\mathrm{HU}=$ hours units, $\mathrm{HT}=$ hours tens.
PBLF = page being looked for, FOUND = low for page found, HAM = hamming error in byte, C4-14 = control bits.

## REGISTER MAP (see Table 2)

Registers R1 to R10 are write only whilst R11 is a read/write register respect to the microprocessor.
The automatic succession on a byte basis is indicated by the arrows in Table 2.
In the normal operating mode TA and TB should be set to logic level 0 .
After power-up the contents of the registers are as follows : all bits in registers R1 to R10 are cleared
to zero with the exception of bits D0 an D1 in registers R5 and R6 which are set to logical one. After power-up all the memory bytes are preset to hexadecimal value 20 H (space) with the exception of the byte corresponding to row 0 of column 7 of chapter 0 which is set to the value corresponding to "alpha white" hexadecimal value 07 H .

Table 2 : Register specification.

REGISTER FUNCTIONS

| Register | Function | Bit(s) | Description |
| :---: | :---: | :---: | :---: |
| R1 | Mode controls | T0,T1 (D0,D1) | These bits control the frame display format. Interlaced or non-interlaced,312/313 or 312/312. |
|  |  | TCS ON (D2) | This bit determines the character display synchronization mode. Teletext composite synchronism (TCS ON =1) or direct broadcast synchronism ( $\mathrm{TCS} O N=0$ ). |
|  |  | $\overline{\mathrm{DEW}} / \mathrm{FULLFIELD}$ (D3) | Selection of field flyback mode or full channel mode ( $\mathrm{D} 3=1$ ) for recovering of Teletext data. |
|  |  | GHOST ROW ENABLE (D4) | Selection of ghost row mode ( $\mathrm{D} 4=1$ ) |
|  |  | ACQUISITION ON/OFF (D5) | Control of acquisition operation (D5 $=0$ enables acquistion) |
|  |  | 7 bits + parity or 8 bits without parity (D6) | Selection of received data format ether 7 bits with parity ( $\mathrm{D} 6=0$ ) or 8 bits without parity $(\mathrm{D} 6=1)$. |
|  |  | TA (D7) | Test bit equal to "0" in the normal operating mode. |
| R2 | Addressing information for a page request | $\begin{gathered} \hline \mathrm{SC0,SC1,SC2} \\ (\mathrm{DO}, \mathrm{D} 1, \mathrm{D} 2) \end{gathered}$ | Address the first column of the on chip page request RAM to be written. |
|  |  | TB (D3) | Test bit equal to "0" in the normal working mode. |
|  |  | A0,A1 (D4,D5) | Address a group of four consecutive pages currently used for data acquisition; |
|  |  | A2 (D6) | Address of one of the two groups of four pages for acquisition in normal mode. |
| R3 | Data relative to the requested page (see Table 3). | PRDO-PRD4 (D0-D4) | Written data in the page request RAM, starting with the columns addressed by SC0,SC1,SC2. |
| R4 | Selection of one of eight pages to display. | A0,A1,A2 (D0,D1,D2) | These three bits correspond to the logical states of the three address lines (A12,A11,A10) during memory read cycles. |
| R5 | Display control for normal operation. | PON (D0,D1) | Picture on (IN. D0, OUT: D1) |
|  |  | TEXT (D2,D3) | Text on (IN: D2, OUT: D3) |
|  |  | COR (D4,D5) | Contrast reduction on (IN• D4, OUT: D5) |
|  |  | BKGND (D6,D7) | Background colour on (IN: D6, OUT: D7) |
|  |  | IN/OUT | Enable inside/outside the box |
| R6 | Display control for news-flash subtitle generation. | See R5 | See R5 |
| R7 | Display mode | $\begin{gathered} \text { BOX ON 0,1-23,24 } \\ \text { (D0,D1,D2) } \\ \hline \end{gathered}$ | The "boxing" function is enabled on row $0,1-23$ and 24 by D0, D1 and D2 set to one. |
|  |  | STATUS ROW BTM/TOP (D7) | The 25th row is displayed before the "Main text Area" (lines 0-23) or after (D7 = 0). |
| R8 to R11 | Active chapter address (R8), active row address (R9), active column address (R10). Data contained in R11 read (written) from (to) memory by microprocessor via $\mathrm{I}^{2} \mathrm{C}$ bus. |  |  |

Table 3 : Register R3.

| START COLUMN | PRD4 | PRD3 | PRD2 | PRD1 | PRDO |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | Do care magazine | $\overline{\text { HOLD }}$ | MAG2 | MAG1 | MAGO |
| 1 | Do care page tens | PT3 | PT2 | PT1 | PTO |
| 2 | Do care page units | PU3 | PU2 | PU1 | PU0 |
| 3 | Do care hours tens | X | X | HT1 | HTO |
| 4 | Do care hours units | HU3 | HU2 | HU1 | HUO |
| 5 | Do care minutes tens | X | MT2 | MT1 | MTO |
| 6 | Do care minutes units | MU3 | MU2 | MU1 | MU0 |

The abbreviations have the same significance as in Table 1 with the exception of the "DO CARE" entries. It is only when this bit is " 1 " that the corresponding digit is taken into consideration on page request. For example, a page defined as "normal" or one difined as "timed" may be selected.

If "HOLD" is low the page is held. The addressing of successive bytes via the $I^{2} \mathrm{C}$ bus is automatic.

## CHARACTER SETS

The selection of the character sets for a particular language is effected by the three control bits (C12-

C14) located in the page header. These three bits are decoded as shown in Table 4.

Table 4a : National character sets control bits for SDA5243

| PHCB | ENGLISH | GERMAN | SWEDISH | ITALIAN | FRENCH | SPANISH |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| C12 | $0(1)(1)$ | 0 | 0 | 0 | 1 | 1 |
| C13 | $0(1)(1)$ | 0 | 1 | 1 | 0 | 0 |
| C14 | $0(0)(1)$ | 1 | 0 | 1 | 0 | 1 |

Table 4b : National character sets control bits for SDA5243/H

| PHCB | POLISH | GERMAN | SWEDISH | SERBO-CROAT | CZECHOSLOVAK | RUMANIAN |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| C12 | 0 | $0(0)(1)$ | 0 | 1 | 1 | 1 |
| C13 | 0 | $0(1)(0)$ | 1 | 0 | 1 | 1 |
| C14 | 0 | $1(1)(0)$ | 0 | 1 | 0 | 1 |

The basic set of the 96 characters is shown in Table 5．The location of the 13 national characters
are shown in Table 5 whilst full national character sets are depicted in Tables 6 and 7.

The complete character set with 8 －bit decoding is given in Table 8.
Characters in columns 0 and 1 are normally dis－ played as blanks．Black dots represent the charac－ ter shape whereas white dots represent the background．
Each character can be identified by a pair of corre－
sponding row and column integers ：for example the character＂ 3 ＂may be indicated by $3 / 3$ ．
A rectangle may be represented as follows ： The characters $8 / 6,8 / 7,9 / 5,9 / 7$ are used as spe－ cial characters，always in conjunction with $8 / 5$ ．
The 13 national characters are placed in columns with bit $8=0$ ．

## COMPUTER-CONTROLLED TELETEXT DECODER

- AUTOMATIC SELECTION OF UP TO SEVEN NATIONAL LANGUAGES
- FOUR SIMULTANEOUS PAGE REQUESTS
- DISPLAY OF THE 25th STATUS ROW
- MICROPROCESSOR CONTROL VIA AN I ${ }^{2} \mathrm{C}$ BUS INTERFACE (SLAVE ADDRESS $0010001 \mathrm{R} / \overline{\mathrm{W}})$
- DATA ACQUISITION AVAILABLE FROM ROWS 2 TO 22 OR FROM A COMPLETE FIELD
- HIGH QUALITY DISPLAY USING A CHARACTER MATRIX OF $12 \times 10$ DOTS
- DIRECT INTERFACE TO ONE 8-BIT x 8K STATIC MEMORY A TWO 4-BIT x 16K DYNAMIC MEMORIES
- 60 Hz RECOGNITION AND INSERTION WITHOUT ADDITIONAL HARDWARE
- FIELD RECOGNITION FOR NOT-INTERLACED MODE AND 25Hz OUTPUT
- VIDEO SIGNAL QUALITY STATUS BIT
- EXTERNAL SYNCHRONIZATION BY H/V TV SIGNALS
- SINGLE +5V SUPPLY VOLTAGE
- NMOSH2 PROCESS

## DESCRIPTION

The SDA5343 is a NMOSH2 integrated circuit which performs all the processing of logical data within a 625 line system teletext decoder. It is designed to operate in conjunction with at less two chips : the SAA5231 integrated chip which extracts Teletext information embedded in a composite video signal and with up to eight kilobytes of static or dynamic RAM memory which can be used to store a maximum of 8 pages of display data. A complete system also comprises a microprocessor controlling the SDA5343 via a 2 -wire serial bus. An on-chip ROM memory contains the character sets. The SDA5343 performs automatic selection of one of up to seven natural languages making the system suitable for the display of text in English, German, Swedish, French, Italian and Spanish. Data bytes may be decoded in either 7-Bit plus parity or in full 8 -Bit formats. The chip set also supports facilities for reception and display of higher-level protocol data.

## PIN CONNECTIONS

PIN DESCRIPTION

| Symbol | Function | Description |
| :---: | :---: | :---: |
| $V_{D D}$ | + 5 V | Positive supply voltage. |
| A11, A12, A10 | Chapter address | Address selection outputs for 1 of 8 chapters each of 1 kBytes. |
| $\overline{\mathrm{OE}}$ | Output enable | Active-low RAM output enable control signal. |
| $\overline{\mathrm{WE}}$ | Write enable | Active-low RAM write enable control signal. It supports write-cycles interleaved with read-cycles. |
| TTD | Teletext data input | An A.C. coupled teletext data input supplied by the SAA5231 chip is latched to $V_{\text {Ss }}$ between 4 and $8 \mu \mathrm{~s}$ after each TV line. |
| TTC | Teletext clock input | A 6.9375 MHz clock signal, supplied by the SAA5231 chip, is internally A.C. coupled, clamped and buffered. |
| EVEN | Interlaced mode state output | High for even numbered and low for odd-numbered frames. |
| F6 | Character display clock signal | The 6 MHz clock signal, supplied by the SAA5231 chip is internally A.C. coupled, clamped and buffered. |
| vCS | Video composite synchronization input signal | Active high VCS input. |
| SAND | Sandcastle | Three level output pulse to the SAA5231 device. Phase lock, blanking signal, and color burst components are contained in this signal. |
| $\overline{T C S} / \overline{\text { SCS }}$ | Input composite synchronization signal | Scan composite input signal ( $\overline{\mathrm{SCS}}$ ) for the display synchronization. |
| RGB | Red, green, blue | Character and background colors active-high open-drain outputs. |
| $\overline{\mathrm{COR}} / \overline{\mathrm{CE}}$ | Contrast reduction | Open-drain active-low output supporting optimal display of characters in "mixed mode" operation. Chip enable for dynamic memory with 8 -Bit configuration $I^{2} \mathrm{C}$ bus programmable. |
| BLAN | Blanking signal output | Open-drain active high output for TV-image blanking in normal and mixed-mode operation. |
| Y | Foreground output | Open-drain active-high output with foreground information. Can be used for printer command. |
| SCL | Serial clock | Microprocessor clock input via serial bus. |
| SDA | Serial data input / output | Open-drain microprocessor serial data input/output via serial bus. |
| $\mathrm{V}_{\mathrm{ss}}$ | 0 Volt | Ground. |
| D0-D7 | Parallel data input / output | Eight tri-state input/output for data read/write |
| A0-A9 | Address signals | Ten addresses output pins for accessing to individual Bytes of a 1 kByte chapter stored in an external SRAM / PSRAM and DRAM (only AO - A7) |
| MC | Address multiplying control | If MC (Pin 3) is grounded, addresses are multiplexed for dynamic RAM's use. |
| $\overline{\mathrm{RAS}}, \overline{\mathrm{CAS}}$ | Address control | Address control for dynamic RAM's - Active low. |

## APPLICATION NOTES

## ORGANIZATION OF A PAGE-MEMORY

The organization of a page-memory is shown below. In contrast with the first generation of Teletext Decoders the new CCT (Computer Controlled Teletext) chip provides a display format of 25 rows of 40 characters per row.
Row number twenty-four is used by the microprocessor for the display of information.
Row zero contains the page header.
The organization is as follows:
The first seven characters (0-6) are used for messages regarding the operational status.
The eighth character is an alphanumeric control character either "white" or "green" defining the
"search" status of the page. When it is "white" the operational state is normal and the header appears white ; when it is "green" the operational state corresponds to "search mode" and the header appears green. The following twenty-four characters give the header of the requested page when the system is in search mode. The last eight characters display the time of day.
Row twenty-five comprises ten bytes of control data concerning the received page (see Table 1) and fourteen free bytes which can be used by the microprocessor.

PAGE MEMORY ORGANISATION

## REGISTER FUNCTIONS

| Register | Function | Bit(s) | Description |
| :---: | :---: | :---: | :---: |
| R0 <br> Address 00 H | R11 adressing and pin functions control | SEL 11B (D0) | Selection of register 11B ( $\mathrm{D} 0=1$ ) or $11 \mathrm{~A}(\mathrm{D0}=0)$ |
|  |  | CE ON (D1) | Selection of signal output on pin $16: \overline{\mathrm{CE}}(\mathrm{D} 1=1)$ or COR (D1 = 0) |
|  |  | EVEN OFF (D2) | Control of EVEN pin : EVEN signal output ( $\mathrm{D} 2=0$ ) or grounded (D2 = 1) |
| R1 <br> Address 01H | Operating mode controls | TCS (D2) | $0=$ TCS OFF, V $_{\text {SYNCH }}$ input <br> $1=$ Not allowed |
|  |  | $\overline{\mathrm{DEW}} /$ FULLFIELD <br> (D3) | Selection of field flyback mode or full channel mode ( $\mathrm{D} 3=1$ ) for recovering of Teletext data. |
|  |  | GHOST ROW ENABLE (D4) | Selection of ghost row mode ( $\mathrm{D} 4=1$ ) |
|  |  | ACQUISITION ON / OFF (D5) | Control of acquisition operatıon (D5 $=0$ enables acquisition) |
|  |  | 7 bits + parity or 8 bits without parity (D6) | Selection of received data format either 7 bits with parity ( $D 6=0$ ) or 8 bits without parity ( $D 6=1$ ). |
| R2 <br> Address $02 \mathrm{H}$ | Addressing information for a page request | $\begin{gathered} \text { SC0, SC1, SC3 } \\ \text { (D0, D1, D2) } \end{gathered}$ | Address the first column of the on chip page request RAM to be written. |
|  |  | TB (D3) | Test bit equal to "0" in the normal working mode. |
|  |  | A0, A1 (D4, D5) | Address a group of four consecutive pages currently used for data acquisition; |
|  |  | A2 (D6) | Address of one of the two groups of four pages for acquisition in normal mode. |
| R3 <br> Address 03 H | Data relative to the requested page (see Table 3) | $\begin{aligned} & \text { PRD0 - PRD4 } \\ & \text { (D0 - D4) } \end{aligned}$ | Written data in the page request RAM, starting with the columns addressed by SC0,SC1,SC2. |
| R4 <br> Address 04H | Selection of one of eight pages to display | $\begin{gathered} \mathrm{A} 0, \ldots \mathrm{~A} 2 \\ (\mathrm{D} 0, \ldots \mathrm{D} 2) \end{gathered}$ | These three bits correspond to the logical states of the three address lines (A10, A11, A12) during access read cycles. |
| R5 <br> Address 05H | Display control for normal operation | PON (D0, D1) | Picture on (IN: D0, OUT: D1) ( $1=\mathrm{ON}, 0=\mathrm{OFF}$ ) |
|  |  | TEXT (D2, D3) | Text on (IN: D2, OUT: D3) ( $1=\mathrm{ON}, 0=\mathrm{OFF}$ ) |
|  |  | $\overline{\mathrm{COR}}$ (D4, D5) | Contrast reduction on (IN: D4, OUT: D5) ( $1=\mathrm{ON}, 0=$ Normal) |
|  |  | BKGND (D6, D7) | Background colour on (IN: D6, OUT: D7) $(1=\mathrm{ON}, 0=\mathrm{OFF})$ |
| R6 <br> Address 06 H | Display control for news-flash subtitle generation | See R5 | Activated by broadcasted bit C5, C6 of Teletext control bit |
| R7 <br> Address <br> 07H | Display mode | BOX ON 0, 1-23,24 <br> (D0, D1, D2) | The "boxing" function is enabled on row 0,1-23 and 24 by D0, D1 and D2 set to one. |
|  |  | $\overline{\text { Single/Double }}$ height (D4/D3) | $\begin{aligned} & \mathrm{X0}=\text { Normal } \\ & 01=\text { double height Rows } 0 \text { to } 11 \\ & 11=\text { double height Rows } 12 \text { to } 23 \end{aligned}$ |
|  |  | Conceal/Reveal (D5) | Conceal Reveal Function |
|  |  | Cursor ON/ $\overline{\text { OFF }}$ (D6) | Cursor poisition given by row/column value of R9/R10 |
|  |  | STATUS ROW BTM / TOP (D7) | The 25th row is displayed before the "Main text Area" (lines 0-23) (D7 = 1) or after ( $\mathrm{D} 7=0$ ). |

REGISTER FUNCTIONS（continued）

| Register | Function | Bit（s） | Description |
| :---: | :---: | :---: | :---: |
| R8 to R11A Address 08 H to $0 \mathrm{BH}^{*}$ | Active chapter address（R8），active row address（R9），active column address（R10）． Data contained in R11A read（written）from（to）memory by microprocessor via $I^{2} C$ Bus． |  |  |
| R11B Address $0 B H^{*}$ | Status | VCS ON（D0） | Good VCS quality sigroal detected（ $\mathrm{D} 0=1$ ）or disturbance（ $\mathrm{DO}=0$ ） |
|  |  | 60 Hz （D7） | VCS received with 60 Hz frequency（ $D 7=1$ ）or 50 Hz （D7＝0）．Valid only when $\mathrm{DO}=1(\mathrm{D7}$ grounded if $\mathrm{DO}=0)$ |

＊Reading of R11A and R11B is determined by register 0 ，bit D0．Nevertheless，write operation is always performed on R11A register．

## REGISTER MAP（see Table 2）

Registers R1 to R10 are write only whilst R11A is a read／write and R11B is a read only register respect to the microprocessor．
The automatic succession on a byte basis is indi－ cated by the arrows in Table 2.
In the normal operating mode TB should be set to logic level 0.
After power－up the contents of the registers are as
follows ：all bits in registers R1 to R11 are cleared to zero with the exception of bits D0 an D1 in registers R5 and R6 which are set to logical one．
After power－up all the memory bytes are preset to hexadecimal value 20 H （space）with the exception of the byte corresponding to row 0 of column 7 of chapter 0 which is set to the value corresponding to＂alpha white＂hexadecimal value 07 H ．

Table 2 : Register specification.

| START COLUMN | PRD4 | PRD3 | PRD2 | PRD1 | PRDO |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | Do care magazine | $\overline{\text { HOLD }}$ | MAG2 | MAG1 | MAGO |
| 1 | Do care page tens | PT3 | PT2 | PT1 | PT0 |
| 2 | Do care page units | PU3 | PU2 | PU1 | PU0 |
| 3 | Do care hours tens | X | X | HT1 | HTO |
| 4 | Do care hours units | HU3 | HU2 | HU1 | HUO |
| 5 | Do care minutes tens | X | MT2 | MT1 | MTO |
| 6 | Do care minutes units | MU3 | MU2 | MU1 | MUO |

The abbreviations have the same significance as in Table 1 with the exception of the "DO CARE" entries. It is only when this bit is " 1 " that the corresponding digit is taken into consideration on page request. For example, a page defined as "normal" or one difined as "timed" may be selected

If "HOLD" is low the page is held. The addressing of successive bytes via the S-bus is automatic.

## CHARACTER SETS

The selection of the character sets for a particular language is effected by the three control bits (C12-

C14) located in the page header. These three bits are decoded as shown in Table 4.

Table 4 : National character sets control bits.

| PHCB | ENGLISH | GERMAN | SWEDISH | ITALIAN | FRENCH | SPANISH |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| C12 | $0(1)(1)$ | 0 | 0 | 0 | 1 | 1 |
| C13 | $0(1)(1)$ | 0 | 1 | 1 | 0 | 0 |
| C14 | $0(0)(1)$ | 1 | 0 | 1 | 0 | 1 |

The basic set of the 96 characters is shown in Table 5.The location of the 13 national characters
are shown in Table 5 whilst full national character sets are depicted in Tables 6 thru 11.

Table 11 : Spanish Basic Character Set

The complete character set with 8－bit decoding and using the German national character is given in Table 7.
Characters in columns 0 and 1 are normally dis－ played as blanks．Black dots represent the charac－ ter shape whereas white dots represent the background．
Each character can be identified by a pair of corre－
Table 7：Complete character set（with 8 bit codes）．
sponding row and column integers ：for example the character＂ 3 ＂may be indicated by $3 / 3$ ．
A rectangle may be represented as follows ：

The characters $8 / 6,8 / 7,9 / 5,9 / 7$ are used as spe－ cial characters，always in conjunction with $8 / 5$ ．
The 13 national characters are placed in columns with bit $8=0$ ．

＊＊These control characters are presumed before each row begins

Figure 12: Character Format

## PACKAGE MECHANICAL DATA

40 PINS - PLASTIC DIP

$40_{\text {pns }}$

## CABLE DRIVER FOR DIGITAL TRANSFER

ADVANCE DATA

- 1 DIFFERENTIAL INPUT, 3 DIFFERENTIAL OUTPUTS
- SUFFICIENT DRIVE CAPABILITY FOR A 300 m LENGTH COAXIAL CABLE
- STABILITY DUE TO MINIMAL WAVEFORM DISTORTION
- BIPOLAR SILICON MONOLITHIC IC

## APPLICATIONS

- DATA TRANSFER BETWEEN DIGITAL SIGNAL PROCESSING EQUIPMENT

## DESCRIPTION

The STV1389AQ offers in a single-chip a complete IC driver for digital data transfer.

## PIN CONNECTIONS

PIN DESCRIPTION

| Pin Number | Symbol | Standard DC Voltage | Equivalent Circuit | Description |
| :---: | :---: | :---: | :---: | :---: |
| 7 9 | $\begin{aligned} & \text { INY } \\ & \text { INX } \end{aligned}$ | -2.7V |  | Input pin of the differential amplifier. Input executed after DC portion is cut off. |
| $\begin{gathered} 1 \\ 2 \\ 17 \\ 18 \\ 25 \\ 26 \end{gathered}$ | $\begin{aligned} & \text { GND2 } \\ & \text { GND3 } \\ & \text { GND4 } \\ & \text { GND5 } \\ & \text { GND6 } \\ & \text { GNDD } \end{aligned}$ | - |  | Collector of the emitter follower output Tr. <br> Connect to GND. |
| $\begin{gathered} 32 \\ 3 \\ 16 \\ 20 \\ 23 \\ 27 \end{gathered}$ | $\begin{aligned} & 1 A \\ & 1 B \\ & 2 A \\ & 2 B \\ & 3 A \\ & 3 B \end{aligned}$ | -2.7V |  | Emitter of emitter follower output Tr. To use, connect pull-down resistor. (Even when only 1 side is used pulldown is executed $\ln$ pairs.) |

## BLOCK DIAGRAM

## ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter | Value | Unit |

TEST CIRCUIT

91DSSTV1389AQ-05

## DESCRIPTION OF OPERATION

The STV1389AQ consists of 3 differential amplifier with a common input and a bias generator, and three differential outputs. Each amplifiers provides a 6 dB gain and is configured as a differential output feeding the bases of a pair of current boosting on-chip emitter follower transistors. The differential input pins are internally biased and the input signal is ac-coupled to remove the D.C. component.
Between the output pins of each differential amplifier and the coaxial cable, an R-C network is con-
nected to remove D.C. component from the output and for impedance matching. The series resistor has a value of 68 to $75 \Omega$ to match a $75 \Omega$ coaxial cable. In this manner a signal almost identitical in level to the input signal is transferred to the coaxial cable.
Optimum PCB layout and matching resistor value are chosen to obtain good eye pattern design at the input pins. This is necessary because the waveform distortion at the input pins is directly transferred to the output waveform.

PACKAGE MECHANICAL DATA
32 PINS - PLASTIC QFP

## Dimensions in mm

## SERIAL INTERFACE TRANSMISSION ENCODER

PRELIMINARY DATA

THIS IC CONTAINS ALL THE CIRCUITS NEEDED FOR CONVERSION FROM PARALLEL DATA, AND PARALLEL CLOCK, INTO SERIAL DATA. APPLICATIONS ARE STRAIGHTFORWARD AS ONLY A FEW EXTERNAL COMPONENTS ARE NEEDED.
OTHER RELATED IC's INCLUDE :

- STV1602A, A SERIAL TRANSMISSION DECODER (WITH A BUILT-IN CABLE EQUALIZER AND PARALLEL-TO-SERIAL CONVERSION)
- STV1389AQ COAXIAL CABLE DRIVER

## STRUCTURE

- Hybrid IC

## APPLICATIONS

SERIAL DATA TRANSMISSION ENCODER

- 100 to $270 \mathrm{Mb} / \mathrm{s}$

## APPLICATIONS EXAMPLES

- Serial data transmission of digital television signal 525-625 lines
- 4:2:2 component $270 \mathrm{Mb} / \mathrm{s}$ (10-BIT)
- 4*FSC PAL composite $177 \mathrm{Mb} / \mathrm{s}$ (10-BIT)
- 4*FSC NTSC composite $143 \mathrm{Mb} / \mathrm{s}$ (10-BIT)

## FUNCTIONS

- Parallel-to-serial conversion
- Scrambler : Modulo - 2 division by $G(x)=\left(x^{9}+x^{4}+1\right)(x+1)$
- PLL for serial clock generation
- PLL lock detection
- Sync word required with the parallel data stream

|  | $\mathbf{8}$ bit | 10 bit |
| :--- | :---: | :---: |
| 1st word | FFH | $3 F F H$ |
| 2nd word | 00 H | 000 H |
| 3rd word | 00 H | 000 H |

Note: The words composing the Sync word given above will not appear during datawords
This limitation includes 00 and FF in 8-bit use and 000 through 003 and 3FC through 3FF in 10-bit use.

SYNC WORD CONVERSION (8-BIT OR 9-BIT TIMING REFERENCE SIGNAL IS INTERNALLY CONVERTED TO 10-BIT).

## CODE LIMITATION

The word composing the Sync word listed above shall not appear during data words.

## DESCRIPTION

The STV1601A is a Hybrid IC encoder that converts parallel data into serial data for a serial transmission line.

## DESCRIPTION

STV1601A internally generates a 10 times clock frequency locked to the parallel input clock thanks to a built-in PLL and converts input parallel data into serial data.
To ease clock extraction at the receiving end, serial
data is scrambled. To minimize polarity effect, serial data is then converted to NRZI and output in differential mode.
A PLL lock detection circuit only enables the serial output when locked.

## 1. Phase relation between input parallel clock and data

The phase relation between the parallel clock and the data is shown in Figure 11. Both clock and data are differential inputs
Parallel clock and data are such that the rising edge of PCX should be at the middle of the data. A clock having the same phase as PCX is internally generated in order to latch the data.
Figure 11 : Phase Relation between Clock and Data

## 2. TTL input operation

Parallel clock and data can be either TTL or ECL inputs. To use as TTL inputs VCC (Pin 29) shall be connected to +5 V . A fixed bias of +1.4 V shall be applied to PCY and DnY ( $\mathrm{n}=0$ to 9 ). TTL signals and their parallel clock will be provided through $1 \mathrm{k} \Omega$ resistors to each "X" input. These $1 \mathrm{k} \Omega$ resistors are effective to minimize the influence of the TTL input signals to the jitter characteristics of the serial output signal. For 8-bit data, unused LSB(s) must be fixed Low. Fixed bias value can be higher, for example, 2.5 V in case of CMOS inputs.

Figure 12 : TTL input operation

## 3. PLL block

Parallel clock input control
PLL, PLL lock detection and the various blocks of the serial output control are shown in Figure 13. When TN1 is connected to GND (set High), the parallel clock input is disabled.
The VCO turns to free running conditions and its frequency can be adjusted through FV.
This frequency decreases when the resistor value between FV and $\mathrm{V}_{\mathrm{EE}}$ is reduced. Oscillation frequency monotoring is performed through PCK which delivers a frequency divided by ten.
When PLL is locked, PLL and PCX input signal phases are nearly matched. The RC network connected to TN1, temporarily, disables the parallel clock in order to avoid mislocking problems.
VCO oscillation frequency range selection is available through RSE ; High : from 140 to 270 MHz ; Low : from 100 to 145 MHz .
TRP (Pin 34) is the phase comparator output. To minimize jitter, a trap circuit, consisting in a serial tuned circuit at parallel clock frequency can be used.

Figure 13 : PLL and Serial Output Control BLock

## PLL lock detection

The LST signal is generated by latching the incoming parallel clock by the internal one (which is $1 / 10$ of the VCO frequency). LST is used as a PLL lock detection signal and also controls the serial output. If the parallel clock input is disabled (by means of TN1), LST turns Low and the serial output is disabled as described in the previous section (SX (Pin $3)=$ High, SY $($ Pin 4$)=$ Low $)$.
If the serial output has to be disabled while no parallel clock input is provided, PCX must be set Low and PCY must be set High.

## 4. Sync word

To convert serial data back to parallel, insertion of some timing reference data indicating the parallel data word boundary in the serial data is needed. This, called TRS (Timing Reference Signal) in the digital interface format, consists of the three consecutive words $3 F F H, 000 \mathrm{H}, 000 \mathrm{H}$.

Conversion to 10-bit TRS from 8-bit, 9-bit data (TRS)

## 8-bit parallel data

8 -bit parallel data can be converted into 10-bit data by using the 8th bit as the MSB and by setting the 2 LSBs at logical states as shown in Figure 14.

Figure 14 : 8-bit Parallel Input Data (ECL level)

The conversion algorithm detects 2 successive 000 H words and sets the two LSBs of the previous word, which is supposed to be FF, according to the standard.
Figure 15 : Conversion from 8-bit TRS to 10-bit TRS

## 9-bit parallel data

Similary, 9-bit parallel input data can be accepted as shown in Figure 16.
Figure 16 : 9-bit Parallel Input Data (ECL level)

Conversion in the case of more than three successive " 000 H " words.
If more than 3 consecutive words of 000 in D1 standard, or 4 consecutive words of 000 in D2 standard occur at the parallel input it does not meet the SHPTE T14.224 proposed standard thus no proper operation is possible.
With TRS, the word before two successive " 000 H " is all "1". Internally, this word is checked and the two LSBs are set to " 1 ".

## 5. Scrambling and NRZ to NRZI conversion

Figure 20 shows the scrambling circuit, the scrambling polynomial is as follows: $x^{9}+x^{4}+1$.

Figure $17:\left(x^{9}+x^{4}+1\right)$ Basic Scrambling Circuit

Figure 18 : $\left(x^{9}+x^{4}+1\right)$ Actual Scrambling Circuit

To eliminate signal polarity of scrambled data, conversion from NRZ to NRZl is performed (Figures 11 and 12).
Therefore, the polarity for output distribution or receiving is not needed. This allows easy system design. The NRZ to NRZI polynominal is $x+1$.

Figure 19 : NRZ To NRZI Conversion and NRZI to NRZ Conversion

Figure 20 : Relation between NRZ and NRZI Signals

VCO temperature compensation and oscillation frequency adjustment
VCO oscillation frequency depends on the temperature as shown inFigures 23 and 24 "Representative characteristics examples". Within the normal range of operation, frequency increases with temperature. FV voltage remains almost constant regardless of temperature. Figure 21 shows an example of a temperature compensation circuit using a diode (transistor with C-B diode short-circuited) and a resistor connected between FV and $V_{E E}$. Examples of representative characteristics for
various temperatures are shown in Figures 23 and 24 concerning oscillation frequency and PLL pull-in range (signal frequency 270, 177 and 143 MHz ).

## VCO free running frequency adjustment

VCO free running frequency adjustment is performed at room temperature.
If TN1 is set High, VCO free runs. Wait for 5 to 10 minutes after turning power supply ON (warm up time). While monitoring PCK output (Pin 36) adjust the signal frequency (within $\pm 1 \%$ ) with the variable resistor connected between FV and $\mathrm{V}_{\mathrm{EE}}$.

Figure 21 : VCO Temperature Compensation and Free Running Adjustment

## Jitter trap

Since the internally generated serial clock is locked to the incoming parallel clock, there exists periodic jitter components which are generated from the phase comparison process of the PLL. A serial resonant circuit (trap) connected between TRP
(Pin 34) and Vee tuned at the parallel clock frequency reduces effectively the fundamental component of the jitter well below the specification $( \pm 0.25 \mathrm{~ns}$ ). Recommended values of C1 and L1 are given in the following table.

RECOMMENDED VALUES OF THE TRAP CIRCUIT

| COMPONENT | STANDARD |  |  |
| :---: | :---: | :---: | :---: |
|  | D1 | D2 |  |
|  |  | PAL | NTSC |
| $\mathrm{C} 1(\mathrm{pF})$ | 150 | 240 | 300 |
| $\mathrm{~L} 1(\mu \mathrm{H})$ | 0.2 | 0.3 | 0.4 |

An important remark in a practical implementation is that TRP node is an input of a very sensitive voltage-frequency converter (VCO) which can be easily disturbed by any pick-up noise.

Hence, the trap circuit should be carefully located and be kept as short as possible from the Pin 34 in order to avoid noise problems.

## SERIAL INTERFACE TRANSMISSION DECODER

PRELIMINARY DATA
BUILT-IN AUTOMATIC EQUALIZER FOR UP TO 30dB ATTENUATION AT 135MHz (TYPICALLY 300m OF HIGH-GRADE COAXIAL CABLE), PLL CIRCUIT FOR RECLOCKING, AND SERIAL-PARALLEL CONVERSION CIRCUIT.
THIS SERIAL TRANSMISSION DECODER REQUIRES ONLY FEW EXTERNALCOMPONENTS. OTHER RELATED IC's INCLUDE :

- STV1601A, A SERIAL TRANSMISSION ENCODER (PARALLEL-TO-SERIAL CONVERSION)
- STV1389AQ COAXIAL CABLE DRIVER

## STRUCTURE

- Hybrid IC

## APPLICATIONS

SERIAL DATA TRANSMISSION DECODER

- 100 to $270 \mathrm{Mb} / \mathrm{s}$

## APPLICATIONS EXAMPLES

- Serial data transmission of digital television signals 525-625 lines
- 4:2:2 component $270 \mathrm{Mb} / \mathrm{s}$ (10-bit)
- $4^{*}$ fsc PAL composite $177 \mathrm{Mb} / \mathrm{s}$ (10-bit)
- $4^{*}$ fsc NTSC Composite $143 \mathrm{Mb} / \mathrm{s}$ (10-bit)

## FUNCTIONS

- Cable equalizer
(maximum gain : 30 dB at 135 MHz )
- PLL for serial clock generation
- Reclocked repeater output (active loop through)
- Descrambler : modulo-2 multiplication by $G(x)=\left(x^{9}+x^{4}+1\right)(x+1)$
- Parallel-to-serial conversion
- Sync monitor output
- Eye pattern monitoring
- Input signal detector

## DESCRIPTION

The STV1602A is a Hybrid IC decoder which converts serial data coming from a serial transmission line into parallel data.

PIN CONNECTIONS

SYN pin guaranteed operation range.
SYNC pin and serial to parallel conversion operate normally within the frequency and ambient temperature ranges according to Figure 2.

## Serial output pin use.

Normal use of the STV1602A is to convert serial data into parallel data. Output serial data is also available. However, when this output is used, the PLL is affected and in some instances, bit slip errors will be generated during long runs of 0 or 1 .
Serial output operation is checked (TRS can be detected from the output) but characteristics cannot be guaranteed. Moreover, simultaneous use of parallel and serial outputs is not advised due to higher power consumption.
When both parallel and serial outputs are needed, use STV1601A to convert the parallel output to serial.

Power saving in repeater mode
Since the parallell output is not always required for a reclocked repeater, the chip has been designed such that the uncessary parallel logic circuit can be disabled by disconnecting Pin 8, one of $\mathrm{V}_{\mathrm{EES}}$, from the power supply. With this arrangement the power
dissipation is reducible to about 45 percent of that of the fully functional mode.
In practice, a test switch should be provided so that some parallel signals may be available during adjustment procedures as shown in Figure 2.

Figure 10

## STV1602A GENERAL

As shown in the overall block diagram on page 7, STV1602A is composed of the following functions :
(1) Analog input as a primary input with automatic equalizer to meet the loss characteristics of coaxial cable
(2) Digital input as a secondary input to receive the encoded signal from short distances within the same printed circuit board or the same equipment
(3) Phase locked loop (PLL) variable oscillator
(4) Reclocked serial output
(5) Serial descrambler
(6) SYNC detector
(7) Deserializer
(8) Parallel output buffer amplifiers
(9) Three diagnostic signals : eye monitor, SYNC monitor and input data presence monitor

A briaf explanation of each function is given in the following sections.

## 1. Cable equalizer

Transmission of high speed digital data by means of coaxial cable can greatly attenuate high frequency components. According to the cable length, received signals can widely differ from those sent;
in such conditions, clock extraction and data identification could be difficult.
The cable equalizer overcomes this problem.
The IC performs up to 30 dB (typical) equalization at 135 MHz , typically 300 m of high-grade coaxial cable. The equalization is automatically performed according to the coaxial cable length.
The input signal can be delivered either through a transformer or through a capacitor.
When the digital input is selected, the equalizer is disabled.

Figure 11: Equalizer Capacitor Coupling Input Circuit

Figure 12 : Equalizer Transformer Input Circuit

MON Pin (31)
Equalized signals can be observed at this pin by connecting an oscilloscope input ( $50 \Omega$ ).

Figure 13 : Equalized Waveforms Monitoring

CX Pin (29) Equalizer detection output
Connect a $10 \mu \mathrm{~F}$ capacitor between this pin and GND. According to input signals, voltage changes from -2 V to -2.4 V can occur.

Figure 14 : An example of technique to improve the return-loss figure for the capacitor coupling input case

Figure 15 : AGC Time Constant

## 2. Digital input

The serial data input can be used without the equalizer.
DIX (Pin 33) and DIY (Pin 34) are differential inputs for ECL signals.
From these pins, input signals are differentially amplified, therefore with no input signals, the data detection signals could go High and erroneous data would be transferred to the parallel output.
To avoid this, a voltage level conforming to ECL specifications must be applied between DIX and DIY pins.
Also, while the analog input is in use, digital input must be kept "quiet" in order to avoid possible errors caused by cross-talk. This cross-talk problem naturally gets most severe when the analog input cable length is close to the limit of the transmission capability.

## 3. Serial input selection

Selection of the serial input is performed by ADS (Pin 32); when High the digital input is enabled; this input can be used for very short transmission lines. When Low, the equalizer input is enabled; this input must be used for long transmission lines.

## 4. PLL

In order to extract clock signals from the equalized serial data, it is processed to generate edge signals which are sent to the phase comparator.
When the PLL is locked, the identifier clock ( $D$ flipflop) will be in phase with the incoming clock. The identifier clock rises at the center of the data period for easy identification.
The PLL detailed block diagram is shown in Figure 16.
ESI is the VCO control input (Pin 37). Normally, the phase comparator output ESO (Pin 1) is connected to ESI.
Through FV (Pin 35) one can adjust the free running frequency; when the FV Voltage is equal to $V_{E E}$, the free running frequency is the lowest; the voltage adjustment can be performed by using a variable resistor connected between FV and VEE. RSE (Pin 22) selects the VCO frequency range; High : 140 to 270 MHz , Low : 100 to 145 MHz .
When TN1 (Pin 6) is set High, input signals are disabled and the VCO free runs. The capacitor connected between TN1 and GND avoids mislocking problem when the power supply is switched on.

Figure 16 : Serial Data Input and PLL

## Data detection

Serial data edges are detected and go through low pass filter. The processed signal is available at DPR (Pin 35).DPR goes High when an input signal is detected, otherwise it stays Low.
The driving capability of this pin is weak. It is recommended to load it with a high impedance CMOS or equivalent.

Using_particular codes to check overall performance
Althrough the scrambling method employed in the proposed SMPTE standard effectively randomizes the incoming data and puts out a signal with a nearly uniform spectrum, there still exist some combinations of codes that give somewhat unfriendly conditions to the transmission path in terms of low frequency component or of a long run without any transitions.
As shown in Figure 17, it is known that if the code words 300, 198 (hex, 10-bit) are given alternately to the parallel input of the encoder, the largest amount of DC component (nearly one TV line period) can be produced at some place with a certain probability (such a sequence is, however, destroyed when different data is input to the encoder).
Even with such signals, error-free reception is possible with the STV1602A if a proper implementation is made (refer to section 12 for a recommended circuit).

Figure 17

## 5. NRZI To NRZ conversion, descrambler

Serial data delivered by the identifier is available in differential mode, SX (Pin 4) and SY (Pin 3). At the same time, to recover the original data, NRZI to NRZ conversion and descrambling are performed.
Figure $18: x^{9}+x^{4}+1$ Descrambler

Figure 19 : Actual $x^{9}+x^{4}+1$ Descrambler

## 6. Serial to parallel conversion

After descrambling, serial data is sent to a 30-bit register to detect the sync word (TRS). When the sequence 111111111100000000000000000000 is detected, sync word detection signal is output, the counter which divides the clock frequency by 10 is initialized and data is converted to parallel (10-bit
word) to be output.
Each time the sync word is detected, SYN (Pin 20) changes state as shown in Figure 20.
As SYN driving capability is weak, the time relation with the parallel data is not constant. Parallel data processing using this signal is not possible.

Figure 20 : TRS Insertion Example and the Indicated Condition Resulting from TRS Detection

## 7. Phase relation ship between parallel data and parallel clock

Parallel data and clock are output so that the rising edge of the parallel clock is located at the center of the parallel data. Both parallel data and clock (ECL single output) have DC levels depending on the
temperature. In order to simplify the driving amplifier, a reference level (EVR) is available at Pin 21. PCX, Dn and EVR use pull down resistors (identical values). A peripheral circuit example is shown in Figure 22. Figure 23 shows a circuit to disable the parallel clock output.

Figure 21 : Phase Relation of Parallel Clock, Data and EVR Voltage Level

Figure 22 : Parallel Clock Data Output Circuit

Figure 23 : A Circuit Example to Disable Parallel Clock

## 8. VCO temperature compensation and oscilIation frequency adjustment.

VCO oscillation frequency depends on the temperature as shown in Figures 26 and 27 "Representative characteristics example". Within the
normal range of operation, frequency increases with temperature.
FV pin voltage remains almost constant regardless of temperature.
Figure 24 shows an example of a temperature compensation circuit using a diode (transistor with C-B diode short-circuited) and a resistor between FV and VEE.
PLL pull-in range (signal frequency 270, 177 and 143 MHz ) are given by Figures 29, 30 and 31.

## 9. VCO free running frequency adjustment

VCO free running frequency adjustment is performed at room temperature.
If TN1 is set High, VCO is free running. Wait for 5 to 10 minutes after turning power supply ON (warm up time).
While monitoring PCK (Pin 19) output, adjust the signal frequency (within $\pm 1 \%$ ) with the variable resistor connected between FV and Vee.

## PACKAGE MECHANICAL DATA

## 37 PINS - CERAMIC PGA

## PAL LUMA-CHROMA \& DEFLECTION PROCESSOR

- ONE RGB AND FB INPUT
- DC-CONTROLLED BRIGHTNESS, CONTRAST AND SATURATION
- CERAMIC 500 kHz VCO FOR LINE DEFLECTION
- PHASE-LOCKED REFERENCE OSCILLATOR USING A STANDARD 4.43MHz QUARTZ
- NO LINE AND FRAME OSCILLATOR ADJUSTMENTS REQUIRED
- OSD CAPABILITY ON OUTPUTS
- VIDEO IDENTIFICATION GENERATOR
- FEW EXTERNAL COMPONENTS

## DESCRIPTION

The STV2100 is a PAL chroma decoder, video and H/V deflection processor for CTV.
Used with the TDA8213, this IC permits a complete low cost solution with external output stages.

## DIGITAL VIDEO FILTERING AND DEMATRIXING

- DIGITAL RESTITUTION OF R,G,B PRIMARY COMPONENTS FROM DIGITAL INPUTS $Y$ (LUMINANCE) AND CR, CB (CHROMINANCE) THROUGH FILTERING AND DEMATRIXING.
- TWO 8-BIT INPUT CHANNELS:
- Y signal at 13.5 Msamples $/ \mathrm{sec}$
- multiplexed CR, CB signal at
13.5 Msamples/sec
- OVERSAMPLING DIGITAL FILTERING TECHNIQUE WITH A FIXED RESPONSE CURVE FOR Y, AND FOUR SELECTABLE RESPONSE CURVES FOR CR, CB.
- DIGITAL DEMATRIXING OPERATOR
- THREE-STATE BUFFERS ON R,G,B OUPUTS
- CMOS TECHNOLOGY
- SINGLE 5 VOLTS POWER SUPPLY

## DESCRIPTION

This circuit associated with a triple Digital-to-Analog converter is dedicated to the restitution of primary components R,G,B of a digital video processing system according to 601 CCIR recommandations.

PRELIMINARY DATA

The STV3300 is also suitable for other TV standards and for still picture applications. Due to the implementation of oversampling technique, complex analog filters are eliminated and the restitution module is greatly simplified.

## PIN CONNECTIONS

## BLOCK DIAGRAM

## PIN DESCRIPTION

| Pin number | Symbol | Description |
| :---: | :---: | :---: |
| 1-29 | $V_{D D}$ | Power supply |
| 2 | $\overline{\mathrm{OEN}}$ | Output Enable: This TTL input controls the output buffers; $\overline{\mathrm{OEN}}=1$, ouput are in three state: $\overline{O E N}=0$, ouputs are valid |
| 3:10 | R7:R0 | 8-bit TTL outputs for R channel. R7 is the MSB, R0 is the LSB |
| 11 | SYNC | This TTL input synchronizes the multiplexing of the CR,CB signals on the $C$ inputs. SYNC must be low when CB is active, every four CLK periods. |
| 12 | CLK | Clock TTL input. Data inputs on $Y$ and $C$ channels are sampled on the falling edge of CLK signal |
| $13: 20$ | Y7 : Y0 | 8-bit inputs for $Y$ channel. $Y 7$ is the MSB, Y0 is the LSB |
| 21:28 | C7: C0 | 8-bit inputs for C channel. C 7 is the MSB, CO is the LSB |
| 30-43-52 | VSS | Ground |
| 31-32 | A0-A1 | TTL inputs for chrominance filter response curve selection |
| 33 | DLY | This TTL input activates a delay of one clock perıod on the output path: active at level 1 |
| 34 | TEST | This signal must be connected to 0 |
| 35:42 | B0 : B7 | 8 -bit TTL outputs for B channel. B7 is the MSB, B0 is the LSB |
| 44 : 51 | G0 : G7 | 8-bit TTL outputs for G channel. G7 is the MSB, G0 is the LSB |

## DEVICE DESCRIPTION

The STV3300 is basicaly constituted of two different parts; a filtering stage and a dematrixing stage.

## Luminance filter

The luminance filter oversamples the $Y$ input signal by a factor of 2 , ( filter output frequency is 27 Msamples/sec. ), and reduces duplicated spectrum introduced by digitization. It is a 19th order finite response filter which includes the compensation of the $\operatorname{Sin} x / x$ attenuation of the digital to analog conversion. Figure 1 shows the luminance filter response curve.

## Chrominance filter

The chrominance filter oversamples CR, CB input signals by a factor of 4 ,
(filter output frequency is $27 \mathrm{Msamples} / \mathrm{sec}$ ). Two filters are implemented in series, each of them oversamples by a factor of 2 . The first filter stage allows four different filter selections via two dedicated pins.

Those filters provide different cutoff frequencies (from 1 MHz to 1.8 MHz ). Figure 2 shows the chrominance filter response curves and the following table the mode selection on the two external pins, A0 and A1.

| A0 | A1 | Filter selected |
| :---: | :---: | :---: |
| 0 | 0 | 1 |
| 0 | 1 | 2 |
| 1 | 0 | 3 |
| 1 | 1 | 4 |

## Dematrixing unit

The dematrixing unit operates at 27 Msamples/sec using the following equations according to the 601 CCIR recommandations:
$R=Y+1.370 \cdot(C R-0.5)$
$G=Y-0.698 \cdot(C R-0.5)-0.336 \cdot(C B-05)$
$B=Y+1.730 \cdot(C B-0.5)$
In addition to the filtering and dematrixing functions two other features are provided:

- An additionnal 27 MHz period can be inserted in the ouput path in order to reproduce the quincunx acquisation principle. This consists in delaying a frame of one 27 MHz period. The external signal DLY controls this operation.
- Output three-state buffers are implemented to provide multiplexing with external signal without external switches. The OEN signal controls this function.

SUMMARY OF CONTROL SIGNALS

## COMPUTER-CONTROLLED TELETEXT DECODER WITH UP TO 64 KBYTES RAM ADDRESSING CAPABILITY

- FULLY COMPATIBLE WITH SDA5243 TELETEXT CONTROLLER
- UP TO 32K x 8 BIT STATIC / PSEUDO-STATIC RAM OR $2 \times(64 \mathrm{~K} \times 4)$ DRAM DIRECT INTERFACE
- 60Hz RECOGNITION AND INSERTION WITHOUT ADDITIONAL HARDWARE
- MASTER OR SLAVE MODE FOR HORIZONTAL AND VERTICAL SYNCHRONIZATION
- VIDEO SIGNAL QUALITY STATUS BIT
- PROGRAMMABLE RAM CONTROL SIGNAL ( $\overline{C E}, \overline{W E})$
- FLEXIBLE CAPABILITIES FOR MANAGEMENT AND REFRESH OF ACQUISITION AND DISPLAY MEMORY
- ON-CHIP MASK PROGRAMMABLE ROM CHARACTER GENERATOR
- AUTOMATIC SELECTION OF UP TO SEVEN NATIONAL LANGUAGES
- MICROPROCESSOR CONTROL VIA AN I ${ }^{2} \mathrm{C}$ BUS
- SINGLE + 5V SUPPLY VOLTAGE

## DESCRIPTION

The STV5343 integrated circuit is a computer-controlled teletext decoder with high RAM addressing capability (up to 64Kbytes) upward software compatible with the SDA5243 device.
It is designed to operate in conjunction with the SAA5231 integrated circuit which extracts the teletext information embedded in a composite video signal.
A complete system also comprises a microprocessor controlling the STV5343 via a 2 -wire serial bus. An on-chip ROM memory contains the character sets. The STV5343 performs automatic selection of one of up to seven natural languages making the system suitable for the display of text in English, German, Swedish, French, Italian and Spanish. Data bytes may be decoded in either 7-Bit plus parity or in full 8-Bit formats. The chip set also supports facilities for reception and display of higher-level protocol data.

PIN CONNECTIONS

## PIN DESCRIPTION

| Symbol | Function | Description |
| :---: | :---: | :--- |
| $V_{\text {DD }}$ | +5 V | Positive supply voltage. |
| A10, A11, A12 | Chapter address | Address selection outputs for 1 of 8 chapters each of 1 kBytes <br> for SRAM / PSRAM. |
| A13, A14 | Group address | Address selection outputs for 1 of 4 groups each of 8 chapters <br> for SRAM / PSRAM. |
| $\overline{\mathrm{OE}}$ | Output enable | Active-low RAM output enable control signal. |
| $\overline{\mathrm{WE}}$ | Write enable | Active-low RAM write enable control signal. It supports <br> write-cycles interleaved with read-cycles. |
| TTD | Teletext data input | An A.C. coupled teletext data input supplied by the SAA5231 <br> chip is latched to Vss between 4 and 8 $\mu \mathrm{s}$ after each TV line. |
| TTC | Teletext clock input | A 6.9375MHz clock signal, supplied by the SAA5231 chip, is <br> internally A.C. coupled, clamped and buffered. |
| $\overline{\text { ODD } / \text { EVEN }}$ | Interlaced mode state output | High for even numbered and low for odd-numbered frames. <br> The value is valid 2 $\mu \mathrm{s}$ before the end of lines 311 and 624. |
| F6 | Character display clock signal | The 6MHz clock signal, supplied by the SAA5231 chip is <br> internally A.C. coupled, clamped and buffered. |

PIN DESCRIPTION (continued)

| Symbol | Function | Description |
| :---: | :---: | :---: |
| vCS | Video composite synchronızation input signal | Active high VCS input. |
| SAND | Sandcastle | Three level output pulse to the SAA5231 device. Phase lock, blanking signal, and color burst components are contained in this signal. |
| $\overline{\mathrm{TCS}} / \overline{\mathrm{SCS}}$ | Input / output composite synchronization signal | Scan composite input signal ( $\overline{\text { SCS }}$ ) for the display synchronization or Text composite sync. (TCS) output signal to the SAA5231. Both signals are active low. |
| RGB | Red, green, blue | Character and background color active-high open-dran outputs. |
| $\overline{\mathrm{COR}}{ }^{*}$ | Contrast reduction | Open-drain active-low output supporting optimal display of characters in "mixed mode" operation. |
| BLAN | Blanking signal output | Open-drain active high output for TV-image blanking in normal and mixed-mode operation. |
| Y * | Foreground output | Open-drain active-high output with foreground information. Can be used for printer command. |
| SCL | Serial clock | Microprocessor clock input via serial bus. |
| SDA | Serial data input / output | Open-drain microprocessor serial data input/output via serial bus. |
| $\mathrm{V}_{\mathrm{Ss}}$ | 0 Volt | Ground. |
| D0-D7 | Parallel data input / output | Eight tri-state input/output for data read/write from/to external RAM |
| A0-A9 | Address signals | Ten addresses output pins for accessing to individual Bytes of a 1 kByte chapter stored in an external SRAM / PSRAM and DRAM (only A0 - A7) |
| MC | Address multiplying control | Address multiplexing control for dynamic RAM - Active low. |
| $\overline{\mathrm{CE}}$ | Chip enable | Chip enable for 32K x 8 pseudostatic RAM - Active low. |
| $\overline{\mathrm{RAS}}, \overline{\mathrm{CAS}}$ | Address control | Address control for 64K dynamic RAM - Active low. |

*42SDIP only.

## TELETEXT DATA INPUT TIMING

## SYNCHRONIZATION TIMING

COMPOSITE SYNC. WAVEFORMS

90DSSTV5343-07
The number positions indicate the end of lines
The Teletext composite synchronization signal (TCS), whether interlacing is present or not, comprises three components.
a) The line-synchronization pulses (LSP)
b) the equalisation pulses (EP)
c) the frame-synchronization pulses (BP).

The timing reference is specified by the descending edge of the signal LSP, with a tolerance spread of $\pm 100 \mathrm{~ns}$.

## APPLICATION NOTES

## ORGANIZATION OF A PAGE-MEMORY

The organization of a page-memory is shown below. In contrast with the first generation of Teletext Decoders the new CCT (Computer Controlled Teletext) chip provides a display format of 25 rows of 40 characters per row.
Row number twenty-four is used by the microprocessor for the display of information.
Row zero contains the page header.
The organization is as follows :
The first seven characters $(0-6)$ are used for messages regarding the operational status.
The eighth character is an alphanumeric control character either "white" or "green" defining the
"search" status of the page. When it is "white" the operational state is normal and the header appears white ; when it is "green" the operational state corresponds to "search mode" and the header appears green. The following twenty-four characters give the header of the requested page when the system is in search mode. The last eight characters display the time of day.
Row twenty-five comprises ten bytes of control data concerning the received page (see Table 1) and fourteen free bytes which can be used by the microprocessor.

PAGE MEMORY ORGANISATION

REGISTER FUNCTIONS

| Register | Function | Bit(s) | Description |
| :---: | :---: | :---: | :---: |
| Ro <br> Address OOH | R11 adressing and pin functions control | SEL 11B (D0) | Selection of register 11B ( $\mathrm{D} 0=1$ ) or $11 \mathrm{~A}(\mathrm{D} 0=0)$ |
|  |  | CE ON (D1) | Selection of signal output on pin 16 (17 in 42SDIP) : $\overline{\mathrm{CE}}(\mathrm{D} 1=1) \text { or } \mathrm{COR}(\mathrm{D} 1=0)$ |
|  |  | EVEN OFF (D2) | Control of $\overline{\text { ODD/EVEN pin : EVEN signal output ( } \mathrm{D} 2=}$ 0) or grounded ( $\mathrm{D} 2=1$ ) |
|  |  | EOE (D3) | $\mathrm{D} 3=1 \overline{\mathrm{OE}}=1, \mathrm{D} 3=0 \overline{\mathrm{OE}}$ active |
|  |  | EWE (D4) | $\mathrm{D} 4=1 \overline{\mathrm{WE}}=1, \mathrm{D} 4=0 \mathrm{WE}$ active |
| R1 <br> Address <br> 01H | Operating mode controls | T0 T1 <br> 0 0 <br> 0 1 <br> 1 0 <br> 1 1 | 312/313 line MIX - mode with interlace $312 / 313$ line TEXT - mode without interlace 312/313 line Terminal mode without interlace External synchronization TCS/SCS is an input |
|  |  | TCS ON (D2) | This bit determines the character display synchronization mode. Teletext composite synchronism (TCS ON = 1) or direct broadcast synchronism (TCS ON $=0$ ). |
|  |  | $\underset{\text { (D3) }}{\overline{\mathrm{DEW}} / \mathrm{FULLFIELD}}$ | Selection of field flyback mode or full channel mode ( $\mathrm{D} 3=1$ ) for recovering of Teletext data. |
|  |  | GHOST ROW <br> ENABLE (D4) | Selection of ghost row mode ( $\mathrm{D} 4=1$ ) |
|  |  | ACQUISITION ON / OFF (D5) | Control of acquisition operation (D5 $=0$ enables acquisition) |
|  |  | 7 bits + parity or 8 bits without parity (D6) | Selection of received data format either 7 bits with parity ( $\mathrm{D} 6=0$ ) or 8 bits without parity ( $\mathrm{D} 6=1$ ). |
| R2 <br> Address 02 H | Addressing information for a page request | $\begin{gathered} \text { SC0, SC1, SC2 } \\ \text { (D0, D1, D2) } \end{gathered}$ | Address the first column of the on chip page request RAM to be written. |
|  |  | TB (D3) | Test bit equal to "0" in the normal working mode. |
|  |  | A0, A1 (D4, D5) | Address a group of four consecutive pages currently used for data acquistion; |
|  |  | A2 (D6) | Address of one of the two groups of four pages for acquisition in normal mode. |
| R3 <br> Address 03H | Data relative to the requested page (see Table 3) | $\begin{aligned} & \hline \text { PRD0 - PRD4 } \\ & \text { (D0-D4) } \end{aligned}$ | Written data in the page request RAM, starting with the columns addressed by $\mathrm{SC} 0, \mathrm{SC} 1, \mathrm{SC} 2$. |
|  | Selection of one of eight pages to display | $\begin{gathered} \mathrm{A} 0, \ldots \mathrm{~A} 5 \\ \text { (D0, ... D5) } \end{gathered}$ | These 6 bits correspond to the logical states of the 6 address lines (A10, ... A15) during memory read cycles. |
| R5Address05 H | Display control for normal operation | PON (D0, D1) | Picture on (IN: D0, OUT: D1) |
|  |  | TEXT (D2, D3) | Text on (IN: D2, OUT: D3) |
|  |  | $\overline{\mathrm{COR}}$ (D4, D5) | Contrast reduction on (IN: D4, OUT: D5) |
|  |  | BKGND (D6, D7) | Background colour on (IN: D6, OUT: D7) |
|  |  | IN / OUT | Enable inside/outside the box |
| R6 Address 06 H | Display control for news-flash subtitle generation | See R5 | See R5 |

REGISTER FUNCTIONS (continued)

| Register | Function | Bit(s) | Description |
| :---: | :---: | :---: | :---: |
| R7 <br> Address $07 \mathrm{H}$ | Display mode | $\begin{gathered} \text { BOX ON 0, 1-23,24 } \\ \text { (D0, D1, D2) } \end{gathered}$ | The "boxing" function is enabled on row 0,1-23 and 24 by D0, D1 and D2 set to one. |
|  |  | STATUS ROW BTM / TOP (D7) | The 25th row is displayed before the "Main text Area" (lines 0-23) or after (D7 = 0). |
| R8 to R11A Address 08 H to 0 BH | Active chapter address (R8), active row address (R9), active column address (R10). Data contained in R11A read (written) from (to) memory by microprocessor via $\mathrm{I}^{2} \mathrm{C}$. |  |  |
| R11B <br> Address 0BH* | Status | VCS ON (D0) | Good VCS quality signal detected ( $\mathrm{DO}=1$ ) or disturbance ( $\mathrm{DO}=0$ ) |
|  |  | 60 Hz (D7) | VCS received with 60 Hz frequency ( $D 7=1$ ) or 50 Hz ( $\mathrm{D} 7=0$ ). Valid only when If good $\mathrm{V}_{\mathrm{CS}}(\mathrm{D} 0=1)$ |
| R12 Address 0 CH | Page request address | $\begin{gathered} \text { A3, A4, A5 } \\ \text { (D0, D1, D2) } \end{gathered}$ | Address one of up to 8 groups of 8 pages currently used for acquisition |
|  |  | A0, A1 (D3, D4) | A0, A1 addresses of displayed page to refresh when using refresh on display function |
|  |  | EROD (D5) | Enable refresh on displayed page function when $=1$ normal acquisition storage if $\mathrm{EROD}=0$ |

* Reading of R11A or R11B is determined by register 0, bit D0. Nevertheless, write operation is always performed on R11A register.

## REGISTER MAP (see Table 2)

Registers R0 to R10 and R12 are write only whilst R11A is a read/write and R11B is a read only register respect to the microprocessor.
The automatic succession on a byte basis is indicated by the arrows in Table 2.
In the normal operating mode TB should be set to logic level 0.
After power-up the contents of the registers are as
follows : all bits in registers R0 to R12 are cleared to zero with the exception of bits D0 an D1 in registers R5 and R6 which are set to logical one. After power-up all the memory bytes are preset to hexadecimal value 20 H (space) with the exception of the byte corresponding to row 0 of column 7 of chapter 0 which is set to the value corresponding to "alpha white" hexadecimal value 07 H .

Table 2 : Register specification.

* Reserved register bits : must be set to 0

## REFRESH ON DISPLAY FUNCTION

This function allows independently to fill the memory using 3 acquisition circuits when the 4th one refreshes the displayed page.

- When EROD (Bit 5 of Reg. 12) is 0, refresh on display function is not active. Four teletext pages are filled into memory corresponding to addresses of acquisition registers.
8 pages bank number, among 0 to 7 , is selected with A5/A4/A3 (b2/b1/b0 of Reg. 12)
Upper or lower bank of 4 pages is selected with A2 (b6 of Reg. 2).
Acquisition circuits are selected with A1/AO (b5/b4 of Reg. 2). This 2 bits also determine the 1 KByte of RAM (the chapter) allocated to each acquisition circuit.
- When EROD = 1 , refresh on display function is active.
3 acquisition circuits store pages as described above. The 4th one stores data into the current displayed chapter. The chapter is selected with addresses

A5/A4/A3/A2/A1/A0 (b5/b4/b3/b2/b1/b0 of Reg. 4). Notice that A1/A0 (b1/b0 of Reg. 4) give the circuit number to be used to refresh this displayed chapter. That means A1/AO of refresh on display function (b4/b3 of Reg. 12) have to be written identical to A1/A0 (b1/b0 of Reg. 4), as A2 of acquisition circuit (b6 of Reg. 2) has to be identical to A2 of displayed chapter (b2 of Reg. 4).

Table 3 : Register R3.

| START COLUMN | PRD4 | PRD3 | PRD2 | PRD1 | PRDO |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | Do care magazine | $\overline{\text { HOLD }}$ | MAG2 | MAG1 | MAGO |
| 1 | Do care page tens | PT3 | PT2 | PT1 | PTO |
| 2 | Do care page units | PU3 | PU2 | PU1 | PU0 |
| 3 | Do care hours tens | X | X | HT1 | HTO |
| 4 | Do care hours units | HU3 | HU2 | HU1 | HUO |
| 5 | Do care minutes tens | X | MT2 | MT1 | MT0 |
| 6 | Do care minutes units | MU3 | MU2 | MU1 | MUO |

The abbreviations have the same significance as in Table 1 with the exception of the "DO CARE" entries. It is only when this bit is " 1 " that the corresponding digit is taken into consideration on page request. For example, a page defined as "normal" or one defined as "timed" may be selected.

If "HOLD" is low the page is held. The addressing of successive bytes via the $I^{2} \mathrm{C}$ is automatic.

## CHARACTER SETS

The selection of the character sets for a particular language is effected by the three control bits (C12-

C14) located in the page header. These three bits are decoded as shown in Table 4.

Table 4 : National character sets control bits.

| PHCB | ENGLISH | GERMAN | SWEDISH | ITALIAN | FRENCH | SPANISH |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| C12 | $0(1)(1)$ | 0 | 0 | 0 | 1 | 1 |
| C 13 | $0(1)(1)$ | 0 | 1 | 1 | 0 | 0 |
| C 14 | $0(0)(1)$ | 1 | 0 | 1 | 0 | 1 |

The basic set of the 96 characters is shown in Table 5.The location of the 13 national characters
are shown in Table 5 whilst full national character sets are depicted in Tables 6 thru 11.

The complete character set with 8-bit decoding and using the German national character is given in Table 7.
Characters in columns 0 and 1 are normally displayed as blanks. Black dots represent the character shape whereas white dots represent the background.
Each character can be identified by a pair of corre-
sponding row and column integers : for example the character " 3 " may be indicated by $3 / 3$.
A rectangle may be represented as follows : $\square$ The characters $8 / 6,8 / 7,9 / 5,9 / 7$ are used as special characters, always in conjunction with 8/5.
The 13 national characters are placed in columns with bit $8=0$.

Table 7: Complete character set (with 8 bit codes).

* These control charcters are reserved for compatibility with other data codes.
** These control characters are presumed before each row begins

## TRIPLE 8-BIT D/A CONVERTER

- 3 CHANNEL D/A CONVERTER
- 8-BIT RESOLUTION
- 70 MEGASAMPLES PER SECOND CONVERSION RATE
- AUXILIARY ANALOG R, G, B, SWITCHING CAPABILITIES
- SINGLE VOL-TAGE +5V OPERATION
- ON-CHIP VOLTAGE REFERENCE
- VOLTAGE OUTPUT BUFFER AMPLIFIER
- TTL COMPATIBLE DIGITAL INPUTS
- BINARY INPUT ON ALL CHANNELS
- 2'S COMPLEMENT INPUT CAPABILITY ON TWO CHANNELS
- MONOLITHIC BIPOLAR
- 850 mW POWER DISSIPATION
- OPERATING TEMPERATURE RANGE $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$
- SHRINK DIP 42-PIN PACKAGE

## DESCRIPTION

This Digital-to-Analog converter is a monolithic voltage output converter which can accept TTLlevel digital input voltages.
The STV8438 contains three 8 -bit D/A converters with a high performance on-chip voltage reference. Internal analog multiplexing between the signals from the internal D/A converter and from auxiliary analog R, G, B signals is provided. Either binary or 2's Complement inputs are available for two of the three channels.
This device is particularly recommended for use in video processing applications with the capability of 70Msps data conversion rate with excellent linearity.

| 26 | GAUX | I | Auxiliary analog input, G channel |
| 27 | GND (A) | I | Analog B channel ground |
| 28 | Bout | O | Analog output, B channel |
| 29 | BAUx | I | Auxiliary analog input, B channel |
| 33 to 40 | B <0:7> | I | Digital input channel B |
| 41 | R/C | I | Binary or 2's complement selection |
| 42 | CLK | I | Clock input |

## PIN DESCRIPTION

## COM : Digital or analog inputs selection

This TTL input selects on the output stage the signal from the D/A converter or the signal from the external analog input. The three internal analog switches are activated by the COM signal.

COM $=0$ connects auxiliary analog inputs to output amplifier
$C O M=1$ connects internal digital channel to output amplifier

## G <0:7> : Digital input channel G

These TTL 8-Bit input data are sampled on the rising edge of the clock CLK. $\mathrm{G}_{0}$ is the LSB and $\mathrm{G}_{7}$ the MSB, coding is binary.

## R <0:7>: Digital input channel R

These TTL 8-Bit input data are sampled on the rising edge of the clock CLK. R $R_{0}$ is the LSB and $R_{7}$ the MSB. Coding is binary if the R/C input is high,
coding is 2's complement if the R/C input is low.

## B <0:7> : Digital input channel B

These TTL 8-Bit input data are sampled on the rising edge of the clock CLK. $\mathrm{B}_{0}$ is the LSB and $\mathrm{B}_{7}$ the MSB. Coding is binary if the R/C input is high, coding is 2's complement if the R/C input is low.

R/C : Binary/2's complement coding selection
This TTL input selects the coding type on $R$ and $B$ channels.
$\mathrm{R} / \mathrm{C}=0$ selects 2 's complement coding on R and B channels
$R / C=1$ selects Binary coding on $R$ and $B$ channels

## Raux : Auxiliary analog input, $\mathbf{R}$ channel

This analog input is connected to the output Rout through the output amplifier if the COM signal is low.

## $G_{A U X}$ : Auxiliary analog input, G channel

This analog input is connected to the output Gout through the output amplfier if the COM signal is low.

## Baux : Auxiliary analog input, B channel

This analog input is connected to the output Bout through the output amplifier if the COM signal is low.

## Rout : Analog output, R channel

This voltage analog output corresponds to the digital channel $R$ if the COM signal is high or to the auxiliary analog input RAUX it the COM signal is low.

## Gout : Analog output, G channel

This voltage analog output corresponds to the digital channel $G$ if the COM signal is high or to the auxiliary analog input $\mathrm{G}_{\mathrm{Aux}}$ if the COM signal is low.

## Bout : Analog output, B channel

This voltage analog output corresponds to the digital channel B if the COM signal is high or to the auxiliary analog input BAUx if the COM signal is low.

## CLK : Clock signal

The digital inputs are sampled on the rising edge of this TTL input signal.

Vcc (A) / GND (A) : Analog power supply
Vcc (D) / GND (D) : Digital power supply.

## CIRCUIT DESCRIPTION

The STV8438 is designed with 3 identical D/A converters. Each D/A converter is constituted of two 4-bit DACs separated by a current divider the elementary DAC is composed of multiple identical current switches supplied with the same current allowing high speed conversion rate.

## DIGITAL INPUT CHANNELS

The STV8438 supports binary coding on the 3 R, $G, B$, input channels when $R / C$ pin is high. When R/C pin is low, a 2's complement coding is applied to the $R$ and $B$ channels this provides the capability to use the STV8438 with luminance and chrominance coded signal ; the luminance signal (usually called $Y$ ) being applied to the $G$ channel, the chrominance signals (called $\mathrm{U}, \mathrm{V}$ ) being applied respectively to the $R$ and $B$ channels.
The input range on Y signal is $0 / 255$ and the input range on both $\mathrm{U}, \mathrm{V}$ signals is $-127 /+128$. Whatever binary coding or 2's complement coding the output voltage is in the range of $1,685 \mathrm{~V}$ for the lowest code to $3,315 \mathrm{~V}$ for the highest code.

## ANALOG INPUT CHANNELS

The STV8438 provides the capability to switch the output voltage from signals coming from the digital channels or from signal coming from auxiliary analog inputs. When COM signal is low, the auxiliary analog signals are connected to the output amplifier internaly clamped to the 16th digital step. When COM signal is high, the digital inputs after D/A conversion are connected to the output amplifier.

## ANALOG OUTPUTS

The output voltage amplifiers have an output range of $1,685 \mathrm{~V}$ to $3,315 \mathrm{~V}$. The $1,685 \mathrm{~V}$ corresponds to the binary code $\varnothing(R / C=1)$ or to the 2's complement code-127 (R/C = 0). The $3,315 \mathrm{~V}$ corresponds to the maximum value on the digital code 255 if $R / C=0,+128$ if $R / C=1$.
The STV8438 provides a step if $6,39 \mathrm{mV}$ per LSB. Using the analog input signal ( $C O M=0$ ), the output amplifier has a gain of 2 .

## PROGRAMMING MANUAL

## INTRODUCTION

This manual deals with the description of instruction set and addressing modes of ST62,63 microcontroller series. The manual is divided in two main sections. The first one includes, after a general family description, the addressing modes description. The second one includes the detailed description of ST62,63 instruction set. Here following each instruction is deeply described and are underlined the differences among each ST6 series. ST6 software has been designed to fully use the hardware in the most efficient way possible while keeping byte usage to a minimum; in short to provide byte efficient programming capability.

Table 1. ST62,63 Series Core Characteristics

## PROGRAMMING MODEL

It is useful at this stage to outline the programming model of the ST62,63 series, by which we mean the available memory spaces, their relation to one another, the interrupt philosophy and so on.

Memory Spaces. The ST6 devices have three different memory spaces: data, program and stack. All addressing modes are memory space specific so there is no need for the user to specify which space is being used as in more complex systems. The stack space, which is used automatically with subroutine and interrupt management for program counter storage, is not accessible to the user.

Figure 3. ST62 Program Memory Example

Data Memory Space. The following registers in the data space have fixed addresses which are hardware selected so as to decrease access times and reduce addressing requirements and hence program length. The Accumulator is an 8 bit register in location OFFH. The X, Y, V \& W registers have the addresses $80 \mathrm{H}-83 \mathrm{H}$ respectively. These are used for short direct addressing, reducing byte requirements in the program while the first two, X \& Y , can also be used as index registers in the indirect addressing mode. These registers are part of the data RAM space. In the ST62 and ST63 for data space ROM a 6 bit ( 64 bytes addressing) window multiplexing in program ROM is available through a dedicated data ROM banking register.

## PROGRAMMING MODEL (Continued)

For data RAM and I/O expansion the lowest 64 bytes of data space $(00 \mathrm{H}-03 \mathrm{FH})$ are paged through a data RAM banking register.
Self-check Interrupt Vector FF8H \& FF9H: jp (self-check interrupt routine)
A jump instruction to the reset and interrupt routines must be written into these locations.
ST62 \& ST63 Program Memory Space. The ST62 and ST63 devices can directly address up to 4 K bytes (program counter is 12 -bit wide). A greater ROM size is obtained by paging the lower 2 K of the program ROM through a dedicated banking register located in the data space. The higher 2K of the program ROM can be seen as static and contains the reset, NMI and interrupt vectors at the following fixed locations:

## Reset Vector FFEH \& FFFH:

jp (reset routine)
NMI Interrupt Vector FFCH \& FFDH:
jp (NMI routine)
Non user Vector FFAH \& FFBH
Non user Vector FF8H \& FF9H
Interrupt \#1 Vector FF6H \& FF7H jp (Int 1 routine) Interrupt \#2 Vector FF4H \& FF5H jp (Int 2 routine) Interrupt \#3 Vector FF2H \& FF3H jp (Int 3 routine) Interrupt \#4 Vector FFOH \& FF1H jp (Int 4 routine)
Program Counter \& Stack Area. The program counter is a twelve bit counter register since it has to cover a direct addressing of 4 K byte program memory space. When an interrupt or a subroutine occurs the current PC value is forward "pushed" into a deep LIFO stacking area. On the return from the routine the top (last in) PC value is "popped" out and becomes the current PC value. The ST60/61 series offer a 4-word deep stack for program counter storage during interrupt and sub-routines calls. In the ST62 and ST63 series the stack is 6-word deep.
Status Flags. Three pairs of status flags, each pair consisting of a Zero flag and a Carry flag, are available. In the ST62 and ST63 an additional third set is available. One pair monitors the normal status while the se-cond monitors the state during
interrupts; the third flags set monitors the status during Non Maskable interrupt servicing. The switching from one set to another one is automatic as the interrupt requests (or NMI request for ST62,ST63 only) are acknowledged and when the program returns after an interrupt service routine. After reset, NMI set is active, until the first RETI instruction is executed.
ST62 \& ST63 Interrupt Description. The ST62 and ST63 devices have 5 user interrupt vectors (plus one vector for testing purposes). Interrupt vector \#0 is connected to the not maskable interrupt input of the core. Interrupts from \#1 to \#4 can be connected to different on-chip and external sources (see individual datasheets for detailed information). All interrupts can be globally disabled through the interrupt option register. After the reset ST62 and ST63 devices are in NMI mode, so no other interrupts can be accepted and the NMI flags set is in use, until the RETI instruction is performed. If an interrupt is detected, a special cycle will be executed, during this cycle the program counter is loaded with the related interrupt vector address. NMI can interrupt other interrupt routines at any time while normal interrupt can't interrupt each other. If more then one interrupt is waiting service, they will be accepted according to their priority. Interrupt \#1 has the highest priority while interrupt \#4 the lowest. This priority relationship is fixed.

Figure 2. ST62 \& ST63 Stack Area

SGS-THOMSON

## ADDRESSING MODES

The ST6 family gives the user nine addressing modes for access to data locations. Some of these are specifically tailored to particular instruction types or groups while others are designed to reduce program length and operating time by using the hardware facilities such as the X, Y, V \& W registers. The data locations can be in either the program memory space or the data memory space when the ST6 is operating due to user software. In addition the ST6 has a stack space for the 12 bit program counter but this is controlled by internal programming and is not accessible by the user. This section will describe all the addressing modes which are provided to the user. The following is the complete list of the ST6 available addressing modes:

- Inherent
- Direct
- Short Direct
- Indirect
- Immediate
- Program Counter Relative
- Extended
- Bit Direct
- Bit Test \& Branch

Inherent. For instructions using the inherent addressing mode the opcode contains all the information necessary for execution. All instructions using this mode are One Byte instructions.

## Example:

| Instruction | Comments |
| :--- | :--- |
| WAIT | Puts ST6 into the low power WAIT mode |
| STOP | Puts the ST6 into the lowest power <br> mode |
| RETI | Returns from interrupt. Pops the PC <br> from the PC stack.Sets the normal set <br> of flags |

Direct. In the direct addressing mode the address of the data is given by the program memory byte immediately following the opcode. This data location is in the data memory space. All instructions using this mode are Two Bytes instructions, lasting Four Cycles.

OPC = Opcode
O. $\mathrm{A}=$ Operand Address

Example:

| Instruction | Comments |
| :--- | :--- |
| LD A,OA3H | Loads the accumulator with the value <br> found in location A3H in the data <br> space. |
| SUB A,11H | The value found in locations 11H in <br> the data memory is subtracted from <br> the value in the accumulator. |

## ADDRESSING MODES (Continued)

Short Direct. ST6 core has four fixed location registers in the data space which may be addressed in a short direct manner. The addresses and names of these registers are $80 \mathrm{H}(\mathrm{X}), 81 \mathrm{H}(\mathrm{Y})$, $82 \mathrm{H}(\mathrm{V})$ and $83 \mathrm{H}(\mathrm{W})$. When using this addressing mode the data is in one of these registers and the address is a part of the opcode. All instructions using this mode are One Byte instructions, lasting Four Cycles.

OPC = Opcode
O.A. = Operand Address

## Example:

| Instruction | Comments |
| :--- | :--- |
| LD A, $X$ | The value of the $X$ register $(80 H)$ is <br> loaded into the accumulator. |
| INC $X$ | The $X$ register is incremented. |

Indirect. The indirect mode must use either the $X$ $(80 \mathrm{H})$ or $\mathrm{Y}(81 \mathrm{H})$ register. This register contains the address of the data. The operand is at the data space address pointed to by the content of X or Y registers. All instructions using this mode are One Byte instructions, lasting Four Cycles.

OPC = Opcode
R.A $=$ Register Address

Example:

| Instruction | Comments |
| :--- | :--- |
| LD A,(X) | The value in the registers pointed to by <br> the X register is loaded into the <br> accumulator. |
| ADD A,(Y) | The value in the register pointed to by <br> the Y register is added to the <br> accumulator value. |
| INC (Y) | The value in the register pointed to by <br> the Y register is incremented. |

Immediate. In the immediate addressing mode the operand is found in the program ROM in a byte which is the last byte of the instruction. This addressing mode can be used for initializing data space registers and supplying constants. Instructions using this mode can be Two or Three Bytes instructions, lasting Four Cycles.

| Program Memory |  |  |
| :---: | :---: | :---: |
| OPC |  |  |
| D.A. |  |  |
|  |  | DESTINATION Memory |
| OPERAND |  |  |
|  |  |  |

OPC = Opcode
D. $A=$ Destination Address

ADDRESSING MODES (Continued)
Example:

| Instruction | Comments |
| :--- | :--- |
| LDI 34H,DFH | Loads immediate value DFH into <br> data space location 34 H. |
| SUBI A,22H | The immediate value 22 H is sub- <br> tracted from the acc. |

Program Counter Relative. This addressing mode is used only with conditional branches within the program. The opcode byte contains the data which is a fixed offset value. This offset is added to the program counter to give the address of the next instruction. The offset can have any value in the range -15 to +16 . It is determined by the last five bits of the opcode. All instructions using this mode are One Byte Instructions, lasting Two Cycles.

OPC = Opcode
D.A. $=$ Destination Address

Example:

| Instruction | Comments |
| :--- | :--- |
| JRC 3 | If the carry flag is set then PC $=$ PC +3 |
| JRNZ -7 | If the zero flag is not set (i.e the result <br> of a previous instruction is not zero) <br> then $P C=P C-7$ |

The relative jump address can be also a label that is automatically handled by the assembler.
Extended. The extended addressirig mode is used to make long jumps within the program memory space (4K). The data requires 12 bits and is provided by half of the opcode byte and all of the second byte. All instructions using this mode are Two Bytes instructions, lasting Four Cycles.

OPC = Opcode

## Example:

| Instruction | Comments |
| :--- | :--- |
| JP 3FAH | Loads 3FAH into program counter and <br> continues with the instruction at 3FAH. |
| CALL ROU1 | The current PC is pushed onto the <br> stack and PC loaded with the value as- <br> sociated to the ROU1 label |

The absolute jump address can be also a label that is automatically handled by the assembler.
Bit Direct. This addressing mode allows the user to set or clear any specified bit in a data memory register. The address of the bit is given in the form: " $b, R$ " where $b$ is the number of the bit and $R$ is the address of the register. The bit is determined by three bits in the opcode and the register address is given by the second byte. All instructions using this mode are Two Byte instructions, lasting Four Cycles.

OPC = Opcode
D. $A=$ Destınation Address

## ADDRESSING MODES (Continued)

## Example:

| Instruction | Comments |
| :--- | :--- |
| SET 4,A | Sets bit 4 of the accumulator to 1. |
| RES 0,PORT | Clears bit 0 of PORT register |

The register address can be associated to a label that is automatically handled by the assembler.

Bit Test \& Branch. The bit test addressing mode is used in conditional jump instructions in which the jump depends on the result of a bit test. The opcode specifies the bit to be tested, the byte following the opcode in the register address in data space, and the third byte is the jump displacement, which is in the range -126 to +129 . This displacement can be determined using a label, which is converted by the assembler. The state of the tested bit is also copied
into the carry flag. All instructions using this mode are Three Byte instructions, lasting Five Cycles.

## Example:

| Instruction | Comments |
| :--- | :--- |
| JRS 3,PORT,LAB1 | If bit three of data memory <br> register <br> associated to PORT label is <br> set then PC=PC+LAB1 <br> (where LAB1 is the jump dis- <br> placement associated to a <br> label |
| JRR 0,0AH,-72 | If bit 0 of data memory regis- <br> ter OAH is reset to 0 then <br> PC=PC-72. |

The register address and the jump displacement can be associated to labels that are automatically handled by the assembler.

OPC = Opcode
R.A. $=$ Relative Address
J.D. = Jump Displacement

## ST62 \& ST63 INSTRUCTION SET

The ST62,63 instructions can be divided functionally into the following seven groups.

- LOAD AND STORE
- ARITHMETIC AND LOGIC
- CONDITIONAL BRANCH
- JUMP AND CALL
- BIT MANIPULATION
- CONTROL
- IMPLIED

The following summary shows the instructions belonging to each group, the number of operands required for each instructions and the number of machine cycles. The flag behaviour is usually the same for both ST62 and ST63. The only difference is present for CP and SUB instructions as specified in the detailed description.

Table 2. Load \& Store Instructions

| Instruction | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: |
|  |  |  | Z | C |

Notes: *. Valid only at the beginning of the cycle
\#. Valid only until t18 of the cycle

1. Add oscillator build up time plus 16 oscillator clocks if a stop instruction has been executed before the interrupt occured

Mnemonic: ADD

Function: Addition

Description: The contents of the source byte is added to the accumulator leaving the result in the accumulator. The source register remains unaltered.

Operation: $\quad$ dst $\leftarrow d s t+$ src
The destination must be the accumulator.

| Instruction Format | Opcode (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| ADD dst,src |  |  |  | Z | C |
| ADD A,A | 5F FF | 2 | 4 | $\Delta$ | $\Delta$ |
| ADD A, X | 5F 80 | 2 | 4 | $\Delta$ | D |
| ADD A, Y | 5F 81 | 2 | 4 | $\Delta$ | D |
| ADD A,V | 5F 82 | 2 | 4 | $\Delta$ | D |
| ADD A,W | 5F 83 | 2 | 4 | $\Delta$ | D |
| ADD A, X ) | 47 | 1 | 4 | $\Delta$ | D |
| ADD A, $(\mathrm{Y})$ | 4F | 1 | 4 | $\Delta$ | D |
| ADD A,rr | 5F rr | 2 | 4 | $\Delta$ | D |

## Notes:

rr. 1 Byte dataspace address.
$\Delta: Z$ is set if the result is zero. Cleared otherwise.
C is cleared before the operation and than set if there is an overflow from the 8 -bit result.

Example: If data space register 22 H contains the value 33 H and the accumulator holds the value 20 H then the instruction,

ADD A,22H
will cause the accumulator to hold 53 H (i.e. $33+20$ ).

Addressing Modes: Source: Direct, Indirect
Destination: Accumulator

## ADDI

## Addition Immediate

Mnemonic: ADDI

Function: Addition Immediate

Description: The immediately addressed data (source) is added to the accumulator leaving the result in the accumulator.

Operation: $\quad d s t \leftarrow d s t+$ src
The destination must be the accumulator.

| Instruction Format | Opcode (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| ADDI dst,src |  |  |  | Z | C |
| ADDI A,nn |  |  |  | 4 | $\Delta$ |

## Notes:

nn 1 Byte immedıate data
$\Delta^{\cdot} \mathrm{Z}$ is set if result is zero Cleared otherwise
C is cleared before the operation and than set if there is an overflow from the 8-bit result

Example: If the accumulator holds the value 20 H then the instruction, ADDI A, 22 H
will cause the accumulator to hold 42 H (i.e. $22+20$ ).

Addressing Modes: Source: Immediate
Destination: Accumulator

Mnemonic: AND

Function: Logical AND
Description: This instruction logically ANDs the source register and the accumulator. The result is left in the destination register and the source is unaltered.

Operation: $\quad d s t \leftarrow$ src AND dst
The destination must be the accumulator.

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| AND dst,src |  |  |  | Z | C |
| AND A,A | BF FF | 2 | 4 | $\Delta$ | * |
| AND A, X | BF 80 | 2 | 4 | $\Delta$ | * |
| AND A, Y | BF 81 | 2 | 4 | $\Delta$ | * |
| AND A,V | BF 82 | 2 | 4 | $\Delta$ | * |
| AND A,W | BF 83 | 2 | 4 | $\Delta$ | * |
| AND A, (X) | A7 | 1 | 4 | $\Delta$ | * |
| AND A, Y ) | AF | 1 | 4 | $\Delta$ | * |
| AND A,rr | BF rr | 2 | 4 | $\Delta$ | * |

## Notes:

rr. 1 Byte dataspace address
*. C is unaffected
$\Delta Z$ is set if the result is zero. Cleared otherwise.

| Example: | If data space register 54 H contains the binary value 11110000 and the accumulator contains the binary value 11001100 then the instruction, |
| :---: | :---: |
|  | AND A,54H |
|  | will cause the accumulator to be altered to 11000000. |

Addressing Modes: Source: Direct, Indirect.
Destination: Accumulator

## Logical AND Immediate

## Mnemonic: ANDI

Function: Logical AND Immediate

Description: This instruction logically ANDs the immediate data byte and the accumulator. The result is left in the accumulator.

Operation: $\quad d s t \leftarrow \operatorname{src}$ AND dst
The source is immediate data and the destination must be the accumulator.

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Z | C |
| ANDI dst,src |  | 2 | 4 | $\Delta$ | $\star$ |
| ANDI A,nn | B7 nn |  |  |  |  |

## Notes:

\#n. 1 Byte immediate data
*. C is unaffected
$\Delta . Z$ is set if the result is zero Cleared otherwise.

| Example: | If the accumulator contains the binary value 00001111 then the instruction, ANDI A,33H will cause the accumulator to hold the value 00000011 . |
| :---: | :---: |
| Addressing Modes: | Source: Immediate <br> Destination: Accumulator |

## Call Subroutine

Mnemonic: CALL

Function: Call Subroutine

Description: The CALL instruction is used to call a subroutine. It "pushes" the current contents of the program counter (PC) onto the top of the stack. The specified destination address is then loaded into the PC and points to the first instruction of a procedure. At the end of the procedure a RETurn instruction can be used to return to the original program flow. RET pops the top of the stack back into the PC.
Because the ST6 stack is 4 levels deep (ST60) and 6 levels deep (ST62,ST63), a maximum of four/six calls or interrupts may be nested. If more calls are nested, the PC values stacked latest will be lost. In this case returns will return to the PC values stacked firṡt.

Operation: $\quad \mathrm{PC} \leftarrow \mathrm{dst}$; Top of stack $\leftarrow \mathrm{PC}$

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| CALL dst |  |  |  | Z | C |
| CALL abc | c0001 ab | 2 | 4 | * | * |

Notes:
${ }_{\star}$ abc. the three half bytes of a twelve bit address, the start location of the subroutine.
*. C,Z not affected

Example: If the current PC is 345 H then the instruction, CALL 8DCH

The current PC 345H is pushed onto the top of the stack and the PC will be loaded with the value 8DCH. The next instruction to be executed will be the instruction at 8 DCH , the first instruction of the called subroutine.

Addressing Modes: Extended

## ST62,63 Instruction Set Description

## CLR

## Clear

Mnemonic: CLR

Function: Clear

Description: The destination register is cleared to 00 H .

Operation: $\quad d s t \leftarrow 0$

| Inst. Format | OPCDE (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| CLR dst |  |  |  | Z | C |
| CLRA | DF FF | 2 | 4 | $\Delta$ | $\Delta$ |
| CLR X | OD 8000 | 3 | 4 | * | * |
| CLR Y | OD 8100 | 3 | 4 | * | * |
| CLR V | OD 8200 | 3 | 4 | * | * |
| CLR W | OD 8300 | 3 | 4 | * | * |
| CLR rr | OD rr 00 | 3 | 4 | * | * |

## Notes:

rr. 1 Byte dataspace address
$\Delta$. $\mathrm{C}, \mathrm{Z}$ set
*. C,Z unaffected

| Example: | If data space register 22 H contains the value 33 H, |
| :--- | :--- |
| CLR 22 H |  |
| will cause register 22 H to hold 00 H. |  |

Addressing Modes: Direct

## Complement

## Mnemonic:

COM

Function: Complement
Description: This instruction complements each bit of the accumulator; all bits which are set to 1 are cleared to 0 and vice-versa.

Operation: $\quad d s t \leftarrow$ NOT dst
The destination must be the accumulator.

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Z | C |
| COM dst |  | 1 | 4 | $\Delta$ | $\Delta$ |

Note:
$\Delta: Z$ is set if the result is zero. Cleared otherwise.
C will contain the value of the MSB before the operation.

Example: If the accumulator contains the binary value 10111001 then the instruction COM A
will cause the accumulator to be changed to 01000110 and the carry flag to be set (since the original MSB was 1 ).

Addressing Modes: Inherent

CP

## Compare

## Mnemonic: CP

## Function: Compare

Description: This instruction compares the source byte (subtracted from) with the destination byte, which must be the accumulator. The carry and zero flags record the result of this comparison.

Operation: dst-src
The destination must be the accumulator, but it will not be changed.

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| CP dst, src |  |  |  | Z | C |
| CPA,A | 3F FF | 2 | 4 | $\Delta$ | $\Delta$ |
| CPA, X | 3F 80 | 2 | 4 | $\Delta$ | $\Delta$ |
| CPA, Y | 3F 81 | 2 | 4 | $\Delta$ | $\Delta$ |
| CPA,V | 3F 82 | 2 | 4 | $\Delta$ | $\Delta$ |
| CPA,W | 3F 83 | 2 | 4 | $\Delta$ | $\Delta$ |
| CPA, (X) | 27 | 1 | 4 | $\Delta$ | $\Delta$ |
| CP A, (Y) | 2 F | 1 | 4 | $\Delta$ | $\Delta$ |
| CP A,rr | 3F rr | 2 | 4 | $\Delta$ | $\Delta$ |

Note: rr. 1 Byte dataspace address

## ST60

$\Delta: Z$ is set if the result is zero. Cleared otherwise.
C is set if Acc $\geq \mathrm{src}$, cleared if $\mathrm{Acc}<\mathrm{src}$.

ST62/63
$\Delta: Z$ is set if the result is zero. Cleared otehrwise.
$C$ is set if Acc < src, cleared if Acc $\geq$ src.

Example: If the accumulator contains the value 11111000 and the register 34 H contains the value 00011100 then the instruction,

CP A, 34H
will clear the Zero flag $Z$ and set the Carry flag C , indicating that Acc $\geq \operatorname{src}$ (on ST60)

Addressing Modes: Source: Direct, Indirect
Destination: Accumulator

## Compare Immediate

Mnemonic: CPI
Function: Compare Immediate

Description: This instruction compares the immediately addressed source byte (subtracted from) with the destination byte, which must be the accumulator. The carry and zero flags record the result of this comparison.

Operation: dst-src
The source must be the immediately addressed data and the destination must be the accumulator, that will not be changed.

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | $\mathbf{Z}$ | $\mathbf{C}$ |
| CPI dst,src |  | 2 | 4 | $\Delta$ | $\Delta$ |

Note: nn. 1 Byte immediate data

ST60

ST62/63
$\Delta: Z$ is set if the result is zero. Cleared otherwise.
$C$ is set if Acc < src, cleared if Acc $\geq$ src.

Example: If the accumulator contains the value 11111000 then the instruction, CPI A,00011100B
will clear the Zero flag $Z$ and set the Carry flag $C$ indicating that $A c c \geq \operatorname{src}$ (on ST60).

Addressing Modes: Source: Immediate
Destination: Accumulator

DEC
Decrement

## Mnemonica: DEC

## Function: Decrement

Description: The destination register's contents are decremented by one.

Operation: $\quad \mathrm{dst} \leftarrow \mathrm{dst}-1$

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| DEC dst |  |  |  | Z | C |
| DEC A | FF FF | 2 | 4 | $\Delta$ | * |
| DEC X | 1D | 1 | 4 | $\Delta$ | * |
| DEC Y | 5D | 1 | 4 | $\Delta$ | * |
| DEC V | 9D | 1 | 4 | $\Delta$ | * |
| DEC W | DD | 1 | 4 | $\Delta$ | * |
| DEC (X) | E7 | 1 | 4 | $\Delta$ | * |
| DEC (Y) | EF | 1 | 4 | $\Delta$ | * |
| DEC rr | FF rr | 2 | 4 | $\Delta$ | * |

## Notes:

*r. 1 Byte dataspace address
*. C is unaffected
$\Delta$. Z is set if the result is zero. Cleared otherwise.

Example: If the X register contains the value 45 H and the data space register 45 H contains the value 16 H then the instruction,
DEC (X)
will cause data space register 45 H to contain the value 15 H .
Addressing Modes: Short direct, Direct, Indirect.

Mnemonic: $\quad$ INC

Function: Increment

Description: The destination register's contents are incremented by one.

Operation: $\quad d s t \leftarrow d s t+1$

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| INC dst |  |  |  | Z | C |
| INC A | 7F FF | 2 | 4 | $\Delta$ | * |
| INC X | 15 | 1 | 4 | $\Delta$ | * |
| INC Y | 55 | 1 | 4 | $\Delta$ | * |
| INC V | 95 | 1 | 4 | $\Delta$ | * |
| INC W | D5 | 1 | 4 | $\Delta$ | * |
| INC (X) | 67 | 1 | 4 | $\Delta$ | * |
| INC (Y) | 6F | 1 | 4 | $\Delta$ | * |
| INC rr | 7F rr | 2 | 4 | $\Delta$ | * |

## Notes:

rr. 1 Byte dataspace address
*. C is unaffected
$\Delta$. Z is set if the result is zero. Cleared otherwise.

> Example: If the X register contains the value 45 H and the data space register 45 H contains the value 16 H then the instruction
> INC (X)
> will cause data space register 45 H to contain the value 17 H .

Addressing Modes: Short direct, Direct, Indirect.

## Jump

Mnemonic: JP
Function: Jump (Unconditional)

Description: The JP instruction replaces the PC value with a twelve bit value thus causing a simple jump to another location in the program memory. The previous PC value is lost, not stacked.

Operation: $\quad \mathrm{PC} \leftarrow d s t$

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Z | C |
| JP dst |  | 2 | 4 | $*$ | $\star$ |

Notes:
abc. the three half bytes of a twelve bit address.
*. C,Z not affected

> The instruction,
> JP 5 CDH
> will cause the PC to be loaded with 5 CDH and the program will continue from that location.

Addressing Modes: Extended

# Jump Relative on Carry Flag 

## Mnemonic: JRC

Function: Jump Relative on Carry Flag
Description: $\quad$ This instruction causes the carry (C) flag to be tested and if this flag is set then a jump is performed within the program memory. This jump is in the range -15 to +16 and is relative to the PC value. The displacemente is of five bits. If $\mathrm{C}=0$ than the next instruction is executed.

Operation: If $\mathrm{C}=1, \mathrm{PC} \leftarrow \mathrm{PC}+\mathrm{e}$
where $\mathrm{e}=5$ bit displacement

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | $\mathbf{Z}$ | $\mathbf{C}$ |
| JRC e | e110 | 1 | 2 | $\star$ | $*$ |

## Notes:

e 5 bit displacement in the range -15 to +16

* C,Z not affected

Example: If the carry flag is set then the instruction,
JRC + 8
will cause a branch forward to PC+8. The user can use labels as indentifiers and the assembler will automatically allow the jump if it is in the range -15 to +16 .

Addressing Modes: Program Counter Relative

## JRNC

## Jump Relative on Non Carry Flag

Mnemonic: JRNC

Function: Jump Relative on Non Carry Flag
Description: $\quad$ This instruction causes the carry (C) flag to be tested and if this flag is cleared to zero then a jump is performed within the program memory. This jump is in the range -15 to +16 and is relative to the $P C$ value. The dispacement is of five bits. If $\mathrm{C}=1$ then the next instruction is executed.

Operation: $\quad$ If $\mathrm{C}=0, \mathrm{PC} \leftarrow \mathrm{PC}+\mathrm{e}$
where $\mathrm{e}=5$ bit displacement

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :--- | :---: | :---: | :---: | :---: |
|  |  |  |  | $\mathbf{Z}$ | $\mathbf{C}$ |
| JRNC e | e 010 | 1 | 2 | $\star$ | $*$ |

## Notes:

e: 5 bit displacement in the range -15 to +16
*: C,Z not affected

Example: If the carry flag is cleared then the instruction, JRNC -5
will cause a branch backward to PC-5. The user can use labels as identifiers and the assembler will automatically allow the jump if it is in the range -15 to +16 .

Addressing Modes: Program Counter Relative

## Jump Relative on Non Zero Flag

## Mnemonic: JRNZ

Function: Jump Relative on Non Zero Flag

Description: This instruction causes the zero $(Z)$ flag to be tested and if this flag is cleared to zero then a jump is performed within the program memory. This jump is in the range -15 to +16 and is relative to the PC value. The displacement is of five bits. If $Z=1$ then the next instruction is executed.

Operation: If $Z=0, P C \leftarrow P C+e$
where $\mathrm{e}=5$ bit displacement

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | $\mathbf{z}$ | $\mathbf{C}$ |
| JRNZ e | e 000 | 1 | 2 | $\star$ | $\star$ |

## Notes:

e. 5 bit displacement in the range -15 to +16 .

C,Z not affected

Example: If the zero flag is cleared then the instruction,
JRNZ - 5
will cause a branch backward to PC-5. The user can use labels as identifiers and the assembler will automatically allow the jump if it is in the range -15 to +16 .

Addressing Modes: Program Counter Relative

## JRR

## Jump Relative if Reset

## Mnemonic: JRR

Function: Jump Relative if RESET

Description: This instruction causes a specified bit in a given dataspace register to be tested. If this bit is reset $(=0)$ then the PC value will be changed and a relative jump will be performed within the program. The relative jump range is -126 to +129 . If the tested bit is not reset then the next instruction is executed.

Operation: $\quad$ If bit $=0, \mathrm{PC} \leftarrow \mathrm{PC}+\mathrm{ee}$
where ee $=8$ bit displacement

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Z | C |
| JRR b,rr,ee | b00011 rr ee | 3 | 5 | * | $\Delta$ |

## Notes:

b 3 bit-address
rr 1 Byte dataspace address
ee 8 bit displacement in the range -126 to +129

* $Z$ is not affected
$\Delta$ The tested bit is shifted into carry

Example: If bit 4 of dataspace register 70 H is reset and the $\mathrm{PC}=110$ then the instruction, JRR 4, 70H, -20
will cause the PC to be changed to $90(110-20)$ and the instruction starting at that address in the program memory to be the next instruction executed.

The user is advised to use labels for conditional jumps. The relative jump will be calculated by the assembler. The jump must be in the range -126 to +129 .

Addressing Modes: Bit Test

## Jump Relative if Set

Mnemonic: JRS

Function: Jump Relative if set
Description: This instruction causes a specified bit in a given dataspace register to be tested. If this bit is set $(=1)$ then the PC value will be changed and a relative jump will be performed within the program. The relative jump range is -126 to +129 . If the tested bit is not set then the next instruction is executed.

Operation: $\quad$ If bit $=1, \mathrm{PC} \leftarrow \mathrm{PC}+\mathrm{ee}$
where ee $=8$ bit displacement

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :--- | :---: | :---: | :---: | :---: |
|  |  |  |  | $\mathbf{Z}$ | $\mathbf{C}$ |
| JRS b,rr,ee | b10011 rr ee | 3 | 5 | ${ }^{*}$ | $\Delta$ |

## Notes:

b 3 bit-address
rr. 1 Byte dataspace address
ee 8 bit displacement in the range -126 to +129

* $Z$ is not affected
$\Delta$ The tested bit is shifted into carry.

Example: If bit 7 of dataspace register AFH is set and the $\mathrm{PC}=123$ then the instruction, JRS 7,AFH,+25
will cause the PC to be changed to $148(123+25)$ and the instruction starting at that address in the program memory to be the next instruction executed.
The user is advised to use labels for conditional jumps. The relative jump will be calculated by the assembler. The jump must be in the range -126 to +129 .

Addressing Modes: Bit Test

JRZ
Jump Relative on Zero Flag

Mnemonic: JRZ

Function: Jump Relative on Zero Flag

Description: This instruction causes the zero $(Z)$ flag to be tested and if this flag is set to one then a jump is performed within the program memory. This jump is in the range -15 to +16 and is relative to the PC value. The displacement is of five bits. If $Z=0$ then next instruction is executed.

Operation: If $Z=1, P C \leftarrow P C+e$
where $\mathrm{e}=5$ bit displacement

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Z | C |
| JRZ e | e100 | 1 | 2 | $*$ | $*$ |

Notes:
e. 5 bit displacement in the range -15 to +16 .
*. C,Z not affected
Example: If the zero flag is set then the instruction,
JRZ +8
will cause a branch forward to PC+8. The user can use labels as identifiers and the assembler will automatically allow the jump if it is in the range -15 to +16 .

Addressing Modes: Program Counter Relative

## Mnemonic: LD

## Function: Load

Description: The contents of the source register are loaded into the destination register. The source register remains unaltered and the previous contents of the destination register are lost.

Operation: $\quad$ dst $\leftarrow$ src
Either the source or the destination must be the accumulator.

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| LD dst,src |  |  |  | Z | c |
| LD A, X | 35 | 1 | 4 | $\Delta$ | * |
| LD A, Y | 75 | 1 | 4 | $\Delta$ | * |
| LD A, V | B5 | 1 | 4 | $\Delta$ | * |
| LD A, W | F5 | 1 | 4 | $\Delta$ | * |
| LD X,A | 3D | 1 | 4 | $\Delta$ | * |
| LD Y,A | 7D | 1 | 4 | $\Delta$ | * |
| LD V,A | BD | 1 | 4 | $\Delta$ | * |
| LD W, A | FD | 1 | 4 | $\Delta$ | * |
| LD A, (X) | 07 | 1 | 4 | $\Delta$ | * |
| LD (X), A | 87 | 1 | 4 | $\Delta$ | * |
| LD A, Y ) | OF | 1 | 4 | $\Delta$ | * |
| LD (Y), A | 8F | 1 | 4 | $\Delta$ | * |
| LD A,rr | 1 Frr | 2 | 4 | $\Delta$ | * |
| LD rr,A | 9 Fr | 2 | 4 | $\Delta$ | * |

## Notes:

rr. 1 Byte dataspace address
*. C not affected
$\Delta . Z$ is set if the result is zero. Cleared otherwise.

Example: If data space register 34 H contains the value 45 H then the instruction;
LD A, 34H
will cause the accumulator to be loaded with the value 45 H . Register 34 H will keep the value 45 H .

Addressing Modes: Source: Direct, Short Direct, Indirect
Destination: Direct, Short Direct, Indirect

LDI

## Load Immediate

Mnemonic:
Function: Load Immediate
Description: The immediately addressed data (source) is loaded into the destination data space register.

Operation: $\quad \mathrm{dst} \leftarrow$ src
The source is always an immediate data while the destination can be the accumulator, one of the $\mathrm{X}, \mathrm{Y}, \mathrm{V}, \mathrm{W}$ registers or one of the available data space registers.

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| LDI dst,src |  |  |  | Z | C |
| LDI A,nn | 17 nn | 2 | 4 | $\Delta$ | * |
| LDI X,nn | 0D 80 nn | 3 | 4 | * | * |
| LDI Y,nn | OD 81 nn | 3 | 4 | * | * |
| LDI V,nn | OD 82 nn | 3 | 4 | * | * |
| LDI W,nn | 0D 83 nn | 3 | 4 | * | * |
| LDI rr,nn | OD rr nn | 3 | 4 | * | * |

Notes:
rr. 1 Byte dataspace address
nn. 1 Byte immediate value
*. Z, C not affected
$\Delta . Z$ is set if the result is zero. Cleared otherwise.

Example: The instruction
LDI $34 \mathrm{H}, 45 \mathrm{H}$
will cause the value 45 H to be loaded into data register at location 34 H .
Addressing Modes: Source: Immediate
Destination: Direct

## No Operation

Mnemonic: NOP

Function: No Operation
Description: No action is performed by this instruction. It is typically used for timing delay.

Operation: No Operation

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Z | C |
| NOP | 04 | 1 | 2 | $*$ | $*$ |

Note: *. C,Z not affected

Addressing Modes: Program Counter Relative

## RES

## Reset Bit

## Mnemonic: <br> RES

## Function: <br> Reset Bit

Description:
The RESET instruction is used to reset a specified bit in a given register in the data space.

Operation:
dst $(n) \leftarrow 0,0 \leq n \leq 7$

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| RES bit,dst |  |  |  | Z | C |
| RES b,A | b01011 FF | 2 | 4 | * | * |
| RES b,rr | b01011 rr | 2 | 4 | * | * |

Notes:
b. 3 bit-address
rr. 1 Byte dataspace address
*. C,Z not affected

Example: If register 23 H of the dataspace contains 11111111 then the instruction, RES 4,23H
will cause register 23 H to hold 11101111.

Addressing Modes: Bit Direct

## Return from Subroutine

Mnemonic: RET
Function: Return From Subroutine

Description: $\quad$ This instruction is normally used at the end of a subroutine to return to the previously executed procedure. The previously stacked program counter (stacked during CALL) is popped back from the stack. The next statement executed is that addressed by the new contents of the PC. If the stack had already reached its highest level (no more PC stacked) before the RET is executed, program execution will be continued at the next instruction after the RET.

Operation: $\quad P C \leftarrow$ Stacked $P C$

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Z | C |
| RET | CD | 1 | 2 | $*$ | $*$ |

Note: *. C,Z not affected

Example: If the current PC value is 456 H and the PC value at the top of the stack is 3DFH then the instruction,
RET
will cause the PC value 456 H to be lost and the current PC value to be 3 DFH .

Addressing Modes: Inherent

## Return from Interrupt

| Mnemonic: | RETI |
| :--- | :--- |
| Function: | Return from Interrupt |
| Description: | This instruction marks the end of the interrupt service routine and returns the <br> ST60/62/63 to the state it was in before the interrupt. It "pops" the top (last in) PC <br> value from the stack into the current PC. This instruction also causes the <br> ST60/62/63 to switch from the interrupt flags to the normal flags. The RETI <br> instruction also applies to the end of NMI routine for ST62/63 devices; in this case <br> the instruction causes the switch from NMI flags to normal flags (if NMI was <br> acknowledged inside a normal routine) or to standard interrupt flags (if NMI was <br> acknowledged inside a standard interrupt service routine). <br> In addition the RETI instruction also clears the interrupt mask (also NMI mask for <br> ST62/63) which was set when the interrupt occurred. If the stack had already <br> reached its highest level (no more PC stacked) before the RETI is executed, <br> program execution will be continued with the next instruction affer the RETI. <br> Because the ST60 is in interrupt mode after reset (NMI mode for ST62/63), RETI <br> has to be executed to switch to normal flags and enable interrupts at the end of the <br> starting routine. If no call was executed during the starting routine, program <br> execution will continue with the instruction after the RETI (supposed no interrupt is <br> active). |
| Operation: | Actual Flags $\leftarrow$ Normal Flags (1) <br> PC $\leftarrow$ Stacked PC <br> IM $\leftarrow 0$ |
| (1) Standard Interrupt flags if NMI was acknowledged inside a standard interrupt |  |

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Z | C |
| RETI | $4 D$ | 1 | 2 | $\Delta$ | $\Delta$ |

Note: $\Delta \mathrm{C}, \mathrm{Z}$ normal flag will be used from now on.

Example: If the current PC value is 456 H and the PC value at the top of the stack is 3 DFH then the instruction
RETI
will cause the value 456 H to be lost and the current PC value to be 3DFH.
The ST6 will switch from interrupt flags to normal flags and the interrupt mask is cleared.

Addressing Modes: Inherent

## Rotate Left Through Carry

Mnemonic: RLC

Function: Rotate Left through Carry

Description: This instruction moves each bit in the accumulator one place to the left (i.e. towards the MSBit. The MSBit (bit 7) is moved into the carry flag and the carry flag is moved into the LSBit (bit0) of the accumulator.

Operation:

$\mathrm{dst}(0) \leftarrow \mathrm{C}$
$C \leftarrow d s t(7)$
$\operatorname{dst}(\mathrm{n}+1) \leftarrow \mathrm{dst}(\mathrm{n}), 0 \leq \mathrm{n} \leq 6$
This instruction can only be performed on the accumulator.

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | $\mathbf{Z}$ | $\mathbf{C}$ |
| RLC A | AD | 1 | 4 | $\Delta$ | $\Delta$ |

Note: $\Delta: Z$ is set if the result is zero. Cleared otherwise.
$C$ will contaın the value of the MSB before the operatıon.

Example: If the accumulator contains the binary value 10001001 and the carry flag is set to 0 then the instruction,
RLC A
will cause the accumulator to have the binary value 00010010 and the carry flag to be set to 1 .

Addressing Modes: Inherent

## SET

## Set Bit

Mnemonic: SET

Function: Set Bit

Description: The SET instruction is used to set a specified bit in a given register in the data space.

Operation: $\quad$ dst $(\mathrm{n}) \leftarrow 1,0 \leq \mathrm{n} \leq 7$

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :--- | :---: | :---: | :---: | :---: |
|  |  |  |  | Z | C |
| SET bit,dst |  | 2 | 4 | ${ }^{*}$ | ${ }^{*}$ |
| SET b,A | b11011 FF | 2 | 4 | ${ }^{*}$ | ${ }^{*}$ |
| SET b,rr | b11011 rr |  |  |  |  |

## Notes:

b. 3 bit-address
rr. 1 Byte dataspace address
*. C,Z not affected

Example: If register 23 H of the dataspace contains 00000000 then the instruction, SET 4,23H
will cause register 23 H to hold 00010000 .

Addressing Modes: Bit Direct

## Shift Left Accumulator

## Mnemonic: SLA

Function: Shift Left Accumulator

Description: This instruction implements an addition of the accumulator to itself (i.e a doubling of the accumulator) causing an arithmetic left shift of the value in the register.

Operation: ADD A,FFH
This instruction can only be performed on the accumulator.

| Inst. Format | OPCPDE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :--- | :---: | :---: | :---: | :---: |
|  |  |  |  | $\boldsymbol{Z}$ | C |
| SLAA | 5F FF | 2 | 4 | $\Delta$ | $\Delta$ |

Note: $\Delta^{\cdot} \mathrm{Z}$ is set if the result is zero Cleared otherwise
$C$ will contain the value of the MSB before the operation

## Example: If the accumulator contains the binary value 11001101 then the instruction, SLA A

will cause the accumulator to have the binary value 10011010 and the carry flag to be set to 1 .

Addressing Modes: Inherent

## STOP

## Stop Operation

## Mnemonic: STOP

## Function: Stop operation

Description: This instruction is used for putting the ST60/62/63 into a stand-by mode in which the power consumption is reduced to a minimum. All the on-chip peripherals and oscillator are stopped (for some peripherals,A/D for example, it is necessary to individually turn-off the macrocell before entering the STOP instruction). To restart the processor an external interrupt or a reset is needed.

Operation: Stop Processor

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Z | C |
| STOP | $6 D$ | 1 | 2 | $\star$ | $*$ |

Note : *: C,Z not affected

Addressing Mode: Inherent

# Subtraction 

## Mnemonic: SUB

Function: Subtraction

Description: This instruction subtracts the source value from the destination value.

Operation: $\quad d s t \leftarrow$ dst-src
The destination must be the accumulator.

| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| SUB dst,src |  |  |  | Z | C |
| SUB A,A | DF FF | 2 | 4 | $\Delta$ | $\Delta$ |
| SUB $A, X$ | DF 80 | 2 | 4 | $\Delta$ | $\Delta$ |
| SUB $A, Y$ | DF 81 | 2 | 4 | $\Delta$ | $\Delta$ |
| SUB A,V | DF 82 | 2 | 4 | $\Delta$ | $\Delta$ |
| SUB A,W | DF 83 | 2 | 4 | $\Delta$ | $\Delta$ |
| SUB A, (X) | C7 | 1 | 4 | $\Delta$ | $\Delta$ |
| SUB A, (Y) | CF | 1 | 4 | $\Delta$ | $\Delta$ |
| SUB A,rr | DF rr | 2 | 4 | $\Delta$ | $\Delta$ |

Note: rr. 1 Byte dataspace address

ST60
$\Delta: Z$ is set if the result is zero. Cleared otherwise.
$C$ is set if $A c c \geq s r c$, cleared if $A c c<s r c$.
ST62/63 $\Delta: Z$ is set if the result is zero. Cleared otherwise.
$C$ is set if $A c c<s r c$, cleared if $A c c \geq s r c$.

Example: If the Y register contains the value 23 H , dataspace register 23 H contains the value 53 H and the accumulator contains the value 78 H then the instruction,

SUB A,(Y)
will cause the accumulator to hold the value 25 H (i.e. $78-53$ ). The zero flag is cleared and the carry flag is set (on ST60), indicating that result is $>0$.

Addressing Modes: Source: Indirect,Direct
Destination: Accumulator

## SUBI

## Subtraction Immediate

| Mnemonic: | SUBI |
| :--- | :--- |
| Function: | Subtraction Immediate |
| Description: | This instruction causes the immediately addressed source data to be subtracted <br> from the accumulator. |
| Operation: | dst $\leftarrow$ dst - src <br> The destination must be the accumulator. |
| Inst. Format  OPCODE (Hex) Bytes Cycles Flags  <br> SUBI dst,src   2 4 $\Delta$  <br> SUBI A,nn D7 nn  $\Delta$ $\Delta$   |  |

Note: nn 1 Byte of immediate data

| ST60 | $\Delta: Z$ is set if the result is zero. Cleared otherwise. <br> C is set if Acc $\geq \mathrm{src}$, cleared if $\mathrm{Acc}<\mathrm{src}$. |
| :---: | :---: |
| ST62/63 | $\Delta: Z$ is set if the result is zero. Cleared otherwise. $C$ is set if Acc $<\operatorname{src}$, cleared if $A c c \geq s r c$. |
| Example: | If the accumulator contains the value 56 H then the instruction, SUBI A,25 <br> will cause the accumulator to contain the value 31 H . The zero flag is cleared and the carry flag is set (on ST60), indicating that the result is $>0$. |

Addressing Modes: Source: Immediate
Destination: Accumulator

## Wait Processor

| Mnemonic: | WAIT |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Function: | Wait Processor |  |  |  |  |
| Description: | This instruction is used for putting the ST60/62/63 into a stand-by mode in which the power consumption is reduced to a minimum. Instruction execution is stopped, but the oscillator and some on-chip peripherals continue to work. To restart the processor an interrupt from an active on-chip peripheral (eg. timer), an external interrupt or reset is needed. For on-chip peripherals active during wait, see ST60/62/63 data sheets. |  |  |  |  |
| Operation: | Put ST6 in stand-by mode |  |  |  |  |
| Inst. Format | OPCODE (Hex) | Bytes | Cycles | Flags |  |
|  |  |  |  | z | c |
| WAIT | ED | 1 | 2 | * | * |

Note: *. C, Z not affected

Addressing Modes: Inherent

- 62.5 KHz Output Pin
- AFC A/D converter with 0.5 V resolution
- 4 interrupt vectors (IRIN/NMI, Timer $1 \& 2$, VSYNC)
- 14-bit counter for Voltage Synthesis Tuning (ST6356,57,58)
- On-chip clock oscillator
- 5 Lines by 15 Characters On-Screen Display Generator with 64 Characters
- Byte efficient instruction set
- Bit test and jump instructions
- Wait and Bit Manipulation instructions
- True LIFO 6 -level stack
- All ROM types are supported by pin-to-pin piggyback versions.
- The development tool of the ST63 microcontrollers consists of the ST63TVS-EMU emulation and development system to be connected via a standard RS232 serial line to an MS-DOS Personal Computer.

## GENERAL DESCRIPTION

The ST632X,5X microcontrollers are members of the 8-bit HCMOS ST63XX family, a series of devices specially oriented to TV applications. Different pinout configurations are available to give the maximum application and cost flexibility. All ST63XX members are based on a building block approach: a common core is surrounded by a combination of on-chip peripherals (macrocells) available from a standard library. These peripherals are designed with the same Core technology providing full compatibility and short design time. Many of these macrocells are specially dedicated to TV applications. The macrocells of the ST632X,5X family: two Timer peripherals each including an 8 -bit counter with a 7 -bit software
programmable prescaler (Timer), a digital hardware activated watchdog function (DHWD), a serial peripheral interface (SPI), four 6-bit PWM D/A converters, an AFC A/D converter with 0.5 V resolution, a 14-bit Voltage Synthesis tuning peripheral (ST635X only), an on-screen display (OSD) with 15 characters per line, 64 characters. In addition all these devices have 8 K of ROM, 256 bytes of data RAM and 128 bytes of EEPROM. Refer to pin configurations figures and to ST632X,5X device summary (Table 1) for the definition of family members and a summary of differences among the different types.

## PIN DESCRIPTION

$V_{D D}$ and $V_{S S}$. Power is supplied to the MCU using these two pins. $V_{D D}$ is power and $V_{S S}$ is the ground connection.
OSCIN, OSCOUT. These pins are internally connected to the on-chip oscillator circuit. A quartz crystal or a ceramic resonator can be connected between these two pins in order to allow the correct operation of the MCU with various stability/cost trade-offs. The OSCIN pin is the input pin, the OSCOUT pin is the output pin. Refer to ON-CHIP CLOCK OSCILLATOR description for additional information.
$\overline{\text { RESET. The active low }} \overline{\operatorname{RESET}}$ pin is used to start the microcontroller to the beginning of its program. Refer to RESET description for additional information.
TEST. The TEST (mode select) pin is used to place the MCU into special operating mode. If TEST is held at $\mathrm{V}_{\text {SS }}$ the MCU enters the normal operating mode. If TEST is held at $V_{D D}$ when RESET is active the test operating mode is automatically selected (the user should connect this pin to $\mathrm{V}_{\text {ss }}$ for normal operation). Refer to TEST mode description for additional information.
PAO-PA7. These 8 lines are organized as one I/O port (A). Each line may be configured as either an input or as an output under software control of the data direction register. Port A has an open-drain ( 12 V drive) output configuration with direct led driving capability ( $30 \mathrm{~mA}, 1 \mathrm{~V}$ ). Refer to I/O PORT description for additional information.
PB0-PB7. These 8 lines are organized as one I/O port (B). Each line may be configured as either an input with or without internal pull-up resistor or as an output under software control of the data direction register. PBO-PB4 have a push-pull configuration in output mode while PB5-PB7 are open-drain (5V drive). PB2 and PB3 lines are connected to the VSYNC and HSYNC control signals of the OSD cell ; to provide the right signals to the OSD these I/O lines should be programmed in input mode and the user can read "on the fly" the state of VSYNC and HSYNC
signals. PB2 is connected with the vertical synchronization signal VSYNC input. The active polarity of this signal is software controlled. PB3 is connected with the horizontal synchronization signal input HSYNC. Oscillator is synchronous with the change to low state. Oscillation stops while signal is in the high state. A ROM mask option is available to change the polarity of this signal. PB5, PB6 and PB7 lines when in output modes are "ANDed" with the SPI control signals. PB5 is connected with the SPI clock signal (SCL), PB6 with the SPI data signal (SDA) while PB7 is connected with SPI enable signal (SEN). Refer to $/ / O$ port and pin configuration description for additional information.
PCO-PC7. These 8 lines are organized as one I/O port (C). Each line may be contigured as either an input with or without internal pull-up resistor or as an output under software control of the data direction register. PC0-PC2, PC4 have a push-pull configuration in output mode while PC3, PC5-PC7 (OSD signals) are open-drain (5V drive). PC3, PC5, PC6 and PC7 lines when in output modes are "ANDed" with the character and blank signals of the OSD cell. PC3 is connected with the OSD BLANK signal, PC5, PC6 and PC7 with the OSD R,G and B signals. These signals are active high. PC2 is also used as TV set On-Off switch ( 5 V drive). Refer to $I / O$ port and pin configuration description for additional information.
DAO-DA3. These pins are the four PWM D/A outputs (with 32 KHz repetition) of the 6 -bit on-chip D/A converters. The PWM function can be disabled by software and these lines can be used as general purpose open-drain outputs ( 12 V drive). Refer to D/A converter description for additional information.
IRIN. This pin is the external NMI of the MCU
OUT1. This pin is the 62.5 KHz output specially suited to drive multi-standard chroma processors. This function can be disabled by software and the pin can be used as general purpose open-drain output ( 12 V drive). Refer to $D / A$ converter description for additional information.

## PIN DESCRIPTION (Continued)

BSW0-BSW3. These output pins can be used to select up to 4 tuning bands. These lines are configured as open-drain outputs ( 12 V drive). Refer to AFC description for additional information.
KBYO-KBY2. These pins are input only and can be used for keyboard scan. They have CMOS threshold levels with schmitt trigger and on-chip $100 \mathrm{~K} \Omega$ pull-up resistors. Refer to AFC description for additional information.
AFC. This is the input of the on-chip 10 levels comparator that can be used to implement the AFC function. This pin is an high impedance input able to withstand signals with a peak amplitude up to 12 V . Refer to AFC description for additional information.
OSDOSCIN, OSDOSCOUT. These are the On Screen display oscillator terminals. An oscillation capacitor and coil network have to be connected to provide the right signal to the OSD.
HSYNC, VSYNC. These are the horizontal and vertical synchronization pins. The active polarity of these pins to the OSD macrocell can be selected by the user as ROM mask option. If the device is
specified to have negative logic inputs, then when these signals are low the OSD oscillator stops. If the device is specified to have positive logic inputs, then when these signals are high the OSD Oscillator stops. Refer to OSD description for additional information.
R, G, B, BLANK. Outputs from the OSD. R, G and $B$ are the color outputs while BLANK is the blanking output. All outputs are open-drain. The active polarity of these pins to can be selected by the user as ROM mask option. Refer to the pin Configurations for additional information.
VS. This is the output pin of the on-chip 14-bit voltage synthesis tuning cell (VS). The tuning signal present at this pin gives an approximate resolution of 40 KHz per step over the UHF band. This line is a push-pull output with standard drive (ST6356,57,58 only).

## Table 2. ST639X Pin Summary

| Pin Function | Description |
| :--- | :--- |
| DA0 to DA3 | Output, Open-Drain, 12V |
| BSW0 to BSW3 | Output, Open-Drain, 12V |
| IRIN | Input, Resistive Bias, Schmitt Trigger |
| AFC | Input, High Impedance, 12V |
| OUT1 | Input, Pull-up, Schmitt Trigger |
| KBY0 to KBY2 | I/O, Open-Drain, 12V, No Input Pull-up, Schmitt Trigger, High Drive |
| PA0 to PA7 | I/O, Push-Pull, 5V, Input Pull-up, Schmitt Trigger |
| PB0-PB4 | I/O, Open-Drain, 5V, Input Pull-up, Schmitt Trigger |
| PB5-PB7 | I/O, Push-Pull, 5V, Input Pull-up, Schmitt Trigger |
| PC0-PC2, PC4 | I/O, Open-Drain, 5V, Input Pull-up, Schmitt Trigger |
| PC3, PC5-PC7 | Output, Push-Pull |
| VS | Output, Open-Drain, 5V |
| R,G,B, BLANK | Input, Pull-up, Schmitt Trigger |
| HSYNC, VSYNC | Input, High Impedance |
| OSDOSCIN | Output, Push-Pull |
| OSDOSCOUT | Input, Pull-Down |
| TEST | Input, Resistive Bias, Schmitt Trigger to Reset Logic Only |
| OSCIN | Output, Push-Pull |
| OSCOUT | Input, Pull-up, Schmitt Trigger Input |
| RESET | Power Supply Pins |
| VDD, VSs |  |

## ST63XX CORE

The Core of the ST63XX Family is implemented independently from the l/O or memory configuration. Consequently, it can be treated as an independent central processor communicating with I/O and memory via internal addresses, data, and control busses. The in-core communication is arranged as shown in the following block diagram figure; the controller being externally linked to both the reset and the oscillator, while the core is linked to the dedicated on-chip macrocells peripherals via the serial data bus and indirectly for interrupt purposes through the control registers.

## Registers

The ST63XX Family Core has five registers and three pairs of flags available to the programmer. They are shown in Figure 9 and are explained in the following paragraphs together with the program and data memory page registers.
Accumulator (A). The accumulator is an 8 -bit general purpose register used in all arithmetic calculations, logical operations, and data manipulations. The accumulator is addressed in the data space as RAM location at the FFH address.

Figure 9. ST63XX Core Programming Model

Figure 8. ST63XX Core Block Diagram

## ST63XX CORE (Continued)

Accordingly, the ST63XX instruction set can use the accumulator as any other register of the data space.
Indirect Registers (X, Y). These two indirect registers are used as pointers to the memory locations in the data space. They are used in the register-indirect addressing mode.These registers can be addressed in the data space as RAM locations at the $80 \mathrm{H}(\mathrm{X})$ and $81 \mathrm{H}(\mathrm{Y})$ addresses. They can also be accessed with the direct, short direct, or bit direct addressing modes. Accordingly, the ST63XX instruction set can use the indirect registers as any other register of the data space.
Short Direct Registers (V, W). These two registers are used to save one byte in short direct addressing mode. These registers can be addressed in the data space as RAM locations at the $82 \mathrm{H}(\mathrm{V})$ and 83H (W) addresses. They can also be accessed with the direct and bit direct addressing modes. Accordingly, the ST63XX instruction set can use the short direct registers as any other register of the data space.

## Program Counter (PC)

The program counter is a 12-bit register that contains the address of the next ROM location to be processed by the core. This ROM location may be an opcode, an operand, or an address of operand. The 12-bit length allows the direct addressing of 4096 bytes in the program space. Nevertheless, if the program space contains more than 4096 locations, the further program space can be addressed by using the Program Bank Switch register. The PC value is incremented, after it is read for the address of the current instruction, by sending it through the ALU, so giving the address of the next byte in the program. To execute relative jumps the PC and the offset values are shifted through the ALU, where they will be added, and the result is shifted back into the PC. The program counter can be changed in the following ways:
JP (Jump) instruction . . . . PC= Jump address
CALL instruction . . . . . . . PC= Call address
Relative Branch
instructions . . . . . . . . . PC= PC+offset
Interrupt . . . . . . . . . . PC= Interrupt vector
Reset . . . . . . . . . . . . PC= Reset vector
Test mode . . . . . . . . . . PC=Test mode vector (1)
RET \& RETI instructions . . . PC= Pop (stack)
Normal instruction . . . . .PC= PC+1
Note: 1. Not available to the user.

## Flags (C, Z)

The ST63XX Core includes three pairs of flags that correspond to 3 different modes: normal mode, interrupt mode and Non-Maskable-Interrupt-Mode. Each pair consists of a CARRY flag and a ZERO flag. One pair (CN, ZN) is used during normal operation, one pair is used during the interrupt mode ( $\mathrm{Cl}, \mathrm{Zl}$ ) and one is used during the not-maskable interrupt mode (CNMI, ZNMI).
The ST63XX Core uses the pair of flags that corresponds to the actual mode: as soon as an interrupt (resp. a Non-Maskable-Interrupt) is generated, the ST63XX Core uses the interrupt flags (resp. the NMI flags) instead of the normal flags. When the RETI instruction is executed, the normal flags (resp. the interrupt flags) are restored if the MCU was in the normal mode (resp. in the interrupt mode) before the interrupt. Should be observed that each flag set can only be addressed in its own routine (Not-maskable interrupt, normal interrupt or main routine). The interrupt flags are not cleared during the context switching and so, they remain in the state they were at the exit of the last routine switching.
The Carry flag is set when a carry or a borrow occurs during arithmetic operations, otherwise it is cleared. The Carry flag is also set to the value of the bit tested in a bit test instruction, and participates in the rotate left instruction.
The Zero flag is set if the result of the last arithmetic or logical operation was equal to zero, otherwise it is cleared.
The switching between these three sets is automatically performed when an NMI, an interrupt and a RETI instructions occur. As the NMI mode is automatically selected after the reset of the MCU, the ST63XX Core uses at first the NMI flags. Refer to INTERRUPT description for additional information.

## Stack

The ST63XX Core includes true LIFO hardware stack that eliminates the need for a stack pointer.

Figure 10. Stack Operation

## ST63XX CORE (Continued)

The stack consists of six separate 12-bit RAM locations that do not belong to the data space RAM area. When a subroutine call (or interrupt request) occurs, the contents of each level is shifted into the next level while the content of the PC is shifted into the first level (the value of the sixth level will be lost). When subroutine or interrupt return occurs (RET or RETI instructions), the first level register is shifted back into the PC and the value of each level is shifted back into the previous level. These two operating modes are described in Figure 10. Since the accumulator, as all other data space registers, is not stored in this stack the handling of this registers shall be performed inside the subroutine. The stack pointer will remain in its deepest position, if more than 6 calls or interrupts are executed, so that the last return address will be lost. It will also remain in its highest position if the stack is empty and a RET or RETI is executed. In this case the next instruction will be executed.

## Memory Registers

Figure 11. Program ROM Page Register

| PRPR |  |  |  |  |  |  |
| :--- | :--- | :--- | :---: | :---: | :---: | :---: |
| Program ROM Page Register |  |  |  |  |  |  |
| (CAH, Write Only) |  |  |  |  |  |  |

The PRPR register can be addressed like a RAM location in the Data Space at the CAH address; nevertheless it is a write-only register that can not be accessed with single-bit operations. This register is used to select the 2-Kbyte ROM bank of the Program Space that will be addressed. The number of the page has to be loaded in the PRPR register. The PRPR register is not cleared during the MCU initialization and should therefore be defined before jumping out of the static page. Refer to the Program Space description for additional information concerning the use of this registers. The PRPR register is not modified when an interrupt or a subroutine occurs.

Figure 12. Data RAM Bank Register

| DRBR <br> Data RAM Bank Register <br> (E8H, Write Only) |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :---: | :---: | :---: |
| D7 | D6 | D5 | D4 |  |  |  |

The DRBR register can be addressed like a RAM location in the Data Space at the E8H address, nevertheless it is write-only register that can not be accessed with single-bit operations. This register is used to select the desired 64-byte RAM/EEPROM bank of the Data Space. The number of the bank has to be loaded in the DRBR register and the instruction has to point to the selected location as it was in the 0 bank (from 00 H address to 3 FH address). This register is cleared during the MCU initialization (the Data space 0 bank is automatically addressed after the Reset). Refer to the Data Space description for additional information. The DRBR register is not modified when a interrupt or a subroutine occurs.

Figure 13. Data ROM Window Register

| DWR <br> Data ROM Window Register <br> (C9H, Write Only) |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\qquad$D7 D6 D5 D4 D3 D2 D1 D0 |  |  |  |  |  |  |

The DWR register can be addressed like a RAM location in the Data Space at the C 9 H address, nevertheless it is write-only register that can not be accessed with single-bit operations. This register is used to move up and down the 64-byte read-only data window (from the 40H address to 7FH address of the Data Space) along the ROM memory of the MCU by step of 64 bytes. The effective address of the byte to be read as a data in the ROM memory is obtained by the concatenation of the 6 less significant bits of the address given in the instruction (as less significant bits) and the content of the DWR register (as most significant bits). Refer to the Data Space description for additional information.

## MEMORY SPACES

The MCUs operate in three different memory spaces: Program Space, Data Space, and Stack

Space. A description of these spaces is shown in Figure 14 and Figure 15.

MEMORY SPACES (Continued)

Figure 16. ST632X,5X Memory Addressing Description Diagram

## Program Space

The program space is physically implemented in the ROM memory and includes all the instructions that are to be executed, as well as the data required for the immediate addressing mode instructions, the reserved test area and user vectors. It is addressed thanks to the 12-bit Program Counter register (PC register) and so, the ST63XX Core can directly address up to 4K bytes of Program Space. Nevertheless, the Program Space can be extended by the addition of 2-Kbyte ROM banks as it is shown in figure 16 in which an 8 Kbyte memory is described. These banks are addressed by pointing to the $000 \mathrm{H}-7 \mathrm{FFH}$ locations of the Program Space thanks to the Program Counter, and by writing the appropriate code in the Program ROM Page Register (PRPR register) located at the CAH address of the Data Space. Because interrupts and common subroutines should be available all the time only the lower 2 K byte of the 4 K program space are bank switched while the upper 2 K byte can be seen as static space. Table 3 gives the different codes that allows the selection of the
corresponding banks. Note that, from the memory point of view, the Page 1 and the Static Page represent the same physical memory: it is only a different way of addressing the same location. On ST632X,5X a total of 8192 bytes of ROM have been implemented; 7948 are available as user ROM while 244 are reserved for testing.

Figure 17. 8K Bytes Program Space Addressing Description

SGS-THOMSON

## MEMORY SPACES (Continued)

Figure 18. Program ROM Page Register

D7-D2. These bits are not used.
PRPR1-PRPRO. These are the program ROM banking bits and the value loaded selects the corresponding page to be addressed in the lower part of 4 K program address space as specified in Table 3 . This register is undefined on reset.

Table 3. ST632X,5X Program ROM Page Register Coding

| PRPR1 | PRPR0 | PC11 | Memory Page |
| :---: | :---: | :---: | :--- |
| $X$ | $X$ | 1 | Static Page (Page 1) |
| 0 | 0 | 0 | Page 0 |
| 0 | 1 | 0 | Page 1 (Static Page) |
| 1 | 0 | 0 | Page 2 |
| 1 | 1 | 0 | Page 3 |

Note. The number of bits implemented depends on the size of the ROM of the device. Only the lower part of address space has been bankswitched because interrupt vectors and common subroutines should be available all the time. The reason of this structure is due to the fact that it is not possible to jump from a dynamic page to another, unless jumping back to the static page, changing contents of PRPR, and, than, jumping to a different dynamic page.
Care is required when handling the PRPR register as it is write only. For this reason, it is not allowed to change the PRPR contents while executing interrupts drivers, as the driver cannot save and than restore its previous content. Anyway, this operation may be necessary if the sum of common routines and interrupt drivers will take more than 2 K bytes; in this case could be necessary to divide the interrupt driver in a (minor) part in the static page (start and end), and in the second (major) part in one dynamic page. If it is impossible to avoid the writing of this register in interrupts drivers, an image of this register must be saved in a RAM location, and each time the program writes the PRPR it writes also the image register. The image register must be written first, so if an interrupt occurs between the two instructions the PRPR register is not affected.

MEMORY SPACE (Continued)

Note 1. EPROM addresses are related to the use of ST63PXX piggyback emulation devices.

## Data Space

The instruction set of the ST63XX Core operates on a specific space, named Data Space that contains all the data necessary for the processing of the program. The Data Space allows the addressing of RAM memory, EEPROM memory, ST63XX Core/peripheral registers, and read-only data such as constants and the look-up tables.
Data ROM Addressing. All the read-only data are physically implemented in the ROM memory in which the Program Space is also implemented. The ROM memory therefore contains the program to be executed and also the constants and the look-up tables needed for the program. The locations of Data Space in which the different constants and look-up tables are addressed by the ST63XX Core can be considered as being a 64-byte window through which it is possible to access to the readonly data stored in the ROM memory. This window is located from the 40 H address to the 7FH address in the Data space and allows the direct reading of the bytes from the 000 H address to the 03 FH address in the ROM memory. All the bytes of the ROM memory can be used to store either instructions or read-only data. Indeed, the window can be moved by step of 64 bytes along the ROM memory in writing the appropriate code in the Write-only Data ROM Window register (DWR register, location C 9 H ). The effective address of the byte to be read as a data in the ROM memory is obtained by the concatenation of the 6 less significant bits of the address in the Data Space (as less significant bits) and the content of the DWR register (as most significant bits). So when addressing location 40 H of data space, and 0 is loaded in the DWR register, the physical addressed location in ROM is 00 H .

Figure 19. Data ROM Window Register

D7. This bit is not used.
DWR6-DWRO. These are the Data Rom Window bits that correspond to the upper bits of data ROM program space. This register is undefined after reset.
Notes Care is required when handling the DWR register as it is write only. For this reason, it is not allowed to change the DWR contents while executing interrupts drivers, as the driver cannot save and than restore its previous content. If it is impossible to avoid the writing of this register in interrupts drivers, an image of this register must be saved in a RAM location, and each time the program writes the DWR it writes also the image register. The image register must be written first, so if an interrupt occurs between the two instructions the DWR register is not affected.

## MEMORY SPACE (Continued)

## Data RAM/EEPROM/OSD RAM Addressing

In all members of the ST63XX family 64 bytes of data RAM are directly addressable in the data space from 80 H to BFH addresses. The additional 192 bytes of RAM the 128 bytes of EEPROM memory and the OSD RAM can be addressed using the banks of 64 bytes located between addresses 00 H and 3 FH . The selection of the bank is done by programming the Data RAM Bank Switching register (DRBR register) located at the E8H address of the Data Space. In this way each bank of RAM, EEPROM or OSD RAM can be selected 64 bytes at a time. No more than one bank should be set at a time.

Figure 20. Data RAM Bank Register

| DRBR <br> Data RAM Bank Register (E8H Write Only) |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| D7 | D6 | D5 | D4 | D3 | D2 | D1 | DO |  |
| $\qquad$ DRBRO = Data RAM Bank 0 <br> DRBR1 = Data RAM Bank 1 <br> DRBR2 $=$ Data RAM Bank 2 <br> DRBR3 = Data RAM Bank 3 <br> DRBR4 = Data RAM Bank 4 <br> DRBR5 = Data RAM Bank 5 <br> DRBR6 $=$ Data RAM Bank 6 <br> Unused |  |  |  |  |  |  |  |  |

D7. This bit is not used.
DRBR6, DRBR5. Each of these bits, when set, will select one OSD RAM register page.
DRBR4,DRBR3,DRBR2. Each of these bits, when set, will select one RAM page.
DRBR1,DRBRO. These bits select the EEPROM pages. Table 5 summarizes how to set the Data RAM Bank Register in order to select the various banks or pages.
This register is undefined after reset.

Table 5. Data RAM Bank Register Set-up

| DRBR Value | Selection |
| :---: | :---: |
| 01 H | EEPROM Page 0 |
| 02 H | EEPROM Page 1 |
| 04 H | RAM Page 2 |
| 08 H | RAM Page 3 |
| 10 H | RAM Page 4 |
| 20 H | OSD Page 5 |
| 40 H | OSD Page 6 |

## Notes :

Care is required when handling the DRBR register as it is write only. For this reason, it is not allowed to change the DRBR contents while executing interrupts drivers, as the driver cannot save and than restore its previous content. If it is impossible to avoid the writing of this register in interrupts drivers, an image of this register must be saved in a RAM location, and each time the program writes the DRBR it writes also the image register.
The image register must be written first, so if an interrupt occurs between the two instructions the DRBR register is not affected.

## EEPROM Description

Through the programming of the Data RAM Bank Register (DRBR=E8H) the user can select the bank or page leaving unaffected the way to address the static registers. The way to address the "dynamic" page is to set the DRBR as described in Table 5 (e.g. to select EEPROM page 0, the DRBR has to be loaded with content 01 H , see Data RAM/EEPROM/OSD RAM addressing for additional information). Bits 0,1 of the DRBR are dedicated to the EEPROM.

The EEPROM module is physically organized in 32 byte modules ( 2 modules per page) and does not require dedicated instructions to be accessed in reading or writing. The EEPROM is controlled by the EEPROM Control Register (EECR=EAH). Any EEPROM location can be read just like any other data location, also in terms of access time.
To write an EEPROM location takes about 5 mSec ( 10 mSec max) and during this time the EEPROM is not accessible by the Core. A busy flag can be read by the Core to know the EEPROM status before trying any access. In writing the EEPROM can work in two modes: Byte Mode (BMODE) and Parallel Mode (PMODE). The BMODE is the normal way to use the EEPROM and consists in accessing one byte at a time. The PMODE consists in accessing 8 bytes per time.

## MEMORY SPACE (Continued)

Figure 21. EEPROM Control Register

D7. Not used
SB. WRITE ONLY. If this bit is set the EEPROM is disabled (any access will be meaningless) and the power consumption of the EEPROM is reduced to the leakage values.
D5, D4. Reserved for testing purposes, they must be set to zero.
PS. SET ONLY. Once in Parallel Mode, as soon as the user software sets the PS bit the parallel writing of the 8 adjacent registers will start. PS is internally reset at the end of the programming procedure. Note that less than 8 bytes can be written; after parallel programming the remaining undefined bytes will have no particular content.
PE. WRITE ONLY. This bit must be set by the user program in order to perform parallel programming (more bytes per time). If PE is set and the "parallel start bit" (PS) is low, up to 8 adjacent bytes can be written at the maximum speed, the content being stored in volatile registers. These 8 adjacent bytes can be considered as row, whose A7, A6, A5, A4, A3 are fixed while A2, A1 and A0 are the changing bytes. PE is automatically reset at the end of any parallel programming procedure. PE can be reset by the user software before starting the programming procedure, leaving unchanged the EEPROM registers.

BS. READ ONLY. This bit will be automatically set by the CORE when the user program modifies an EEPROM register. The user program has to test it before any read or write EEPROM operation; any attempt to access the EEPROM while "busy bit" is set will be aborted and the writing procedure in progress completed.
EN. WRITE ONLY. This bit MUST be set to one in order to write any EEPROM register. If the user program will attempt to write the EEPROM when $\mathrm{EN}=0$ the involved registers will be unaffected and the "busy bit" will not be set.
After RESET the content of EECR register will be 00 H .

## Notes :

When the EEPROM is busy ( $B S=1$ ) the EECR can not be accessed in write mode, it is only possible to read BS status. This implies that as long as the EEPROM is busy it is not possible to change the status of the EEPROM control register. EECR bits 4 and 5 are reserved for testing purposes, and the user must never set them to 1 .
Additional Notes on Parallel Mode. If the user wants to perform a parallel programming the first action should be the set to one the PE bit; from this moment the first time the EEPROM will be addressed in writing, the ROW address will be latched and it will be possible to change it only at the end of the programming procedure or by resetting PE without programming the EEPROM. After the ROW address latching the Core can "see" just one EEPROM row (the selected one) and any attempt to write or read other rows will produce errors. Do not read the EEPROM while PR is set.
As soon as PE bit is set, the 8 volatile ROW latches are cleared. From this moment the user can load data in the whole ROW or just in a subset. PS setting will modify the EEPROM registers corresponding to the ROW latches accessed after PE. For example, if the software sets PE and accesses EEPROM in writing at addresses $18 \mathrm{H}, 1 \mathrm{AH}, 1 \mathrm{BH}$ and then sets PS, these three registers will be modified at the same time; the remaining bytes will have no particular content. Note that PE is internally reset at the end of the programming procedure. This implies that the user must set PE bit between two parallel programming procedures. Anyway the user can set and then reset PE without performing any EEPROM programming. PS is a set only bit and is internally reset at the end of the programming procedure. Note that if the user tries to set PS while PE is not set there will not be any programming procedure and the PS bit will be unaffected. Consequently PS bit can not be set if EN is low. PS can be affected by the user set if, and only if, EN and PE bits are also set to one.

## MEMORY SPACE (Continued)

Warning : Parallel programming of the EEPROM with less than eight bytes may corrupt other bytes and should therefore be used with care, as here after underlined.
a. Reason for limitation:
betweeen PE (Parallel Enable) and PS (Parallel Start) of the EEPROM, the user writes up to eight bytes into the volatile data registers, a latch is also set to indicate which bytes have been accessed; the accessed bytes will be programmed when PS arrives. The logic is such that it is possible to set the latches of bytes which have NOT been accessed. The latches are set whenever ANY register in the banked dataspace (00h-3FH) is accessed for READ or WRITE between a PE and PS. The latch which is set will be determined by the three least significant bits of the register address. Only the latch is set, so finaal data of a corrupted byte after the parallel programming is always FFH.
Note: read operations also occur internally to the micro for most instructions. Even if bytes are not seen to be corrupted within the parallel programming routine, care should be taken, since they could become corrupted by an interrupt routine being serviced during loading of parallel bytes.
This is logic related and is not a marginality or race condition; piggyback devices perform in the same way as ROM devices. Parallel programming is tested with only LDI rr,nn instructions which do not corrupt other bytes.
b. To Avoid Corrupted Bytes:

- use Single Byte Mode, or
- always define all eight bytes in Parallel Programming Mode, or
- when programming less than eight bytes, the remaining EEPROM bytes should do not used by the program.
Additional Notes Regarding Differences Between ST63XX Devices and Corresponding Emulators. While PE is set, all the EEPROM page currently selected is accessible in reading and the writing of the bytes happens at the row to which belongs the last byte written before setting PS. The sequence: set $P E$, write in 10 H the value X , write in 21 H the value Y , set PS, will result in: 10 H unchanged, 20 H loaded with value $\mathrm{X}, 21 \mathrm{H}$ loaded with value Y . In the emulator bits 4 and 5 of the EECR are implemenfed. If the user set to 1 one or both of these bits the contents of the EEPROM will be destroyed. The user should use care in using EEPROM emulation as in general the emulator does not emulate the behaviour of the EEPROM when it is misused.

## STACK SPACE

The stack space consists of six 12 bit registers that are used for stacking subroutine and interrupt return addresses plus the current program counter register.

## TEST MODE

The test mode can be entered by connecting the TEST pin to an high logic level when reset is active; this action enables the factory test mode. The user is recommended to avoid this situation for normal operation. (TEST pin should be tied to ground).

## INTERRUPT

The ST63XX Core can manage 4 different maskable interrupt sources, plus one non-maskable interrupt source (top priority level interrupt). Each source is associated with a particular interrupt vector that contains a Jump instruction to the related interrupt service routine. Each vector is located in the Program Space at a particular address (see Table 6). When a source provides an interrupt request, and the request processing is also enabled by the ST63XX Core, then the PC register is loaded with the address of the interrupt vector (i.e. of the Jump instruction). Finally, the PC is loaded with the address of the Jump instruction and the interrupt routine is processed.
The relationship between vector and source and the associated priority is hardware fixed for the different ST63XX devices. For some interrupt sources it is also possible to select by software the kind of event that will generate the interrupt.
All interrupts can be disabled by writing to the GEN bit (global interrupt enable) of the interrupt option register (address C 8 H ). After a reset, ST63XX is in non maskable interrupt mode, so no interrupts will be accepted and NMI flags will be used, until a RETI instruction is executed. If an interrupt is executed, one special cycle is made by the core, during that the PC is set to the related interrupt vector address. A jump instruction at this address has to redirect program execution to the beginning of the related interrupt routine. The interrupt detecting cycle, also resets the related interrupt flag (not available to the user), so that another interrupt can be stored for this current vector, while its driver is under execution.
If additional interrupts arrive from the same source, they will be lost. NMI can interrupt other interrupt routines at any time, while other interrupts cannot interrupt each other. If more than one interrupt is waiting for service, they are executed according to their priority. The lower the number, the higher the priority. Priority is, therefore, fixed. Interrupts are checked during the last cycle of an instruction

## INTERRUPT (Continued)

(RETI included). Level sensitive interrupts have to be valid during this period.
Table 6 details the different interrupt vectors/sources relationships.

## Table 6. Interrupt Vectors/Sources Relationships

| Interrupt <br> Source | Associated <br> Vector | Vector Address |
| :---: | :---: | :---: |
| IRIN/NMI <br> Pin (1) | Interrupt <br> Vector \# 0 (NMI) | OFFCH-0FFDH |
| None (2) | Interrupt <br> Vector \# 1 | OFF6H-0FF7H |
| Vsync | Interrupt <br> Vector \# 2 | 0FF4H-0FF5H |
| Timer 1 | Interrupt <br> Vector \# 3 | OFF2H-0FF3H |
| Timer 2 | Interrupt <br> Vector \# 4 | OFF0H-0FF1H |

Notes:

1. This pin is associated with the NMI Interrupt Vector.
2. This vector is not used in ST632X,5X

## Interrupt Vectors/Sources

The ST63XX Core includes 5 different interrupt vectors in order to branch to 5 different interrupt routines. The interrupt vectors are located in the fixed (or static) page of the Program Space.
The interrupt vector associated with the non-maskable interrupt source is named interrupt vector \#0. It is located at the (FFCH,FFDH) addresses in the Program Space. On ST632X,5X this vector is associated to the rising edge sensitive external interrupt pin.
The interrupt vectors located at addresses (FF6H,FF7H), (FF4H,FF5H), (FF2H,FF3H), (FFOH,FF1H) are named interrupt vectors \#1, \#2, \#3 and \#4 respectively. These vectors are associated with VSYNC (\#2), TIMER 1 (\#3) and TIMER 2 (\#4); Interrupt vector (\#1) is not used on ST6356,57,58. Refer to the Interrupt Details description for more information.

## Interrupt Priority

The non-maskable interrupt request has the highest priority and can interrupt any other interrupt routines at any time, nevertheless the other interrupts cannot interrupt each other. If more than one interrupt request is pending, they are processed by
the ST63XX Core according to their priority level: vector \#1 has the higher priority while vector \#4 the lower. The priority of each interrupt source is hardware fixed.

## Interrupt Option Register

The Interrupt Option Register (IOR register, location C 8 H ) is used to enable/disable the individual interrupt sources and to select the operating mode of the external interrupt inputs. This register can be addressed in the Data Space as RAM location at the C 8 H address, nevertheless it is write-only register that can not be accessed with single-bit operations. The operating modes of the external interrupt inputs associated to interrupt vectors \#1 and \#2 are selected through bits 4 and 5 of the IOR register.

Figure 22. Interrupt Option Register

## D7. Not used.

EL1. This is the Edge/Level selection bit of interrupt \#1. When set to one, the interrupt is generated on low level of the related signal; when cleared to zero, the interrupt is generated on falling edge. The bit is cleared to zero after reset and as no interrupt source is associated to vector \#1 on ST63XX, the user must keep this bit to zero to avoid ghost interrupts from this source.
ES2. This is the edge selection bit on interrupt \#2. This bit is used on the ST63XX devices with on-chip OSD generator for VSYNC detection.
GEN. This is the global enable bit. When set to one all interrupts are globally enabled; when this bit is cleared to zero all interrupts are disabled (including NMI).
D3 - D0. These bits are not used.

## INTERRUPT (Continued)

## Interrupt Procedure

The interrupt procedure is very similar to a call procedure; the user can consider the interrupt as an asynchronous call procedure. As this is an asynchronous event the user does not know about the context and the time at which it occurred. As a result the user should save all the data space registers which will be used inside the interrupt routines. There are separate sets of processor flags for normal, interrupt and non-maskable interrupt modes which are automatically switched and so these do not need to be saved.
The following list summarizes the interrupt procedure (refer also to Figure 23. Interrupt Processing Flow Chart):

- Interrupt detection
- The flags $C$ and $Z$ of the main routine are exchanged with the flags $C$ and $Z$ of the interrupt routine (resp. the NMI flags)
- The value of the PC is stored in the first level of the stack - The normal interrupt lines are inhibited (NMI still active)
- The edge flip-flop is reset
- The related interrupt vector is loaded in the PC.
- User selected registers are saved inside the interrupt service routine (normally on a software stack)
- The source of the interrupt is found by polling (if more than one source is associated to the same vector)
- Interrupt servicing
- Return from interrupt (RETI)
- Automatically the ST63XX core switches back to the normal flags (resp the interrupt flags) and pops the previous PC value from the stack
The interrupt routine begins usually by the identification of the device that has generated the interrupt request. The user should save the registers which are used inside the interrupt routine (that holds relevant data) into a software stack.
After the RETI instruction execution, the Core carries out the previous actions and the main routine can continue.

## ST632X/5X Interrupt Details

IR Interrupt (\#0). The IRIN Interrupt is associated with the first interrupt \#0 (NMI, OFFCH). If enabled, then an interrupt will be generated on a rising edge at the pin.
Interrupt (\#1). On ST632X/5X no sources are associated to vector (\#1). To avoid any ghost interrupt due to interrupt (\#1) the user must keep to zero the EL1 bit of IOR register.

Figure 23. Interrupt Processing Flow-Chart

VSYNC Interrupt (\#2). The VSYNC Interrupt is connected to the interrupt \#2. When disabled the VSYNCINT signal is low. Bit 5 of the interrupt option register C 8 H is used to select the negative edge ( $B 2=0$ ) or the positive edge ( $\mathrm{B} 2=1$ ); the edge will depend on the application. Note that once an edge has been latched, then the only way to remove the latched signal is to service the interrupt. Care must be taken not to generate spurious interrupts. This interrupt may be used for synchronize to the VSYNC signal in order to change characters in the OSD only when the screen is on vertical blanking (if desired). This method may also be used to blink characters.

## INTERRUPT (Continued)

TIMER 1 Interrupt (\#3). The TIMER 1 Interrupt is connected to the fourth interrupt \#3 (0FF2H) which detects a high to low level (latched in the timer). For more information on the timer interrupt refer to the timer section.
Timer 2 Interrupt (\#4). The TIMER 2 Interrupt is connected to the fifth interrupt \#4 (0FFOH) which detecty a high to low level (latched in the timer). For more information on the timer interrupt refer to the timer section.
Notes Global disable does not reset edge sensitive interrupt flags. These edge sensitive interrupts become pending again when global disabling is released. Moreover, edge sensitive interrupts are stored in the related flags also when interrupts are globally disabled, unless each edge sensitive interrupt is also individually disabled before the interrupting event happens. Global disable is done by clearing the GEN bit of Interrupt option register, while any individual disable is done in the control register of the peripheral. The on-chip Timer peripherals have an interrupt request flag bit (TMZ), this bit is set to one when the device wants to generate an interrupt request and a mask bit (ETI) that must be set to one to allow the transfer of the flag bit to the Core.

## RESET

The ST63XX devices can be reset in two ways: by the external reset input (RESET) tied low and by the hardware activated digital watchdog peripheral.

## RESET Input

The external active low reset pin is used to reset the ST63XX devices and provide an orderly software startup procedure. The activation of the Reset pin may occur at any time in the RUN or WAIT mode. Even short pulses at the reset pin will be accepted since the reset signal is latched internally and is only cleared after 2048 clocks at the oscillator pin. The clocks from the oscillator pin to the reset circuitry are buffered by a schmit trigger so that an oscillator in start-up conditions will not give spurious clocks. The MCU is configured in the Reset mode as long as the signal of the RESET pin is low. The processing of the program is stopped and the standard Input/Output ports (port A, port B and port C) are in the input state (except PC2). As soon as the level on the reset pin becomes high, the initialization sequence is executed. Refer to the MCU initialization sequence for additional information.

## Watchdog Reset

The ST63XX devices are provided with an on-chip hardware activated digital watchdog function in order to provide a graceful recovery from a software upset. If the watchdog register is not refreshed and the end-of-count is reached, then the reset state will be latched into the MCU and an internal circuit pulls down the reset pin. This also

Figure 24. Internal Reset Circuit

RESET (Continued)
Figure 25. Reset \& Interrupt Processing Flow-chart

resets the watchdog which subsequently turns off the pull-down and activates the pull-up device at the reset pin. This causes the positive transition at the reset pin. The MCU will then exit the reset state after 2048 clocks on the oscillator pin.

## Application Notes

An external resistor between $V_{D D}$ and the reset pin is not required because an internal pull-up device is provided. The user may prefer to add an external pull-up resistor.
An internal Power-on device does not guarantee that the MCU will exit the reset state when V $V_{D D}$ is above 4.5 V and therefore the RESET pin should be externally controlled.

Figure 26. Restart Initialization Program Flow-chart

## MCU Initialization Sequence

When a reset occurs the stack is reset to program counter, the PC is loaded with the address of the reset vector (located in the program ROM at addresses FFEH \& FFFH). A jump instruction to the beginning of the program has to be written into these locations. After a reset the interrupt mask is automatically activated so that the Core is in nonmaskable interrupt mode to prevent false or ghost interrupts during the restart phase. Therefore the restart routine should be terminated by a RETI instruction to switch to normal mode and enable interrupts. If no pending interrupt is present at the end of the reset routine, the ST63XX will continue with the instruction after the RETI; otherwise the pending interrupt will be serviced.

## WAIT \& STOP MODES

The STOP and WAIT modes have been implemented in the ST63XX Core in order to reduce the consumption of the device when the latter has no instruction to execute. These two modes are described in the following paragraphs. On ST63XX as the hardware activated digital watchdog function is present the STOP instruction is de-activated and any attempt to execute it will cause the automatic execution of a WAIT instruction.

## WAIT Mode

The configuration of the MCU in the WAIT mode occurs as soon as the WAIT instruction is executed. The microcontroller can also be considered as being in a "software frozen" state where the Core stops processing the instructions of the routine, the contents of the RAM locations and peripheral registers are saved as long as the power supply voltage is higher than the RAM retention voltage but where the peripherals are still working.
The WAIT mode is used when the user wants to reduce the consumption of the MCU when it is in idle, while not loosing count of time or monitoring of external events. The oscillator is not stopped in order to provide clock signal to the peripherals. The timers counting may be enabled (writing the PSI bit in TSCR register) and the timer interrupt may be also enabled before entering the WAIT mode; this allows the WAIT mode to be left when timer interrupt occurs. If the exit from the WAIT mode is performed with a general RESET (either from the activation of the external pin or by watchdog reset) the MCU will enter a normal reset procedure as described in the RESET chapter. If an interrupt is generated during WAIT mode the MCU behaviour depends on the state of the ST63XX Core before the initialization of the WAIT sequence, but also of the kind of the interrupt request that is generated. This case will be described in the following paragraphs. In any case, the ST63XX Core does not generate any delay after the occurrence of the interrupt because the oscillator clock is still available.

## STOP Mode

On ST63XX the hardware watchdog is present and the STOP instruction has been de-activated. Any attempt to execute a STOP will cause the automatic execution of a WAIT instruction.

## Exit from WAIT Mode

The following paragraphs describe the output procedure of the ST63XX Core from WAIT mode when
an interrupt occurs. It must be noted that the restart sequence depends on the original state of the MCU (normal, interrupt or non-maskable interrupt mode) before the start of the WAIT sequence, but also of the type of the interrupt request that is generated.
Normal Mode. If the ST63XX Core was in the main routine when the WAIT instruction has been executed, the ST63XX Core outputs from the wait mode as soon as any interrupt occurs; the related interrupt routine is executed and at the end of the interrupt service routine the instruction that follows the WAIT instruction is executed if no other interrupts are pending.
Non-maskable Interrupt Mode. If the WAIT instruction has been executed during the execution of the non-maskable interrupt routine, the ST63XX Core outputs from the wait mode as soon as any interrupt occurs: the instruction that follows the WAIT instruction is executed and the ST63XX Core is still in the non-maskable interrupt mode even if an other interrupt has been generated.
Normal Interrupt Mode. If the ST63XX Core was in the interrupt mode before the initialization of the WAIT sequence, it outputs from the wait mode as soon as any interrupt occurs. Nevertheless, two cases have to be considered:

- If the interrupt is a normal interrupt, the interrupt routine in which the WAIT was entered will be completed with the execution of the instruction that follows the WAIT and the ST63XX Core is still in the interrupt mode. At the end of this routine pending interrupts will be serviced in accordance to their priority.
- If the interrupt is a non-maskable interrupt, the non-maskable routine is processed at first. Then, the routine in which the WAIT was entered will be completed with the execution of the instruction that follows the WAIT and the ST63XX Core is still in the normal interrupt mode.

## Notes:

If all the interrupt sources are disabled, the restart of the MCU can only be done by a Reset activation. The Wait instruction is not executed if an enabled interrupt request is pending. In the ST63XX the hardware activated digital watchdog function is present. As the watchdog is always activated the STOP instruction is de-activated and any attempt to execute the STOP instruction will cause an execution of a WAIT instruction.

## ON-CHIP CLOCK OSCILLATOR

The internal oscillator circuit is designed to require a minimum of external components. A crystal quartz, a ceramic resonator, or an external signal (provided to the OSCIN pin) may be used to generate a system clock with various stability/cost tradeoffs. The typical clock frequency is 8 MHz . Please note that different frequencies will affect the operation of those peripherals (D/As, SPI, 62.5 KHz OUT) whose reference frequencies are derived from the system clock.
The different clock generator options connection methods are shown in Figure 27, crystal specifications and suggested PC board layouts are given in Figure 28 and Figure 29. One machine cycle takes 13 oscillator pulses; 12 clock pulses are needed to increment the PC while and additional 13th pulse is needed to stabilize the internal latches during memory addressing. This means that with a clock frequency of 8 MHz the machine cycle is $1.625 \mu \mathrm{Sec}$.
The crystal oscillator start-up time is a function of many variables: crystal parameters (especially RS), oscillator load capacitance (CL), IC parameters, ambient temperature, and supply voltage. It must be observed that the crystal or ceramic leads and circuit connections must be as short as possible. Typical values for CL1 and CL2 are in the range of 15 pF to 22pF but these should be chosen based on the crystal manufacturers specification. Typical input capacitance for OSCIN and OSCOUT pins is 5 pF .
The oscillator output frequency is internally divided by 13 to produce the machine cycle and by 12 to produce the Timer and the Watchdog clock. A byte cycle is the smallest unit needed to execute any operation (i.e., increment the program counter). An instruction may need two, four, or five byte cycles to be executed (See Table 7).

Table 7. Instructions Timing with 8MHz Clock

| Instruction Type | Cycles | Execution <br> Time |
| :--- | :---: | :---: |
| Branch if set/reset | 5 Cycles | $8.125 \mu \mathrm{~s}$ |
| Branch \& Subroutine Branch | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Bit Manipulation | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Load Instruction | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Arithmetic \& Logic | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Conditional Branch | 2 Cycles | $3.25 \mu \mathrm{~s}$ |
| Program Control | 2 Cycles | $3.25 \mu \mathrm{~s}$ |

Figure 29. PC Board Layouts Examples

Figure 30. OSCIN, OSCOUT Configuration Diagram

## INPUT/OUTPUT PORTS

The ST63XX microcontrollers use three standard I/O ports ( $A, B, C$ ) with up to eight pins on each port; refer to the device pin configurations to see which pins are available.
Each line can be individually programmed either in the input mode or the output mode as follows by software.

- Output
- Input with on-chip pull-up resistor (selected by software)
- Input without on-chip pull-up resistor (selected by software)
Note: pins with 12 V open-drain capability do not have pull-up resistors.
In output mode the following hardware configurations are available:
- Open-drain output 12V (PA0-PA7)
- Open-drain output 5V (PB5-PB7, PC3, PC5-PC7)
- Push-pull output (PB0-PB4, PC0-PC2,PC4)

The lines are organized in three ports (port A,B,C). The ports occupies 6 registers in the data space. Each bit of these registers is associated with a particular line (for instance, the bits 0 of the Port A Data and Direction registers are associated with the PAO line of Port A).
There are three Data registers (DRA, DRB, DRC), that are used to read the voltage level values of the lines programmed in the input mode, or to write the logic value of the signal to be output on the lines configured in the output mode. The port Data Registers can be read to get the effective logic levels of the pins, but they can be also written by the user software, in conjunction with the related Data Direction Register, to select the different input mode options. Single-bit operations on I/O registers (bit set/reset instructions) are possible but care is necessary because reading in input mode is done from $1 / O$ pins and therefore they might be influenced by the external load, while writing will directly affect the Port data register causing an undesired changes of the input configuration. The three Data Direction registers (DDRA, DDRB,DDRB) allow the selection of the direction of each pin (input or output).
All the I/O registers can be read or written as any other RAM location of the data space, so no extra RAM cell is needed for port data storing and manipulation. During the initialization of the MCU, all the I/O registers are cleared and the input mode with pull-up is selected on all the pins thus avoiding pin conflicts (with the exception of PC2 that is set in output mode and is set low).

## INPUT/OUTPUT PORTS (Continued)

## Details of I/O Ports

When programmed as an input a pull-up resistor (if available) can be switched active under program control. When programmed as an output the I/O port will operate either in the push-pull mode or the open-drain mode according to the hardware fixed configuration as specified below.
Port A is available as an open-drain only (no pushpull programmability and no resistive pull-up in input mode) capable of withstanding 12 V while the normal open drain has standard ratings of $V_{D D}+$ 0.3 V . This I/O port has been specially designed for direct led driving and is able to sink up to 30 mA with a maximum Vol of 1 V .
Some Port B and C lines are also used as I/O buffers for signals coming from the on-chip SPI and OSD. In this case the final signal on the output pin is equivalent to a wired AND with the programmed data output. If the user needs to use the SPI or the OSD, then the I/O line should be set in output mode while the open-drain configuration is harware fixed ; the corresponding data bit must set to one.
PB2 and PB3 must be programmed in input mode to provide the HSYNC and VSYNC signal to the OSD.
On ST632X,5X the I/O pins with double or special functions are:

- PB2/VSYNC (connected to the OSD VSYNC signal)
- PB3/HSYNC (connected to the OSD HSYNC signal)
- PB5/SCL (connected to the SPI clock signal)
- PB6/SDA (connected to the SPI data signal)
- PB7/SEN (connected to the SPI enable signal)
- PC2/ON-OFF, this I/O is specially suited for TV SET ON-OFF and for this reason at reset the related Data Direction bit will be automatically set to one (I/O line is in output mode), while the rest of the port is in input mode.
- PC3/BLANK (connected to the OSD Blank signal)
- PC5/R, PC6/G, PC7/B (connected to the OSD R-G-B signals)
All the Port A, B and C I/O lines have Schmitt-trigger input configuration with a typical hysteresis of 1 V .

## I/O Pin Programming

Each pin can be individually programmed as input or output with different input and output configurations.
This is achieved by writing to the relevant bit in the data (DR) and data direction register (DDR). Table 8 shows all the port configurations that can be selected by the user software.

Table 8. I/O Port Options Selection

| DDR | DR | Mode | Option |
| :---: | :---: | :---: | :---: |
| 0 | 0 | Input | With on-chip pull-up <br> resistor |
| 0 | 1 | Input | Without on-chip pull-up resis- <br> tor |
| 1 | $X$ | Output | Open-drain or Push-Pull |

Note. X. Means don't care
Figure 31. I/O Port Data Registers

PA7-PAO. These are the I/O port A data bits with open-drain configuration and high-drive capability. Reset at power on.
PB7/SEN. This is a general purpose open-drain I/O line. The output is the AND between this data bit and the SEN (Enable) signal coming from the SPI peripherals. Reset at power on.
PB6/SDA. This is a general purpose open-drain I/O line. The output is the AND between this data bit and the SDA (Data) signal coming from the SPI peripheral. Reset at power on.
PB5/SCL. This is a general purpose open-drain I/O line. The output is the AND between this data bit and the SCL (Clock) signal coming from the SPI peripheral. Reset at power on.
PC7-PC3,PC1-PC0. These are the I/O port C data bits. Reset at power on.
PC2/ON-OFF. This is a general purpose I/O line suitable for TV set ON-OFF. Reset at power on.

Figure 32. I/O Port Data Direction Registers

## INPUT/OUTPUT PORTS (Continued)

PA7-PA0. These are the I/O port A data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Reset at power-on.
PB7-PB0. These are the I/O port B data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Reset at power-on.
PC7-PCO. These are the I/O port C data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Set to 04 H at power-on. Bit 2 (PC2 pin) is set to one (output mode selected) as this line is intended for TV ON-OFF switching.

## Input/Output Configurations

The following schematics show the I/O lines hardware configuration for the different options. Figure 34 shows the I/O configuration for an I/O pin with open-drain 12 V capability (standard drive and high drive). Figure 33 shows the I/O configuration for an I/O pin with push-pull and with open drain 5 V capability.

## Notes :

The WAIT instruction allows the ST63XX to be used in situations where low power consumption is needed. This can only be achieved however if the

I/O pins either are programmed as inputs with well defined logic levels or have no power consuming resistive loads in output mode. As the same die is used for the different ST63XX versions the unavailable I/O lines of ST63XX should be programmed in output mode.
Single-bit operations on I/O registers are possible but care is necessary because reading in input mode is done from I/O pins while writing will directly affect the Port data register causing an undesired changes of the input configuration.

Figure 34. Port A I/O Configuration Diagram

Figure 33. Port B \& C I/O Configuration Diagram

## TIMERS

The ST63XX devices offer two on-chip Timer peripherals consisting of an 8 -bit counter with a 7 -bit programmable prescaler, thus giving a maximum count of $2^{15}$, and a control logic that allows configuring the peripheral in three operating modes. Figure 35 shows the timer block diagram. These timers do not have the external TIMER pin available for the user. The content of the 8-bit counter can be read/written in the Timer/Counter register TCR that can be addressed in the data space as RAM location at the D3H (Timer 1) and DBH (Timer 2) addresses. The state of the 7 -bit prescaler can be read in the PSC register at the D2H (Timer 1) and DAH (Timer 2) addresses. The control logic device can be managed thanks to the TSCR register D4H (Timer 1) and DCH (Timer 2) addresses as it is described in the following paragraphs.
The following description applies to both Timer 1 and Timer 2. The 8 -bit counter is decrement by the output (rising edge) coming from the 7 -bit prescaler and can be loaded and read under program control. When it decrements to zero then the TMZ (timer zero) bit in the TSCR is set to one. If the ETI (enable timer interrupt) bit in the TSCR is also set to one an
interrupt request, associated to interrupt vector \#3 (for Timer 1) and \#4 for (Timer 2), is generated. The interrupt of the timer can be used to exit the MCU from the WAIT mode.

The prescaler decrements on rising edge. The prescaler input can be the oscillator frequency divided by 12 or an external clock at TIMER pin (this is not available in ST63XX).
Depending on the division factor programmed by PS2/PS1/PS0 (see table 9) bits in the TSCR, the clock input of the timer/counter register is multiplexed to different sources.
On division factor 1 , the clock input of the prescaler is also that of timer/counter; on factor 2, bit 0 of prescaler register is connected to the clock input of TCR.

This bit changes its state with the half frequency of prescaler clock input. On factor 4, bit 1 of PSC is connected to clock input of TCR, and so on. On division factor 128, the MSB bit 6 of PSC is connected to clock input of TCR. The prescaler initialize bit (PSI) in the TSCR register must be set to one to allow the prescaler (and hence the counter) to start. If it is cleared to zero then all of the prescaler bits are set to one and the counter is inhibited from counting.

Figure 35. Timer Peripheral Block Diagram

TIMERS (Continued)
Figure 36. Timer Working Principle

The prescaler can be given any value between 0 and 7 FH by writing to the related register address, if bit PSI in the TSCR register is set to one. The tap of the prescaler is selected using the PS2/PS1/PS0 bits in the control register. Figure 36 shows the timer working principle.

## Timer Operating Modes

As on ST63XX devices the external TIMER pin is not available the only allowed operating mode is the output mode that have to be selected by setting to 1 bit 4 and by clearing to 0 bit 5 in the TSCR1 register. This procedure will enable both Timer 1 and Timer 2. Any other combination written into these two bits will disable any Timer 1 and Timer 2 operation.
Output Mode (TSCR1 D4 = 1, TSCR1 D5 = 0). On this mode the timer prescaler is clocked by the prescaler clock input (OSC/12). The user can select the desired prescaler division ratio through the PS2/PS1/PS0 bits. When TCR count reaches 0, it sets the TMZ bit in the TSCR.

The TMZ bit can be tested under program control to perform a timer function whenever it goes high. Bit D4 and D5 on TSCR2 (Timer 2) register are not implemented.

## Timer Interrupt

When the counter register decrements to zero and the software controlled ETI (enable timer interrupt) bit is set to one then an interrupt request associated to interrupt vector \#3 (for Timer 1) and to interrupt vector \#4 (for Timer 2) is generated. When the counter decrements to zero also the TMZ bit in the TSCR register is set to one.

## Notes :

TMZ is set when the counter reaches 00 H ; however, it may be set by writing 00 H in the TCR register or setting the bit 7 of the TSCR register. TMZ bit must be cleared by user software when servicing the timer interrupt to avoid undesired interrupts when leaving the interrupt service routine. After reset, the 8 -bit counter register is loaded to FFH while the 7 -bit prescaler is loaded to 7 FH , and the TSCR register is cleared which means that timer is stopped ( $\mathrm{PSI}=0$ ) and timer interrupt disabled.
A write to the TCR register will predominate over the 8 -bit counter decrement to 00 H function, i.e. if a write and a TCR register decrement to 00 H occur simultaneously, the write will take precedence, and the TMZ bit is not set until the 8 -bit counter reaches 00 H again. The values of the TCR and the PSC registers can be read accurately at any time.

TIMERS (Continued)

## Timer Registers

Figure 37. Timer Status Control Registers

TMZ. Low-to-high transition indicates that the timer count register has decrement to zero. This bit must be cleared by user software before to start with a new count.

ETI. This bit, when set, enables the timer interrupt (vector \#3 for Timer 1, vector \#4 for Timer 2) request. If $\mathrm{ET\mid}=0$ the timer interrupt is disabled. If $\mathrm{ET} \mid=1$ and TMZ $=1$ an interrupt request is generated.
D5. This is the timers enable bit D5. It must be cleared to 0 together with a set to 1 of bit D4 to enable both Timer 1 and Timer 2 functions. It is not implemented on TSCR2 register. Any other combination of TSCR1 D4 and D5 bits will disable any operation of both Timer 1 and Timer 2.
D4. This is the timers enable bit D4. It must be set to 1 together with a clear to 0 of bit D5 to enable both Timer 1 and Timer 2 functions. It is not implemented on TSCR2 register. Any other combination of TSCR1 D4 and D5 bits will disable any operation of both Timer 1 and Timer 2.
PSI. Used to initialize the prescaler and inhibit its counting while $\mathrm{PSI}=0$ the prescaler is set to 7 FH and the counter is inhibited. When PSI $=1$ the prescaler is enabled to count downwards. As long as $\mathrm{PSI}=0$ both counter and prescaler are not running.
PS2-PSO. These bits select the division ratio of the prescaler register. (see table 9)

The TSCR1 and TSCR2 registers are cleared on reset. The correct D4-D5 combination must be written in TSCR1 by user's software to enable the operation of Timer 1 and Timer 2.

Table 9. Prescaler Division Factors

| PS2 | PS1 | PS0 | Divided By |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 1 |
| 0 | 0 | 1 | 2 |
| 0 | 1 | 0 | 4 |
| 0 | 1 | 1 | 8 |
| 1 | 0 | 0 | 16 |
| 1 | 0 | 1 | 32 |
| 1 | 1 | 0 | 64 |
| 1 | 1 | 1 | 128 |

Figure 38. Timer Counter Registers

Figure 39. Prescaler Registers

## HARDWARE ACTIVATED DIGITAL WATCHDOG FUNCTION

The hardware activated digital watchdog function consists of a down counter that is automatically initialized after reset so that this function does not need to be activated by the user program. As the watchdog function is always activated this down counter can't be used as a timer. The watchdog is using one data space register (HWDR location D8H). The watchdog register is set to FEH on reset and immediately starts to count down, requiring no software start. Similarly the hardware activated watchdog can not be stopped or delayed by software.
The watchdog time can be programmed using the 6 MSbits in the watchdog register, this gives the possibility to generate a reset in a time between 3072 to 196608 oscillator cycles in 64 possible steps. (With a clock frequency of 8 MHz this means from $384 \mu$ s to 24.576 ms ). The reset is prevented if the register is reloaded with the desired value before bits 2-7 decrement from all zeros to all ones.
The presence of the hardware watchdog deactivates the STOP instruction and a WAIT instruction is automatically executed instead of a STOP. Bit 1 of the watchdog register (set to one at reset) can be used to generate a software reset if cleared to zero). Figure 40 shows the watchdog block diagram while Figure 41 shows its working principle.

Figure 41. Hardware Activated Watchdog Working Principle

Figure 40. Hardware Activated Watchdog Block Diagram

## HARDWARE ACTIVATED DIGITAL WATCHDOG FUNCTION (Continued)

Figure 42. Watchdog Register

T1-T6. These are the watchdog counter bits. It should be noted that D7 (T1) is the LSB of the counter and D2 (T6) is the MSB of the counter, these bits are in the opposite order to normal.
SR. This bit is set to one during the reset phase and will generate a software reset if cleared to zero.
C. This is the watchdog activation bit that is hardware set to one; the user can't change the value of this bit (the watchdog is always active).
The register reset value is FEH (Bit 1-7 set to one, Bit 0 cleared).

## SERIAL PERIPHERAL INTERFACE

The ST63XX Serial Peripheral Interface macrocell (SPI) has been designed to be cost effective and flexible in interfacing the various peripherals in TV applications.
It maintains the software flexibility but adds hardware configurations suitable to drive devices which require a fast exchange of data. The three pins dedicated for serial data transfer (single master only) can operate in the following ways:

- as standard I/O lines (software configuration)
- as S-BUS or as $\mathrm{I}^{2}$ CBUS (two pins)
- as standard (shift register) SPI

When using the hardware SPI, a fixed clock rate of 62.5 kHz is provided.

It has to be noted that the first bit that is output on the data line by the 8 -bit shift register is the MSB.

## SPI Data/Control Registers

For I/O details on SCL (Serial Clock), SDA (Serial Data) and SEN (Serial Enable) please refer to I/O Ports description with reference to the following registers:

Port B data register, Address C1H (Read/Write).

- BIT D5 "SCL"
- BIT D6 "SDA"
- BIT D7 "SEN"

Port B data direction register, Address C 5 H (Read/Write).

Figure 43. SPI Serial Data Register

D7-D0. These are the SPI data bits. They can be neither read nor written when SPI is operating (BUSY bit set). They are undefined after reset.

Figure 44. SPI Control Register 1

D7-D4. These bits are not used.
STR. This is Start bit for $I^{2}$ CBUS/S-BUS. This bit is meaningless when STD/SPI enable bit is cleared to zero. If this bit is set to one STD/SPI bit is also set to "1" and SPI Start generation, before beginning of transmission, is enabled. Set to zero after reset.
STP. This is Stop bit for $I^{2}$ CBUS/S-BUS. This bit is meaningless when STD/SPI enable bit is cleared to zero. If this bit is set to one STD/SPI bit is also set to "1" and SPI Stop condition generation is enabled. STP bit must be reset when standard protocol is used (this is also the default reset conditions). Set to zero after reset.

SERIAL PERIPHERAL INTERFACE (Continued)
S-BUS $/{ }^{2}$ CBUS Selection. This bit, in conjunction with STD/SPI bit, allows the SPI disable and will select between $I^{2}$ CBUS and S-BUS protocols. If this bit is cleared to " 0 " when STD bit is also " 0 ", the SPI interface is disabled. If this bit is cleared to zero when STD bit is set to " 1 ", the I ${ }^{2}$ CBUS protocol will be selected. If this bit is set to one when STD bit is set to "1", the S-BUS protocol will be selected. Cleared to zero after reset.
STD, SPI Enable. This bit, in conjunction with S-BUS $/ /^{2} C B U S$ bit, allows the SPI disable and will select between $1^{2}$ CBUS/S-BUS and Standard shift register protocols. If this bit is set to one, it selects both $I^{2}$ CBUS and S-BUS protocols; final selection between them is made by $S$ BUS $/ I^{2} C B U S$ bit. If this bit is cleared to zero when $S-B U S / \|^{2} C B U S$ is set to " 1 " the Standard shift register protocol is selected. If this bit is cleared to " 0 " when S-BUS $/ I^{2} \mathrm{CBUS}$ is cleared to 0 the SPI is disabled. Set to zero after reset.

Table 10. SPI Modes Selection

| D0 <br> S-Bus/ ${ }^{2}$ CBUS | D1 <br> STD/SPI | SPI Function |
| :---: | :---: | :---: |
| 0 | 0 | Disabled |
| 1 | 0 | STD Shift <br> Register |
| 0 | 1 | I $^{2}$ CBUS |
| 1 | 1 | S-BUS |

Figure 45. SPI Control Register 2

D7-D4. These bits are not used.
TX/RX.Write Only. When this bit is set, current byte operation is a transmission. When it is reset, current operation is a reception. Set to zero after reset.

VRY/S.Read Only/Write Only. This bit has two different functions in relation to read or write operation. Reading Operation: when STD and/or TRX bits are cleared to 0 , this bit is meaningless. When bits STD and TX are set to 1 , this bit is set each time BSY bit is set. This bit is reset during byte operation if real data on SDA line are different from the ones output from the shift register. Set to zero after reset. Writing Operation : it enables (if set to one) or disables (if cleared to zero) the interrupt coming from VSYNC pin. Undefined after reset. Refer to OSD description for additional information.
ACN.Read Only. If STD bit (D1 of SCR1 register) is cleared to zero this bit is meaningless. When STD is set to one, this bit is set to one if no Acknowledge has been received. In this case it is automatically reset when BSY is set again. Set to zero after reset.
BSY.Read/Set Only. This is the busy bit zero. When a one is loaded into this bit the SPI interface start the transmission of the data byte loaded into SSDR data register or receiving and building the receive data into the SSDR data register. This is done in accordance with protocol, direction and start/stop condition(s). This bit is automatically cleared at the end of the current byte operation. Cleared to zero after reset.

## Note :

The SPI shift register is also the data transmission register and the data received register; this new feature is made possible by using the serial structure of the ST63XX and thus reducing size and complexity.
During transmission or reception of data, all access to serial data register is therefore disabled. The reception or transmission of data is started by setting the BUSY bit to " 1 "; this will be automatically reset at the end of the operation. After reset, the busy bit is cleared to " 0 ", and the hardware SPI disabled by clearing bit 0 and bit 1 of SPI control register 1 to " 0 ". The outputs from the harware SPI are "ANDed" to the standard I/O software controlled outputs. If the hardware SPI is in operation then Port B ouputs related to the SPI should be set high or the pins should pin configured as inpus using the data direction register. When the SPI is configured as the S-BUS, the three pins PB5, PB6 and PB7 become the pins SCL, SDA and SEN respectively. When configured as the $1^{2}$ CBUS the pins PB5 and PB6 are configured as the pins SCL and SDA; PB7 is not driven and can be used as general purpose I/O pin. In the case of the STDSPI the pins PB5 and PB6 become the signals CLOCK and DATA, PB7 is not driven and can be used as general purpose I/O pin. The VERIFY bit is available when the SPI is configured as either S-BUS or $I^{2}$ CBUS. At the start of a byte transmission, the verify bit is set to one. If at any time during the transmission of the

## SERIAL PERIPHERAL INTERFACE (Continued)

following eight bits, the data on the SDA line does not match the data forced by the SPI (while SCL is high), then the VERIFY bit is reset. The verify is available only during transmission for the S-BUS and $I^{2}$ CBUS; for other protocol it is not definfited. The SDA and SCL signal entering the SPI are buffered in order to remove any minor glitches. When STD bit is set to one ( $S$-BUS or $1^{2} C B U S$ selected), and TRX bit is reset (receiving data), and STOP bit is set (last byte of current communication), the SPI interface does not generate the Acknowledge, according to $\mathrm{S}-\mathrm{BUS} / I^{2} \mathrm{CBUS}$ specifications. PB5-SCL, PB6-SDA and PB7-SEN lines are standard drive I/O port pins with opendrain output configuration (maximum voltage that can be applied to these pins is $V_{D D}+0.3 \mathrm{~V}$ ).

## S-BUS/ $/{ }^{2}$ CBUS Protocol Information

The S-BUS is a three-wire bidirectional data-bus with functional features similar to the $\mathrm{I}^{2} \mathrm{CBUS}$. In fact the S-BUS includes decoding of Start/Stop conditions and the arbitration procedure in case of multimaster system configuration (the ST63XX SPI allows a single-master only operation). The SDA line, in the $1^{2}$ CBUS represents the AND combination of SDA and SEN lines in the S-BUS. If the SDA and the SEN lines are short-circuit connected, they appear as the SDA line of the $I^{2}$ CBUS. The Start/Stop conditions are detected (by the external peripherals suited to work with $\mathrm{S}-\mathrm{BUS} / /^{2} \mathrm{CBUS}$ ) in the following way:

- On S-BUS by a transition of the SEN line (1 to 0 Start, 0 to 1 Stop) while the SCL line is at high level.
- On $I^{2}$ CBUS by a transition of the SDA line (10 Start, 01Stop) while the SCL line is at high level.
Start and Stop condition are always generated by the master (ST63XX SPI can only work as single master). The bus is busy after the start condition and can be considered again free only when a certain time delay is left after the stop condition. In the S-BUS configuration the SDA line is only allowed to change during the time SCL line is low. After the start information the SEN line returns to high level and remains unchanged for all the data transmission time. When the transmission is completed the SDA line is set to high level and, at the same time, the SEN line returns to the low level in order to supply the stop information with a low to high transition, while the SCL line is at high level. On the S-BUS, as on the $I^{2}$ CBUS, each eight bit information (byte) is followed by one acknowledged bit which is a high level put on the SDA line by the transmitter. A peripheral that acknowledges has to pull down the SDA line during the acknowledge clock pulse. An addressed receiver has to generate an acknowledge after the reception of each byte; otherwise the SDA line remains at the high level during the ninth clock pulse time. In this case the
master transmitter can generate the Stop condition, via the SEN (or SDA in $I^{2} C B U S$ ) line, in order to abort the transfer.
Start/Stop Acknowledge. The timing specs of the S-BUS protocol require that data on the SDA (only on this line for $I^{2}$ CBUS) and SEN lines be stable during the "high" time of SCL. Two exceptions to this rule are foreseen and they are used to signal the start and stop condition of data transfer.
- On S-BUS by a transition of the SEN line ( 10 Start, 01 Stop) while the SCL line is at high level.
- On $I^{2}$ CBUS by a transition of the SDA line ( 10 Start, 01 Stop) while the SCL line is at high level.
Data are transmitted in 8 -bit groups; after each group, a ninth bit is interposed, with the purpose of acknowledging the transmitting sequence (the transmit device place a "1" on the bus, the acknowledging receiver a "0").
Interface Protocol. This paragraph deals with the description of data protocol structure. The interface protocol includes:

## - A start condition

- A "slave chip address" byte, transmitted by the master, containing two different information:
a. the code identifying the device the master wants to address (this information is present in the first seven bits)
b. the direction of transmission on the bus (this information is given in the 8th bit of the byte); " 0 " means "Write", that is from the master to the slave, while "1" means "Read". The addressed slave must always acknowledge.
The sequence from, now on, is different according to the value of $R / W$ bit.

## 1. $\mathrm{R} / \overline{\mathrm{W}}=$ " $0 "(\overline{\mathrm{Write}})$

In all the following bytes the master acts as transmitter; the sequence follows with:
a. an optional data byte to address (if needed) the slave location to be written (it can be a word address in a memory or a register address, etc.).
b. a "data" byte which will be written at the address given in the previous byte.
c. further data bytes.
d. a STOP condition

A data transfer is always terminated by a stop condition generated from the master. The ST63XX peripheral must finish with a stop condition before another start is given. Figure 46 shows an example of write operation.
2. $R / \bar{W}=" 1 "$ (Read)

In this case the slave acts as transmitter and, therefore, the transmission direction is changed. In read mode two different conditions can be considered:

SERIAL PERIPHERAL INTERFACE (Continued)
a. The master reads slave immediately after first byte. In this case after the slave address sent from the master with read condition enabled the master transmitter becomes master receiver and the slave receiver becomes slave transmitter.
b. The master reads a specified register or location of the slave. In this case the first sent byte will contain the slave address with write condition enabled, then the second byte will specify the address of the register to be read. At this moment a new start is given together with the slave address in read mode and the procedure will proceed as described in previous point "a".

Figure 46. Master Transmit to Slave Receiver (Write Mode)

## S-BUS $/{ }^{2}$ CBUS Timing Diagrams

The clock of the S-BUS $/ I^{2}$ CBUS of the ST63XX SPI (single master only) has a fixed bus clock frequency
of 62.5 KHz . All the devices connected to the bus must be able to follow transfers with frequencies up to 62.5 KHz , either by being able to transmit or receive at that speed or by applying the clock synchronization procedure which will force the master into a wait state and stretch low periods.

Figure 49. S-BUS Timing Diagrams

SERIAL PERIPHERAL INTERFACE (Continued)
Figure $50.1^{2} \mathrm{C}$ BUS Timing Diagrams

Note: The third pin, SEN, should be high; it's not used in the $I^{2} C B U S$. Logically SDA is the AND of the S-BUS SDA and SEN.

SERIAL PERIPHERAL INTERFACE (Continued)

## Compatibility S-BUS $/ I^{2} \mathrm{CBUS}$

Using S-BUS protocol it is possible to implement mixed system including S-BUS $/ /^{2} C B U S$ bus peripherals. In order to have the compatibility with the $I^{2}$ CBUS peripherals, the devices including the $S$ BUS interface must have their SDA and SEN pins
connected together as shown in the following Figure 51 ( $a$ and $b$ ). It is also possible to use mixed S-BUS $/ I^{2} C B U S$ protocols as showed in figure 51 (c). S-BUS peripherals will only react to S-BUS protocol signals, while $\left.\right|^{2} \mathrm{CBUS}$ peripherals will only react to $I^{2} \mathrm{CBUS}$ signals. Multimaster configuration is not possible with ST63XX SPI (single master only).

Figure 51. S-BUS $/ I^{2} \mathrm{C}$ BUS Mixed Configurations

SERIAL PERIPHERAL INTERFACE (Continued)

Figure 52. STD Bus (hardware bus disabled) Timing Diagram

## STD SPI Protocol (Shift Register)

This protocol is similar to the $1^{2} \mathrm{CBUS}$ with the exception that there is no acknowledge pulse and there are no stop or start bits. The clock cannot be slowed down by the external peripherals.
The I/O ports associated with the SPI should be programmed as outputs with data high in order not to inhibit the functionality of the hardware SPI.

## SPI APPLICATION NOTES

Stop Clock Slowdown: In the ST63XX family of devices when operating in the $I^{2} \mathrm{C}$ or SBUS modes, there is no internal clock slowdown for the final STOP clock. Slowdown means that if an external peripheral requires extra time it will hold the ST63XX SCL clock low. To be fully $I^{2} \mathrm{C}$ and SBUS
compatible in this respect, the SW should check that the SCL line is indeed high before proceeding with the START of another $\mathrm{I}^{2} \mathrm{C}$ or SBUS transmission. In all other cases the SCL clock slowdown feature is operational.
SPI Standard Bus Protocol: The standard bus protocol is selected by loading the SPI Control Register 1 (SCR1 Add. EBH). Bit 0 named $I^{2} C$ must be set at one and bit 1 named STD must be reset. When the standard bus protocol is selected bit 2 of the SCR1 is meaningless.
This bit named STOP bit is used only in $1^{2}$ CBUS or SBUS. However take care that the STOP BIT MUST BE RESET WHEN THE STANDARD PROTOCOL IS USED. This bit is set to ZERO after RESET.

## 6-BIT PWM D/A CONVERTERS AND 62.5 KHz OUTPUT FUNCTION

The D/A macrocell contains four PWM D/A outputs (32Khz repetition, DAO-DA3) with six bit resolution plus a 62.5 KHz open-drain output pin (OUT1) specially suited for multistandard chroma processors driving. Both the D/A and OUT1 functions can be disabled by software allowing the DAO-DA3 and OUT1 pins to be used as general purpose opendrain output pins able to withstand signals with up to 12 V amplitude.

## 6-Bit D/A Converters

Each D/A converter of ST63XX is composed by the following main blocks:

## - pre-divider

- 6-bit counter
- data latches and compare circuits

The pre-divider uses the clock input frequency ( 8 MHz ) and its output clocks the 6 -bit free-running counter. The data latched in the four registers ( EOH , E1H, E2H and E3H) control the four D/A outputs (DA0,1,2 and 3). When all zeros are loaded the relevant output is an high logic level; all 1's correspond to a pulse with a $1 / 64$ duty cycle and almost $100 \%$ zero level. A 7th bit (bit D6) is used to enable the relevant D/A output; when zero, the D/A is no longer enabled and it forces the output to zero. If the other six bits are all zero then the output is controlled only by the enable bit.
he repetition frequency is 32.5 KHz and is related to the 8 MHz clock frequency. All D/A outputs are open-drain with standard current drive capability and able to withstand up to 12 V .

Figure 53. 6-BIT PWM D/A \& 62.5KHz Output Configuration

### 62.5 KHZ Output

This pin provides a 62.5 KHz signal with a $50 \%$ duty cycle; the output is enabled by a dedicated enable bit ( EOH register bit 7 ). When the 62.5 KHz frequency is disabled then the output is controlled by the OUT1 bit and the line can be used as general purpose open-drain output (E1H bit 7). The OUT1 output is open-drain with standard current drive capability and able to withstand signals with up to 12 V amplitude. The pin can be used to drive the SGS-THOMSON TEA5640 chroma processor. Refer to the TEA5640 data sheet for more information on the use of this pin. Care must be taken to respect the frequency tolerances required by the TEA5640 by chosing a quartz with PPM variations within the limits required by the chroma processor.

## D/A and OUT1 Data/Control Registers

This paragraph deals with the description of D/A and OUT1 data/control registers. Some bits of DA2 and DA3 data/control registers are used for external interrupt enable and $A / D$ reference voltage shift, please refer to A/D and IR descriptions for additional information.

Figure 54. D/AO Data/Enable Register

DAO-DA5. These are the 6 bits of the PWM digital to analog converter. Undefined after reset.
DAE. This is the D/A 0 enable bit. If zero, the output of the D/A is forced to zero; if one, the output of the D/A depends on bits DAO..DA5. Undefined after reset.
FO1. This is the 62.5 KHz frequency output/ OUT1 selection bit. If one, the OUT1 pin will give a 62.5 KHz frequency; if zero the OUT1 pin can be used as general purpose open-drain output and the value present on the pin depends on the value of OUT1 bit programmed in the DA1 data/control register. Undefined after reset.

## 6-BIT PWM D/A CONVERTERS AND 62.5 KHz OUTPUT FUNCTION (Continued)

Figure 55. D/A1 Data/Enable Register

DAO-DA5. These are the 6 bits of the PWM digital to analog converter. Undefined after reset.
DAE. This is the D/A 1 enable bit. If zero, the output of the D/A is forced to zero; if one, the output of the D/A depends on bits DAO..DA5. Undefined after reset.

OUT1. This is the OUT1 data bit. The content of this bit is output on the OUT1 pin when the 62.5 KHz frequency function is disabled (FO1 bit in DAO register is cleared to zero). Undefined after reset.

Figure 56. D/A2 Data/Enable Register

DAO-DA5. These are the 6 bits of the PWM digital to analog converter bits. Undefined after reset.
DAE. This is the D/A 2 enable bit. If zero, the output of the $D / A$ is forced to zero; if one, the output of the D/A depends on bits DAO..DA5. Undefined after reset.
IEN. This is the external interrupt enable. If set to one, the interrupt coming from the external interrupt pin is enabled, if this bit is cleared the interrupt is disabled. Undefined after reset. This interrupt is associated to the NMI interrupt vector. Refer to IR and interrupt descriptions for additional information.

Figure 57. D/A3 Data/Enable Register

DAO-DA5. These are the 6 bits of the PWM digital to analog converter. Undefined after reset.
DAE. This is the D/A 3 enable bit. If zero, the output of the $D / A$ is forced to zero; if one, the output of the D/A depends on bits DAO..DA5. Undefined after reset.
ADSH. This is the analog to digital converter reference voltage shift bit. If set to one, the AFC block has reference voltages on 1 V border. If set to zero, on 0.5 V border. Undefined after reset. Refer to AFC for additional information.

## AFC A/D INPUT, KEYBOARD INPUTS AND BANDSWITCH OUTPUTS

The AFC macrocell contains an A/D comparator with five levels at intervals of 1 V from 1 V to 5 V . The levels can all be lowered by 0.5 v to effectively double the resolution. This A/D can be used to perform the AFC function. In addition this cell offers also a keyboard input register of three bits used to perform a keyboard scan and 4 open-drain outputs (able to withstand signals up to 12 V ) that can be used to perform band switch function.

Figure 58. AFC, KBY Inputs Configuration Diagrams

Figure 59. BSW, DA, OUT1 Output Configuration Diagram

## A/D Comparator

The A/D used to perform the AFC function (when high threshold is selected) has the following voltage levels: 1,2,3,4 and 5V. Bits 0-2 of AFC result register (E4H address) will provide the result in binary form (less than 1 V is 000 , greater than 5 V is 101).
If the application requires a greater resolution, the sensitivity can be doubled by clearing to zero bit 7 of DA3 Data/Control register, address E3H (refer to D/A description for additional information). In this case all levels are shifted lower by 0.5 V . If the two results are now added within a software routine then the A/D S-curve can be located within a resolution of 0.5 V . The $\mathrm{A} / \mathrm{D}$ input has high impedance able to withstand up to 13 V signals (input level tolerances $\pm 200 \mathrm{mv}$ absolute and $\pm 100 \mathrm{mv}$ relative to 5 V ).
AFC, Keyboard Inputs and Bandswitch Outputs Data/Control Registers
Figure 60. AFC Result Register

D7-D3. These bits are not used.
AD0-AD2. These bits store the real time conversion of the value present on the AFC input pin. No reset value.

## AFC A/D INPUT, KEYBOARD INPUTS AND BANDSWITCH OUTPUTS (Continued)

Figure 61. Keyboard Input Register

D7-D3. These bits are not used.
KBYO-KBY2. These bits store the logic level present at KBYO, KBY1 and KBY2 input pins. No reset value. This input pins have CMOS levels with onchip pull-up resistor (100Kohm typical).

Figure 62. Bandswitch Output Register

D6-D3. These bits are not used.
BSW0-BSW2,BSW3. The writing into these bits will cause the corresponding BSW open-drain output line to switch to the programmed level. Undefined after reset.

## INFRARED INPUT (IRIN)

The IRIN pin is directly connected to the NMI interrupt and acts as external interrupt pin (refer to interrupt description for additional information).
The enable/disable of this interrupt can be managed with the write only IRINTEN bit available in the D/A2 Data/Control register (Address E2H, bit D7). When this bit is set to one the interrupt is enabled otherwise it is disabled.
The IRIN pin is RISING EDGE sensitive.

## Application Note

When the IR interrupt is enabled, then a rising edge on the IR pin will generate an interrupt; if the IR interrupt is disabled, no IR interrupts can occur. Care should be taked because if the IR pin is high when the IR interrupt is enabled, an interrupt will also be generated; the following method to eliminate noise can also be used if the SW engineer wishes to enable/disable the IR interrupt.
If A Low-cost infra-red receiver is used, the customer may wish to test the IR signal by software after an interrupt in order to verify that there is a good pulse and not just noise. The IRIN pin cannot be read, so in this case it should be connected in parallel with another pin so the signal can be read. Furthermore the IRIN pin is sensitive to a rising edge interrupt; this means that the input to the pin should be low in the presence of no infra-red signal, but since most infra-red receiver modules give a high signal, the signal will need to be inverted with a transistor.

## ON-SCREEN DISPLAY (OSD)

The ST632X,5X OSD macrocell is a CMOS LSI character generator which enable display of characters and symbols on the TV screen. The character rounding function enhances the readability of the characters. The ST632X,5X OSD receives horizontal and vertical synchronization signal and outputs screen information viaR, $\mathrm{G}, \mathrm{B}$ and blanking pins. The main characteristics of the macrocell are listed below:

- Number of display characters: 5 lines by 15 columns.
- Number of character types: 64 characters in one bank.
- Character size: Four character heights ( $18 \mathrm{H}, 36 \mathrm{H}$ $54 \mathrm{H}, 72 \mathrm{H})$, two available per screen programmable by line.
- Character format: $6 \times 9$ dots with character rounding function.
- Character color: Eight colors available programmable by word.
- Display position: 64 horizontal positions by 2/fos and 63 vertical positions by 4 H
- Word spacing: 64 positions programmable from 2/fosc to 128/fosc.
- Line spacing: 63 positions programmable from 4 to 252 H .
- Background: No background, square background or fringe background programmable by word.
- Background color: Two of eight colors available programmable by word.
- Display output: Three character data output terminals ( $R, G, B$ ) and a blank output terminal.
- Display on/off: Display data may be programmed on or off by word or entire screen. Entire screen may be blanked.

## ON-SCREEN DISPLAY (Continued)

## Format Specification

The entire display can be turned on or off thru the use of global enable bit or the display may be selectively turned on or off by word. To turn off the entire display, the global enable bit (GE) should be zero. If the global enable is one, the display is controlled by the word enable bits (WE). The global enable bit is located in the global enable register and the word enable bit is located in the space character preceding the word.
Each line must begin with a format character which describes the format of that line and of the first word. This character is not displayed.
A space character defines the format of subsequent words. A space character is denoted by a one in bit 6 in the display RAM. If bit 6 of the display RAM is a zero, the other six bits define one of the 64 display characters.
The color, background and enable can be programmed by word. This information is encoded in the space character between words or in the format character at the beginning of each line. Five bits define the color and background of the following word, and determine whether it will be displayed or not.
Characters are stored in a $6 \times 9$ dot format. One dot is defined vertically as 2 H (horizontal lines) and horizontally as 2 /fosc if the smallest character size is enabled. There is no space between characters or lines if the vertical space enable (VSE) and horizontal space enable (HSE) bits are both zero. This allows the use of special graphics characters.
The normal alphanumeric character set is formatted to be $5 \times 7$ with on empty row at the top and one at the bottom and one empty column at the right. If VSE and HSE are both zero, then the spacing between alphanumeric characters is 1 dot and the spacing between lines of alphanumeric characters is 2 H .
The character size is programmed by line thru the use of the size bit ( S ) in the format character and the global size bits (GS1 and GS2). The vertical spacing enable bit (VSE) located in the format character controls the spacing between lines. If this bit is set to one, the spacing between lines is defined by the vertical spacing register, otherwise the spacing between lines is 0 .
The spacing between words is controlled by the horizontal space enable bit (HSE) located in the space character. If this bit is set to one, the spacing between words is defined by the horizontal spacing register, otherwise the space character width of 6 dots is the spacing between words.

The formats for the display character, space character and format character are described hereafter.

Figure 65. Space Character Register Explanation

D7. Not used.
D6. This pin is fixed to " 1 ".
R, G, B. Color. The 3 color control bits define the color of the following word as shown in table 11.
Table 11. Space Character Register Colour Setting.

| $\mathbf{R}$ | $\mathbf{G}$ | $\mathbf{B}$ | Color |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | Black |
| 0 | 0 | 1 | Blue |
| 0 | 1 | 0 | Green |
| 0 | 1 | 1 | Cyan |
| 1 | 0 | 0 | Red |
| 1 | 0 | 1 | Magenta |
| 1 | 1 | 0 | Yellow |
| 1 | 1 | 1 | White |

BGS. Background Select. The background select bit selects the desired background for the following word. There are two possible backgrounds defined by the bits in the Background Control Register.
" 0 " - The background on the following word is enabled by BGO and the color is set by RO, GO, and BO .
"1" - The background on the following word is enabled by BG1 and the color is set by R1, G1, and B1.

## ON-SCREEN DISPLAY (Continued)

WE. Word Enable. The word enable bit defines whether or not the following word is displayed.
" 0 " - The word is not displayed.
"1" - If the global enable bit is one, then the word is displayed.
HSE. Horizontal Space Enable. The horizontal space enable bit determines the spacing between words. The space between characters is always 0 . The alphanumeric character set is implemented in a $5 \times 7$ format with one empty column to the right and one empty row above and below so that the space between alphanumeric characters will be one dot.
" 0 " - The space between words is equal to the width of the space character, which is 6 dots.
"1" - The space between words is defined by the value in the horizontal space register plus the width of the space character.

Figure 66. Format Character Register Explanation

D7. This bit is not used
S. Character Size. The character size bit, along with the global size bits (GS2 and GS1) located in the horizontal space register, specify the character size for each line as defined in Table 13.
BGS. Background Select. The background select bit selects the desired background for the following word. There are two possible backgrounds defined by the bits in the Background Control Register.
" 0 " - The background on the following word is enabled by BGO and the color is set by R0, GO, and BO.
" 1 " - The background on the following word is enabled by BG1 and the color is set by R1, G1, and B1.
WE. Word Enable. The word enable bit defines whether or not the following word is displayed.
" 0 " - The word is not displayed.
" 1 " - If the global enable bit is one, then the word is displayed.
R, G, B. Color. The 3 color control bits define the color of the following word as shown in Table 12.
VSE. Vertical Space Enable. The vertical space enable bit determines the spacing between lines.
" 0 " - The space between lines is equal to 0 H . The alphanumeric character set is implemented in a $5 \times 7$ format with one empty column to the right and one empty row above and one below and stored in a $6 \times 9$ format.
" 1 " - The space between lines is defined by the value in the vertical space register.

Table 12. Format Character Register Colour Setting.

| $\mathbf{R}$ | $\mathbf{G}$ | $\mathbf{B}$ | Color |
| :---: | :---: | :---: | :---: |

[^3]ON-SCREEN DISPLAY (Continued)
Figure 67. Display Character Register Explanation

D7. This bit is not used.
D6. This bit is fixed to " 0 ".
C5-C0. Character type. The 6 character type bits define one of the 64 available character types. These character types are shown on the following pages.

## Character Types

The character set is user defined as ROM mask option.

## Register and RAM Addressing

The OSD contains six registers and 80 RAM locations. The seven registers are the Vertical Start Address register, Horizontal Start Address register, Vertical Space register, Horizontal Space register, Background Control register and Global Enable register. The Global Enable register can be written at any time by the ST63 Core. The other five registers and the RAM can only be read or written to if the global enable is zero.
The six registers and the RAM are located on two pages of the paged memory of the ST63XX MCUs. Each page contains 64 memory locations. This paged memory is at memory locations 00 H to 3 FH in the ST63XX memory map. A page of memory is enabled by setting the desired page bit, located in the data RAM bank switching register, to a one. The page register is location E 8 H . A one in bit five selects page 5, located on the OSD and a one in bit 6 selects page 6 on the OSD. Table 14 shows the addresses of the OSD registers and RAM.

Table 14. OSD Control Registers and Data RAM Addressing

| Page | Address | Register or RAM |
| :---: | :---: | :---: |
| 5 | $00 \mathrm{H}-3 \mathrm{FH}$ | RAM Locations $00 \mathrm{H}-3 \mathrm{FH}$ |
| 6 | $00 \mathrm{H}-$ OFH | RAM Locations $00 \mathrm{H}-$ 0FH |
| 6 | 10 H | Vertical Start Register |
| 6 | 11 H | Horizontal Start Register |
| 6 | 12 H | Vertical Space Register |
| 6 | 13 H | Horizontal Space Register |
| 6 | 14 H | Background Control Register |
| 6 | 17 H | Global Enable Register |

## OSD Global Enable Register

This register contains the global enable bit (GE). It is the only register that can be written at any time regardless of the state of the GE bit. It is a write only register.

Figure 68. Global Enable register

D7-D1. These bits are not used
GE. Global Enable. This bit allows the entire display to be turned off.
" 0 " - The entire display is disabled. The RAM and other registers of the OSD can be accessed by the Core.
"1" - Display of words is controlled by the word enable bits (WE) located in the format or space character.
The other registers and RAM cannot be accessed by the Core.

ON-SCREEN DISPLAY (Continued)
Figure 69. Vertical Start Address Register

D7. This bit is not used
FR. Fringe Background. This bit changes the background from a box background to a fringe background. The background is enabled by word as defined by either BKO or BK1.
" 0 " - The background is defined to be a box which is $7 \times 9$ dots.
" 1 " - The background is defined to be a fringe.
VSA5-VSAO. Vertical Start Address. These bits determine the start position of the first line in the vertical direction. The 6 bits can specify 63 display start positions of interval 4 H . The first start position will be the fourth line of the display. The vertical start address is defined VSAO by the following formula.
Vertical Start Address $=4 \mathrm{H}\left(2^{5}(\right.$ VSA 5$)+2^{4}($ VSA4 $)$ $+2^{3}($ VSA3 $)+2^{2}($ VSA2 $)+2^{1}($ VSA 1$)+2^{0}($ VSAO $\left.)\right)$ The case of all Vertical Start Address bits being zero is 111 .

Figure 70. Horizontal Start Address Register

D7. This bit is not used.
SBD. Space Blanking Disable. This bit controls whether or not the background is displayed when
outputting spaces. If two background colors are used on adjacent words, then the background should not be displayed on spaces in order to make a nice break between colors. If an even background around an area of text is desired, as in a menu, then the background should be displayed when outputting spaces.
" 0 " - The background during spaces is controlled by the background enable bits (BKO and BK1) located in the Background Control register.
"1" - The background is not displayed when outputting spaces.
HSA5, HSAO - Horizontal Start Address bits. These bits determine the start position of the first character in the horizontal direction. The 6 bits can specify 64 display start positions of interval $2 / f 0 s c$ or 400 ns . The first start position will be at $4.0 \mu$ s because of the time needed to access RAM and ROM before the first character can be displayed. The horizontal start address is defined by the following formula.
Horizontal Start Address $=2 /$ fosc $\left(10.0+2^{5}(\right.$ HSA5 $)$ $+2^{4}(\mathrm{HSA} 4)+2^{3}(\mathrm{HSA} 3)+2^{2}(\mathrm{HSA} 2)+2^{1}(\mathrm{HSA} 1)+$ $2^{0}$ (HSAO))

Figure 71. Vertical Space Register

D7. This bit is not used
SCB. Screen Blanking. This bit allows the entire screen to be blanked.
" 0 " - The blanking output signal (VBLK) is active only when displaying characters.
"1" - The blanking output signal (VBLK) is always active. Characters in the display RAM are still displayed.
When this bit is set to one, the screen is blanked also without setting the Global Enable bit to one (OSD disabled).

## ON-SCREEN DISPLAY (Continued)

VS5, VSO. Vertical Space. These bits determine the spacing between lines if the Vertical Space Enable bit (VSE) in the format character is one. If VSE is zero there will be no spaces between lines. The Vertical Space bits can specify one of 63 spacing values from 4 H to 252 H . The space between lines is defined by the following formula.
Space between lines $=4 \mathrm{H}\left(2^{5}(\right.$ VS5 $)+2^{4}($ VS 4$)+$ $\left.2^{3}(\mathrm{VS} 3)+2^{2}(\mathrm{VS} 2)+2^{1}(\mathrm{VS} 1)+2^{0}(\mathrm{VSO})\right)$
The case of all Vertical Start Address bits being zero is ill.

Figure 72. Horizontal Space Register

GS2,GS1. Global Size. These bits along with the size bit (S) located in the Character format word specify the character size for each line as defined in table 15.
Table 15. Horizontal Space Register Size Setting.

| GS2 | GS1 | $\mathbf{S}$ | Vertical Height | Horizontal <br> Lenght |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 18 H | 6 TDOT |
| 0 | 0 | 1 | 36 H | 12 TDOT |
| 0 | 1 | 0 | 18 H | 6 TDOT |
| 0 | 1 | 1 | 54 H | 18 TDOT |
| 1 | 0 | 0 | 36 H | 12 TDOT |
| 1 | 0 | 1 | 54 H | 18 TDOT |
| 1 | 1 | 0 | 36 H | 12 TDOT |
| 1 | 1 | 1 | 72 H | 24 TDOT |

Note: TDOT $=2$ fosc
HS5, HSO . Horizontal Space. These bits determine the spacing between words if the Horizontal Space Enable bit (HSE) located in the space character is a one. The space between words is then equal to the width of the space character plus the number of tdots specified by the Horizontal Space
bits. The 6 bits can specify one of 64 spacing values ranging from $2 /$ fosc to $128 /$ fosc. The formula is shown below for the smallest size character $(18 \mathrm{H})$. If larger size characters are being displayed the spacing between words will increase proportionately. Multiply the value below by 2, 3 or 4 for character sizes of $36 \mathrm{H}, 54 \mathrm{H}$ and 72 H respectively.
Space between words (not including the space character $)=2 / \mathrm{fosc}\left(\left(1+2^{5}(\mathrm{HS} 5)+2^{4}(\mathrm{HS} 4)+2^{3}(\mathrm{HS} 3)\right.\right.$ $\left.+2^{2}(\mathrm{HS} 2)+2^{1}(\mathrm{HS} 1)+2^{0}(\mathrm{HSO})\right)$

## Background Control Register

This register sets up two possible backgrounds. The background select bit (BGS) in the format or space character will determine which background is selected for the current word.

Figure 73. Background Control Registers

R1,R0,G1,G0,B1,B0. Background Color. These bits define the color of the specified background, either background 1 or background 0 as defined in Table 16.

Table 16. Background Register Colour Setting.

| $\mathbf{R X}$ | $\mathbf{G X}$ | $\mathbf{B X}$ | Color |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | Black |
| 0 | 0 | 1 | Blue |
| 0 | 1 | 0 | Green |
| 0 | 1 | 1 | Cyan |
| 1 | 0 | 0 | Red |
| 1 | 0 | 1 | Magenta |
| 1 | 1 | 0 | Yellow |
| 1 | 1 | 1 | White |

## ON-SCREEN DISPLAY (Continued)

BK1,BK0. Background Enable.These bits determine if the specified background is enabled or not.
" 0 " - The following word does not have a background.
"1" - There is a background around the following word.

## OSD Data RAM

The contents of the data RAM can be accessed by the ST63XX MCUs only when the global enable bit (GE) in the Global Enable register is a zero.
The first character in every line is the format character. This character is not displayed. It defines the size of the characters in the line and contains the vertical space enable bit. This character also defines the color, background and display enable for the first word in the line. Subsequent characters are either spaces or one of the 64 available character types.
The space character defines the color, background, display enable and horizontal space enable for the following word. Since there are 5 display lines of 15 characters each, the display RAM must contain 5 lines $x$ ( 15 characters +1 format character) or 80 locations. The RAM size is 80 locations $\times 7$ bits. The data RAM map is shown inTable 17.

## Emulator Remarks

There are a few differences between emulator and silicon. For noise reasons, the OSD oscillator pins are not available: the internal oscillator cannot be disabled and replaced by an external coil.

## Application Notes

1 - The OSD character generator is composed of a dual port video ram and some circuitry. It needs two input signals VSYNC and HSYNC to syncronize its dedicated oscillator to the TV picture. It generates 4 output signals, that can be used from the TV set to generate the characters on the screen. For instance, they can be used to feed the SCART plug, providing an adequate buffer to drive the low impedance ( $75 \Omega$ ) of the SCART inputs.
2 - The Core sees the OSD as a number of RAM locations (80) plus a certain number of control registers (6). These 86 locations are mapped in two pages of the dynamic data ram address range ( $\mathrm{OH} . .3 \mathrm{FH}$ ).
In page 5 (load 20H in the register 0E8H), there are 64 bytes of RAM, the ones of the first 4 rows ( 16 bytes each row, 15 characters per row maximum, plus an hidden leading format character). In page 6 (load 40 H in register 0 E 8 H ), the 16 bytes of the fith row ( $0 . .0 \mathrm{FH}$ ), and the 6 control registers ( $10 \mathrm{H} . .14 \mathrm{H}, 17 \mathrm{H}$ ).
3 - The video RAM is a dual port ram. That means that it can be addressed either from the Core or from the OSD circuitry itself. To reduce the complexity of the circuitry, and thus its cost, some restrictions have been introduced in the use of the OSD.

## ON-SCREEN DISPLAY (Continued)

a. The Core can Only write to any of the 86 locations (either video RAM or control registers).
b. The Core can Only write to any of the leading 85 locations when the OSD oscillator is OFF. Only the last location (control register 17H in page 6) can be addressed at any time. This is the Global Enable Register, which contains only the GE bit. If it is set, the OSD is on, if it is reset the OSD is off.
4 - The timing of the on/off switching of the OSD oscillator is the following:
a. GE bit is set. The OSD oscillator will start on the next VSYNC signal.
b. GE bit is reset. The OSD oscillator will be immediately switched off.
To avoid a bad visual impression, it is important that the GE bit is set before the end of the flyback time when changing characters. This can be done inside the VSYNC interrupt routine. The following diagram can explain better:

Figure 74. OSD Oscillator ON/OFF Timing

## Notes:

A. Picture time: 20 mS in PAL/SECAM.
B. VSYNC interrupt, if enabled.
C. Starting of OSD oscillator, if $\mathrm{GE}=1$.
D. Flyback tıme.

When modifying the picture display (i.e.: a bar graph for an analog control), it is important that the switching on of the GE bit is done before the the end of the flyback time ( D in Figure 67). If the GE bit is set after the end of the flyback time then the OSD will not start until the begining of the next frame. This results in one frame being lost and will result in a Flicker on the screen. One method to be sure to avoid the flicker is to wait for the VSYNC interrupt at the start of the flyback; once the VSYNC interrupt is detected, then the GE bit can be set to zero, the characters changed, and the the GE set to one. All this should occur before the end of the flyback time in order not to loose a frame. The correct edge of the interrupt must be chosen. The VSYNC pin may alternatively be sampled by software in order to know the status; this can be done by reading the pin PB2 (VSYNC).
6 - An OSD end of line Bar is present in the ST63PXX piggyback and ST63XX ROM devices when using the background mode. If this bar is present with software running in the piggybacks then it is also present on the ROM mask version. If the end of line bar is seen to be eliminated by software in the piggyback, then it is also be eliminated in the ROM mask version.
The bar appears at the end of the line in the background mode when the last character is a space character and the first format character is defined with $\mathrm{S}=0$ (size 0 ). The bar is the color of the background defined by the space character. To eliminate bar:
a. If two backgrounds are used then the bar should be moved off the screen by using large word spaces instead of character spaces. If there are not enough spaces before the end of the line, then the location of the valid characters should be moved so they appear at the end of the line (and hence no bar); positioning can be compensated using the horizontal start register.
b. If only one background is used, then the other background should be transparent in order to eliminate the bar.
7 - The OSD oscillator external network should consist of a capacitor on each of the OSD oscillator pins to ground together with an inductance between the the pin. The user should select the two capacitors to be the same value (15pF to 25 pF each is recommended). The inductance is chosen to give the desired OSD oscillator frequency for the application (normally $56 \mu \mathrm{H}$ ).

## 14-BIT VOLTAGE SYNTHESIS TUNING PERIPHERAL (ST6356,57,58 only)

The ST635X on-chip voltage synthesis tuning peripheral has been integrated to allow the generation of tuning reference voltage in low/mid end TV set applications. The peripheral is composed of a 14bit counter that allows the conversion of the digital content in a tuning voltage, available at the VS output pin, by using PWM and BRM techniques. The 14-bit counter gives 16384 steps which allows a resolution of approximately 2 mV over a tuning voltage of 32 V ; this corresponds to a tuning resolution of about 40 KHz per step in UHF band (the actual value will depend on the characteristics of the tuner).
The tuning word consists of a 14-bit word contained in the registers VSDATA1 (location OEDH) and VSDATA2 (location OEEH). Course tuning (PWM) is performed using the seven MSBit, while the fine tuning (BRM) is performed using the data in the seven LSBIT. With all zeros loaded the output is zero ; as the tuning voltage increseses from all zeros, the number of pulses in one period increses to 128 with all pulses being the same width. For values larger than 18, the PWM takes over and the number of pulses in one period remains constant at 128 , but the width changes. At the other end of the scale, when almost all ones are loaded, the pulses will start to link together and the number of pulses will decrease. When all ones are loaded, the output will be almost $100 \%$ high but will have a low pulse ( $1 / 16384$ of the high pulse).

## Output Details

Inside the on-chip Voltage Synthesis cell are included the register latches, a reference counter, PWM and BRM control circuitry ; the structure is one used in many devices currenlty in production from SGS-THOMSON (M106, M193, M293, M490/91/94). In the ST635X the clock for the 14-bit reference counter is 2 MHz derived from the 8 MHz system clock. From the circuit point of view, the seven most significant bits controls the course tuning, while the seven least significant bits the fine tuning. From the application and software point of view, the 14 bits can be considered as one binary number.
As already mentioned the course tuning consists of a PWM signal with 128 steps ; we can consider the fine tuning to cover 128 course tuning cycles. The addition of pulses is described in the following Table 18.

Table 18. Fine Tuning Pulse Addition

| Fine Tuning <br> $(7 \mathrm{LSB})$ | N of Pulses added at <br> the following cycles <br> $(0 . .127)$ |
| :--- | :--- |
| 0000001 | 64 |
| 0000010 | 32,96 |
| 0000100 | $16,48,80,112$ |
| 0001000 | $8,24, \ldots .104,120$ |
| 0010000 | $4,12, \ldots .116,124$ |
| 0100000 | $2,6, \ldots . .122,126$ |
| 1000000 | $1,3, \ldots . .125,127$ |

The VS output pin has a standard drive push-pull output configuration.

## VS Tuning Cell Registers

Figure 75. VS Data Register 1

D7-DO. These are the 8 least significant VS data bits. Bit 0 is the LSB. This register is undefined on reset.

Figure 76. VS Data Register 2

D7-D6. These bits are not used.
D5-DO. These are the 6 most significant VS data bits. Bit 5 is the MSB. This register is undefined on reset.

## SOFTWARE DESCRIPTION

The ST63XX software has been designed to fully use the hardware in the most efficient way possible while keeping byte usage to a minimum; in short to provide byte efficient programming capability. The ST63XX Core has the ability to set or clear any register or RAM location bit of the Data space with a single instruction. Furthermore, the program may branch to a selected address depending on the status of any bit of the Data space. The carry bit is stored with the value of the bit when the SET or RES instruction is processed.

## Addressing Modes

The ST63XX Core has nine addressing modes which are described in the following paragraphs. The ST63XX Core uses three different address spaces: Program space, Data space, and Stack space. Program space contains the instructions which are to be executed, the data for immediate mode instructions, and in this space is physically allocated the data ROM which is addressed as data space. Data space contains the Accumulator, the $X, Y, V$ and $W$ registers, the Core control registers, peripheral and Input/Output registers, the RAM locations and the window to address the Data ROM (physically located into the program memory) locations (for storage of tables and constants). Stack space contains six 12-bit RAM bytes used to stack the return addresses for subroutines and interrupts.
Immediate. In the immediate addressing mode, the operand of the instruction follows the opcode location. As the operand is a ROM byte, the immediate addressing mode is used to access constants which do not change during program execution (e.g., a constant used to initialize a loop counter).
Direct. In the direct addressing mode, the address of the byte that is processed by the instruction is stored in the location that follows the opcode. Direct addressing allows the user to directly address the 256 bytes in Data space memory with a single two-byte instruction.
Short Direct. The Core can address the four RAM registers X,Y,V,W (locations $80 \mathrm{H}, 81 \mathrm{H}, 82 \mathrm{H}, 83 \mathrm{H}$ ) in the short-direct addressing mode. In this case, the instruction is only one byte long and the selection of the location to be processed is contained in the opcode. Short direct addressing is a subset of the direct addressing mode. (Note : 80H and 81H are also indirect registers).
Extended. In the extended addressing mode, the 12 -bit address needed to define the instruction is
obtained by concatenating the four less significant bits of the opcode with the byte following the opcode. The instructions (JP, CALL) that use the extended addressing mode are able to branch any address of the directly addressable Program space. An extended addressing mode instruction is two-byte long.
Program Counter Relative. The relative addressing mode is only used in conditional branch instructions. The instruction is used to perform a test and, if the condition is true, a branch with a span of -15 to +16 locations around the address of the relative instruction. If the condition is not true, the instruction that follows the relative instruction is executed. The relative addressing mode instruction is onebyte long. The opcode is obtained by adding the three most significant bits that characterize the kind of test, one bit that determines whether the branch is a toward (when it is 0 ) or backward (when it is 1 ) branch and the four less significant bits that give the span of the branch ( 0 H to FH ) that must be added or subtracted to the address of the relative instruction to obtain the address of the branch.
Bit Direct. In the bit direct addressing mode, the bit to be set or cleared is part of the opcode, and the byte following the opcode points to the address of the byte in which the specified bit must be set or cleared. Thus, any bit in the 256 directly addressable locations of Data space memory can be set or cleared.
Bit Test \& Branch. The bit test and branch addressing mode is a combination of direct addressing and relative addressing. The bit test and branch instruction is three-byte long. The bit identification and the tested condition are included in the opcode byte. The address of the byte to be tested follows immediately the opcode in the Program space. The third byte is the jump displacement, which is in the range from -126 to +129 . This displacement can be determined using a label, which is converted by the assembler.
Indirect. In the indirect addressing mode, the byte processed by the register-indirect instruction is at the address pointed by the content of one of the indirect registers, X or $\mathrm{Y}(80 \mathrm{H}, 81 \mathrm{H})$. The indirect register is selected by the bit 4 of the opcode. A register indirect instruction is one byte long.
Inherent. In the inherent addressing mode, all the information necessary to execute the instruction is contained in the opcode. These instructions are one byte long.

## SOFTWARE DESCRIPTION (Continued)

## Instruction Set

The ST63XX Core has a set of 40 basic instructions. When these instructions are combined with nine addressing modes, 244 usable opcodes can be obtained. They can be divided into six different types : load/store, arithmetic/logic, conditional branch, control instructions, jump/call, bit manipulation. The following paragraphs describe the dif-
ferent types. All the instructions within a given type are presented in individual tables.
Load \& Store. These instructions use one,two or three bytes in relation with the addressing mode. One operand is the Accumulator for LOAD and the other operand is obtained from data memory using one of the addressing modes. For LOAD Immediate one operand can be any of the 256 data space bytes while the other is always an immediate data. Refer to Table 19.

Table 19. Load \& Store instructions

Arithmetic and Logic. These instructions are used to perform the arithmetic calculations and logic operations. In AND, ADD, CP, SUB instructions one operand is always the accumulator while the other
can be either a data space memory content or an immediate value in relation with the addressing mode. In CLR,DEC,INC instructions the operand can be any of the 256 data space addresses. In COM, RLC, SLA the operand is always the accumulator. Refer to Table 20.

| e | 5 Bit Displacement |
| b | 3 Bit Address |
| mr | 1byte dataspace address |
| nn | 1 byte immedlate data |
| abc | 12 bit address |
| ee | 8 bit Displacement |

## ABSOLUTE MAXIMUM RATINGS

This product contains devices to protect the inputs against damage due to high static voltages, however it is advised to take normal precaution to avoid application of any voltage higher than maximum rated voltages.
For proper operation it is recommended that VI and VO must be higher than VSS and smaller than VDD. Reliability is enhanced if unused inputs are connected to an appropriated logic voltage level (VDD or VSS).

Power Considerations. The average chip-junction temperature. Tj , in Celsius can be obtained form.:

$$
T j=T A+P D \times R t h J A
$$

Where: TA = Ambient Temperature,
RthJA = Package thermal resistance (junction-to ambient),
PD $=$ Pint + Pport,
Pint $=I_{D D} \times V_{D D}$ (chip internal power),
Pport $=$ Port power dissipation (determined by the user).

| Symbol | Parameter | Value | Unit |
| :---: | :---: | :---: | :---: |
| VDD | Supply Voltage | -0.3 to 7.0 | V |
| $\mathrm{V}_{1}$ | Input Voltage (AFC IN) | VSS -0.3 to +13 | V |
| $V_{1}$ | Input Voltage (Other Inputs) | VSS -0.3 to $\mathrm{V}_{\text {DD }}+0.3$ | V |
| Vo | Output Voltage (Port A, DA0-3, BSW0-3, OUT1) | $V_{S S}-0.3$ to +13 | V |
| Vo | Output Voltage (Other Inputs) | VSS -0.3 to VDD +0.3 | V |
| 10 | Current Drain per Pin Excluding VDD, VSS, Port A | $\pm 10$ | mA |
| 10 | Current Drain per Pin (Port A) | $\pm 50$ | mA |
| IVḊD | Total Current into VDD (source) | 50 | mA |
| IVss | Total Current out of VSS (sink) | 150 | mA |
| Tj | Junction Temperature | 150 | ${ }^{\circ} \mathrm{C}$ |
| Tsta | Storage Temperature | -60 to 150 | ${ }^{\circ} \mathrm{C}$ |

Note: Stresses above those listed as "absolute maximum ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these conditions is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

## THERMAL CHARACTERISTIC

| Symbol | Parameter | Test Conditions | Value |  |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Min. | Typ. | Max. |  |
| RthJA | Thermal Resistance | PDIP40 PSDIP42 PDIP48 |  |  | 38 39 40 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

## RECOMMENDED OPERATING CONDITIONS

| Symbol | Parameter |  | Test Conditions | Value |  |  |

| $\mathrm{V}_{\mathrm{DD}}$ | Operating Supply Voltage |  | 4.5 |  | 5.5 | V |
| fosC | Oscillator Frequency <br> RUN \& WAIT Modes |  | 8.0 | 8.1 | MHz |  |
| fosDosC | On-Screen Display Oscillator <br> Frequency |  |  |  | 8.0 | MHz |

## EEPROM INFORMATION

The ST63XX EEPROM macrocell and the single poly EEPROM process have been specially de-
veloped to achieve 1.000.000 Write/Erase cycles and a 10 years data retention.

## DC ELECTRICAL CHARACTERISTICS

## Notes:

1. A clock other than 8 MHz will affect the frequency response of those peripherals ( $\mathrm{D} / \mathrm{A}, 62.5 \mathrm{KHz}$ and SPI ) whose clock is derived from the system clock.
2. The fall tumes of PORT A have been reduced in order to avoid current spikes while maintaining a high drive capability
3. Not $100 \%$ Tested
4. Based on extrapolated data

## ORDERING INFORMATION

The following chapter deals with the procedure for transfer the Program/Data ROM codes to SGSTHOMSON.

Communication of the ROM Codes. To communicate the contents of Program /Data ROM memories to SGS-THOMSON, the customer has to send:

- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS 5" diskette) for the PROGRAM Memory
- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS 5 " diskette) for the ODD and EVEN ODD OSD Characters
- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS 5" diskette) for the EEPROM initial content (this file is optional)
- a filled Option List form as described in the OPTION LIST paragraph.
The program ROM should respect the ROM Memory Map as in Table 26.
The ROM code must be generated with ST6 assembler. Before programming the EPROM, the buffer of the EPROM programmer must be filled with FFH. For shipment to SGS-THOMSON the EPROMs should be placed in a conductive IC carrier and packaging carefully.

Table 26. ROM Memory Map

| ROM Page | Device Address | EPROM <br> Address (1) | Description |
| :---: | :---: | :---: | :---: |
| Page 0 | $\begin{aligned} & 0000 \mathrm{H}-007 \mathrm{FH} \\ & 0080 \mathrm{H}-07 \mathrm{FFH} \end{aligned}$ | $\begin{aligned} & 0000 \mathrm{H}-007 \mathrm{FH} \\ & 0080 \mathrm{H}-07 \mathrm{FFH} \end{aligned}$ | Reserved User ROM |
| Page 1 "STATIC" | $\begin{aligned} & \text { 0800H-0F9FH } \\ & \text { 0FAOH-OFEFH } \\ & \text { 0FFOH-0FF7H } \\ & \text { 0FF8H-0FFBBH } \\ & \text { OFFCH-OFFDH } \\ & \text { OFFEH-OFFFH } \end{aligned}$ | $\begin{aligned} & \text { 0800H-0F9FH } \\ & \text { 0FAOH-0FEFFH } \\ & \text { 0FFOH-0FF7H } \\ & \text { 0FF8H-0FFBH } \\ & \text { OFFCH-0FFFDH } \\ & \text { OFFEH-0FFFFH } \end{aligned}$ | User ROM Reserved Interrupt Vectors Reserved NMI Vector Reset Vector |

| PAGE 3 | $\begin{aligned} & 0000 \mathrm{H}-000 \mathrm{FH} \\ & 0010 \mathrm{H}-07 \mathrm{FFH} \end{aligned}$ | $\begin{aligned} & 1800 \mathrm{H}-180 \mathrm{FH} \\ & 1810 \mathrm{H}-1 \mathrm{FFFH} \end{aligned}$ | Reserved user ROM |

Note: 1. EPROM addresses are related to the use of ST63P2X/P5X piggyback emulation devices.

## ORDERING INFORMATION (Continued)

## Customer EEPROM Initial Contents: Format

a. The content should be written into an INTEL INTELLEC format file.
b. The starting address in 000 h and the end in 7 Fh .
c. Undefined or don't care bytes should have the content FFH.
OSD Test Character. In order to allow the testing of the on-chip OSD macrocell the following character must be provided at the fixed 3FH (63).
Listing Generation \& Verification. When SGSTHOMSON receives the Codes, they are compared and a computer listing is generated from them. This listing refers extractly to the mask that will be used to produce the microcontroller. Then the listing is returned to the customer that must thoroughly check, complete, sign and return it to SGS-THOMSON. The signed list constitutes a part

Figure 79. OSD Test Character

of the contractual agreement for the creation of the customer mask. SGS-THOMSON sales organization will provide detailed information on contractual points.

## Ordering Information Table

| Sales Type | ROM/EEPROM Size | Temperature Range | Package |
| :---: | :---: | :---: | :---: |
| ST6326B1/XX | $8 \mathrm{~K} / 128$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PDIP40 |
| ST6327B1/XX | $8 \mathrm{~K} / 128$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PSDIP42 |
| ST6328B1/XX | $8 \mathrm{~K} / 128$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PDIP48 |
| ST6356B1/XX | $8 \mathrm{~K} / 128$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PDIP40 |
| ST6357B1/XX | $8 \mathrm{~K} / 128$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PSDIP42 |
| ST6358B1/XX | $8 \mathrm{~K} / 128$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PDIP48 |

Note: "XX" Is the ROM code identifier that is allocated by SGS-THOMSON after receipt of all required options and the related ROM file.

## 8 BIT HCMOS LOW COST MCUs FOR TV FREQUENCY \& VOLTAGE SYNTHESIS WITH OSD

- 8-bit Architecture
- HCMOS Technology
- 8 MHz Clock
- User Program ROM: 3884 byte
- Reserved Test ROM: 212 bytes
- Data ROM: User selectable size
- Data RAM:
- Data EEPROM: 48 bytes
- 28-Pin Dual in Line Plastic Package for the ST6340,42,44
- 40-Pin Dual in Line Plastic Package for the ST6346
- Up to 12, software programmable general purpose Inputs/Outputs
- 3 Inputs for keyboard scan (KBYO-2)
- Up to 4 High voltage outputs (BSWO-2)
- Two Timers each including an 8-bit counter with a 7-bit programmable prescaler
- Digital Watchdog Function
- Up to 4 6-Bit PWM D/A Converters
- 62.5 KHz Output Pin
- AFC A/D converter with 0.5 V resolution
- 4 interrupt vectors (IRIN/NMI, Timer $1 \& 2$, VSYNC)
- 14-bit counter for Voltage Synthesis Tuning (Not available on ST6342)
- On-chip clock oscillator
- 2 Lines by 15 Characters On-Screen Display Generator with 64 Characters
- Byte efficient instruction set
- Bit test and jump instructions
- Wait and Bit Manipulation instructions
- True LIFO 6-level stack
- The development tool of the ST63 microcontrollers consists of the ST63TVS-EMU emulation and development system to be connected via a standard RS232 serial line to an MS-DOS Personal Computer.

## GENERAL DESCRIPTION

The ST634X microcontrollers are members of the 8 -bit HCMOS ST63XX family, a series of devices specially oriented to TV applicatıons. Different pinout configurations are available to give the maximum application and cost flexibility. All ST63XX members are based on a building block approach: a common core is surrounded by a combination of on-chip peripherals (macrocells) avalable from a standard library. These peripherals are designed with the same Core technology providing full compatibility and short design time. Many of these macrocells are specially dedicated to TV applications. The macrocells of the ST634X family: two Timer peripherals each including an 8 -bit counter with a 7 -bit software programmable prescaler (Timer). a digital hardware activated watchdog function (DHWD), four 6-bit PWM D/A converters, an AFC A/D converter with 0.5 V resolution, a 14 -bit Voltage Synthesis tuning peripheral, an on-screen display (OSD) with 15 characters per line, 64 characters. In addition all these devices have 4 K of ROM, 64 bytes of data RAM and 48 bytes of EEPROM. Refer to pin configurations figures and to ST634X device summary (Table 1) for the definition of family members and a summary of differences among the different types.

## PIN DESCRIPTION

$V_{D D}$ and $V_{S s}$. Power is supplied to the MCU using these two pins. $V_{D D}$ is power and $V_{S s}$ is the ground connection.
OSCIN, OSCOUT. These pins are internally connected to the on-chip oscillator circuit. A quartz crystal or a ceramic resonator can be connected between these two pins in order to allow the correct operatıon of the MCU with varıous stability/cost trade-offs. The OSCIN pin is the input pin, the OSCOUT pin is the output pin. Refer to ON-CHIP CLOCK OSCILLATOR description for additional information.
$\overline{\text { RESET. The active low } \overline{\text { RESET }} \text { pin is used to start }}$ the microcontroller to the beginning of its program. Refer to RESET description for additional information.
TEST. The TEST (mode select) pin is used to place the MCU into special operating mode. If TEST is held at $V_{S S}$ the MCU enters the normal operating mode. If TEST is held at Vod when RESET is active the test operating mode is automatically selected (the user should connect this pin to $\mathrm{V}_{\text {SS }}$ for normal operation). Refer to TEST mode description for additional information.
PAO-PA7. These 8 lines are organized as one I/O port (A). Each line may be configured as either an input or as an output under software control of the
data direction register. Port A has an open-drain ( 5 V drive) output configuration. Refer to I/O PORT description for additional information.
PB0-PB3. These 4 lines are organized as one I/O port (B). Each line may be configured as either an input with or without internal pull-up resistor or as an output under software control of the data direction register. PB0-PB4 have a push-pull configuration in output mode. PB2 and PB3 lines are connected to the VSYNC and HSYNC control signals of the OSD cell ; to provide the right signals to the OSD these I/O lines should be programmed in input mode and the user can read "on the fly" the state of VSYNC and HSYNC signals. PB2 is connected with the vertical synchronization signal VSYNC input. The active polarity of this signal is software controlled. PB3 is connected with the horizontal synchronization signal input HSYNC. Oscillator is synchronous with the change to low state. Oscillation stops while signal is in the high state. A ROM mask option is available to change the polarity of this signal. Refer to I/O port and pin configuration description for additional information.
PC2-PC6. These 5 lines are organized as one I/O port (C). Each line may be configured as either an input with or without internal pull-up resistor or as an output under software control of the data direction register. PC2 and PC4 have a push-pull configuration in output mode while PC3, PC5-PC6 (OSD signals) are open-drain ( 5 V drive). PC3, PC5 and PC6 lines when in output modes are "ANDed" with the character and blank signals of the OSD cell. PC3 is connected with the OSD BLANK signal, PC5 and PC6 with the OSD R and G signals. These signals are active high. PC2 is also used as TV set On-Off switch (5V drive). Refer to I/O port and pin configuration description for additional information.
DAO-DA3. These pins are the four PWM D/A outputs (with 32 KHz repetition) of the 6 -bit on-chip D/A converters. The PWM function can be disabled by software and these lines can be used as general purpose open-drain outputs ( 12 V drive). Refer to D/A converter description for additional information.
IRIN. This pin is the external NMI of the MCU. This pin is not available on ST634X.
OUT1. This pin is the 62.5 KHz output specially suited to drive multi-standard chroma processors. This function can be disabled by software and the pin can be used as general purpose open-drain output (12V drive). Refer to D/A converter description for additional information.
BSW0-BSW3. These output pins can be used to select up to 4 tuning bands. These lines are configured as open-drain outputs (12V drive). Refer to AFC description for additional information.

## PIN DESCRIPTION（Continued）

KBYO－KBY2．These pins are input only and can be used for keyboard scan．They have CMOS threshold levels with schmitt trigger and on－chip $100 \mathrm{~K} \Omega$ pull－up resistors．Refer to AFC description for additional information．
AFC．This is the input of the on－chip 10 levels comparator that can be used to implement the AFC function．This pin is an high impedance input able to withstand signals with a peak amplitude up to 12 V ． Refer to AFC description for additional information．
OSDOSCIN，OSDOSCOUT．These are the On Screen display oscillator terminals．An oscillation capacitor and coil network have to be connected to provide the right signal to the OSD．
HSYNC，VSYNC．These are the horizontal and vertical synchronization pins．The active polarity of these pins to the OSD macrocell can be selected by
the user as ROM mask option．If the device is specified to have negative logic inputs，then when these signals are low the OSD oscillator stops．If the device is specified to have positive logic inputs， then when these signals are high the OSD oscillator stops．Refer to OSD description for additiona infor－ mation，
R，G，BLANK．Outputs from the OSD．R，and G are the color outputs while BLANK is the blanking output．All outputs are open－drain．The active po－ larity of these pins can be selected by the user as ROM mask option．Refer to the pin configurations for additional information．
VS．This is the output pin of the on－chip 14－bit voltage synthesis tuning cell（VS）．The tuning sig－ nal present at this pin gives an approximate resol－ ution of 40 KHz per step over the UHF band．This line is a push－pull output with standard drive（Not available on ST6342）．

Table 2．ST634X Pin Summary

| Pin Function | Description |
| :--- | :--- |
| DA0 to DA3 | Output，Open－Drain，12V |
| BSW0 to BSW3 | Output，Open－Dran，12V |

| VDD，VSS | Power Supply Pins |

## ST63XX CORE

The Core of the ST63XX Family is implemented independently from the l/O or memory configuration. Consequently, it can be treated as an independent central processor communicating with $1 / \mathrm{O}$ and memory via internal addresses, data, and control busses. The in-core communication is arranged as shown in the following block diagram figure; the controller being externally linked to both the reset and the oscillator, while the core is linked to the dedicated on-chip macrocells peripherals via the serial data bus and indirectly for interrupt purposes through the control registers.

## Registers

The ST63XX Family Core has five registers and three pairs of flags available to the programmer. They are shown in Figure 7 and are explained in the following paragraphs together with the program and data memory page registers.
Accumulator (A). The accumulator is an 8 -bit general purpose register used in all arithmetic calculations, logical operations, and data manipulations. The accumulator is addressed in the data space as RAM location at the FFH address.

Figure 7. ST63XX Core Programming Model

Figure 6. ST63XX Core Block Diagram

## ST63XX CORE (Continued)

Accordingly, the ST63XX instruction set can use the accumulator as any other register of the data space.
Indirect Registers (X, Y). These two indirect registers are used as pointers to the memory locations in the data space. They are used in the register-indirect addressing mode.These registers can be addressed in the data space as RAM locations at the $80 \mathrm{H}(\mathrm{X})$ and $81 \mathrm{H}(\mathrm{Y})$ addresses. They can also be accessed with the direct, short direct, or bit direct addressing modes. Accordingly, the ST63XX instruction set can use the indirect registers as any other register of the data space.
Short Direct Registers (V, W). These two registers are used to save one byte in short direct addressing mode. These registers can be addressed in the data space as RAM locations at the $82 \mathrm{H}(\mathrm{V})$ and $83 \mathrm{H}(\mathrm{W})$ addresses. They can also be accessed with the direct and bit direct addressing modes. Accordingly, the ST63XX instruction set can use the short direct registers as any other register of the data space.

## Program Counter (PC)

The program counter is a 12 -bit register that contains the address of the next ROM location to be processed by the core. This ROM location may be an opcode, an operand, or an address of operand. The 12 -bit length allows the direct addressing of 4096 bytes in the program space. The PC value is incremented, after it is read for the address of the current instruction, by sending it through the ALU, so giving the address of the next byte in the program. To execute relative jumps the PC and the offset values are shifted through the ALU, where they will be added, and the result is shifted back into the PC. The program counter can be changed in the following ways:

> JP (Jump) instruction . . . . PC= Jump address
> CALL instruction . . . . . . . PC= Call address

Relative Branch
instructions . . . . . . . . . PC= PC+offset
Interrupt . . . . . . . . . . PC= Interrupt vector

Reset . . . . . . . . . . . . .PC= Reset vector
Test mode . . . . . . . . . .PC=Test mode vector (1)
RET \& RETI instructions . . .PC= Pop (stack)
Normal instruction . . . . .PC= PC +1
Note: 1. Not available to the user.

## Flags (C, Z)

The ST63XX Core includes three pairs of flags that correspond to 3 different modes: normal mode, interrupt mode and Non-Maskable-Interrupt-Mode. Each pair consists of a CARRY flag and a ZERO flag. One pair (CN, ZN) is used during normal operation, one pair is used during the interrupt mode ( $\mathrm{Cl}, \mathrm{Zl}$ ) and one is used during the not-maskable interrupt mode (CNMI, ZNMI).
The ST63XX Core uses the pair of flags that corresponds to the actual mode: as soon as an interrupt (resp. a Non-Maskable-Interrupt) is generated, the ST63XX Core uses the interrupt flags (resp. the NMI flags) instead of the normal flags. When the RETI instruction is executed, the normal flags (resp. the interrupt flags) are restored if the MCU was in the normal mode (resp. in the interrupt mode) before the interrupt. Should be observed that each flag set can only be addressed in its own routine (Not-maskable interrupt, normal interrupt or main routine). The interrupt flags are not cleared during the context switching and so, they remain in the state they were at the exit of the last routine switching.
The Carry flag is set when a carry or a borrow occurs during arithmetic operations, otherwise it is cleared. The Carry flag is also set to the value of the bit tested in a bit test instruction, and participates in the rotate left instruction.
The Zero flag is set if the result of the last arithmetic or logical operation was equal to zero, otherwise it is cleared.
The switching between these three sets is automatically performed when an NMI, an interrupt and a RETI instructions occur. As the NMI mode is automatically selected after the reset of the MCU, the ST63XX Core uses at first the NMI flags. Refer to INTERRUPT description for additional information.

## ST63XX CORE (Continued)

## Stack

The ST63XX Core includes true LIFO hardware stack that eliminates the need for a stack pointer. The stack consists of six separate 12-bit RAM locations that do not belong to the data space RAM area. When a subroutine call (or interrupt request) occurs, the contents of each level is shifted into the next level while the content of the PC is shifted into the first level (the value of the sixth level will be lost). When subroutine or interrupt return occurs (RET or RETI instructions), the first level register is shifted back into the PC and the value of each level is shifted back into the previous level. These two operating modes are described in Figure 8. Since the accumulator, as all other data space registers, is not stored in this stack the handling of this registers shall be performed inside the subroutine.

Figure 8. Stack Operation

The stack pointer will remain in its deepest position, if more than 6 calls or interrupts are executed, so that the last return address will be lost. It will also remain in its highest position if the stack is empty and a RET or RETI is executed. In this case the next instruction will be executed.

## Memory Registers

Figure 9. Data RAM Bank Register

The DRBR register can be addressed like a RAM location in the Data Space at the E8H address, nevertheless it is write-only register that can not be accessed with single-bit operations. This register is used to select the desired 64-byte RAM/EEPROM bank of the Data Space. The number of the bank has to be loaded in the DRBR register and the instruction has to point to the selected location as it was in the 0 bank (from 00 H address to 3FH address). This register is cleared during the MCU initialization (the Data space 0 bank is automatically addressed after the Reset). Refer to the Data Space description for additional information. The DRBR register is not modified when a interrupt or a subroutine occurs.

Figure 10. Data ROM Window Register

| DWR <br> Data ROM Window Register <br> (C9H, Write Only) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\qquad$$D 7$ D6 D5 D4 D3 D2 D1 D0 |  |  |  |  |  |

The DWR register can be addressed like a RAM location in the Data Space at the C 9 H address, nevertheless it is write-only register that can not be accessed with single-bit operations. This register is used to move up and down the 64-byte read-only data window (from the 40 H address to 7FH address of the Data Space) along the ROM memory of the MCU by step of 64 bytes. The effective address of the byte to be read as a data in the ROM memory is obtained by the concatenation of the 6 less significant bits of the address given in the instruction (as less significant bits) and the content of the DWR register (as most significant bits). Refer to the Data Space description for additional information.

## MEMORY SPACES

The MCUs operate in three different memory spaces: Program Space, Data Space, and Stack Space. A description of these spaces is shown in Figure 11 and Figure 12.

Figure 11. ST634X Data Space

## MEMORY SPACES (Continued)

Figure 13. ST63XX Memory Addressing Description Example

## Program Space

The program space is physically implemented in the ROM memory and includes all the instructions that are to be executed, as well as the data required for the immediate addressing mode instructions, the reserved test area and user vectors. It is addressed thanks to the 12-bit Program Counter register (PC register) and so, the ST63XX Core can directly address up to 4 K bytes of Program Space. On ST634X a total of 4096 bytes of ROM have been implemented; 3884 are available as user ROM while 214 are reserved for testing.

## Data Space

The instruction set of the ST63XX Core operates on a specific space, named Data Space that contains all the data necessary for the processing of the program. The Data Space allows the addressing of RAM memory, EEPROM memory, ST63XX Core/peripheral registers, and read-only data such as constants and the look-up tables.
Data ROM Addressing. All the read-only data are physically implemented in the ROM memory in which the Program Space is also implemented. The

ROM memory therefore contains the program to be executed and also the constants and the look-up tables needed for the program. The locations of Data Space in which the different constants and look-up tables are addressed by the ST63XX Core can be considered as being a 64-byte window through which it is possible to access to the readonly data stored in the ROM memory. This window is located from the 40 H address to the 7FH address in the Data space and allows the direct reading of the bytes from the 000 H address to the 03FH address in the ROM memory. All the bytes of the ROM memory can be used to store either instructions or read-only data. Indeed, the window can be moved by step of 64 bytes along the ROM memory in writing the appropriate code in the Write-only Data ROM Window register (DWR register, location $\mathrm{C} 9 \mathrm{H})$. The effective address of the byte to be read as a data in the ROM memory is obtained by the concatenation of the 6 less significant bits of the address in the Data Space (as less significant bits) and the content of the DWR register (as most significant bits). So when addressing location 40 H of data space, and 0 is loaded in the DWR register, the physical addressed location in ROM is 00 H .

Note 1. EPROM addresses are related to the use of ST63PXX piggyback emulation devices.

Figure 14. Data ROM Window Register

D6,D7. This bit is not used however care should be taken to reset these bits to ensure compatibility with the emulator and piggybacks.
DWR6-DWRO. These are the Data Rom Window bits that correspond to the upper bits of data ROM program space. This register is undefined after reset.
Notes Care is required when handling the DWR register as it is write only. For this reason, it is not allowed to change the DWR contents while executing interrupts drivers, as the driver cannot save and than restore its previous content. If it is impossible to avoid the writing of this register in interrupts drivers, an image of this register must be saved in a RAM location, and each time the program writes the DWR it writes also the image register. The image register must be written first, so if an interrupt occurs between the two instructions the DWR register is not affected.

## Data RAM/EEPROM/OSD RAM Addressing

In ST634X 64 bytes of data RAM are directly addressable in the data space from 80 H to BFH addresses. The 48 bytes of EEPROM memory and the OSD RAM can be addressed using the banks of 64 bytes located between addresses 00 H and 3 FH . The selection of the bank is done by programming the Data RAM Bank Switching register (DRBR register) located at the E8H address of the Data Space. In this way each bank of EEPROM or OSD RAM can be selected 64 bytes at a time. No more than one bank should be set at a time.

Figure 15. Data RAM Bank Register

D7. This bit is not used.
DRBR6, DRBR5. Each of these bits, when set, will select one OSD RAM register page.

## MEMORY SPACE (Continued)

DRBR4,DRBR3,DRBR2. Each of these bits, when set, will select one RAM page.
DRBR1,DRBRO. These bits select the EEPROM pages. Table 5 summarizes how to set the Data RAM Bank Register in order to select the various banks or pages.
This register is undefined after reset.

## Notes :

Care is required when handling the DRBR register as it is write only. For this reason, it is not allowed to change the DRBR contents while executing interrupts drivers, as the driver cannot save and than restore its previous content. If it is impossible to avoid the writing of this register in interrupts drivers, an image of this register must be saved in a RAM location, and each time the program writes the DRBR it writes also the image register.
The image register must be written first, so if an interrupt occurs between the two instructions the DRBR register is not affected.

Table 4. Data RAM Bank Register Set-up

| DRBR Value | Selection |
| :---: | :---: |
| 01 H | EEPROM Page 0 |
| 20 H | OSD Page 5 |
| 40 H | OSD Page 6 |

## EEPROM Description

Through the programming of the Data RAM Bank Register (DRBR=E8H) the user can select the bank or page leaving unaffected the way to address the static registers. The way to address the "dynamic" page is to set the DRBR as described in Table 4 (e.g. to select EEPROM page 0, the DRBR has to be loaded with content 01 H , see Data RAM/EEPROM/OSD RAM addressing for additional information). Bit 0 of the DRBR is dedicated to the EEPROM.
The EEPROM module is physically organized in 32 byte modules ( 2 modules per page) and does not require dedicated instructions to be accessed in reading or writing. The EEPROM is controlled by the EEPROM Control Register (EECR=EAH). Any EEPROM location can be read just like any other data location, also in terms of access time.
To write an EEPROM location takes about 5 mSec ( 10 mSec max ) and during this time the EEPROM is not accessible by the Core. A busy flag can be read by the Core to know the EEPROM status be-
fore trying any access. In writing the EEPROM can work in two modes: Byte Mode (BMODE) and Parallel Mode (PMODE). The BMODE is the normal way to use the EEPROM and consists in accessing one byte at a time. The PMODE consists in accessing 8 bytes per time.

Figure 16. EEPROM Control Register

D7. Not used
SB. WRITE ONLY. If this bit is set the EEPROM is disabled (any access will be meaningless) and the power consumption of the EEPROM is reduced to the leakage values.
D5, D4. Reserved for testing purposes, they must be set to zero.
PS. SET ONLY. Once in Parallel Mode, as soon as the user software sets the PS bit the parallel writing of the 8 adjacent registers will start. PS is internally reset at the end of the programming procedure. Note that less than 8 bytes can be written; after parallel programming the remaining undefined bytes will have no particular content.
PE. WRITE ONLY. This bit must be set by the user program in order to perform parallel programming (more bytes per time). If PE is set and the "parallel start bit" (PS) is low, up to 8 adjacent bytes can be written at the maximum speed, the content being stored in volatile registers. These 8 adjacent bytes can be considered as row, whose A7, A6, A5, A4, A3 are fixed while A2, A1 and A0 are the changing bytes. PE is automatically reset at the end of any parallel programming procedure. PE can be reset by the user software before starting the programming procedure, leaving unchanged the EEPROM registers.

## MEMORY SPACE (Continued)

BS. READ ONLY. This bit will be automatically set by the CORE when the user program modifies an EEPROM register. The user program has to test it before any read or write EEPROM operation; any attempt to access the EEPROM while "busy bit" is set will be aborted and the writing procedure in progress completed.
EN. WRITE ONLY. This bit MUST be set to one in order to write any EEPROM register. If the user program will attempt to write the EEPROM when $\mathrm{EN}=0$ the involved registers will be unaffected and the "busy bit" will not be set.
After RESET the content of EECR register will be 00 H .

## Notes :

When the EEPROM is busy $(B S=1)$ the EECR can not be accessed in write mode, it is only possible to read BS status. This implies that as long as the EEPROM is busy it is not possible to change the status of the EEPROM control register. EECR bits 4 and 5 are reserved for testing purposes, and the user must never set them to 1 .
Additional Notes on Parallel Mode. If the user wants to perform a parallel programming the first action should be the set to one the PE bit; from this moment the first time the EEPROM will be addressed in writing, the ROW address will be latched and it will be possible to change it only at the end of the programming procedure or by resetting PE without programming the EEPROM. After the ROW address latching the Core can "see" just one EEPROM row (the selected one) and any attempt to write or read other rows will produce errors. Do not read the EEPROM while PR is set.
As soon as PE bit is set, the 8 volatile ROW latches are cleared. From this moment the user can load data in the whole ROW or just in a subset. PS setting will modify the EEPROM registers corresponding to the ROW latches accessed after PE. For example, if the software sets PE and accesses EEPROM in writing at addresses $18 \mathrm{H}, 1 \mathrm{AH}, 1 \mathrm{BH}$ and then sets PS, these three registers will be modified at the same time; the remaining bytes will have no particular content. Note that PE is internally reset at the end of the programming procedure. This implies that the user must set PE bit between two parallel programming procedures. Anyway the user can set and then reset PE without performing any EEPROM programming. PS is a set only bit and is internally reset at the end of the programming procedure. Note that if the user tries to set PS while PE is not set there will not be any programming procedure and the PS bit will be unaffected. Consequently PS bit can not be set if EN is low. PS can be affected by the user set if, and only if, EN and PE bits are also set to one.

Warning : Parallel programming of the EEPROM with less than eight bytes may corrupt other bytes and should therefore be used with care, as here after underlined.
a. Reason for limitation:
betweeen PE (Parallel Enable) and PS (Parallel Start) of the EEPROM, the user writes up to eight bytes into the volatile data registers, a latch is also set to indicate which bytes have been accessed; the accessed bytes will be programmed when PS arrives. The logic is such that it is possible to set the latches of bytes which have NOT been accessed. The latches are set whenever ANY register in the banked dataspace (00h-3FH) is accessed for READ or WRITE between a PE and PS. The latch which is set will be determined by the three least significant bits of the register address. Only the latch is set, so finaal data of a corrupted byte after the parallel programming is always FFH.
Note: read operations also occur internally to the micro for most instructions. Even if bytes are not seen to be corrupted within the parallel programming routine, care should be taken, since they could become corrupted by an interrupt routine being serviced during loading of parallel bytes.
This is logic related and is not a marginality or race condition; piggyback devices perform in the same way as ROM devices. Parallel programming is tested with only LDI rr,nn instructions which do not corrupt other bytes.
b. To Avoid Corrupted Bytes:

- use Single Byte Mode, or
- always define all eight bytes in Parallel Piogramming Mode, or
- when programming less than eight bytes, the remaining EEPROM bytes should do not used by the program.
Additional Notes Regarding Differences Between ST63XX Devices and Corresponding Emulators. While PE is set, all the EEPROM page currently selected is accessible in reading and the writing of the bytes happens at the row to which belongs the last byte written before setting PS. The sequence: set PE, write in 10 H the value X , write in 21 H the value Y , set $P S$, will result in: 10 H unchanged, 20 H loaded with value $\mathrm{X}, 21 \mathrm{H}$ loaded with value Y . In the emulator bits 4 and 5 of the EECR are implemented. If the user set to 1 one or both of these bits the contents of the EEPROM will be destroyed. The user should use care in using EEPROM emulation as in general the emulator does not emulate the behaviour of the EEPROM when it is misused.

## STACK SPACE

The stack space consists of six 12 bit registers that are used tor stacking subioutine and interrupt return i.ddiesse:; pius tiie curient piogram counter register.

## TESIMODE

The test mode can be entered by connecting the TEST pin to an higin logic level when reset is active: tinis action enables the factory test mode. The user is recommended to avoid this situation for normal operation. (TES 「 piin should be tied to ground).

## INTERPUPT

The ST63XX Core can manage 4 different maskable mierrupt sources, plus one non-maskable interrupt source (top priority level interrupt). Each scuice is associated with a particular interrupt vec. tor that contains a Jump instruction to the related inteirupt service routine Each vector is located in the Progiam Space at a particular address (see rable 5). When a source provides an interrupt request. and the request processing is also enabled by the ST63XX Core. then the PC register is ionaed with the address of the iriterrupt vector (i.e. of the Jump instiuction). Finally, the PC is loaded with the address of the Jump instruction and the interlupt toutine is processed
the relationship between vector and source and the associated prority is hardware fixed for the diterent ST63XX devices. For some interrupt sources it is also possible to select by software the kind of event that will generate the interrupt.
All interrupts can be disabled by writing to the GEN bit (global interrupt enable) of the interrupt option iegister (address C8H) After a reset. ST63XX is in nun miaskable interrupt mode. so no interrupts will be accepted and $\mid V I M I$ flags will be used, until a rETI nistruction is executed If an interrupt is excouted. one spuctal cycle is mude by the core, cuing thiat the PC is set to the related interiupt veclor addiess A jump instruction at this address has to recirect program execution to the beginning of the related interiupi routine The interrupt detecting cycle. also resets the related interiupt flag (not avcilable to the user). so that another interiupt can be shied fur this curient vector. while its driver is undel execulion.
If additional interrupts arrive from the same source, they will be lost. Nivil can interrupt other interrupt routmes at any time, while other interrupts cannot interiupt each other. If more than one interrupt is weiting tor service. they are executed according to
their priority. The lower the number, the higher the priority. Priority is, therefore. fixed. Interrupts are checked during the last cycle of an instruction (RETI included). Level sensitive interrupts have to be valid during this period.
Table 5 details the different interrupt vectors/sources relationships.

## Table 5. Interrupt Vectors/Sources

 Relationships$\left[\begin{array}{c|c|c|}\hline \begin{array}{c}\text { Interrupt } \\ \text { Source }\end{array} & \begin{array}{c}\text { Associated } \\ \text { Vector }\end{array} & \text { Vector Address } \\ \hline \begin{array}{c}\text { IRIN/NMI } \\ \text { Pin (1) }\end{array} & \begin{array}{c}\text { Interrupt } \\ \text { Vector \# } 0 \text { (NMI) }\end{array} & \text { OFFCH-OFFDH } \\ \hline \text { None (2) } & \begin{array}{c}\text { Interrupt } \\ \text { Vector \# 1 }\end{array} & \text { OFF6H-OFF7H } \\ \hline \text { Vsync } & \begin{array}{c}\text { Interrupt } \\ \text { Vector \# 2 }\end{array} & \text { OFF4H-OFF5H } \\ \hline \text { Timer 1 } & \begin{array}{c}\text { Interrupt } \\ \text { Vector \# 3 } \\ \text { Interrupt } \\ \text { Vector \# 4 }\end{array} & \text { OFF2H OFF3H } \\ \hline \text { Timer 2 } & \text { OFFH-OFF1H } \\ \hline\end{array}\right.$

Notes
1 This pin is associated with the NMI Interiupt Vector Not available on ST6340
2 This vecior is not used in ST634X

## Interrupt Vectors/Sources

The ST63XX Core includes 5 different interrupt vectors in order to branch to 5 different interrupt routines. The interrupt vectors are located in the fixed (or static) page of the Program Space.
The interrupt vector associated with the non-maskable interrupt source is named interrupt vector \#0. It is located at the (FFCH,FFDH) addresses in the Program Space. On STC34X this vector is associated to the rising edge sensitive external interrupt pin.
The interrupt vectors located at addresses (FF6H.FF7H). (FF4H.FF5H), (FF2H.FF3H), (FFOH.FF1H) are named interiupt vectors \#1, \#2, \#3 and \#4 respectively. These vectors are associated with VSYNC (\#2), TIMER 1 (\#3) and TIMER 2 (\#4); Interrupt vector (\#1) is not used on ST6356.57.58. Refer to the Interrupt Detalls description for more information.

## INTERRUPT (Continued)

## Interrupt Priority

The non-maskable interrupt request has the highest priority and can interrupt any other interrupt routines at any time, nevertheless the other interrupts cannot interrupt each other. If more than one interrupt request is pending, they are processed by the ST63XX Core according to their priority level: vector \#1 has the higher priority while vector \#4 the lower. The priority of each interrupt source is hardware fixed.

## Interrupt Option Register

The Interrupt Option Register (IOR register, location C 8 H ) is used to enable/disable the individual interrupt sources and to select the operating mode of the external interrupt inputs. This register can be addressed in the Data Space as RAM location at the C 8 H address, nevertheless it is write-only register that can not be accessed with single-bit operations. The operating modes of the external interrupt inputs associated to interrupt vectors \#1 and \#2 are selected through bits 4 and 5 of the IOR register.

Figure 17. Interrupt Option Register

## D7. Not used.

EL1. This is the Edge/Level selection bit of interrupt \#1. When set to one, the interrupt is generated on low level of the related signal; when cleared to zero, the interrupt is generated on falling edge. The bit is cleared to zero after reset and as no interrupt source is associated to vector \#1 on ST63XX, the user must keep this bit to zero to avoid ghost interrupts from this source.

ES2. This is the edge selection bit on interrupt \#2. This bit is used on the ST63XX devices with on-chip OSD generator for VSYNC detection.
GEN. This is the global enable bit. When set to one all interrupts are globally enabled ; when this bit is cleared to zero all interrupts are disabled (including NMI).
D3 - D0. These bits are not used.

## Interrupt Procedure

The interrupt procedure is very similar to a call procedure; the user can consider the interrupt as an asynchronous call procedure. As this is an asynchronous event the user does not know about the context and the time at which it occurred. As a result the user should save all the data space registers which will be used inside the interrupt routines. There are separate sets of processor flags for normal, interrupt and non-maskable interrupt modes which are automatically switched and so these do not need to be saved.
The following list summarizes the interrupt procedure (refer also to Figure 18. Interrupt Processing Flow Chart):

- Interrupt detection
- The flags $C$ and $Z$ of the main routine are exchanged with the flags $C$ and $Z$ of the interrupt routine (resp. the NMI flags)
- The value of the PC is stored in the first level of the stack - The normal interrupt lines are inhibited (NMI still active)
- The edge flip-flop is reset
- The related interrupt vector is loaded in the PC.
- User selected registers are saved inside the interrupt service routine (normally on a software stack)
- The source of the interrupt is found by polling (if more than one source is associated to the same vector)
- Interrupt servicing
- Return from interrupt (RETI)
- Automatically the ST63XX core switches back to the normal flags (resp the interrupt flags) and pops the previous PC value from the stack
The interrupt routine begins usually by the identification of the device that has generated the interrupt request. The user should save the registers which are used inside the interrupt routine (that holds relevant data) into a software stack.
After the RETI instruction execution, the Core carries out the previous actions and the main routine can continue.

## INTERRUPT (Continued)

Figure 18. Interrupt Processing Flow-Chart

## ST634X Interrupt Details

IR Interrupt (\#0). The IRIN Interrupt is associated with the first interrupt \#0 (NMI, OFFCH). If enabled, then an interrupt will be generated on a rising edge at the pin. The IRIN pin is nt available on ST6340.

Interrupt (\#1). On ST634X no sources are associated to vector (\#1). To avoid any ghost interrupt due to interrupt (\#1) the user must keep to zero the EL1 bit of IOR register.
VSYNC Interrupt (\#2). The VSYNC Interrupt is connected to the interrupt \#2. When disabled the VSYNCINT signal is low. Bit 5 of the interrupt option register C 8 H is used to select the negative edge ( $B 2=0$ ) or the positive edge ( $B 2=1$ ); the edge will depend on the application. Note that once an edge has been latched, then the only way to remove the latched signal is to service the interrupt. Care must be taken not to generate spurious interrupts. This interrupt may be used for synchronize to the VSYNC signal in order to change characters in the OSD only when the screen is on vertical blanking (if desired). This method may also be used to blink characters.
TIMER 1 Interrupt (\#3). The TIMER 1 Interrupt is connected to the fourth interrupt \#3 (0FF2H) which detects a high to low level (latched in the timer). For more information on the timer interrupt refer to the timer section.
Timer 2 Interrupt (\#4). The TIMER 2 Interrupt is connected to the fifth interrupt \#4 (0FFOH) which detecty a high to low level (latched in the timer). For more information on the timer interrupt refer to the timer section.
Notes Global disable does not reset edge sensitive interrupt flags. These edge sensitive interrupts become pending again when global disabling is released. Moreover, edge sensitive interrupts are stored in the related flags also when interrupts are globally disabled, unless each edge sensitive interrupt is also individually disabled before the interrupting event happens. Global disable is done by clearing the GEN bit of Interrupt option register, while any individual disable is done in the control register of the peripheral. The on-chip Timer peripherals have an interrupt request flag bit (TMZ), this bit is set to one when the device wants to generate an interrupt request and a mask bit (ETI) that must be set to one to allow the transfer of the flag bit to the Core.

## RESET

The ST63XX devices can be reset in two ways: by the external reset input (RESET) tied low and by the hardware activated digital watchdog peripheral.

## RESET Input

The external active low reset pin is used to reset the ST63XX devices and provide an orderly software startup procedure. The activation of the Reset pin may occur at any time in the RUN or WAIT mode. Even short pulses at the reset pin will'be accepted since the reset signal is latched internally and is only cleared after 2048 clocks at the oscillator pin. The clocks from the oscillator pin to the reset circuitry are buffered by a schmit trigger so that an oscillator in start-up conditions will not give spurious clocks. The MCU is configured in the Reset mode as long as the signal of the RESET pin is low. The processing of the program is stopped and the standard Input/Output
ports (port A, port B and port C) are in the input state (except PC2). As soon as the level on the reset pin becomes high, the initialization sequence is executed. Refer to the MCU initialization sequence for additional information.

## Watchdog Reset

The ST63XX devices are provided with an on-chip hardware activated digital watchdog function in order to provide a graceful recovery from a software upset. If the watchdog register is not refreshed and the end-of-count is reached, then the reset state will be latched into the MCU and an internal circuit pulls down the reset pin. This also resets the watchdog which subsequently turns off the pull-down and activates the pull-up device at the reset pin. This causes the positive transition at the reset pin. The MCU will then exit the reset state after 2048 clocks on the oscillator pin.

Figure 19. Internal Reset Circuit

RESET (Continued)
Figure 20. Reset \& Interrupt Processing
Flow-chart

## Application Notes

An external resistor between $V_{D D}$ and the reset pin is not required because an internal pull-up device is provided. The user may prefer to add an external pull-up resistor.
An internal Power-on device does not guarantee that the MCU will exit the reset state when $V_{D D}$ is above 4.5 V and therefore the RESET pin should be externally controlled.

## MCU Initialization Sequence

When a reset occurs the stack is reset to program counter, the PC is loaded with the address of the

Figure 21. Restart Initialization Program Flow-chart

reset vector (located in the program ROM at addresses FFEH \& FFFH). A jump instruction to the beginning of the program has to be written into these locations. After a reset the interrupt mask is automatically activated so that the Core is in nonmaskable interrupt mode to prevent false or ghost interrupts during the restart phase. Therefore the restart routine should be terminated by a RETI instruction to switch to normal mode and enable interrupts. If no pending interrupt is present at the end of the reset routine, the ST63XX will continue with the instruction after the RETI; otherwise the pending interrupt will be serviced.

## WAIT \& STOP MODES

The STOP and WAIT mades havo been im plemented in the ST63. $\times$ Core in order to reduce the consumption of the device when the latter has no instruction to execute. These two modes are described in the following paragraphs. On ST63XX as the hardware activated digital watchdog function is present the STOP instruction is de-activated and any attempt to execute it will cause the automatic execution of a WAIT instruction.

## WAIT Mode

The configuration of the MCU in the WAIT mode occurs as soon as the WAIT instruction is executed. The microcontroller can also be considered as being in a "software frozen" state where the Core stops processing the instructions of the routine. the contents of the RAM locations and peripheral registers are saved as long as the power supply voltage is higher than the RAM retention voltage but where the peripherals are still working.
The WAIT mode is used when the user wants to reduce the consumption of the MCU when it is in idle. while not loosing count of time or monitoring of external events. The oscillator is not stopped in order to provide clock signal to the peripherals. The tımers counting may be enabled (writing the PSI bit in TSCR register) and the timer intcrrupt may be also enabled before entering the WAIT mode; this allows the WAIT mode to be left when timer interrupt occurs. If the exit from the WAIT mode is performed with a general RESET (either from the activation of the external pin or by watchdog reset) the MCU will enter a normal reset procedure as described in the RESET chapter. If an interrupt is generated during WAIT mode the MCU behaviour depends on the state of the ST63XX Core before the initialization of the WAIT sequence, but also of the kind of the interrupt request that is generated. This case will be described in the following paragraphs. In any case, the ST63XX Core does not generate any delay after the occurrence of the interrupt because the oscillator clock is still avallable.

## STOP Mode

On ST63XX the hardware watchdog is present and the STOP instruction has been de-activated Any attempt to execute a STOP will cause the automatic execution of a WAIT instruction.

## Exit from WAIT Mode

The following paragraphs describe the output pro cedure of the ST63XX Core from WAIT mode when
 secuence depends on the oriminal state of tho MCll (normal, interrupt or non maskable intorrupt nedio) before the start of the WAIT sequence. but alen of the type of the interrupt request that is gen rated
Normal Mode. If the ST63XX Core was in the m?:i routine when the WAIT instruction has been everited the ST63XX Core outputs from the wait mode as soon as any interrupt occurs; the related interrupt routine is executed and at the end of the interrupt service routinn the instruction that follows the WAIT instruction is executed if no other interrupts are pending.
Non-maskable Interrupt Mode. If the W/AIT in struction has been executed during the execution of the non-maskable interrupt routine, the ST63Y.X Core outputs from the wait mode as sonn as any interrupt occurs: the instruction that follows the WAIT instruction is executed and the ST63XX Core is still in the non-maskable interrupt mode even if an other interrupt has been generated.
Normal Interrupt Mode. If the ST63XX Core was in the interrupt mode before the initialization of the WAIT sequence, it outputs from the wat mode as soon as any interrupt occurs. Nevertheless. two case have to be considered:

- If the interrupt is a normal inte rrupt, the interiupt routine in which the WAIT was entered will be completed with the execution of the instruction that follows the WAIT and the ST63XX Core is still in the interrupt mode. At the end of this routine pending interrupts will be serviced in accordance to their prority.
- If the interrupt is a non ma-kable intemupt. tho non-maskable routine is procesend at first Then the routine in which the WAIT was entered will be completed with the execution of the instruc tion that follows the WAIT and the ST63XX Core is still in the normal interrupt mode

## Notes:

If all the interrupt sources are disabler! the re trat of the MCU can only be done by a Resent actr:'ation The Wait instruction is not executed if an enabint interrupt request is pending. In the STGZXX tho hardware activated digital watchdog function is present As the watchdog is always armated the STOP instruction is de-actrated and any attnmnt to execute the STOP instruction will cause an execution of a WAIT instruction.

## ON-CHIP CLOCK OSCILLATOR

The internal oscillator circuit is designed to require a minimum of external components. A crystal quartz, a ceramic resonator, or an external signal (provided to the OSCIN pın) may be used to generate a system clock with various stability/cost tradeoffs. The typical clock frequency is 8 MHz . Please note that different frequencies will affect the operation of those peripherals (D/As, SPI, 62.5 KHz OUT) whose reference frequencies are derived from the system clock.
The different clock generator options connection methods are shown in Figure 22, crystal specifications and suggested PC board layouts are given in Figure 23 and Figure 24. One machine cycle takes 13 oscillator pulses; 12 clock pulses are needed to incremert the PC while and additional 13th pulse is needed to stabilize the internal latches during memory addressing. This means that with a clock frequency of 8 MHz the machine cycle is $1.625 \mu \mathrm{Sec}$.
The crystal oscillator start-up time is a function of many variables: crystal parameters (especially RS), oscillator load capacitance (CL), IC parameters, ambient temperature, and supply voltage. It must be observed that the crystal or ceramic leads and circuit connections must be as short as possible. Typical values for CL 1 and CL2 are in the range of 15 pF to 22pF but these should be chosen based on the crystal manufacturers specification. Typical input capacitance for OSCIN and OSCOUT pins is 5 pF .
The oscillator cutput frequency is internally divided by 13 to produce the machine cycle and by 12 to produce the Timer and the Watchdog clock. A byte cycle is the smallest unit needed to execute any operation (i.e., increment the program counter). An instruction may need two, four, or five byte cycles to be executed (See Table 6).

Table 6. Instructions Timing with 8 MHz Clock

| Instruction Type | Cycles | Execution <br> Time |
| :--- | :---: | :---: |
| Branch if set/reset | 5 Cycles | $8.125 \mu \mathrm{~s}$ |
| Branch \& Subroutine Branch | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Eit Manipulation | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Load Instruction | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Arıthmetic \& Logıc | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Conditional Branch | 2 Cycles | $3.25 \mu \mathrm{~s}$ |
| Program Control | 2 Cycies | $3.25 \mu \mathrm{~s}$ |

## INPUT/OUTPUT PORTS

The ST63XX microcontrollers use three standard I/O ports ( $A, B, C$ ) with up to eight pins on each port; refer to the device pin configurations to see which pins are available.
Each line can be individually programmed either in the input mode or the output mode as follows by software.

- Output
- Input with on-chip pull-up resistor (selected by software)
- Input without on-chip pull-up resistor (selected by software)
In output mode the following hardware configurations are available:
- Open-drain output 5V (PAO-PA7)
- Open-drain output 5V (PC3, PC5, PC6)
- Push-pull output (PB0-PB3, PC2,PC4)

The lines are organized in three ports (port A,B.C). The ports occupies 6 registers in the data space. Each bit of these registers is associated with a particular line (for instance, the bits 0 of the Port A Data and Direction registers are associated with the PAO line of Port A).
There are three Data registers (DRA, DRB, DRC), that are used to read the voltage level values of the lines programmed in the input mode, or to write the logic value of the signal to be output on the lines configured in the output mode. The port Data Registers can be read to get the effective logic levels of the pins, but they can be also written by the user software, in conjunction with the related Data Direction Register, to select the different input mode options. Single-bit operations on I/O registers (bit set/reset instructions) are possible but care is necessary because reading in input mode is done from I/O pins and therefore they might be influenced by the external load, while writing will directly affect the Port data register causing an undesired changes of the input configuration. The three Data Direction registers (DDRA, DDRB,DDRB) allow the selection of the direction of each pin (input or output).
All the I/O registers can be read or written as any other RAM location of the data space, so no extra RAM cell is needed for port data storing and manipulation. During the initialization of the MCU, all the I/O registers are cleared and the input mode with pull-up is selected on all the pins thus avoiding pin conflicts (with the exception of PC2 that is set in output mode and is set low).

## INPUT/OUTPUT PORTS (Continued)

## Details of I/O Ports

When programmed as an input a pull-up resistor (if available) can be switched active under program control. When programmed as an output the I/O port will operate either in the push-pull mode or the open-drain mode according to the hardware fixed configuration as specified below.
Port A is available as an open-drain only (no pushpull programmability and no resistive pull-up in input mode) capable of withstanding 5 V .
Some Port B and C lines are also used as I/O buffers for signals coming from the on-chip OSD. In this case the final signal on the output pin is equivalent to a wired AND with the programmed data output. If the user needs to use the OSD, then the I/O line should be set in output mode while the open-drain configuration is harware fixed ; the corresponding data bit must set to one.
PB2 and PB3 must be programmed in input mode to provide the HSYNC and VSYNC signal to the OSD.
On ST634X the I/O pins with double or special functions are:

- PB2/VSYNC (connected to the OSD VSYNC signal)
- PB3/HSYNC (connected to the OSD HSYNC signal)
- PC2/ON-OFF, this I/O is specially suited for TV SET ON-OFF and for this reason at reset the related Data Direction bit will be automatically set to one (I/O line is in output mode), while the rest of the port is in input mode.
- PC3/BLANK (connected to the OSD Blank signal)
- PC5/R, PC6/G (connected to the OSD R-G signals)
All the Port A, B and C I/O lines have Schmitt-trigger input configuration with a typical hysteresis of 1 V .

## I/O Pin Programming

Each pin can be individually programmed as input or output with different input and output configurations. This is achieved by writing to the relevant bit in the data (DR) and data direction register (DDR). Table 8 shows all the port configurations that can be selected by the user software.

Table 7. I/O Port Options Selection

| DDR | DR | Mode | Option |
| :---: | :---: | :---: | :---: |
| 0 | 0 | Input | With on-chip pull-up resistor |
| 0 | 1 | Input | Without on-chip pull-up resistor |
| 1 | $X$ | Output | Open-drain or Push-Pull |

Note: X•Means don't care
Figure 26. I/O Port Data Registers

PA7-PAO. These are the I/O port A data bits with open-drain configuration.
Reset at power on.
PB3-PB0. These are the I/O Port B data bits. Reset at power on.
PC3-PC6. These are the I/O port C data bits. Reset at power on.
PC2/ON-OFF. This is a general purpose I/O line suitable for TV set ON-OFF. Reset at power on.

Figure 27. I/O Port Data Direction Registers

PA7-PAO. These are the I/O port A data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Reset at power-on.

## INPUT/OUTPUT PORTS (Continued)

PB3-PB0. These are the I/O port B data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Reset at power-on.
PC6-PC2. These are the I/O port C data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Set to 04 H at power-on. Bit 2 (PC2 pin) is set to one (output mode selected) as this line is intended for TV ON-OFF switching.

## Input/Output Configurations

The following schematics show the I/O lines hardware configuration for the different options. Figure 29 shows the I/O configuration for an I/O pin with open-drain capability. Figure 28 shows the I/O configuration for an I/O pin with push-pull and with open drain 5 V capability.

## Notes :

The WAIT instruction allows the ST63XX to be used in situations where low power consumption is needed. This can only be achieved however if the l/O pins either are programmed as inputs with well defined logic levels or have no power consuming
resistive loads in output mode. As the same die is used for the different ST63XX versions the unavailable I/O lines of ST63XX should be programmed in output mode.
Single-bit operations on I/O registers are possible but care is necessary because reading in input mode is done from I/O pins while writing will directly affect the Port data register causing an undesired changes of the input configuration.

Figure 28. Port A,B \& C I/O Configuration Diagram

## TIMERS

The ST63XX devices offer two on-chip Timer peripherals consisting of an 8 -bit counter with a 7 -bit programmable prescaler, thus giving a maxımum count of $2^{15}$, and a control logic that allows configuring the peripheral in three operating modes. Figure 30 shows the timer block diagram. These timers do not have the external TIMER pin available for the user. The content of the 8-bit counter can be read/written in the Timer/Counter register TCR that can be addressed in the data space as RAM location at the D3H (Timer 1) and DBH (Timer 2) addresses. The state of the 7 -bit prescaler can be read in the PSC register at the D2H (Timer 1) and DAH (Timer 2) addresses. The control logic device can be managed thanks to the TSCR register D4H (Timer 1) and DCH (Timer 2) addresses as it is described in the following paragraphs.
The following description applies to both Timer 1 and Timer 2. The 8 -bit counter is decrement by the output (rising edge) coming from the 7 -bit prescaler and can be loaded and read under program control. When it decrements to zero then the TMZ (timer zero) bit in the TSCR is set to one. If the ETI (enable timer interrupt) bit in the TSCR is also set to one an
interrupt request, associated to interrupt vector \#3 (for Timer 1) and \#4 for (Timer 2), is generated. The interrupt of the timer can be used to exit the MCU from the WAIT mode.

The prescaler decrements on rising edge. The prescaler input can be the oscillator frequency divided by 12 or an external clock at TIMER pin (this is not available in ST63XX).
Depending on the division factor programmed by PS2/PS1/PS0 (see table 9) bits in the TSCR, the clock input of the timer/counter register is multiplexed to different sources.
On division factor 1 , the clock input of the prescaler is also that of timer/counter; on factor 2, bit 0 of prescaler register is connected to the clock input of TCR.

This bit changes its state with the half frequency of prescaler clock input. On factor 4, bit 1 of PSC is connected to clock input of TCR, and so on. On division factor 128, the MSB bit 6 of PSC is connected to, clock input of TCR. The prescaler initialize bit (PSI) in the TSCR register must be set to one to allow the prescaler (and hence the counter) to start. If it is cleared to zero then all of the prescaler bits are set to one and the counter is inhibited from counting.

Figure 30. Timer Peripheral Block Diagram

TIMERS (Continued)
Figure 31. Timer Working Principle

The prescaler can be given any value between 0 and 7 FH by writing to the related register address, if bit PSI in the TSCR register is set to one. The tap of the prescaler is selected using the PS2/PS1/PS0 bits in the control register. Figure 36 shows the timer working principle.

## Timer Operating Modes

As on ST63XX devices the external TIMER pin is not available the only allowed operating mode is the output mode that have to be selected by setting to 1 bit 4 and by clearing to 0 bit 5 in the TSCR1 register. This procedure will enable both Timer 1 and Timer 2. Any other combination written into these two bits will disable any Timer 1 and Timer 2 operation.
Output Mode (TSCR1 D4 = 1, TSCR1 D5 = 0). On this mode the timer prescaler is clocked by the prescaler clock input (OSC/12). The user carrselect the desired prescaler division ratio through the PS2/PS1/PS0 bits. When TCR count reaches 0 , it sets the TMZ bit in the TSCR.
The TMZ bit can be tested under program control to perform a timer function whenever it goes high. Bit D4 and D5 on TSCR2 (Timer 2) register are not implemented.

## Timer Interrupt

When the counter register decrements to zero and the software controlled ETI (enable timer interrupt) bit is set to one then an interrupt request associated to interrupt vector \#3 (for Timer 1) and to interrupt vector \#4 (for Timer 2) is generated. When the counter decrements to zero also the TMZ bit in the TSCR register is set to one.

## Notes:

TMZ is set when the counter reaches 00 H ; however, it may be set by writing 00 H in the TCR register or setting the bit 7 of the TSCR register. TMZ bit must be cleared by user software when servicing the timer interrupt to avoid undesired interrupts when leaving the interrupt service routine. After reset, the 8 -bit counter register is loaded to FFH while the 7 -bit prescaler is loaded to 7 FH , and the TSCR register is cleared which means that timer is stopped ( $\mathrm{PSI}=0$ ) and timer interrupt disabled.
A write to the TCR register will predominate over the 8 -bit counter decrement to 00 H function, i.e. if a write and a TCR register decrement to 00 H occur simultaneously, the write will take precedence, and the TMZ bit is not set until the 8 -bit counter reaches 00 H again. The values of the TCR and the PSC registers can be read accurately at any time.

TIMERS (Continued)

## Timer Registers

Figure 32. Timer Status Control Registers

TMZ. Low-to-high transition indicates that the tımer count register has decrement to zero. This bit must be cleared by user software before to start with a new count.
ETI. This bit, when set, enables the timer interrupt (vector \#3 for Timer 1, vector \#4 for Timer 2) request. If $\mathrm{ETI}=0$ the timer interrupt is disabled. If $\mathrm{ETI}=1$ and $T M Z=1$ an interrupt request is generated.
D5. This is the timers enable bit D5. It must be cleared to 0 together with a set to 1 of bit D4 to enable both Timer 1 and Timer 2 functions. It is not implemented on TSCR2 register. Any other combination of TSCR1 D4 and D5 bits will disable any operation of both Timer 1 and Timer 2.
D4. This is the tımers enable bit D4. It must be set to 1 together with a clear to 0 of bit D5 to enable both Timer 1 and Timer 2 functions. It is not implemented on TSCR2 register. Any other combination of TSCR1 D4 and D5 bits will disable any operation of both Timer 1 and Timer 2.
PSI. Used to initialize the prescaler and inhubit its counting while $\mathrm{PSI}=0$ the prescaler is set to 7FH and the counter is inhibited. When PSI $=1$ the prescaler is enabled to count downwards. As long as $\mathrm{PSI}=0$ both counter and prescaler are not running.
PS2-PS0. These bits select the division ratio of the prescaler register. (see table 8)

The TSCR1 and TSCR2 registers aro cleared on reset. The correct D4-D5 combination must be written in TSCR1 by user's software to enable the operation of Timer 1 and Timer 2.

Table 8. Prescaler Division Factors

| PS2 | PS1 | PS0 | Divided By |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 1 |
| 0 | 0 | 1 | 2 |
| 0 | 1 | 0 | 4 |
| 0 | 1 | 1 | 8 |
| 1 | 0 | 0 | 16 |
| 1 | 0 | 1 | 32 |
| 1 | 1 | 0 | 64 |
| 1 | 1 | 1 | 128 |

Figure 33. Timer Counter Registers

Figure 34. Prescaler Registers

## HARDWARE ACTIVATED DIGITAL WATCHDOG FUNCTION

The hardware activated digital watchdog function consists of a down counter that is automatically initialized after reset so that this function does not need to be activated by the user program. As the watchdog function is always activated this down counter can't be used as a timer. The watchdog is using one data space register (HWDR location D 8 H ). The watchdog register is set to FEH on reset and immediately starts to count down, requiring no software start. Similarly the hardware activated watchdog can not be stopped or delayed by software.

The watchdog time can be programmed using the 6 MSbits in the watchdog register, this gives the possibility to generate a reset in a time between 3072 to 196608 oscillator cycles in 64 possible steps. (With a clock frequency of 8 MHz this means from $384 \mu$ s to 24.576 ms ). The reset is prevented if the register is reloaded with the desired value before bits 2-7 decrement from all zeros to all ones.
The presence of the hardware watchdog deactivates the STOP instruction and a WAIT instruction is automatically executed instead of a STOP. Bit 1 of the watchdog register (set to one at reset) can be used to generate a software reset if cleared to zero). Figure 35 shows the watchdog block diagram while Figure 36 shows its working principle.

Working Principle

## 6-BIT PWM D/A CONVERTERS AND 62.5 KHz OUTPUT FUNCTION

The D/A macrocell contains four PWM D/A outputs (32Khz repetition, DA0-DA3) with six bit resolution plus a 62.5 KHz open-drain output pin (OUT1) specially suited for multistandard chroma processors driving. Both the D/A and OUT1 functions can be disabled by software allowing the DAO-DA3 and OUT1 pins to be used as general purpose opendrain output pins able to withstand signals with up to 12 V amplitude.

## 6-Bit D/A Converters

Each D/A converter of ST63XX is composed by the following main blocks:

- pre-divider
- 6-bit counter
- data latches and compare circuits

The pre-divider uses the clock input frequency ( 8 MHz ) and its output clocks the 6 -bit free-running counter. The data latched in the four registers ( EOH , E1H, E2H and E3H) control the four D/A outputs (DA0,1,2 and 3). When all zeros are loaded the relevant output is an high logic level; all 1's correspond to a pulse with a $1 / 64$ duty cycle and almost $100 \%$ zero level. A 7th bit (bit D6) is used to enable the relevant D/A output; when zero, the D/A is no longer enabled and it forces the output to zero. If the other six bits are all zero then the output is controlled only by the enable bit.
The repetition frequency is 32.5 KHz and is related to the 8 MHz clock frequency. All D/A outputs are open-drain with standard current drive capability and able to withstand up to 12 V .
Only DAO is available on ST6340,42,44.
Figure 38. 6-BIT PWM D/A \& 62.5KHz Output Configuration

### 62.5 KHZ Output

This pin provides a 62.5 KHz signal with a $50 \%$ duty cycle; the output is enabled by a dedicated enable bit ( EOH register bit 7 ). When the 62.5 KHz frequency is disabled then the output is controlled by the OUT1 bit and the line can be used as general purpose open-drain output (E1H bit 7). The OUT1 output is open-drain with standard current drive capability and able to withstand signals with up to 12 V amplitude. The pin can be used to drive the SGS-THOMSON TEA5640 chroma processor. Refer to the TEA5640 data sheet for more information on the use of this pin. Care must be taken to respect the frequency tolerances required by the TEA5640 by chosing a quartz with PPM variations within the limits required by the chroma processor.

## D/A and OUT1 Data/Control Registers

This paragraph deals with the description of D/A and OUT1 data/control registers. Some bits of DA2 and DA3 data/control registers are used for external interrupt enable and A/D reference voltage shift, please refer to A/D and IR descriptions for additional information.

Figure 39. D/AO Data/Enable Register

DAO-DA5. These are the 6 bits of the PWM digital to analog converter. Undefined after reset.
DAE. This is the D/A 0 enable bit. If zero, the output of the D/A is forced to zero; if one, the output of the D/A depends on bits DAO..DA5. Undefined after reset.
FO1. This is the 62.5 KHz frequency output/ OUT1 selection bit. If one, the OUT1 pin will give a 62.5 KHz frequency; if zero the OUT1 pin can be used as general purpose open-drain output and the value present on the pin depends on the value of OUT1 bit programmed in the DA1 data/control register. Undefined after reset.

DA0-DA5. These are the 6 bits of the PWM digital to analog converter bits. Undefined after reset.
DAE. This is the D/A 2 enable bit. If zero, the output of the D/A is forced to zero; if one, the output of the D/A depends on bits DAO..DA5. Undefined after reset.
IEN. This is the external interrupt enable. If set to one, the interrupt coming from the external interrupt pin is enabled, if this bit is cleared the interrupt is disabled. Undefined after reset. This interrupt is associated to the NMI interrupt vector. This bit must be cleared to zero on ST6340 (IRIN pin not available). Refer to IR and interrupt descriptions for additional information.

Figure 42. D/A3 Data/Enable Register

DA0-DA5. These are the 6 bits of the PWM digital to analog converter. Undefined after reset.
DAE. This is the D/A 3 enable bit. If zero, the output of the D/A is forced to zero; if one, the output of the D/A depends on bits DAO..DA5. Undefined after reset.
ADSH. This is the analog to digital converter reference voltage shift bit. If set to one, the AFC block has reference voltages on 1 V border. If set to zero, on 0.5 V border. Undefined after reset. Refer to AFC for additional information.

## AFC A/D INPUT, KEYBOARD INPUTS AND BANDSWITCH OUTPUTS

The AFC macrocell contains an A/D comparator with five levels at intervals of 1 V from 1 V to 5 V . The levels can all be lowered by 0.5 v to effectively double the resolution. This A/D can be used to perform the AFC function. In addition this cell offers also a keyboard input register of three bits used to perform a keyboard scan and 4 open-drain outputs (able to withstand signals up to 12V) that can be used to perform band switch function.

Figure 43. AFC, KBY Inputs Configuration Diagrams

Figure 44. BSW, DA, OUT1 Output Configuration Diagram

## A/D Comparator

The A/D used to perform the AFC function (when high threshold is selected) has the following voltage levels: 1,2,3,4 and 5V. Bits 0-2 of AFC result register ( E 4 H address) will provide the result in binary form (less than 1 V is 000 , greater than 5 V is 101).
If the application requires a greater resolution, the sensitivity can be doubled by clearing to zero bit 7 of DA3 Data/Control register, address E3H (refer to D/A description for additional information). In this case all levels are shifted lower by 0.5 V . If the two results are now added within a software routine then the A/D S-curve can be located within a resolution of 0.5 V . The $\mathrm{A} / \mathrm{D}$ input has high impedance able to withstand up to 13 V signals (input level tolerances $\pm 200 \mathrm{mv}$ absolute and $\pm 100 \mathrm{mv}$ relative to 5 V ).

## AFC, Keyboard Inputs and Bandswitch Outputs Data/Control Registers

## Figure 45. AFC Result Register

D7-D3. These bits are not used.
ADO-AD2. These bits store the real time conversion of the value present on the AFC input pin. No reset value.

D7-D3. These bits are not used.
KBYO-KBY2. These bits store the logic level present at KBY0, KBY1 and KBY2 input pins. No reset value. This input pins have CMOS levels with onchip pull-up resistor (100Kohm typical).

Figure 47. Bandswitch Output Register

D6-D3. These bits are not used.
BSW0-BSW2,BSW3. The writing into these bits will cause the corresponding BSW open-drain output line to switch to the programmed level. Undefined after reset.

## INFRARED INPUT (IRIN)

The IRIN pin is directly connected to the NMI interrupt and acts as external interrupt pin (refer to interrupt description for additional information).
IRIN pin is not available on ST6340.
The enable/disable of this interrupt can be managed with the write only IRINTEN bit available in the D/A2 Data/Control register (Address E2H, bit D7). When this bit is set to one the interrupt is enabled otherwise it is disabled.
The IRIN pin is RISING EDGE sensitive.

## Application Note

When the IR interrupt is enabled, then a rising edge on the IR pin will generate an interrupt; if the IR interrupt is disabled, no IR interrupts can be latched. Care should be taked because if the IR pin is high when the IR interrupt is enabled, an interrupt will also be generated; the following method to eliminate noise can also be used if the SW engineer wishes to enable/disable the IR interrupt.
If A Low-cost infra-red receiver is used, the customer may wish to test the IR signal by software after an interrupt in order to verify that there is a good pulse and not just noise. The IRIN pin cannot be read, so in this case it should be connected in parallel with another pin so the signal can be read. Furthermore the IRIN pin is sensitive to a rising edge interrupt; this means that the input to the pin should be low in the presence of no infra-red signal, but since most infra-red receiver modules give a high signal, the signal will need to be inverted with a transistor.
The IR interrupt must be disabled on ST6340 to prevent false interrupts as the IRIN pin is not available.

## ON-SCREEN DISPLAY (OSD)

The ST634X OSD macrocell is a CMOS LSI character generator which enable display of characters and symbols on the TV screen. The character rounding function enhances the readability of the characters. The ST634X OSD receives horizontal and vertical synchronization signal and outputs screen information via R, G and blanking pins. The main characteristics of the macrocell are listed below:

- Number of display characters: 2 lines by 15 columns.
- Number of character types: 64 characters in one bank.
- Character size: Four character heights (18H,36H $54 \mathrm{H}, 72 \mathrm{H}$ ), two available per screen programmable by line.
- Character format: $6 \times 9$ dots with character rounding function.
- Character color: Up to four colors available programmable by word; refer to the specific pin configuration.
- Display position: 64 horizontal positions by 2/fos and 63 vertical positions by 4 H
- Word spacing: 64 positions programmable from 2/fosc to 128/fosc.
- Line spacing: 63 positions programmable from 4 to 252 H .
- Background: No background, square background or fringe background programmable by word.
- Background or fringe color: Can be enabled or disabled on a word by word basis.
The color is selectable from any of the available colors (refer to pin configurations) on screen by basis.
- Display output: Character data output terminals (R,G) and a blank output terminal; refer to the specific pin configuration.
- Display on/off: Display data may be programmed on or off by word or entire screen. Entire screen may be blanked.

## Special OSD Notes for Emulation and Piggyback

The ST634X devices feature two lines of OSD while the emulator and the piggyback devices always five
lines of OSD. The OSD of the ST634X devices is in fact a direct subset of the emulator and piggyback OSD.
Special care must be taken to make sure that the user uses only the features of the ST634X devices. The registers must be loaded such that the correct two lines are used and such that only one background is used. The ST634X uses only the second and fourth lines of the emulator and piggyback OSD; the first, third and fifth lines are not available. Registers in these unused lines MUST BE LOADED WITH THE VALUE 3CH; i.e. no vertical space enable, background 1 selected. This also implies that BACKGROUND 1 MUST BE DEFINED AS TRANSPARENT.

## Format Specification

The entire display can be turned on or off thru the use of global enable bit or the display may be selectively turned on or off by word. To turn off the entire display, the global enable bit (GE) should be zero. If the global enable is one, the display is controlled by the word enable bits (WE). The global enable bit is located in the global enable register and the word enable bit is located in the space character preceding the word.
Each line must begin with a format character which describes the format of that line and of the first word. This character is not displayed.
A space character defines the format of subsequent words. A space character is denoted by a one in bit 6 in the display RAM. If bit 6 of the display RAM is a zero, the other six bits define one of the 64 display characters.
The color, background and enable can be programmed by word. This information is encoded in the space character between words or in the format character at the beginning of each line. Five bits define the color and background of the following word, and determine whether it will be displayed or not.
Characters are stored in a $6 \times 9$ dot format. One dot is defined vertically as 2 H (horizontal lines) and horizontally as 2 /fosc if the smallest character size is enabled. There is no space between characters or lines if the vertical space enable (VSE) and

## ON-SCREEN DISPLAY (Continued)

horizontal space enable (HSE) bits are both zero. This allows the use of special graphics characters.
The normal alphanumeric character set is formatted to be $5 \times 7$ with on empty row at the top and one at the bottom and one empty column at the right. If VSE and HSE are both zero, then the spacing between alphanumeric characters is 1 dot and the spacing between lines of alphanumeric characters is 2 H .
The character size is programmed by line thru the use of the size bit ( S ) in the format character and the global size bits (GS1 and GS2). The vertical spacing enable bit (VSE) located in the format character controls the spacing between lines. If this bit is set to one, the spacing between lines is defined by the vertical spacing register, otherwise the spacing between lines is 0 .
The spacing between words is controlled by the horizontal space enable bit (HSE) located in the space character. If this bit is set to one, the spacing between words is defined by the horizontal spacing register, otherwise the space character width of 6 dots is the spacing between words.
The formats for the display character, space character and format character are described hereafter.

Figure 49. Space Character Register Explanation

D7. Not used.
D6. This pin is fixed to " 1 ".
R, G, B. Color. The 3 color control bits define the color of the following word as shown in table 9. Refer to the specific pin configuration to see which colors are available.

Table 9. Space Character Register Colour Setting.

| R | G | B | Color |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | Black |
| 0 | 0 | 1 | Blue |
| 0 | 1 | 0 | Green |
| 0 | 1 | 1 | Cyan |
| 1 | 0 | 0 | Red |
| 1 | 0 | 1 | Magenta |
| 1 | 1 | 0 | Yellow |
| 1 | 1 | 1 | White |

BGS. Background Select. The background select bit selects the desired background for the following word. There are two possible backgrounds defined by the bits in the Background Control Register.
" 0 " - The background on the following word is enabled by BGO and the color is set by R0, G0, and BO.
"1" - The background on the following word is enabled by BG1 and the color is set by R1, G1, and B1.
WE. Word Enable. The word enable bit defines whether or not the following word is displayed.
" 0 " - The word is not displayed.
"1" - If the global enable bit is one, then the word is displayed.
HSE. Horizontal Space Enable. The horizontal space enable bit determines the spacing between words. The space between characters is always 0 . The alphanumeric character set is implemented in a $5 \times 7$ format with one empty column to the right and one empty row above and below so that the space between alphanumeric characters will be one dot.
" 0 " - The space between words is equal to the width of the space character, which is 6 dots.
"1" - The space between words is defined by the value in the horizontal space register plus the width of the space character.

## ON-SCREEN DISPLAY (Continued)

Figure 50. Format Character Register Explanation

D7. This bit is not used
S. Character Size. The character size bit, along with the global size bits (GS2 and GS1) located in the horizontal space register, specify the character size for each line as defined in Table 11.
BGS. Background Select. The background select bit selects the desired background for the following word. There are two possible backgrounds defined by the bits in the Background Control Register.
" 0 " - The background on the following word is enabled by BGO and the color is set by RO, G0, and B0.
"1" - The background on the following word is enabled by BG1 and the color is set by R1, G1, and B1.
WE. Word Enable. The word enable bit defines whether or not the following word is displayed.
" 0 " - The word is not displayed.
" 1 " - If the global enable bit is one, then the word is displayed.
R, G, B. Color. The 3 color control bits define the color of the following word as shown in Table 10. Refer to the specific pin configuration to see which colors are available.

VSE. Vertical Space Enable. The vertical space enable bit determines the spacing between lines.
" 0 " - The space between lines is equal to 0 H . The alphanumeric character set is implemented in a $5 \times 7$ format with one empty column to the right and one empty row above and one below and stored in a $6 \times 9$ format.
"1" - The space between lines is defined by the value in the vertical space register.

Table 10. Format Character Register Colour Setting.

| R | G | B | Color |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | Black |
| 0 | 0 | 1 | Blue |
| 0 | 1 | 0 | Green |
| 0 | 1 | 1 | Cyan |

## ON-SCREEN DISPLAY (Continued)

Figure 51. Display Character Register Explanation

D7. This bit is not used.
D6. This bit is fixed to " 0 ".
C5-C0. Character type. The 6 character type bits define one of the 64 available character types. These character types are shown on the following pages.

## Character Types

The character set is user defined as ROM mask option.

## Register and RAM Addressing

The OSD contains six registers and 80 RAM locations. The seven registers are the Vertical Start Address register, Horizontal Start Address register, Vertical Space register, Horizontal Space register, Background Control register and Global Enable register. The Global Enable register can be written at any time by the ST63 Core. The other five registers and the RAM can only be read or written to if the global enable is zero.
The six registers and the RAM are located on two pages of the paged memory of the ST63XX MCUs. Each page contains 64 memory locations. This paged memory is at memory locations 00 H to 3 FH in the ST63XX memory map. A page of memory is enabled by setting the desired page bit, located in the data RAM bank switching register, to a one. The page register is location E8H. A one in bit five selects page 5, located on the OSD and a one in bit 6 selects page 6 on the OSD. Table 12 shows the addresses of the OSD registers and RAM. Some bytes of the RAM must be set-up as described in the section "Special OSD Notes for Emulation and Piggybacks".

Table 12. OSD Control Registers and Data RAM Addressing

| Page | Address | Register or RAM |
| :---: | :---: | :---: |
| 5 | $00 \mathrm{H}-3 \mathrm{FH}$ | RAM Locations $00 \mathrm{H}-3 \mathrm{FH}$ |
| 6 | $00 \mathrm{H}-0 \mathrm{FH}$ | RAM Locations $00 \mathrm{H}-0 \mathrm{FH}$ |
| 6 | 10 H | Vertical Start Register |
| 6 | 11 H | Horizontal Start Register |
| 6 | 12 H | Vertical Space Register |
| 6 | 13 H | Horizontal Space Register |
| 6 | 14 H | Background Control Register |
| 6 | 17 H | Global Enable Register |

## OSD Global Enable Register

This register contains the global enable bit (GE). It is the only register that can be written at any time regardless of the state of the GE bit. It is a write only register.

Flgure 52. Global Enable Register

D7-D1. These bits are not used
GE. Global Enable. This bit allows the entire display to be turned off.
" 0 " - The entire display is disabled. The RAM and other registers of the OSD can be accessed by the Core.
"1" - Display of words is controlled by the word enable bits (WE) located in the format or space character.
The other registers and RAM cannot be accessed by the Core.

## ON-SCREEN DISPLAY (Continued)

Figure 53. Vertical Start Address Register

D7. This bit is not used
FR. Fringe Background. This bit changes the background from a box background to a fringe background. The background is enabled by word as defined by either BKO or BK1.
" 0 " - The background is defined to be a box which is $7 \times 9$ dots.
"1" - The background is defined to be a fringe.
VSA5-VSAO. Vertical Start Address. These bits determine the start position of the first line in the vertical direction. The 6 bits can specify 63 display start positions of interval 4 H . The first start position will be the fourth line of the display. The vertical start address is defined VSAO by the following formula. Vertical Start Address $=4 \mathrm{H}\left(2^{5}(\right.$ VSA5 $)+2^{4}($ VSA4 $)$ $+2^{3}($ VSA3 $)+2^{2}($ VSA2 $)+2^{1}($ VSA1 $)+2^{0}($ VSA0 $\left.)\right)$
The case of all Vertical Start Address bits being zero is 111.
Figure 54. Horizontal Start Address Register

| HSAR <br> Horizontal Start Address Register (11H - Page 6, Write Only) |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| D7 | D6 | D5 | D4 | D3 | D2 | D1 | D |  |
|  |  |  |  |  |  |  |  |  |

D7. This bit is not used.
SBD. Space Blanking Disable. This bit controls whether or not the background is displayed when outputting spaces. If two background colors are
used on adjacent words, then the background should not be displayed on spaces in order to make a nice break between colors. If an even background around an area of text is desired, as in a menu, then the background should be displayed when outputting spaces.
" 0 " - The background during spaces is controlled by the background enable bits (BK0 and BK1) located in the Background Control register.
"1" - The background is not displayed when outputting spaces.
HSA5, HSAO - Horizontal Start Address bits. These bits determine the start position of the first character in the horizontal direction. The 6 bits can specify 64 display start positions of interval $2 / f$ fosc or 400 ns . The first start position will be at $4.0 \mu$ s because of the time needed to access RAM and ROM before the first character can be displayed. The horizontal start address is defined by the following formula.
Horizontal Start Address $=2$ /fosc $\left(10.0+2^{5}(\right.$ HSA5 $)$ $+2^{4}($ HSA4 $)+2^{3}(\mathrm{HSA} 3)+2^{2}($ HSA 2$)+2^{1}($ HSA1 $)+$ $2^{0}$ (HSAO))

Figure 55. Vertical Space Register

D7. This bit is not used
SCB. Screen Blanking. This bit allows the entire screen to be blanked.
" 0 " - The blanking output signal (VBLK) is active only when displaying characters.
"1" - The blanking output signal (VBLK) is always active. Characters in the display RAM are still displayed.
When this bit is set to one, the screen is blanked also without setting the Global Enable bit to one (OSD disabled).
VS5, VSO. Vertical Space. These bits determine the spacing between lines if the Vertical Space Enable bit (VSE) in the format character is one. If VSE is zero there will be no spaces between lines.

## ON-SCREEN DISPLAY (Continued)

The Vertical Space bits can specify one of 63 spacing values from 4 H to 252 H . The space between lines is defined by the following formula.
Space between lines $=4 \mathrm{H}\left(2^{5}(\mathrm{VS} 5)+2^{4}(\mathrm{VS} 4)+\right.$ $\left.2^{3}(\mathrm{VS} 3)+2^{2}(\mathrm{VS} 2)+2^{1}(\mathrm{VS} 1)+2^{0}(\mathrm{VSO})\right)$
The case of all Vertical Start Address bits being zero is ill.

Figure 56. Horizontal Space Register

GS2,GS1. Global Size. These bits along with the size bit (S) located in the Character format word specify the character size for each line as defined in table 13.
Table 13. Horizontal Space Register Size Setting.

| GS2 | GS1 | S | Vertical Height | Horizontal <br> Lenght |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 18 H | 6 TDOT |
| 0 | 0 | 1 | 36 H | 12 TDOT |
| 0 | 1 | 0 | 18 H | 6 TDOT |
| 0 | 1 | 1 | 54 H | 18 TDOT |
| 1 | 0 | 0 | 36 H | 12 TDOT |
| 1 | 0 | 1 | 54 H | 18 TDOT |
| 1 | 1 | 0 | 36 H | 12 TDOT |
| 1 | 1 | 1 | 72 H | 24 TDOT |

Note: TDOT=2/fosc
HS5, HSO . Horizontal Space. These bits determine the spacing between words if the Horizontal Space Enable bit (HSE) located in the space character is a one. The space between words is then equal to the width of the space character plus the number of tdots specified by the Horizontal Space bits. The 6 bits can specify one of 64 spacing values ranging from $2 /$ fosc to 128 /fosc. The formula is shown below for the smallest size character $(18 \mathrm{H})$.

If larger size characters are being displayed the spacing between words will increase proportionately. Multiply the value below by 2, 3 or 4 for character sizes of $36 \mathrm{H}, 54 \mathrm{H}$ and 72 H respectively.
Space between words (not including the space character $)=2 /$ fosc $\left(\left(1+2^{5}(\mathrm{HS} 5)+2^{4}(\mathrm{HS} 4)+2^{3}(\mathrm{HS} 3)\right.\right.$
$\left.+2^{2}(\mathrm{HS} 2)+2^{1}(\mathrm{HS} 1)+2^{0}(\mathrm{HSO})\right)$

## Background Control Register

This register sets up two possible backgrounds. The background select bit (BGS) in the format or space character will determine which background is selected for the current word. The background control register must be set-up as described in the section "Special OSD Notes for Emulation and Piggybacks".
Figure 57. Background Control Registers

R1,R0,G1,G0,B1,B0. Background Color. These bits define the color of the specified background, either background 1 or background 0 as defined in Table 14.
Table 14. Background Register Colour Setting.

| $\mathbf{R X}$ | GX | $\mathbf{B X}$ | Color |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | Black |
| 0 | 0 | 1 | Blue |
| 0 | 1 | 0 | Green |
| 0 | 1 | 1 | Cyan |
| 1 | 0 | 0 | Red |
| 1 | 0 | 1 | Magenta |
| 1 | 1 | 0 | Yellow |
| 1 | 1 | 1 | White |

## ON-SCREEN DISPLAY (Continued)

BK1,BKO. Background Enable.These bits determine if the specified background is enabled or not.
" 0 " - The following word does not have a background.
"1" - There is a background around the following word.

## OSD Data RAM

The contents of the data RAM can be accessed by the ST63XX MCUs only when the global enable bit (GE) in the Global Enable register is a zero.
The first character in every line is the format character. This character is not displayed. It defines the size of the characters in the line and contains the vertical space enable bit. This character also defines the color, background and display enable for the first word in the line. Subsequent characters are either spaces or one of the 64 available character types.
The space character defines the color, background, display enable and horizontal space enable for the following word. Since there are 5 display lines of 15 characters each, the display RAM must contain 5 lines $\times$ ( 15 characters +1 format character) or 80 locations. The RAM size is 80 locations $x 7$ bits. The data RAM map is shown in Table 15.

## Emulator Remarks

There are several differences between emulator and silicon. For noise reasons, the OSD oscillator pins are not available: the internal oscillator cannot be disabled and replaced by an external coil. Also refer to the section "Special OSD Notes for Emulation and Piggybacks".

## Application Notes

1 - The OSD character generator is composed of a dual port video ram and some circuitry. It needs two input signals VSYNC and HSYNC to syncronize its dedicated oscillator to the TV picture. It generates 4 output signals, that can be used from the TV set to generate the characters on the screen. For istance, they can be used to feed the SCART plug, providing an adequate buffer to drive the low impedance ( $75 \Omega$ ) of the SCART inputs.
2 - The Core sees the OSD as a number of RAM locations (80) plus a certain number of control registers (6). These 86 locations are mapped in two pages of the dynamic data ram address range ( $\mathrm{OH} . .3 \mathrm{FH}$ ).
In page 5 (load 20 H in the register 0 E 8 H ), there are 64 bytes of RAM, the ones of the first 4 rows ( 16 bytes each row, 15 characters per row maximum, plus an hidden leading format character). In page 6 (load 40 H in register 0 E 8 H ), the 16 bytes of the fith row ( $0 . .0 \mathrm{FH}$ ), and the 6 control registers (10H..14H,17H).

Table 15. OSD RAM Map

AVAILABLE SCREEN SPACE

Notes: FT The format character required for each line. Characters in columns 1 thru 15 are displayed.

## ON-SCREEN DISPLAY (Continued)

3 - The video RAM is a dual port ram. That means that it can be addressed either from the Core or from the OSD circuitry itself. To reduce the complexity of the circuitry, and thus its cost, some restrictions have been introduced in the use of the OSD.
a. The Core can Only write to any of the 86 locatıons (either video RAM or control registers).
b. The Core can Only write to any of the leading 85 locations when the OSD oscillator is OFF. Only the last location (control register 17 H in page 6) can be addressed at any time. This is the Global Enable Register, which contains only the GE bit. If it is set, the OSD is on, if it is reset the OSD is off.
4 - The timing of the on/off switching of the OSD oscillator is the following:
a. GE bit is set. The OSD oscillator will start on the next VSYNC signal.
b. GE bit is reset. The OSD oscillator will be immediately switched off.
To avoid a bad visual impression, it is important that the GE bit is set before the end of the flyback time when charging character. This can be done inside

Figure 58. OSD Oscillator ON/OFF Timing

## Notes:

A Picture time 20 mS in PAL/SECAM
B VSYNC interrupt, if enabled.
C. Startıng of OSD oscillator, if $G E=1$
D. Flyback time.
the VSYNC interrupt routine. The following diagram can explain better:
When modifying the picture display (i.e.: a bar graph for an analog control), it is important that the switching on of the GE bit is done before the the end of the flyback time ( D in Figure 67). If the GE bit is set after the end of the flyback time then the OSD will not start until the begining of the next frame. This results in one frame being lost and will result in a Flicker on the screen. One method to be sure to avoid the flicker is to wait for the VSYNC interrupt at the start of the flyback; once the VSYNC interrupt is detected, then the GE bit can be set to zero, the characters changed, and the the GE set to one. All this should occur before the end of the flyback time in order not to loose a frame. The correct edge of the interrupt must be chosen. The VSYNC pin may alternatively be sampled by software in order to know the status; this can be done by reading the pin PB2 (VSYNC).
6 - An OSD end of line Bar is present in the ST63PXX piggyback and ST63XX ROM devices when using the background mode. If this bar is present with software running in the piggybacks then it is also present on the ROM mask version. If the end of line bar is seen to be eliminated by software in the piggyback, then it is also be eliminated in the ROM mask version.
The bar appears at the end of the line in the background mode when the last character is a space character and the first format character is defined with $\mathrm{S}=0$ (size 0 ). The bar is the color of the background defined by the space character. To eliminate bar:
a. If two backgrounds are used then the bar should be moved off the screen by using large word spaces instead of character spaces. If there are not enough spaces before the end of the line, then the location of the valid characters should be moved so they appear at the end of the line (and hence no bar); positioning can be compensated using the horizontal start register.
b. If only one background is used, then the other background should be transparent in order to eliminate the bar.
7 - The OSD oscillator external network should consist of a capacitor on each of the OSD oscillator pins to ground together with an inductance between the the pin. The user should select the two capacitors to be the same value ( 15 pF to 25 pF each is recommended). The inductance is chosen to give the desired OSD oscillator frequency for the application (normally $56 \mu \mathrm{H}$ ).

## 14-BIT VOLTAGE SYNTHESIS TUNING PERIPHERAL (Not available on ST6342)

The ST634X on-chip voltage synthesis tuning peripheral has been integrated to allow the generation of tuning reference voltage in low/mid end TV set applications. The peripheral is composed of a 14bit counter that allows the conversion of the digital content in a tuning voltage, available at the VS output pin, by using PWM and BRM techniques. The 14-bit counter gives 16384 steps which allows a resolution of approximately 2 mV over a tuning voltage of 32 V ; this corresponds to a tuning resolution of about 40 KHz per step in UHF band (the actual value will depend on the characteristics of the tuner).
The tuning word consists of a 14-bit word contained in the registers VSDATA1 (location OEDH) and VSDATA2 (location OEEH). Course tuning (PWM) is performed using the seven MSBit, while the fine tuning (BRM) is performed using the data in the seven LSBIT. With all zeros loaded the output is zero ; as the tuning voltage increseses from all zeros, the number of pulses in one period increses to 128 with all pulses being the same width. For values larger than 18, the PWM takes over and the number of pulses in one period remains constant at 128 , but the width changes. At the other end of the scale, when almost all ones are loaded, the pulses will start to link together and the number of pulses will decrease. When all ones are loaded, the output will be almost $100 \%$ high but will have a low pulse ( $1 / 16384$ of the high pulse).

## Output Details

Inside the on-chip Voltage Synthesis cell are included the register latches, a reference counter, PWM and BRM control circuitry ; the structure is one used in many devices currenlty in production from SGS-THOMSON (M106, M193, M293, M490/91/94). In the ST635X the clock for the 14-bit reference counter is 2 MHz derived from the 8 MHz system clock. From the circuit point of view, the seven most significant bits controls the course tuning, while the seven least significant bits the fine tuning. From the application and software point of view, the 14 bits can be considered as one binary number.
As already mentioned the course tuning consists of a PWM signal with 128 steps ; we can consider the fine tuning to cover 128 course tuning cycles. The addition of pulses is described in the following Table 16.

Table 16. Fine Tuning Pulse Addition

| Flne Tuning <br> (7 LSB) | N of Pulses added at <br> the following cycles <br> (0...127) |
| :--- | :--- |
| 0000001 | 64 |
| 0000010 | 32,96 |
| 0000100 | $16,48,80,112$ |
| 0001000 | $8,24, \ldots .104,120$ |
| 0010000 | $4,12, \ldots .116,124$ |
| 0100000 | $2,6, \ldots . .122,126$ |
| 1000000 | $1,3, \ldots . .125,127$ |

The VS output pin has a standard drive push-pull output configuration.

## VS Tuning Cell Registers

Figure 59. VS Data Register 1

D7-DO. These are the 8 least significant VS data bits. Bit 0 is the LSB. This register is undefined on reset.

Figure 60. VS Data Register 2

D7-D6. These bits are not used.
D5-DO. These are the 6 most significant VS data bits. Bit 5 is the MSB. This register is undefined on reset.

## SOFTWARE DESCRIPTION

The ST63XX software has been designed to fully use the hardware in the most efficient way possible while keeping byte usage to a minimum; in short to provide byte efficient programming capability. The ST63XX Core has the ability to set or clear any register or RAM location bit of the Data space with a single instruction. Furthermore, the program may branch to a selected address depending on the status of any bit of the Data space. The carry bit is stored with the value of the bit when the SET or RES instruction is processed.

## Addressing Modes

The ST63XX Core has nine addressing modes which are described in the following paragraphs. The ST63XX Core uses three different address spaces: Program space, Data space, and Stack space. Program space contains the instructions which are to be executed, the data for immediate mode instructions, and in this space is physically allocated the data ROM which is addressed as data space. Data space contains the Accumulator, the $\mathrm{X}, \mathrm{Y}, \mathrm{V}$ and W registers, the Core control registers, peripheral and Input/Output registers, the RAM locations and the window to address the Data ROM (physically located into the program memory) locations (for storage of tables and constants). Stack space contains six 12-bit RAM bytes used to stack the return addresses for subroutines and interrupts.
Immediate. In the immediate addressing mode, the operand of the instruction follows the opcode location. As the operand is a ROM byte, the immediate addressing mode is used to access constants which do not change during program execution (e.g., a constant used to initialize a loop counter).
Direct. In the direct addressing mode, the address of the byte that is processed by the instruction is stored in the location that follows the opcode. Direct addressing allows the user to directly address the 256 bytes in Data space memory with a single two-byte instruction.
Short Direct. The Core can address the four RAM registers X,Y,V,W (locations $80 \mathrm{H}, 81 \mathrm{H}, 82 \mathrm{H}, 83 \mathrm{H}$ ) in the short-direct addressing mode. In this case, the instruction is only one byte long and the selection of the location to be processed is contained in the opcode. Short direct addressing is a subset of the direct addressing mode. (Note : 80H and 81 H are also indirect registers).
Extended. In the extended addressing mode, the 12-bit address needed to define the instruction is
obtained by concatenating the four less significant bits of the opcode with the byte following the opcode. The instructions (JP, CALL) that use the extended addressing mode are able to branch any address of the directly addressable Program space. An extended addressing mode instruction is two-byte long.
Program Counter Relative. The relative addressing mode is only used in conditional branch instructions. The instruction is used to perform a test and, if the condition is true, a branch with a span of -15 to +16 locations around the address of the relative instruction. If the condition is not true, the instruction that follows the relative instruction is executed. The relative addressing mode instruction is onebyte long. The opcode is obtained by adding the three most significant bits that characterize the kind of test, one bit that determines whether the branch is a toward (when it is 0 ) or backward (when it is 1 ) branch and the four less significant bits that give the span of the branch $(0 \mathrm{H}$ to FH$)$ that must be added or subtracted to the address of the relative instruction to obtain the address of the branch.
Bit Direct. In the bit direct addressing mode, the bit to be set or cleared is part of the opcode, and the byte following the opcode points to the address of the byte in which the specified bit must be set or cleared. Thus, any bit in the 256 directly addressable locations of Data space memory can be set or cleared.
Bit Test \& Branch. The bit test and branch addressing mode is a combination of direct addressing and relative addressing. The bit test and branch instruction is three-byte long. The bit identification and the tested condition are included in the opcode byte. The address of the byte to be tested follows immediately the opcode in the Program space. The third byte is the jump displacement, which is in the range from -126 to +129 . This displacement can be determined using a label, which is converted by the assembler.
Indirect. In the indirect addressing mode, the byte processed by the register-indirect instruction is at the address pointed by the content of one of the indirect registers, X or $\mathrm{Y}(80 \mathrm{H}, 81 \mathrm{H})$. The indirect register is selected by the bit 4 of the opcode. A register indirect instruction is one byte long.
Inherent. In the inherent addressing mode, all the information necessary to execute the instruction is contained in the opcode. These instructions are one byte long.

## SOFTWARE DESCRIPTION (Continued)

## Instruction Set

The ST63XX Core has a set of 40 basic instructions. When these instructions are combined with nine addressing modes, 244 usable opcodes can be obtained. They can be divided into six different types : load/store, arithmetic/logic, conditional branch, control instructions, jump/call, bit manipulation. The following paragraphs describe the dif-
ferent types. All the instructions within a given type are presented in individual tables.
Load \& Store. These instructions use one,two or three bytes in relation with the addressing mode. One operand is the Accumulator for LOAD and the other operand is obtained from data memory using one of the addressing modes. For LOAD Immediate one operand can be any of the 256 data space bytes while the other is always an immediate data. Refer to Table 17.

Table 17. Load \& Store instructions

| Instruction | Addressing Mode | Bytes | Cycles | Flags |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Z | C |
| LD A, X | Short Direct | 1 | 4 | $\Delta$ | * |

## SOFTWARE DESCRIPTION (Continued)

Arithmetic and Logic. These instructions are used to perform the arithmetic calculations and logic operations. In AND, ADD, CP, SUB instructions one operand is always the accumulator while the other
can be either a data space memory content or an immediate value in relation with the addressing mode. In CLR,DEC,INC instructions the operand can be any of the 256 data space addresses. In COM, RLC, SLA the operand is always the accumulator. Refer to Table 18.

Table 18. Arithmetic \& Logic instructions

## SOFTWARE DESCRIPTION (Continued)

Conditional Branch. The branch instructions achieves a branch in the program when the selected condition is met. Refer to Table 19.
Bit Manipulation Instructions. These instructions can handle (set or reset) any bit in data space memory. Refer to Table 20.

Control Instructions. The control instructions control the MCU operations during program execution. Refer to Table 21.
Jump and Call. These two instructions are used to perform long (12-bit) jumps or subroutines call inside the whole program space. Refer to Table 22.

Table 19. Conditional Branch instructions

| Instruction | Branch If | Bytes | Cycles | Flags |  |

Abbreviations for Addressing Modes.

| dir | Direct |
| :--- | :--- |
| sd | Short Direct |
| imm | Immedıate |
| inh | Inherent |
| ext | Extended |
| bd | Bit Direct |
| bt | Bit Test |
| pcr | Program Counter Relative |
| ind | Indirect |

Legend.

| \# | Indicates Illegal Instructions |
| :--- | :--- |
| e | 5 Bit Displacement |
| b | 3 Bit Address |
| rr | 1 byte dataspace address |
| nn | 1 byte immediate data |
| abc | 12 bit address |
| ee | 8 bit Displacement |

## ABSOLUTE MAXIMUM RATINGS

This product contains devices to protect the inputs against damage due to high static voltages, however it is advised to take normal precaution to avoid application of any voltage higher than maximum rated voltages.
For proper operation it is recommended that $V_{I}$ and Vo must be higher than VSS and smaller than VDD. Reliability is enhanced if unused inputs are connected to an appropriated logic voltage level (VDD or VSS).

Power Considerations. The average chip-junction temperature. Tj , in Celsius can be obtained form.:

$$
\mathrm{Tj}=\mathrm{TA}+\mathrm{PD} \times \text { RthJA }
$$

Where: TA = Ambient Temperature,
RthJA = Package thermal resistance (junction-to ambient),
PD = Pint + Pport,
Pint $=l_{D D} \times V_{D D}$ (chip internal power),
Pport = Port power dissipation (determined by the user).

| Symbol | Parameter | Value | Unit |
| :---: | :---: | :---: | :---: |
| VDD | Supply Voltage | -0.3 to 7.0 | V |
| VI | Input Voltage (AFC IN) | VSS -0.3 to +13 | V |
| $V_{1}$ | Input Voltage (Other Inputs) | VSS -0.3 to VDD +0.3 | V |
| Vo | Output Voltage <br> (Port A, DAO-3, BSW0-3, OUT1) | VSS -0.3 to +13 | V |
| Vo | Output Voltage (Other Inputs) | VSS -0.3 to VDD +0.3 | $\checkmark$ |
| 10 | Current Drain per Pin Excluding VDD, VSS, | $\pm 10$ | mA |
| IVss | Total Current out of VSS (sink) | 150 | mA |
| $\mathrm{T}_{\mathrm{j}}$ | Junction Temperature | 150 | ${ }^{\circ} \mathrm{C}$ |
| Tsta | Storage Temperature | -60 to 150 | ${ }^{\circ} \mathrm{C}$ |

Note: Stresses above those listed as "absolute maximum ratings" may cause permanent damage to the device This is a stress rating only and functional operation of the device at these conditions is not implied Exposure to maximum rating conditions for extended periods may affect device rellability.

THERMAL CHARACTERISTIC

| Symbol | Parameter | Test Conditions | Value |  |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Min. | Typ. | Max. |  |
| RthJA | Thermal Resistance | $\begin{aligned} & \text { PDIP40 } \\ & \text { PDIP28 } \end{aligned}$ |  |  | 40 55 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

## RECOMMENDED OPERATING CONDITIONS

| Symbol | Parameter | Test Conditions | Value |  |  | Unit |
| :---: | :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Min. | Typ. | Max. |  |
| $\mathrm{T}_{\mathrm{A}}$ | Operating Temperature |  | 0 |  | 70 | ${ }^{\circ} \mathrm{C}$ |
| VDD | Operating Supply Voltage |  | 4.5 |  | 5.5 | V |
| fosC | Oscillator Frequency <br> RUN \& WAIT Modes |  | 8.0 | 8.1 | MHz |  |
| fosDosc | On-Screen Display Oscillator <br> Frequency |  |  | 8.0 | MHz |  |

## EEPROM INFORMATION

The ST63XX EEPROM macrocell and the single poly EEPROM process have been specially de-
veloped to achieve 1.000.000 Write/Erase cycles and a 10 years data retention.

## PACKAGE MECHANICAL DATA

Figure 61. 40-Pin Dual in Line Plastic

Figure 62. 28-Pin Dual in Line Plastic

## ORDERING INFORMATION

The following chapter deals with the procedure for transfer the Program/Data ROM codes to SGSTHOMSON.

Communication of the ROM Codes. To communicate the contents of Program /Data ROM memories to SGS-THOMSON, the customer has to send:

- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS 5" diskette) for the PROGRAM Memory
- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS5" diskette) for the ODD and EVEN ODD OSD Characters
- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS 5" diskette) for the EEPROM initial content (this file is optional)
- a filled Option List form as described in the OPTION LIST paragraph.
The program ROM should respect the ROM Memory Map as in Table 24.
The ROM code must be generated with ST6 assembler. Before programming the EPROM, the buffer of the EPROM programmer must be filled with FFH. For shipment to SGS-THOMSON the EPROMs should be placed in a consecutive IC carrier and packaging carefully.

Table 24. ROM Memory Map

| ROM Page | Device Address | EPROM Address (1) | Description |
| :---: | :---: | :---: | :---: |
| Page 0 | $\begin{aligned} & 0000 \mathrm{H}-007 \mathrm{FH} \\ & 0080 \mathrm{H}-07 \mathrm{FFH} \end{aligned}$ | $\begin{aligned} & 0000 \mathrm{H}-007 \mathrm{FH} \\ & 0080 \mathrm{H}-07 \mathrm{FFH} \end{aligned}$ | Reserved User ROM |
| Page 1 "STATIC" | 0800H-0F9FH OFAOH-OFEFH OFFOH-0FF7H 0 FF8H-0FFBH OFFCH-OFFDH OFFEH-0FFFH | 0800H-0F9FH OFAOH-OFEFH OFFOH-0FF7H 0 FF8H-0FFBH OFFCH-OFFDH OFFEH-0FFFH | User ROM Reserved Interrupt Vectors Reserved NMI Vector Reset Vector |

Note: 1. EPROM addresses are related to the use of ST63P4X piggyback emulation devices.

SGS-THOMSON

## ORDERING INFORMATION (Continued)

Customer EEPROM Initial Contents: Format
a. The content should be written into an INTEL INTELLEC format file.
b. The starting address in 000 h and the end in 7Fh.
c. Undefined or don't care bytes should have the content FFH.
OSD Test Character. In order to allow the testing of the on-chip OSD macrocell the following character must be provided at the fixed 3FH (63).
Listing Generation \& Verification. When SGSTHOMSON receives the Codes, they are compared and a computer listing is generated from them. This listing refers extractly to the mask that will be used to produce the microcontroller. Then the listing is returned to the customer that must thoroughly check, complete, sign and return it to SGS-THOMSON. The signed list constitutes a part

Figure 63. OSD Test Character

of the contractual agreement for the creation of the customer mask. SGS-THOMSON sales organization will provide detailed information on contractual points.

Ordering Information Table

| Sales Type | ROM/EEPROM Size | Temperature Range | Package |
| :---: | :---: | :---: | :---: |
| ST6340B1/XX | $4 K / 48$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PDIP28 |
| ST6342B1/XX | $4 K / 48$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PDIP28 |
| ST6344B1/XX | $4 K / 48$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PDIP28 |
| ST6346B1/XX | $4 K / 48$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PDIP40 |

Note: "XX" Is the ROM code identifier that is allocated by SGS-THOMSON after recelpt of all required options and the related ROM file.

## 8 BIT HCMOS MCUs FOR <br> TV VOLTAGE SYNTHESIS WITH OSD

- 8-bit Architecture
- HCMOS Technology
- 8MHz Clock
- User Program ROM: 20140 bytes
- Reserved Test ROM: 336 bytes
- Data ROM: User selectable size
- Data RAM: 256 bytes
- Data EEPROM: 384 bytes
- 42-Pin Shrink Dual in Line Plastic Package
- Up to 22 software programmable general purpose Inputs/Outputs, including 2 direct LED driving Outputs
- Two Timers each including an 8-bit counter with a 7-bit programmable prescaler
- Digital Watchdog Function
- Serial Peripheral Interface (SPI) supporting S-BUS/ $I^{2} C$ BUS and standard serial protocols
- Up to Six 6-Bit PWM D/A Converters
- 62.5 KHz Output Pin (ST6386,88 Only)
- AFC A/D converter with 0.5 V resolution
- Five interrupt vectors (IRIN/NMI, Timer $1 \& 2$, VSYNC, PWR INT.)
- 14 bit counter for voltage synthesis tuning
- On-chip clock oscillator
- 5 Lines by 15 Characters On-Screen Display Generator with 128 Characters
- Byte efficient instruction set
- Bit test and jump instructions
- Wait and Bit Manipulation instructions
- True LIFO 6-level stack
- All ROM types are supported by pin-to-pin piggyback versions.
- The development tool of the ST638X microcontrollers consists of the ST638X-EMU emulation and development system to be connected via a standard RS232 serial line to an MS-DOS Personal Computer.

## GENERAL DESCRIPTION

The ST6385,86,87,88 microcontrollers are members of the 8 -bit HCMOS ST638X family, a series of devices specially oriented to TV applications. Different pin-out and peripheral configurations are available to give the maximum application and cost flexibility. All ST638X members are based on a building block approach: a common core is surrounded by a combination of on-chip peripherals (macrocells) available from a standard library. These peripherals are designed with the same Core technology providing full compatibility and short design time. Many of these macrocells are specially dedicated to TV applications. The macrocells of the ST638X family are : two Timer peripherals each including an 8-bit
counter with a 7-bit software programmable prescaler (Timer), a digital hardware activated watchdog function (DHWD), a 14-bit voltage synthesis tuning pripheral, a serial peripheral interface (SPI), up to six 6-bit PWM D/A converters, an AFC A/D converter with 0.5 V resolution, an on-screen display (OSD) with 15 characters per line, 128 characters (in two banks each of 64 characters). In addition the following memory resources are available: program ROM (20K), data RAM (256 bytes), EEPROM ( 384 bytes). Refer to pin configurations figures and to ST638X device summary (Table 1) for the definition of ST638X family members and a summary of differences among the different types.

Note: 1. Low power in RESET function disables the oscillator when RESET pin is active (LOW).

## PIN DESCRIPTION

$V_{D D}$ and $V_{S s}$. Power is supplied to the MCU using these two pins. $V_{D D}$ is power and $V_{S S}$ is the ground connection.
OSCIN, OSCOUT. These pins are internally connected to the on-chip oscillator circuit. A quartz crystal or a ceramic resonator can be connected between these two pins in order to allow the correct operation of the MCU with various stability/cost trade-offs. The OSCIN pin is the input pin, the OSCOUT pin is the output pin. Refer to ON-CHIP CLOCK OSCILLATOR description for additional information.
 the microcontroller to the beginning of its program. Additionally the quartz oscillator will be disabled when the RESET pin is low to reduce power consumption during reset phase. Refer to RESET description for additional information.
TEST. The TEST (mode select) pin is used to place the MCU into special operating mode. If TEST is held at $\mathrm{V}_{\text {ss }}$ the MCU enters the normal operating mode. If TEST is held at $V_{D D}$ when RESET is active the test operating mode is automatically selected (the user should connect this pin to Vss for normal operation). Refer to TEST mode description for additional information.
PAO-PA7. These 8 lines are organized as one I/O port (A). Each line may be configured as either an input with or without pull-up resistor or as an output under software control of the data direction register. Pins PA4 to PA7 are configured as open-drain outputs (12V drive). On PA4-PA7 pins the input pull-up option is not available while PA6 and PA7 have additional current driving capability ( 25 mA , 1 V ). PA0 to PA3 pins are configured as push-pull.

Refer to I/O PORT description for additional information.
PB0-PB2, PB4-PB6. These 6 lines are organized as one I/O port (B). Each line may be configured as either an input with or without internal pull-up resistor or as an output under software control of the data direction register. Refer to I/O PORT description and Pin configurations (Figures 1 to 4) for additional information.
PCO-PC7. These 8 lines are organized as one I/O port (C). Each line may be configured as either an input with or without internal pull-up resistor or as an output under software control of the data direction register. Pins PC0 to PC3 are configured as open-drain ( 5 V drive) in output mode while PC4 to PC7 are open-drain with 12 V drive and the input pull-up options does not exist on these four pins. PC0, PC1 and PC3 lines when in output mode are "ANDed" with the SPI control signals and are all open-drain. PCO is connected to the SPI clock signal (SCL), PC1 with the SPI data signal (SDA) while PC3 is connected with SPI enable signal (SEN, used in S-BUS protocol). Pin PC4 and PC6 can also be inputs to software programmable edge sensitive latches which can generate interrupts; PC4 can be connected to Power Interrupt while PC6 can be connected to the IRIN/NMI interrupt line. Refer to I/O PORT description, Pin Configurations (Figures 1 to 4), INTERRUPT description for additional information.
DAO-DA5. These pins are the six PWM D/A outputs of the 6 -bit on-chip D/A converters. These lines have open-drain outputs with 12 V drive. The output repetition rate is 31.25 KHz (with 8 MHz clock). Refer to Pin Configurations (Figures 1 to 4) and D/A description for additional information.

## PIN DESCRIPTION (Continued)

AFC. This is the input of the on-chip 10 levels comparator that can be used to implement the AFC function. This pin is an high impedance input able to withstand signals with a peak amplitude up to 12V. Refer to Pin Configurations (Figures 1 to 4) and AFC description for additional information.
OSDOSCIN, OSDOSCOUT. These are the On Screen display oscillator terminals. An oscillation capacitor and coil network have to be connected to provide the right signal to the OSD.
HSYNC, VSYNC. These are the horizontal and vertical synchronization pins. The active polarity of these pins to the OSD macrocell can be selected by the user as ROM mask option. If the device is specified to have negative logic inputs, then when these signals are low the OSD oscillator stops. If the device is specified to have positive logic inputs,
then when these signals are high the OSD oscillator stops. Refer to OSD description for additional information.
R, G, B, BLANK. Outputs from the OSD. R, G and $B$ are the color outputs while BLANK is the blanking output. All outputs are push-pull. The active polarity of these pins can be selected by the user as ROM mask option. Refer to the pin configurations for additional information.
62.5 kHz OUT. This pin is an open drain (12V) output at a frequency of 62.5 kHz (with an 8 MHz clock). The pin can be used to drive the SGSTHOMSON TEA5640 chroma processor. Refer to the TEA5640 data sheet for more information.
VS. This is the output pin of the on-chip 14-bit voltage synthesis tuning cell (VS). The tuning signal present at this pin gives an approximate resolution of 40 KHz per step ovre the UHF band. This line is a push-pull output with standard drive .

Table 2. ST638X Pin Summary

| Pin Function | Description |
| :--- | :--- |
| DA0 to DA5 | Output, Open-Drain, 12V |
| 62.5KHz OUT | Output, Open-Drain, 12V |
| AFC | Input, High Impedance, 12V |
| VS | Output, Push-Pull |
| R,G,B, BLANK | Output, Push-Pull |
| HSYNC, VSYNC | Input, Pull-up, Schmitt Trigger |
| OSDOSCIN | Input, High Impedance |
| OSDOSCOUT | Output, Push-Pull |
| TEST | Input, Pull-Down |
| OSCIN | Input, Resistive Bias, Schmitt Trigger to Reset Logic Only |
| OSCOUT | Output, Push-Pull |
| RESET | Input, Pull-up, Schmitt Trigger Input |
| PA0-PA3 | I/O, Push-Pull, Software Input Pull-up, Schmitt Trigger Input |
| PA4-PA5 | I/O, Open-Drain, 12V, No Input Pull-up, Schmitt Trigger Input |
| PA6-PA7 | I/O, Open-Drain, 12V, No Input Pull-up, Schmitt Trigger Input, High Drive |
| PB0-PB2 | I/O, Push-Pull, Software Input Pull-up, Schmitt Trigger Input |

| PC0-PC3 | I/O, Open-Drain, 5V , Software Input Pull-up, Schmitt Trigger Input |
| PC4-PC7 | I/O, Open-Drain, 12V, No Input Pull-up, Schmitt Trigger Input |
| VDD, VSS | Power Supply Pins |

## ST638X CORE

The Core of the ST638X Family is implemented independently from the l/O or memory configuration. Consequently, it can be treated as an independent central processor communicating with I/O and memory via internal addresses, data, and control busses. The in-core communication is arranged as shown in the following block diagram figure; the controller being externally linked to both the reset and the oscillator, while the core is linked to the dedicated on-chip macrocells peripherals via the serial data bus and indirectly for interrupt purposes through the control registers.

## Registers

The ST638X Family Core has five registers and three pairs of flags available to the programmer. They are shown in Figure 7 and are explained in the following paragraphs together with the program and data memory page registers.
Accumulator (A). The accumulator is an 8 -bit general purpose register used in all arithmetic calculations, logical operations, and data manipulations. The accumulator is addressed in the data space as RAM location at the FFH address.

Figure 7. ST638X Core Programming Model

Figure 6. ST638X Core Block Diagram

## ST638X CORE (Continued)

Accordingly, the ST638X instruction set can use the accumulator as any other register of the data space.
Indirect Registers (X, Y). These two indirect registers are used as pointers to the memory locations in the data space. They are used in the register-indirect addressing mode.These registers can be addressed in the data space as RAM locations at the $80 \mathrm{H}(\mathrm{X})$ and $81 \mathrm{H}(\mathrm{Y})$ addresses. They can also be accessed with the direct, short direct, or bit direct addressing modes. Accordingly, the ST638X instruction set can use the indirect registers as any other register of the data space.
Short Direct Registers (V, W). These two registers are used to save one byte in short direct addressing mode. These registers can be addressed in the data space as RAM locations at the $82 \mathrm{H}(\mathrm{V})$ and 83H (W) addresses. They can also be accessed with the direct and bit direct addressing modes. Accordingly, the ST638X instruction set can use the short direct registers as any other register of the data space.

## Program Counter (PC)

The program counter is a 12 -bit register that contains the address of the next ROM location to be processed by the core. This ROM location may be an opcode, an operand, or an address of operand. The 12-bit length allows the direct addressing of 4096 bytes in the program space. Nevertheless, if the program space contains more than 4096 locations, the further program space can be addressed by using the Program Bank Switch register. The PC value is incremented, after it is read for the address of the current instruction, by sending it through the ALU, so giving the address of the next byte in the program. To execute relative jumps the PC and the offset values are shifted through the ALU, where they will be added, and the result is shifted back into the PC. The program counter can be changed in the following ways:

| JP (Jump) instruction | PC= Jump address |
| :---: | :---: |
| CALL instruction | $\mathrm{PC}=$ Call address |
| Relative Branch instructions | . PC= PC+offset |
| Interrupt | . $\mathrm{PC}=$ Interrupt vector |
| Reset | . $\mathrm{PC=}$ Reset vector |
| Test mode | . $\mathrm{PC}=$ Test mode vector (1) |
| RET \& RETI instructions | . PC= Pop (stack) |
| Normal instruction | $\mathrm{C}=\mathrm{PC}+1$ |

Note: 1. Not available to the user.

## Flags (C, Z)

The ST63 Core includes three pairs of flags that correspond to 3 different modes: normal mode, interrupt mode and Non-Maskable-Interrupt-Mode. Each pair consists of a CARRY flag and a ZERO flag. One pair ( $\mathrm{CN}, \mathrm{ZN}$ ) is used during normal operation, one pair is used during the interrupt mode ( $\mathrm{Cl}, \mathrm{Zl}$ ) and one is used during the not-maskable interrupt mode (CNMI, ZNMI).
The ST63 Core uses the pair of flags that corresponds to the actual mode: as soon as an interrupt (resp. a Non-Maskable-Interrupt) is generated, the ST638X Core uses the interrupt flags (resp. the NMI flags) instead of the normal flags. When the RETI instruction is executed, the normal flags (resp. the interrupt flags) are restored if the MCU was in the normal mode (resp. in the interrupt mode) before the interrupt. Should be observed that each flag set can only be addressed in its own routine (Not-maskable interrupt, normal interrupt or main routine). The interrupt flags are not cleared during the context switching and so, they remain in the state they were at the exit of the last routine switching.
The Carry flag is set when a carry or a borrow occurs during arithmetic operations, otherwise it is cleared. The Carry flag is also set to the value of the bit tested in a bit test instruction, and participates in the rotate left instruction.
The Zero flag is set if the result of the last arithmetic or logical operation was equal to zero, otherwise it is cleared.
The switching between these three sets is automatically performed when an NMI, an interrupt and a RETI instructions occur. As the NMI mode is automatically selected after the reset of the MCU, the ST638X Core uses at first the NMI flags. Refer to INTERRUPT description for additional information.

## Stack

The ST638X Core includes true LIFO hardware stack that eliminates the need for a stack pointer.

Figure 8. Stack Operation

ST638X CORE (Continued)

The stack consists of six separate 12-bit RAM locations that do not belong to the data space RAM area. When a subroutine call (or interrupt request) occurs, the contents of each level is shifted into the next level while the content of the PC is shifted into the first level (the value of the sixth level will be lost). When subroutine or interrupt return occurs (RET or RETI instructions), the first level register is shifted back into the PC and the value of each level is shifted back into the previous level. These two operating modes are described in Figure 8. Since the accumulator, as all other data space registers, is not stored in this stack the handling of this registers shall be performed inside the subroutine. The stack pointer will remain in its deepest position, if more than 6 calls or interrupts are executed, so that the last return address will be lost. It will also remain in its highest position if the stack is empty and a RET or RETI is executed. In this case the next instruction will be executed.

## Memory Registers

Figure 9. Program ROM Page Register

| PRPR <br> Program ROM Page Register <br> (CAH, Write Only) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $D 7$ $D 6$ $D 5$ D4 D3 D2 D1 D0 |  |  |  |  |  |

The PRPR register can be addressed like a RAM location in the Data Space at the GAH address; nevertheless it is a write-only register that can not be accessed with single-bit operations. This register is used to select the 2-Kbyte ROM bank of the Program Space that will be addressed. The number of the page has to be loaded in the PRPR register. The PRPR register is not cleared during the MCU initialization and should therefore be defined before jumping out of the static page. Refer to the Program Space description for additional information concerning the use of this registers. The PRPR register is not modified when an interrupt or a subroutine occurs.

Figure 10. Data RAM Bank Manager

The DRBR register can be addressed like a RAM location in the Data Space at the E8H address, nevertheless it is write-only register that can not be accessed with single-bit operations. This register is used to select the desired 64-byte RAM/EEPROM bank of the Data Space. The number of the bank has to be loaded in the DRBR register and the instruction has to point to the selected location as it was in the 0 bank (from 00 H address to 3 FH address). This register is cleared during the MCU initialization (the Data space 0 bank is automatically addressed after the Reset). Refer to the Data Space description for additional information. The DRBR register is not modified when a interrupt or a subroutine occurs.

Figure 11. Data ROM Window Register

The DWR register can be addressed like a RAM location in the Data Space at the C 9 H address, nevertheless it is write-only register that can not be accessed with single-bit operations. This register is used to move up and down the 64-byte read-only data window (from the 40 H address to 7 FH address of the Data Space) along the ROM memory of the MCU by step of 64 bytes. The effective address of the byte to be read as a data in the ROM memory is obtained by the concatenation of the 6 less significant bits of the address given in the instruction (as less significant bits) and the content of the DWR register (as most significant bits). Refer to the Data Space description for additional information.

## MEMORY SPACES

The MCUs operate in three different memory spaces: Program Space, Data Space, and Stack

Figure 12. ST638X Data Space

Space. A description of these spaces is shown in Figure 12 and Figure 13. (Figure 14 refers to the ST638X which has a total of 20K bytes of ROM).

MEMORY SPACES (Continued)

Figure 14. ST638X Memory Addressing Description Diagram

## Program Space

The program space is physically implemented in the ROM memory and includes all the instructions that are to be executed, as well as the data required for the immediate addressing mode instructions, the reserved test area and user vectors. It is addressed thanks to the 12-bit Program Counter register (PC register) and so, the ST638X Core can directly address up to 4 K bytes of Program Space. Nevertheless, the Program Space can be extended by the addition of 2-Kbyte ROM banks as it is shown in figure 14 in which a 20K bytes memory is described. These banks are addressed by pointing to the $000 \mathrm{H}-7 \mathrm{FFH}$ locations of the Program Space thanks to the Program Counter, and by writing the appropriate code in the Program ROM Page Register (PRPR register) located at the CAH address of the Data Space. Because interrupts and common subroutines should be available all the time only the lower 2 K byte of the 4 K program space are bank switched while the upper 2K byte can be seen as static space. Table 3 gives the different codes that allows the selection of the
corresponding banks. Note that, from the memory point of view, the Page 1 and the Static Page represent the same physical memory: it is only a different way of addressing the same location. On the ST638X a total of 20480 bytes of ROM have been implemented; 20140 are available as user ROM while 340 are reserved for testing.

| 1 | 0 | 0 | 0 | 0 | Page 8 |
| 1 | 0 | 0 | 1 | 0 | Page 9 |

Note. The number of bits implemented depends on the size of the ROM of the device. Only the lower part of address space has been bankswitched because interrupt vectors and common subroutines should be available all the time. The reason of this structure is due to the fact that it is not possible to jump from a dynamic page to another, unless jumping back to the static page, changing contents of PRPR, and, than, jumping to a different dynamic page.
Care is required when handling the PRPR register as it is write only. For this reason, it is not allowed to change the PRPR contents while executing interrupts drivers, as the driver cannot save and than restore its previous content. Anyway, this operation may be necessary if the sum of common routines and interrupt drivers will take more than 2 K bytes; in this case could be necessary to divide the interrupt driver in a (minor) part in the static page (start and end), and in the second (major) part in one dynamic page. If it is impossible to avoid the writing of this register in interrupts drivers, an image of this register must be saved in a RAM location, and each time the program writes the PRPR it writes also the image register. The image register must be written first, so if an interrupt occurs between the two instructions the PRPR register is not affected.

## Notes:

1. EPROM addresses are related to the use of ST63P8X piggyback emulation devices.

## MEMORY SPACE (Continued)

## Data Space

The instruction set of the ST638X Core operates on a specific space, named Data Space that contains all the data necessary for the processing of the program. The Data Space allows the addressing of RAM memory (up to 256 bytes for the ST638X family), EEPROM memory (up to 384 bytes for the ST638X family), ST638X Core/peripheral registers, and read-only data such as constants and the look-up tables.
Data ROM Addressing. All the read-only data are physically implemented in the ROM memory in which the Program Space is also implemented. The ROM memory therefore contains the program to be executed and also the constants and the look-up tables needed for the program. The locations of Data Space in which the different constants and look-up tables are addressed by the ST638X Core can be considered as being a 64-byte window through which it is possible to access to the readonly data stored in the ROM memory. This window is located from the 40 H address to the 7 FH address in the Data space and allows the direct reading of the bytes from the 000 H address to the 03 FH address in the ROM memory. All the bytes of the ROM memory can be used to store either instructions or read-only data. Indeed, the window can be moved by step of 64 bytes along the ROM memory in writing the appropriate code in the Write-only Data ROM Window register (DWR register, location C 9 H ). The effective address of the byte to be read as a data in the ROM memory is obtained by the concatenation of the 6 less significant bits of the address in the Data Space (as less significant bits) and the content of the DWR register (as most significant bits). So when addressing location 40 H of data space, and 0 is loaded in the DWR register, the physical addressed location in ROM is 00 H .
Note. The data ROM window cannot address windows above the 16 k byte range.

Figure 17. Data ROM Window Register

DWR7-DWRO. These are the Data Rom Window bits that correspond to the upper bits of data ROM program space. This register is undefined after reset.
Notes Care is required when handling the DWR register as it is write only. For this reason, it is not allowed to change the DWR contents while executing interrupts drivers, as the driver cannot save and than restore its previous content. If it is impossible to avoid the writing of this register in interrupts drivers, an image of this register must be saved in a RAM location, and each time the program writes the DWR it writes also the image register. The image register must be written first, so if an interrupt occurs between the two instructions the DWR register is not affected.

## Data RAM/EEPROM/OSD RAM Addressing

In all members of the ST638X family 64 bytes of data RAM are directly addressable in the data space from 80 H to BFH addresses. The additional 192 bytes of RAM, the 384 bytes of EEPROM memory, and the

## MEMORY SPACE (Continued)

OSD RAM can be addressed using the banks of 64 bytes located between addresses 00 H and 3FH. The selection of the bank is done by programming the Data RAM Bank Switching register (DRBR register) located at the E8H address of the Data Space. In this way each bank of RAM, EEPROM or OSD RAM can select 64 bytes at a time. No more than one bank should be set at a time.

Figure 18. Data RAM Bank Register

DRBR7,DRBR1,DRBRO. These bits select the EEPROM pages.
DRBR6, DRBR5. Each of these bits, when set, will select one OSD RAM register page.
DRBR4,DRBR3,DRBR2. Each of these bits, when set, will select one RAM page.
This register is undefined after reset.
Table 5 summarizes how to set the Data RAM Bank Register in order to select the various banks or pages.

## Notes :

Care is required when handling the DRBR register as it is write only. For this reason, it is not allowed to change the DWR contents while executing interrupts drivers, as the driver cannot save and than restore its previous content. If it is impossible to avoid the writing of this register in interrupts drivers, an image of this register must be saved in a RAM location, and each time the program writes the DRBR it writes also the image register.
The image register must be written first, so if an interrupt occurs between the two instructions the DRBR register is not affected.

## EEPROM Description

The data space of ST638X family from 00 H to 3FH is paged as described in Table 5. 384 bytes of EEPROM located in six pages of 64 bytes (pages $0,1,2,3,4,5$ and 6 , see Table 5).
Through the programming of the Data RAM Bank Register (DRBR=E8H) the user can select the bank or page leaving unaffected the way to address the static registers. The way to address the "dy-

Table 5. Data RAM Bank Register Set-up

## MEMORY SPACE (Continued)

namic" page is to set the DRBR as described in Table 5 (e.g. to select EEPROM page 0, the DRBR has to be loaded with content 01 H , see Data RAM/EEPROM/OSD RAM addressing for additional information). Bits 0,1 and 7 of the DRBR are dedicated to the EEPROM.
The EEPROM module is physically organized in 32 byte modules ( 2 modules per page) and does not require dedicated instructions to be accessed in reading or writing. The EEPROM is controlled by the EEPROM Control Register (EECR=EAH). Any EEPROM location can be read just like any other data location, also in terms of access time.
To write an EEPROM location takes about 5 mSec ( 10 mSec max ) and during this time the EEPROM is not accessible by the Core. A busy flag can be read by the Core to know the EEPROM status before trying any access. In writing the EEPROM can work in two modes: Byte Mode (BMODE) and Parallel Mode (PMODE). The BMODE is the normal way to use the EEPROM and consists in accessing one byte at a time. The PMODE consists in accessing 8 bytes per time.

Figure 19. EEPROM Control Register

D7. Not used
SB. WRITE ONLY. If this bit is set the EEPROM is disabled (any access will be meaningless) and the power consumption of the EEPROM is reduced to the leakage values.
D5, D4. Reserved for testing purposes, they must be set to zero.

PS. SET ONLY. Once in Parallel Mode, as soon as the user software sets the PS bit the parallel writing of the 8 adjacent registers will start. PS is internally reset at the end of the programming procedure. Note that less than 8 bytes can be written; after parallel programming the remaining undefined bytes will have no particular content.
PE. WRITE ONLY. This bit must be set by the user program in order to perform parallel programming (more bytes per time). If PE is set and the "parallel start bit" (PS) is low, up to 8 adjacent bytes can be written at the maximum speed, the content being stored in volatile registers. These 8 adjacent bytes can be considered as row, whose A7, A6, A5, A4, A3 are fixed while A2, A1 and A0 are the changing bytes. PE is automatically reset at the end of any parallel programming procedure. PE can be reset by the user software before starting the programming procedure, leaving unchanged the EEPROM registers.
BS. READ ONLY. This bit will be automatically set by the CORE when the user program modifies an EEPROM register. The user program has to test it before any read or write EEPROM operation; any attempt to access the EEPROM while "busy bit" is set will be aborted and the writing procedure in progress completed.
EN. WRITE ONLY. This bit MUST be set to one in order to write any EEPROM register. If the user program will attempt to write the EEPROM when $\mathrm{EN}=0$ the involved registers will be unaffected and the "busy bit" will not be set.
After RESET the content of EECR register will be 00 H .

## Notes:

When the EEPROM is busy $(B S=1)$ the EECR can not be accessed in write mode, it is only possible to read BS status. This implies that as long as the EEPROM is busy it is not possible to change the status of the EEPROM control register. EECR bits 4 and 5 are reserved for testing purposes, and the user must never set them to 1 .
Additional Notes on Parallel Mode. If the user wants to perform a parallel programming the first action should be the set to one the PE bit; from this moment the first time the EEPROM will be addressed in writing, the ROW address will be latched and it will be possible to change it only at the end of the programming procedure or by resetting PE without programming the EEPROM. After the ROW address latching the Core can "see" just one EEPROM row (the selected one) and any attempt to write or read other rows will produce errors. Do not read the EEPROM while PR is set.
As soon as PE bit is set, the 8 volatile ROW latches are cleared. From this moment the user can load

## MEMORY SPACE (Continued)

data in the whole ROW or just in a subset. PS setting will modify the EEPROM registers corresponding to the ROW latches accessed after PE. For example, if the software sets PE and accesses EEPROM in writing at addresses $18 \mathrm{H}, 1 \mathrm{AH}, 1 \mathrm{BH}$ and then sets PS, these three registers will be modified at the same time; the remaining bytes will have no particular content. Note that PE is internally reset at the end of the programming procedure. This implies that the user must set PE bit between two parallel programming procedures. Anyway the user can set and then reset PE without performing any EEPROM programming. PS is a set only bit and is internally reset at the end of the programming procedure. Note that if the user tries to set PS while PE is not set there will not be any programming procedure and the PS bit will be unaffected. Consequently PS bit can not be set if EN is low. PS can be affected by the user set if, and only if, EN and PE bits are also set to one.
Warning : Parallel programming of the EEPROM with less than eight bytes may corrupt other bytes and should therefore be used with care, as here after underlined.
a. Reason for limitation:
betweeen PE (Parallel Enable) and PS (Parallel Start) of the EEPROM, the user writes up to eight bytes into the volatile data registers, a latch is also set to indicate which bytes have been accessed; the accessed bytes will be programmed when PS arrives. The logic is such that it is possible to set the latches of bytes which have NOT been accessed. The latches are set whenever ANY register in the banked dataspace (00h-3FH) is accessed for READ or WRITE between a PE and PS. The latch which is set will be determined by the three least significant bits of the register address. Only the latch is set, so final data of a corrupted byte after the parallel programming is always FFH.
Note: read operations also occur internally to the micro for most instructions. Even if bytes are not seen to be corrupted within the parallel programming routine, care should be taken, since they could become corrupted by an interrupt routine being serviced during loading of parallel bytes.
This is logic related and is not a marginality or race condition; piggyback devices perform in the same way as ROM devices. Parallel programming is tested with only LDI rr,nn instructions which do not corrupt other bytes.
b. To Avoid Corrupted Bytes:

- use Single Byte Mode, or
- always define all eight bytes in Parallel Programming Mode, or
- when programming less than eight bytes, the remaining EEPROM bytes should do not used by the program.
Additional Notes Regarding Differences Between ST638X Devices and Corresponding Emulators. While PE is set, all the EEPROM page currently selected is accessible in reading and the writing of the bytes happens at the row to which belongs the last byte written before setting PS. The sequence: set PE, write in 10 H the value X , write in 21 H the value Y , set $P S$, will result in: 10 H unchanged, 20 H loaded with value $\mathrm{X}, 21 \mathrm{H}$ loaded with value Y . In the emulator bits 4 and 5 of the EECR are implemented. If the user set to 1 one or both of these bits the contents of the EEPROM will be destroyed. The user should use care in using EEPROM emulation as in general the emulator does not emulate the behaviour of the EEPROM when it is misused.

## STACK SPACE

The stack space consists of six 12 bit registers that are used for stacking subroutine and interrupt return addresses plus the current program counter register.

## TEST MODE

The test mode can be entered by connecting the TEST pin to an high logic level when reset is active; this action enables the factory test mode. The user is recommended to avoid this situation for normal operation. (TEST pin should be tied to ground).

## INTERRUPT

The ST638X Core can manage 4 different maskable interrupt sources, plus one non-maskable interrupt source (top priority level interrupt). Each source is associated with a particular interrupt vector that contains a Jump instruction to the related interrupt service routine. Each vector is located in the Program Space at a particular address (see Table 6). When a source provides an interrupt request, and the request processing is also enabled by the ST638X Core, then the PC register is loaded with the address of the interrupt vector (i.e. of the Jump instruction). Finally, the PC is loaded with the address of the Jump instruction and the interrupt routine is processed.
The relationship between vector and source and the associated priority is hardware fixed for the different ST638X devices. For some interrupt sources it is also possible to select by software the kind of event that will generate the interrupt.
All interrupts can be disabled by writing to the GEN bit (global interrupt enable) of the interrupt option register (address C8H). After a reset, ST638X is in non maskable interrupt mode, so no interrupts will be accepted and NMI flags will be used, until a RETI

## INTERRUPT (Continued)

RETI instruction is executed. If an interrupt is executed, one special cycle is made by the core, during that the PC is set to the related interrupt vector address. A jump instruction at this address has to redirect program execution to the beginning of the related interrupt routine. The interrupt detecting cycle, also resets the related interrupt flag (not available to the user), so that another interrupt can be stored for this current vector, while its driver is under execution.
If additional interrupts arrive from the same source, they will be lost. NMI can interrupt other interrupt routines at any time, while other interrupts cannot interrupt each other. If more than one interrupt is waiting for service, they are executed according to their priority. The lower the number, the higher the priority. Priority is, therefore, fixed. Interrupts are checked during the last cycle of an instruction (RETI included). Level sensitive interrupts have to be valid during this period.

## Table 6. Interrupt Vectors/Sources Relationships

| Interrupt Source | Associated <br> Vector | Vector Address |
| :---: | :---: | :---: |
| PC6/IRIN <br> Pin (1) | Interrupt <br> Vector \# 0 (NMI) | OFFCH-OFFDH |
| Timer 2 | Interrupt <br> Vector \# 1 | OFF6H-0FF7H |
| Vsync | Interrupt <br> Vector \# 2 | OFF4H-0FF5H |
| Timer 1 | Interrupt <br> Vector \# 3 | OFF2H-OFF3H |
| PC4/PWRIN | Interrupt <br> Vector \# 4 | OFFOH-OFF1H |

Note: 1. This pin is associated with the NMI Interrupt Vector

Table 6 details the different interrupt vectors/sources relationships.

## Interrupt Vectors/Sources

The ST638X Core includes 5 different interrupt vectors in order to branch to 5 different interrupt routines. The interrupt vectors are located in the fixed (or static) page of the Program Space.
The interrupt vector associated with the non-maskable interrupt source is named interrupt vector \#0. It is located at the (FFCH,FFDH) addresses in the Program Space. This vector is associated with the PC6/IRIN pin; refer to the ST638X Interrupt Details section for more information.

The interrupt vectors located at addresses (FF6H,FF7H), (FF4H,FF5H), (FF2H,FF3H), (FFOH,FF1H) are named interrupt vectors \#1, \#2, \#3 and \#4 respectively. These vectors are associated with TIMER 2 (\#1), VSYNC (\#2), TIMER 1 (\#3) and PC4(PWRIN) (\#4); refer to the ST638X Interrupt Details description for more information.

## Interrupt Priority

The non-maskable interrupt request has the highest priority and can interrupt any other interrupt routines at any time, nevertheless the other interrupts cannot interrupt each other. If more than one interrupt request is pending, they are processed by the ST638X Core according to their priority level: vector \#1 has the higher priority while vector \#4 the lower. The priority of each interrupt source is hardware fixed.

## Interrupt Option Register

The Interrupt Option Register (IOR register, location C 8 H ) is used to enable/disable the individual interrupt sources and to select the operating mode of the external interrupt inputs. This register can be addressed in the Data Space as RAM location at the C 8 H address, nevertheless it is write-only register that can not be accessed with single-bit operations. The operating modes of the external

Figure 20. Interrupt Option Register

interrupt inputs associated to interrupt vectors \#1 and \#2 are selected through bits 4 and 5 of the IOR register.
D7. Not used.
EL1. This is the Edge/Level selection bit of interrupt \#1. When set to one, the interrupt is generated on low level of the related signal; when cleared to zero, the interrupt is generated on falling edge. The bit is cleared to zero after reset.

## INTERRUPT (Continued)

ES2. This is the edge selection bit on interrupt \#2. This bit is used on the ST638X devices with onchip OSD generator for VSYNC detection.
GEN. This is the global enable bit. When set to one all interrupts are globally enabled; when this bit is cleared to zero all interrupts are disabled (including NMI).
D3 - D0. These bits are not used.

## Interrupt Procedure

The interrupt procedure is very similar to a call procedure; the user can consider the interrupt as an asynchronous call procedure. As this is an asynchronous event the user does not know about the context and the time at which it occurred. As a result the user should save all the data space registers which will be used inside the interrupt routines. There are separate sets of processor flags for normal, interrupt and non-maskable interrupt modes which are automatically switched and so these do not need to be saved.
The following list summarizes the interrupt procedure (refer also to Figure 21. Interrupt Processing Flow Chart):

- Interrupt detection
- The flags $C$ and $Z$ of the main routine are exchanged with the flags $C$ and $Z$ of the interrupt routine (resp. the NMI flags)
- The value of the PC is stored in the first level of the stack - The normal interrupt lines are inhibited (NMI still active)
- The edge flip-flop is reset
- The related interrupt vector is loaded in the PC.
- User selected registers are saved inside the interrupt service routine (normally on a software stack)
- The source of the interrupt is found by polling (if more than one source is associated to the same vector)
- Interrupt servicing
- Return from interrupt (RETI)
- Automatically the ST638X core switches back to the normal flags (resp the interrupt flags) and pops the previous PC value from the stack
The interrupt routine begins usually by the identification of the device that has generated the interrupt request. The user should save the registers which are used inside the interrupt routine (that holds relevant data) into a software stack.
After the RETI instruction execution, the Core carries out the previous actions and the main routine can continue.

Figure 20. Interrupt Processing Flow-Chart

## ST638X Interrupt Details

IR Interrupt (\#0). The IRIN/PC6 Interrupt is connected to the first interrupt \#0 (NMI, OFFCH). If the IRINT interrupt is disabled at the Latch circuitry, then it will be high. The \#0 interrupt input detects a high to low level. Note that once \#O has been latched, then the only way to remove the latched \# 0 signal is to service the interrupt. \# 0 can interrupt the other interrupts. A simple latch is provided from the PC6(IRIN) pin in order to generate the IRINT signal. This latch can be triggered by either the positive or negative edge of IRIN signal. IRINT is inverted with respect to the latch. The latch can be read by software and reset by software.
TIMER 2 Interrupt (\#1). The TIMER 2 Interrupt is connected to the interrupt \# 1 (OFF6H). The TIMER2 interrupt generates a low level (which is latched in the timer). For more information on the timer interrupt

## INTERRUPT (Continued)

to remove the latched signal is to service the interrupt.
VSYNC Interrupt (\#2). The VSYNC Interrupt is connected to the interrupt \#2. When disabled the VSYNCINT signal is low. The VSYNCINT signal is inverted with respect to the signal applied to the VSYNCN pin. Bit 5 of the interrupt option register C 8 H is used to select the negative edge $(\mathrm{B} 2=0)$ or the positive edge ( $B 2=1$ ); the edge will depend on the application. Note that once an edge has been latched, then the only way to remove the latched signal is to service the interrupt. Care must be taken not to generate spurious interrupts. This interrupt may be used for synchronize to the VSYNC signal in order to change characters in the OSD only when the screen is on vertical blanking (if desired). This method may also be used to blink characters.
TIMER 1 Interrupt (\#3). The TIMER 1 Interrupt is connected to the fourth interrupt \#3 (0FF2H) which detects a high to low level (latched in the timer). For more information on the timer interrupt refer to the timer section.
PWR Interrupt (\#4). The PWR Interrupt is connected to the fifth interrupt \#4 (0FFOH). If the PWRINTN is disabled at the PWR circuitry, then it will be high. The \#4 interrupt input detects a low level. A simple latch is provided from the PC4 (PWRIN)pin in order to generate the PWRINTN signal. This latch can be triggered by either the positive or negative edge of the PWRIN signal.

PWRINTN is inverted with respect to the latch. The latch can be reset by software.
Notes Global disable does not reset edge sensitive interrupt flags. These edge sensitive interrupts become pending again when global disabling is released. Moreover, edge sensitive interrupts are stored in the related flags also when interrupts are globally disabled, unless each edge sensitive interrupt is also individually disabled before the interrupting event happens. Global disable is done by clearing the GEN bit of Interrupt option register, while any individual disable is done in the control register of the peripheral. The on-chip Timer peripherals have an interrupt request flag bit (TMZ), this bit is set to one when the device wants to generate an

## RESET

The ST638X devices can be reset in two ways: by the external reset input (RESET) tied low and by the hardware activated digital watchdog peripheral.

## RESET Input

The external active low reset pin is used to reset the ST638X devices and provide an orderly software startup procedure. The activation of the Reset pin may occur at any time in the RUN or WAIT mode. Even short pulses at the reset pin will be accepted since the reset signal is latched internally and is only cleared after 2048 clocks at the oscillator pin. The clocks from the oscillator pin to the reset circuitry are buffered by a schmit trigger so that an oscillator in start-up conditions will not give spurious clocks. When the reset pin is held low, the extemal quartz oscillator is

Figure 22. Internal Reset Circuit

RESET (Continued)
Figure 23. Reset \& Interrupt Processing Flow-chart

When the reset pin is held low, the external quartz oscillator is also disabled in order to reduce current consumption. The MCU is configured in the Reset mode as long as the signal of the RESET pin is low. The processing of the program is stopped and the standard Input/Output ports (port A, port B and port C) are in the input state. As soon as the level on the reset pin becomes high, the initialization sequence is executed. Refer to theMCU initialization sequence for additional information.

## Watchdog Reset

The ST638X devices are provided with an on-chip hardware activated digital watchdog function in order to provide a graceful recovery from a software upset. If the watchdog register is not refreshed and the end-of-count is reached, then the reset state will be latched into the MCU and an internal circuit pulls down the reset pin. This also resets the watchdog which subsequently turns off the pull-down and activates the pull-up device at the reset pin. This causes the positive transition at

Figure 24. Restart Initialization Program Flow-chart

the reset pin. The MCU will then exit the reset state after 2048 clocks on the oscillator pin.

## Application Notes

An external resistor between VDD and the reset pin is not required because an internal pull-up device is provided. The user may prefer to add an external pull-up resistor.
An internal Power-on device does not guarantee that the MCU will exit the reset state when $V_{D D}$ is above 4.5 V and therefore the RESET pin should be externally controlled.

## MCU Initialization Sequence

When a reset occurs the stack is reset to program counter, the PC is loaded with the address of the reset vector (located in the program ROM at addresses FFEH \& FFFH). A jump instruction to the beginning of the program has to be written into these locations.After a reset the interrupt mask is automatically activated so that the Core is in nonmaskable interrupt mode to prevent false or ghost interrupts during the restart phase. Therefore the restart routine should be terminated by a RETI instruction to switch to normal mode and enable interrupts. If no pending interrupt is present at the end of the reset routine, the ST638X will continue with the instruction after the RETI; otherwise the pending interrupt will be serviced.

## RESET (Continued)

## RESET Low Power Mode

When the reset pin is low, the quartz oscillator is Disabled allowing reduced current consumption. When the reset pin is raised the quartz oscillator is enabled and oscillations will start to build up. The internal reset circuitry will count 2048 clocks on the oscillator pin before allowing the MCU to go out of the reset state;the clocks are after a schmtit trigger so that false or multiple counts are not possible.

The stack space consists of six 12 bit registers that are used for stacking subroutine and interrupt return addresses plus the current program counter register.

## TEST MODE

The test mode can be entered by connecting the TEST pin to an high logic level when reset is active; this action enables the factory test mode. The user is recommended to avoid this situation for normal operation. (TEST pin should be tied to ground).

## WAIT \& STOP MODES

The STOP and WAIT modes have been implemented in the ST638X Core in order to reduce the consumption of the device when the latter has no instruction to execute. These two modes are described in the following paragraphs. On ST638X as the hardware activated digital watchdog function is present the STOP instruction is de-activated and any attempt to execute it will cause the automatic execution of a WAIT instruction.

## WAIT Mode

The configuration of the MCU in the WAIT mode occurs as soon as the WAIT instruction is executed. The microcontroller can also be considered as being in a "software frozen" state where the Core stops processing the instructions of the routine, the contents of the RAM locations and peripheral registers are saved as long as the power supply voltage is higher than the RAM retention voltage but where the peripherals are still working.
The WAIT mode is used when the user wants to reduce the consumption of the MCU when it is in idle, while not loosing count of time or monitoring of external events. The oscillator is not stopped in order to provide clock signal to the peripherals. The timers counting may be enabled (writing the PSI bit in TSCR register) and the timer interrupt may be also enabled before entering the WAIT mode; this allows the WAIT mode to be left when timer interrupt occurs. If the exit from the WAIT mode is performed
with a general RESET (either from the activation of the external pin or by watchdog reset) the MCU will enter a normal reset procedure as described in the RESET chapter. If an interrupt is generated during WAIT mode the MCU behaviour depends on the state of the ST638X Core before the initialization of the WAIT sequence, but also of the kind of the interrupt request that is generated. This case will be described in the following paragraphs. In any case, the ST638X Core does not generate any delay after the occurrence of the interrupt because the oscillator clock is still available.

## STOP Mode

On ST638X the hardware watchdog is present and the STOP instruction has been de-activated. Any attempt to execute a STOP will cause the automatic execution of a WAIT instruction.

## Exit from WAIT Mode

The following paragraphs describe the output procedure of the ST638X Core from WAIT mode when an interrupt occurs. It must be noted that the restart sequence depends on the original state of the MCU (normal, interrupt or non-maskable interrupt mode) before the start of the WAIT sequence, but also of the type of the interrupt request that is generated.
Normal Mode. If the ST638X Core was in the main routine when the WAIT instruction has been executed, the ST638XCore outputs from the wait mode as soon as any interrupt occurs; the related interrupt routine is executed and at the end of the interrupt service routine the instruction that follows the WAIT instruction is executed if no other interrupts are pending.
Non-maskable Interrupt Mode. If the WAIT instruction has been executed during the execution of the non-maskable interrupt routine, the ST638X Core outputs from the wait mode as soon as any interrupt occurs: the instruction that follows the WAIT instruction is executed and the ST638X Core is still in the non-maskable interrupt mode even if an other interrupt has been generated.
Normal Interrupt Mode. If the ST638X Core was in the interrupt mode before the initialization of the WAIT sequence, it outputs from the wait mode as soon as any interrupt occurs. Nevertheless, two cases have to be considered:

- If the interrupt is a normal interrupt, the interrupt routine in which the WAIT was entered will be completed with the execution of the instruction that follows the WAIT and the ST638X Core is still in the interrupt mode. At the end of this routine pending interrupts will be serviced in accordance to their priority.
- If the interrupt is a non-maskable interrupt, the non-maskable routine is processed at first. Then, the routine in which the WAIT was entered
tered will be completed with the execution of the instruction that follows the WAIT and the ST638X Core is still in the normal interrupt mode.

## Notes:

If all the interrupt sources are disabled, the restart of the MCU can only be done by a Reset activation. The Wait instruction is not executed if an enabled interrupt request is pending. In the ST638X the hardware activated digital watchdog function is present. As the watchdog is always activated the STOP instruction is de-activated and any attempt to execute the STOP instruction will cause an execution of a WAIT instruction.

## ON-CHIP CLOCK OSCILLATOR

The internal oscillator circuit is designed to require a minimum of external components. A crystal quartz, a ceramic resonator, or an external signal (provided to the OSCIN pin) may be used to generate a system clock with various stability/cost tradeoffs. The typical clock frequency is 8 MHz . Please note that different frequencies will affect the operation of those peripherals (D/As, SPI, 62.5 KHz OUT) whose reference frequencies are derived from the system clock.
The different clock generator options connection methods are shown in Figure 25, crystal specifications and suggested PC board layouts are given in Figure 26 and Figure 27. One machine cycle takes 13 oscillator pulses; 12 clock pulses are needed to increment the PC while and additional 13th pulse is needed to stabilize the internal latches during memory addressing. This means that with a clock frequency of 8 MHz the machine cycle is $1.625 \mu \mathrm{Sec}$.
The crystal oscillator start-up time is a function of many variables: crystal parameters (especially RS), oscillator load capacitance (CL), IC parameters, ambient temperature, and supply voltage.It must be

Table 7. Instructions Timing with 8 MHz Clock

| Instruction Type | Cycles | Execution <br> Time |
| :--- | :--- | :--- |
| Branch if set/reset | 5 Cycles | $8.125 \mu \mathrm{~s}$ |
| Branch \& Subroutine Branch | 4 Cycles | $6.50 \mu \mathrm{~s}$ |

## INPUT/OUTPUT PORTS

The ST638X microcontrollers use three standard I/O ports (A,B,C) with up to eight pins on each port; refer to the device pin configurations to see which pins are available.
Each line can be individually programmed either in the input mode or the output mode as follows by software.

- Output
- Input with on-chip pull-up resistor (selected by software)
- Input without on-chip pull-up resistor (selected by software)
Note: pins with 12 V open-drain capability do not have pull-up resistors.
In output mode the following hardware configurations are available:
- Open-drain output 12V (PA4-PA7, PC4-PC7)
- Open-drain output 5V (PC0-PC3)
- Push-pull output (PA0-PA3, PB0-PB6)

The lines are organized in three ports (port $A, B, C$ ).
The ports occupie 6 registers in the data space. Each bit of these registers is associated with a particular line (for instance, the bits 0 of the Port A Data and Direction registers are associated with the PAO line of Port A).
There are three Data registers (DRA, DRB, DRC), that are used to read the voltage level values of the lines programmed in the input mode, or to write the logic value of the signal to be output on the lines configured in the output mode. The port Data Registers can be read to get the effective logic levels of the pins, but they can be also written by the user software, in conjunction with the related Data Direction Register, to select the different input mode options. Single-bit operations on I/O registers (bit set/reset instructions) are possible but care is necessary because reading in input mode is done from I/O pins and therefore they might be influenced by the external load, while writing will directly affect the Port data register causing an undesired changes of the input configuration. The three Data Direction registers (DDRA, DDRB,DDRB) allow the selection of the direction of each pin (input or output).
All the I/O registers can be read or written as any other RAM location of the data space, so no extra RAM cell is needed for port data storing and manipulation. During the initialization of the MCU, all the $I / O$ registers are cleared and the input mode with pull-up is selected on all the pins thus avoiding pin conflicts (with the exception of PC2 that is set in output mode and is set high ie. high impedence).

## INPUT/OUTPUT PORTS (Continued)

## Details of I/O Ports

When programmed as an input a pull-up resistor (if available) can be switched active under program control. When programmed as an output the I/O port will operate either in the push-pull mode or the open-drain mode according to the hardware fixed configuration as specified below.
Port A. PAO-PA3 are available as push-pull when outputs. PA4-PA7 are available as open-drain (no push-pull programmability) capable of withstanding 12V (no resistive pull-up in input mode). PA6PA7 has been specially designed for higher driving capability and are able to sink 25 mA with a maximum VOL of 1 V .
Port B. All lines are configured as push-pull when outputs.
Port C. PCO-PC3 are available as open-drain capable of withstanding a maximum $V_{D D}+0.3 \mathrm{~V}$. PC4-PC7 are available as open-drain capable of withstanding 12 V (no resistive pull-up in input mode). Some lines are also used as I/O buffers for signals coming from the on-chip SPI.
In this case the final signal on the output pin is equivalent to a wired AND with the programmed data output.
If the user needs to use the serial peripheral, the I/O line should be set in output mode while the open-drain configuration is hardware fixed; the corresponding data bit must set to one. If the latched interrupt functions are used (IRIN, PWRIN) then the corresponding pins should be set to input mode.
On ST638X the I/O pins with double or special functions are:

- PCO/SCL (connected to the SPI clock signal)
- PC1/SDA (connected to the SPI data signal)
- PC3/SEN (connected to the SPI enable signal)
- PC4/PWRIN (connected to the PWRIN interrupt latch)
- PC6/IRIN (connected to the IRIN interrupt latch)

All the Port A,B and C I/O lines have Schmitt-trigger input configuration with a typical hysteresis of 1 V .

## I/O Pin Programming

Each pin can be individually programmed as input or output with different input and output configurations.
This is achieved by writing to the relevant bit in the data (DR) and data direction register (DDR). Table 8 shows all the port configurations that can be selected by the user software.

Table 8. I/O Port Options Selection

| DDR | DR | Mode | Option |
| :---: | :---: | :---: | :---: |
| 0 | 0 | Input | With on-chip pull-up <br> resistor |
| 0 | 1 | Input | Without on-chip pull-up resistor |
| 1 | $X$ | Output | Open-drain or Push-Pull |

Note: X. Means don't care

Figure 29. I/O Port Data Registers

Figure 30. I/O Port Data Direction Registers

PC7-PCO. Set to 04H at power-on. Bit 2 (PC2 pin) is set to one (open drain therefore high impedence).
PA7-PAO. These are the I/O port A data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Reset at power-on.

## INPUT/OUTPUT PORTS (Continued)

PB7-PB0. These are the I/O port B data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Reset at power-on.
PC7-PC0. These are the I/O port C data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Set to 04 H at power-on. Bit 2 (PC2 pin) is set to one (output mode selected).

## Input/Output Configurations

The following schematics show the I/O lines hardware configuration for the different options. Figure 31 shows the I/O configuration for an I/O pin with open-drain 12 V capability (standard drive and high drive). Figure 31 shows the I/O configuration for an I/O pin with push-pull and with open drain 5 V capability.

## Notes:

The WAIT instruction allows the ST638X to be used in situations where low power consumption is needed. This can only be achieved however if the I/O pins either are programmed as inputs with well
defined logic levels or have no power consuming resistive loads in output mode. As the same die is used for the different ST638X versions the unavailable I/O lines of ST638X should be programmed in output mode.

Figure 31. I/O Configuration Diagram (Open Drain 5V, Push-pull)

## TIMERS

The ST638X devices offer two on-chip Timer peripherals consisting of an 8-bit counter with a 7 -bit programmable prescaler, thus giving a maximum count of $2^{15}$, and a control logic that allows configuring the peripheral in three operating modes. Figure 33 shows the timer block diagram. This timers do not have the external TIMER pin available for the user. The content of the 8 -bit counter can be read/written in the Timer/Counter register TCR that can be addressed in the data space as RAM location at the D3H (Timer 1) and DBH (Timer 2) addresses. The state of the 7-bit prescaler can be read in the PSC register at the D2H (Timer 1) and DAH (Timer2) addresses. The control logic device can be managed thanks to the TSCR register D4H (Timer 1) and DCH (Timer 2) addresses as it is described in the following paragraphs.
The following description applies to both Timer 1 and Timer 2. The 8 -bit counter is decrement by the output (rising edge) coming from the 7 -bit prescaler and can be loaded and read under program control. When it decrements to zero then the TMZ (timer zero) bit in the TSCR is set to one. If the ETI (enable timer interrupt) bit in the TSCR is also set to one an
interrupt request, associated to interrupt vector \#3 (for Timer 1) and \#1 for Timer 2, is generated. The interrupt of the timer can be used to exit the MCU from the WAIT mode.

The prescaler decrements on rising edge. The prescaler input can be the oscillator frequency divided by 12 or an external clock at TIMER pin (this is not available in ST638X).
Depending on the division factor programmed by PS2/PS1/PS0 (see table 9) bits in the TSCR, the clock input of the timer/counter register is multiplexed to different sources.
On division factor 1, the clock input of the prescaler is also that of timer/counter; on factor 2, bit 0 of prescaler register is connected to the clock input of TCR.

This bit changes its state with the half frequency of prescaler clock input. On factor 4, bit 1 of PSC is connected to clock input of TCR, and so on. On division factor 128, the MSB bit 6 of PSC is connected to clock input of TCR. The prescaler initialize bit (PSI) in the TSCR register must be set to one to allow the prescaler (and hence the counter) to start. If it is cleared to zero then all of the prescaler bits are set to one and the counter is inhibited from counting.

Figure 33. Timer Peripheral Block Diagram

TIMERS (Continued)
Figure 34. Timer Working Principle

The prescaler can be given any value between 0 and 7 FH by writing to the related register address, if bit PSI in the TSCR register is set to one. The tap of the prescaler is selected using the PS2/PS1/PS0 bits in the control register. Figure 34 shows the timer working principle.

## Timer Operating Modes

As on ST638X devices the external TIMER pin is not available the only allowed operating mode is the output mode that have to be selected by setting to 1 bit 4 and by clearing to 0 bit 5 in the TSCR1 register. This procedure will enable both Timer 1 and Timer 2. Any other combination written into these two bits will disable any Timer 1 and Timer 2 operation.
Output Mode (TSCR1 D4 = 1, TSCR1 D5 = 0). On this mode the timer prescaler is clocked by the prescaler clock input (OSC/12). The user can select the desired prescaler division ratio through the PS2/PS1/PS0 bits. When TCR count reaches 0 , it sets the TMZ bit in the TSCR.
The TMZ bit can be tested under program control to perform a timer function whenever it goes high. Bit D4 and D5 on TSCR2 (Timer 2) register are not implemented.

## Timer Interrupt

When the counter register decrements to zero and the software controlled ETI (enable timer interrupt) bit is set to one then an interrupt request associated to interrupt vector \#3 (for Timer 1) and to interrupt vector \#1 (for Timer 2) is generated. When the counter decrements to zero also the TMZ bit in the TSCR register is set to one.

## Notes :

TMZ is set when the counter reaches 00 H ; however, it may be set By writing 00 H in the TCR register or setting the bit 7 of the TSCR register. TMZ bit must be cleared by user software when servicing the timer interrupt to avoid undesired interrupts when leaving the interrupt service routine. After reset, the 8 -bit counter register is loaded to FFH while the 7-bit prescaler is loaded to 7FH , and the TSCR register is cleared which means that timer is stopped ( $\mathrm{PSI}=0$ ) and timer interrupt disabled.
A write to the TCR register will predominate over the 8 -bit counter decrement to 00 H function, i.e. if a write and a TCR register decrement to 00 H occur simultaneously, the write will take precedence, and the TMZ bit is not set until the 8 -bit counter reaches 00 H again. The values of the TCR and the PSC registers can be read accurately at any time.

TIMERS (Continued)

## Timer Registers

Figure 35. Timer Status Control Registers

TMZ. Low-to-high transition indicates that the timer count register has decrement to zero. This bit must be cleared by user software before to start with a new count.

ETI. This bit, when set, enables the timer interrupt (vector \#3 for Timer 1, vector \#1 for Timer 2) request. If $\mathrm{ETI}=0$ the timer interrupt is disabled. If $\mathrm{ET}=1$ and TMZ $=1$ an interrupt request is generated.
D5. This is the timers enable bit D5. It must be cleared to 0 together with a set to 1 of bit D4 to enable both Timer 1 and Timer 2 functions. It is not implemented on TSCR2 register. Any other combination of TSCR1 D4 and D5 bits will disable any operation of both Timer 1 and Timer 2.

D4. This is the timers enable bit D4. It must be set to 1 together with a clear to 0 of bit D5 to enable both Timer 1 and Timer 2 functions. It is not implemented on TSCR2 register. Any other combination of TSCR1 D4 and D5 bits will disable any operation of both Timer 1 and Timer 2.

PSI. Used to initialize the prescaler and inhibit its counting while $\mathrm{PSI}=0$ the prescaler is set to 7 FH and the counter is inhibited. When PSI $=1$ the prescaler is enabled to count downwards. As long as PSI= 0 both counter and prescaler are not running.
PS2-PSO. These bits select the division ratio of the prescaler register. (see table 9)

The TSCR1 and TSCR2 registers are cleared on reset. The correct D4-D5 combination must be written in TSCR1 by user's software to enable the operation of Timer 1 and Timer 2.

Table 9. Prescaler Division Factors

| PS2 | PS1 | PS0 | Divided By |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 1 |

## HARDWARE ACTIVATED DIGITAL WATCHDOG FUNCTION

The hardware activated digital watchdog function consists of a down counter that is automatically initialized after reset so that this function does not need to be activated by the user program. As the watchdog function is always activated this down counter can't be used as a timer. The watchdog is using one data space register (HWDR location D8H). The watchdog register is set to FEH on reset and immediately starts to count down, requiring no software start. Similarly the hardware activated watchdog can not be stopped or delayed by software.
The watchdog time can be programmed using the 6 MSbits in the watchdog register, this gives the possibility to generate a reset in a time between 3072 to 196608 oscillator cycles in 64 possible steps. (With a clock frequency of 8 MHz this means from $384 \mu$ s to 24.576 ms ). The reset is prevented if the register is reloaded with the desired value before bits 2-7 decrement from all zeros to all ones.
The presence of the hardware watchdog deactivates the STOP instruction and a WAIT instruction is automatically executed instead of a STOP. Bit 1 of the watchdog register (set to one at reset) can be used to generate a software reset if cleared to zero). Figure 38 shows the watchdog block diagram while Figure 39 shows its working principle.

Figure 39. Hardware Activated Watchdog Working Principle

Figure 38. Hardware Activated Watchdog Block Diagram

## HARDWARE ACTIVATED DIGITAL WATCHDOG FUNCTION (Continued)

Figure 40. Watchdog Register

T1-T6. These are the watchdog counter bits. It should be noted that D7 (T1) is the LSB of the counter and D2 (T6) is the MSB of the counter, these bits are in the opposite order to normal.
SR. This bit is set to one during the reset phase and will generate a software reset if cleared to zero.
C. This is the watchdog activation bit that is hardware set to one; the user can't change the value of this bit (the watchdog is always active).
The register reset value is FEH (Bit 1-7 set to one, Bit 0 cleared).

## SERIAL PERIPHERAL INTERFACE

The ST638X Serial Peripheral Interface macrocell (SPI) has been designed to be cost effective and flexible in interfacing the various peripherals in TV applications.
It maintains the software flexibility but adds hardware configurations suitable to drive devices which require a fast exchange of data. The three pins dedicated for serial data transfer (single master only) can operate in the following ways:

- as standard I/O lines (software configuration)
- as S-BUS or as $I^{2} C B U S$ (two pins)
- as standard (shift register) SPI

When using the hardware SPI, a fixed clock rate of 62.5 kHz is provided.

It has to be noted that the first bit that is output on the data line by the 8 -bit shift register is the MSB.

## SPI Data/Control Registers

For I/O details on SCL (Serial Clock), SDA (Serial Data) and SEN (Serial Enable) please refer to I/O Ports description with reference to the following registers:

Port C data register, Address C2H (Read/Write).

- BIT DO "SCL"
- BIT D1 "SDA"
- BIT D3 "SEN"

Port C data direction register, Address C 6 H (Read/Write).

Figure 41. SPI Serial Data Register

D7-DO. These are the SPI data bits. They can be neither read nor written when SPI is operating (BUSY bit set). They are undefined after reset.

Figure 42. SPI Control Register 1

D7-D4. These bits are not used.
STR. This is Start bit for $I^{2}$ CBUS/S-BUS. This bit is meaningless when STD/SPI enable bit is cleared to zero. If this bit is set to one STD/SPI bit is also set to "1" and SPI Start generation, before beginning of transmission, is enabled. Set to zero after reset.
STP. This is Stop bit for $I^{2}$ CBUS/S-BUS. This bit is meaningless when STD/SPI enable bit is cleared to zero. If this bit is set to one STD/SPI bit is also set to "1" and SPI Stop condition generation is enabled. STP bit must be reset when standard protocol is used (this is also the default reset conditions). Set to zero after reset.
STD, SPI Enable. This bit, in conjunction with S-BUS $/ I^{2}$ CBUS bit, allows the SPI disable and will select between $1^{2}$ CBUS/S-BUS and Standard

SERIAL PERIPHERAL INTERFACE (Continued)
shift register protocols. If this bit is set to one, it selects both $1^{2}$ CBUS and S-BUS protocols; final selection between them is made by $S$ BUS $/ l^{2} \mathrm{CBUS}$ bit. If this bit is cleared to zero when S-BUS $/ I^{2}$ CBUS is set to " 1 " the Standard shift register protocol is selected. If this bit is cleared to " 0 " when S-BUS $/ I^{2} \mathrm{CBUS}$ is cleared to 0 the SPI is disabled. Set to zero after reset.
S-BUS $/ /^{2}$ CBUS Selection. This bit, in conjunction with STD/SPI bit, allows the SPI disable and will select between $I^{2} C B U S$ and S-BUS protocols. If this bit is cleared to " 0 " when STD bit is also " 0 ", the SPI interface is disabled. If this bit is cleared to zero when STD bit is set to " 1 ", the I ${ }^{2}$ CBUS protocol will be selected. If this bit is set to one when STD bit is set to "1", the S-BUS protocol will be selected. Cleared to zero after reset.

Table 10. SPI Modes Selection

| D0 <br> S-BUS/ $/{ }^{2}$ CBUS | D1 <br> STD/SPI | SPI Function |
| :---: | :---: | :---: |
| 0 | 0 | Disabled |
| 1 | 0 | STD Shift <br> Register |
| 0 | 1 | $1^{2}$ CBUS |
| 1 | 1 | S-BUS |

Figure 43. SPI Control Register 2

D7-D4. These bits are not used.
TX/RX. Write Only. When this bit is set, current byte operation is a transmission. When it is reset, current operation is a reception. Set to zero after reset.
VRY/S.Read Only/Write Only. This bit has two different functions in relation to read or write oper-
ation. Reading Operation: when STD and/or TRX bits are cleared to 0 , this bit is meaningless. When bits STD and TX are set to 1 , this bit is set each time BSY bit is set. This bit is reset during byte operation if real data on SDA line are different from the ones output from the shift register. Set to zero after reset. Writing Operation : it enables (if set to one) or disables (if cleared to zero) the interrupt coming from VSYNC pin. Undefined after reset. Refer to OSD description for additional information.
ACN. Read Only. If STD bit (D1 of SCR1 register) is cleared to zero this bit is meaningless. When STD is set to one, this bit is set to one if no Acknowledge has been received. In this case it is automatically reset when BSY is set again. Set to zero after reset.
BSY.Read/Set Only. This is the busy bit zero. When a one is loaded into this bit the SPI interface start the transmission of the data byte loaded into SSDR data register or receiving and building the receive data into the SSDR data register. This is done in accordance with protocol, direction and start/stop condition(s). This bit is automatically cleared at the end of the current byte operation. Cleared to zero after reset.

## Note :

The SPI shift register is also the data transmission register and the data received register; this new feature is made possible by using the serial structure of the ST638X and thus reducing size and complexity.
During transmission or reception of data, all access to serial data register is therefore disabled. The reception or transmission of data is started by setting the BUSY bit to " 1 "; this will be automatically reset at the end of the operation. After reset, the busy bit is cleared to " 0 ", and the hardware SPI disabled by clearing bit 0 and bit 1 of SPI control register 1 to " 0 ". The outputs from the harware SPI are "ANDed" to the standard I/O software controlled outputs. If the hardware SPI is in operation then Port C ouputs related to the SPI should be set high or the pins should pin configured as inpus using the data direction register. When the SPI is configured as the S-BUS, the three pins PC0, PC1 and PC3 become the pins SCL, SDA and SEN respectively. When configured as the $\mathrm{I}^{2} \mathrm{CBUS}$ the pins PCO and PC1 are configured as the pins SCL and SDA; PC3 is not driven and can be used as general purpose I/O pin. In the case of the STDSPI the pins PCO and PC1 become the signals CLOCK and DATA, PC3 is not driven and can be used as general purpose I/O pin. The VERIFY bit is available when the SPI is configured as either S-BUS or $I^{2}$ CBUS. At the start of a byte transmission, the verify bit is set to one. If at any time during the transmission of the following eight bits, the data on the SDA line does not match the data forced by the SPI (while SCL is

## SERIAL PERIPHERAL INTERFACE (Continued)

high), then the VERIFY bit is reset. The verify is available only during transmission for the S-BUS and $I^{2}$ CBUS; for other protocol it is not definfited. The SDA and SCL signal entering the SPI are buffered in order to remove any minor glitches. When STD bit is set to one (S-BUS or $1^{2} C B U S$ selected), and TRX bit is reset (receiving data), and STOP bit is set (last byte of current communication), the SPI interface does not generate the Acknowledge, according to S-BUS $/ /^{2} C B U S$ specifications. PCO-SCL, PC1-SDA and PC3-SEN lines are standard drive I/O port pins with opendrain output configuration (maximum voltage that can be applied to these pins is $V_{D D}+0.3 \mathrm{~V}$ ).

## S-BUS $/$ I $^{2}$ CBUS Protocol Information

The S-BUS is a three-wire bidirectional data-bus with functional features similar to the $I^{2}$ CBUS. In fact the S-BUS includes decoding of Start/Stop conditions and the arbitration procedure in case of multimaster system configuration (the ST638X SPI allows a single-master only operation). The SDA line, in the $I^{2} C B U S$ represents the AND combination of SDA and SEN lines in the S-BUS. If the SDA and the SEN lines are short-circuit connected, they appear as the SDA line of the $I^{2} C B U S$. The Start/Stop conditions are detected (by the external peripherals suited to work with $\mathrm{S}-\mathrm{BUS} / \mathrm{I}^{2} \mathrm{CBUS}$ ) in the following way:

- On S-BUS by a transition of the SEN line ( 1 to 0 Start, 0 to 1 Stop) while the SCL line is at high level.
- On $I^{2}$ CBUS by a transition of the SDA line (10 Start, 01Stop) while the SCL line is at high level.

Start and Stop condition are always generated by the master (ST638X SPI can only work as single master). The bus is busy after the start condition and can be considered again free only when a certain time delay is left after the stop condition. In the S-BUS configuration the SDA line is only allowed to change during the time SCL line is low. After the start information the SEN line returns to high level and remains unchanged for all the data transmission time. When the transmission is completed the SDA line is set to high level and, at the same time, the SEN line returns to the low level in order to supply the stop information with a low to high transition, while the SCL line is at high level. On the S-BUS, as on the $1^{2}$ CBUS, each eight bit information (byte) is followed by one acknowledged bit which is a high level put on the SDA line by the transmitter. A peripheral that acknowledges has to pull down the SDA line during the acknowledge clock pulse. An addressed receiver has to generate an acknowledge after the reception of each byte; otherwise the SDA line remains at the high level during the ninth clock pulse time. In this case the master transmitter can generate the Stop condition,
via the SEN (or SDA in $1^{2} \mathrm{CBUS}$ ) line, in order to abort the transfer.
Start/Stop Acknowledge. The timing specs of the S-BUS protocol require that data on the SDA (only on this line for $I^{2} \mathrm{CBUS}$ ) and SEN lines be stable during the "high" time of SCL. Two exceptions to this rule are foreseen and they are used to signal the start and stop condition of data transfer.

- On S-BUS by a transition of the SEN line (10 Start, 01 Stop) while the SCL line is at high level.
- On $I^{2}$ CBUS by a transition of the SDA line ( 10 Start, 01 Stop) while the SCL line is at high level.
Data are transmitted in 8 -bit groups; after each group, a ninth bit is interposed, with the purpose of acknowledging the transmitting sequence (the transmit device place a "1" on the bus, the acknowledging receiver a "0").
Interface Protocol. This paragraph deals with the description of data protocol structure. The interface protocol includes:

## - A start condition

- A "slave chip address" byte, transmitted by the master, containing two different information:
a. the code identifying the device the master wants to address (this information is present in the first seven bits)
b. the direction of transmission on the bus (this information is given in the 8th bit of the byte); " 0 " means "Write", that is from the master to the slave, while "1" means "Read". The addressed slave must always acknowledge.
The sequence from, now on, is different according to the value of $R / \bar{W}$ bit.

1. $R / \bar{W}=" 0 "(\overline{W r i t e})$

In all the following bytes the master acts as transmitter; the sequence follows with:
a. an optional data byte to address (if needed) the slave location to be written (it can be a word address in a memory or a register address, etc.).
b. a "data" byte which will be written at the address given in the previous byte.
c. further data bytes.
d. a STOP condition

A data transfer is always terminated by a stop condition generated from the master. The ST638X peripheral must finish with a stop condition before another start is given. Figure 44 shows an example of write operation.
2. $\mathrm{R} / \overline{\mathrm{W}}=$ "1" (Read)

In this case the slave acts as transmitter and, therefore, the transmission direction is changed. In read mode two different conditions can be considered:

SERIAL PERIPHERAL INTERFACE (Continued)
a. The master reads slave immediately after first byte. In this case after the slave address sent from the master with read condition enabled the master transmitter becomes master receiver and the slave receiver becomes slave transmitter.
b. The master reads a specified register or location of the slave. In this case the first sent byte will contain the slave address with write condition enabled, then the second byte will specify the address of the register to be read. At this moment a new start is given together with the slave address in read mode and the procedure will proceed as described in previous point "a".

Figure 44. Master Transmit to Slave Receiver (Write Mode)

Figure 45. Master Reads Slave Immediately After First Byte (read Mode)

Figure 46. Master Reads After Setting Slave Register Address (Write Address, Read Data)

SERIAL PERIPHERAL INTERFACE (Continued)
S-BUS $/ 1^{2}$ CBUS Timing Diagrams
The clock of the S-BUS $/ /^{2}$ CBUS of the ST638X SPI (single master only) has a fixed bus clock frequency
of 62.5 KHz . All the devices connected to the bus must be able to follow transfers with frequencies up to 62.5 KHz , either by being able to transmit or receive at that speed or by applying the clock synchronization procedure which will force the master into a wait state and stretch low periods.

Figure 47. S-BUS Timing Diagrams

SERIAL PERIPHERAL INTERFACE (Continued)
Figure 48. ${ }^{2} \mathrm{C}$ BUS Timing Diagrams

Note: The third pin, SEN, should be high; it's not used in the I ${ }^{2}$ CBUS. Logically SDA is the AND of the S-BUS SDA and SEN.)

SERIAL PERIPHERAL INTERFACE (Continued)

## Compatibility S-BUS $/ I^{2}$ CBUS

Using S-BUS protocol it is possible to implement mixed system including S-BUS $/ I^{2} C B U S$ bus peripherals. In order to have the compatibility with the ${ }^{2}$ CBUS peripherals, the devices including the $S$ BUS interface must have their SDA and SEN pins
connected together as shown in the following Figure 49 (a and b). It is also possible to use mixed S-BUS $/ /^{2}$ CBUS protocols as showed in figure 49 (c). S-BUS peripherals will only react to S-BUS protocol signals, while ${ }^{2} \mathrm{CBUS}$ peripherals will only react to $I^{2} \mathrm{CBUS}$ signals. Multimaster configuration is not possible with ST63XX SPI (single master only).

Figure 49. $\mathrm{S}-\mathrm{BUS} / \mathrm{I}^{2} \mathrm{C}$ BUS Mixed Configurations

## SERIAL PERIPHERAL INTERFACE (Continued)

Figure 50. Software Bus (hardware bus disabled) Timing Diagram

## STD SPI Protocol (Shift Register)

This protocol is similar to the $I^{2}$ CBUS with the exception that there is no acknowledge pulse and there are no stop or start bits. The clock cannot be slowed down by the external peripherals.

In this case all three outputs should be high in order not to lock the software I/Os from functioning.

## SPI APPLICATION NOTES

Stop Clock Slowdown: In the ST638X family of devices when operating in the $I^{2} \mathrm{C}$ or SBUS modes, there is no internal clock slowdown for the final STOP clock. Slowdown means that if an external peripheral requires extra time it will hold the ST638X SCL clock low. To be fully ${ }^{2} \mathrm{C}$ and SBUS
compatible in this respect, the SW should check that the SCL line is indeed high before proceeding with the START of another $\mathrm{I}^{2} \mathrm{C}$ or SBUS transmission. In all other cases the SCL clock slowdown feature is operational.
SPI Standard Bus Protocol: The standard bus protocol is selected by loading the SPI Control Register 1 (SCR1 Add. EBH). Bit 0 named I ${ }^{2} \mathrm{C}$ must be set at one and bit 1 named STD must be reset. When the standard bus protocol is selected bit 2 of the SCR1 is meaningless.
This bit named STOP bit is used only in $I^{2}$ CBUS or SBUS. However take care that the STOP BIT MUST BE RESET WHEN THE STANDARD PROTOCOL IS USED. This bit is set to ZERO after RESET.

## 14-BIT VOLTAGE SYNTHESIS TUNING PERIPHERAL

The ST638X on-chip voltage synthesis tuning peripheral has been integrated to allow the generation of tuning reference voltage in low/mid end TV set applications. The peripheral is composed of a 14bit counter that allows the conversion of the digital content in a tuning voltage, available at the VS output pin, by using PWM and BRM techniques. The 14-bit counter gives 16384 steps which allows a resolution of approximately 2 mV over a tuning voltage of 32 V ; this corresponds to a tuning resolution of about 40 KHz per step in UHF band (the actual value will depend on the characteristics of the tuner).
The tuning word consists of a 14 -bit word contained in the registers VSDATA1 (location OEEH) and VSDATA2 (location OEFH). Course tuning (PWM) is performed using the seven MSBit, while the fine tuning (BRM) is performed using the data in the seven LSBIT. With all zeros loaded the output is zero ; as the tuning voltage increseses from all zeros, the number of pulses in one period increses to 128 with all pulses being the same width. For values larger than 18 , the PWM takes over and the number of pulses in one period remains constant at 128, but the width changes. At the other end of the scale, when almost all ones are loaded, the pulses will start to link together and the number of pulses will decrease. When all ones are loaded, the output will be almost $100 \%$ high but will have a low pulse ( $1 / 16384$ of the high pulse).

## Output Details

Inside the on-chip Voltage Synthesis cell are included the register latches, a reference counter, PWM and BRM control circuitry ; the structure is one used in many devices currenlty in production from SGS-THOMSON (M106, M193, M293, M490/91/94). In the ST638X the clock for the 14-bit reference counter is 2 MHz derived from the 8 MHz system clock. From the circuit point of view, the seven most significant bits controls the course tuning, while the seven least significant bits the fine tuning. From the application and software point of view, the 14 bits can be considered as one binary number.

As already mentioned the course tuning consists of a PWM signal with 128 steps ; we can consider the dine tuning to cover 128 course tuning cycles. The addition of pulses is described in the following Table 11.

Table 11. Fine Tuning Pulse Addition

| Fine Tuning <br> (7 LSB) | N of Pulses added at <br> the following cycles <br> (0...127) |
| :--- | :--- |
| 0000001 | 64 |
| 0000010 | 32,96 |
| 0000100 | $16,48,80,112$ |
| 0001000 | $8,24, \ldots .104,120$ |
| 0010000 | $4,12, \ldots .116,124$ |
| 0100000 | $2,6, \ldots . .122,126$ |
| 1000000 | $1,3, \ldots . .125,127$ |

The VS output pin has a standard drive push-pull output configuration.

## VS Tuning Cell Registers

Figure 51. VS Data Register 1

D7-DO. These are the 8 least significant VS data bits. Bit 0 is the LSB. This register is undefined on reset.

Figure 52. VS Data Register 2

D7-D6. These bits are not used.
D5-DO. These are the 6 most significant VS data bits. Bit 5 is the MSB. This register is undefined on reset.

## 6-BIT PWM D/A CONVERTERS

The D/A macrocell contains up to six PWM D/A outputs (32Khz repetition, DA0-DA5) with six bit resolution .
Each D/A converter of ST638X is composed by the following main blocks:

- pre-divider
- 6-bit counter
- data latches and compare circuits

The pre-divider uses the clock input frequency ( 8 MHz typical ) and its output clocks the 6-bit free-running counter. The data latched in the six registers (E0H, E1H, E2H, E3H, E6H and E7H) control the six D/A outputs (DAO,1,2, 3, 4 and 5). When all zeros are loaded the relevant output is an high logic level; all 1's correspond to a pulse with a $1 / 64$ duty cycle and almost $100 \%$ zero level.
The repetition frequency is 31.25 KHz and is related to the 8 MHz clock frequency. Use of a different oscillator frequency will result in wrong repetition frequency. All D/A outputs are open-drain with standard current drive capability and able to withstand up to 12 V .

## D/A Data/Control Registers

This paragraph deals with the description of D/A data/control registers.

Figure 54. DAO-DA5 Data Control Registers

DAO-DA5. These are the 6 bits of the PWM digital to analog converter. Undefined after reset.

## AFC A/D INPUT, IR/PC6 RESULT, VSYNC RESULT AND 62.5 KHz OUTPUTS

The AFC macrocell contains an A/D comparator with five levels at intervals of 1 V from 1 V to 5 V . The levels can all be lowered by 0.5 V to effectively double the resolution. This A/D can be used to perform the AFC function. In addition this cell offers also a keyboard input register of three bits used to perform a keyboard scan and 4 open-drain outputs (able to withstand signals up to 12 V ) that can be used to perform band switch function.

Figure 55. AFC Inputs Configuration Diagram

# - 

$\square$

Figure 53. 6-BIT PWM D/A Output Configuration

## AFC A/D INPUT, IR/PC6 RESULT, VSYNC RESULT, AND 62.5 KHz OUTPUT (Continued)

## A/D Comparator

The A/D used to perform the AFC function (when high threshold is selected) has the following voltage levels: $1,2,3,4$ and 5 V . Bits $0-2$ of AFC result register ( E 4 H address) will provide the result in binary form (less than 1 V is 000 , greater than 5 V is 101).
If the application requires a greater resolution, the sensitivity can be doubled by clearing to zero bit 2 of the OUTPUTS control register, address E5H. In this case all levels are shifted lower by 0.5 V . If the two results are now added within a software routine then the A/D S-curve can be located within a resolution of 0.5 V .
The $A / D$ input has high impedance able to withstand up to 13 V signals (input level tolerances $\pm$ 200 mV absolute and $\pm 100 \mathrm{mv}$ relative to 5 V ).

Figure 56. AFC, IR and OSD Result Register

D7-D5. These bits are not used.
VSYNC. This bit reads the status of the VSYNC pin. It is inverted with respect to the pin. Refer to the OSD description for additional information.
IR. This bit reads the status of the IR latch. If a signal has been latched this bit will be high. Refer to the DEDICATED LATCHES description for additional information.

AD2-ADO. These bits store the real time conversion of the value present on the AFC input pin. No reset value.

Figure 57. Outputs Control Register

D7, D6, D5, D3, D2. These bits are not used.
A/D Shift. This bit determines the voltage range of the AFC input. Writing a zero will select the 0.5 V to 4.5 V range. Writing a one will select the 1.0 V to 5.0 V range. Undefined after reset.

### 62.5 KHz Output

This bit is available only on ST6386,88. The pin is push-pull output at a frequency of 62.5 KHz (with an 8 MHz clock). The pin can used to drive the SGSTHOMSON TEA5640 chroma processor. Refer to the TEA5640 data sheet for more information. Care must be taken to respect the frequency tolerances required by the TEA5640 by chosing a quartz with PPM variations within the limits required by the chroma processor.

## DEDICATED LATCHES

Two latches are available which may generate interrupts to the ST638X core. The IR latch is set either by the falling or rising edge of the signal on pin PC6(IRIN). If bit 1 (IRPOSEDGE) of the latches register (E9H) is high, then the latch will be triggered on the rising edge of the signal at PC6(IRIN). If bit 1 (IRPOSEDGE) is low, then the latch will be triggered on the rising edge of the signal at PC6(IRIN). The IR latch can be reset by setting bit 3 (RESIRLAT) of the latches register; the bit is set only and a high should be written every time the IR latch needs to be reset. If bit 2 (IRINTEN) of the latches register (E9H) is high, then the output of the IR latch, IRINTN, may generate an interrupt (\#0). IRINTN is inverted with respect to the state of the

## DEDICATED LATCHES (Continued)

IR latch. If bit 2 (IRINTEN) is low, then the output of the IR latch, IRINTN, is forced high. For more information see the interrupts section. The state of the IR latch may be read from bit 3 (IRLATCH) of register E 4 H ; if the IR latch is set, then bit 3 will be high. The PWR latch is set either by the falling or rising edge of the signal on pin PC4(PWRIN). If bit 4 (PWREDGE) of the latches register (E9H) is high, then the latch will be triggered on the rising edge of the signal at PC4(PWRIN). If bit 4 (PWREDGE) is low, then the latch will be triggered on the falling edge of the signal at PC4(PWRIN). The PWR latch can be reset by setting bit 6 (RESPWRLAT) of the latches register; the bit is set only and a high should be written every time the PWR latch needs to be reset. If bit 5 (PWRINTEN) of the latches register (E9H) is high, then the output of the PWR latch, PWRINTN, may generate an interrupt (\#4). PWRINTN is inverted with respect to the state of the PWR latch. If bit 5 (PWRINTEN) is low, then the output of the PWR latch, PWRINTN, is forced high. For more information see the interrupts section.

Figure 58. Dedicated Latched Control Register

D7. This bit is not used
RESPWRLAT. Resets the PWR latch; this bit is set only.
PWRINTEN. This bit enables the PWRINTN signal (\#4) from the latch to the ST638X core. Undefined after reset.
PWRIN. The bit determines the edge which will cause the PWRIN latch to be set. If this bit is high, than the PWRIN latch will be set on the rising edge of the PWRIN signal. Undefined after reset.

RESIRLAT. Resets the IR latch; this bit is set only.
IRINTEN. This bit enables the IRINTN signal (\#O) from the latch to the ST638X core. Undefined after reset.
IRPOSEDGE. The bit determines the edge which will cause the IR latch to be set. If this bit is high, than the IR latch will be set on the rising edge of the IR signal. Undefined after reset.
DO. This bit is not used

## ON-SCREEN DISPLAY (OSD)

The ST638X OSD macrocell is a CMOS LSI character generator which enable display of characters and symbols on the TV screen. The character rounding function enhances the readability of the characters. The ST638X OSD receives horizontal and vertical synchronization signal and outputs screen information via $R, G, B$ and blanking pins. The main characteristics of the macrocell are listed below:

- Number of display characters: 5 lines by 15 columns.
- Number of character types: 128 characters in two banks of 64 characters. Only one bank per screen can be used.
- Character size: Four character heights ( $18 \mathrm{H}, 36 \mathrm{H}$ $54 \mathrm{H}, 72 \mathrm{H}$ ), two available per screen programmable by line.
- Character format: 6x9 dots with character rounding function.
- Character color: Eight colors available programmable by word.
- Display position: 64 horizontal positions by 2/fos and 63 vertical positions by 4 H
- Word spacing: 64 positions programmable from 2/fosc to 128/fosc.
- Line spacing: 63 positions programmable from 4 to 252 H .
- Background: No background, square background or fringe background programmable by word.
- Background color: Two of eight colors available programmable by word.
- Display output: Three character data output terminals ( $\mathrm{R}, \mathrm{G}, \mathrm{B}$ ) and a blank output terminal.
- Display on/off: Display data may be programmed on or off by word or entire screen. Entire screen may be blanked.

## Format Specification

The entire display can be turned on or off thru the use of global enable bit or the display may be selectively turned on or off by word. To turn off the entire display, the global enable bit (GE) should be

## ON-SCREEN DISPLAY (Continued)

zero. If the global enable is one, the display is controlled by the word enable bits (WE). The global enable bit is located in the global enable register and the word enable bit is located in the space character preceding the word.
Each line must begin with a format character which describes the format of that line and of the first word. This character is not displayed.
A space character defines the format of subsequent words. A space character is denoted by a one in bit 6 in the display RAM. If bit 6 of the display RAM is a zero, the other six bits define one of the 64 display characters.
The color, background and enable can be programmed by word. This information is encoded in the space character between words or in the format character at the beginning of each line. Five bits define the color and background of the following word, and determine whether it will be displayed or not.
Characters are stored in a $6 \times 9$ dot format. One dot is defined vertically as 2 H (horizontal lines) and horizontally as $2 /$ fosc if the smallest character size is enabled. There is no space between characters or lines if the vertical space enable (VSE) and horizontal space enable (HSE) bits are both zero. This allows the use of special graphics characters.
The normal alphanumeric character set is formatted to be $5 \times 7$ with on empty row at the top and one at the bottom and one empty column at the right. If VSE and HSE are both zero, then the spacing between alphanumeric characters is 1 dot and the spacing between lines of alphanumeric characters is 2 H .
The character size is programmed by line thru the use of the size bit ( S ) in the format character and the global size bits (GS1 and GS2). The vertical spacing enable bit (VSE) located in the format character controls the spacing between lines. If this bit is set to one, the spacing between lines is defined by the vertical spacing register, otherwise the spacing between lines is 0 .
The spacing between words is controlled by the horizontal space enable bit (HSE) located in the space character. If this bit is set to one, the spacing between words is defined by the horizontal spacing register, otherwise the space character width of 6 dots is the spacing between words.
The formats for the display character, space character and format character are described hereafter.

Figure 59. Space Character Register Explanation

## D7. Not used.

D6. This pin is fixed to "1".
R, G, B. Color. The 3 color control bits define the color of the following word as shown in table 12.
Table 12. Space Character Register Colour Setting.

| $\mathbf{R}$ | $\mathbf{G}$ | $\mathbf{B}$ | Color |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | Black |
| 0 | 0 | 1 | Blue |
| 0 | 1 | 0 | Green |
| 0 | 1 | 1 | Cyan |
| 1 | 0 | 0 | Red |
| 1 | 0 | 1 | Magenta |
| 1 | 1 | 0 | Yellow |
| 1 | 1 | 1 | White |

BGS. Background Select. The background select bit selects the desired background for the following word. There are two possible backgrounds defined by the bits in the Background Control Register.
" 0 " - The background on the following word is enabled by BGO and the color is set by R0, GO, and BO.
"1" - The background on the following word is enabled by BG1 and the color is set by R1, G1, and B1.
WE. Word Enable. The word enable bit defines whether or not the following word is displayed.
" 0 " - The word is not displayed.

## ON-SCREEN DISPLAY (Continued)

" 1 " - If the global enable bit is one, then the word is displayed.

HSE. Horizontal Space Enable. The horizontal space enable bit determines the spacing between words. The space between characters is always 0 . The alphanumeric character set is implemented in a $5 \times 7$ format with one empty column to the right and one empty row above and below so that the space between alphanumeric characters will be one dot.
" 0 " - The space between words is equal to the width of the space character, which is 6 dots.
"1" - The space between words is defined by the value in the horizontal space register plus the width of the space character.

Figure 60. Format Character Register Explanation

D7. This bit is not used
S. Character Size. The character size bit, along with the global size bits (GS2 and GS1) located in the horizontal space register, specify the character size for each line as defined in Table 14.
R, G, B. Color. The 3 color control bits define the color of the following word as shown in Table 13.
BGS. Background Select. The background select bit selects the desired background for the following word. There are two possible backgrounds defined by the bits in the Background Control Register.
" 0 " - The background on the following word is enabled by BGO and the color is set by RO, G0, and BO .
"1" - The background on the following word is enabled by BG1 and the color is set by R1, G1, and B1.
WE. Word Enable. The word enable bit defines whether or not the following word is displayed.
" 0 " - The word is not displayed.
"1" - If the global enable bit is one, then the word is displayed.

VSE. Vertical Space Enable. The vertical space enable bit determines the spacing between lines.
" 0 " - The space between lines is equal to 0 H . The alphanumeric character set is implemented in a $5 \times 7$ format with one empty column to the right and one empty row above and one below and stored in a $6 \times 9$ format.
"1" - The space between lines is defined by the value in the vertical space register.

## ON-SCREEN DISPLAY (Continued)

Figure 61. Display Character Register Explanation

D7. This bit is not used.
D6. This bit is fixed to " 0 ".
C5-C0. Character type. The 6 character type bits define one of the 64 available character types. These character types are shown on the following pages.

## Character Types

The character set is user defined as ROM mask option.

## Register and RAM Addressing

The OSD contains seven registers and 80 RAM locations. The seven registers are the Vertical Start Address register, Horizontal Start Address register, Vertical Space register, Horizontal Space register, Background Control register, Global Enable register and Character Bank Select register. The Global Enable register can be written at any time by the ST638X Core. The other six registers and the RAM can only be read or written to if the global enable is zero.
The six registers and the RAM are located on two pages of the paged memory of the ST638X MCUs; the Character Bank Select register is located outside the paged memory at address EDH. Each page contains 64 memory locations. This paged memory is at memory locations 00 H to 3 FH in the ST638X memory map. A page of memory is enabled by setting the desired page bit, located in the data RAM bank switching register, to a one. The page register is location E 8 H . A one in bit five selects page 5, located on the OSD and a one in bit 6 selects page 6 on the OSD. Table 15 shows the addresses of the OSD registers and RAM.

Table 15. OSD Control Registers and Data RAM Addressing

| Page | Address | Register or RAM |
| :---: | :---: | :---: |
| 5 | $00 \mathrm{H}-3 \mathrm{FH}$ | RAM Locations 00H - 3FH |
| 6 | $00 \mathrm{H}-0 \mathrm{FH}$ | RAM Locations 00H - 0FH |
| 6 | 10 H | Vertical Start Register |
| 6 | 11 H | Horizontal Start Regıster |
| 6 | 12 H | Vertical Space Register |
| 6 | 13 H | Horizontal Space Register |
| 6 | 14 H | Background Control Register |
| 6 | 17 H | Global Enable Regıster |
| No <br> Page | EDH | Character Bank Select Regıster |

## OSD Global Enable Register

This register contains the global enable bit (GE). It is the only register that can be written at any time regardless of the state of the GE bit. It is a write only register.

Figure 62. Global Enable register

D7-D1. These bits are not used
GE. Global Enable. This bit allows the entire display to be turned off.
" 0 " - The entire display is disabled. The RAM and other registers of the OSD can be accessed by the Core.
"1" - Display of words is controlled by the word enable bits (WE) located in the format or space character.
The other registers and RAM cannot be accessed by the Core.

ON-SCREEN DISPLAY (Continued)
Figure 63. Vertical Start Address Register

D7. This bit is not used
FR. Fringe Background. This bit changes the background from a box background to a fringe background. The background is enabled by word as defined by either BKO or BK1.
" 0 " - The background is defined to be a box which is $7 \times 9$ dots.
"1" - The background is defined to be a fringe.
VSA5-VSAO. Vertical Start Address. These bits determine the start position of the first line in the vertical direction. The 6 bits can specify 63 display start positions of interval 4H. The first start position will be the fourth line of the display. The vertical start address is defined VSAO by the following formula.
Vertical Start Address $=4 \mathrm{H}\left(2^{5}(\right.$ VSA5 $)+2^{4}($ VSA4 $)$ $+2^{3}($ VSA3 $)+2^{2}($ VSA2 $)+2^{1}($ VSA1 $)+2^{0}($ VSAO $\left.)\right)$
The case of all Vertical Start Address bits being zero is 111 .

Figure 64. Horizontal Start Address Register

D7. This bit is not used.
SBD. Space Blanking Disable. This bit controls whether or not the background is displayed when outputting spaces. If two background colors are used on adjacent words, then the background should not be displayed on spaces in order to make a nice break between colors. If an even background around an area of text is desired, as in a menu, then the background should be displayed when outputting spaces.
" 0 " - The background during spaces is controlled by the background enable bits (BKO and BK1) located in the Background Control register.
"1" - The background is not displayed when outputting spaces.
HSA5, HSAO - Horizontal Start Address bits. These bits determine the start position of the first character in the horizontal direction. The 6 bits can specify 64 display start positions of interval $2 /$ fosc or 400 ns. The first start position will be at $4.0 \mu$ s because of the time needed to access RAM and ROM before the first character can be displayed. The horizontal start address is defined by the following formula.
Horizontal Start Address $=2 /$ fosc $\left(10.0+2^{5}\right.$ (HSA5) $+2^{4}$ (HSA4) $+2^{3}(\mathrm{HSA} 3)+2^{2}($ HSA 2$)+2^{1}($ HSA1 $)+$ $2^{0}$ (HSAO))

# ON-SCREEN DISPLAY (Continued) 

Figure 65. Vertical Space Register

D7. This bit is not used
SCB. Screen Blanking. This bit allows the entire screen to be blanked.
" 0 " - The blanking output signal (VBLK) is active only when displaying characters.
"1" - The blanking output signal (VBLK) is always active. Characters in the display RAM are still displayed.
When this bit is set to one, the screen is blanked also without setting the Global Enable bit to one (OSD disabled).
VS5, VSO. Vertical Space. These bits determine the spacing between lines if the Vertical Space Enable bit (VSE) in the format character is one. If VSE is zero there will be no spaces between lines. The Vertical Space bits can specify one of 63 spacing values from 4 H to 252 H . The space between lines is defined by the following formula.
Space between lines $=4 \mathrm{H}\left(2^{5}(\right.$ VS5 $)+2^{4}($ VS 4$)+$ $\left.2^{3}(\mathrm{VS} 3)+2^{2}(\mathrm{VS} 2)+2^{1}(\mathrm{VS} 1)+2^{0}(\mathrm{VSO})\right)$
The case of all Vertical Start Address bits being zero is ill.

Figure 66. Horizontal Space Register

GS2,GS1. Global Size. These bits along with the size bit (S) located in the Character format word specify the character size for each line as defined in table 16.

Table 16. Horizontal Space Register Size Setting.

| GS2 | GS1 | $\mathbf{S}$ | Vertical Height | Horizontal <br> Lenght |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 18 H | 6 TDOT |
| 0 | 0 | 1 | 36 H | 12 TDOT |
| 0 | 1 | 0 | 18 H | 6 TDOT |
| 0 | 1 | 1 | 54 H | 18 TDOT |
| 1 | 0 | 0 | 36 H | 12 TDOT |
| 1 | 0 | 1 | 54 H | 18 TDOT |
| 1 | 1 | 0 | 36 H | 12 TDOT |
| 1 | 1 | 1 | 72 H | 24 TDOT |

Note: TDOT $=2 /$ fosc
HS5, HSO . Horizontal Space. These bits determine the spacing between words if the Horizontal Space Enable bit (HSE) located in the space character is a one. The space between words is then equal to the width of the space character plus the number of tdots specified by the Horizontal Space bits. The 6 bits can specify one of 64 spacing values ranging from 2 /fosc to $128 / f o s c$. The formula is shown below for the smallest size character(18H). If larger size characters are being displayed the spacing between words will increase proportionately. Multiply the value below by 2,3 or 4 for character sizes of $36 \mathrm{H}, 54 \mathrm{H}$ and 72 H respectively.
Space between words (not including the space character) $=2 /$ fosc $\left(\left(1+2^{5}(\mathrm{HS} 5)+2^{4}(\mathrm{HS} 4)+2^{3}(\mathrm{HS} 3)\right.\right.$ $\left.+2^{2}(\mathrm{HS} 2)+2^{1}(\mathrm{HS} 1)+2^{0}(\mathrm{HSO})\right)$

## ON-SCREEN DISPLAY (Continued)

## Background Control Register

This register sets up two possible backgrounds. The background select bit (BGS) in the format or space character will determine which background is selected for the current word.

Figure 67. Background Control Registers

R1,R0,G1,G0,B1,B0. Background Color. These bits define the color of the specified background, either background 1 or background 0 as defined in Table 17.

Table 17. Background Register Colour Setting.

| $\mathbf{R X}$ | $\mathbf{G X}$ | $\mathbf{B X}$ | Color |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | Black |
| 0 | 0 | 1 | Blue |
| 0 | 1 | 0 | Green |
| 0 | 1 | 1 | Cyan |
| 1 | 0 | 0 | Red |
| 1 | 0 | 1 | Magenta |
| 1 | 1 | 0 | Yellow |
| 1 | 1 | 1 | White |

BK1,BKO. Background Enable.These bits determine if the specified background is enabled or not.
" 0 " - The following word does not have a background.
"1" - There is a background around the following word.

Figure 68. Character Bank Select Register

D7-D1. These bits are not used
BS. Bank Select. This bit select the character bank to be used. The lower bank is selected with 0 . The value can be modified only when the OSD is OFF ( $G E=0$ ). No reset value.

## OSD Data RAM

The contents of the data RAM can be accessed by the ST638X MCUs only when the global enable bit (GE) in the Global Enable register is a zero.
The first character in every line is the format character. This character is not displayed. It defines the size of the characters in the line and contains the vertical space enable bit. This character also defines the color, background and display enable for the first word in the line. Subsequent characters are either spaces or one of the 64 available character types.
The space character defines the color, background, display enable and horizontal space enable for the following word. Since there are 5 display lines of 15 characters each, the display RAM must contain 5 lines $x$ ( 15 characters +1 format character) or 80 locations. The RAM size is 80 locations $\times 7$ bits. The data RAM map is shown inTable 18.

ON-SCREEN DISPLAY (Continued)
Table 18. OSD RAM Map

AVAILABLE SCREEN SPACE
Notes: FT. The format character required for each line. Characters in columns 1 thru 15 are displayed.

## Emulator Remarks

There are a few differences between emulator and silicon. For noise reasons, the OSD oscillator pins are not available: the internal oscillator cannot be disabled and replaced by an external coil. In the emulator, the Character Bank Select register can be written also with Global Enable bit set, while this is not allowed in the device.

## Application Notes

1 - The OSD character generator is composed of a dual port video ram and some circuitry. It needs two input signals VSYNC and HSYNC to syncronize its dedicated oscillator to the TV picture. It generates 4 output signals, that can be used from the TV set to generate the characters on the screen. For istance, they can be used to feed the SCART plug, providing an adequate buffer to drive the low impedance ( $75 \Omega$ ) of the SCART inputs.
2 - The Core sees the OSD as a number of RAM locations (80) plus a certain number of control registers (6). These 86 locations are mapped in two pages of the dynamic data ram address range ( 0 H ..3FH).
In page 5 (load 20H in the register 0E8H), there are 64 bytes of RAM, the ones of the first 4 rows ( 16 bytes each row, 15 characters per row maximum, plus an hidden leading format character). In page

6 (load 40 H in register 0 E 8 H ), the 16 bytes of the fith row ( $0 . .0 \mathrm{FH}$ ), and the 6 control registers ( $10 \mathrm{H} . .14 \mathrm{H}, 17 \mathrm{H}$ ).
3 - The video RAM is a dual port ram. That means that it can be addressed either from the Core or from the OSD circuitry itself. To reduce the complexity of the circuitry, and thus its cost, some restrictions have been introduced in the use of the OSD.
a. The Core can Only write to any of the 86 locations (either video RAM or control registers).
b. The Core can Only write to any of the leading 85 locations when the OSD oscillator is OFF. Only the last location (control register 17H in page 6) can be addressed at any time. This is the Global Enable Register, which contains only the GE bit. If it is set, the OSD is on, if it is reset the OSD is off.
4 - The timing of the on/off switching of the OSD oscillator is the following:
a. GE bit is set. The OSD oscillator will start on the next VSYNC signal.
b. GE bit is reset. The OSD oscillator will be immediately switched off.

## ON-SCREEN DISPLAY (Continued)

To avoid a bad visual impression, it is important that the GE bit is set before the end of the flyback time when charging character. This can be done inside the VSYNC interrupt routine. The following diagram can explain better:

Figure 69. OSD Oscillator ON/OFF Timing

Notes: A - Picture time 20 mS in PAL/SECAM.
B - VSYNC interrupt, if enabled.
C - Starting of OSD oscillator, if $\mathrm{GE}=1$.
D - Flyback time.
When modifying the picture display (i.e.: a bar graph for an analog control), it is important that the switching on of the GE bit is done before the the end of the flyback time ( D in Figure 69). If the GE bit is set after the end of the flyback time then the OSD will not start until the begining of the next frame. This results in one frame being lost and will result in a Flicker on the screen. One method to be sure to avoid the flicker is to wait for the VSYNC
interrupt at the start of the flyback; once the VSYNC interrupt is detected, then the GE bit can be set to zero, the characters changed, and the GE set to one. All this should occur before the end of the flyback time in order not to loose a frame. The correct edge of the interrupt must be chosen. The VSYNC pin may alternatively be sampled by software in order to know the status; this can be done by reading bit 4 of register E4H; this bit is inverted with respect to the VSYNC pin.
6 - An OSD end of line Bar is present in the ST63P8X piggyback and ST638X ROM devices when using the background mode. If this bar is present with software running in the piggybacks then it is also present on the ROM mask version. If the end of line bar is seen to be eliminated by software in the piggyback, then it is also be eliminated in the ROM mask version.
The bar appears at the end of the line in the background mode when the last character is a space character and the first format character is defined with $\mathrm{S}=0$ (size 0 ). The bar is the color of the background defined by the space character. To eliminate bar:
a. If two backgrounds are used then the bar should be moved off the screen by using large word spaces instead of character spaces. If there are not enough spaces before the end of the line, then the location of the valid characters should be moved so they appear at the end of the line (and hence no bar); positioning can be compensated using the horizontal start register.
b. If only one background is used, then the other background should be transparent in order to eliminate the bar.
7 - The OSD oscillator external network should consist of a capacitor on each of the OSD oscillator pins to ground together with an inductance between pins. The user should select the two capacitors to be the same value ( 15 pF to 25 pF each is recommended). The inductance is chosen to give the desired OSD oscillator frequency for the application (normally $56 \mu \mathrm{H}$ ).

## SOFTWARE DESCRIPTION

The ST638X software has been designed to fully use the hardware in the most efficient way possible while keeping byte usage to a minimum; in short to provide byte efficient programming capability. The ST638X Core has the ability to set or clear any register or RAM location bit of the Data space with a single instruction. Furthermore, the program may branch to a selected address depending on the status of any bit of the Data space. The carry bit is stored with the value of the bit when the SET or RES instruction is processed.

## Addressing Modes

The ST638X Core has nine addressing modes which are described in the following paragraphs. The ST638X Core uses three different address spaces: Program space, Data space, and Stack space. Program space contains the instructions which are to be executed, the data for immediate mode instructions, and in this space is physically allocated the data ROM which is addressed as data space. Data space contains the Accumulator, the $\mathrm{X}, \mathrm{Y}, \mathrm{V}$ and W registers, the Core control registers, peripheral and Input/Output registers, the RAM Iocations and the window to address the Data ROM (physically located into the program memory) locations (for storage of tables and constants). Stack space contains six 12-bit RAM bytes used to stack the return addresses for subroutines and interrupts.
Immediate. In the immediate addressing mode, the operand of the instruction follows the opcode location. As the operand is a ROM byte, the immediate addressing mode is used to access constants which do not change during program execution (e.g., a constant used to initialize a loop counter).
Direct. In the direct addressing mode, the address of the byte that is processed by the instruction is stored in the location that follows the opcode. Direct addressing allows the user to directly address the 256 bytes in Data space memory with a single two-byte instruction.
Short Direct. The Core can address the four RAM registers X,Y,V,W (locations $80 \mathrm{H}, 81 \mathrm{H}, 82 \mathrm{H}, 83 \mathrm{H}$ ) in the short-direct addressing mode. In this case, the instruction is only one byte long and the selection of the location to be processed is contained in the opcode. Short direct addressing is a subset of the direct addressing mode. (Note : 80H and 81H are also indirect registers).
Extended. In the extended addressing mode, the 12-bit address needed to define the instruction is
obtained by concatenating the four less significant bits of the opcode with the byte following the opcode. The instructions (JP, CALL) that use the extended addressing mode are able to branch any address of the directly addressable Program space. An extended addressing mode instruction is two-byte long.
Program Counter Relative. The relative addressing mode is only used in conditional branch instructions. The instruction is used to perform a test and, if the condition is true, a branch with a span of -15 to +16 locations around the address of the relative instruction. If the condition is not true, the instruction that follows the relative instruction is executed. The relative addressing mode instruction is onebyte long. The opcode is obtained by adding the three most significant bits that characterize the kind of test, one bit that determines whether the branch is a toward (when it is 0 ) or backward (when it is 1 ) branch and the four less significant bits that give the span of the branch ( OH to FH ) that must be added or subtracted to the address of the relative instruction to obtain the address of the branch.

Bit Direct. In the bit direct addressing mode, the bit to be set or cleared is part of the opcode, and the byte following the opcode points to the address of the byte in which the specified bit must be set or cleared. Thus, any bit in the 256 directly addressable locations of Data space memory can be set or cleared.

Bit Test \& Branch. The bit test and branch addressing mode is a combination of direct addressing and relative addressing. The bit test and branch instruction is three-byte long. The bit identification and the tested condition are included in the opcode byte. The address of the byte to be tested follows immediately the opcode in the Program space. The third byte is the jump displacement, which is in the range from -126 to +129 . This displacement can be determined using a label, which is converted by the assembler.

Indirect. In the indirect addressing mode, the byte processed by the register-indirect instruction is at the address pointed by the content of one of the indirect registers, $X$ or $Y(80 \mathrm{H}, 81 \mathrm{H})$. The indirect register is selected by the bit 4 of the opcode. A register indirect instruction is one byte long.
Inherent. In the inherent addressing mode, all the information necessary to execute the instruction is contained in the opcode. These instructions are one byte long.

## SOFTWARE DESCRIPTION (Continued)

## Instruction Set

The ST638X Core has a set of 40 basic instructions. When these instructions are combined with nine addressing modes, 244 usable opcodes can be obtained. They can be divided into six different types : load/store, arithmetic/logic, conditional branch, control instructions, jump/call, bit manipulation. The following paragraphs describe the dif-
ferent types. All the instructions within a given type are presented in individual tables.
Load \& Store. These instructions use one,two or three bytes in relation with the addressing mode. One operand is the Accumulator for LOAD and the other operand is obtained from data memory using one of the addressing modes. For LOAD Immediate one operand can be any of the 256 data space bytes while the other is always an immediate data. Refer to Table 19.

Table 19. Load \& Store instructions

## SOFTWARE DESCRIPTION (Continued)

Arithmetic and Logic. These instructions are used to perform the arithmetic calculations and logic operations. In AND, ADD, CP, SUB instructions one operand is always the accumulator while the other
can be either a data space memory content or an immediate value in relation with the addressing mode. In CLR,DEC,INC instructions the operand can be any of the 256 data space addresses. In COM, RLC, SLA the operand is always the accumulator. Refer to Table 20.

Table 20. Arithmetic \& Logic instructions

## SOFTWARE DESCRIPTION (Continued)

Conditional Branch. The branch instructions achieves a branch in the program when the selected condition is met. Refer to Table 21.
Bit Manipulation Instructions. These instructions can handle (set or reset) any bit in data space memory. Refer to Table 22.

Control Instructions. The control instructions control the MCU operations during program execution. Refer to Table 23.
Jump and Call. These two instructions are used to perform long (12-bit) jumps or subroutines call inside the whole program space. Refer to Table 24.

Table 21. Conditional Branch instructions

| Instruction | Branch If | Bytes | Cycles | Flags |  |

Legend

## ABSOLUTE MAXIMUM RATINGS

This product contains devices to protect the inputs against damage due to high static voltages, however it is advised to take normal precaution to avoid application of any voltage higher than maximum rated voltages.

For proper operation it is recommended that $\mathrm{V}_{1}$ and Vo must be higher than Vss and smaller than VDD. Reliability is enhanced if unused inputs are connected to an appropriated logic voltage level (VDD or VSS).

Power Considerations. The average chip-junction temperature. Tj, in Celsius can be obtained form.:

$$
\mathrm{Tj}=\mathrm{TA}+\mathrm{PD} \times \mathrm{RthJA}
$$

Where: TA = Ambient Temperature,
RthJA = Package thermal resistance
(junction-to ambient),
PD $=$ Pint + Pport,
Pint $=l_{D D} \times V_{D D}$ (chip internal power),
Pport = Port power dissipation (determined by the user).

| Symbol | Parameter | Value | Unit |
| :---: | :---: | :---: | :---: |
| VDD | Supply Voltage | -0.3 to 7.0 | V |
| V I | Input Voltage (AFC IN) | VSS -0.3 to +13 | V |
| $V_{1}$ | Input Voltage (Other Inputs) | VSS -0.3 to VDD +0.3 | V |
| Vo | Output Voltage <br> (PA4-PA7, PC4-PC7, DAO-DA5) | VSS -0.3 to +13 | V |
| Vo | Output Voltage (Other Inputs) | VSS - 0.3 to $\mathrm{V}_{\text {DD }}+0.3$ | V |
| 10 | Current Drain per Pin Excluding VDD, VSS, PA6, PA7 | $\pm 10$ | mA |
| 10 | Current Drain per Pin (PA6, PA7) | $\pm 50$ | mA |
| IVDD | Total Current into VDD (source) | 50 | mA |
| IVSS | Total Current out of VSS (sink) | 150 | mA |
| T ${ }_{\text {j }}$ | Junction Temperature | 150 | ${ }^{\circ} \mathrm{C}$ |
| TSTG | Storage Temperature | -60 to 150 | ${ }^{\circ} \mathrm{C}$ |

Note: Stresses above those listed as "absolute maximum ratıngs" may cause permanent damage to the device. This is a stress ratıng only and functional operation of the device at these conditions is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability

## THERMAL CHARACTERISTIC

| Symbol | Parameter | Test Conditions | Value |  |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Min. | Typ. | Max. |  |
| RthJA | Thermal Resistance | PSDIP42 |  |  | ${ }^{\circ} \mathrm{C} W$ |  |

## RECOMMENDED OPERATING CONDITIONS

| Symbol | Parameter | Test Conditions | Value |  | Unit |  |
| :---: | :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Min. | Typ. |  |  |
| TA | Operating Temperature |  | 0 |  | 70 | ${ }^{\circ} \mathrm{C}$ |
| VDD | Operating Supply Voltage |  | 4.5 |  | 6.0 | V |
| fosc | Oscillator Frequency <br> RUN \& WAIT Modes |  |  | 8.0 | 8.1 | MHz |
| fOSDOSC | On-Screen Display Oscillator <br> Frequency |  |  |  | 8.0 | MHz |

## EEPROM INFORMATION

The ST638X EEPROM macrocell and the single poly EEPROM process have been specially de-
veloped to achieve 1.000.000 Write/Erase cycles and a 10 years data retention.

DC ELECTRICAL CHARACTERISTICS

Notes:

1. A clock other than 8 MHz will affect the frequency response of those peripherals ( $\mathrm{D} / \mathrm{A}, 62.5 \mathrm{KHz}$ and SPI) whose clock is derived from the system clock.
2 The rise and fall tımes of PORT A have been reduced in order to avoid current spikes while maıntaınıng a high drive capability
3 Not 100\% Tested
4 Based on extrapolated data

## PACKAGE MECHANICAL DATA

Figure 70. 42-Pin Shrink Dual in Line Plastic (JEDEC MO-015 BB)

## ORDERING INFORMATION

The following chapter deals with the procedure for transfer the Program/Data ROM codes to SGSTHOMSON.

Communication of the ROM Codes. To communicate the contents of Program/Data ROM memories to SGS-THOMSON, the customer has to send:

- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS 5 " diskette) for the PROGRAM Memory
- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS 5 " diskette) for the ODD and EVEN ODD OSD Characters
- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS 5" diskette) for the EEPROM initial content (this file is optional)
- a filled Option List form as described in the OPTION LIST paragraph.
The program ROM should respect the ROM Memory Map as in Table 26.
The ROM code must be generated with ST6 assembler. Before programming the EPROM, the buffer of the EPROM programmer must be filled with FFH. For shipment to SGS-THOMSON the EPROMs should be placed in a consecutive IC carrier and packaging carefully.

## ORDERING INFORMATION (Continued)

## Notes:

1. EPROM addresses are related to the use of ST63P8X piggyback emulation devices.

ORDERING INFORMATION (Continued)

## Customer EEPROM Initial Contents: Format

a. The content should be written into an INTEL INTELLEC format file.
b. In the case of 384 bytes of EEPROM, the starting address is 000 H and the end address is 7 FH . The order of the pages ( 64 bytes each) is an in the specification (ie. b7, b1 b0: 001, 010, 011, 101, 110. 111).
c. Undefined or don't care bytes should have the content FFH.
OSD Test Character. In order to allow the testing of the on-chip OSD macrocell the following character must be provided at the fixed 3FH (63) position of the second OSD bank.
Listing Generation \& Verification. When SGSTHOMSON receives the Codes, they are compared and a computer listing is generated from them. This listing refers extractly to the mask that will be used to produce the microcontroller. Then the listing is returned to the customer that must thoroughly

Figure 71. OSD Test Character

check, complete, sign and return it to SGS-THOMSON. The signed list constitutes a part of the contractual agreement for the creation of the customer mask. SGS-THOMSON sales organization will provide detailed information on contractual points.

## GENERAL DESCRIPTION

The ST6391,93,94,95,96,99 microcontrollers are members of the 8 -bit HCMOS ST639X family, a series of devices specially oriented to TV applications. Different pin-out and peripheral configurations are available to give the maximum application and cost flexibility. All ST639X members are based on a building block approach: a common core is surrounded by a combination of on-chip peripherals (macrocells) available from a standard library. These peripherals are designed with the same Core technology providing full compatibility and short design time. Many of these macrocells are specially dedicated to TV applications. The macrocells of the ST639X family are : two Timer peripherals each
including an 8 -bit counter with a 7 -bit software programmable prescaler (Timer), a digital hardware activated watchdog function (DHWD), a serial peripheral interface (SPI), up to six 6-bit PWM D/A converters, an AFC A/D converter with 0.5 V resolution, an on-screen display (OSD) with 15 characters per line, 128 characters (in two banks each of 64 characters). In addition the following memory resources are available: program ROM (up to 20K), data RAM (up to 256 bytes), EEPROM (up to 384 bytes). Refer to pin configurations figures and to ST639X device summary (Table 1) for the definition of ST639X family members and a summary of differences among the different types.

Note: 1. Low power in RESET function disables the oscillator when RESET pin is active (LOW)

## PIN DESCRIPTION

$V_{D D}$ and $V_{s s}$. Power is supplied to the MCU using these two pins. $V_{D D}$ is power and $V_{S s}$ is the ground connection.
OSCIN, OSCOUT. These pins are internally connected to the on-chip oscillator circuit. A quartz crystal or a ceramic resonator can be connected between these two pins in order to allow the correct operation of the MCU with various stability/cost trade-offs. The OSCIN pin is the input pin, the OSCOUT pin is the output pin. Refer to ON-CHIP CLOCK OSCILLATOR description for additional information.
RESET. The active low RESET pin is used to start the microcontroller to the beginning of its program. Additionally in the ST6394/96/99 the quartz oscillator will be disabled when the RESET pin is low to reduce power consumption during reset phase. Refer to RESET description for additional information.
TEST. The TEST (mode select) pin is used to place the MCU into special operating mode. If TEST is held at $V_{S S}$ the MCU enters the normal operating mode. If TEST is held at $V_{D D}$ when RESET is active the test operating mode is automatically selected (the user should connect this pin to Vss for normal operation). Refer to TEST mode description for additional information.
PAO-PA7. These 8 lines are organized as one I/O port (A). Each line may be configured as either an input with or without pull-up resistor or as an output under software control of the data direction register. Pins PA4 to PA7 are configured as open-drain outputs (12V drive). On PA4-PA7 pins the input pull-up option is not available while PA6 and PA7
have additional current driving capability ( 25 mA , $1 \mathrm{~V})$. PA0 to PA3 pins are configured as push-pull. Refer to I/O PORT description for additional information.
PB0-PB6. These 7 lines are organized as one I/O port (B). Each line may be configured as either an input with or without internal pull-up resistor or as an output under software control of the data direction register. Refer to I/O PORT description and Pin configurations (Figures 1 to 4 ) for additional information.
PC0-PC7. These 8 lines are organized as one I/O port (C). Each line may be configured as either an input with or without internal pull-up resistor or as an output under software control of the data direction register. Pins PC0 to PC3 are configured as open-drain ( 5 V drive) in output mode while PC4 to PC7 are open-drain with 12 V drive and the input pull-up options does not exist on these four pins. PC0, PC1 and PC3 lines when in output mode are "ANDed" with the SPI control signals and are all open-drain. PCO is connected to the SPI clock signal (SCL), PC1 with the SPI data signal (SDA) while PC3 is connected with SPI enable signal (SEN, used in S-BUS protocol). Pin PC4 and PC6 can also be inputs to software programmable edge sensitive latches which can generate interrupts; PC4 can be connected to Power Interrupt (not available on ST6391 and ST6393) while PC6 can be connected to the IRIN/NMI interrupt line. Refer to I/O PORT description, Pin Configurations (Figures 1 to 4), INTERRUPT description for additional information.
O0, 01. These two lines are available only on ST6394 and ST6396. They are output open-drain pins with 12 V drive.

## PIN DESCRIPTION (Continued)

DAO-DA5. These pins are the six PWM D/A outputs of the 6-bit on-chip D/A converters. These lines have open-drain outputs with 12 V drive. The output repetition rate is 31.25 KHz (with 8 MHz clock) with the exception of ST6395 which has a repetition rate of 25 KHz (with 8 MHz clock). Refer to Pin Configurations (Figures 1 to 4) and D/A description for additional information.
AFC. This is the input of the on-chip 10 levels comparator that can be used to implement the AFC function. This pin is an high impedance input able to withstand signals with a peak amplitude up to 12V. Refer to Pin Configurations (Figures 1 to 4) and AFC description for additional information.
OSDOSCIN, OSDOSCOUT. These are the On Screen display oscillator terminals. An oscillation capacitor and coil network have to be connected to provide the right signal to the OSD.

HSYNC, VSYNC. These are the horizontal and vertical synchronization pins. The active polarity of these pins to the OSD macrocell can be selected by the user as ROM mask option. If the device is specified to have negative logic inputs, then when these signals are low the OSD oscillator stops. If the device is specified to have positive logic inputs, then when these signals are high the OSD oscillator stops. Refer to OSD description for additiona information,
R, G, B, BLANK. Outputs from the OSD. R, G and $B$ are the color outputs while BLANK is the blanking output. All outputs are push-pull. The active polarity of these pins to can be selected by the user as ROM mask option. Refer to the pin configurations for additional information.
62.5 kHz OUT. This pin is available only on the ST6399. The pin is an open-drain (12V) output at a frequency of 62.5 kHz (with an 8 MHz clock). The pin can be used to drive the SGS-THOMSON TEA5640 chroma processor. Refer to the TEA5640 data sheet for more information.

## Table 2. ST639X Pin Summary

| Pin Function | Description |
| :--- | :--- |
| DA0 to DA5 | Output, Open-Drain, 12V |
| 62.5 KHz OUT | Output, Open-Drain, 12V |
| PB0-PB6 | I/O, Push-Pull, Software Input Pull-up, Schmitt Trigger Input |
| AFC | Input, High Impedance, 12V |
| PA0-PA3 | I/O, Push-Pull, Software Input Pull-up, Schmitt Trigger Input |
| PA4-PA5 | I/O, Open-Drain, 12V, No Input Pull-up, Schmitt Trigger Input |
| PA6-PA7 | I/O, Open-Drain, 12V, No Input Pull-up, Schmitt Trigger Input, High Drive |
| O0, 01 | Output, Open-Drain, 12V |
| R,G,B, BLANK | Output, Push-Pull |
| HSYNC, VSYNC | Input, Pull-up, Schmitt Trigger |
| OSDOSCIN | Input, High Impedance |
| OSDOSCOUT | Output, Push-Pull |
| TEST | Input, Pull-Down |
| OSCIN | Input, Resistive Bias, Schmitt Trigger to Reset Logic Only |
| OSCOUT | Output, Push-Pull |
| RESET | Input, Pull-up, Schmitt Trigger Input |
| PC4-PC7 | I/O, Open-Drain, 12V, No Input Pull-up, Schmitt Trigger Input |
| PC0-PC3 | I/O, Open-Drain, 5V , Software Input Pull-up, Schmitt Trigger Input |
| VDD, VSS | Power Supply Pins |

## ST639X CORE

The Core of the ST639X Family is implemented independently from the l/O or memory configuration. Consequently, it can be treated as an independent central processor communicating with $\mathrm{I} / \mathrm{O}$ and memory via internal addresses, data, and control busses. The in-core communication is arranged as shown in the following block diagram figure; the controller being externally linked to both the reset and the oscillator, while the core is linked to the dedicated on-chip macrocells peripherals via the serial data bus and indirectly for interrupt purposes through the control registers.

## Registers

The ST639X Family Core has five registers and three pairs of flags available to the programmer. They are shown in Figure 7 and are explained in the following paragraphs together with the program and data memory page registers.
Accumulator (A). The accumulator is an 8 -bit general purpose register used in all arithmetic calculations, logical operations, and data manipulations. The accumulator is addressed in the data space as RAM location at the FFH address.

Figure 7. ST639X Core Programming Model

Figure 6. ST639X Core Block Diagram

## ST639X CORE (Continued)

Accordingly, the ST639X instruction set can use the accumulator as any other register of the data space.
Indirect Registers (X, Y). These two indirect registers are used as pointers to the memory locations in the data space. They are used in the register-indirect addressing mode.These registers can be addressed in the data space as RAM locations at the $80 \mathrm{H}(\mathrm{X})$ and $81 \mathrm{H}(\mathrm{Y})$ addresses. They can also be accessed with the direct, short direct, or bit direct addressing modes. Accordingly, the ST639X instruction set can use the indirect registers as any other register of the data space.
Short Direct Registers (V, W). These two registers are used to save one byte in short direct addressing mode. These registers can be addressed in the data space as RAM locations at the $82 \mathrm{H}(\mathrm{V})$ and $83 \mathrm{H}(\mathrm{W})$ addresses. They can also be accessed with the direct and bit direct addressing modes. Accordingly, the ST639X instruction set can use the short direct registers as any other register of the data space.

## Program Counter (PC)

The program counter is a 12-bit register that contains the address of the next ROM location to be processed by the core. This ROM location may be an opcode, an operand, or an address of operand. The 12 -bit length allows the direct addressing of 4096 bytes in the program space. Nevertheless, if the program space contains more than 4096 locations, the further program space can be addressed by using the Program Bank Switch register. The PC value is incremented, after it is read for the address of the current instruction, by sending it through the ALU, so giving the address of the next byte in the program. To execute relative jumps the PC and the offset values are shifted through the ALU, where they will be added, and the result is shifted back into the PC. The program counter can be changed in the following ways:
JP (Jump) instruction . . . . PC= Jump address CALL instruction . . . . . . . PC= Call address
Relative Branch
instructions . . . . . . . . . PC= PC+offset
Interrupt . . . . . . . . . . PC= Interrupt vector
Reset . . . . . . . . . . . . PC= Reset vector
Test mode . . . . . . . . . . PC=Test mode vector (1)
RET \& RETI instructions . . . PC= Pop (stack)
Normal instruction . . . . .PC= PC+1
Note: 1. Not available to the user.

## Flags (C, Z)

The ST63 Core includes three pairs of flags that correspond to 3 different modes: normal mode, interrupt mode and Non-Maskable-Interrupt-Mode. Each pair consists of a CARRY flag and a ZERO flag. One pair (CN, ZN) is used during normal operation, one pair is used during the interrupt mode ( $\mathrm{Cl}, \mathrm{Zl}$ ) and one is used during the not-maskable interrupt mode (CNMI, ZNMI).
The ST63 Core uses the pair of flags that corresponds to the actual mode: as soon as an interrupt (resp. a Non-Maskable-Interrupt) is generated, the ST639X Core uses the interrupt flags (resp. the NMI flags) instead of the normal flags. When the RETI instruction is executed, the normal flags (resp. the interrupt flags) are restored if the MCU was in the normal mode (resp. in the interrupt mode) before the interrupt. Should be observed that each flag set can only be addressed in its own routine (Not-maskable interrupt, normal interrupt or main routine). The interrupt flags are not cleared during the context switching and so, they remain in the state they were at the exit of the last routine switching.
The Carry flag is set when a carry or a borrow occurs during arithmetic operations, otherwise it is cleared. The Carry flag is also set to the value of the bit tested in a bit test instruction, and participates in the rotate left instruction.
The Zero flag is set if the result of the last arithmetic or logical operation was equal to zero, otherwise it is cleared.
The switching between these three sets is automatically performed when an NMI, an interrupt and a RETI instructions occur. As the NMI mode is automatically selected after the reset of the MCU, the ST639X Core uses at first the NMI flags. Refer to INTERRUPT description for additional information.

## Stack

The ST639X Core includes true LIFO hardware stack that eliminates the need for a stack pointer.

Figure 8. Stack Operation

## ST639X CORE (Continued)

The stack consists of six separate 12-bit RAM locations that do not belong to the data space RAM area. When a subroutine call (or interrupt request) occurs, the contents of each level is shifted into the next level while the content of the PC is shifted into the first level (the value of the sixth level will be lost). When subroutine or interrupt return occurs (RET or RETI instructions), the first level register is shifted back into the PC and the value of each level is shifted back into the previous level. These two operating modes are described in Figure 8. Since the accumulator, as all other data space registers, is not stored in this stack the handling of this registers shall be performed inside the subroutine. The stack pointer will remain in its deepest position, if more than 6 calls or interrupts are executed, so that the last return address will be lost. It will also remain in its highest position if the stack is empty and a RET or RETI is executed. In this case the next instruction will be executed.

## Memory Registers

Figure 9. Program ROM Page Register

| PRPR <br> Program ROM Page Register <br> (CAH, Write Only) |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| D7 | D6 | D5 | D4 | D3 | D2 | D1 | DO |

The PRPR register can be addressed like a RAM location in the Data Space at the CAH address; nevertheless it is a write-only register that can not be accessed with single-bit operations. This register is used to select the 2-Kbyte ROM bank of the Program Space that will be addressed. The number of the page has to be loaded in the PRPR register. The PRPR register is not cleared during the MCU initialization and should therefore be defined before jumping out of the static page. Refer to the Program Space description for additional information concerning the use of this registers. The PRPR register is not modified when an interrupt or a subroutine occurs.

Figure 10. Data RAM Bank Register

The DRBR register can be addressed like a RAM location in the Data Space at the E8H address, nevertheless it is write-only register that can not be accessed with single-bit operations. This register is used to select the desired 64-byte RAM/EEPROM bank of the Data Space. The number of the bank has to be loaded in the DRBR register and the instruction has to point to the selected location as it was in the 0 bank (from 00 H address to 3 FH address). This register is cleared during the MCU initialization (the Data space 0 bank is automatically addressed after the Reset). Refer to the Data Space description for additional information. The DRBR register is not modified when a interrupt or a subroutine occurs.

Figure 11. Data ROM Window Register

| DWR <br> Data ROM Window Register <br> (C9H, Write Only) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| D7 D6 D5 D4 D3 D2 D1 D0 |  |  |  |  |  |

The DWR register can be addressed like a RAM location in the Data Space at the C 9 H address, nevertheless it is write-only register that can not be accessed with single-bit operations. This register is used to move up and down the 64-byte read-only data window (from the 40 H address to 7 FH address of the Data Space) along the ROM memory of the MCU by step of 64 bytes. The effective address of the byte to be read as a data in the ROM memory is obtained by the concatenation of the 6 less significant bits of the address given in the instruction (as less significant bits) and the content of the DWR register (as most significant bits). Refer to the Data Space description for additional information.

## MEMORY SPACES

The MCUs operate in three different memory spaces: Program Space, Data Space, and Stack

Space. A description of these spaces is shown in Figure 12 and Figure 13. (Figure 14 refers to the ST6394 which has a total of 8 K bytes of ROM).

Figure 12. ST639X Data Space

Figure 13. ST639X data Space (Continued)

## MEMORY SPACES (Continued)

Figure 14. ST6394 Memory Addressing Description Diagram

## Program Space

The program space is physically implemented in the ROM memory and includes all the instructions that are to be executed, as well as the data required for the immediate addressing mode instructions, the reserved test area and user vectors. It is addressed thanks to the 12-bit Program Counter register (PC register) and so, the ST639X Core can directly address up to 4 K bytes of Program Space. Nevertheless, the Program Space can be extended by the addition of 2-Kbyte ROM banks as it is shown in figure 14 in which an 8 Kbyte (as it is in ST6394) memory is described. These banks are addressed by pointing to the $000 \mathrm{H}-7 \mathrm{FFH}$ locations of the Program Space thanks to the Program Counter, and by writing the appropriate code in the Program ROM Page Register (PRPR register) located at the CAH address of the Data Space.
Because interrupts and common subroutines should be available all the time only the lower 2 K byte of the 4 K program space are bank switched while the upper 2 K byte can be seen as static space. Table 3 gives the different codes that allows the selection of the corresponding banks. Note that, from the memory point of view, the Page 1 and the Static Page represent the same physical mem-
ory: it is only a different way of addressing the same location. On ST6394 a total of 8192 bytes of ROM have been implemented; 7948 are available as user ROM while 244 are reserved for testing. On the ST6391, ST6393 and ST6399 a total of 16384 bytes of ROM have been implemented; 16076 are available as user ROM while 308 are reserved for testing. On the ST6395, ST6396 a total of 20480 bytes of ROM have been implemented; 20140 are available as user ROM while 340 are reserved for testing.

## MEMORY SPACES (Continued)

Figure 16. Program ROM Page Register

D7-D5. These bits are not used.
PRPR4-PRPRO. These are the program ROM banking bits and the value loaded selects the corresponding page to be addressed in the lower part of 4 K program address space as specified in Table 3 . This register is undefined on reset.

Table 3. ST639X Program ROM Page Register Coding

| PRPR3 | PRPR2 | PRPR1 | PRPR0 | PC11 | Memory <br> Page |
| :---: | :---: | :---: | :---: | :---: | :--- |
| $X$ | $X$ | $X$ | $X$ | 1 | Static Page <br> (Page 1) |
| 0 | 0 | 0 | 0 | 0 | Page 0 |
| 0 | 0 | 0 | 1 | 0 | Page 1 <br> (Static <br> Page) |
| 0 | 0 | 1 | 0 | 0 | Page 2 |
| 0 | 0 | 1 | 1 | 0 | Page 3 |
| 0 | 1 | 0 | 0 | 0 | Page 4 |
| 0 | 1 | 0 | 1 | 0 | Page 5 |
| 0 | 1 | 1 | 0 | 0 | Page 6 |
| 0 | 1 | 1 | 1 | 0 | Page 7 |
| 1 | 0 | 0 | 0 | 0 | Page 8 |
| 1 | 0 | 0 | 1 | 0 | Page 9 |

Note. The number of bits implemented depends on the size of the ROM of the device. Only the lower part of address space has been bankswitched because interrupt vectors and common subroutines should be available all the time. The reason of this structure is due to the fact that it is not possible to jump from a dynamic page to another, unless jumping back to the static page, changing contents of PRPR, and, than, jumping to a different dynamic page.
Care is required when handling the PRPR register as it is write only. For this reason, it is not allowed to change the PRPR contents while executing interrupts drivers, as the driver cannot save and than restore its previous content. Anyway, this operation may be necessary if the sum of common routines and interrupt drivers will take more than 2 K bytes; in this case could be necessary to divide the interrupt driver in a (minor) part in the static page (start and end), and in the second (major) part in one dynamic page. If it is impossible to avoid the writing of this register in interrupts drivers, an image of this register must be saved in a RAM location, and each time the program writes the PRPR it writes also the image register. The image register must be written first, so if an interrupt occurs between the two instructions the PRPR register is not affected.

4. End address for ST6395,96

## MEMORY SPACE (Continued)

## Data Space

The instruction set of the ST639X Core operates on a specific space, named Data Space that contains all the data necessary for the processing of the program. The Data Space allows the addressing of RAM memory (up to 256 bytes for the ST639X family), EEPROM memory (up to 384 bytes for the ST639X family), ST639X Core/peripheral registers, and read-only data such as constants and the look-up tables.
Data ROM Addressing. All the read-only data are physically implemented in the ROM memory in which the Program Space is also implemented. The ROM memory therefore contains the program to be executed and also the constants and the look-up tables needed for the program. The locations of Data Space in which the different constants and look-up tables are addressed by the ST639X Core can be considered as being a 64-byte window through which it is possible to access to the readonly data stored in the ROM memory. This window is located from the 40 H address to the 7FH address in the Data space and allows the direct reading of the bytes from the 000 H address to the 03FH address in the ROM memory. All the bytes of the ROM memory can be used to store either instructions or read-only data. Indeed, the window can be moved by step of 64 bytes along the ROM memory in writing the appropriate code in the Write-only Data ROM Window register (DWR register, location C 9 H ). The effective address of the byte to be read as a data in the ROM memory is obtained by the concatenation of the 6 less significant bits of the address in the Data Space (as less significant bits) and the content of the DWR register (as most significant bits). So when addressing location 40 H of data space, and 0 is loaded in the DWR register, the physical addressed location in ROM is 00 H .
Note. The data ROM window cannot address windows above the 16 k byte range.

Figure 17. Data ROM Window Register

DWR7-DWRO. These are the Data Rom Window bits that correspond to the upper bits of data ROM program space. The ST6394 is an 8k byte device and as such DWR7 is not used. This register is undefined after reset.
Notes Care is required when handling the DWR register as it is write only. For this reason, it is not allowed to change the DWR contents while executing interrupts drivers, as the driver cannot save and than restore its previous content. If it is impossible to avoid the writing of this register in interrupts drivers, an image of this register must be saved in a RAM location, and each time the program writes the DWR it writes also the image register. The image register must be written first, so if an interrupt occurs between the two instructions the DWR register is not affected.

## Data RAM/EEPROM/OSD RAM Addressing

In all members of the ST639X family 64 bytes of data RAM are directly addressable in the data space from 80 H to BFH addresses. The additional 192 bytes of

## MEMORY SPACE (Continued)

RAM (depending on the device), the 384 bytes of EEPROM memory (depending on the device), and the OSD RAM can be addressed using the banks of 64 bytes located between addresses 00 H and $3 F H$. The selection of the bank is done by programming the Data RAM Bank Switching register (DRBR register) located at the E8H address of the Data Space. In this way each bank of RAM, EEPROM or OSD RAM can select 64 bytes at a time. No more than one bank should be set at a time.

Figure 18. Data RAM Bank Register

DRBR7,DRBR1,DRBR0. These bits select the EEPROM pages.
DRBR6, DRBR5. Each of these bits, when set, will select one OSD RAM register page.
DRBR4,DRBR3,DRBR2. Each of these bits, when set, will select one RAM page.
This register is undefined after reset.
Table 5 summarizes how to set the Data RAM Bank Register in order to select the various banks or pages.

## Notes :

Care is required when handling the DRBR register as it is write only. For this reason, it is not allowed to change the DWR contents while executing interrupts drivers, as the driver cannot save and than restore its previous content. If it is impossible to avoid the writing of this register in interrupts drivers, an image of this register must be saved in a RAM location, and each time the program writes the DRBR it writes also the image register.
The image register must be written first, so if an interrupt occurs between the two instructions the DRBR register is not affected.

## EEPROM Description

The data space of ST639X family from 00 H to 3FH is paged as described in Table 5. The ST6391, ST6393 and ST6399 have 128 bytes of EEPROM located in two pages of 64 bytes (pages 0 and 1). The ST6394,ST6395 and ST6396 have 384 bytes of EEPROM located in six pages of 64 bytes (pages $0,1,2,3,4,5$ and 6 , see Table 5).
Through the programming of the Data RAM Bank Register (DRBR = E8H) the user can select the bank or page leaving unaffected the way to address the

Table 5. Data RAM Bank Register Set-up

## MEMÓRY SPACE (Continued)

static registers. The way to address the "dynamic" page is to set the DRBR as described in Table 5 (e.g. to select EEPROM page 0, the DRBR has to be loaded with content 01H, see Data RAM/EEPROM/OSD RAM addressing for additional information). Bits 0,1 and 7 of the DRBR are dedicated to the EEPROM.
The EEPROM module is physically organized in 32 byte modules ( 2 modules per page) and does not require dedicated instructions to be accessed in reading or writing. The EEPROM is controlled by the EEPROM Control Register (EECR=EAH). Any EEPROM location can be read just like any other data location, also in terms of access time.
To write an EEPROM location takes about 5 mSec ( 10 mSec max ) and during this time the EEPROM is not accessible by the Core. A busy flag can be read by the Core to know the EEPROM status before trying any access. In writing the EEPROM can work in two modes: Byte Mode (BMODE) and Parallel Mode (PMODE). The BMODE is the normal way to use the EEPROM and consists in accessing one byte at a time. The PMODE consists in accessing 8 bytes per time.

Figure 19. EEPROM Control Register

D7. Not used
SB. WRITE ONLY. If this bit is set the EEPROM is disabled (any access will be meaningless) and the power consumption of the EEPROM is reduced to the leakage values.
D5, D4. Reserved for testing purposes, they must be set to zero.

PS. SET ONLY. Once in Parallel Mode, as soon as the user software sets the PS bit the parallel writing of the 8 adjacent registers will start. PS is internally reset at the end of the programming procedure. Note that less than 8 bytes can be written; after parallel programming the remaining undefined bytes will have no particular content.
PE. WRITE ONLY. This bit must be set by the user program in order to perform parallel programming (more bytes per time). If PE is set and the "parallel start bit" (PS) is low, up to 8 adjacent bytes can be written at the maximum speed, the content being stored in volatile registers. These 8 adjacent bytes can be considered as row, whose A7, A6, A5, A4, A3 are fixed while A2, A1 and A0 are the changing bytes. PE is automatically reset at the end of any parallel programming procedure. PE can be reset by the user software before starting the programming procedure, leaving unchanged the EEPROM registers.
BS. READ ONLY. This bit will be automatically set by the CORE when the user program modifies an EEPROM register. The user program has to test it before any read or write EEPROM operation; any attempt to access the EEPROM while "busy bit" is set will be aborted and the writing procedure in progress completed.
EN. WRITE ONLY. This bit MUST be set to one in order to write any EEPROM register. If the user program will attempt to write the EEPROM when $\mathrm{EN}=0$ the involved registers will be unaffected and the "busy bit" will not be set.
After RESET the content of EECR register will be 00 H .

## Notes :

When the EEPROM is busy ( $\mathrm{BS}=1$ ) the EECR can not be accessed in write mode, it is only possible to read BS status. This implies that as long as the EEPROM is busy it is not possible to change the status of the EEPROM control register. EECR bits 4 and 5 are reserved for testing purposes, and the user must never set them to 1.
Additional Notes on Parallel Mode. If the user wants to perform a parallel programming the first action should be the set to one the PE bit; from this moment the first time the EEPROM will be addressed in writing, the ROW address will be latched and it will be possible to change it only at the end of the programming procedure or by resetting PE without programming the EEPROM. After the ROW address latching the Core can "see" just one EEPROM row (the selected one) and any attempt to write or read other rows will produce errors. Do not read the EEPROM while PR is set.
As soon as PE bit is set, the 8 volatile ROW latches are cleared. From this moment the user can load

## MEMORY SPACE (Continued)

data in the whole ROW or just in a subset. PS setting will modify the EEPROM registers corresponding to the ROW latches accessed after PE . For example, if the software sets PE and accesses EEPROM in writing at addresses $18 \mathrm{H}, 1 \mathrm{AH}, 1 \mathrm{BH}$ and then sets PS, these three registers will be modified at the same time; the remaining bytes will have no particular content. Note that PE is internally reset at the end of the programming procedure. This implies that the user must set PE bit between two parallel programming procedures. Anyway the user can set and then reset PE without performing any EEPROM programming. PS is a set only bit and is internally reset at the end of the programming procedure. Note that if the user tries to set PS while PE is not set there will not be any programming procedure and the PS bit will be unaffected. Consequently PS bit can not be set if EN is low. PS can be affected by the user set if, and only if, EN and PE bits are also set to one.
Warning : Parallel programming of the EEPROM with less than eight bytes may corrupt other bytes and should therefore be used with care, as here after underlined.
a. Reason for limitation:
betweeen PE (Parallel Enable) and PS (Parallel Start) of the EEPROM, the user writes up to eight bytes into the volatile data registers, a latch is also set to indicate which bytes have been accessed; the accessed bytes will be programmed when PS arrives. The logic is such that it is possible to set the latches of bytes which have NOT been accessed. The latches are set whenever ANY register in the banked dataspace (00h-3FH) is accessed for READ or WRITE between a PE and PS. The latch which is set will be determined by the three least significant bits of the register address. Only the latch is set, so final data of a corrupted byte after the parallel programming is always FFH.
Note: read operations also occur internally to the micro for most instructions. Even if bytes are not seen to be corrupted within the parallel programming routine, care should be taken, since they could become corrupted by an interrupt routine being serviced during loading of parallel bytes.
This is logic related and is not a marginality or race condition; piggyback devices perform in the same way as ROM devices. Parallel programming is tested with only LDI rr,nn instructions which do not corrupt other bytes.
b. To Avoid Corrupted Bytes:

- use Single Byte Mode, or
- always define all eight bytes in Parallel Programming Mode, or
- when programming less than eight bytes, the remaining EEPROM bytes should do not used by the program.

## Additional Notes Regarding Differences Be-

 tween ST639X Devices and Corresponding Emulators. While PE is set, all the EEPROM page currently selected is accessible in reading and the writing of the bytes happens at the row to which belongs the last byte written before setting PS. The sequence: set PE, write in 10 H the value X , write in 21 H the value Y , set PS , will result in: 10 H unchanged, 20 H loaded with value $\mathrm{X}, 21 \mathrm{H}$ loaded with value Y . In the emulator bits 4 and 5 of the EECR are implemented. If the user set to 1 one or both of these bits the contents of the EEPROM will be destroyed. The user should use care in using EEPROM emulation as in general the emulator does not emulate the behaviour of the EEPROM when it is misused.
## STACK SPACE

The stack space consists of six 12 bit registers that are used for stacking subroutine and interrupt return addresses plus the current program counter register.

## TEST MODE

The test mode can be entered by connecting the TEST pin to an high logic level when reset is active; this action enables the factory test mode. The user is recommended to avoid this situation for normal operation. (TEST pin should be tied to ground).

## INTERRUPT

The ST639X Core can manage 4 different maskable interrupt sources, plus one non-maskable interrupt source (top priority level interrupt). Each source is associated with a particular interrupt vector that contains a Jump instruction to the related interrupt service routine. Each vector is located in the Program Space at a particular address (see Table 6). When a source provides an interrupt request, and the request processing is also enabled by the ST639X Core, then the PC register is loaded with the address of the interrupt vector (i.e. of the Jump instruction). Finally, the PC is loaded with the address of the Jump instruction and the interrupt routine is processed.
The relationship between vector and source and the associated priority is hardware fixed for the different ST639X devices. For some interrupt sources it is also possible to select by software the kind of event that will generate the interrupt.
All interrupts can be disabled by writing to the GEN bit (global interrupt enable) of the interrupt option register (address C8H). After a reset, ST639X is in non maskable interrupt mode, so no interrupts will be accepted and NMI flags will be used, until a RETI

## INTERRUPT (Continued)

instruction is executed. If an interrupt is executed, one special cycle is made by the core, during that the PC is set to the related interrupt vector address. A jump instruction at this address has to redirect program execution to the beginning of the related interrupt routine. The interrupt detecting cycle, also resets the related interrupt flag (not available to the user), so that another interrupt can be stored for this current vector, while its driver is under execution.
If additional interrupts arrive from the same source, they will be lost. NMI can interrupt other interrupt routines at any time, while other interrupts cannot interrupt each other. If more than one interrupt is waiting for service, they are executed according to their priority. The lower the number, the higher the priority. Priority is, therefore, fixed. Interrupts are checked during the last cycle of an instruction (RETI included). Level sensitive interrupts have to be valid during this period.
Table 6 details the different interrupt vectors/sources relationships.

Table 6. Interrupt Vectors/Sources Relationships

| Interrupt Source | Associated <br> Vector | Vector Address |
| :---: | :---: | :---: |
| PC6/IRIN <br> Pin (1) | Interrupt <br> Vector \# 0 (NMI) | OFFCH-0FFDH |
| Timer 2 | Interrupt <br> Vector \# 1 | OFF6H-0FF7H |
| Vsync | Interrupt <br> Vector \# 2 | 0FF4H-0FF5H |
| Timer 1 | Interrupt <br> Vector \# 3 | OFF2H-0FF3H |
| PC4/PWRIN | Interrupt <br> Vector \# 4 | OFF0H-0FF1H |

Note: 1. This pin is associated with the NMI Interrupt Vector

## Interrupt Vectors/Sources

The ST639X Core includes 5 different interrupt vectors in order to branch to 5 different interrupt routines. The interrupt vectors are located in the fixed (or static) page of the Program Space.
The interrupt vector associated with the non-maskable interrupt source is named interrupt vector \#0. It is located at the (FFCH,FFDH) addresses in the Program Space. This vector is associated with the PC6/IRIN pin; refer to the ST639X Interrupt Details section for more information.
The interrupt vectors located at addresses (FF6H,FF7H), (FF4H,FF5H), (FF2H,FF3H), (FF0H,FF1H) are named interrupt vectors \#1, \#2,
\#3 and \#4 respectively. These vectors are associated with TIMER 2 (\#1), VSYNC (\#2), TIMER 1 (\#3) and PC4(PWRIN) (\#4); refer to the ST639X Interrupt Details description for more information.

## Interrupt Priority

The non-maskable interrupt request has the highest priority and can interrupt any other interrupt routines at any time, nevertheless the other interrupts cannot interrupt each other. If more than one interrupt request is pending, they are processed by the ST639X Core according to their priority level: vector \#1 has the higher priority while vector \#4 the lower. The priority of each interrupt source is hardware fixed.

## Interrupt Option Register

The Interrupt Option Register (IOR register, location C 8 H ) is used to enable/disable the individual interrupt sources and to select the operating mode of the external interrupt inputs. This register can be addressed in the Data Space as RAM location at the C 8 H address, nevertheless it is write-only register that can not be accessed with single-bit operations. The operating modes of the external interrupt inputs associated to interrupt vectors \#1 and \#2 are selected through bits 4 and 5 of the IOR register.

Figure 20. Interrupt Option Register

## D7. Not used.

EL1. This is the Edge/Level selection bit of interrupt \#1. When set to one, the interrupt is generated on low level of the related signal; when cleared to zero, the interrupt is generated on falling edge. The bit is cleared to zero after reset.
ES2. This is the edge selection bit on interrupt \#2. This bit is used on the ST639X devices with on-chip OSD generator for VSYNC detection.

## INTERRUPT (Continued)

GEN. This is the global enable bit. When set to one all interrupts are globally enabled; when this bit is cleared to zero all interrupts are disabled (including NMI).
D3 - D0. These bits are not used.

## Interrupt Procedure

The interrupt procedure is very similar to a call procedure; the user can consider the interrupt as an asynchronous call procedure. As this is an asynchronous event the user does not know about the context and the time at which it occurred. As a result the user should save all the data space registers which will be used inside the interrupt routines. There are separate sets of processor flags for normal, interrupt and non-maskable interrupt modes which are automatically switched and so these do not need to be saved.
The following list summarizes the interrupt procedure (refer also to Figure 21. Interrupt Processing Flow Chart):

- Interrupt detection
- The flags $C$ and $Z$ of the main routine are exchanged with the flags $C$ and $Z$ of the interrupt routine (resp. the NMI flags)
- The value of the PC is stored in the first level of the stack - The normal interrupt lines are inhibited (NMI still active)
- The edge flip-flop is reset
- The related interrupt vector is loaded in the PC.
- User selected registers are saved inside the interrupt service routine (normally on a software stack)
- The source of the interrupt is found by polling (if more than one source is associated to the same vector)
- Interrupt servicing
- Return from interrupt (RETI)
- Automatically the ST639X core switches back to the normal flags (resp the interrupt flags) and pops the previous PC value from the stack
The interrupt routine begins usually by the identification of the device that has generated the interrupt request. The user should save the registers which are used inside the interrupt routine (that holds relevant data) into a software stack.
After the RETI instruction execution, the Core carries out the previous actions and the main routine can continue.

## ST639X Interrupt Details

IR Interrupt (\#0). The IRIN/PC6 Interrupt is connected to the first interrupt \#0 (NMI, OFFCH). If the IRINT interrupt is disabled at the Latch circuitry, then it will be high. The \#0 interrupt input detects a

Figure 20. Interrupt Processing Flow-Chart

high to low level. Note that once \#0 has been latched, then the only way to remove the latched \#0 signal is to service the interrupt. \#0 can interrupt the other interrupts. A simple latch is provided from the PC6(IRIN) pin in order to generate the IRINT signal. This latch can be triggered by either the positive or negative edge of IRIN signal. IRINT is inverted with respect to the latch. The latch can be read by software and reset by software.
TIMER 2 Interrupt (\#1). The TIMER 2 Interrupt is connected to the interrupt \#1 (0FF6H). The TIMER 2 interrupt generates a low level (which is latched in the timer). For more information on the timer interrupt refer to the timer section. Either the low level or negative edge selection for \#1 can be used. Bit 6 of the interrupt option register C 8 H is used to select negative edge ( $\mathrm{B} 1=0$ ) or low level $(\mathrm{B} 1=1)$ interrupts. Note that once a negative edge has been latched, then the only way to remove the latched signal is to service the interrupt.

## INTERRUPT (Continued)

VSYNC Interrupt (\#2). The VSYNC Interrupt is connected to the interrupt \#2. When disabled the VSYNCINT signal is low. The VSYNCINT signal is inverted with respect to the signal applied to the VSYNCN pin. Bit 5 of the interrupt option register C 8 H is used to select the negative edge $(\mathrm{B} 2=0)$ or the positive edge ( $\mathrm{B} 2=1$ ); the edge will depend on the application. Note that once an edge has been latched, then the only way to remove the latched signal is to service the interrupt. Care must be taken not to generate spurious interrupts. This interrupt may be used for synchronize to the VSYNC signal in order to change characters in the OSD only when the screen is on vertical blanking (if desired). This method may also be used to blink characters.
TIMER 1 Interrupt (\#3). The TIMER 1 Interrupt is connected to the fourth interrupt \#3 (0FF2H) which detects a high to low level (latched in the timer). For more information on the timer interrupt refer to the timer section.
PWR Interrupt (\#4). The PWR Interrupt is connected to the fifth interrupt \#4 (0FFOH). If the PWRINTN is disabled at the PWR circuitry, then it will be high. The \#4 interrupt input detects a low level. This interrupt is not available on the ST6391 and ST6393. A simple latch is provided from the PC4 (PWRIN)pin in order to generate the PWRINTN signal. This latch can be triggered by either the positive or negative edge of the PWRIN signal. PWRINTN is inverted with respect to the latch. The latch can be reset by software.

Notes Global disable does not reset edge sensitive interrupt flags. These edge sensitive interrupts become pending again when global disabling is released. Moreover, edge sensitive interrupts are stored in the related flags also when interrupts are globally disabled, unless each edge sensitive interrupt is also individually disabled before the interrupting event happens. Global disable is done by clearing the GEN bit of Interrupt option register, while any individual disable is done in the control register of the peripheral. The on-chip Timer peripherals have an interrupt request flag bit (TMZ), this bit is set to one when the device wants to generate an interrupt request and a mask bit (ETI) that must be set to one to allow the transfer of the flag bit to the Core.

## RESET

The ST639X devices can be reset in two ways: by the external reset input (RESET) tied low and by the hardware activated digital watchdog peripheral.

## RESET Input

The external active low reset pin is used to reset the ST639X devices and provide an orderly software startup procedure. The activation of the Reset pin may occur at any time in the RUN or WAIT mode. Even short pulses at the reset pin will be accepted since the reset signal is latched internally and is only cleared after 2048 clocks at the oscillator pin. The clocks from the oscillator pin to the reset circuitry are buffered by a schmit trigger so that an oscillator in start-up conditions will not give spurious clocks. When the reset pin of the ST6394, ST6396 and ST6399 is

Figure 22. Internal Reset Circuit

RESET (Continued)
Figure 23. Reset \& Interrupt Processing Flow-chart

held low, the external quartz oscillator is also disabled in order to reduce current consumption. The MCU is configured in the Reset mode as long as the signal of the RESET pin is low. The processing of the program is stopped and the standard Input/Output ports (port A, port B and port C) are in the input state. As soon as the level on the reset pin becomes high, the initialization sequence is executed. Refer to the MCU initialization sequence for additional information.

## Watchdog Reset

The ST639X devices are provided with an on-chip hardware activated digital watchdog function in order to provide a graceful recovery from a software upset. If the watchdog register is not refreshed and the end-of-count is reached, then the reset state will be latched into the MCU and an internal circuit pulls down the reset pin. This also resets the watchdog which subsequently turns off the pull-down and activates the pull-up device at the reset pin. This causes the positive transition at

Figure 24. Restart Initialization Program Flow-chart

it :
the reset pin. The MCU will then exit the reset state after 2048 clocks on the oscillator pin.

## Application Notes

An external resistor between $V_{D D}$ and the reset pin is not required because an internal pull-up device is provided. The user may prefer to add an external pull-up resistor.
An internal Power-on device does not guarantee that the MCU will exit the reset state when VDD is above 4.5 V and therefore the RESET pin should be externally controlled.

## MCU Initialization Sequence

When a reset occurs the stack is reset to program counter, the PC is loaded with the address of the reset vector (located in the program ROM at addresses FFEH \& FFFH). A jump instruction to the beginning of the program has to be written into these locations.After a reset the interrupt mask is automatically activated so that the Core is in nonmaskable interrupt mode to prevent false or ghost interrupts during the restart phase. Therefore the restart routine should be terminated by a RETI instruction to switch to normal mode and enable interrupts. If no pending interrupt is present at the end of the reset routine, the ST639X will continue with the instruction after the RETI; otherwise the pending interrupt will be serviced.

## RESET (Continued)

## RESET Low Power Mode

The ST6394/96 and ST6399 have a special low power mode when the reset pin is held low. When the reset pin is low, the quartz oscillator is Disabled allowing reduced current consumption. When the reset pin is raised the quartz oscillator is enabled and oscillations will start to build up.The internal reset circuitry will count 2048 clocks on the oscillator pin before allowing the MCU to go out of the reset state;the clocks are after a schmtit trigger so that false or multiple counts are not possible.

## WAIT \& STOP MODES

The STOP and WAIT modes have been implemented in the ST639X Core in order to reduce the consumption of the device when the latter has no instruction to execute. These two modes are described in the following paragraphs. On ST639X as the hardware activated digital watchdog function is present the STOP instruction is de-activated and any attempt to execute it will cause the automatic execution of a WAIT instruction.

## WAIT Mode

The configuration of the MCU in the WAIT mode occurs as soon as the WAIT instruction is executed. The microcontroller can also be considered as being in a "software frozen" state where the Core stops processing the instructions of the routine, the contents of the RAM locations and peripheral registers are saved as long as the power supply voltage is higher than the RAM retention voltage but where the peripherals are still working.
The WAIT mode is used when the user wants to reduce the consumption of the MCU when it is in idle, while not loosing count of time or monitoring of external events. The oscillator is not stopped in order to provide clock signal to the peripherals. The timers counting may be enabled (writing the PSI bit in TSCR register) and the timer interrupt may be also enabled before entering the WAIT mode; this allows the WAIT mode to be left when timer interrupt occurs. If the exit from the WAIT mode is performed with a general RESET (either from the activation of the external pin or by watchdog reset) the MCU will enter a normal reset procedure as described in the RESET chapter. If an interrupt is generated during WAIT mode the MCU behaviour depends on the state of the ST639X Core before the initialization of the WAIT sequence, but also of the kind of the interrupt request that is generated. This case will be described in the following paragraphs. In any case, the ST639X Core does not generate any delay after the occurrence of the interrupt because the oscillator clock is still available.

## STOP Mode

On ST639X the hardware watchdog is present and the STOP instruction has been de-activated. Any attempt to execute a STOP will cause the automatic execution of a WAIT instruction.

## Exit from WAIT Mode

The following paragraphs describe the output procedure of the ST639X Core from WAIT mode when an interrupt occurs. It must be noted that the restart sequence depends on the original state of the MCU (normal, interrupt or non-maskable interrupt mode) before the start of the WAIT sequence, but also of the type of the interrupt request that is generated:
Normal Mode. If the ST639X Core was in the main routine when the WAIT instruction has been executed, the ST639X Core outputs from the wait mode as soon as any interrupt occurs; the related interrupt routine is executed and at the end of the interrupt service routine the instruction that follows the WAIT instruction is executed if no other interrupts are pending.
Non-maskable Interrupt Mode. If the WAIT instruction has been executed during the execution of the non-maskable interrupt routine, the ST639X Core outputs from the wait mode as soon as any interrupt occurs: the instruction that follows the WAIT instruction is executed and the ST639X Core is still in the non-maskable interrupt mode even if an other interrupt has been generated.
Normal Interrupt Mode. If the ST639X Core was in the interrupt mode before the initialization of the WAIT sequence, it outputs from the wait mode as soon as any interrupt occurs. Nevertheless, two cases have to be considered:

- If the interrupt is a normal interrupt, the interrupt routine in which the WAIT was entered will be completed with the execution of the instruction that follows the WAIT and the ST639X Core is still in the interrupt mode. At the end of this routine pending interrupts will be serviced in accordance to their priority.
- If the interrupt is a non-maskable interrupt, the non-maskable routine is processed at first. Then, the routine in which the WAIT was entered will be completed with the execution of the instruction that follows the WAIT and the ST639X Core is still in the normal interrupt mode.

## Notes :

If all the interrupt sources are disabled, the restart of the MCU can only be done by a Reset activation. The Wait instruction is not executed if an enabled interrupt request is pending. In the ST639X the hardware activated digital watchdog function is present. As the watchdog is always activated the STOP instruction is de-activated and any attempt to execute the STOP instruction will cause an execution of a WAIT instruction.

## ON-CHIP CLOCK OSCILLATOR

The internal oscillator circuit is designed to require a minimum of external components. A crystal quartz, a ceramic resonator, or an external signal (provided to the OSCIN pin) may be used to generate a system clock with various stability/cost tradeoffs. The typical clock frequency is 8 MHz . Please note that different frequencies will affect the operation of those peripherals (D/As, SPI, 62.5 KHz OUT) whose reference frequencies are derived from the system clock.
The different clock generator options connection methods are shown in Figure 25, crystal specifications and suggested PC board layouts are given in Figure 26 and Figure 27. One machine cycle takes 13 oscillator pulses; 12 clock pulses are needed to increment the PC while and additional 13th pulse is needed to stabilize the internal latches during memory addressing. This means that with a clock frequency of 8 MHz the machine cycle is $1.625 \mu \mathrm{Sec}$.
The crystal oscillator start-up time is a function of many variables: crystal parameters (especially RS), oscillator load capacitance (CL), IC parameters, ambient temperature, and supply voltage. It must be observed that the crystal or ceramic leads and circuit connections must be as short as possible. Typical values for CL1 and CL2 are in the range of 15pF to 22 pF but these should be chosen based on the crystal manufacturers specification. Typical input capacitance for OSCIN and OSCOUT pins is 5 pF .
The oscillator output frequency is internally divided by 13 to produce the machine cycle and by 12 to produce the Timer and the Watchdog clock. A byte cycle is the smallest unit needed to execute any operation (i.e., increment the program counter). An instruction may need two, four, or five byte cycles to be executed (See Table 7).

Table 7. Instructions Timing with 8 MHz Clock

| Instruction Type | Cycles | Execution <br> Time |
| :--- | :---: | :---: |
| Branch if setreset | 5 Cycles | $8.125 \mu \mathrm{~s}$ |
| Branch \& Subroutine Branch | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Bit Manipulation | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Load Instruction | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Arithmetic \& Logic | 4 Cycles | $6.50 \mu \mathrm{~s}$ |
| Conditional Branch | 2 Cycles | $3.25 \mu \mathrm{~s}$ |
| Program Control | 2 Cycles | $3.25 \mu \mathrm{~s}$ |

## ON-CHIP CLOCK OSCILLATOR (Continued)

Figure 27. PC Board Layouts Examples

Figure 28. OSCIN, OSCOUT Configuration Diagram

## INPUT/OUTPUT PORTS

The ST639X microcontrollers use three standard I/O ports ( $A, B, C$ ) with up to eight pins on each port; refer to the device pin configurations to see which pins are available.
Each line can be individually programmed either in the input mode or the output mode as follows by software.

- Output
- Input with on-chip pull-up resistor (selected by software)
- Input without on-chip pull-up resistor (selected by software)
Note: pins with 12 V open-drain capability do not have pull-up resistors.
In output mode the following hardware configurations are available:
- Open-drain output 12V (PA4-PA7, PC4-PC7)
- Open-drain output 5V (PC0-PC3)
- Push-pull output (PAO-PA3, PB0-PB6)

The lines are organized in three ports (port A,B,C). The ports occupies 6 registers in the data space. Each bit of these registers is associated with a particular line (for instance, the bits 0 of the Port A Data and Direction registers are associated with the PAO line of Port A).
There are three Data registers (DRA, DRB, DRC), that are used to read the voltage level values of the lines programmed in the input mode, or to write the logic value of the signal to be output on the lines configured in the output mode. The port Data Registers can be read to get the effective logic levels of the pins, but they can be also written by the user software, in conjunction with the related Data Direction Register, to select the different input mode options. Single-bit operations on I/O registers (bit set/reset instructions) are possible but care is necessary because reading in input mode is done from I/O pins and therefore they might be influenced by the external load, while writing will directly affect the Port data register causing an undesired changes of the input configuration. The three Data Direction registers (DDRA, DDRB, DDRB) allow the selection of the direction of each pin (input or output).
All the I/O registers can be read or written as any other RAM location of the data space, so no extra RAM cell is needed for port data storing and manipulation. During the initialization of the MCU, all the I/O registers are cleared and the input mode with pull-up is selected on all the pins thus avoiding pin conflicts (with the exception of PC2 that is set in output mode and is set high ie. high impedence).

## INPUT/OUTPUT PORTS (Continued)

## Details of I/O Ports

When programmed as an input a pull-up resistor (if available) can be switched active under program control. When programmed as an output the I/O port will operate either in the push-pull mode or the open-drain mode according to the hardware fixed configuration as specified below.
Port A. PAO-PA3 are available as push-pull when outputs. PA4-PA7 are available as open-drain (no push-pull programmability) capable of withstanding 12 V (no resistive pull-up in input mode). PA6-PA7 has been specially designed for higher driving capability and are able to sink 25 mA with a maximum VOL of 1 V .
Port B. All lines are configured as push-pull when outputs.
Port C. PC0-PC3 are available as open-drain capable of withstanding a maximum $\mathrm{V}_{\mathrm{DD}}+0.3 \mathrm{~V}$. PC4PC7 are available as open-drain capable of withstanding 12 V (no resistive pull-up in input mode). Some lines are also used as I/O buffers for signals coming from the on-chip SPI.
In this case the final signal on the output pin is equivalent to a wired AND with the programmed data output.
If the user needs to use the serial peripheral, the I/O line should be set in output mode while the open-drain configuration is hardware fixed; the corresponding data bit must set to one. If the latched interrupt functions are used (IRIN, PWRIN) then the corresponding pins should be set to input mode.
On ST639X the I/O pins with double or special functions are:

- PCO/SCL (connected to the SPI clock signal)
- PC1/SDA (connected to the SPI data signal)
- PC3/SEN (connected to the SPI enable signal)
- PC4/PWRIN (connected to the PWRIN interrupt latch)
- PC6/IRIN (connected to the IRIN interrupt latch)

All the Port $A, B$ and $C I / O$ lines have Schmitt-trigger input configuration with a typical hysteresis of 1 V .

## I/O Pin Programming'

Each pin can be individually programmed as input or output with different input and output configurations.
This is achieved by writing to the relevant bit in the data (DR) and data direction register (DDR). Table 8 shows all the port configurations that can be selected by the user software.

Table 8. I/O Port Options Selection

| DDR | DR | Mode | Option |
| :---: | :---: | :---: | :---: |
| 0 | 0 | Input | With on-chip pull-up <br> resistor |
| 0 | 1 | Input | Without on-chip pull-up resis- <br> tor |
| 1 | X | Output | Open-drain or Push-Pull |

Note. X: Means don't care
Figure 29. I/O Port Data Registers

PA7-PAO. These are the I/O port A data bits. Reset at power-on.
PB7-PB0. These are the I/O port B data bits. Reset at power-on.
PC7-PC0. Set to 04H at power-on. Bit 2 (PC2 pin) is set to one (open drain therefore high impedence).

Figure 30. I/O Port Data Direction Registers

PA7-PAO. These are the I/O port A data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Reset at power-on.
PB7-PB0. These are the 1/O port B data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Reset at power-on.

## INPUT/OUTPUT PORTS (Continued)

PC7-PC0. These are the I/O port C data direction bits. When a bit is cleared to zero the related I/O line is in input mode, if bit is set to one the related I/O line is in output mode. Set to 04H at power-on. Bit 2 (PC2 pin) is set to one (output mode selected).

## Input/Output Configurations

The following schematics show the I/O lines hardware configuration for the different options. Figure 31 shows the I/O configuration for an I/O pin with open-drain 12 V capability (standard drive and high drive). Figure 31 shows the I/O configuration for an I/O pin with push-pull and with open drain 5 V capability.

## Notes :

The WAIT instruction allows the ST639X to be used in situations where low power consumption is needed. This can only be achieved however if the I/O pins either are programmed as inputs with well defined logic levels or have no power consuming resistive loads in output mode. As the same die is used for the different ST639X versions the unavailable I/O lines of ST639X should be programmed in output mode.

Single-bit operations on 1/O registers are possible but care is necessary because reading in input mode is done from I/O pins while writing will directly affect the Port data register causing an undesired changes of the input configuration.

Figure 32. I/O Configuration Diagram (Open Drain 12V)

Figure 31. I/O Configuration Diagram (Open Drain 5V, Push-pull)

## TIMERS

The ST639X devices offer two on-chip Timer peripherals consisting of an 8 -bit counter with a 7 -bit programmable prescaler, thus giving a maximum count of $2^{15}$, and a control logic that allows configuring the peripheral in three operating modes. Figure 33 shows the timer block diagram. This timers do not have the external TIMER pin available for the user. The content of the 8 -bit counter can be read/written in the Timer/Counter register TCR that can be addressed in the data space as RAM location at the D3H (Timer 1) and DBH (Timer 2) addresses. The state of the 7-bit prescaler can be read in the PSC register at the D2H (Timer 1) and DAH (Timer2) addresses. The control logic device can be managed thanks to the TSCR register D4H (Timer 1) and DCH (Timer 2) addresses as it is described in the following paragraphs.
The following description applies to both Timer 1 and Timer 2. The 8 -bit counter is decrement by the output (rising edge) coming from the 7 -bit prescaler and can be loaded and read under program control. When it decrements to zero then the TMZ (timer zero) bit in the TSCR is set to one. If the ETI (enable timer interrupt) bit in the TSCR is also set to one an
interrupt request, associated to interrupt vector \#3 (for Timer 1) and \#1 for Timer 2, is generated. The interrupt of the timer can be used to exit the MCU from the WAIT mode.

The prescaler decrements on rising edge. The prescaler input can be the oscillator frequency divided by 12 or an external clock at TIMER pin (this is not available in ST639X).
Depending on the division factor programmed by PS2/PS1/PS0 (see table 9) bits in the TSCR, the clock input of the timer/counter register is multiplexed to different sources.
On division factor 1 , the clock input of the prescaler is also that of timer/counter; on factor 2, bit 0 of prescaler register is connected to the clock input of TCR.
This bit changes its state with the half frequency of prescaler clock input. On factor 4, bit 1 of PSC is connected to clock input of TCR, and so on. On division factor 128, the MSB bit 6 of PSC is connected to clock input of TCR. The prescaler initialize bit (PSI) in the TSCR register must be set to one to allow the prescaler (and hence the counter) to start. If it is cleared to zero then all of the prescaler bits are set to one and the counter is inhibited from counting.

Figure 33. Timer Peripheral Block Diagram

TIMERS (Continued)
Figure 34. Timer Working Principle

The prescaler can be given any value between 0 and 7 FH by writing to the related register address, if bit PSI in the TSCR register is set to one. The tap of the prescaler is selected using the PS2/PS1/PS0 bits in the control register. Figure 34 shows the timer working principle.

## Timer Operating Modes

As on ST639X devices the external TIMER pin is not available the only allowed operating mode is the output mode that have to be selected by setting to 1 bit 4 and by clearing to 0 bit 5 in the TSCR1 register. This procedure will enable both Timer 1 and Timer 2. Any other combination written into these two bits will disable any Timer 1 and Timer 2 operation.
Output Mode (TSCR1 D4 = 1, TSCR1 D5 = 0). On this mode the timer prescaler is clocked by the prescaler clock input (OSC/12). The user can select the desired prescaler division ratio through the PS2/PS1/PS0 bits. When TCR count reaches 0 , it sets the TMZ bit in the TSCR.

The TMZ bit can be tested under program control to perform a timer function whenever it goes high. Bit D4 and D5 on TSCR2 (Timer 2) register are not implemented.

## Timer Interrupt

When the counter register decrements to zero and the software controlled ETI (enable timer interrupt) bit is set to one then an interrupt request associated to interrupt vector \#3 (for Timer 1) and to interrupt vector \#1 (for Timer 2) is generated. When the counter decrements to zero also the TMZ bit in the TSCR register is set to one.

## Notes:

TMZ is set when the counter reaches 00 H ; however, it may be set by writing 00 H in the TCR register or setting the bit 7 of the TSCR register. TMZ bit must be cleared by user software when servicing the timer interrupt to avoid undesired interrupts when leaving the interrupt service routine. After reset, the 8-bit counter register is loaded to FFH while the 7-bit prescaler is loaded to 7FH , and the TSCR register is cleared which means that timer is stopped ( $\mathrm{PSI}=0$ ) and timer interrupt disabled.

A write to the TCR register will predominate over the 8 -bit counter decrement to 00 H function, i.e. if a write and a TCR register decrement to 00 H occur simultaneously, the write will take precedence, and the TMZ bit is not set until the 8 -bit counter reaches 00 H again. The values of the TCR and the PSC registers can be read accurately at any time.

## TIMERS (Continued)

## Timer Registers

## Figure 35. Timer Status Control Registers

TMZ. Low-to-high transition indicates that the timer count register has decrement to zero. This bit must be cleared by user software before to start with a new count.

ETI. This bit, when set, enables the timer interrupt (vector \#3 for Timer 1, vector \#1 for Timer 2) request. If $E T I=0$ the timer interrupt is disabled. If $E T I=1$ and TMZ= 1 an interrupt request is generated.

D5. This is the timers enable bit D5. It must be cleared to 0 together with a set to 1 of bit D4 to enable both Timer 1 and Timer 2 functions. It is not implemented on TSCR2 register. Any other combination of TSCR1 D4 and D5 bits will disable any operation of both Timer 1 and Timer 2.

D4. This is the timers enable bit D4. It must be set to 1 together with a clear to 0 of bit D5 to enable both Timer 1 and Timer 2 functions. It is not implemented on TSCR2 register. Any other combination of TSCR1 D4 and D5 bits will disable any operation of both Timer 1 and Timer 2.

PSI. Used to initialize the prescaler and inhibit its counting while $\mathrm{PSI}=0$ the prescaler is set to 7 FH and the counter is inhibited. When PSI = 1 the prescaler is enabled to count downwards. As long as PSI= 0 both counter and prescaler are not running.
PS2-PSO. These bits select the division ratio of the prescaler register. (see table 9)

The TSCR1 and TSCR2 registers are cleared on reset. The correct D4-D5 combination must be written in TSCR1 by user's software to enable the operation of Timer 1 and Timer 2.

Table 9. Prescaler Division Factors

| PS2 | PS1 | PS0 | Divided By |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 1 |
| 0 | 0 | 1 | 2 |

Figure 36. Timer Counter Registers

Figure 37. Prescaler Registers

## HARDWARE ACTIVATED DIGITAL WATCHDOG FUNCTION

The hardware activated digital watchdog function consists of a down counter that is automatically initialized after reset so that this function does not need to be activated by the user program. As the watchdog function is always activated this down counter can't be used as a timer. The watchdog is using one data space register (HWDR location D8H). The watchdog register is set to FEH on reset and immediately starts to count down, requiring no software start. Similarly the hardware activated watchdog can not be stopped or delayed by software.
The watchdog time can be programmed using the 6 MSbits in the watchdog register, this gives the possibility to generate a reset in a time between 3072 to 196608 oscillator cycles in 64 possible steps. (With a clock frequency of 8 MHz this means from $384 \mu \mathrm{~s}$ to 24.576 ms ). The reset is prevented if the register is reloaded with the desired value before bits 2-7 decrement from all zeros to all ones.
The presence of the hardware watchdog deactivates the STOP instruction and a WAIT instruction is automatically executed instead of a STOP. Bit 1 of the watchdog register (set to one at reset) can be used to generate a software reset if cleared to zero). Figure 38 shows the watchdog block diagram while Figure 39 shows its working principle.

Figure 39. Hardware Activated Watchdog Working Principle

Figure 38. Hardware Activated Watchdog Block Diagram

## HARDWARE ACTIVATED DIGITAL WATCHDOG FUNCTION (Continued)

Figure 40. Watchdog Register

T1-T6. These are the watchdog counter bits. It should be noted that D7 (T1) is the LSB of the counter and D2 (T6) is the MSB of the counter, these bits are in the opposite order to normal.
SR. This bit is set to one during the reset phase and will generate a software reset if cleared to zero.
C. This is the watchdog activation bit that is hardware set to one; the user can't change the value of this bit (the watchdog is always active).
The register reset value is FEH (Bit 1-7 set to one, Bit 0 cleared).

## SERIAL PERIPHERAL INTERFACE

The ST639X Serial Peripheral Interface macrocell (SPI) has been designed to be cost effective and flexible in interfacing the various peripherals in TV applications.
It maintains the software flexibility but adds hardware configurations suitable to drive devices which require a fast exchange of data. The three pins dedicated for serial data transfer (single master only) can operate in the following ways:

- as standard I/O lines (software configuration)
- as S-BUS or as $I^{2}$ CBUS (two pins)
- as standard (shift register) SPI

When using the hardware SPI, a fixed clock rate of 62.5 kHz is provided. The ST6395 uses a fixed clock rate at 100 KHz .
It has to be noted that the first bit that is output on the data line by the 8 -bit shift register is the MSB.

## SPI Data/Control Registers

For I/O details on SCL (Serial Clock), SDA (Serial Data) and SEN (Serial Enable) please refer to I/O Ports description with reference to the following registers:

Port C data register, Address C2H (Read/Write).

- BIT DO "SCL"
- BIT D1 "SDA"
- BIT D3 "SEN"

Port C data direction register, Address C 6 H (Read/Write).

Figure 41. SPI Serial Data Register

D7-D0. These are the SPI data bits. They can be neither read nor written when SPI is operating (BUSY bit set). They are undefined after reset.

Figure 42. SPI Control Register 1

D7-D4. These bits are not used.
STR. This is Start bit for $I^{2}$ CBUS/S-BUS. This bit is meaningless when STD/SPI enable bit is cleared to zero. If this bit is set to one STD/SPI bit is also set to "1" and SPI Start generation, before beginning of transmission, is enabled. Set to zero after reset.
STP. This is Stop bit for $I^{2}$ CBUS/S-BUS. This bit is meaningless when STD/SPI enable bit is cleared to zero. If this bit is set to one STD/SPI bit is also set to "1" and SPI Stop condition generation is enabled. STP bit must be reset when standard protocol is used (this is also the default reset conditions). Set to zero after reset.
STD, SPI Enable. This bit, in conjunction with S-BUS $/ 1^{2} C B U S$ bit, allows the SPI disable and will select between $1^{2} \mathrm{CBUS} / \mathrm{S}-\mathrm{BUS}$ and Standard

## SERIAL PERIPHERAL INTERFACE (Continued)

shift register protocols. If this bit is set to one, it selects both $1^{2}$ CBUS and $S$-BUS protocols; final selection between them is made by $S$ BUS $/ I^{2} C B U S$ bit. If this bit is cleared to zero when S-BUS $/{ }^{2}$ CBUS is set to "1" the Standard shift register protocol is selected. If this bit is cleared to " 0 " when S-BUS $/ I^{2} C B U S$ is cleared to 0 the SPI is disabled. Set to zero after reset.
S-BUS $/{ }^{2}$ CBUS Selection. This bit, in conjunction with STD/SPI bit, allows the SPI disable and will select between $I^{2} \mathrm{CBUS}$ and S-BUS protocols. If this bit is cleared to " 0 " when STD bit is also " 0 ", the SPI interface is disabled. If this bit is cleared to zero when STD bit is set to " 1 ", the $I^{2}$ CBUS protocol will be selected. If this bit is set to one when STD bit is set to "1", the S-BUS protocol will be selected. Cleared to zero after reset.

Table 10. SPI Modes Selection

| D0 <br> S-BUS/I ${ }^{2}$ CBUS | D1 <br> STD/SPI | SPI Function |
| :---: | :---: | :---: |
| 0 | 0 | Disabled |
| 1 | 0 | STD Shift <br> Register |
| 0 | 1 | I $^{2}$ CBUS |
| 1 | 1 | S-BUS |

Figure 43. SPI Control Register 2

D7-D4. These bits are not used.
TX/RX. Write Only. When this bit is set, current byte operation is a transmission. When it is reset, current operation is a reception. Set to zero after reset.
VRY/S.Read Only/Write Only. This bit has two different functions in relation to read or write oper-
ation. Reading Operation: when STD and/or TRX bits are cleared to 0 , this bit is meaningless. When bits STD and TX are set to 1 , this bit is set each time BSY bit is set. This bit is reset during byte operation if real data on SDA line are different from the ones output from the shift register. Set to zero after reset. Writing Operation : it enables (if set to one) or disables (if cleared to zero) the interrupt coming from VSYNC pin. Undefined after reset. Refer to OSD description for additional information.
ACN.Read Only. If STD bit (D1 of SCR1 register) is cleared to zero this bit is meaningless. When STD is set to one, this bit is set to one if no Acknowledge has been received. In this case it is automatically reset when BSY is set again. Set to zero after reset.
BSY.Read/Set Only. This is the busy bit zero. When a one is loaded into this bit the SPI interface start the transmission of the data byte loaded into SSDR data register or receiving and building the receive data into the SSDR data register. This is done in accordance with protocol, direction and start/stop condition(s). This bit is automatically cleared at the end of the current byte operation. Cleared to zero after reset.

## Note :

The SPI shift register is also the data transmission register and the data received register; this new feature is made possible by using the serial structure of the ST639X and thus reducing size and complexity.
During transmission or reception of data, all access to serial data register is therefore disabled. The reception or transmission of data is started by setting the BUSY bit to " 1 "; this will be automatically reset at the end of the operation. After reset, the busy bit is cleared to " 0 ", and the hardware SPI disabled by clearing bit 0 and bit 1 of SPI control register 1 to " 0 ". The outputs from the harware SPI are "ANDed" to the standard I/O software controlled outputs. If the hardware SPI is in operation then Port C ouputs related to the SPI should be set high or the pins should pin configured as inpus using the data direction register. When the SPI is configured as the S-BUS, the three pins PC0, PC1 and PC3 become the pins SCL, SDA and SEN respectively. When configured as the ${ }^{2} \mathrm{CBUS}$ the pins PCO and PC1 are configured as the pins SCL and SDA; PC3 is not driven and can be used as general purpose I/O pin. In the case of the STDSPI the pins PCO and PC1 become the signals CLOCK and DATA, PC3 is not driven and can be used as general purpose I/O pin. The VERIFY bit is available when the SPI is configured as either S-BUS or $I^{2}$ CBUS. At the start of a byte transmission, the verify bit is set to one. If at any time during the transmission of the following eight bits, the data on the SDA line does not match the data forced by the SPI (while SCL is

SERIAL PERIPHERAL INTERFACE (Continued)
high), then the VERIFY bit is reset. The verify is available only during transmission for the S-BUS and $I^{2}$ CBUS; for other protocol it is not definfited. The SDA and SCL signal entering the SPI are buffered in order to remove any minor glitches. When STD bit is set to one (S-BUS or $1^{2}$ CBUS selected), and TRX bit is reset (receiving data), and STOP bit is set (last byte of current communication), the SPI interface does not generate the Acknowledge, according to $\mathrm{S}-\mathrm{BUS} / \mathrm{I}^{2} \mathrm{CBUS}$ specifications. PCO-SCL, PC1-SDA and PC3-SEN lines are standard drive I/O port pins with opendrain output configuration (maximum voltage that can be applied to these pins is $V_{D D}+0.3 \mathrm{~V}$ ).

## S-BUS $/$ l $^{2}$ CBUS Protocol Information

The S-BUS is a three-wire bidirectional data-bus with functional features similar to the $\mathrm{I}^{2} \mathrm{CBUS}$. In fact the S-BUS includes decoding of Start/Stop conditions and the arbitration procedure in case of multimaster system configuration (the ST639X SPI allows a single-master only operation). The SDA line, in the $1^{2} \mathrm{CBUS}$ represents the AND combination of SDA and SEN lines in the S-BUS. If the SDA and the SEN lines are short-circuit connected, they appear as the SDA line of the $I^{2} C B U S$. The Start/Stop conditions are detected (by the external peripherals suited to work with $\mathrm{S}-\mathrm{BUS} / /^{2} \mathrm{CBUS}$ ) in the following way:

- On S-BUS by a transition of the SEN line (1 to 0 Start, 0 to 1 Stop) while the SCL line is at high level.
- On $I^{2}$ CBUS by a transition of the SDA line ( 10 Start, 01 Stop) while the SCL line is at high level.

Start and Stop condition are always generated by the master (ST639X SPI can only work as single master). The bus is busy after the start condition and can be considered again free only when a certain time delay is left after the stop condition. In the S-BUS configuration the SDA line is only allowed to change during the time SCL line is low. After the start information the SEN line returns to high level and remains unchanged for all the data transmission time. When the transmission is completed the SDA line is set to high level and, at the same time, the SEN line returns to the low level in order to supply the stop information with a low to high transition, while the SCL line is at high level. On the S-BUS, as on the $1^{2}$ CBUS, each eight bit information (byte) is followed by one acknowledged bit which is a high level put on the SDA line by the transmitter. A peripheral that acknowledges has to pull down the SDA line during the acknowledge clock pulse. An addressed receiver has to generate an acknowledge after the reception of each byte; otherwise the SDA line remains at the high level during the ninth clock pulse time. In this case the master transmitter can generate the Stop condition,
via the SEN (or SDA in $1^{2} \mathrm{CBUS}$ ) line, in order to abort the transfer.
Start/Stop Acknowledge. The timing specs of the S-BUS protocol require that data on the SDA (only on this line for $I^{2} \mathrm{CBUS}$ ) and SEN lines be stable during the "high" time of SCL. Two exceptions to this rule are foreseen and they are used to signal the start and stop condition of data transfer.

- On S-BUS by a transition of the SEN line (10 Start, 01 Stop) while the SCL line is at high level.
- On $I^{2}$ CBU by a transition of the SDA line ( 10 Start, 01 Stop) while the SCL line is at high level.
Data are transmitted in 8 -bit groups; after each group, a ninth bit is interposed, with the purpose of acknowledging the transmitting sequence (the transmit device place a "1" on the bus, the acknowledging receiver a " 0 ").
Interface Protocol. This paragraph deals with the description of data protocol structure. The interface protocol includes:

## - A start condition

- A "slave chip address" byte, transmitted by the master, containing two different information:
a. the code identifying the device the master wants to address (this information is present in the first seven bits)
b. the direction of transmission on the bus (this information is given in the 8th bit of the byte); "0" means "Write", that is from the master to the slave, while "1" means "Read". The addressed slave must always acknowledge.
The sequence from, now on, is different according to the value of $R / \bar{W}$ bit.

1. $R \bar{W}=" 0 "(\overline{W r i t e})$

In all the following bytes the master acts as transmitter; the sequence follows with:
a. an optional data byte to address (if needed) the slave location to be written (it can be a word address in a memory or a register address, etc.).
b. a "data" byte which will be written at the address given in the previous byte.
c. further data bytes.
d. a STOP condition

A data transfer is always terminated by a stop condition generated from the master. The ST639X peripheral must finish with a stop condition before another start is given. Figure 44 shows an example of write operation.
2. $R \bar{W}=$ "1" (Read)

In this case the slave acts as transmitter and, therefore, the transmission direction is changed. In read mode two different conditions can be considered:

SERIAL PERIPHERAL INTERFACE (Continued)
a. The master reads slave immediately after first byte. In this case after the slave address sent from the master with read condition enabled the master transmitter becomes master receiver and the slave receiver becomes slave transmitter.
b. The master reads a specified register or location of the slave. In this case the first sent byte will contain the slave address with write condition enabled, then the second byte will specify the address of the register to be read. At this moment a new start is given together with the slave address in read mode and the procedure will proceed as described in previous point "a".

Figure 44. Master Transmit to Slave Receiver (Write Mode)

Figure 45. Master Reads Slave Immediately After First Byte (read Mode)

Figure 46. Master Reads After Setting Slave Register Address (Write Address, Read Data)

SERIAL PERIPHERAL INTERFACE (Continued)

## S-BUS $/ \mathbf{I}^{2}$ CBUS Timing Diagrams

The clock of the S-BUS $/ /^{2}$ CBUS of the ST639X SPI (single master only) has a fixed bus clock frequency of $62.5 \mathrm{KHz}(100 \mathrm{KHz}$ for ST6395). All the devices
connected to the bus must be able to follow transfers with frequencies up to $62.5 \mathrm{KHz}(100 \mathrm{KHz}$ for ST6395), either by being able to transmit or receive at that speed or by applying the clock synchronization procedure which will force the master into a wait state and stretch low periods.

Figure 47. S-BUS Timing Diagrams

SERIAL PERIPHERAL INTERFACE (Continued)
Figure 48. ${ }^{2}$ C BUS Timing Diagrams

Note: The third pin, SEN, should be high; tt's not used in the $I^{2}$ CBUS. Logically SDA is the AND of the S-BUS SDA and SEN.)

SERIAL PERIPHERAL INTERFACE (Continued)

## Compatibility S-BUS $/ I^{2}$ CBUS

Using S-BUS protocol it is possible to implement mixed system including S-BUS $/ /^{2}$ CBUS bus peripherals. In order to have the compatibility with the $I^{2}$ CBUS peripherals, the devices including the $S$ BUS interface must have their SDA and SEN pins
connected together as shown in the following Figure 49 ( $a$ and $b$ ). It is also possible to use mixed S-BUS $/ /^{2}$ CBUS protocols as showed in figure 49 (c). S-BUS peripherals will only react to S-BUS protocol signals, while ${ }^{2}$ CBUS peripherals will only react to $I^{2}$ CBUS signals. Multimaster configuration is not possible with ST63XX SPI (single master only).

Figure 49. S-BUS $/{ }^{2} \mathrm{C}$ BUS Mixed Configurations

SERIAL PERIPHERAL INTERFACE (Continued)

Figure 50. Software Bus (hardware bus disabled) Timing Diagram

## STD SPI Protocol (Shift Register)

This protocol is similar to the $1^{2}$ CBUS with the exception that there is no acknowledge pulse and there are no stop or start bits. The clock cannot be slowed down by the external peripherals.
In this case all three outputs should be high in order not to lock the software I/Os from functioning.

## SPI APPLICATION NOTES

Stop Clock Slowdown: In the ST639X family of devices when operating in the ${ }^{2} \mathrm{C}$ or SBUS modes, there is no internal clock slowdown for the final STOP clock. Slowdown means that if an external peripheral requires extra time it will hold the ST639X SCL clock low. To be fully ${ }^{2} \mathrm{C}$ and SBUS
compatible in this respect, the SW should check that the SCL line is indeed high before proceeding with the START of another $\mathrm{I}^{2} \mathrm{C}$ or SBUS transmission. In all other cases the SCL clock slowdown feature is operational.
SPI Standard Bus Protocol: The standard bus protocol is selected by loading the SPI Control Register 1 (SCR1 Add. EBH). Bit 0 named I ${ }^{2} \mathrm{C}$ must be set at one and bit 1 named STD must be reset. When the standard bus protocol is selected bit 2 of the SCR1 is meaningless.
This bit named STOP bit is used only in $1^{2}$ CBUS or SBUS. However take care that the STOP BIT MUST BE RESET WHEN THE STANDARD PROTOCOL IS USED. This bit is set to ZERO after RESET.

## 6-BIT PWM D/A CONVERTERS

The D/A macrocell contains up to six PWM D/A outputs (32Khz repetition, DA0-DA5) with six bit resolution.
Each D/A converter of ST639X is composed by the following main blocks:

- pre-divider
- 6-bit counter
- data latches and compare circuits

The pre-divider uses the clock input frequency ( 8 MHz typical) and its output clocks the 6 -bit free-running counter. The data latched in the six registers (E0H, E1H, E2H, E3H, E6H and E7H) control the six D/A outputs (DAO,1,2, 3, 4 and 5). When all zeros are loaded the relevant output is an high logic level; all 1 's correspond to a pulse with a $1 / 64$ duty cycle and almost $100 \%$ zero level.

The repetition frequency is 31.25 KHz (except the ST6395 which is 25 KHz ) and is related to the 8 MHz clock frequency. Use of a different oscillator frequency will result in wrong repetition frequency. All D/A outputs are open-drain with standard current drive capability and able to withstand up to 12 V.

## D/A Data/Control Registers

This paragraph deals with the description of D/A data/control registers.

Figure 51. 6-BIT PWM D/A Output Configuration

Figure 52. DA0-DA5 Data Control Registers

DA0-DA5. These are the 6 bits of the PWM digital to analog converter. Undefined after reset.

## AFC A/D INPUT, IR/PC6 RESULT, VSYNC RESULT, O0, O1 AND 62.5 KHz OUTPUTS

The AFC macrocell contains an A/D comparator with five levels at intervals of 1 V from 1 V to 5 V . The levels can all be lowered by 0.5 V to effectively double the resolution. This A/D can be used to perform the AFC function. In addition this cell offers also a keyboard input register of three bits used to perform a keyboard scan and 4 open-drain outputs (able to withstand signals up to 12V) that can be used to perform band switch function. This pin is not available on ST6391 and ST6395

Figure 53. AFC Inputs Configuration Diagram

## AFC A/D INPUT, IR/PC6 RESULT, VSYNC RESULT, O0, O1 AND 62.5KHz OUTPUT (Continued)

## A/D Comparator

The A/D used to perform the AFC function (when high threshold is selected) has the following voltage levels: $1,2,3,4$ and 5 V . Bits $0-2$ of AFC result register (E4H address) will provide the result in binary form (less than 1 V is 000 , greater than 5 V is 101).
If the application requires a greater resolution, the sensitivity can be doubled by clearing to zero bit 2 of the OUTPUTS control register, address E5H. In this case all levels are shifted lower by 0.5 V . If the two results are now added within a software routine then the A/D S-curve can be located within a resolution of 0.5 V .

The A/D input has high impedance able to withstand up to 13 V signals (input level tolerances $\pm$ 200 mV absolute and $\pm 100 \mathrm{mv}$ relative to 5 V ).

D7-D5. These bits are not used.
VSYNC. This bit reads the status of the VSYNC pin. It is inverted with respect to the pin. Refer to the OSD description for additional information.
IR. This bit reads the status of the IR latch. If a signal has been latched this bit will be high. Refer to the DEDICATED LATCHES description for additional information.
AD2-ADO. These bits store the real time conversion of the value present on the AFC input pin. No reset value.

Figure 55. Outputs Control Register

## D7, D6, D5, D3, D2. These bits are not used.

A/D Shift. This bit determines the voltage range of the AFC input. Writing a zero will select the 0.5 V to 4.5 V range. Writing a one will select the 1.0 V to 5.0 V range. Undefined after reset.
$\mathrm{O1}, \mathrm{O}$. These bit control the output pins $\mathrm{O} 1, \mathrm{O} 0$ (ST6394, ST6396 only). They are undefined after reset.

### 62.5 KHz Output

This bit is available only on ST6399. The pin is an open-drain (12V) output at a frequency of 62.5 KHz (with an 8 MHz clock). The pin can used to drive the SGS-THOMSON TEA5640 chroma processor. Refer to the TEA5640 data sheet for more information. Care must be taken to respect the frequency tolerances required by the TEA5640 by chosing a quartz with PPM variations within the limits required by the chroma processor.

## DEDICATED LATCHES

Two latches are available which may generate interrupts to the ST639X core. The IR latch is set either by the falling or rising edge of the signal on pin PC6(IRIN). If bit 1 (IRPOSEDGE) of the latches register (E9H) is high, then the latch will be triggered on the rising edge of the signal at PC6(IRIN). If bit 1 (IRPOSEDGE) is low, then the latch will be triggered on the rising edge of the signal at PC6(IRIN). The IR latch can be reset by setting bit 3 (RESIRLAT) of the latches register; the bit is set only and a high should be written every time the IR latch needs to be reset. If bit 2 (IRINTEN) of the latches register (E9H) is high, then the output of the IR latch, IRINTN, may generate an interrupt (\#0). IRINTN is inverted with respect to the state of the

## DEDICATED LATCHES(Continued)

IR latch. If bit 2 (IRINTEN) is low, then the output of the IR latch, IRINTN, is forced high. For more information see the interrupts section. The state of the IR latch may be read from bit 3 (IRLATCH) of register E 4 H ; if the IR latch is set, then bit 3 will be high. The PWR latch is set either by the falling or rising edge of the signal on pin PC4(PWRIN). If bit 4 (PWREDGE) of the latches register (E9H) is high, then the latch will be triggered on the rising edge of the signal at PC4(PWRIN). If bit 4 (PWREDGE) is low, then the latch will be triggered on the falling edge of the signal at PC4(PWRIN). The PWR latch can be reset by setting bit 6 (RESPWRLAT) of the latches register; the bit is set only and a high should be written every time the PWR latch needs to be reset. If bit 5 (PWRINTEN) of the latches register (E9H) is high, then the output of the PWR latch, PWRINTN, may generate an interrupt (\#4). PWRINTN is inverted with respect to the state of the PWR latch. If bit 5 (PWRINTEN) is low, then the output of the PWR latch, PWRINTN, is forced high. For more information see the interrupts section. The PWR latch is not available on the ST6391 and the ST6393.

Figure 56. Dedicated Latched Control Register

D7. This bit is not used
RESPWRLAT. Resets the PWR latch; this bit is set only.
PWRINTEN. This bit enables the PWRINTN signal (\#4) from the latch to the ST639X core. Undefined after reset.
PWRIN. The bit determines the edge which will cause the PWRIN latch to be set. If this bit is high, than the PWRIN latch will be set on the rising edge of the PWRIN signal. Undefined after reset.

RESIRLAT. Resets the IR latch; this bit is set only.
IRINTEN. This bit enables the IRINTN signal (\#O) from the latch to the ST639X core. Undefined after reset.

IRPOSEDGE. The bit determines the edge which will cause the IR latch to be set. If this bit is high, than the IR latch will be set on the rising edge of the IR signal. Undefined after reset.

## D0. This bit is not used

## ON-SCREEN DISPLAY (OSD)

The ST639X OSD macrocell is a CMOS LSI character generator which enable display of characters and symbols on the TV screen. The character rounding function enhances the readability of the characters. The ST639X OSD receives horizontal and vertical synchronization signal and outputs screen information via R, G, B and blanking pins. The main characteristics of the macrocell are listed below:

- Number of display characters: 5 lines by 15 columns.
- Number of character types: 128 characters in two banks of 64 characters. Only one bank per screen can be used.
- Character size: Four character heights ( $18 \mathrm{H}, 36 \mathrm{H}$ $54 \mathrm{H}, 72 \mathrm{H}$ ), two available per screen programmable by line.
- Character format: $6 \times 9$ dots with character rounding function.
- Character color: Eight colors available programmable by word. The ST6394 and ST6396 have only one color available
- Display position: 64 horizontal positions by $2 / f o s$ and 63 vertical positions by 4 H
- Word spacing: 64 positions programmable from $2 /$ fosc to $128 / f o s c$.
- Line spacing: 63 positions programmable from 4 to 252 H .
- Background: No background, square background or fringe background programmable by word.
- Background color: Two of eight colors available programmable by word.
- Display output: Three character data output terminals ( $R, G, B$ ) and a blank output terminal. The ST6394 and ST6396 have only the B and Blank output terminals.
- Display on/off: Display data may be programmed on or off by word or entire screen. Entire screen may be blanked.

## Format Specification

The entire display can be turned on or off thru the use of global enable bit or the display may be

## ON-SCREEN DISPLAY (Continued)

selectively turned on or off by word. To turn off the entire display, the global enable bit (GE) should be zero. If the global enable is one, the display is controlled by the word enable bits (WE). The global enable bit is located in the global enable register and the word enable bit is located in the space character preceding the word.
Each line must begin with a format character which describes the format of that line and of the first word. This character is not displayed.
A space character defines the format of subsequent words. A space character is denoted by a one in bit 6 in the display RAM. If bit 6 of the display RAM is a zero, the other six bits define one of the 64 display characters.

The color, background and enable can be programmed by word. This information is encoded in the space character between words or in the format character at the beginning of each line. Five bits define the color and background of the following word, and determine whether it will be displayed or not.
Characters are stored in a $6 \times 9$ dot format. One dot is defined vertically as 2 H (horizontal lines) and horizontally as 2 /fosc if the smallest character size is enabled. There is no space between characters or lines if the vertical space enable (VSE) and horizontal space enable (HSE) bits are both zero. This allows the use of special graphics characters.
The normal alphanumeric character set is formatted to be $5 \times 7$ with on empty row at the top and one at the bottom and one empty column at the right. If VSE and HSE are both zero, then the spacing between alphanumeric characters is 1 dot and the spacing between lines of alphanumeric characters is 2 H .
The character size is programmed by line thru the use of the size bit ( S ) in the format character and the global size bits (GS1 and GS2). The vertical spacing enable bit (VSE) located in the format character controls the spacing between lines. If this bit is set to one, the spacing between lines is defined by the vertical spacing register, otherwise the spacing between lines is 0 .
The spacing between words is controlled by the horizontal space enable bit (HSE) located in the space character. If this bit is set to one, the spacing between words is defined by the horizontal spacing register, otherwise the space character width of 6 dots is the spacing between words.
The formats for the display character, space character and format character are described hereafter.

Figure 57. Space Character Register Explanation

D7. Not used.
D6. This pin is fixed to "1".
R, G, B. Color. The 3 color control bits define the color of the following word as shown in table 11.
Table 11. Space Character Register Colour Setting.

| $\mathbf{R}$ | $\mathbf{G}$ | $\mathbf{B}$ | Color |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | Black |
| 0 | 0 | 1 | Blue |
| 0 | 1 | 0 | Green |
| 0 | 1 | 1 | Cyan |
| 1 | 0 | 0 | Red |
| 1 | 0 | 1 | Magenta |
| 1 | 1 | 0 | Yellow |
| 1 | 1 | 1 | White |

BGS. Background Select. The background select bit selects the desired background for the following word. There are two possible backgrounds defined by the bits in the Background Control Register.
" 0 " - The background on the following word is enabled by BGO and the color is set by RO, GO, and BO.
"1" - The background on the following word is enabled by BG1 and the color is set by R1, G1, and B 1 .
WE. Word Enable. The word enable bit defines whether or not the following word is displayed.
" 0 " - The word is not displayed.

## ON-SCREEN DISPLAY (Continued)

"1" - If the global enable bit is one, then the word is displayed.
HSE. Horizontal Space Enable. The horizontal space enable bit determines the spacing between words. The space between characters is always 0 . The alphanumeric character set is implemented in a $5 \times 7$ format with one empty column to the right and one empty row above and below so that the space between alphanumeric characters will be one dot.
" 0 " - The space between words is equal to the width of the space character, which is 6 dots.
"1" - The space between words is defined by the value in the horizontal space register plus the width of the space character.

Figure 58. Format Character Register Explanation

D7. This bit is not used
S. CharacterSize. The character size bit, along with the global size bits (GS2 and GS1) located in the horizontal space register, specify the character size for each line as defined in Table 13.
R, G, B. Color. The 3 color control bits define the color of the following word as shown in Table 12.
BGS. Background Select. The background select bit selects the desired background for the following word. There are two possible backgrounds defined by the bits in the Background Control Register.
" 0 " - The background on the following word is enabled by BGO and the color is set by R0, G0, and B0.
"1" - The background on the following word is enabled by BG1 and the color is set by R1, G1, and B1.
WE. Word Enable. The word enable bit defines whether or not the following word is displayed.
" 0 " - The word is not displayed.
"1" - If the global enable bit is one, then the word is displayed.

VSE. Vertical Space Enable. The vertical space enable bit determines the spacing between lines.
" 0 " - The space between lines is equal to 0 H . The alphanumeric character set is implemented in a $5 \times 7$ format with one empty column to the right and one empty row above and one below and stored in a $6 \times 9$ format.
"1" - The space between lines is defined by the value in the vertical space register.

ON-SCREEN DISPLAY (Continued)
Figure 59. Display Character Register Explanation

D7. This bit is not used.
D6. This bit is fixed to " 0 ".
C5-C0. Character type. The 6 character type bits define one of the 64 available character types. These character types are shown on the following pages.

## Character Types

The character set is user defined as ROM mask option.

## Register and RAM Addressing

The OSD contains seven registers and 80 RAM locations. The seven registers are the Vertical Start Address register, Horizontal Start Address register, Vertical Space register, Horizontal Space register, Background Control register, Global Enable register and Character Bank Select register. The Global Enable register can be written at any time by the ST639X Core. The other six registers and the RAM can only be read or written to if the global enable is zero.
The six registers and the RAM are located on two pages of the paged memory of the ST639X MCUs; the Character Bank Select register is located outside the paged memory at address EDH. Each page contains 64 memory locations. This paged memory is at memory locations 00 H to 3 FH in the ST639X memory map. A page of memory is enabled by setting the desired page bit, located in the data RAM bank switching register, to a one. The page register is location E8H. A one in bit five selects page 5, located on the OSD and a one in bit 6 selects page 6 on the OSD. Table 14 shows the addresses of the OSD registers and RAM.

Table 14. OSD Control Registers and Data RAM Addressing

| Page | Address | Register or RAM |
| :---: | :---: | :---: |
| 5 | $00 \mathrm{H}-3 \mathrm{FH}$ | RAM Locations $00 \mathrm{H}-3 F \mathrm{H}$ |
| 6 | $00 \mathrm{H}-0 \mathrm{FH}$ | RAM Locations $00 \mathrm{H}-0 \mathrm{FH}$ |
| 6 | 10 H | Vertical Start Register |
| 6 | 11 H | Horizontal Start Register |
| 6 | 12 H | Vertical Space Register |
| 6 | 13 H | Horizontal Space Register |
| 6 | 14 H | Background Control Register |
| 6 | 17 H | Global Enable Register |
| No <br> Page | EDH | Character Bank Select Register |

## OSD Global Enable Register

This register contains the global enable bit (GE). It is the only register that can be written at any time regardless of the state of the GE bit. It is a write only register.

Figure 60. Global Enable register

D7-D1. These bits are not used
GE. Global Enable. This bit allows the entire display to be turned off.
" 0 " - The entire display is disabled. The RAM and other registers of the OSD can be accessed by the Core.
"1" - Display of words is controlled by the word enable bits (WE) located in the format or space character.
The other registers and RAM cannot be accessed by the Core.

## ON-SCREEN DISPLAY (Continued)

Figure 61. Vertical Start Address Register

D7. This bit is not used
FR. Fringe Background. This bit changes the background from a box background to a fringe background. The background is enabled by word as defined by either BK0 or BK1.
" 0 " - The background is defined to be a box which is $7 \times 9$ dots.
"1" - The background is defined to be a fringe.
VSA5-VSAO. Vertical Start Address. These bits determine the start position of the first line in the vertical direction. The 6 bits can specify 63 display start positions of interval 4 H . The first start position will be the fourth line of the display. The vertical start address is defined VSAO by the following formula.
Vertical Start Address $=4 \mathrm{H}\left(2^{5}(\right.$ VSA5 $)+2^{4}($ VSA4 $)$ $+2^{3}($ VSA3 $)+2^{2}($ VSA2 $)+2^{1}($ VSA1 $)+2^{0}($ VSAO $\left.)\right)$
The case of all Vertical Start Address bits being zero is 111 .

Figure 62. Horizontal Start Address Register

D7. This bit is not used.
SBD. Space Blanking Disable. This bit controls whether or not the background is displayed when outputting spaces. If two background colors are used on adjacent words, then the background should not be displayed on spaces in order to make a nice break between colors. If an even background around an area of text is desired, as in a menu, then the background should be displayed when outputting spaces.
" 0 " - The background during spaces is controlled by the background enable bits (BK0 and BK1) located in the Background Control register.
"1" - The background is not displayed when outputting spaces.
HSA5, HSA0 - Horizontal Start Address bits. These bits determine the start position of the first character in the horizontal direction. The 6 bits can specify 64 display start positions of interval $2 / f 0 s c$ or 400 ns. The first start position will be at $4.0 \mu \mathrm{~s}$ because of the time needed to access RAM and ROM before the first character can be displayed. The horizontal start address is defined by the following formula.
Horizontal Start Address $=2 / \mathrm{fosc}\left(10.0+2^{5}(\right.$ HSA5 $)$ $+2^{4}($ HSA4 $)+2^{3}(\mathrm{HSA} 3)+2^{2}($ HSA 2$)+2^{1}($ HSA1 $)+$ $2^{0}$ (HSAO))

ON-SCREEN DISPLAY (Continued)
Figure 63. Vertical Space Register

D7. This bit is not used
SCB. Screen Blanking. This bit allows the entire screen to be blanked.
" 0 " - The blanking output signal (VBLK) is active only when displaying characters.
"1" - The blanking output signal (VBLK) is always active. Characters in the display RAM are still displayed.
When this bit is set to one, the screen is blanked also without setting the Global Enable bit to one (OSD disabled).
VS5, VSO. Vertical Space. These bits determine the spacing between lines if the Vertical Space Enable bit (VSE) in the format character is one. If VSE is zero there will be no spaces between lines. The Vertical Space bits can specify one of 63 spacing values from 4 H to 252 H . The space between lines is defined by the following formula.
Space between lines $=4 \mathrm{H}\left(2^{5}(\mathrm{VS} 5)+2^{4}(\mathrm{VS} 4)+\right.$ $\left.2^{3}(\mathrm{VS} 3)+2^{2}(\mathrm{VS} 2)+2^{1}(\mathrm{VS} 1)+2^{0}(\mathrm{VSO})\right)$
The case of all Vertical Start Address bits being zero is ill.

Figure 64. Horizontal Space Register

GS2,GS1. Global Size. These bits along with the size bit (S) located in the Character format word specify the character size for each line as defined in table 15.

Table 15. Horizontal Space Register Size Setting.

| GS2 | GS1 | $\mathbf{S}$ | Vertical Height | Horizontal <br> Lenght |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 18 H | 6 TDOT |
| 0 | 0 | 1 | 36 H | 12 TDOT |
| 0 | 1 | 0 | 18 H | 6 TDOT |
| 0 | 1 | 1 | 54 H | 18 TDOT |
| 1 | 0 | 0 | 36 H | 12 TDOT |
| 1 | 0 | 1 | 54 H | 18 TDOT |
| 1 | 1 | 0 | 36 H | 12 TDOT |
| 1 | 1 | 1 | 72 H | 24 TDOT |

Note: TDOT $=2 / \mathrm{fosc}$
HS5, HSO . Horizontal Space. These bits determine the spacing between words if the Horizontal Space Enable bit (HSE) located in the space character is a one. The space between words is then equal to the width of the space character plus the number of tdots specified by the Horizontal Space bits. The 6 bits can specify one of 64 spacing values ranging from 2 /fosc to $128 / f o s c$. The formula is shown below for the smallest size character $(18 \mathrm{H})$. If larger size characters are being displayed the spacing between words will increase proportionately. Multiply the value below by 2,3 or 4 for character sizes of $36 \mathrm{H}, 54 \mathrm{H}$ and 72 H respectively.

Space between words (not including the space character $)=2 / \mathrm{fosc}\left(\left(1+2^{5}(\mathrm{HS} 5)+2^{4}(\mathrm{HS} 4)+2^{3}(\mathrm{HS} 3)\right.\right.$
$\left.+2^{2}(\mathrm{HS} 2)+2^{1}(\mathrm{HS} 1)+2^{0}(\mathrm{HSO})\right)$

## ON-SCREEN DISPLAY (Continued)

## Background Control Register

This register sets up two possible backgrounds. The background select bit (BGS) in the format or space character will determine which background is selected for the current word.

Figure 65. Background Control Registers

| 1 | 1 | 0 | Yellow |
| 1 | 1 | 1 | White |

BK1,BKO. Background Enable.These bits determine if the specified background is enabled or not.
" 0 " - The following word does not have a background.
"1" - There is a background around the following word.

Figure 66. Character Bank Select Register

D7-D1. These bits are not used
BS. Bank Select. This bit select the character bank to be used. The lower bank is selected with 0 . The value can be modified only when the OSD is OFF ( $G E=0$ ). No reset value.

## OSD Data RAM

The contents of the data RAM can be accessed by the ST639X MCUs only when the global enable bit (GE) in the Global Enable register is a zero.
The first character in every line is the format character. This character is not displayed. It defines the size of the characters in the line and contains the vertical space enable bit. This character also defines the color, background and display enable for the first word in the line. Subsequent characters are either spaces or one of the 64 available character types.
The space character defines the color, background, display enable and horizontal space enable for the following word. Since there are 5 display lines of 15 characters each, the display RAM must contain 5 lines $\times$ ( 15 characters +1 format character) or 80 locations. The RAM size is 80 locatıons $\times 7$ bits. The data RAM map is shown inTable 17.

AVAILABLE SCREEN SPACE
Notes: FT. The format character required for each line. Characters in columns 1 thru 15 are displayed.

## Emulator Remarks

There are a few differences between emulator and silicon. For noise reasons, the OSD oscillator pins are not available: the internal oscillator cannot be disabled and replaced by an external coil. In the emulator, the Character Bank Select register can be written also with Global Enable bit set, while this is not allowed in the device.

## Application Notes

1 - The OSD character generator is composed of a dual port video ram and some circuitry. It needs two input signals VSYNC and HSYNC to syncronize its dedicated oscillator to the TV picture. It generates 4 output signals, that can be used from the TV set to generate the characters on the screen. For istance, they can be used to feed the SCART plug, providing an adequate buffer to drive the low impedance ( $75 \Omega$ ) of the SCART inputs.
2 - The Core sees the OSD as a number of RAM locations (80) plus a certain number of control registers (6). These 86 locations are mapped in two pages of the dynamic data ram address range ( $0 \mathrm{H} . .3 \mathrm{FH}$ ).
In page 5 (load 20H in the register 0E8H), there are 64 bytes of RAM, the ones of the first 4 rows ( 16 bytes each row, 15 characters per row maximum, plus an hidden leading format character). In page

6 (load 40 H in register 0E8H), the 16 bytes of the fith row ( $0 . .0 \mathrm{FH}$ ), and the 6 control registers ( $10 \mathrm{H} . .14 \mathrm{H}, 17 \mathrm{H}$ ).
3 - The video RAM is a dual port ram. That means that it can be addressed either from the Core or from the OSD circuitry itself. To reduce the complexity of the circuitry, and thus its cost, some restrictions have been introduced in the use of the OSD.
a. The Core can Only write to any of the 86 locations (either video RAM or control registers).
b. The Core can Only write to any of the leading 85 locations when the OSD oscillator is OFF. Only the last location (control register 17 H in page 6) can be addressed at any time. This is the Global Enable Register, which contains only the GE bit. If it is set, the OSD is on, if it is reset the OSD is off.
4 - The timing of the on/off switching of the OSD oscillator is the following:
a. GE bit is set. The OSD oscillator will start on the next VSYNC signal.
b. GE bit is reset. The OSD oscillator will be immediately switched off.

## ON-SCREEN DISPLAY (Continued)

To avoid a bad visual impression, it is important that the GE bit is set before the end of the flyback time when charging character. This can be done inside the VSYNC interrupt routine. The following diagram can explain better:

Figure 67. OSD Oscillator ON/OFF Timing

Notes: A - Picture time. 20 mS in PAL/SECAM. B - VSYNC interrupt, if enabled.
C - Startıng of OSD oscillator, if GE $=1$
D - Flyback time.
When modifying the picture display (i.e.: a bar graph for an analog control), it is important that the switching on of the GE bit is done before the the end of the flyback time ( D in Figure 67). If the GE bit is set after the end of the flyback time then the OSD will not start until the begining of the next frame. This results in one frame being lost and will result in a Flicker on the screen. One method to be sure to avoid the flicker is to wait for the VSYNC
interrupt at the start of the flyback; once the VSYNC interrupt is detected, then the GE bit can be set to zero, the characters changed, anid the GE set to one. All this should occur before the end of the flyback time in order not to loose a frame. The correct edge of the interrupt must be chosen. The VSYNC pin may alternatively be sampled by software in order to know the status; this can be done by reading bit 4 of register E 4 H ; this bit is inverted with respect to the VSYNC pin.
6 - An OSD end of line Bar is present in the ST63P9X piggyback and ST639X ROM devices when using the background mode. If this bar is present with software running in the piggybacks then it is also present on the ROM mask version. If the end of line bar is seen to be eliminated by software in the piggyback, then it is also be eliminated in the ROM mask version.
The bar appears at the end of the line in the background mode when the last character is a space character and the first format character is defined with $\mathrm{S}=0$ (size 0 ). The bar is the color of the background defined by the space character. To eliminate bar:
a. If two backgrounds are used then the bar should be moved off the screen by using large word spaces instead of character spaces. If there are not enough spaces before the end of the line, then the location of the valid characters should be moved so they appear at the end of the line (and hence no bar); positioning can be compensated using the horizontal start register.
b. If only one background is used, then the other background should be transparent in order to eliminate the bar.
7 - The OSD oscillator external network should consist of a capagitor on each of the OSD oscillator pins to ground together with an inductance between pins. The user should select the two capacitors to be the same value ( 15 pF to 25 pF each is recommended). The inductance is chosen to give the desired OSD oscillator frequency for the application (normally $56 \mu \mathrm{H}$ ).

## SOFTWARE DESCRIPTION

The ST639X software has been designed to fully use the hardware in the most efficient way possible while keeping byte usage to a minimum; in short to provide byte efficient programming capability. The ST639X Core has the ability to set or clear any register or RAM location bit of the Data space with a single instruction. Furthermore, the program may branch to a selected address depending on the status of any bit of the Data space. The carry bit is stored with the value of the bit when the SET or RES instruction is processed.

## Addressing Modes

The ST639X Core has nine addressing modes which are described in the following paragraphs. The ST639X Core uses three different address spaces: Program space, Data space, and Stack space. Program space contains the instructions which are to be executed, the data for immediate mode instructions, and in this space is physically allocated the data ROM which is addressed as data space. Data space contains the Accumulator, the $\mathrm{X}, \mathrm{Y}, \mathrm{V}$ and W registers, the Core control registers, peripheral and Input/Output registers, the RAM Iocations and the window to address the Data ROM (physically located into the program memory) locations (for storage of tables and constants). Stack space contains six 12-bit RAM bytes used to stack the return addresses for subroutines and interrupts.
Immediate. In the immediate addressing mode, the operand of the instruction follows the opcode location. As the operand is a ROM byte, the immediate addressing mode is used to access constants which do not change during program execution (e.g., a constant used to initialize a loop counter).
Direct. In the direct addressing mode, the address of the byte that is processed by the instruction is stored in the location that follows the opcode. Direct addressing allows the user to directly address the 256 bytes in Data space memory with a single two-byte instruction.
Short Direct. The Core can address the four RAM registers X,Y,V,W (locations $80 \mathrm{H}, 81 \mathrm{H}, 82 \mathrm{H}, 83 \mathrm{H}$ ) in the short-direct addressing mode. In this case, the instruction is only one byte long and the selection of the location to be processed is contained in the opcode. Short direct addressing is a subset of the direct addressing mode. (Note : 80 H and 81 H are also indirect registers).
Extended. In the extended addressing mode, the 12 -bit address needed to define the instruction is
obtained by concatenating the four less significant bits of the opcode with the byte following the opcode. The instructions (JP, CALL) that use the extended addressing mode are able to branch any address of the directly addressable Program space. An extended addressing mode instruction is two-byte long.
Program Counter Relative. The relative addressing mode is only used in conditional branch instructions. The instruction is used to perform a test and, if the condition is true, a branch with a span of -15 to +16 locations around the address of the relative instruction. If the condition is not true, the instruction that follows the relative instruction is executed. The relative addressing mode instruction is onebyte long. The opcode is obtained by adding the three most significant bits that characterize the kind of test, one bit that determines whether the branch is a toward (when it is 0 ) or backward (when it is 1) branch and the four less significant bits that give the span of the branch ( OH to FH ) that must be added or subtracted to the address of the relative instruction to obtain the address of the branch.

Bit Direct. In the bit direct addressing mode, the bit to be set or cleared is part of the opcode, and the byte following the opcode points to the address of the byte in which the specified bit must be set or cleared. Thus, any bit in the 256 directly addressable locations of Data space memory can be set or cleared.
Bit Test \& Branch. The bit test and branch addressing mode is a combination of direct addressing and relative addressing. The bit test and branch instruction is three-byte long. The bit identification and the tested condition are included in the opcode byte. The address of the byte to be tested follows immediately the opcode in the Program space. The third byte is the jump displacement, which is in the range from -126 to +129 . This displacement can be determined using a label, which is converted by the assembler.
Indirect. In the indirect addressing mode, the byte processed by the register-indirect instruction is at the address pointed by the content of one of the indirect registers, $X$ or $Y(80 \mathrm{H}, 81 \mathrm{H})$. The indirect register is selected by the bit 4 of the opcode. A register indirect instruction is one byte long.
Inherent. In the inherent addressing mode, all the information necessary to execute the instruction is contained in the opcode. These instructions are one byte long.

## SOFTWARE DESCRIPTION (Continued)

## Instruction Set

The ST639X Core has a set of 40 basic instructions. When these instructions are combined with nine addressing modes, 244 usable opcodes can be obtained. They can be divided into six different types : load/store, arithmetic/logic, conditional branch, control instructions, jump/call, bit manipulation. The following paragraphs describe the dif-
ferent types. All the instructions within a given type are presented in individual tables.
Load \& Store. These instructions use one,two or three bytes in relation with the addressing mode. One operand is the Accumulator for LOAD and the other operand is obtained from data memory using one of the addressing modes. For LOAD Immediate one operand can be any of the 256 data space bytes while the other is always an immediate data. Refer to Table 18.

Table 18. Load \& Store instructions

| Instruction | Addressing Mode | - Bytes | Cycles | Flags |  |

## SOFTWARE DESCRIPTION (Continued)

Arithmetic and Logic. These instructions are used to perform the arithmetic calculations and logic operations. In AND, ADD, CP, SUB instructions one operand is always the accumulator while the other
can be either a data space memory content or an immediate value in relation with the addressing mode. In CLR,DEC,INC instructions the operand can be any of the 256 data space addresses. In COM, RLC, SLA the operand is always the accumulator. Refer to Table 19.

Conditional Branch. The branch instructions achieves a branch in the program when the selected condition is met. Refer to Table 20.
Bit Manipulation Instructions. These instructions can handle (set or reset) any bit in data space memory. Refer to Table 21.

Control Instructions. The control instructions control the MCU operations during program execution. Refer to Table 22.
Jump and Call. These two instructions are used to perform long (12-bit) jumps or subroutines call inside the whole program space. Fiefer to Table 23.

## ABSOLUTE MAXIMUM RATINGS

This product contains devices to protect the inputs against damage due to high static voltages, however it is advised to take normal precaution to avoid application of any voltage higher than maximum rated voltages.
For proper operation it is recommended that VI and VO must be higher than VSS and smaller than VDD. Reliability is enhanced if unused inputs are connected to an appropriated logic voltage level (VDD or VSS).

Power Considerations. The average chip-junction temperature. Tj , in Celsius can be obtained form.:

$$
T j=T A+P D \times R t h J A
$$

Where: TA = Ambient Temperature, RthJA = Package thermal resistance (junction-to ambient),
PD $=$ Pint + Pport,
Pint $=I_{D D} \times V_{D D}$ (chip internal power),
Pport = Port power dissipation (determined by the user).

| Symbol | Parameter | Value | Unit |
| :---: | :---: | :---: | :---: |
| VDD | Supply Voltage | -0.3 to 7.0 | V |
| $V_{1}$ | Input Voltage (AFC IN) | VSS -0.3 to +13 | V |
| $V_{1}$ | Input Voltage (Other Inputs) | VSS -0.3 to VDD +0.3 | V |
| Vo | Output Voltage <br> (PA4-PA7, PC4-PC7, DA0-DA5, O0, O1) | VSS -0.3 to +13 | V |
| Vo | Output Voltage (Other Inputs) | VSS -0.3 to VDD +0.3 | V |
| Io | Current Drain per Pin Excluding VDD, VSS, PA6, PA7 | $\pm 10$ | mA |
| 10 | Current Drain per Pin (PA6, PA7) | $\pm 50$ | mA |
| IVDD | Total Current into VDD (source) | 50 | mA |
| IVSS | Total Current out of VSS (sink) | 150 | mA |
| $\mathrm{T}_{\mathrm{J}}$ | Junction Temperature | 150 | ${ }^{\circ} \mathrm{C}$ |
| TSTG | Storage Temperature | -60 to 150 | ${ }^{\circ} \mathrm{C}$ |

Note Stresses above those listed as "absolute maximum ratings" may cause permanent damage to the device This is a stress rating only and functional operation of the device at these conditions is not implied Exposure to maximum rating conditions for extended periods may affect device reliability.

THERMAL CHARACTERISTIC

## EEPROM INFORMATION

The ST639X EEPROM macrocell and the single poly EEPROM process have been specially de-
veloped to achieve 1.000.000 Write/Erase cycles and a 10 years data retention.

PSDIP42

## ORDERING INFORMATION

The following chapter deals with the procedure for transfer the Program/Data ROM codes to SGSTHOMSON.

Communication of the ROM Codes. To communicate the contents of Program/Data ROM memories to SGS-THOMSON, the customer has to send:

- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS 5" diskette) for the PROGRAM Memory
- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS 5 " diskette) for the ODD and EVEN ODD OSD Characters
- one file in INTEL INTELLEC 8/MDS FORMAT (either as an EPROM or in a MS-DOS 5" diskette) for the EEPROM initial content (this file is optional)
- a filled Option List form as described in the OPTION LIST paragraph.
The program ROM should respect the ROM Memory Map as in Table 25.
The ROM code must be generated with ST6 assembler. Before programming the EPROM, the buffer of the EPROM programmer must be filled with FFH. For shipment to SGS-THOMSON the EPROMs should be placed in a consecutive IC carrier and packaging carefully.

Notes:

1. EPROM addresses are related to the use of ST63P9X piggyback emulation devices.
2. End address for ST6394
3. End address for ST6391,93,99
4. End address for ST6395,96

ORDERING INFORMATION (Continued)

## Customer EEPROM Initial Contents:

## Format

a. The content should be written into an INTEL INTELLEC format file.
b. In the case of 128 bytes of EEPROM, the starting address in 000h and the end in 7Fh.
c. In the case of 384 bytes of EEPROM, the starting address is 000 H and the end address is 7 FH . The order of the pages ( 64 bytes each) is an in the specification (ie. b7, b1 b0: 001, 010, 011, 101, 110. 111).
d. Undefined or don't care bytes should have the content FFH.
OSD Test Character. In order to allow the testing of the on-chip OSD macrocell the following character must be provided at the fixed 3FH (63) position of the second OSD bank.
Listing Generation \& Verification. When SGSTHOMSON receives the Codes, they are compared and a computer listing is generated from them. This

Figure 69. OSD Test Character

listing refers extractly to the mask that will be used to produce the microcontroller. Then the listing is returned to the customer that must thoroughly check, complete, sign and return it to SGS-THOMSON. The signed list constitutes a part of the contractual agreement for the creation of the customer mask. SGS-THOMSON sales organization will provide detailed information on contractual points.

## Ordering Information Table

| Sales Type | ROM/EEPROM Size | Temperature Range | Package |
| :---: | :---: | :---: | :---: |
| ST6391B1/XX | $16 \mathrm{~K} / 128$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PSDIP42 |
| ST6393B1/XX | $16 \mathrm{~K} / 128$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PSDIP42 |
| ST6394B1/XX | $8 \mathrm{~K} / 384$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PSDIP42 |
| ST6395B1/XX | $20 \mathrm{~K} / 384$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PSDIP42 |
| ST6396B1/XX | $20 \mathrm{~K} / 384$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PSDIP42 |
| ST6399B1/XX | $16 \mathrm{~K} / 128$ Bytes | 0 to $+70^{\circ} \mathrm{C}$ | PSDIP42 |

Note: "XX" Is the ROM code identifier that is allocated by SGS-THOMSON after recelpt of all requred options and the related ROM file.

- Display format of 26 characters $\times 11$ rows
- Character Matrix of $12 \times 18$ pixels
- Character color selectable on a character by character basis. (up to four different colors per screen).
- Character fonts: 128 ROM and 4 RAM based characters.
- Character background selectable on a character by character basis (no background, background 1 or background 2 ; one backround color set per screen).
- Character border (fringe) enable/disable for each row (one border color per screen).
- Programmable vertical and horizontal start position for the display.
- Programmable horizontal offset position for each row.
- Row enable/disable feature.
- Raster Control: The whole screen can be displayed in a color (display off, screen background enabled) or together with the characters (display on, screen background enabled); or transparent (display on/off,screen backround disabled).
- Vertical row spacing: Rows can be spaced or squeezed by up to 17 lines; a squeezed row will have its height reduced by skipping the required number of lines.
- An extra pin MONITOR (enable / disable) is available to indicate the presence of a character pixel or border (fringe).
- Microcontroller interface with a 3 line serial bus
- Oscillator enable/disable.
- Package: 20 pins DIP (300 mils).
- Power Supply: 4.5 to 5.5 volts.

Figure 1. ST6398 Pin Configuration

Figure 2. ST6398 Block Diagram

## GENERAL DESCRIPTION

The ST6398 is a stand alone on-screen-display peripheral with advanced features.
The device is controlled by an external microcontroller via the serial bus interface. Four characters which can be defined in RAM give great flexibility since characters can be defined and redefined via the serial bus without limit and without changing the character ROM mask. Updating of control registers and characters via the serial bus is not limited to the flyback intervals but can also be performed during the display of characters. Most information
is stored in on-chip RAM organized in three main structures: page, attribute and pattern store. The data for the 12 -bit words is entered via the serial bus however it is not necessary to redefine all twelve bits via the serial bus when writing similar data to successive addresses.
The device (sales type ST6398B1/B) is delivered with a standard set of ROM based characters; extra characters particular to the application are defined via the RAM characters. If a customized set of ROM based characters is required then contact your SGS-THOMSON sales office.

## PIN DESCRIPTION

$V_{\text {DD }}$ and $V_{\text {ss. }}$. Power is supplied via these two pins.
$V_{D D}$ is power and $V_{S S}$ is the ground connection.
DATA. Serial bus data input; high impedance.
CLK. Serial bus clock input; high impedance.
STB. Serial bus strobe input; high impedance.
OSCIN and OSCOUT. These are the oscillator terminals for the on screen display. A capacitor and coil network should be connected across these pins in order to provide the desired oscillation frequency.
HSYNC. Horizontal synchronization input; high impedance. When the signal goes high the OSD oscillator is started and characters can be displayed. A different polarity can be defined with a customized ROM mask.
VSYNC. Vertical synchronization input, high impedance. When the signal goes high, this indicates the start of the TV display. The OSD oscillator is not affected by this signal. A different polarity can be defined with a customized ROM mask.
R, G, B, BLANK. Color and blanking outputs; push-pull. These outputs are all active high. A different polarity can be defined with a customized ROM mask.

MONITOR. Output pin which indicates the presence of a character pixel or border; push-pull. This output is active LOW. A different polarity can be defined with a customized ROM mask.
NC. The pins are not used in the application and should be left unconnected.

## ST6398 ARCHITECTURE OVERVIEW

The ST6398 consists of the following blocks:

- SERIAL MICROPROCESSOR INTERFACE. Most data received through this interface is stored in the on-chip RAM.
- RAM. The RAM holds 12 -bit words. It is logically organized in three structures: PAGE, ATTRIBUTE TABLE, PATTERN STORE.
- ROM. This is where the 128 ROM based characters are stored.
- TIMING GENERATOR: This is synchronized by the VSYNC and HSYNC inputs. Its timing is derived from the oscillator ( 7.5 MHz nomimal).
- MEMORY ADDRESS MODULE. Controls the addressing of the RAM and ROM.
- PIXEL LOGIC. Used to determine when to output the color, blanking or monitor informatıon including the backgrounds and border.

## RAM STRUCTURE

## RAM Addressing

Random access to any word is performed by a logical 11 bit address, comprised of three fields (see Ram Memory Map):

- A Structure Identifier: 2 bits.
- A Buffer Index: 4 bits.
- A Displacement from the buffer origin: 5 bits.

Figure 3. RAM Addressing

| 11 | 8 | 7 | 6 | 5 | 4 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| BUFFER | STRUC | 0 | DISPLACEMENT |  |  |

## RAM Structure Description

The three structures PAGE, ATTRIBUTE TABLE and PATTERN STORE are divided as follows:

## PAGE:

- 11 row buffers, numbered from 0 to 10. Each row buffer holds 26 character words. Inside a buffer, characters words are numbered from 0 to 25 ; Sequential addressing: Character first, then row buffer.

## ATTRIBUTE TABLE:

- 11 row attribute words ( 0 to 10). Each of the row attribute words ( 0 to 10) controls the display of the corresponding row buffer.
- The foreground colors (word number 12) which holds the 4 color foreground set ( FC0 to FC3).
- The background colors (word number 13) which holds the 2 color character background set (BCO and BC1 ), the foreground border color (FBC) and the screen background color (SBC).
- The raster control (word number 14).
- The position register (word number 15) which has been mapped into the RAM for convenience.

The raster control word, foreground color word, background color word and the current row attribute word are retrieved at the begining of each tv line.
PATTERN STORE:

- Sufficient RAM to describe four character patterns (0 to 3).
Each character pattern is comprised of 18 pattern lines ( 0 to 17; one word each). Line 0 is displayed topmost; the msb is displayed leftmost. Sequential addressing: Line first, then character index.

RAM STRUCTURE (Continued)
Figure 4. RAM Memory Map

## SERIAL INTERFACE

## Microprocessor Interface

The OSD RAM is down loaded from the microcontroller through the three input pins DATA, CLK and STB.
At the rising edge of CLK the DATA input is sampled and shifted in; either 0 bit, 8 bit or 16 bit messages can be received. The MSB is transmitted first.
At the rising edge of STB the number of clock periods counted from last falling edge of STB is sampled; the clock is ignored when STB is high.
According to this count 0,8 or 16 bits from the shift register are latched into the 16 bit DATA IN register. Short messages do not modify the most significant bits of DATA IN. The twelve least significant bits of DATA IN can be transfered either to the RAM as DATA or as the WRITE RAM ADDRESS depending on the four most significant bits ( 4 bit tag).
Transfer to the RAM is done into the location currently pointed to by the WRITE RAM ADDRESS register; this register is automatically post-incremented.
The STB raising edge requests a transfer which is quickly granted providing that the oscillator is running. As the oscillator is blocked during HSYNC, the STB worse case minimum period is related to the maximum HSYNC duration and the oscillator period.

SERIAL INTERFACE (Continued)
Figure 6. Serial Bus Waveforms

## Writing To RAM

Writing into RAM consists of two steps:
a. Sending a RAM address.

This selects a starting address in a given structure, together with an auto-incrementation scheme (see auto-incrementation).
b. Sending a string of DATA TO RAM messages. These will be stored sequentially in the selected structure from the starting address.

## Long Messages

The 16 bit message consists of:

- A 12 bit word.
- A 4 bit tag (most significant bits).

Figure 5. Summary of 16-Bit Messages

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | RAM ADDRESS |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 00 |  | BUF |  |  |  | STRUC |  | 0 | DISPLACEMENT |  |  |  |  |  |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | LONG DATATO RAM |
| 0 | 00 |  | 1 | X | X | X | X | X | X | X | X | X | X | X | X |  |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | DISABLE OSCILLATOR |
| 0 | 0 | 1 | 0 | X | X | X | X | X | X | X | X | X | X | X | X |  |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | RESET |
| 0 | 0 | 1 | 1 | X | X | X | X |  | X X | X | X | X | X | X | X |  |

## Auto-incrementation

Sequential addressing is performed by an automatic incrementation of the address after every command that loads data into the RAM; it is therefore not necessary to redefine the address when addressing sequentially.
The auto-incrementation is valid for the TABLE (a single buffer structure which contains the attributes and general control registers) and the PATTERN STORE (a four buffer structure which contains the definition of the RAM based characters).
When in PAGE (an 11 buffer structure which defines the characters used on each line), the auto-incrementation can be programmed to wraparound from the last character of a row either to the begining of the same row or to the begining of next row depending on the value of the two bits that define the structure (as defined the the table below). Refer also to RAM ADDRESSING section.
The TABLE holds a single buffer so auto-incrementation to the next buffer is not applicable. Note that auto-incrementation never allows you to go from one structure to the next one: after the last address of any structure, an illegal address is reached (some are reserved for testing) so AFTER WRITing THE LAST WORD OF ANY STRUCTURE, THE ADDRESS MUST BE REINITIALIZED

## Short Data To Ram Messages

In order to minimize the transmission time of character words (or row attributes) differing only by the eight least significant bits, the common four most significant bits may be transmitted only once. This is done by transmitting these MSBs, together with the first word, in a full size 16 bit message (long data to RAM). The subsequent strings may then be
compressed by using the short DATA TO RAM message (8 bits).

Figure 7. Short Data to RAM Format

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| DATA |  |  |  |  |  |  |  |
| SHORT <br> DATA <br> TO RAM |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |

A more radical compression can be achieved when a string of identical words is down loaded into RAM at successive addresses. This is done, as already suggested, by sending the common value once, and then by toggling STB without toggling CLK. This 0 bit message writes the full current content of the DATA IN register into RAM.

## Reset And Disable Oscillator Messages

In order to initialize the circuit after power on, it is mandatory to send TWO SUCCESSIVE RESET MESSAGES; this procedure resets the clock count and starts the oscillator.

The oscillator starts regardless of the SYNC input terminals. The RESET messages clear the raster control word (screen background transparent, display disabled). After these two RESET messages the OSD is ready to store subsequent messages. After a DISABLE OSCILLATOR message, the oscillator stops immediately. As long as the oscillator is stopped, the video output terminals remain in their retrace state: RGB, BLANK and MONITOR are all inactive. The RAM contents remain unmodified. When OSD is not in use it is best to disable the oscillator. The oscillator can be restarted by a single RESET message.

Table 1. Auto-Incrementation to Next Buffer Summary

| Structure | Buffer Index | Displacement | To Next Buffer by <br> Auto-Incrementation |
| :--- | :---: | :---: | :---: |
| Page 00 | 0 to 10 | 0 to 25 | YES |
| Page 01 | 0 to 10 | 0 to 25 | NO |
| Pattern 10 | 0 to 3 | 0 to 17 | YES |
| Table 11 | 0 | 0 to 15 | N/A |

## RAM DATA FORMAT

Page: Character Word Format
Figure 8. Character Words

| 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| FS1 | FSO | BE | BS | CHAR INDEX |  |  |  |  |  |  |  |

## CHAR INDEX

0xxxxxxx Addresses one character pattern out
of 128 in ROM.

100000xx Addresses one character out of 4 in RAM pattern store.

BE BS Character background color selection
10 Selects BC0
(in background color word)
11 Selects BC1
(in background color word)
0 - Disables character background; the screen background is therefore displayed if enabled (SBC Screen Background Color in background color word).
If $\mathrm{SBE}=0$ in the raster control word then there is no screen background; if SBE $=1$ screen background color is displayed.

FS1 FS0 Character foreground color selection.
$0 \quad 0$ Selects FC0
(in foreground color word).
01 Selects FC1
(in foreground color word).
10 Selects FC2
(in foreground color word).
11 Selects FC3
(in foreground color word).

## Note on Blanking:

Whenever a background, border or character is outputed, the BLANK signal will also go high This is used to externally switch off the normal screen display so that the RGB signals from the OSD can be displayed.

Table
ROW ATTRIBUTE WORDS (numbered 0 to 10).
Figure 9. Row Attribute Word

## HPOS OFFSET:

VPOS
OFFSET:
0xxxxx

1xxxxx

RE: Row Enable

FBE: Foreground border (fringe) enable.
Adds a horizontal offset (0 to 15 Tosc) to the basic horizontal position for any line belonging to the row (bit 8 is Isb ).

Adds $n(0$ to 17) tv lines at the top of the plain 18 line row. These lines are displayed in the character background color ( as defined by the current BE, BS) during character period. During the horizontal front and back porch period these lines are displayed in the screen background if enabled or transparent if disabled (bit 0 is lsb).

Jumps directly to line n ( 0 to 17) in the display of that particular row. This means that the row height is reduced by $n$ lines (bit 0 is Isb ).

Border (fringe) effect disabled.
Border (fringe) effect enabled; any background pixel in the vicinity of a foreground pixel is diplayed in foreground border color ( fetched from the background color word).

The row is disabled; nothing is displayed except the screen background color if enable;
VPOS OFFSET is still interpreted. Row enable

## RAM DATA FORMAT (Continued)

FOREGROUND COLOR WORD (number 12)
Figure 10. Foreground Color Word

| 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

\end{array}
$$

NOTE: Correct operation is not guaranteed if these parameters are programmed under the minımum values given above

RAM DATA FORMAT (Continued)

## PATTERN WORDS

Figure 14. Pattern Words

| 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| P0 | P1 | P2 | P3 | P4 | P5 | P6 | P7 | P8 | P9 | P10 | P 11 |

Word 0 in the pattern buffer is displayed topmost on the screen.

Most significant bit is displayed on the left of the screen.

The foreground pixels are set to 1 .
The background pixels (ie. no pixel) are 0 .
This set of rules also applies to the ROM pattern store.

## VIDEO TIMING

## Introduction

The OSD cycles through three main states: RETRACE, PORCH and CHARACTER.

The vertical and horizontal RETRACE are determined by the VSYNC and HSYNC signals.

The vertical and horizontal FRONT PORCH are determined by the POSITION REGISTER. For the vertical front porch, VPOS horizontal lines are counted down from the VSYNC trailing edge. For the vertical front porch HPOS + HPOS OFFSET clock periods are counted down from the HSYNC trailing edge.
The CHARACTER state is when the 11 rows of 26 CHARACTERS are interpreted. The horizontal and vertical BACK PORCH occur after the last character or row respectively.

Figure 15. Typical OSD Display

VR001422

## VIDEO TIMING (Continued)

## Horizontal Timing

The leading edge of HSYNC is resynchronized at TOSC and the 24 subsequent oscillator periods ( 2 character cycles) are used to fetch the current row attribute word, the foreground color word, the background color word and the raster control word. The oscillator is then is stopped.
HSYNC lasts nominally for 10us depending on the application. When enabled, the oscillator is restarted at the trailing edge of HSYNC. HPOS + HPOS ROW OFFSET oscillator periods are counted during this HORIZONTAL FRONT PORCH period. After this the 26 CHARACTER periods ( 12 Tosc each) are counted. The HORIZONTAL BACKPORCH period occurs after the last character while waiting for the next HSYNC.
If HSYNC arrives before the end of the 26th character, then there will be no backporch; HSYNC will restart full line process.

Figure 16. Horizontal Timing During Retrace

## Vertical Timing

VSYNC marks the vertical retrace. It lasts nominally for 0.9 ms ( 14 TV lines) but will depend on the application. The VSYNC signal has no influence on the oscillator and does not start or stop it.
VPOS lines ( leading HSYNC edges ) are counted down during VERTICALFRONT PORCH PERIOD. VPOS is a 6 bit binary parameter.

During the display of the eleven rows, the number of lines per row depends on the VPOS OFFSET row attribute. The VERTICAL BACKKPORCH period occurs after the last row while waiting for the next VSYNC.

## Ram Time Sharing

The RAM is cycled in 2 tosc ( 300 ns approximately) so that six access time slots can be provided along any character display period ( 12 tosc):

Four slots are reserved for character interpretation: one slot for fetching the character word and three slots for fetching three successive character lines in the pattern store (this is required for deriving the foreground border when the character pattern is stored in RAM).

The two remaining slots are available to store a serially received word.

## VIDEO OUTPUT

## Retrace And Porch

The video terminal outputs RGB, BLANK and MONITOR are driven according to:

- The video timing state: RETRACE, PORCH or CHARACTER;
- The programmed context retrieved from RAM.

## DURING RETRACE

- RGB are inactive.
- BLANK and MONITOR are inactive. These values prevail also during the full field when the oscillator has been disabled.

## DURING PORCH

- RGB are inactive unless the screen background is enabled ( $\mathrm{SBE}=1$ ) in which case RGB will set to the screen background color (SBC).
- BLANK is inactive unless the screen background is enabled ( $\mathrm{SBE}=1$ ) in which case it will be active.
- MONITOR is inactive. These values prevail also during the character period when the display is disabled ( $\mathrm{DON}=0$ ) or when the current row is disabled ( $\mathrm{RE}=0$ in the current row attribute word).

## Character State

## CHARACTER DISPLAY

During a character display, the video terminal outputs are driven according to the pixel type, the current row attribute word, the foreground and background color words, the raster control word and the oscillator status. In this section the following is assumed: oscillator enabled, display enabled, row enabled.
The pattern indexed by the character word is mapped onto the screen and determines the pixel type:

- Foreground. Active when the bit in the pattern store is set to 1.
- Background: When the bit in the pattern store is reset to 0 and when not in the vicinity of a foreground pixel, then the background will be displayed. When VPOS adds $n$ tv lines to the row, these extra lines will be implicitly displayed as background pixels.
- Border (or fringe): The border occurs when the bit in the pattern store is reset to 0 , when in the vicinity of at least one foreground pixel and when $\mathrm{FBE}=1$ in the row attribute word. If $\mathrm{FBE}=0$ then there is no border. The border will outline the shape of the character.

## VICINITY

Each pixel has four neighbours (two vertical, two horizontal). The vicinity is horizontally continuous from character to character so that the first column of a charactacter neighbours the last column of the previous character. Vicinity is not vertically cointinuous between different lines. Refer to the following diagram for examples on vicinity in order to see how the border is formed.

Figure 17. Examples of Borders

Table 2. The Different Character States

| Type of Pixel Condition |  | Outputs |  |  |
| :--- | :--- | :--- | :--- | :---: |
|  | RGB | Blank | Monitor * |  |
| Background |  |  |  |  |
| $\mathrm{BE}=1$ | Background color | Active | Inactive |  |

## STANDARD CHARACTERS

The default device (sales type ST6398B1/B) is delivered with a standard set of ROM based characters and masked pin polarities; extra characters particular to the application are defined via the RAM characters.
The pin polarities have been fixed as follows:
HSYNC,VSYNC . . . . . . . negative (input low during retrace)
R,G,B,BLANK . . . . . . . . positive
MONITOR . . . . . . . . . . negative

Forty standard alphanumeric characters has been defined in character locations 00 to 27 h ; the remaining characters up to address 7Fh are not defined. Should these characters (together with the user definable and variable RAM characters) not be sufficient for the customer's application, then a customized set can be defined (see the section on customized characters). The standard set of ROM based characters is fixed as shown below.

## ABSOLUTE MAXIMUM RATINGS

This product contains devices to protect the inputs against damage due to high static voltages, however it is advised to take normal precaution to avoid application of any voltage higher than maximum
rated voltages. For proper operation it is recommended that $\mathrm{V}_{1}$ and $\mathrm{V}_{0}$ must be high than $\mathrm{V}_{\text {ss }}$ and smaller than $V_{D D}$. Reliability is enhanced if unused inputs are connected to an appropriated logic voltage level ( $V_{D D}$ or $V_{S S}$ ).

| Symbol | Parameter | Value |  | Unit |
| :---: | :---: | :---: | :---: | :---: |
|  |  | Min. | Max. |  |
| VDD | Supply Voltage | -0.3 | 7 | V |
| VIN | Input Voltage | $V_{S S}-0.3$ | $V_{D D}+0.3$ | V |
| Vout | Output Voltage | $V_{\text {SS }}-0.3$ | $V_{D D}+0.3$ | V |
| TJ | Junction Temperature |  | 150 | ${ }^{\circ} \mathrm{C}$ |
| Tstg | Storage Temperature | -60 | 150 | ${ }^{\circ} \mathrm{C}$ |
| 10 | Current per pin | -5 | +5 | mA |

Note: Stresses above those listed as "absolute maximum ratings" may cause permanent damage to the device. This is a stress rating only and functional operatıon of the device at these conditions is not implied. Exposure to maximum rating conditions for extended periods may affect device reliabilty.

RECOMMENDED OPERATING CONDITIONS

| Symbol | Parameter |  | Value |  |  |
| :---: | :--- | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |
|  |  | Min. | Typ. | Max. |  |
| $V_{\text {DD }}-V_{S S}$ | Supply Voltage | 4.5 | 5.0 | 5.5 | V |
| fosC | Oscillation Frequency | 4.0 | 7.5 | 8.0 | MHz |
| fCLK | Clock Frequency | 0 |  | 2 | MHz |
| TOPT | Operating Temperature | 0 |  | 70 | ${ }^{\circ} \mathrm{C}$ |

## THERMAL CHARACTERISTICS

| Symbol | Parameter | Test <br> Condition | Value |  |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Min. | Typ. | Max. |  |
| Rth $\mathrm{JAA}^{\circ}$ | Thermal Resistance |  |  |  | 60 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

## POWER CONSIDERATIONS

The average chip-junction temperature, Tj , in Celsius can be obtained from:
$T_{J}=T_{A}+P_{D} \times$ Rth $_{J A}$

Where: $\mathrm{T}_{\mathrm{A}}=$ Ambient Temperature, Rth $\mathrm{JA}=$ Package thermal resistance (junc-tion-to ambient), Pd $=$ Pint + Pport,
Pint $=\operatorname{lDD} \times V_{D D}$ (chip internal power),
Pport = Port power dissipation (determined by the user).

DC ELECTRICAL CHARACTERISTICS
( $T_{A}=0$ to $70^{\circ} \mathrm{C}, \mathrm{V}_{D D}=4.5 \mathrm{~V}$ to 5.5 V unless otherwise specified)

## PACKAGE MECHANICAL DATA

Figure 22. 20 Lead Plastic Dual In Line Package (B)

## CUSTOMED CHARACTERS AND ORDERING INFORMATION

## Character Definition

If necessary Customized characters can be developed using the ST6398 CHARACTER DEVELOPMENT BOARD (emulator board). The board is inserted into a PC and is used to develop and simulate the OSD characters and functions. The graphics system is built around the alphanumeric and graphics contoller TS68483 which contains a separate dedicated display memory.
For ST6398 CHARACTER DEVELOPMENT BOARD (emulator board) ordering information contact your SGS-THOMSON sales representative.

## Code Procedure

Upon completion of character development, the file created by the SAVE command should be given to SGS-THOMSON (on a MS-DOS $5^{\prime \prime}$ diskette) together with the option list.
When SGS-THOMSON receives the file, a character listing is generated and returned to the customer together with a copy of the option list for approval. The signed list constitutes a part of the contractual agreement for the creation of the customer mask. A mask charge together with a minimum quantity of parts will be charged to the customer. The SGSTHOMSON sales organization will provide detailed information on contractual points.

ORDERING INFORMATION

## ROMLESS HCMOS MCU WITH EEPROM, RAM AND A/D

ADVANCE DATA

- Single chip microcontroller with 256 bytes of RAM and 256 bytes of Register File with 224 general purpose registers available as RAM, accumulators or index pointers.
- Romless to allow maximum external memory flexibility in development and production phases.
- 512 bytes of high-reliability EEPROM on-chip, with 300,000 erase/write cycle capability and 10 year data retention.
- $8 / 16$ bit CORE with full feature DMA controller, a powerful interrupt handler and a Standard Serial Peripheral Interface (SPI) handling S-BUS, $I^{2} \mathrm{C}$ bus, IM-bus and Standard Serial Peripheral Interfaces.
- Up to 8 external interrupts edge-selectable plus 1 non-maskable interrupt.
- 16 bit programmable Timer with 8 bit Prescaler, able to be used as a Watchdog Timer for system integrity.
- Two 16 bit Multifunction Timer modules, each with an 8 bit prescaler and 13 operating modes, allowing simple use for complex waveform generation and measurement, PWM functions and many other system timing operations.
- 8 channel Analog to Digital Converter, with integral sample and hold, fast $11 \mu$ s conversion time, 8 bit $\pm 1 / 2$ LSB resolution with Analog Watchdog on two channels.
- Full function Serial Communications Interface with 110 to 375000 baud rate generator, asyn-

chronous and byte synchronous capability (fully programmable format) and address/wake-up bit option.
- On-chip DMA channels associated to the Multifunction Timers and the Serial Communications Interface.
- Up to six 8 bit I/O ports with programmable input thresholds and output characteristics. Alternative functions allow the full use of all pins.
- Powerful software development tools, including assembler, linker, C-compiler, archiver, software and hardware emulators.
- Compatible with ST9040, 16k ROM devices (also available in windowed and One Time Programmable EPROM packages).
- 68-lead Plastic Leaded Chip Carrier package for ST90R40.

Figure 1. ST90R40 Block Diagram

Figure 2. ST90R40 Pin Configuration

## GENERAL DESCRIPTION

The ST90R40 is a ROMLESS member of the ST9 family of microcontrollers, completely developed and produced by SGS-THOMSON Microelectronics using a proprietary n-well HCMOS process.
The ROMLESS part may be used for the prototyping and pre-production phases of development, and offers the maximum in program flexibility in production systems.
The ST90R40 is fully compatible with the ST9040 ROM version and this datasheet will thus provide only information specific to the ROMLESS device.

## the reader is asked to refer to the DATASHEET OF THE ST9040 ROM-BASED DEVICE, OR ST90R50 FOR FURTHER DETAILS.

The ROMLESS ST90R40 can be configured as a microcontroller able to manage up to 128 K bytes of external memory, or as a parallel processing element in a system with other processors and peripheral controllers.
A key point of the ST90R40 architecture is related to its modular approach which allows software commonality with all other members of the ST9 family.
The nucleus of the modular design of the ST90R40 is the advanced Core which includes the Central

Processing Unit (CPU), the Register File, a 16 bit Timer/Watchdog with 8 bit Prescaler, a Serial Peripheral Interface supporting S-BIJS, $I^{2} \mathrm{C}$-bus and IM-bus Interface, plus two 8 bit I/C) ports. The Core has independent memory and register buses allowing a high degree of pipelining to add to the efficiency of the code execution speed of the extensive instruction set.

The powerful I/O capabilities demanded by microcontroller applications are fulfilled by the ST90R40 with up to $48 \mathrm{I} / \mathrm{O}$ lines dedicated to digital Input/Output. These lines are grouped into up to six 8 bit I/O Ports and can be configured on a bit basis under software control to provide timing and status signals, address lines, timer inputs and outputs, analog inputs, external interrupts and serial or parallel I/O with or without handshake.
Three memory spaces are available: Program Memory (external), Data Memory (internal and external) and the Register File, which includes the control and status registers of the on-chip peripherals.

Two 16 bit MultiFunction Timers, each with an 8 bit Prescaler and 13 operating modes allow simple use for complex waveform generation and measurement, PWM functions and many other system timing functions by the usage of the two associated DMA channels for each timer.

## GENERAL DESCRIPTION (Continued)

In addition there is an 8 channel Analog to Digital Converter with integral sample and hold, fast $11 \mu \mathrm{~s}$ conversion time and 8 bit $\pm 1 / 2$ LSB resolution. An Analog Watchdog feature is included for two input channels.
Completing the device is a full duplex Serial Communications Interface with an integral 110 to 375000 baud rate generator, asynchronous and byte synchronous capability (fully programmable format) and associated address/wake-up option, plus two DMA channels.

## PIN DESCRIPTION

$\overline{\text { AS. Address Strobe (output, active low, 3-state). }}$ Address Strobe is pulsed low once at the beginning of each memory cycle. The rising edge of $\overline{\mathrm{AS}}$ indicates that address, Read/Write (R/W), and Data Memory signals are valid for program or data memory transfers. Under program control, $\overline{\mathrm{AS}}$ can be placed in a high-impedance state along with Port 0 and Port 1, Data Strobe ( $\overline{\mathrm{DS}}$ ) and R/W.
$\overline{\text { DS. Data Strobe (output, active low, 3-state). Data }}$ Strobe provides the timing for data movement to or from Port 0 for each memory transfer. Dúring a write cycle, data out is valid at the leading edge of $\overline{\mathrm{DS}}$. During a read cycle, Data In must be valid prior to the trailing edge of DS. When the ST90R40 accesses on-chip Data memory, $\overline{\mathrm{DS}}$ is held high during the whole memory cycle. It can be placed in a high impedance state along with Port 0, Port 1, $\overline{\mathrm{AS}}$ and R/W.
R/W. Read/Write (output, 3-state). Read/Write determines the direction of data transfer for memory transactions. $\mathrm{R} / \overline{\mathrm{W}}$ is low when writing to program or data memory, and high for all other transactions. It can be placed in a high impedance state along with Port 0, Port $1, \overline{\mathrm{AS}}$ and $\overline{\mathrm{DS}}$.

RESET. Reset (input, active low). The ST9 is initialised by the Reset signal. With the deactivation of RESET, program execution begins from the Program memory location pointed to by the vector contained in program memory locations 00 h and 01h.
OSCIN, OSCOUT. Oscillator (input and output). These pins connect a parallel-resonant crystal ( 24 MHz maximum), or an external source to the on-chip clock oscillator and buffer. OSCIN is the input of the oscillator inverter and internal clock generator; OSCOUT is the output of the oscillator inverter.
$A V_{D D}$. Analog $V_{D D}$ of the Analog to Digital Converter.
AV ${ }_{\text {ss }}$. Analog $\mathrm{V}_{\text {SS }}$ of the Analog to Digital Converter.

## VDD. Main Power Supply Voltage ( $5 \mathrm{~V} \pm 10 \%$ )

Vss. Digital Circuit Ground.
AD0-AD7, (P0.0-P0.7) Address/Data Lines (Input/Output, TTL or CMOS compatible). 8 lines providing a multiplexed address and data bus, under control of the $\overline{\mathrm{AS}}$ and $\overline{\mathrm{DS}}$ timing signals.
P1.0-P1.7, P2.0-P2.7 P3.0-P3.7, P4.0-P4.7, P5.0P5.7, P7.0-P7.7 I/O Port Lines (Input/Output, TTL or CMOS compatible). 48 lines grouped into I/O ports of 8 bits, bit programmable under program control as general purpose I/O or as Alternate functions (see next section).

## I/O Port Alternate Functions.

Each pin of the I/O ports of the ST90R40 may assume software programmable Alternative Functions as shown in the Pin Configuration Drawings. Figure 1.2 shows the Functions allocated to each I/O Port pins.

PIN DESCRIPTION (Continued)

## MEMORY

The memory of the ST90R40 is functionally divided into two areas, the Register File and Memory. The Memory may optionally be divided into two spaces, each having a maximum of 65,536 bytes. The two memory spaces are separated by function, one space for Program code, the other for Data. The ST90R40 addresses all program memory in the external PROGRAM space. The DATA space includes the 512 bytes of on-chip EEPROM at ad-
dresses 0 through 1FFh and the 256 bytes of on-chip RAM memory at memory addresses 200 h through 2FFh.
The External Memory spaces are addressed using the multiplexed address and data buses on Ports 0 and 1. Additional Data Memory may be decoded externally by using the $P / \bar{D}$ Alternate Function output. The on-chip general purpose (GP) Registers may be used as RAM memory.

MEMORY (Continued)
Figure 3. Memory Spaces

## ROMLESS HCMOS MCU WITH BANKSWITCH AND A/D CONVERTER

ADVANCE DATA

- Single chip microcontroller with 256 bytes of register file with 224 general purpose registers available as RAM, accumulators or index pointers.
- Romless to allow maximum external memory flexibility in development and production phases.
- BankSwitch logic allowing a maximum addressing capability of 8M bytes for program and data spaces (16M byte total).
- 8/16 bit CORE with full feature DMA controller, a powerful interrupt handler and a Standard Serial Peripheral Interface (SPI) handling S-bus, $I^{2} \mathrm{C}$-bus, IM-bus and Standard Serial Peripheral Interfaces.
- Up to 8 external interrupts edge-selectable plus 1 non-maskable interrupt.
- 16 bit programmable Timer with 8 bit Prescaler, able to be used as a Watchdog Timer for system integrity.
- Three 16 bit Multifunction Timer modules, each with an 8 bit prescaler and 13 operating modes, allowing simple use for complex waveform generation and measurement, PWM functions and many other system timing operations.
- 8 channel Analog to Digital Converter, with inte-
- gral sample and hold, fast $11 \mu$ s conversion time, 8 bit $\pm 1 / 2$ LSB resolution with Analog Watchdog on two channels.
- Two full function Serial Communications Interfaces with 110 to 375000 baud rate generator, asynchronous and byte synchronous capability

(fully programmable format) and address/wakeup bit option.
- On-chip DMA channels associated to the Multifunction Timers and the Serial Communications Interface.
- Up to nine 8 bit $/ / O$ ports with programmable input thresholds and output characteristics. Alternative functions allow the full use of all pins.
- Powerful software development tools, including assembler, linker, C-compiler, archiver, software and hardware emulators.
- Compatible with ST9054, 32k ROM devices (also available in windowed and One Time Programmable EPROM packages).

## GENERAL DESCRIPTION

The ST90R50 is a ROMLESS member of the ST9 family of microcontrollers, completely developed and produced by SGS-THOMSON Microelectronics using a proprietary n-well HCMOS process.
The ROMLESS part may be used for the prototyping and pre-production phases of development, and offers the maximum in program flexibility in production systems with its 16 M byte addressing space when using the Bankswitch memory expansion.

A key point of the ST90R50 architecture is its modular approach which allows software commonality with all other members of the ST9 family.
The nucleus of the modular design of the ST90R50 is the advanced Core which includes the Central Processing Unit (CPU), the Register File, a 16 bit Timer/Watchdog with 8 bit Prescaler, a Serial Peripheral Interface supporting S-bus, $I^{2} \mathrm{C}$-bus and IM-bus Interface, plus two 8 bit I/O ports. The Core has independent memory and register buses allowing a high degree of pipelining to add to the efficiency of the code execution speed of the extensive instruction set.

## GENERAL DESCRIPTION (Continued)

The powerful I/O capabilities demanded by microcontroller applications are fulfilled by the ST90R50 with up to 72 I/O lines dedicated to digital Input/Output. These lines are grouped into up to nine 8 bit l/O Ports and can be configured on a bit basis under software control to provide timing, status signals, address and data buses for interfacing external memory, timer inputs and outputs, analog inputs, external interrupts and serial or parallel I/O with or without handshake.
Three basic memory spaces are available to support this wide range of configurations: Program Memory (external), Data Memory (internal and external) and the Register File, which includes the control and status registers of the on-chip peripherals.
Three 16 bit MultiFunction Timers, each with an 8 bit Prescaler and 13 operating modes allow simple use for complex waveform generation and measurement, PWM functions and many other system timing functions by the usage of the two associated DMA channels for each timer.
In addition there is an 8 channel Analog to Digital Converter with integral sample and hold, fast $11 \mu \mathrm{~s}$ conversion time and 8 bit $\pm 1 / 2$ LSB resolution. An Analog Watchdog feature is included for two input channels.
Completing the device are two full duplex Serial Communications Interfaces, each with an integral 110 to 375000 baud rate generator, asynchronous and byte synchronous capability (fully programmable format) and associated address/wake-up option, plus two DMA channels.

## PIN DESCRIPTION

$\overline{\text { AS. Address Strobe (output, active low, 3-state). }}$ Address Strobe is pulsed low once at the beginning of each memory cycle. The rising edge of $\overline{\text { AS }}$ indicates that address, Read/Write ( $/ / \bar{W}$ ), and Data Memory signals are valid for program or data memory transfers. Under program control, $\overline{\mathrm{AS}}$ can be placed in a high-impedance state along with Port 0, Port 1, Port 6, Data Strobe ( $\overline{\mathrm{DS}}$ ) and R/W.
$\overline{\mathrm{DS}}$. Data Strobe (output, active Iow, 3-state). Data Strobe provides the timing for data movement to or from Port 0 for each memory transfer. During a write cycle, data out is valid at the leading edge of $\overline{\mathrm{DS}}$. During a read cycle, Data In must be valid prior to the trailing edge of DS. When the ST90R50
accesses on-chip RAM memory, $\overline{\mathrm{DS}}$ is held high during the whole memory cycle. It can be placed in a high impedance state along with Port 0, Port 1 , Port 6, $\overline{A S}$ and R/W.
R/W. Read/Write (output, 3-state). Read/Write determines the direction of data transfer for external memory transactions. $R / \bar{W}$ is low when writing to external program or data memory, and high for all other transactions. The timing of $\mathrm{R} / \overline{\mathrm{W}}$ may be modified when using the Bank Switch Logic memory expansion to prevent external timing conflicts. R/W can be placed in a high impedance state along with Port 0, Port 1, Port 6, $\overline{\mathrm{AS}}$ and $\overline{\mathrm{DS}}$.
RESET. Reset (input, active low). The ST9 is initialised by the Reset signal. With the deactivation of RESET, program execution begins from the Program memory location pointed to by the vector contained in program memory locations 00 h and 01h.

OSCIN, OSCOUT. Oscillator (input and output). These pins connect a parallel-resonant crystal ( 24 MHz maximum), or an external source to the on-chip clock oscillator and buffer. OSCIN is the input of the oscillator inverter and internal clock generator; OSCOUT is the output of the oscillator inverter.
AV $D$. Analog $V_{D D}$ of the Analog to Digital Converter.

AVss. Analog Vss of the Analog to Digital Converter.

VDD. Main Power Supply Voltage ( $5 \mathrm{~V} \pm 10 \%$ )
Vss. Digital Circuit Ground.
P0.0-P0.7, P1.0-P1.7, P6.0-P6. 7 (Input/Output, TTL or CMOS compatible). 8 lines grouped into I/O ports of 8 bits providing the external memory interface to address the external program memory.
P2.0-P2.7, P4.0-P4.7, P5.0-P5.7, P7.0-P7.7, P8.0P8.7, P9.0-P9.7 I/O Port Lines (Input/Output, TTL or CMOS compatible). 8 lines grouped into I/O ports of 8 bits, bit programmable under program control as general purpose I/O or as Alternate functions (see next section).

## I/O Port Alternate Functions.

Each pin of the I/O ports of the ST90R50 may assume software programmable Alternative Functions as shown in the Pin Configuration Drawings. Table 1 shows the Functions allocated to each I/O Port pins

PIN DESCRIPTION (Continued)
Table 1. ST90R50 I/O Port Alternate Function Summary

| I/O PORT | Name | Function IN/OUT | Alternate Function | Pin Number |
| :---: | :---: | :---: | :---: | :---: |

## ST90R50 CORE

The Core or Central Processing Unit (CPU) of the ST90R50 includes the 8 bit Arithmetic Logic Unit and the 16 bit Program Counter, System and User Stack Pointers. The microcoded Instruction Set is highly optimised for both byte (8 bit) and word (16 bit) data, BCD and Boolean data types, with 14 addressing modes. Two 8 bit I/O ports are connected to the Core module for external memory interfacing, while a 16 bit Timer/Watchdog gives system security and timing functions, and a Serial Peripheral Interface allows for synchronous communication. Three independent buses are controlled by the Core, a 16 bit Memory bus, an 8 bit Register addressing bus and a 6 bit Interrupt/DMA bus connected to the interrupt and DMA controllers in the on-chip peripherals and the Core. This multiple bus architecture allows a high degree of pipelining and parallel operation within the ST90R50, giving it its efficiency in both numerical calculations and communication with the on-chip peripherals.

## MEMORY

The memory of the ST90R50 is functionally divided into two areas, the Register File and Memory. The Memory may optionally be divided into two spaces, each having a maximum of 65,536 bytes. The Memory may be expanded with the Bankswitch logic to give paging of the top 32K bytes of each space to expand the ST90R50 addressing capability to 8 M bytes in each space. The two memory spaces are separated by function, one space for Program code, the other for Data. The ST90R50 addresses all program memory in the external PROGRAM space.
Off-chip memory, addressed using the address and data buses (Port 0, Port 1 and Port 6) and may be divided into the Program and Data spaces by the external decoding of the Program/Data select pin $(P / \bar{D})$ available as an Alternate function. The memory spaces are selected by the execution of the SDM and SPM instructions (Set Data Memory and Set Program Memory, respectively).

## MEMORY (Continued)

Figure 3. Memory Spaces, Bankswitch Disabled

Figure 4. Memory Spaces, Bankswitch Enabled

## MEMORY (Continued)

There is no need to use either of these instructions again until the memory area required is to be changed. This requirement is not necessary in two cases: first, when operating with external stacks (the Data memory is automatically selected) and, secondly, when using the memory indirect to memory indirect post-increment addressing mode (the memory types are specified in the instructions: LDPP, LDPD, LDDP, LDDD).
Either the Data Memory or the Program Memory can be addressed using any of the memory addressing modes.

## Program Space

The Program memory space of the ST90R50, 64 K bytes of off-chip memory is fully available to the User. The ST90R50 executes external memory cycles for instruction fetches. The first 256 memory locations from address 0 to OFFh (hexadecimal) hold the Reset Vector, the Top-Level (Pseudo NonMaskable) interrupt, the Divide by Zero Trap vector
and, optionally, the interrupt vector table for use with the on-chip peripherals and the external interrupt sources. Each vector is contained in two consecutive byte locations, the high order address held in the lower (even) byte, the low order address held in the upper (odd) byte, forming the address which is loaded into the Program Counter when selected by the interrupt vector provided by the interrupt source. This should point to the relevant Interrupt Service routine provided by the User for immediate response to the interrupt.

## Data Space

The ST90R50 addresses External Data through the External Memory Interface when decoded with the $P / \overline{\mathrm{D}}$ pin. On-chip general purpose Registers may be used as additional RAM memory for minimum chip count systems.
The Data Space is selected by the execution of the SDM instruction. All subsequent memory references will access the Data Space. When a separate Data Space is not required, data may stored in external RAM or ROM memory within the Program Space.

Figure 5. Program and Data Spaces

## REGISTERS

The ST90R50 register file consists of 240 registers (224 general purpose) plus pages of 16 registers supporting the configuration and control registers for the on-chip peripherals. The 224 general purpose registers all have 8 and 16 bit arithmetic capability and may be used as accumulators, onchip RAM, internal Stack areas (for system and/or user stacks), or, with the appropriate addressing modes, as index, offset or stack pointers.

The register file is arranged into 16 groups of 16 registers, where the general purpose registers OCcupy the first 14 groups. The 15th group, E , contains the system registers and Group F contains the pages of the on-chip peripheral control registers.

Group $F$ is paged in this manner due to the modularity of the ST9 family of microcontrollers. Each member of the family retains all general purpose

Figure 6. Register Grouping

and system registers, only the paged register groups changing owing to the different on-chip peripheral organizations of each device. The User can therefore generate code libraries which use the general purpose registers knowing that they will not be lost on future ST9 devices. To address a paged register, the Page Pointer (PPR, R234) within the system register group must be loaded with the relevant page number using the SPP instruction. Subsequently any access to registers in the top group (R240-R255) will refer to the selected page. This remains set until the next change to the Page Pointer register (by the SPP instruction).

The System group (Group E, registers RE0 to REF) includes the system and user stack pointers, the Mode register, the ALU FLAG register and the Page pointer register. In addition the data registers for the first 6 l/O ports are present, the configuration registers for the ports being in the paged area. This allows the immediate access to these I/O ports at all times.

The Register Pointers, present in the system register group, select groups of registers as "Working Registers", which have faster addressing modes than direct Register addressing and allows smaller code size. The Register Pointers may either be used singly, creating a register group of 16 working registers, or as two independent groups of 8 working registers which may be placed at any 8 register
boundary within the register file. The single and twin working register modes are automatically set by hardware when the respective SRP and either SRP0 or SRP 1 instructions are executed. If working registers are used as accumulators and RAM locations for particular tasks, fast context switching on interrupts may be achieved by setting the register pointer to another group for the Interrupt Service

## REGISTERS (Continued)

Routine, ISR, (e.g. saving the Register pointer on the stack), using the new group in the ISR and subsequently restoring the original group before the Return from Interrupt instruction. Working registers also allow the use of the ABAR - Any Bit-Any Register Boolean operations (including directly on the I/O port data registers).
In the ST9 syntax, directly addressed Registers are indicated with a capital R e.g. R0, R224, RBF, with Regıster Pairs (16 bit accumulators or memory pointers) as RRO, RR24. When using Working Registers, groups of 16 registers (SRP instruction) are denoted as rO to r 15 (rr0 to rr14), while the dual working register group are addressed as r0 to r7 (rrO to $\mathrm{rr6}$ ), for the first group of 8 registers (SRP0), with r 8 to r 15 ( rr 8 to $\mathrm{rr14}$ ) for the second set.(SRP1).
Working register addressing requires a 4 bit field within the instruction. When packed into a byte, the upper nibble is set to Dh (1101b), this being the escape code to indicate the use of the working registers. As a result, group D CANNOT be selected with direct register addressing, it is recommended that this group be used as internal stacking area when using register file based system or user stack pointers.

## STACK POINTERS

There are two separate, double register stack pointers available (System and User), both of which can operate in register or Data memory address spaces. These operate in a Pre-Decrement mode when data is PUSHed onto the Stack and in a Post-Increment mode when data is poped from the stack.
The SYSTEM Stack Pointer (SSPR, R238:R239) is used for the storage of temporarily suspended system and/or control registers (ie the the Program Counter and FLAG register) while interrupts are being serviced, and is used for the storage of the Program Counter following the CALLing of a subroutine.
The USER Stack Pointer (USPR, R236:R237) is completely free from all interference from automatic operations and so provides for a totally User controlled stack area.

Figure 12. Internal Stack Pointers

Both Stack pointers may operate with both byte (PUSH,POP) and word (PUSHW,POPW) data, and are differentiated by appending a " U " to the instruction mnemonic for the User Stack (PUSHU/PUSHUW, POPU/POPUW).

When the Stack Pointers are using RAM Memory as the stack areas, a full word register is used as the pointer, while when operating with the stack area within the Register File (Groups 0 to 14 only, but not the within the system and paged groups) only an 8 bit register is required for addressing and consequently only the low byte of the word registers are used (R239 for the System Stack and R237 for the User Stack). In this latter case the upper byte of the stack pointer registers (R238 and R236) must be considered as reserved. The Stack Pointers may be selected to point to RAM or Register file by the setting of the SSP (MODER.7) and USP (MODER.6) of the ST90R50 configuration register (MODER, R235) where a "1" denotes Register file operation (Default at Reset) and "0" causes external Data space operation.

Figure 13. External Stack Pointers

## INTERRUPTS

The ST90R50 offers a powerful solution to the response requirements of real-time systems with its advanced interrupt structure. Interrupt trigger sources can be prioritized within 8 levels to match the priorities assigned to the application. In addition a top-level or non-maskable interrupt is available.

The ST90R50 interrupts follow the logical flow of Figure 14.
Interrupt events (selectable with each function) cause the setting of the Interrupt Pending (IP) bit within the status register of the peripheral. This bit may also be set by software in order to generate a software interrupt, and should normally be reset by software within the interrupt service routine. If the interrupt is not Masked with the corresponding Interrupt Mask bit, the interrupt is passed to the central interrupt control logic where the priority level assigned by the User to the interrupt source is compared with the priority level of the core (User programmed dynamically in the 3 bits of the Central Priority register (CPL, CICR.0-2, Level 7 is the lowest priority and level 0 the highest). If the incoming priority level is higher than the CPL, and Global

Interrupts are enabled (by the EI instruction, interrupts are disabled by the execution of the DI instruction), the interrupt is acknowledged. If interrupts are globally disabled, the priority level of the source is lower than or equal to the CPL or the Interrupt is masked, then the IP bit remains set and the interrupt is held pending until the EI instruction is executed, the CPL is set to a lower level AND the interrupt is un-masked. Alternatively the IP bit of a masked interrupt source may be used in a polled interrupt environment, with the IP bit being reset by software within the service routire.

The interrupt acknowledge cycle causes the Program Counter and FLAGS register to be pushed onto the System Stack (PC low byte first, PC high byte, then FLAGS Register) and all maskable interrupts to be disabled by reselting the IEN bit (CICR.4). The peripheral Interrupt Vector, IVR, a User programmable feature of the peripheral interrupt control registers, is used as an offset into the vector table, pointing to the high byte (even address) of the 16 bit address which should contain the starting address of the interrupt service routine. Addresses 0 through 255 of the program space comprise the interrupt vector table. Where multiple

Figure 14. Interrupt Logic

## INTERRUPTS (Continued)

Figure 15. Interrupt Vector Table Usage

interrupt sources may occur within a peripheral, the peripheral interrupt vector source may be encoded by hardware set bits within the IVR register. This means that the vector address defined in the peripheral IVR is the base address for a block of vectors servicing that peripheral. The address pointed to by the vector is loaded into the Program Counter and execution restarts from this point.
The interrupt service routine should clear the interrupt pending flag of the interrupt source and take the appropriate action. The last instruction of the interrupt service routine should be the IRET instruction, the action of this is to restore the Program Counter and Flags register to their value prior to the interrupt acknowledgment, and to re-enable interrupts. Within the interrupt service routine, use may be made of the working register pointer mechanism to reduce the context switching time.
Two interrupt arbitration modes are available for use with the 8 level priority scheme, Nested and Concurrent modes. These are selected by the status of the IAM bit (CICR.3).

Concurrent mode, selected when IAM = "0" (the reset condition) is the standard interrupt arbitration mode, where the arbitration phase of every instruction acknowledges interrupts according to their priority level (if higher than the CPL) and follows the sequence shown. All pending interrupts existing or having eventually occurred during interrupt service routine execution, remain pending until the Enable Interrupt instruction (EI) (even if it is executed during the interrupt service routine). EI within the interrupt service routine is not recommended for use with the Concurrent arbitration mode as this can trigger a Last $\ln$, First Out condition where high priority interrupts are masked by lower priority interrupts which are all higher than the CPL value.
Nested mode, selected when IAM = "1", uses the same arbitration phase as concurrent mode, the difference being that the CPL is modified during the interrupt processing cycle to that of the acknowledged interrupt level. The CPL value is pushed by hardware into the Nested Interrupt Control register (NICR, R247 page 0) by setting the NICR bit corresponding to the CPL value. The interrupt service

INTERRUPTS (Continued)
Figure 16. Interrupt Modes Example of Usage

routine is entered in the normal manner. The revised CPL level is used for arbitration of further interrupts, each higher level being saved on the NICR stack, and being restored automatically by hardware with the IRET instruction. This allows the execution of the EI instruction within the interrupt service routine to operate the correct nesting of interrupts. The two modes are shown graphically in Figure 16, where the Y axis shows the CPL value. It should be noted that in the example INT1 will not be acknowledged until the CPL level is programmed to a lower level.
Interrupts coming from on-chip sources at the same instant, and at the same priority level, are resolved during the arbitration phase according to a hardware daisy-chain. This follows the priorities of the table shown in Table 2.

Table 2. ST90R50 Interrupt Hardware Daisy Chain

| INTA | High Priority |
| :--- | :--- |
| INTB |  |
| INTC |  |
| INTD |  |
| MFTIMER0 |  |
| SCI 0 |  |
| SCI 1 |  |
| A/D |  |
| MFTIMER3 |  |
| MFTIMER1 | Lowest Priority |

## INTERRUPTS (Continued)

External Interrupts. Up to 8 external interrupts are available on the ST90R50 as alternate function inputs of I/O pins. These may be selected to. be triggered on rising or falling edges and can be independently masked. The eight external interrupt sources are grouped into four pairs or channels which can be assigned to independent interrupt priority levels. Within each channel the even interrupt number takes the even priority level and the odd channel the odd priority level (even+1).
Table 3. External Interrupt Channel Grouping

| External Interrupt | Channel |
| :---: | :---: |
| INT7 | INTD1 |
| INT6 | INTD0 |
| INT5 | INTC1 |
| INT4 | INTC0 |
| INT3 | INTB1 |
| INT2 | INTB0 |
| INT1 | INTA1 |
| INT0 | INTA0 |

Several of the External Interrupt channels have their inputs selectable between the external interrupt source and on-chip peripheral sources.

Table 4. ST90R50 External Interrupt Souce Selection

| INTO |  |
| :---: | :---: |
| Timer/Watchdog <br> End of Count |  |
| INTA0 |  |
| INT2 | INTB0 |
| SPI Interrupt |  |

Top Level Interrupt. The Top Level Interrupt channel can be assigned either to the external NMI pin or to the Timer/Watchdog output. When selected as the external NMI pin, the active edge may be programmed to be rising or falling. The TLI event will cause the setting of the TLIP bit (CICR.6) and according to the mask situation, a Top Level Interrupt request may be generated. Two masking conditions are available, a Maskable Mask and a Not-Maskable Mask.
The Maskable Top Level Interrupt may be enabled or disabled by software and follows the state of the Global Interrupt Enable bit IEN (CICR.4), while the Not-Maskable Mask bit (TLI, CICR.5) is a set-only mask. Once set, the Top Level Interrupt is active independently of IEN and cannot be disabled until the next Reset cycle.

Figure 17. Top-Level Interrupt Structure

## DMA

The ST90R50 has on-chip DMA channels to provide high-speed data transaction between peripherals and Memory or Register File. Multi-channel DMA is fully supported because each peripheral can have its own DMA channel(s). Each DMA channel transfers data to/from contiguous locations of the Register File, Program Memory or Data Memory. The maximum number of transactions that each DMA channel can perform is 222 if the Register File is selected and 65536 if Program or Data Memory are selected.

DMA transfer to (or from) the Register File takes 8 INTCLK cycles, DMA transfer to (or from) Memory takes 16 INTCLK cycles. If the ST90R50 is in the idle mode (following the execution of the WFI instruction), DMA requests are acknowledged according to their priority and control is returned to the idle mode pending an interrupt, this operation increases the number of INTCLK cycles by 2 for both Register File and Memory DMA transactions.

Each DMA channel has its own control registers located in the page(s) related to the peripheral.

There are two pointer registers, DAPR which points to a register or register pair containing the current DMA address to/from which data will be transferred, and DCPR, which points; to a register or register pair which contain the transaction counter for the DMA operations. Each DMA transfer consists of three operations:

- A load from/to the peripheral data register to/from a location of Register File (or Memory) addressed through the DMA Address Register (or Register Pair)
- A post-increment of the DMA Address Register (or Register Pair)
- A post-decrement of the DMA transaction counter, which contains the number of transactions that have still to be performed.
When the transaction counter reaches 0 (all data has been transferred) an End of Block Interrupt event is generated to allow the processing of the DMA data block, or, by reloading the Address and counter registers and retriggering, a repeated DMA cycle.

Figure 18. DMA Between Registers and Peripheral

## DMA (Continued)

A SWAP mode, allowing continuous DMA operation, is available for the Multifunction Timer and is described in the section relating to the Multifunction Timer.
The ST90R50 has DMA channels associated with the Serial Communications Interface Input and Output Serial data channels; the 16 bit Load/Cap-
ture Register 0, CAPTOR, of each Multifunction Timer allowing the timing of external signals to be captured into a table for off-line analysis or for the automatic output of PWM signals of variable width and timing; and the 16 bit Comparison Register 0, COMPOR, of each Multifunction Timer which can be programmed to cause output or input of parallel data through the handshake ports under DMA.

Figure 19. DMA Between Memory and Peripheral

## CLOCK GENERATION, WAIT, HALT AND RESET

## Clock Generation

The ST90R50 Clock Generator module generates the internal clock for the ST9 core and the on-chip peripherals, it may be driven by an external quartz crystal circuit, connected to the OSCIN and OSCOUT pins, or by an external pulse generator connected to OSCIN (Figures 20, 21).
The conceptual schematic of the ST9 internal clock circuit is shown in Figure 22.

Figure 20. Crystal Oscillator

The maximum external frequency of the ST9 is 24 MHz , while the maximum internal operating frequency is 12 MHz , thus a programmable divide by two circuit is present, this allows the use of high frequency crystals for economy, or low frequency crystals for reduction in radiated noise. This divider is active upon exit from the reset condition, the User may bypass the divide by two circuit by setting the DIV2 bit (MODER.5). The resulting clock from this section is named INTCLK, the internal clock which drives the timebases of the on-chip clock for the ST90R50 peripherals (eg the Multifunction Timer,

Figure 21. External Oscillator

Figure 22. Internal Clock Circuit

## CLOCK GENERATION, WAIT, HALT AND <br> RESET (Continued)

Timer/Watchdog, Serial Communications Interface) and also the input of the CPU prescaler section. The CPU of the ST9 includes the instruction execution logic and may run at different rates according to the setting of the PRS2,PRS1 and PRSO bits (MODER.4-2) (figure 23). The resulting clock is named CPUCLK and it should be noted that this does not maintain a $50 \%$ duty cycle, but stretches the high level of the clock until completion. The CPUCLK prescaler allows the User to slow down the program execution time (eg for lower power consumption), while time-critical sections of the program may tune the CPUCLK execution speed to high speed and then restore it to its original speed.

## Wait States

The output from the prescaler can also be affected by wait states. Wait states from two sources allow the User to tailor timing for slow external memories or peripherals. The internal Wait State generator will insert from 0 to 7 wait states, independently programmable for both Program and Data Spaces, via the Wait Control Register WCR (R252, page 0). The second source of wait states is the external Wait input pin when enabled as the Alternate Function. Fig 24 shows the External Memory Interface timing as it relates to CPUCLK prescaling of 2 and 5 added wait states. The added wait states are derived from the INTCLK clock cycle, not CPUCLK. Internal memory is always accessed with no Wait states.

Figure 23. CPUCLK Prescaler

## CLOCK GENERATION, WAIT, HALT AND RESET (Continued)

Figure 24. External Memory Interface Timing with CPUCLK Prescaling and 5 Added Wait States

## Halt and Wait for Interrupt (WFI) States

The schematic of the on-chip oscillator circuit is shown in figure 25. The HALT condition, caused by the execution of the HALT instruction, disables the oscillator, forcing OSCOUT high. This places the ST90R50 into the lowest power mode. The exit of the HALT condition and the restarting of the oscillator requires a RESET pulse with a minimum duration of 10 ms (figure 26). It must be noted that if the TIMER/WATCHDOG has the WATCHDOG mode enabled, a HALT instruction will not disable the oscillator; this is to avoid stopping the Watchdog if, by an error, a HALT instruction is executed. If this occurs, the ST90R50 runs in an endless loop terminated only by the Watchdog reset (or hardware reset).
The WFI (Wait for Interrupt) instruction suspends program execution until an interrupt request is acknowledged. During this period, DMA transactions are allowed if their priority is higher than or equal to the CPL level; the ST90R50 returns to WFI

Figure 25. Oscillator Schematic

## CLOCK GENERATION, WAIT, HALT AND RESET (Continued)

mode after completion of the DMA transfer. The CPUCLK is halted during Wait For Interrupt while INTCLK continues to run, thus the power consumption of the processor is lowered by the CORE power consumption value.
The External Memory Interface lines status during HALT and WFI modes is shown in Table 5.

Table 5. External Memory Interface Line Status During WFI and Halt

| P0 (AD0-AD7) | High Impedance |
| :--- | :--- |
| P1 (A8-A15) | Forced to Address of Next Opcode |
| $\overline{\text { AS }}$ | Forced High |
| $\overline{D S}$ | Forced High |
| R $\bar{W}$ | Forced High |

## Reset

The processor Reset overrides all other conditions and forces the ST90R50 to the reset state. During Reset, the internal registers are set to their Reset values, as shown in Table 6 for the system and Page 0 Registers. The l/O Ports pins are set to the Bidirectional Weak Pull-up mode. The User must then initialize the ST90R50 registers to give the required functions.
The Reset condition can be generated from the external RESET pin or by the on-chip TIMER/WATCHDOG operating in Watchdog mode. To guarantee the complete reset of the ST90R50, the RESET input pin must be held low for at minimum of 53 crystal periods in addition to the crystal start-up period. The Watchdog RESET will occur if the Watchdog mode is enabled (WDEN, WCR.6, is reset) and if the programmed period has elapsed without the code 0AAh,55h written to the appropriate register. The input pin RESET is not driven low by the on-chip reset generated by the TIMER/WATCHDOG.

Figure 26. Reset Timing Requirements from Halt State

## CLOCK GENERATION, WAIT, HALT AND RESET (Continued)

Table 6. System and Page 0 Reset Values

| 2 | (PORT2) $=$ FFh | $(E I T R)=00 \mathrm{~h}$ |
| 1 | $($ PORT1) $=$ FFh | Reserved |
| 0 | $($ PORT 0$)=$ FFh | Reserved |

During the $\overline{\mathrm{RESET}}$ state, $\overline{\mathrm{DS}}$ is held low and $\overline{\mathrm{AS}}$ is toggled with the frequency of the crystal (OSCIN) divided by 32. This condition may be recognized by external peripherals as a Reset condition. It may also be used to enable the synchronization of multiple ST90R50 running from the same clock in a multi-processing or high security majority voting system.

Once the Reset pin reaches a logical high, the ST90R50 fetches the starting address from locations 0 and 1 of the program space and begins program execution from this address after 67 crystal cycles.

## INTERFACING TO EXTERNAL MEMORY

External Memory and/or peripherals may be connected to the ST90R50 through its External Memory Interface. This provides the multiplexed Address bits A0 to A7 and Data bits D0 to D7 on Port 0, and the higher order address bits A8 to A15 on Port 1, giving the full 64 K bytes addressing capability. Port 6 is available to be programmed as non-multiplexed address outputs $A 0$ to $A 7$ to reduce the requirement for an external latch to demultiplex the low order addresses. Port 0 , in this case, becomes solely the Data I/O port. The Program/Data ( $\mathrm{P} / \overline{\mathrm{D}}$ ) output, when selected as an Alternate function, allows external decoding to provide for the two independent pages for Program and Data.

Data transfer timing is generated by the Address strobe $\overline{\mathrm{AS}}$ and the data strobe $\overline{\mathrm{DS}}$. Address strobe low indicates that the data present on AD0 to AD7 is the low order address and is guaranteed valid on the rising edge of $\overline{A S}$ allowing for latching of the
address bits by an external latch (if Port 6 is not used). Data transfer direction is indicated by the status of the Read/Write (R/W) pin; for write cycles ( $\mathrm{R} / \overline{\mathrm{W}}$ low), data out is valid at the falling edge of $\overline{\mathrm{DS}}$; for read cycles ( $R / \bar{W}$ high), data in must be valid prior to the rising edge of $\overline{\mathrm{DS}}$. The timing of the $R / \bar{W}$ signal may be modified by the setting of the RW bit (bit 0 Register OFFh, page 0 ) in order to accomodate different types of external memories. In addition, when the Bank Switch logic is enabled, the timing of the Bank Switch outputs may be modified by software to prevent potential conflicts on the data bus. Please refer to following sections for further details.
The Data Strobe low period may be extended to accomodate slow external devices by the adding of internally generated wait cycles ( 0 to 7 cycles for both program and data memory maps) or by an external input on the WAIT input pin also available as an Alternative Function of an I/O bit. Suggested interface circuits are shown in figures 27 and 28.

Figure 27. External Memory Addressing Circuit

## INTERFACING TO EXTERNAL MEMORY (Continued)

Figure 28. External Memory Addressing Circuit

## BANKSWITCH LOGIC

Port 2 of the ST90R50 may be programmed by the User to become extended address lines allowing expansion of the memory to a maximum of 8 M bytes in both program and data pages. This is achieved by paging of the top 32K bytes of memory (A15 high, addresses 8000h to FFFFh), with the lower 32 K bytes (A15 low addresses 0000 h to 7FFFh) remaining static. The static area, segment 0 , allows for the direct access to interrupt service and page change routines, and other common sub-routines, while the paged segments ( 1 to 256) of 32 K bytes may contain additional program code, database entries, printer fonts, buffer space, or any other function requiring a large amount of memory. The setting of Port 2 is made during the Reset cycle, by the latched status of the signals BSH_EN1 and BSL_EN1. These control the high and low nibbles of Port 2 between Address Expansion lines and normal I/O lines as shown in Table 7.

Table 7. Port 2 Nibble Programming For Bank Switch and I/O

| BSH_EN1 | BSL_EN1 | BS Port Nibble |  | BS Port <br> Reset Value |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | High | Low | High | Value |
| O | 0 | I/O | I/O | $\cdots$ | $\cdots$ |
| O | I | I/O | BS | $\cdots$ | OFEh |
| I | O | I/O | BS | $\cdots$ | OFEh |
| I | 1 | BS | BS | OFEh | OFEh |

In order to program the functions, weak pullup/down resistors (100k ohm) on the BSH_EN1 and BSL_EN1 designated lines are used to generate the logic level latched on the rising edge of the Reset input. After this event, these lines may be used as I/O and be programmed in the normal way.

Figure 29. Bank Switch Memory Maps

When the Address Expansion is selected, several I/O port configuration registers take an alternative function. The Port Data Registers for I/O ports 2 and 3 (Registers E2h and E3h) become the Bank Switch Data Segment Register and Bank Switch Program Segment Register respectively. The values held in these registers are output on Port 2 whenever a memory access is made to either data or program spaces with A15 high. This allows Port 2 bits to represent either extended address lines A16 to A23 or to output chip-selects to external memories. For this second option the reset value for these registers, and the value output whenever A15 is low, is OFEh, generating the selection of a standard "startup" page automatically. Port 2 Configuration registers P2C0 and P2C1 contained in

I/O Page 2 hold the User programmed values output on Port 2 for DMA cycles with addresses in the the high 32 K byte of the memory for data and program spaces respectively.
Warning: The Bankswitch Program DMA register occupies the same register as Port 2 Control Register 2 (P2CR), so caution must be taken in writing to BS_PDSR when the high nibble is used as I/O and the low nibble is used for the Bankswitch output as P2C2 is used for the port configuration. The Program and Data Segment Registers are located in the direct Register file within the System Register group in order to be immediately accessible, while the DMA Segment Registers are held within an I/O page as, once programmed, they do not need constant service.

## ST90R50

## BANKSWITCH LOGIC (Continued)

Figure 30. Bank Switch Register Mapping

## BANKSWITCH LOGIC (Continued)

## Output Timing

In order to prevent potential bus conflicts on Port 0 (Address/Data multiplexed) during the address strobe time when using the Bankswitch logic, the timing of the Bankswitch outputs may be modified by software. This is achieved by setting to "1" bit 1 of Register OFFh in I/O page 0 . This causes the Bankswitch outputs to be all high during the address strobe period. The reset condition provides normal timing and status.

The timing of the Read/Write signal may be modified as shown in the next figure by setting to " 1 " bit 0 of Register OFFh in I/O page 0 . This allows the use of different types of external memories. When this bit is " 0 " (the reset state) normal timing is generated.

Note : The LST9 ST9 Incremental Linker supports the paging mechanism of the ST90R50 and is able to allocate program and data code into specific segments if required.

Figure 31. Bankswitch Output Timing Modification

BANKSWITCH LOGIC (Continued)
Figure 32. R/W Output Timing Modification

## BUS CONTROL

Multi-processing or external program testing may be accomplished by disabling the I/O ports used for external memory addressing and the associated timing signals.

## High Impedance Mode

The User may place the External Memory Interface (I/O Port 0, Port 1 and Port 6, Address Strobe, Data Strobe and Read/Write) into the high impedance state by setting the HIMP bit (MODER.0). External test equipment may then drive the memory lines for automatic test, external memory validation or programming. The ST9 will continue to execute internal programs, providing no external memory is addressed, allowing the execution of security routines without showing externally the addresses used.

## Bus Request/Acknowledge

The External Memory Interface address ports and timing signals may be forced to their high impedance state by utilizing the $\overline{B U S R E} \bar{Q}$, Bus Request, and BUSACK, Bus Acknowledge, signals available as Alternate Functions of two I/O pins. The signals, BUSREQ and BUSACK, must be enabled by setting the BRQEN bit (MODER.1). Once enabled, a low level detected on the $\overline{B U S R E Q}$ pin at the start of an internal machine cycle will cause the stretching of the CPUCLK, and BUSACK to go low indicating that the External Memory Interface is disabled. The BUSREQ pin is then continuously monitored, and when sampled high, the External Memory Interface pins are driven by the ST9 within two INTCLK cycles.

## I/O PORTS

## Summary of Function

For the ST90R50 84 pin package, only twelve pins have a Reserved function: $\mathrm{V}_{\mathrm{DD}}(\mathrm{x} 2), \mathrm{V}_{\mathrm{SS}}(\mathrm{x} 2)$, $\overline{R E S E T}, \overline{\mathrm{AS}}, \overline{\mathrm{DS}}, \mathrm{R} / \overline{\mathrm{W}}, \mathrm{OSCIN}, \mathrm{OSCOUT}$, the Analog to Digital Converter Voltage references. All other pins are available as Input/Output (I/O) for the User, grouped into Ports of 8 bits. These may be programmed to be Input, Output, Bidirectional or Alternate Function (Peripheral or Memory Interface), on a bit by bit basis, at any time. When programmed as an Input the pin may be set to TTL or CMOS input threshold levels, while, when programmed as Output, Push-Pull or Open Drain configuration may be selected. The Bidirectional mode sets the pin with a weak pull-up resistor to VDD or to Open Drain, allowing bidirectional communication with external logic. The Alternate Function setting is predetermined for each pin as shown in the Pin Configuration Table.
The circuitry of the I/O port allows for several ST90R50 peripheral functions to address, as Alternate Functions, the same pin, for both input and output, the User selects which peripheral function is to be active by enabling its individual Input or Output function. This multi-function I/O capability of the ST90R50 allows for easy adaptation to external

Table 8. I/O Setting Options

| Bidirectional | Open Drain |
|  | Weak Pull-up |
| Alternate Function | Open Drain |
|  | Push Pull |

circuits. The options available for each bit are summarized in Table 8.

## I/O Port Configuration

The configuration of each general I/O bit of the ST90R50 is set by the corresponding bits in three 1/O Port control registers. These affect the status of the input and output buffers of the pin, and enable the Alternate function Outputs. Alternate Function inputs are always connected, and are used by enabling the function from within the configuration registers of the relevant peripheral function. The configuration of an I/O bit is shown in figure 33. Outputs follow a Master/Slave buffer, data is tran-

Figure 33. I/O Port Schematic

## I/O PORTS (Continued)

ferred from the ST9 internal data bus at the beginning of the machine cycle, and, if enabled as output, is passed to the output latch at the end of the cycle. This synchronization allows for the Bidirectional use of the pin without potential conflicts.

## Configuration Registers.

Three registers are used to allow the setting of each pin, generically PxC2R, PxC1R, PxC0R, where $x$ relates to the 8 bit l/O port in which the bit is present. The setting of the corresponding bit in each register
to achieve the desired functionality of the $1 / O$ pin is shown in Table 9.

The effect of the configuration settings of Table 9 on the $\mathrm{I} / \mathrm{O}$ ports structure is shown in Figures 34 to 37.

## I/O Register Map

The Data Registers which correspond to the pin status (after configuration) of I/O port 0 to 5 , are found in Group E of the Register File, for immediate access at all times, while the configuration registers and the Data Registers for Additional Ports are found within I/O pages (Group F) 2. 3 and 43 (2Bh).

## I/O PORTS (Continued)

## Handshake and DMA

I/O Ports 4 and 5 of the ST90R50 are able to support a parallel interface with handshake capability. This allows one, two or four wire interconnecting handshake signals and facilitates very fast parallel transfer of data for input and output, or for the interconnection of peripheral devices requiring strobe signals for synchronization. Table 10 shows the available options for input and output status and strobe signals available as Alternate Functions of I/O port bits (see Pin Configuration). The Handshake configuration is set within the Handshake Control Register (HDCnR) for the relevant I/O port $n$.
Data transfer through a parallel I/O port with handshake can also be triggered through a DMA channel. Timing is generated by the ST90R50 TIMER ON-CHIP EVENT strobe signal (see the TIMER section for information on generatıng these signals), which causes the programmed transfer of data to or from the memory source which can be Register File, Program space memory or Data space memory. An example of application of this
technique is shown in figure 39, a complex stepper motor timing sequence automatically being transferred from a table in the Register File (or memory spaces) to the stepper motor drivers. After initialization, this operation is transparent until the task (complex microstepping) is completed.

## TIMER/WATCHDOG

A 16 bit down-counter, complete with 8 bit prescaler, is integrated into the ST90R50 core. This is able to operate both as a general purpose timer with associated input and output pins for timing functions, and also as a Watchdog Timer offering a security against possible processor malfunctions due to external events.

## Timer Modes

When operating as a Timer, with a timing resolution from 333ns to 5.59 s (INTCLK $=12 \mathrm{MHz}$ ), an input pin (WDIN) and output pin (WDOUT) may be selected as the Alternate Functions of two I/O pins. When WDIN is enabled by the User by setting INEN high (WDTCR.3) and the Alternate Function is set, 4 operating modes are available: The WDIN input may be programmed to act as an event counter input, with high to low transitions causing the counter to decrement (the time duration between the falling edges of the input clock must be at least 333 ns , allowing a maximum input frequency of 3 MHz ). It may also be used for pulse width measurement by being selected as a counter clock gate signal (prescaler to the counter being driven by INTCLK/4), counting being enabled when WDIN is at a high level. Trigger and Re-trigger modes cause a reload of the timer User preset values (providing STSP, WDTCR. 7 is active) for a high to low transi-
tion on WDIN at any time (Re-trigger mode) or when the counter is at the end of count (Trigger mode). The counter decrements at a rate driven by INTCLK/4.
The WDOUT pin, when set as the Alternate Function, is enabled by OUTEN high (WDTCR.0), and may either toggle the state of the I/O bit (frequency generation, OUTMD = " 0 ", WDTCR.2) or pass the state of the WROUT bit to the output allowing PWM generation (OUTMD $=" 1 "$ ) at the end of count (timer value $=0$ ) condition.

## Watchdog Mode

The timer functions may be disabled, and the Timer configured for a Watchdog operation by re-setting WDEN (WCR.6) to zero. Once the Watchdog has been selected it CANNOT be set back into the standard timer mode until the next Hardware Reset cycle. The User should set the watchdog timer prescaler and timer reload value before enabling the Watchdog mode. The Watchdog Timer must then be retriggered, causing the reloading of the timer value, by the operation of writing of the byte sequence OAAh, 055h to the WDTLR register. If this is not done before the Watchdog counts to zero, the Watchdog Timeout condition occurs. This causes a Hardware Reset of the ST90R50. The Watchdog reset signal is not output on the external Reset pin.

Figure 40. Timer/Watchdog Block Diagram

## TIMER/WATCHDOG (Continued)

## Timer/Watchdog Interrupts

The Timer/Watchdog may provide several levels of interrupts selectable by the User. The Timer mode offers two interrupt sources, triggered on the timer value reaching 0 , either a prioritized level (by taking the Interrupt priority channel from the External Interrupt INTAO) or by a top level, non-maskable interrupt (taking the external NMI input channel). The interrupt channels are multiplexed from the alternative source according to the status of the IAOS (EIVR.1) and TLIS (EIVR.2) bits as shown in figure 42. Please refer to the ST9 Technical Manual for further details on changing the interrupt sources of the Timer/Watchdog. When the Watchdog mode is set (WDEN = " 0 "), the timer value equal to 0 event generates a Hardware reset of the ST90R50. The Timer/Watchdog control registers are located within Page 0 of the Paged I/O register group.

Figure 42. Timer/Watchdog Interrupt Sources

Figure 41. Timer/Watchdog in Watchdog Mode

## MULTIFUNCTION TIMER

The ST90R50 includes three identical 16 bit Multifunction Timers (MFT) in addition to the TIMER/WATCHDOG. The following description applies to Timer 0, Timer 1 and Timer 3.
Each timer is a 16 bit Up/Down counter, driven by the output of an 8 bit prescaler which may be driven by INTCLK/3 (giving a minimum timing resolution of 250 ns at $\operatorname{INTCLK}=12 \mathrm{MHz}$ ) or by an external source. This timer is supported by two 16 bit Comparison Registers for generating timed functions and two 16 bit Capture/Load Registers for timing and variable timebase functions. These features coupled with 2 input pins (TxINA and TxINB) and 2 output pins (TxOUTA and TxOUTB, where $x=0$ or 1), available as Alternate Functions, giving the timer 13 operating modes for virtually all required timing functions.

## MFT Operating Modes

The operating modes are selected by the programming of the Timer Control Register (TCR Timer x ) and the Timer Mode Register (TMR) as follows:
One-Shot Mode. The counter stops at the End Of Count Condition (up or down count).
Continuous Mode. At End Of Count the timer is reloaded from a Load Register.

Trigger Mode. A Trigger causes reload from a load register only if the Timer is at End of Count.
RETrigger Mode. A Trigger causes reload from a load register at any time.
Gate Mode. Counting is performed only when the external gate input (TxINA or TxINB) is active (logical 0).
Capture Mode. A Trigger causes the timer value to be latched into the selected Capture register.
Up/Down Mode. A Trigger causes a count up or down, or a change in counting direction.
Free-Running Mode. Up or Down counting is performed to the full range with no action at End of Count. This is used in Bicapture and Capture Modes.
Monitor Mode. One Capture register follows the contents of the timer.
Autoclear Mode. The timer is reset to 0000 h or FFFFh (up or down count respectively) on a trigger. This gives delta time measurement or free running with a modulo of less than $2^{16}$.
Biload Mode. The counter is reloaded on an End Of Count condition alternately from the two Load Registers. (PWM output).
BICapture Mode. A Trigger causes the current timer value to be transferred alternately to the two Capture registers. (Pulse width measurement).

Figure 43. Multifunction Timer Block Diagram

## MULTIFUNCTION TIMER (Continued)

Parallel Mode. The prescaler output of Timer 0 is internally connected to the input of the prescaler of Timer 1, if this is then set to 00 h (= divide by 1 ), then the two timers may be run in parallel.
The trigger events may be either caused by software, or an action on the two input pins which may be programmed to respond to rising, falling or both edges of the input. The input modes are selected in the Input Control Register (ICR) as shown in Table 11. This includes the Autodiscriminator mode, which causes the timer to count up or down depending on the phase between the two input edges, such as the signals generated by optical encoders.
The two output pins (available as Alternate Functions) may be programmed through the Output Control Registers OACR and OBCR to be modified (Set, Reset, Toggle or No Operation) on each of Overflow/Underflow (OVF/UNF), Compare on CMPO valid (CMO), or Compare on CMP1 (COMP1) valid events. This allows repetitive signals such as PWM drive to be output with minimum CPU overhead. Fig 44 shows some typical waveforms available from these signals.

Table 11. Input Pin Function Settings

| Input Control <br> Register <br> IN3-INO bits | TxINA Input <br> Function | TxINB Input <br> Function |
| :---: | :---: | :---: |

Figure 44. Example Output Waveforms

## MULTIFUNCTION TIMER (Continued)

The Overflow/Underflow event and the Compare 0 event may also be programmed to give On-chip Event timing signals to trigger other peripheral operations on the ST90R50. These are as shown in Table 12.

Table 12. ST90R50 On-Chip Event Settings

| MFT0 | Handshake Trigger Port 4 |
| :--- | :--- |
| MFT1 | Handshake Trigger Port 5 |
| MFT3 | A/D Conversion Trigger |

The TxOUTA and TxINA lines for each timer may be connected internally, by setting of the SCx bits of the I/O Connection Register (IOCR).
The Multifunction Timers are enabled for counting by the Counter Enable bit (CEN, TCR.7) of the respective timer unit. When CEN is low, both prescaler and timer are halted. CEN is logically ANDed with the Global Counter Enable bit (GCEN, CICR.7), so that all timers may be started in synchronism, i.e. when the timers are set into Parallel mode, this allows initialization of the Timers before triggering at the same instant.

## MFT Interrupts

Each Multifunction Timer can generate interrupt requests from 5 different interrupt sources which are grouped into 3 independent groups. The Interrupt Vector has the source of the interrupt group encoded by hardware into the least significant 3 bits of the vector. This allows the programming of the base address to an 8 byte block within the interrupt vector area of the Program Space. The groups and respective addresses are shown in Table 13.

Table 13. MFT Interrupt Vectors

| Interrupt Source | Vector Address |
| :---: | :---: |
| COMP0 | $\mathrm{xxxx} \times 110$ |
| COMP1 | $\mathrm{xxxx} \times 100$ |
| CAPT0 <br> CAPT1 | $\mathrm{xxxx} \times 000$ |
| Overflow/Underflow |  |

Each source may be independently masked, in addition all Tımer interrupts may be disabled by the

Global Timer Interrupt enable (GTIEN, IDMR.7) control bit. If a Timer interrupt on Compare 0 or Capture 0 does not have its corresponding pending bit reset before the next interrupt, then an overrun condition occurs. This condition is flagged in two dedicated overrun bits in the Timer FLAGS register.

## MFT DMA Channels

Two independent DMA channels are present within each MFT, associated to the Compare 0 and Capture 0 sources. This allows 16 bit DMA transactions from Register File/Memory to COMPO registers, and from CAPT0 registers to Register File/Memory. The DMA channels allow the capture of external event timings in memory allowing off-line analysis, and creating of variable pulse width signal trains, as required by the drive of Triacs in certain modes.
The two interrupt mask sources are independently masked by two DMA mask bits, mapped in the IDMR register. The End of Block (EOB) procedures are as described in the INTERRUPT/DMA section.
The DMA counter and address pointer registers share the most significant User-programmable 6 bits for both DMA channels (COMP 0 and CAPT 0), thus the mapping of the counter and address registers use automatic offsets from the base address. The actual mapping changes dependent on whether the Register File or Memory is addressed for the transfer. The offsets are shown in Table 14.

Table 14-1. MFT DMA Address and Counter Registers for Memory DMA Transfers

SGS-THOMSON

MULTIFUNCTION TIMER (Continued)
Table 14-2. MFT DMA Address and Counter Registers for Register File DMA Transfers

| POINTERS FOR REGISTER FILE DMA |
| :--- | :--- | :--- | :--- |

After the transfer of the complete block of data to/from the MFT, the count registers reach the zero value and an end of block interrupt occurs so that the ST9 may process the new data. In many cases, the time taken to reload the data tables and to re-trigger the DMA action causes speed limitations, especially in those applications requiring a continu-
ous high speed data flow, because of the time consumed by the restore routine. An additional DMA function, the SWAP mode, overcomes this limitation. This is enabled by the setting of the SWEN (IDCR.3) bit. This causes hardware generated signals to replace the User address bit 2 of both the address and counter pointers. The address and counter registers are thus duplicated at an offset of 4 registers. At the End Of Block condition, the EOB interrupt is generated to signal the end of DMA, and the state of pointer address bit 2 toggles state automatically and the new address and count values are used. Thus the ST9 can safely process the previous block of clata while the new block is being transferred. This will continue until the SWAP mode is disabled.

A software protection scheme is implemented to prevent non-updated pointer registers from being used if a second EOB interrupt arrives during the servicing of the first. This mechanism locks the state of the DMA mask bit to prevent further transfers from taking place. The User should check for this condition in the EOB routine to ensure that all the DMA transfers are properly serviced.
The control Registers of each MFT occupy 20 registers within the I/O paged area. These are mapped as shown in Figure 45.
In addition the MFT is able to trigger byte DMA transfers in both directions through an I/O port with Handshake (see I/O Handshake and DMA).

Figure 45. Multifunction Timer Page Maps

## SERIAL PERIPHERAL INTERFACE (SPI)

The Serial Peripheral Interface (SPI) is integrated into the Core module of the ST9 and provides a general purpose shift register based peripheral allowing synchronous serial $1 / \mathrm{O}$, with special modes allowing compatibility with $\mathrm{I}^{2} \mathrm{C}$-bus and IM bus Communication standards in addition to the standard serial bus protocol. The SPI uses 3 lines comprising Serial Data Out (SDO), Serial Data In
full duplex transmission with both data-out and data-in synchronized with the same clock signal. Thus the byte transmitted is replaced by the byte received, eliminating the need to separate "Tx Empty" and "Rx full" status bits. After the 8 clock cycles have been concluded, the received data in SPIDR is parallel transferred to the read buffer and data becomes available for the ST90R50 during the next read cycle of SPIDR. The BUSY bit

Figure 46. SPI Functional Diagram

(SDI) and the Synchronous Serial Clock (SCK) which are available as Alternate Functions of I/O pins. Additional I/O pins may act as device selects or IM-bus address ident signals. The functional diagram of the SPI is shown in figure 46.
The SPI, when enabled (SPEN, SPICR.7, high), receives input data from the ST9 internal data bus into the SPIDR, and originates the SCK to shift the data serially through SDO (Most Significant bit first) to the slave device which responds by sending data to the master device via the SDI pin. This implies
(SPICR.4) is set when transmission is in progress, this allows the User to monitor the status of the SPI by polling of this bit.
The SPI can operate only in master mode, i.e. the clock is always generated by the ST90R50, however the SCK polarity and phase can be programmed to suit all peripheral requirements (figure 47). This, together with the 4 programmable bit rates (divided from the INTCLK, Table 15), provide the large flexibility in handling different protocols.

SERIAL PERIPHERAL INTERFACE (Continued)
Figure 47. SPI Data and Clock Timing

Table 15. SPI Rate Selection

| SPR1 | SPR0 | Clock <br> Divider | SCK Frequency <br> (INTCLK $=12 \mathrm{MHz})$ |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 8 | $1500 \mathrm{KHz}(\mathrm{T}=0.67 \mu \mathrm{~s})$ |
| 0 | 1 | 16 | $750 \mathrm{KHz}(\mathrm{T}=1.33 \mu \mathrm{~s})$ |
| 1 | 0 | 12 | $93.50 \mathrm{KHz}(\mathrm{T}=10.66 \mu \mathrm{~s})$ |
| 1 | 1 | 256 | $46.87 \mathrm{KHz}(\mathrm{T}=21.33 \mu \mathrm{~s})$ |

## $I^{2} \mathrm{C}$-bus COMPATIBILITY

The SPI includes additional circuitry to enable the use of external $I^{2} \mathrm{C}$-bus peripherals. The $I^{2} \mathrm{C}$-bus mode is a 2 wire bus while the SPI operates with 3 wires, however wire-ANDing SDO and SDI gives the required signalling, while setting the BMS bit causes the enabling of the special $I^{2} \mathrm{C}$-bus features: Clock Slowdown by external devices and Arbitration Lost detection. This mode also affects the Interrupt sources as shown in the next section.

## SPI Interrupts

The SPI, when enabled, uses the INT2 external interrupt channel source, using the priority selected for INT2 within the External Interrupt Priority registers. The INT2 mask bit should be set and INT2 pending bit reset before enabling the SPI through SPEN. The BMS (SPICR.6) and SPEN bits select the SPI internal interrupt source as shown in Table 6.

Table 16. SPI Interrupt Sources

| SPEN | BMS | Interrupt Source |
| :---: | :---: | :--- |
| 0 | 0 | External channel INT2 |
| 0 | 1 | S-BUS/I ${ }^{2} C$ start or stop condition |
| 1 | $X$ | End of one byte transmıssion |

## SPI Registers

The two registers controlling the SPI are located in I/O page 0, the Data Register, SPIDR, at R253 and the control register, SPICR, at R254.

## SERIAL COMMUNICATIONS INTERFACE

## Function

The two Serial Communications Interfaces (SCIs) of the ST90R50 offers a means of full-duplex serial data transfer to a wide range of external equipment. Each has a fully programmable character format control for asynchronous and byte synchronous serial I/O, an integral Baud Rate Generator, giving a maximum baud rate of 375 K Baud in Asynchronous mode (Internal Clock), and two DMA channels for transparent transmission and reception of characters. Support is also present in hardware for Line Break Detection and generation, character search, network interfacing with 9th bit Address logic, and Local Loop Back and Auto echo modes for Self- Test. The control registers for an

SClexistwithin one I/O page within the I/O page group.

## Character Formats

When used for asynchronous character transmission and reception, the character format may be changed (through the Character Control Register CHCR) to suit external equipment requirements. This is summarized in figure 49.
The baud rate clock for asynchronous mode should be set to the $\div 16$ Mode and the frequency of the clock input (from an external source or the internal baud-rate generator output) set to suit this.
This format control is also available for the byte synchronous mode (Clock divider set to $\div 1$ ), when the data and clock are output in synchronism, the data being sampled once per clock period (figure

Figure 48. SCI Functional Block Diagram

## SERIAL COMMUNICATION INTERFACE

 (Continued)50). For a second synchronous mode, CLKOUT is activated only for the data section of the word (figure 51) on serial data output, and input data is latched on the rising edge of the external synchronised clock input on the RXCLK pin. This mode may be used to access external synchronous peripherals.
The Address bit/D9 is optional and may be added to any word format, it is commonly used in network or machine control applications. When enabled (AB, CHCR. $4=" 1 "$ ), an address or ninth data bit can be added to a transmitted word by setting the Set Address bit (SA, IDPR.5). This is then appended to the next word entered into the (empty)

Transmitter Buffer Register and then cleared by hardware. On character input an Address Bit set can indicate that the data preceding the bit is an address which may be compared in hardware with the value in the Address Compare Register (ACR) to generate an Address Match interrupt when equal.
The Address bit and Address Comparison Register can also be combined to generate an Address Interrupt in 4 modes to suit different protocols, based upon the status of the Address Mode Enable bit (AMEN, IDPR.7) and the Address Mode bit (AM, CHCR.7) as shown in Table 17.
The character match Address Interrupt mode may be used as a powerful character search mode, giving an interrupt on reception of a predetermined

Figure 49. SCI Character Format

| If Character Match |
| If Character Match and 9th Data Bit $=1$ |
| If Character Match on Word Immediately Following <br> Break |

character e.g. Carriage Return or End of Block codes.

The Line Break condition is fully supported for both transmission and detection. Line Break is sent by setting the SET_BREAK bit (SB, IDPR.6). This causes the transmitter output to be held low (after all buffered data has been transmitted) for a minimum of one complete word length and until the SB bit is Reset.

## SCI Interrupts

Each SCl is able to generate interrupts from multiple sources. Receive interrupts include data pending, receive errors (overrun, framing and parity), address or break pending and transmit interrupts are software selectable for either the Transmit Holding Register Empty (HSN, IMR. $7=$ "1") or for the Transmit Shift Register Empty (HSN $=$ " 0 "). Interrupt sources are indicated by the Interrupt pending bits, shown in Table 18. These bits

Table 18. SCI Interrupt Vector

| Interrupt Source | Vector <br> Address |
| :--- | :---: |
| Transmitter Buffer or Shift <br> Register Empty/Transmit DMA <br> end of Block | $\mathrm{xxx} \times 110$ |
| Received Read/Receive DMA <br> end of Block | $\mathrm{xxxx} \times 100$ |

| Receiver Error | $\mathrm{xxxx} \times 000$ |

Figure 52. SCI Interrupt Typical Usage

## SERIAL COMMUNICATION INTERFACE (Continued)

should be reset by the User during the Interrupt Service routine.
When DMA is active the Receive Data Pending bit (RXDP, ISR.2), and the Transmit status bit interrupt sources are replaced by the DMA End Of Block Interrupt sources for transmit and receive, respectively.
Typical Usage of the Interrupts provided by the SCl are show in figure 52.

Table 19. SCI Interrupt Internal Priority

| Receive DMA Request | Highest Priority |
| :--- | :--- |
| Transmit DMA Request |  |
| Receive Interrupt |  |
| Transmit Interrupt | Lowest Priority |

The SCI interrupts have an internal priority structure (Table 19) in order to resolve simultaneous events.

The four major levels of interrupt are encoded in hardware to provide two bits of the interrupt vector register, allowing the position of the block of pointer vectors to be resolved to a block size of 8 bytes.

## SCI DMA

Two DMA channels are associated with each SCl , for transmit and for receive. These follow the register scheme as described in the DMA Section. It should be noted that, after initializing the DMA counter and pointer registers and enabling DMA, data transmission is triggered by a character written into the Transmit Holding register. The DMA End Of Block Interrupts generated on completion of the DMA transfer take the place of the normal transmit and receive character interrupt vectors.

## SCI Clock Generation

The communication bit frequency of the SCI transmitter and receiver sections can be provided from the integral Baud Rate Generator (allowing a maximum asynchronous bit rate of 350 k Baud) or from external sources (maximum bit rate 175k Baud). This clock is divided by 16 for asynchronous mode (CD, CCR.3, = "0"), or divided by 1 for synchronous modes (CD = "1").

## External Clock Sources.

The External Clock input pin TXCLK may be programmed in Alternate function by bits TXCLK (CCR.7) and OCLK (CCR.6) to be: the transmit clock input (respecting the $\div 16$ and $\div 1$ timing requirements), to act as the output of the Baud Rate Generator (allowing an external divider circuit to provide the receive clock for split rate transmit and receive e.g. 1200/75 baud), or to be CLKOUT, the clock output for the synchronous mode. Receive clock input via RXCLK Alternate function is enabled by the XRX bit CCR.5, this input should be set according to the setting of the CD bit.

## Baud Rate Generator.

The integral Baud Rate Generator is a 16 bit divide by n circuit of the Internal Clock INTCLK. Thus INTCLK should be chosen to provide a suitable frequency for division by the Baud Rate Generator to give the required transmit and receive bit rates. Suitable INTCLK frequencies and the divider values for standard Baud rates are shown in Table 20.

The act of writing to either of the two registers comprising the 16 bit divider causes a reset of the SCI, allowing initialization of the SCI settings before the writing of the other Baud Rate Generator register.

## Self Test

Testing of the communications channel may be performed using the facilities of the SCI. Auto Echo mode (SCI SOUT disconnected, SIN pin internally connected to SOUT pin) and Loopback mode (SCI transmitter and receiver sections disconnected

from SOUT and SIN pins and directly connected internally) may be used individually or together.

## ANALOG TO DIGITAL CONVERTER

The ST90R50 Analog to Digital Converter (A/D) is comprised of an 8 channel multiplexed input selector and a Successive Approximation converter. The conversion time is a function of the INTCLK frequency; for the maximum 12 MHz clock rate, conversion of the selected channel requires $11 \mu \mathrm{~s}$. This time also includes the $3 \mu \mathrm{~s}$ of the integral Sample and Hold circuitry, which minimizes need for external components. The resolution of the converted channel is 8 bits $\pm 1 / 2$ LSB between the Analog Vss and $V_{D D}$ references which occupy two pins of the

ST90R50 ( $\mathrm{A} \mathrm{V}_{\text {SS }}$ and $A V_{D D}$ respectively). This allows the full 256 bit resolution to apply over a reduced input range such as provided by various sensors and allows the best supply noise rejection. The input Analog channel is selected by using the Alternate Function setting as shown in the I/O ports section. The I/O bit structure of the port connected to the A/D converter (Port 4) is modified as shown in figure 55 to prevent the Analog voltage present at the I/O pin from causing high power dissipation across the input buffer. Un-selected analog channels should also be maintained in the Alternate function mode for this reason. A Power Down mode is available for applications which require low power dissipation, this is selected by setting to zero

Figure 53. A/D Block Diagram

ANALOG TO DIGITAL CONVERTER (Continued)
Figure 54. A/D Input Configuration Status

VA00219
the POW bit (CLR.2) which turns off all Analog functions within the A/D converter.

## Conversion

Each of the input Analog channels (AINO-7) can be converted singly or continuously. In single mode (CONT, CLR.1, = "0") conversions are triggered by setting the Start/Stop bit ST (CLR.0), this is reset by hardware at the end of a group of conversions and conversion stops. The Autoscan mode (CONT $=$ "1") converts each input channel in sequence, starting from the channel number selected in the Start Conversion Address (SC1-3) bits and Increasing to channel 7 (AIN7), repeating so that the data registers will be maintained with the latest converted result. Conversion start is triggered by internal or external events. An external trigger (enabled by EXTG, CLR. $4,=$ " 1 ") is caused by a pulse on the ADTRG pin available as an Input Alternate Function. This should have a minimum length of 80 nS and of a period greater than the conversion time. The Internal trigger is enabled by setting INTG, CLR.3, to "1" (this is ORed with EXTG to prevent hardware conflicts, but the correct procedure is to enable only one source at a time), in this case

Figure 55. A/D Trigger Sources

## ANALOG DIGITAL CONVERTER (Continued)

triggering is either by setting the ST bit by software or by enabling the ON-CHIP EVENT signal from the TIMER module.
The resulting data from the converted Analog channel AINx is stored in the appropriate Data Register DxR. Two channels AIN6 and AIN7 have a special feature known as the Analog Watchdog, by the use of two Threshold Registers for each channel. The Upper, (UT6R, UT7R), and lower, (LT6R, LT7R), registers contain User preset values. These values are automatically compared to the value in the Data Registers D6R and D7R following each new conversion. If the resulting data is less than the corresponding Lower Threshold Register, or higher than the contents of the corresponding Upper Threshold

Register, then an interrupt may be generated. This hardware feature minimizes arıalog monitoring overhead and is particularly useful in motor control applications as shown in figure 56.

## A/D Interrupts

The ST90R50 A/D converter provides two interrupt sources, End of Conversion and an Analog Watchdog Request. The interrupt vector register (IVR) provides 1 bit automatically generated in hardware to follow the interrupt source, allowing the User to select the base address of a four byte area of the interrupt vector table in which to store the A/D Interrupt Service Routines. The Analog Watchdog Request requires the User to poll within the Compare Result Register (CRR) to determine which of the four thresholds has been exceeded, the threshold status bits should be reset by software in the service routine. The interrupt pending flags, ECV (End of Conversion, ICR.7) and AWD (Analog

Figure 56. Analog Watchdog Used in Motor Speed Control

Watchdog, ICR.6) should also be reset by the User in the Interrupt service routine before the return.
The ST90R50 Analog to Digital converter occupies I/O page 63 (Group F).

## SOFTWARE DESCRIPTION

## Addressing Modes

The ST90R50 offers a wide variety of addressing modes and combinations to facilitate full and rapid access to the address spaces while reducing program length. Register addressing (using the working register group mechanism or directly addressed) can be used as 8 or 16 bit values for data or indirect addressing into the memory spaces

Table 21. Addressing Mode

| Addressing Mode | Notation |  |
| :--- | :--- | :--- |
| Immediate Data | \#N | \#NN |
| Register Direct | R;r | RR;rr |

| Bit Address | r.b, |  |

[^6]or the Register File. The selection between Program Memory and Data Memory is performed through the DP bit in the FLAG Register, all subsequent actions on the memory space will affect the selected map only, apart from the memory map to memory map post-increment addressing mode which allows the map to be specified as part of the instruction for both destination and source operands. Apart from the immediate data and condition codes all operands are expressed as register file or memory addresses.
The available addressing modes, with the ST9 macro-assembler notation, are in Table 21.

## Notes:

1 Load Word only
2. Load Byte only

Table 22 describes the addressing modes available for the register file and the memory (both as a destination and as a source) for the two operand arithmetic, logic or load instructions.

## Instruction Set

The ST90R50 instruction set consists of 87 instruction types functionally divided into eight groups as in Table 23, they are:

- Load (two operands)
- Arithmetic \& Logic (two operands)
- Arithmetic Logic and Shift (one operand)
- Stack (one operand)
- Multiply \& Divide (two operands)
- Boolean (one or two operands)
- Program Control (zero to three operands)
- Miscellaneous (zero to two operands)

The wide range of instructions facilitates the full use of the register file and address spaces, reducing execution times, while the register pointers mechanism allows an unmatched code efficiency and ultrafast context switching. A particularly notable feature is the comprehensive "Any Bit, Any Register" (ABAR) addressing capability of the Boolean instructions.
The ST90R50 can operate with a wide range of data lengths from single bit, 4 -bit nibbles which can be in the form of Binary Coded Decimal (BCD) digits, 8 -bit bytes and 16 -bit words. The summary on Table 22 shows the instructions belonging to

each group and the number of operands required for each. The source operand is "src", "dst" is the destination operand, and "cc" is the condition code selection.

## Processor Flags

An important aspect of any single chip microcontroller is the ability to test data and make the appropriate action based on the results. In order to provide this facility, register 231 in the Register File is used as a Flag Register. Six bits of this register are used as the following flags:
C - Carry

Z-Zero
S - Sign
V - Overflow
D - Decimal Adjust
H - Half Carry
One of the two remaining bits in the flag register is available to the user (bit 1, F1). Bit 0 is the Program/Data Memory selector bit and is operated on directly by the hardware within the ST90R50. The $P / \bar{D}$ pin will follow the status of this bit.

SOFTWARE DESCRIPTION (Continued)

| ULE | Unsigned Less Than or Equal | $(\mathrm{C}$ or Z$)=1$ |
|  |  |  |

Condition Codes. Flags $C, Z, S$, and $V$ control the operation of the "conditional" Jump instructions. Table 24 shows the condition codes and the flag settings affecting the jump.

## POWERFUL DEVELOPMENT ENVIRONMENT

## ST9 Software Tools

The following Software Tools are available for MSDOS, SUN-3 and SUN-4 operating systems:
AST9 high-level macro assembler with predefinited macro instructions (IF/ELSE,

WHILE, DO, LOOP, SWITCH, BREAK, PROCEDURE, RESTURN).
LST9 Incremental Linker/Loader.
CST9 Optimised C-Compiler (ANSI STANDARD).
ARST9 Library Archiver.
SIMST9 Software Simulator with realtime emulation executor
ST90R50 Hardware Emulator. Realtime emulation of the ST90R50 in all packaging options is performed by a modular emulation system, interfaced to the host computer through an RS232

ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter | Value | Unit |
| :---: | :--- | :---: | :---: |
| $\mathrm{V}_{\mathrm{DD}}$ | Supply Voltage | -0.3 to 7.0 | V |
| $\mathrm{AV}_{\mathrm{DD}}, \mathrm{AV}$ SS | Analog Supply Voltage | $\mathrm{V}_{\mathrm{SS}} \leq \mathrm{AV}_{\mathrm{SS}}<\mathrm{AV} V_{D D} \leq \mathrm{V}_{\mathrm{DD}}$ | V |
| $\mathrm{V}_{1}$ | Input Voltage | $\mathrm{V}_{S S}-0.3$ to $\mathrm{V}_{\mathrm{DD}}+0.3$ | V |
| $\mathrm{~V}_{\mathrm{O}}$ | Output Voltage | $\mathrm{V}_{\mathrm{SS}}-0.3$ to $\mathrm{V}_{\mathrm{DD}}+0.3$ | V |

- LOOP GAIN AND TIME CONSTANT SWITCHING ( VCR)
- COMPOSITE BLANKING AND KEY PULSE GENERATOR
- PROTECTION CIRCUITS
- OUTPUT STAGES WITH HIGH CURRENT CAPABILITY

## DESCRIPTION

The TDA1180P is a horizontal processor circuit for b.w. and colour monitors. It is a monolithic integrated circuit encapsulated in 16-lead dual in-line plastic package.

PIN CONNECTIONS

## ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter | Value | Unit |
| :---: | :---: | :---: | :---: |
| $V_{S}$ | Supply voltage (Pin 1) | 15 | V |
| $V_{2}$ | Voltage at Pin 2 | 18 | V |
| $V_{4}$ | Voltage at Pın 4 | $\mathrm{V}_{S}$ |  |
| $V_{8}$ | Voltage at Pin 8 | -6, VS | V |
| $V_{9}$ | Voltage at Pin 9 | $\pm 6$ | V |
| $V_{11}$ | Voltage at Pın 11 | $\mathrm{V}_{S}$ |  |
| $\mathrm{I}_{2}$ | Pin 2 peak current | 1 | A |
| $\mathrm{I}_{3}$ | Pin 3 peak current | 0.5 | A |
| $I_{6}$ | Pin 6 current | 30 | mA |
| $I_{7}$ | Pin 7 current | 20 | mA |
| $\mathrm{l}_{10}$ | Pin 10 current | 30 | mA |
| $\mathrm{P}_{\text {tot }}$ | Total power dissipation at Tamb $\leq 70^{\circ} \mathrm{C}$ | 1 | W |
| $\mathrm{T}_{\text {stg }}, \mathrm{T}_{\mathrm{j}}$ | Storage and junction temperature | $-40,+150$ | ${ }^{\circ} \mathrm{C}$ |

## THERMAL DATA

| $\mathrm{R}_{\text {th ( }-\mathrm{a} \text { ) }}$ | Thermal Resistance Junction-Ambient | Max | 80 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| :---: | :--- | :---: | :---: | :---: |

## ELECTRICAL CHARACTERISTICS

(refer to the test circuit, $\mathrm{V}_{S}=12 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise specified)

| Symbol | Parameter | Test conditions | Min. | Typ. | Max. | Unit |
| :---: | :--- | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\mathrm{S}}$ | Supply voltage range |  | 9.5 | 12 | 13.2 | V |
| $\mathrm{I}_{\mathrm{s}}$ | Supply current | $\mathrm{I}_{3}=0$ |  | 42 | 52 | mA |
| $\mathrm{~V}_{\mathrm{S}}$ | Supply voltage at which the output pulses <br> (at pin 2 and 3) are switched off |  |  | 4 | V |  |

HORIZONTAL SYNC. SEPARATOR

| $\mathrm{V}_{1}$ | Peak to peak input signal |  | 1 | 3 | 6 | V |
| :---: | :--- | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{~V}_{8}$ | Input switching voltage | $\mathrm{I}_{8}=80 \mu \mathrm{~A}$ |  | 1.5 |  | V |
| $\mathrm{I}_{8}$ | Input switching current | $\mathrm{V}_{8}=1.4 \mathrm{~V}$ |  | 10 |  | $\mu \mathrm{~A}$ |
| $\mathrm{I}_{8}$ | Leakage current | $\mathrm{V}_{8}=-5 \mathrm{~V}$ |  |  | 1 | $\mu \mathrm{~A}$ |

ELECTRICAL CHARACTERISTICS (continued)

| Symbol | Parameter | Test conditions | Min. | Typ. | Max. | Unit |
| :---: | :--- | :--- | :---: | :---: | :---: | :---: | :---: | | VERTICAL SYNC. SEPARATOR |  | 1 | 3 | 6 | V |
| :---: | :--- | :--- | :---: | :---: | :---: |
| $\mathrm{~V}_{1}$ | Peak to Peak Input Signal | $\mathrm{I} 9=80 \mu \mathrm{~A}$ |  | 1.5 |  |
| $\mathrm{~V}_{9}$ | Input Switching Voltage | $\mathrm{V}_{9}=1.4 \mathrm{~V}$ |  | 5 |  |
| $\mathrm{I}_{9}$ | Input Switching Current | $\mathrm{V}_{9}=-5 \mathrm{~V}$ | $\mu \mathrm{~A}$ |  |  |
| $\mathrm{I}_{9}$ | Leakage Current | No Load Pin10 | 11 |  | 1 |
| $\mathrm{~V}_{10}$ | Vertical Sync. Pulse Output Voltage | $\mu \mathrm{A}$ |  |  |  |
| $\mathrm{R}_{10}$ | Output Resistance |  |  | 10 |  |
| tLV | Delay between Leading Edge of Input and <br> Output Signals |  | 17 | $\mathrm{k} \Omega$ |  |
| tLv | Delay between Trailing Edge of Input and <br> Output Signals |  |  | 5 s |  |
| tv | Vertical Sync Pulse Duration |  |  | 190 |  |

## PROTECTION CIRCUIT

| $\mathrm{V}_{4}$ | Input Voltage for Switching off the Output <br> Pulses | Output Pulses OFF <br> Output Pulses ON | 1 |  | 0.5 | V |
| :---: | :--- | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{R}_{4}$ | Input Resistance |  |  | 200 |  | $\mathrm{k} \Omega$ |
| $\mathrm{I}_{4}$ | Input Current |  | 5 |  |  | $\mu \mathrm{~A}$ |

## FLYBACK PULSE

| $\mathrm{V}_{6}$ | Input Threshold Voltage of Blanking <br> Generator |  | 1.8 | V |  |
| :---: | :--- | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{~V}_{6}$ | Input Threshold Voltage of Phase <br> Comparator |  | 7.6 |  | V |
| $\mathrm{I}_{6}$ | Input Switching Current | $\mathrm{V}_{6} \geq 1.7 \mathrm{~V}$ |  | 0.45 | mA |

## OUTPUT PULSE

| $V_{3}$ | Peak-to-Peak Output Voltage | $I_{3}=150 \mathrm{mApp}$ |  | 10 |  | V |
| :---: | :--- | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{I}_{3}$ | Output Current | $\mathrm{V}_{3}=5 \mathrm{~V}$ |  | 500 |  | mA |
| $\mathrm{R}_{3}$ | Output Resistance | At Leading Edge of <br> output pulse <br> At Training Edge of <br> Output Pulse |  | 3 |  | $\Omega$ |
| $\mathrm{t}_{\mathrm{p}}$ | Output Pulse Duration |  | 20 | 22 | 26 | $\mu \mathrm{~s}$ |

## COMPOSITE BLANKING AND KEY PULSE

| $\mathrm{V}_{7 \mathrm{k}}$ | Key Pulse Output Peak Voltage |  | 9 | 11 |  | V |
| :---: | :--- | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{~V}_{7 \mathrm{~B}}$ | Blanking Pulse Output Voltage |  | 4.2 | 4.5 | 4.8 | V |
| $\mathrm{R}_{7}$ | Output Resistance |  |  | 100 |  | $\Omega$ |
| $\mathrm{t}_{\mathrm{sk}}$ | Phase Relatıon Between Tralling Edge of <br> Key Pulse and Middle of Sync. Input Pulse |  | 2.7 |  | $\mu \mathrm{~s}$ |  |
| $\mathrm{t}_{\mathrm{k}}$ | Key Pulse Duration |  | 3.5 | 3.8 |  | $\mu \mathrm{~s}$ |
| $\mathrm{t}_{\mathrm{tb}}$ | Delay between Flyback Pulse and Blanking <br> Pulse | $\mathrm{V}_{6}=1.7 \mathrm{~V}$ |  |  | 0.2 | $\mu \mathrm{~s}$ |

ELECTRICAL CHARACTERISTICS (continued)

| Symbol | Parameter | Test conditions | Min. | Typ. | Max. | Unit |
| :---: | :--- | :---: | :---: | :---: | :---: | :---: |

| $\mathrm{t}_{\mathrm{g}}$ | Gating Pulse Duration |  |  |  |  |
| :---: | :--- | :--- | :---: | :---: | :---: |
| t | Phase Relation between Middle of Sync. <br> Pulse and Trailing and Leading Edge of <br> Gating Pulse |  | 3.75 |  | $\mu \mathrm{~s}$ |

COINCIDENCE DETECTOR

| $\mathrm{V}_{11}$ | Output Voltage | With Coincidence <br> Without Coincidence |  | 6.8 | 4 | V <br> V |
| :---: | :--- | :--- | :--- | :---: | :---: | :---: |
| $\mathrm{I}_{11}$ | Peak Output Current |  |  | 0.5 |  | mA |

## VCR SWITCH

| $\mathrm{V}_{11}$ | Input Voltage |  | 0 to 4 or 8.5 to 12 |  | V |  |
| :---: | :--- | :--- | :---: | :---: | :---: | :---: |
| $-\mathrm{I}_{11}$ | Output Current |  | 35 |  |  | $\mu \mathrm{~A}$ |
| $\mathrm{I}_{11}$ | Output Current |  | 0.4 |  |  | mA |

TIME CONSTANT SWITCH

| $\mathrm{V}_{12}$ | Output Voltage |  |  | 3 |  | V |
| :---: | :--- | :--- | :--- | :---: | :---: | :---: |
| $\mathrm{R}_{12}$ | Output Resistance | $4.5 \mathrm{~V}<\mathrm{V}_{11}<8 \mathrm{~V}$ <br>  | $\mathrm{~V}_{11}>8.5 \mathrm{~V}$ or $\mathrm{V}_{11}<4 \mathrm{~V}$ |  | 100 |  |
| 40 |  | $\Omega$ |  |  |  |  |
| $\mathrm{k} \Omega$ |  |  |  |  |  |  |

OSCILLATOR

## APPLICATION INFORMATION

## Pin 1 - Positive supply

The operating supply voltage of the device ranges from 10 V to 13.2 V

## Pin 2 and 3 - Output

The outputs of TDA1180P are suitable for driving transistor output stages, they deliver positive pulse at Pin 3 and negative pulse at Pin 2.
The negative pulse is used for direct driving of the output stage, while positive pulse is useful when a driver stage is required.
The rise and fall times of the output pulses are about 150 ns so that interference due to radiation are avoided.
Furthermore the output stages are internally protected against short circuit.

## Pin 4 - Protection circuit input

By connecting Pin 4 of the IC to earth the output pulses at Pin 2 and 3 are shut off ; this function has been introduced to produced to protect the final stages from overloads.
The same pulses are also shut off when the supply voltage falls below 4 V .

## Pin 5 - Phase shifter filter

To compensate for the delay introduced by the line final stages, the flyback pulses to Pin 6 and the oscillator waveform are compared in the oscillatorflyback pulse phase comparator.

Figure 4 : Loop Gain

The result of the comparison is a control current which, after it has been filtered by the external capacitor connected to Pin 5 , is sent to a phase shifter which adequately regulates the phase of the output pulses.
The maximum phase shift allowed is: $\mathrm{t}_{\mathrm{d}}=\mathrm{t}_{\mathrm{p}}-\mathrm{t}_{f}$ where $t_{f}$ is the flyback pulse duration.
Pin 5 has high input and output resistance (current generator).

## Pin 6 - Flyback input

The flyback pulse drives the high impedance input through a resistor in order to limit the input current to suitable maximum values.
The flyback input pulses are processed by a double threshold circuit; this generates the blanking pulses by sensing low level flyback voltage and the pulses to drive the phase comparator by sensing high level flyback voltage, therefore phase jitter caused by ringing normally associated with the flyback pulse, is avoided.

## Pin 7-Key and blanking pulse output

The key pulse for taking out the burst from the chrominance signal is generated from the oscillator ramp and has therefore a fixed phase position with respect to the sync.
The key pulse is then added internally to the blanking pulse obtained by correctly forming the flyback pulse present at Pin 6.
The sum of the two signals (sandcastle pulse) is available on low impedance at output Pin 7.

## Pin 8 and 9 - Sync separators inputs

The video signal is applied by means of two distinct biasing networks to pins 8 and 9 of the IC and therefore to the respective vertical and horizontal sync separators.
The latter take the sync pulses out of the video signal and make them available to the rest of the circuit for further processing.

## Pin 10 - Vertical sync output

The vertical sync pulse, obtained by internal integration of the synchronizing signal, is available at this pin.
The output impedance is typically $10 \mathrm{k} \Omega$ and the lowest amplitude without load is 11 V .

## Pin 11 - Coincidence detector

From the oscillator waveform a gate pulse $7 \mu \mathrm{~s}$ wide is taken whose phase position is centered on the horizontal synchronism.
The gate pulse not only controls a logic block which permits the sync to reach the oscillator-sync phase comparator only for as long as its duration, but also allows the latching and de-latching conditions of the oscillator to be established.This function is obtained by a coincidence detector which compares the phase of the gate pulses with that of the sync.
When the two signals are not accurately aligned in time it means that the oscillator is not synchronized. In this case the detector acts on the logic block to eliminate its filtering effect and on the time constant switching block to establish a high impedance on Pin 12 (small time constant of low-pass filter).
This latter block also acts on the oscillator-sync phase detector to increase its sensitivity and with it the loop gain of the synchronizing system.
In this conditions the phase lock has low noise immunity (wide equivalent noise bandwidth) and rapid pull-in time which allows fairly short synchronization times.
Once locking has taken place the coincidence detector enables the logic block, causes a low impedance on Pin 12 and reduces the sensitivity of the phase comparator.
In these conditions the phase lock has high noise immunity ( narrow equivalent noise bandwidth) due
to the complete elimination of interference which occurs during the scanning period and the greater inertia with which the oscillator can change its frequency.
To optimize the behaviour of the IC if a video recorder is used, the state of the detector can be forced by connecting Pin 11 to earth or to $+V_{s}$. The characteristics of the phase lock thus correspond to the lack of synchronization.

Pin 12 - Time constant switch, (see Pin 11)

## Pin 13 - Control current output

The oscillator is synchronized by comparing the phase of its waveform with that of the sync pulses in the oscillator-sync phase comparator and sending its output current 113 (proportional to the phase difference between the two signals) to Pin 15 of the oscillator after it has been filtered properly with an external low-pass circuit.
The time constant of the filter can be switched between two values according to the impedance presented by Pin 12.
The voltage limiter at the output of the phase comparator limits the voltage excursion on Pin 13 and therefore the frequency range in which the oscillator remains held-in.
The output resistance of Pin 13 is:

- low when V13 > 4.3 or V13 < 1.6 V
- high when $1.6 \mathrm{~V}<\mathrm{V} 13<4.3 \mathrm{~V}$

To prevent the vertical sync from reaching the oscillator-sync phase comparator along with the horizontal sync,a signal which inhibits the phase detector during the vertical interval is taken from the vertical output stage; inhibition remain even if the video signal is not present.
The free running frequenc of the oscillator is determined by the values of the capacitor and of the resistor connected to Pins 14 and 15 respectively. To generate the line frequency output pulses, two theresholds are fixed along the fall ramp of the triangular waveform of the oscillator.

## COMPLETE TV SOUND CHANNEL

The TDA 11902 is a monolithic integrated circuit in a 12-lead quad in-line plastic package. It performs all the functions needed for the TV sound channel :

- IF LIMITER-AMPLIFIER
- ACTIVE LOW-PASS FILTER
- FM DETECTOR
- DC VOLUME CONTROL
- AF PREAMPLIFIER
- AF OUTPUT STAGE

## DESCRIPTION

The TDA 11902 can give an output power of 4.2 W ( $\mathrm{d}=10 \%$ ) into a $16 \Omega$ load at $\mathrm{V}_{\mathrm{s}}=24 \mathrm{~V}$, or 1.5 W ( $\mathrm{d}=10 \%$ ) into an $8 \Omega$ load at $\mathrm{V}_{\mathrm{S}}=12 \mathrm{~V}$. This performance, together with the FM-IF section characteristics of high sensitivity, high AM rejection and low distortion, enables the device to be used in almost every type of television receivers.
The device has no irradiation problems, hence no external screening is needed.

## APPLICATION INFORMATION

The electrical characteristics of the TDA $1190 Z$ remain almost constant over the frequency range of 4.5 to 6 MHz , therefore it can be used in all television standard (FM mod.). The TDA $1190 Z$ has a high input impedance, so it can work with a ceramic filter or with a tuned circuit that provide the necessary input selectivity.
The value of the resistors connected to pin 7 , determine the AC gain of the audio frequency amplifier. This enables the desired gain to be selected in relation to the frequency deviation at which the output

Figure 16 : Typical Application Circuit.

Figure 17 : P.C. Board and Component Layout of the Circuit Shown in Fig. 16.

## MOUNTING INSTRUCTION

The $R_{\text {th }}$-amb of the TDA1190Z can be reduced by soldering the tabs to a suitable copper area of the printed circuit board (fig. 18) or to an external heatsink (fig. 19).

The diagram of figure 20 shows the maximum dissipable power $\mathrm{P}_{\text {tot }}$ and the $\left.\mathrm{R}_{\text {th }}\right\}$-amb as a function of the side "I" of two equal square copper areas having
Figure 18 : Example of P.C. Board Copper Area Which is Used as Heatsink.

Figure 20 : Maximum Dissipable Power and Junction to Ambient Thermal Resistance versus Side "I" .

a thickness of $35 \mu$ ( 1.4 mils).
During soldering the tab temperature must not exceed $260{ }^{\circ} \mathrm{C}$ and the soldering time mumst not be longer than 12 seconds.
The external heatsink or printed circuit copper area must be connected to electrical ground.

## DESCRIPTION

The TDA2540 and 2541 are IF amplifier and A.M. demodulator circuits for colour and black and white television receivers using PNP or NPN tuners. They are intended for reception of negative or positive modulation CCIR standard.
They incorporate the following functions :

- Gain controlled amplifier
- Synchronous demodulator
- White spot inverter
- Video preamplifier with noise protection
- Switchable AFC
- AGC with noise gating
- Tuner AGC output (NPN tuner for 2540)-(PNP tuner for 2541)
- VCR switch for video output inhibition (VCR play back)

## PACKAGE MECHANICAL DATA

16 PINS - PLASTIC DIP

## SYNCHRO AND HORIZONTAL DEFLECTION CONTROL FOR COLOR TV SET

- LINE OSCILLATOR (two levels switching)
- PHASE COMPARISON BETWEEN SYNCHROPULSE AND OSCILLATOR VOLTAGE Ø1, ENABLED BY AN INTERNAL PULSE, (better parasitic immunity)
- PHASE COMPARISON BETWEEN THE FLYBACK PULSES AND THE OSCILLATOR VOLTAGE $\varnothing 2$
- COINCIDENCE DETECTOR PROVIDING A LARGE HOLD-IN-RANGE
- FILTER CHARACTERISTICS AND GATE SWITCHING FOR VIDEO RECORDER APPLICATION
- NOISE GATED SYNCHRO SEPARATOR
- FRAME PULSE SEPARATOR
- BLANKING AND SAND CASTLE OUTPUT PULSES
- HORIZONTAL POWER STAGE PHASE LAGGING CIRCUIT
- SWITCHING OF CONTROL OUTPUT PULSE WIDTH
- SEPARATED SUPPLY VOLTAGE OUTPUT STAGE ALLOWING DIRECT DRIVE OF SCR'S CIRCUIT
- SECURITY CIRCUIT MAKES THE OUTPUT PULSE SUPPRESSED WHEN LOW SUPPLY voltage

## DESCRIPTION

The TDA2593 is a circuit intended for the horizontal deflection of color TV sets, supplied with transistors or SCR'S.

## PIN CONNECTIONS

MAIN CHARACTERISTICS

| Symbol | Parameter | Typ. | Unit |
| :---: | :---: | :---: | :---: |
| $\mathrm{V}(1-16)$ | Supply Voltage | 12 | V |
| I(1) | Supply Current | 30 | mA |
|  | Input Signals |  |  |
| $\mathrm{V}(9-16)(\mathrm{pp})$ | Synchro Separator Input Voltage | 3 to 4 | V |
| $\begin{gathered} \mathrm{V}(10-16) \\ (\mathrm{pp}) \end{gathered}$ | Noise Separators Input Voltage | 3 to 4 | V |
| $\begin{aligned} & V(4-16) \\ & V(4-16) \\ & V(4-16) \end{aligned}$ | Control Voltage of the Output Pulse Switching Circuit $\begin{aligned} & t=7 \mu \mathrm{~s} \text { (thyristor) } \\ & \mathrm{t}=14 \mu \mathrm{~s}+\mathrm{t}_{\mathrm{d}} \text { (transistor) } \\ & \mathrm{t}=0(\mathrm{~V}(3-16)=0) \end{aligned}$ | $\begin{gathered} 9.4 \text { to } V(1-15) \\ 0 \text { to } 3.5 \\ 54 \text { to } 5.6 \\ \hline \end{gathered}$ | $\begin{aligned} & V \\ & V \\ & V \\ & \hline \end{aligned}$ |
|  | Output Signals |  |  |
| V (8-16) (pp) | Frame Synchro Pulse | 11 | V |
| $\mathrm{V}(7-16)(\mathrm{pp})$ | Sandcastle Pulse | 11 | V |
| $\mathrm{V}(3-16)(\mathrm{pp})$ | Horizontal Driver Stage Control Puise | 10.5 | V |

## ABSOLUTE MAXIMUM RATINGS

Maximum Ratings According to CEI 134 Data Sheet

| Symbol | Parameter | Value | Unit |
| :---: | :--- | :---: | :---: |
| $V(1-16)$ | Supply Voltage to Pin 1 | 13.2 | V |
| $\mathrm{~V}(2-16)$ | Supply Voltage to Pin 2 | 18 | V |
| $\mathrm{~V}(4-16)$ | Voltage to Pin 4 | 13.2 | V |
| $\mathrm{~V}(9-16)$ | Voltage to Pın 9 | $\pm 6$ | V |
| $\mathrm{~V}(10-16)$ | Voltage to Pın 10 | $\pm 6$ | V |
| $\mathrm{~V}(11-16)$ | Voltage to Pin 11 | 132 | V |
| $\mathrm{I}_{2 \mathrm{M}}=-\mathrm{I}_{3 \mathrm{M}}$ | Current at Pıns 2 and 3 (with thyrıstor) | 650 | mA |
| $\mathrm{I}_{2 \mathrm{M}}=\mathrm{I}_{3 M}$ | Current at Pıns 2 and 3 (with transistor) | 400 | mA |
| $\mathrm{I}(4)$ | Current to Pın 4 | 1 | mA |
| $\mathrm{I}(6)$ | Current to Pin 6 | -10 | mA |
| $\mathrm{I}(7)$ | Current to Pın 7 | 2 | mA |
| $\mathrm{I}(11)$ | Current to Pin 11 | 800 | mA |
| $P_{\text {tot }}$ | Power Dissıpatıon | -20 to +70 | mW |
| $T_{\text {amb }}$ | Operatıng Ambient Temperature | -25 to +125 | ${ }^{\circ} \mathrm{C}$ |
| $T_{\text {stg }}$ | Storage Temperature |  | ${ }^{\circ} \mathrm{C}$ |

ELECTRICAL OPERATING CHARACTERISTICS
$\mathrm{T}_{\text {amb }}=25^{\circ} \mathrm{C}, \mathrm{V} 1-\mathrm{V} 16=12 \mathrm{~V}$ (unless otherwise specified).

## PACKAGE MECHANICAL DATA

16 PINS - PLASTIC DIP

## COMPLETE TV SOUND CHANNEL

The TDA3190 is a monolithic integrated circuit in a 16-lead dual in-line plastic package. It performs all the functions needed for the TV sound channel :

- IF LIMITER AMPLIFIER
- ACTIVE LOW-PASS FILTER
- FM DETECTOR
- DC VOLUME CONTROL
- AF PREAMPLIFIER
- AF OUTPUT STAGE

## DESCRIPTION

The TDA3190 can give an output power of 4.2 W ( $\mathrm{d}=10 \%$ ) into a $16 \Omega$ load at $\mathrm{V}_{\mathrm{s}}=24 \mathrm{~V}$, or 1.5 W ( $\mathrm{d}=10 \%$ ) into an $8 \Omega$ load at $\mathrm{V}_{\mathrm{S}}=12 \mathrm{~V}$. This performance, together with the FM-IF section characteristics of high sensitivity, high AM rejection and low distortion, enables the device to be used in almost every type of television receivers.
The device has no irradiation problems, hence no external screening is needed.
The TDA3190 is a pin to pin replacement of TDA1190Z.

PIN CONNECTIONS

## APPLICATION INFORMATION

The electrical characteristics of the TDA3190 remain almost constant over the frequency range 4.5 to 6 MHz , therefore it can be used in all television standards (FM mod.). The TDA3190 has a high input impedance, so it can work with a ceramic filter or with a tuned circuit that provide the necessary input selectivity.
The value of the resistors connected to pin 9, determine the AC gain of the audio frequency amplifier. This enables the desired gain to be selected in relation to the frequency deviation at which the output stage of the AF amplifier, must enter into clipping.

Capacitor C8, connected between pins 10 and 11, determines the upper cutoff frequency of the audio bandwidth. To increase the bandwidth the values of C8 and C7 must be reduced, keeping the ratio C7/C8 as shown in the table of fig. 16.
The capacitor connected between pin 16 and ground, together with the internal resistor of $10 \mathrm{~K} \Omega$ forms the de-emphasis network. The Boucherot cell eliminates the high frequency oscillations caused by the inductive load and the wires connecting the loudspeaker.

Figure 16 : Typical Application Circuit.

Figure 17 : P.C. Board and Component Layout of the Circuit Shown in Fig. 16 ( $1: 1$ scale).

## MOUNTING INSTRUCTION

The Rth j-amb of the TDA3190 can be reduced by soldering the GND pins to a suitable copper area of the printed circuit board (fig. 18) or to an external heatsink (fig. 19).
The diagram of figure 20 shows the maximum dissipable power Ptot and the Rth $j$-amb as a function of the side "l" of two equal square copper areas hav-
ing a thickness of $35 \mu$ ( 1.4 mils).
During soldering the pins temperature must not exceed $260{ }^{\circ} \mathrm{C}$ and the soldering time must not be longer than 12 seconds.

The external heatsink or printed circuit copper area must be connected to electrical ground.

Figure 18 : Example of P.C. Board Copper Area which is used as Heatsink.

## PAL/NTSC ONE-CHIP DECODER

- CHROMINANCE SIGNAL PROCESSOR
- LUMINANCE SIGNAL PROCESSING WITH CLAMPING
- HORIZONTAL AND VERTICAL BLANKING
- LINEAR TRANSMISSION OF INSERTED RGB SIGNALS
- LINEAR CONTRAST AND BRIGHTNESS CONTROL ACTING ON INSERTED AND MATRIXED SIGNALS
- AUTOMATIC CUT-OFF CONTROL
- NTSC HUE CONTROL

## DESCRIPTION

The TDA3562A is a monolithic IC designed as decode PAL and/or NTSC colour television standards and it combines all functions required for the identification and demodulation of PAL and NTSC signals.

## TV SOUND CHANNEL WITH DC CONTROLS

- INTERNAL VCR INPUT/OUTPUT SWITCHING
- 4W OUTPUT POWER INTO $16 \Omega$
- NO SCREENING REQUIRED
- HIGH SENSITIVITY
- EXCELLENT AM REJECTION
- LOW DISTORTION
- DC TONE/VOLUME CONTROLS
- THERMAL PROTECTION

## DESCRIPTION

The TDA4190 is a complete TV sound channel with DC tone and volume controls plus an internally switched VCR input/output. Mounted in a Powerdip $16+2+2$ package, the device delivers an output power of 4 W into $16 \Omega\left(\mathrm{~d}=10 \%, \mathrm{~V}_{\mathrm{s}}=24 \mathrm{~V}\right)$ or 1.5 W into $8 \Omega \quad\left(d=10 \%, V_{s}=12 V\right)$. Included in the TDA4190 are: IF amplifier limiter, active low-pass filter, AF preamplifier and power amplifier, turn-off muting, VCR switch, mute circuit and thermal protection.

High output, high sensitivity, excellent AM rejection and low distortion make the device suitable for use in TVs of almost every type. Further, no screening is necessary because the device is free of radiation problems.

APPLICATION INFORMATION (refer to the block diagram)

IF AMPLIFIER-LIMITER
It is made by six differential stages of 15 dB gain each so that an open loop gain of 90 dB is obtained.
While a unity DC gain is provided, the AC closed loop gain is internally fixed at 70dB that allows a typical input sensitivity of $50 \mu \mathrm{~V}$.
The differential output signal is single ended by a 20 dB gain amplifier that through a buffer stage, feeds the detector system.
Internal diodes protect the inputs against overloads.

- Pin 2 is the IF non-inverting input
- Pin 3 is decoupled by a capacitor to open the AC loop
- Pin 4 grounded by a capacitor, allows a typical sensitivity of $50 \mu \mathrm{~V}$. (see VCR facility too).

## LOW-PASS FILTER, FM DETECTOR AND AMPLIFIER

The IF signal is detected by converting the frequency modulation into amplitude modulation and then detecting it.
Since the available modulated signal is a square wave, a $40 \mathrm{~dB} /$ decade low-pass filter cuts its harmonics so that a sine wave can feed the two-resonances external network L1, C8 and C9.

This network defines the working frequency value, the amplitude of the recovered audio signal and its distortion at the highest frequency deviations.
The two resonances $\mathfrak{f 1}$ (series resonance) and $\mathfrak{f} 2$ (parallel resonance) can be computed respectively by :

$$
X_{C 9}=\frac{X_{\mathrm{L} 1} \cdot X_{\mathrm{C} 8}}{X_{\mathrm{L} 1}+\mathrm{X}_{\mathrm{C} 8}} \text { and } \mathrm{X}_{\mathrm{L} 1}=\mathrm{X}_{\mathrm{C} 8}
$$

The ratio of these frequencies defines the peak-topeak separation of the " S " curve :
$\frac{\mathrm{f} 2}{\mathrm{f1}}=\sqrt{1 \frac{\mathrm{C}_{9}}{\mathrm{C}_{8}}}$
A differential peak detector detects the audio frequency signal that amplified, reaches the deemphasis network R0; C11.
The AF amplifier can be muted (see turn-on and turn-off switch and VCR facility).

- Pin 7 is the output of the low-pass filter and one input of the differential peak detector
- Pin 8 is the other input of the differential peak detector
_ Pin 9 is used to provide the required deemphasis time constant by grounding it with C11. At this pin, the internal impedance of which is typically of $1.1 \mathrm{~K} \Omega$, is available the recovered audio signal as auxiliary output.

## VCR FACILITY

The deemphathized AF signal reaches the switch follower block can provide to change the impedance of its output depending on the VCR function required.
The switch follower is driven by the threshold sensor block. This one switches both the amplifier and the switch follower by sensing the voltage at pin 4.
When no voltage is forced at pin 4 the function of pin 10 is of VCR output with low impedance ; when the voltage at pin 4 is lower or higher than its quiescent value, the amplifier is muted and the impedance of pin 10 is switched to a high value for a proper VCR input operation.
Since pin 4 reaches also the inverting input of the IF amplifier-limiter, this one can be switched off two for best insulation of the pin 10 with the TV signal path.
So, the VCR facility followed this truth table :

| Mode | Vsw | or $V_{4}$ | Function <br> of Pin 10 | Impedance <br> of Pin 10 |
| :---: | :---: | :---: | :---: | :---: |
| Recording <br> Playback | $\leq 2 \mathrm{~V}$ | No One | Output | $\leq 100 \Omega$ |
| 8 V | $\leq 2 \mathrm{~V}$ | Input | $\geq 10 \mathrm{~K} \Omega$ |  |

The output signal available when operating during recording is not dependent from both the volume and tone controls while, during playback, the input signal can be regulated by P1 and P2.
Pin 10, as input, can accept until 1 VRMS of overload.

- Pin 4 is the VCR switch driver
- Pin 10 is the VCR input/output pin.

## DC TONE CONTROL

The same signal available or applied to pin 10, after a voltage to current converter, reaches, the DC Tone Control block. It operates, inside the 10 KHz bandwidth, by cutting the high audio frequencies with a variable slope of an RC network, by means of $P_{1}$
The maximum slope of the RC network is of 20 dB per decade and its pole is defined by :
$X_{C 11}=6.8 \mathrm{~K} \Omega$, typically.
Pin 11 - At this pin is tied the tone capacitor
Pin 12 - is the DC Tone Control input.

DC VOLUME CONTROL
After tone control regulation, the AF current signal reaches the DC volume control block, that controls its intensity. The normal control, for which the block has been designed for a narrow spread, is produced by P2 ; however, without P2, a voltage control can be operated by forcing a voltage at pin 13 through R8.

- Pin 12, already seen as a DCTC input, is the reference voltage for the DCVC. Because of this, a small interface between tone and volume regulation can be expected.
- Pin 13 is the DC volume control input.
- Pin 14 after a current to voltage converter, the audio frequency signal comes out a this pin.

## AUDIO FREQUENCY POWER AMPLIFIER AND THERMAL PROTECTION

Through C12 the signal reaches the amplifier noninverting input. The closed loop gain is. defined by
the feedback at pin 19 (inverting input) or by the ratio :

$$
\mathrm{G}_{\mathrm{v}}=20 \log \frac{\mathrm{R} 5+\mathrm{R} 4}{\mathrm{R} 5}(\mathrm{~dB})
$$

The amplifier, thermally protected, can supply 4 W of power into a $16 \Omega$ load with 24 V of supply voltage. The power output stage is a class $B$ type.

- Pin 20 is the non-inverting input
- Pin 19 is the inverting input
- Pin 17 is the output of the AFPA.

## TURN-ON AND TURN-OFF SWITCH

This block has been mainly designed to avoid, turning on the TV set, that transients, produced by the vision output, can reach the speaker.
Moreover this block, together an optimized rise time and full time of the supply voltage $\mathrm{V}_{\mathrm{s}}$, can avoid any pop generally produced during the turn-on and the turn-off transients.
Turning on, pin 1 follows the supply voltage $\mathrm{V}_{\mathrm{s}}$ by means of C 7 ; a threshold is reached and the muting of the AFPA output (pin 17) is suddenly produced.
When Vs reaches it stop, C7 charges itself through the input impedance of pin 1 and the muting is removed with a time constant depending on the C7 value.

Turning off, the $\mathrm{V}_{\mathrm{s}}$ trend, in series to the voltage VS - $\mathrm{V}_{1}$ and which C7 is charged, drives pin 1 at a low level threshold and a sudden muting is produced again.
Since the turn-off can be operated with high output power, if the muting operates when the current through the inductance of the speaker is different from zero, a flyback is generated and then a small pop can be produced.
The flyback is clipped by integrated diodes.
The threshold that produce the muting have been chosen in the way that 1 Vpp of ripple on the supply voltage does not produce any switching.
By shorting pin 1 to ground through a $10 \mathrm{~K} \Omega$ resistor the muting can be obtained.

- Pin 1 is the turn-on and turn-off muting input.

## SUPPLY

An integrated voltage regulator with different output levels, supplies all the blocks operating with small signal.

- Pin 18 is the main supply of the device.
- Pin 5 ; pin 6 ; pin 15 and pin 16 are the ground of the supply. These pins are used to drain out from the device the heat produced by the dissipated power.

Figure 16 : Application Circuit.

## TEST CIRCUIT

## APPLICATION INFORMATION (refer to the block diagram)

TV SIGNAL IDENTIFICATION CIRCUIT :
The circuit recognizes only TV signals by checking logically during one line the coincidence between the horizontal flyback pulse and the pulse detected by a sync. separator.
The signal identification is carried out by charging the capacitor connected to pin 5 ; when the capacitor voltage overcomes a fixed threshold voltage, a Schmitt trigger switches and enables the AFC control. If a TV signal is recognized, the capacitor is slightly charged every line and its voltage reaches the threshold after a number of line which is defined
by the value of the capacitor itself. The sensitivity of the identification circuit, hence the number of lines required to charge the capacitor, can be adjusted by means of the resistor connected between pin 11 and ground.
When the identification has been made, a signal (level L ) is available at pin 10.

## THRESHOLD CIRCUIT :

The circuit detects 3 ranges of AFC voltage and in combination with the TV signal identification circuit drives the electronic switches.

With a correct TV signal, the output levels corresponding to the 3 ranges are :

|  | TDA4433 |  |
| :--- | :---: | :---: |
|  | $\left(\mathbf{V}_{2}\right)$ | $\left(\mathbf{V}_{6}\right)$ |
| $\mathrm{f}_{\mathrm{o}}-\delta \mathrm{f}$ | H | L |
| $\mathrm{f}_{\mathrm{o}}$ | L | L |
| $\mathrm{f}_{\mathrm{o}}+\delta \mathrm{f}$ | L | H |

$L=$ Low level.
$H=$ High level.

The TDA4433 has two separate outputs which can have only two states, high (H) or low (L). The outputs at pin 2 and at pin 6 remain at a low level with no video signal input or with a video signal not identified as a true TV signal. Both pin 2 and pin 6 are open collector outputs and must be pulled-up to the positive supply voltage by external resistors.

## VOLTAGE REGULATOR

The circuit can deliver 1 mA and it can be used as D/A converter reference to supply fine tuning voltage.

## EPM SYSTEM CONFIGURATIONS

## PACKAGE MECHANICAL DATA

## 14 PINS - PLASTIC DIP

## MULTISTANDARD VIDEO IF AMPLIFIER

- SWITCHING OFF THE IF AMPLIFIER WHEN OPERATING IN VTR MODE
- DEMODULATION OF NEGATIVE OR POSITIVE IF SIGNALS. THE OUTPUT REMAINS ON THE SAME POLARITY IN EVERY CASE
- IF AGC AUTOMATICALLY ADJUSTED TO THE ACTUAL STANDARD
- TWO AGC POSSIBILITIES FOR B/G MODE : 1. GATED AGC

2. UNGATED AGC ON SYNC. LEVEL AND CONTROLLED DISCHARGE DEPENDENT ON THE AVERAGE SIGNAL LEVEL FOR VTR AND PERI TV APPLICATIONS
FOR STANDARD L : FAST AGC ON PEAK WHITE BY CONTROLLED DISCHARGE

- POSITIVE OR NEGATIVE GATING PULSE
- EXTREMELY HIGH INPUT SENSITIVITY
- LOW DIFFERENTIAL DISTORTION
- CONSTANT INPUT IMPEDANCE
- VERY HIGH SUPPLY VOLTAGE REJECTION
- FEW EXTERNAL COMPONENTS
- LOW IMPEDANCE VIDEO OUTPUT
- SMALL TOLERANCES OF THE FIXED VIDEO SIGNAL AMPLITUDE
- ADJUSTABLE, DELAYED AGC FOR PNP TUNERS

## DESCRIPTION

The TDA4443 is a Video IF amplifier with standard switch for multistandard colour or monochrome TV sets, and VTR's.

DIP16
(Plastic Package)
ORDER CODE : TDA4443

## PIN CONNECTIONS

## BLOCK DIAGRAM

## GENERAL DESCRIPTION

This video IF processing circuit integrates the following functional blocks :

- Three symmetrical, very stable, gain controlled wideband amplifier stages - without feedback by a quasi-galvanic coupling.
- Demodulator controlled by the picture carrier
- Video output amplifier with high supply voltage rejection
- Polarity switch for the video output signal
- AGC on peak white level
- Gated AGC
- Discharge control
- Delayed tuner AGC
- At VTR Reading mode the video output signal is at ultra white level

## ABSOLUTE MAXIMUM RATINGS

## DEFINITION OF MODE SWITCHING

| Status | Pin 2 | Pin 4 | Function |
| :---: | :--- | :--- | :--- |
| A | Not connected | No External Voltage | Standard B/G mode, gated charge and discharge. |
| B | 12 V <br> High Impedance | No External Voltage | Standard B/G, ungated, charging up to sync. level, discharging <br> dependant from average signal (peri operation). |
| C | 12 V <br> Low Impedance | No External Voltage | At standard L ungated, charging up to peak white level, <br> discharge dependant from average signal level, Inverted polarity <br> of the video output. |
| D | No specifications | $\geq 7.5 \mathrm{~V}$ | In VTR reading mode the IF amplifier is blocked, turned gain <br> controlled down : the video output signal is fixed at constant ultra <br> white level for standard B/G mode. |

The gating pulse at Pin 7 is internally switched off.
STATUS OF MODE SWITCHING, REFERRING TO CONTROL VOLTAGE PIN 2

| Control Voltage <br> Pin 2 | Connections of <br> Pin 2 | Status | Function |
| :---: | :--- | :---: | :--- |
| 1.2 to $2.5 \mathrm{~V}^{*}$ | Open | A | Standard B/G gated sync. operation |
| 3.0 to 5.0 V | High Impedance | B | Standard B/G, no sync., operation |
| $>6.5 \mathrm{~V}$ | Low Impedance | C | Standard L |
| 0.0 to 0.8 V | Ground | D | Standard L |

* Voltage measured on PIn 2

## PACKAGE MECHANICAL DATA

16 PINS - PLASTIC DIP

## SOUND IF AMPLIFIER

- QUADRATURE INTERCARRIER DEMODULATOR
- VERY HIGH INPUT SENSITIVITY
- GOOD SIGNAL TO NOISE RATIO
- FAST AVERAGING AGC
- IF AMPLIFIER CAN BE SWITCHED OFF FOR VTR MODE
- GOOD AM SUPPRESSION
- OUTPUT SIGNAL STABILIZED AGAINST SUPPLY VOLTAGE VARIATIONS
- VERY FEW EXTERNAL COMPONENTS

## DESCRIPTION

TDA4445A :
Sound IF amplifier, with FM processing for quasi parallel sound system.
TDA4445B :
Sound IF amplifier, with FM processing and AM demodulator, for multi-standard sound TV appliances.
TDA4445B additionnal :
Bistandard applications (B/G and L)
No adjustment of the AM demodulator
Low AM distortion

DIP16
(Plastic Package)
ORDER CODE : TDA4445A - TDA4445B

PIN CONNECTIONS

## BLOCK DIAGRAMS

## GENERAL DESCRIPTION

This circuit includes the following functions:

- Three symmetrical and gain controlled wide band amplifier stages, which are extremely stable by quasi DC coupling without feedback.
- Averaging AGC with discharge control circuit
- AGC voltage generator

Quasi parallel sound operation :

- High phase accuracy of the carrier signal pro-
cessing, independent from AM
- Linear quadrature demodulator
- Sound-IF-amplifier stage with impedance converter
AM-Demodulation (only TDA4445B) :
- Carrier controlled demodulator
- Audio frequency stage with impedance converter
- Averaging low pass AGC

## TYPICAL APPLICATION

Figure 2 : Bistandard Operation (FM stereo sound + AM sound).

PACKAGE MECHANICAL DATA : 16 PINS - PLASTIC DIP

## SINGLE CHIP STEREO CASSETTE PLAYBACK SYSTEM

ADVANCE DATA

- WIDE OPERATING SUPPLY VOLTAGE ( 1.8 V to 7 V )
- INPUT COUPLING WITHOUT CAPACITORS
- BUILT-IN DC STEREO VOLUME CONTROL
- BUILT-IN RIPPLE FILTERS
- LOW QUIESCENT CURRENT
- NO EXTERNAL BOUCHEROT CELL
- MAX OUTPUT CURRENT 70mA PEAK

## DESCRIPTION

The TDA7273 is a monolithic integrated circuit designed for portable cassette players market.
It comprises preamplifiers, DC volume control, and headphone drivers.

## DIGITAL CONTROLLED STEREO AUDIO PROCESSOR

- SINGLE SUPPLY OPERATION
- FOUR STEREO INPUT SOURCE SELECTION
- MONO INPUT
- TREBLE, BASS, VOLUME, AND BALANCE CONTROL
- FOUR INDEPENDENT SPEAKER CONTROL (FRONT/REAR)
- SINGLE SUPPLY OPERATION
- ALL FUNCTIONS PROGRAMMABLE VIA SERIAL BUS
- VERY LOW NOISE AND VERY LOW DISTORTION
- POP FREE SWITCHING

## DESCRIPTION

The TDA7300 is a volume, tone (bass and treble), balance (left/right) and fader (front/rear) proces-

> ORDERING NUMBERS:
> TDA7300
sor for high quality audio applications in car radio and Hi -Fi systems.
Control is accomplished by serial bus microprocessor interface.
The AC signal setting is obtained by resistor networks and analog switches combined with operational amplifiers.
The results are: low noise, low distortion and high dynamic range.

|  | Digital Input Current |  | -5 |  | +5 | $\mu \mathrm{~A}$ |

## Notes:

(1) The circuit can be supplied either at $\mathrm{V}_{\mathrm{S} 1}$ or without the use of the internal voltage regulator at $\mathrm{V}_{\mathrm{S} 2}$. The circuit also operates at a supply voltage $\mathrm{V}_{\mathrm{S} 1}$ lower than 10 V . In this case the ripple rejection of $\mathrm{V}_{\mathrm{S} 2}$ is valid, because the voltage regulator saturates to a saturation voltage of about 08 V .
(2) The selected input is grounded thru the $2.2 \mu \mathrm{~F}$ capacitor
(3) Bass and Treble response see attached diagram The center frequency and quality of the resonance behaviour can be choosen by the external circuitry. A standard first order bass response can be realized by a standard feedback network.

## APPLICATION INFORMATION

## Volume Control Concept

Traditional electronic volume control circuits use a multiplier technique with all the disadvantages of high noise and distortion.
The used concept, as shown in Fig. 15 with digital switched resistor dividers, provides extremely low noise and distortion. The multiplexing of the resistive dividers is realized with a multiple-input operational amplifier.

## Bass and Treble Control

The principle operation of the bass control is shown in Fig. 16. The external filter together with the internal buffer allows a flexible filter design according to the different requirements in car radios. The function of the treble is similar to the bass. A typical curve is shown in Fig.19.

## Outputs

A special class-A output amplifier with a modulated sink current provides low distortion and ground compatibility with low current consumption.

## APPLICATION INFORMATION (continued)

SERIAL BUS INTERFACE

## S-BUS Interface and $I^{2}$ CBUS Compatibility

Data transmission from microprocessor to the TDA7300 and viceversa takes place thru the 3wire S-BUS interface, consisting of the three lines SDA, SCL, SEN. If SDA and SEN inputs are short-circuited together, then the TDA7300 appears as a standard $I^{2}$ CBUS slave.
According to $1^{2}$ CBUS specification the S-BUS lines are connected to a positive supply voltage via pull-up resistors.

## Data Validity

As shown in fig. 21, the data on the SDA line must be stable during the high period of the clock. The HIGH and LOW state of the data line can only change when the clock signal on the SCL line is LOW.
Figure 21: Data Validity on the $I^{2} C B U S$

## Start and Stop Conditions

$1^{2}$ cBus:
as shown in fig. 22 a start condition is a HIGH to
Figure 22: Timing Diagram of S-BUS and $I^{2} C B U S$

LOW transition of the SDA line while SCL is HIGH. The stop condition is a LOW to HIGH transition of the SDA line while SCL is HIGH.
S-bus:
the start/stop conditions (points 1 and 6) are detected exclusively by a transition of the SEN line $(1 \rightarrow 0 / 0 \rightarrow 1)$ while the SCL line is at the HIGH level.
The SDA line is only allowed to change during the time the SCL line is low (points 2, 3, 4, 5). After the start information (point 1) the SEN line returns to the HIGH level and remains unchanged for all the time the transmission is performed.

## Byte Format

Every byte transferred on the SDA line must contain 8 bits. Each byte must be followed by an acknowledge bit. The MSB is transferred first.

## Acknowledge

The master ( $\mu \mathrm{P}$ ) puts a resistive HIGH level on the SDA line during the acknowledge clock pulse (see fig. 23). The peripheral (audioprocessor) that acknowledges has to pull-down (LOW) the SDA line during the acknowledge clock pulse, so that the SDA line is stable LOW during this clock pulse.
The audioprocessor which has been addressed has to generate an acknowledge after the reception of each byte, otherwise the SDA line remains at the HIGH level during the ninth clock pulse time. In this case the master transmitter can generate the STOP information in order to abort the transfer.

## APPLICATION INFORMATION (continued)

Figure 23: Acknowledge on the $I^{2}$ CBUS

## Transmission without Acknowledge

Avoiding to detect the acknowledge of the audioprocessor, the $\mu \mathrm{P}$ can use a simplier transmission: simply it waits one clock without checking the slave acknowledging, and sends the new data.
This approach of course is less protected from misworking and decreases the noise immunity.

## Interface Protocol

The interface protocol comprises:

- A start condition (S)
- A chip address byte, containing the TDA7300 address (the 8th bit of the byte must be 0 ). The TDA7300 must always acknowledge at the end of each transmitted byte.
- A sequence of data ( N -bytes + acknowledge)
- A stop condition (P)

ACK = Acknowledge
$\mathrm{S}=$ Start
$\mathrm{P}=$ Stop
MAX CLOCK SPEED 100kbits/s

C3 $=$ Sign
For example Bass at -12.5 dB is obtained by the following 8 bit string: 01100010 $1^{2} C$ Patent Rights to use these components in an $1^{2} C$ system, provided that the system conforms to the $I^{2} C$ Standard Specifications as defined by Philips.

## DIGITAL CONTROLLED STEREO AUDIO PROCESSOF

- INPUT AND OUTPUT PINS FOR EXTERNAL EQUALIZER
- THREE STEREO INPUT SOURCE SELECTION PLUS MONO INPUT
- TREBLE, BASS, VOLUME AND BALANCE CONTROL
- FOUR INDEPENDENT SPEAKER CONTROL (FRONT/REAR)
- SINGLE SUPPLY OPERATION
- ALL FUNCTIONS PROGRAMMABLE VIA SERIAL BUS
- VERY LOW NOISE AND VERY LOW DISTORTION
- POP FREE SWITCHING

## DESCRIPTION

The TDA7302 is a volume, tone (bass and treble), balance (left/right) and fader (front/rear) processor for high quality audio applications in car radio

## BLOCK DIAGRAM

and $\mathrm{Hi}-\mathrm{Fi}$ system.
Control is accomplished by serial bus microprocessor interface.
The AC signal setting is obtained by resistor networks and analog switches combined with operational amplifiers.
The results are: low noise, low distortion and high dynamic range.

## C3 = Sign

For example Bass at -12.5 dB is obtained by the following 8 bit string: 01100010

Purchase of $I^{2} C$ Components of SGS-THOMSON Microelectronics, conveys a license under the Philips $I^{2} \mathrm{C}$ Patent Rights to use these components in an $I^{2} \mathrm{C}$ system, provided that the system conforms to the $I^{2} C$ Standard Specifications as defined by Philips.

## DIGITAL CONTROLLED STEREO AUDIO PROCESSOR

ADVANCE DATA

- CONTROL IS ACCOMPLISHED BY MICROWIRE/SPI - COMPATIBLE SERIAL BUS INTERFACE
- INPUT AND OUTPUT PINS FOR EXTERNAL EQUALIZER
- THREE STEREO INPUT SOURCE SELECTION PLUS MONO INPUT
- TREBLE, BASS, VOLUME AND BALANCE CONTROL
- FOUR INDEPENDENT SPEAKER CONTROL (FRONT/REAR)
- SINGLE SUPPLY OPERATION
- VERY LOW NOISE AND VERY LOW DISTORTION
- POP FREE SWITCHING

## DESCRIPTION

The TDA7306 is a volume, tone (bass and treble),

balance (left/right) and fader (front/rear) processor for high quality audio applications in car radio and Hi -Fi systems.
The AC signal setting is obtained by resistor networks and analog switches combined with operational amplifiers.
The results are: low noise, low distortion and high dynamic range.

## APPLICATION INFORMATION

## Volume Control Concept

Traditional electronic volume control circuits use a multiplier technique with all the disadvantages of high noise and distortion.
The used concept, as shown in Fig. 12 with digital switched resistor dividers, provides extremely low noise and distortion. The multiplexing of the resistive dividers is realized with a multiple-input operational amplifier.

Figure 12: Volume Control

Bass and Treble Control
The principle operation of the bass control is shown in Fig. 13. The external filter together with the internal buffer allows a flexible filter design according to the different requirements in car radios. The function of the treble is similar to the bass. A typical curve is shown in Fig.14.

Figure 13: Bass Control

## APPLICATION INFORMATION (continued)

## Outputs

A special class-A output amplifier with a modu-
lated sink current provides low distortion and ground compatibility with low current consumption.

Figure 14: Typical Tone Response

Figure 15: Complete Car-Radio System using Digital Controlled Audio Processor

## APPLICATION INFORMATION (continued)

SERIAL BUS INTERFACE
The serial bus interface is compatible to MICROWIRE and SPI bus systems.
During the LOW state of the chip enable signal (CE) the data on pin DA are clocked into the shift register at the LOW to HIGH transition of the clock signal CL.
At the LOW to HIGH transition of the CE signal the content of the internal shift register is stored into the addressed latches.

The transmission is separated into bytes with 8 bit according to the data specification of the audioprocessor. After every byte a positive slope of the CE signal has to be generated in order to store the data byte.
A special clock counter enables the latch of the data byte only, if exactly 8 clocks were present during the LOW state of the CE signal. This results in a high immunity against spikes on the clock line and avoids a storage of wrong databytes.

Figure 16: BUS Timing

| Nr. | Parameter | Min. | Max. | Units |

For example if you want setting the volume at -25.6 dB the 8 bit string is: 00100001
SPEAKER ATTENUATORS

For example attenuation of 20dB on speaker RF is given by: 10110010

SOFTWARE SPECIFICATION (continued)
AUDIO SWITCH - Select the input Channel to Activate

$X=$ don't care
For example to set the stereo 2 channel the 8 bit string must be: 01000001

BASS AND TREBLE - Control Range of $\pm 15 \mathrm{~dB}$ (boost and cut) Steps of 2.5 dB

C3 $=$ Sign
For example Bass at -12.5 dB is obtained by the following 8 bit string: 01100010

## DIGITAL CONTROLLED STEREO AUDIO PROCESSOR

ADVANCE DATA

- INPUT MULTIPLEXER:
- 4 STEREO INPUTS
- SELECTABLE INPUT GAIN FOR OPTIMAL ADAPTION TO DIFFERENT SOURCES
- INPUT AND OUTPUT FOR EXTERNAL EQUALIZER OR NOISE REDUCTION SYSTEM
- VOLUME CONTROL IN 1.25dB STEPS
- TREBLE AND BASS CONTROL
- FOUR SPEAKER ATTENUATORS:
- 4 INDEPENDENT SPEAKERS CONTROL IN 1.25dB STEPS FOR BALANCE AND
FADER FACILITIES
- INDEPENDENT MUTE FUNCTION
- ALL FUNCTIONS PROGRAMMABLE VIA SERIAL ${ }^{2}$ CBUS

## DESCRIPTION

The TDA7318 is a volume, tone (bass and treble) balance (Left/Right) and fader (front/rear) processor for quality audio applications in car radio and $\mathrm{Hi}-\mathrm{Fi}$ systems.

Selectable input gain is provided. Control is accomplished by serial $I^{2} \mathrm{C}$ bus microprocessor interface. The AC signal setting is obtained by resistor networks and switches combined with operational amplifiers.
Thanks to the used BIPOLAR/CMOS Tecnology, Low Distortion, Low Noise and Low DC stepping are obtained.

## $I^{2} C$ bus interface

Data transmission from microprocessor to the TDA7318 and viceversa takes place thru the 2 wires $I^{2} \mathrm{C}$ BUS interface, consisting of the two lines SDA and SCL (pull-up resistors to positive supply voltage must be connected).

## Data Validity

As shown in fig. 14, the data on the SDA line must be stable during the high period of the clock. The HIGH and LOW state of the data line can only change when the clock signal on the SCL line is LOW.

## Start and Stop Conditions

As shown in fig. 15 a start condition is a HIGH to LOW transition of the SDA line while SCL is HIGH. The stop condition is a LOW to HIGH transition of the SDA line while SCL is HIGH.

## Byte Format

Every byte transferred on the SDA line must contain 8 bits. Each byte must be followed by an ac-
knowledge bit. The MSB is transferred first.

## Acknowledge

The master ( $\mu \mathrm{P}$ ) puts a resistive HIGH level on the SDA line during the acknowledge clock pulse (see fig. 16). The peripheral (audioprocessor) that acknowledges has to pull-down (LOW) the SDA line during the acknowledge clock pulse, so that the SDA line is stable LOW during this clock pulse.
The audioprocessor which has been addressed has to generate an acknowledge after the reception of each byte, otherwise the SDA line remains at the HIGH level during the ninth clock pulse time. In this case the master transmitter can generate the STOP information in order to abort the transfer.

## Transmission without Acknowledge

Avoiding to detect the acknowledge of the audioprocessor, the $\mu \mathrm{P}$ can use a simplier transmission: simply it waits one clock without checking the slave acknowledging, and sends the new data.
This approach of course is less protected from misworking and decreases the noise immunity.

Figure 16: Acknowledge on the $\mathrm{I}^{2} \mathrm{CBUS}$

## SOFTWARE SPECIFICATION

## Interface Protocol

The interface protocol comprises:

- A start condition (s)
- A chip address byte, containing the TDA7318
address (the 8th bit of the byte must be 0 ). The TDA7318 must always acknowledge at the end of each transmitted byte.
- A sequence of data ( N -bytes + acknowledge)
- A stop condition (P)

TDA7318 ADDRESS

Data Transferred (N-bytes + Acknowledge)
ACK = Acknowledge
S = Start
$\mathrm{P}=$ Stop
MAX CLOCK SPEED 100kbits/s

## SOFTWARE SPECIFICATION

## Volume

| MSB |  |  |  |  |  |  | $\begin{aligned} & \text { LSB } \\ & \hline \text { AO } \\ & \hline \end{aligned}$ | FUNCTION |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | B2 | B1 | B0 | A2 | A1 |  | Volume 1.25dB steps |
|  |  |  |  |  | $\begin{aligned} & \hline 0 \\ & 0 \\ & 0 \\ & 0 \\ & 1 \\ & 1 \\ & 1 \\ & 1 \end{aligned}$ | $\begin{aligned} & 0 \\ & 0 \\ & 1 \\ & 1 \\ & 1 \\ & 0 \\ & 0 \\ & 1 \\ & 1 \end{aligned}$ | $\begin{aligned} & 0 \\ & 1 \\ & 1 \\ & 0 \\ & 1 \\ & 0 \\ & 1 \\ & 1 \\ & 0 \\ & 1 \end{aligned}$ | $\begin{gathered} \hline 0 \\ -1.25 \\ -2.5 \\ -3.75 \\ -5 \\ -6.25 \\ -7.5 \\ -8.75 \end{gathered}$ |
| 0 | 0 | B2 | B1 | B0 | A2 | A1 | A0 | Volume 10dB steps |
|  |  | $\begin{aligned} & \hline 0 \\ & 0 \\ & 0 \\ & 0 \\ & 1 \\ & 1 \\ & 1 \\ & 1 \\ & 1 \end{aligned}$ | $\begin{aligned} & \hline 0 \\ & 0 \\ & 1 \\ & 1 \\ & 0 \\ & 0 \\ & 1 \\ & 1 \end{aligned}$ | $\begin{aligned} & \hline 0 \\ & 1 \\ & 0 \\ & 1 \\ & 1 \\ & 0 \\ & 1 \\ & 0 \\ & 1 \end{aligned}$ |  |  |  | $\begin{gathered} 0 \\ -10 \\ -20 \\ -30 \\ -40 \\ -50 \\ -50 \\ -60 \\ -70 \end{gathered}$ |

For example a volume of -45 dB is given by:
00100100

## Speaker Attenuators

For example attenuation of 25 dB on speaker RF is given by:
10110100

Audio Switch

| MSB |  |  |  |  |  |  | $\begin{gathered} \hline \text { LSB } \\ \hline \text { SO } \\ \hline \end{gathered}$ | FUNCTION |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | 0 | G1 | G0 | S2 | S1 |  | Audio Switch |
|  |  |  |  |  | $\begin{aligned} & 0 \\ & 0 \\ & 0 \\ & 0 \\ & 1 \\ & 1 \\ & 1 \\ & 1 \\ & \hline \end{aligned}$ | $\begin{aligned} & 0 \\ & 0 \\ & 1 \\ & 1 \\ & 0 \\ & 0 \\ & 0 \\ & 1 \\ & 1 \end{aligned}$ | $\begin{aligned} & 0 \\ & 1 \\ & 0 \\ & 1 \\ & 0 \\ & 1 \\ & 0 \\ & 1 \end{aligned}$ | Stereo 1 <br> Stereo 2 <br> Stereo 3 <br> Stereo 4 <br> Not allowed <br> Not allowed <br> Not allowed <br> Not allowed |
|  |  |  | 0 <br> 0 <br> 1 <br> 1 | 0 1 0 1 |  |  |  |  |

For example to select the stereo 2 input with a gain of +12.5 dB the 8 bit string is:
01001001

Bass and Treble

C3 = Sign
For example Bass at -10 dB is obtained by the following 8 bit string:
01100010

Purchase of $\mathrm{I}^{2} \mathrm{C}$ Components of SGS-THOMSON Microelectronics, conveys a licence under the Philips $1^{2} \mathrm{C}$ Patent Rights to use these components in an $I^{2} \mathrm{C}$ system, provided that the system conforms to the $I^{2} C$ Standard Specifications as defined by Philips.

## H/V PROCESSOR FOR TTL V.D.U

## HORIZONTAL SECTION

- SYNCHRONIZATION INPUT : TTL COMPATIBLE, NEGATIVE EDGE TRIGGERED
- SYNCHRONIZATION INDEPENDENT FROM DUTY CYCLE TIME
- OSCILLATOR : FREQUENCY RANGE FROM 15 kHz to 100 kHz
- HORIZONTAL OUTPUT PULSE SHAPER AND SHIFTER
- PHASE COMPARATOR BETWEEN SYNCHRO AND OSCILLATOR (PLL1)
- PHASE COMPARATOR BETWEEN FLYBACK AND OSCILLATOR (PLL2)
- INTERNAL VOLTAGE REGULATOR
- DC COMPATIBLE CONTROLS FOR PHASE AND FREQUENCY

## VERTICAL SECTION

- SYNCHRONIZATION INPUT : TTL COMPATIBLE, NEGATIVE EDGE TRIGGERED
- SYNCHRONIZATION INDEPENDENT FROM DUTY CYCLE TIME
- OSCILLATOR : FREQUENCY RANGE FROM 30 Hz to 120 Hz
- RAMP GENERATOR WITH VARIABLE GAIN STAGE
- VERTICAL RAMP VOLTAGE REFERENCE
- INTERNAL VOLTAGE REGULATOR
- DC COMPATIBLE CONTROLS FOR FREQUENCY, AMPLITUDE AND LINEARITY

## DESCRIPTION

The TDA8102B is a monolithic integrated circuit for horizontal and vertical sync processing in monochrome and color video displays driven by input TTL compatible signals.

The TDA8102B is supplied in a 20 pin dual in line package with pin 11 connected to ground and used for heatsinking.

## ELECTRICAL CHARACTERISTICS

( $\mathrm{T}_{\text {amb }}=25^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{S}}=12 \mathrm{~V}$, refer to the test circuits, unless otherwise specified)
VERTICAL SECTION (continued)

| Symbol | Parameter | Test conditions | Min. | Typ. | Max. | Unit |
| :---: | :--- | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{19}$ | Voltage reference at Pın 19 | (See technical note 5 ) | 7.6 | 8 | 8.2 | V |
| $\left\|\mathrm{I}_{19}\right\|$ | Current at Pın 19 |  |  |  | 2 | mA |
| $\mathrm{~K}_{17}$ | Frequency drift versus supply voltage $\mathrm{K}_{17}=\frac{\mathrm{dF} \cdot 10^{6}}{\mathrm{dV} \cdot \mathrm{fV}^{6}}$ | $\mathrm{~V}_{\mathrm{S}}=10.5 \mathrm{~V}$ to 15.5 V |  |  | 4500 | ppm |

## Technical note 1:

$\mathrm{f}_{\mathrm{H}(\mathrm{nom})}=26.8 \mathrm{kHz}$
$\mathrm{R} 1=6.8 \mathrm{k} \Omega$
$\mathrm{R} 2=56 \mathrm{k} \Omega$
$\mathrm{C} 2=1.8 \mathrm{nF}$
$f_{\text {pull-In }}=f_{H}$ (nom) $\frac{\left|V_{3}-V_{1}\right| / R 2}{V_{1} / R 1}=f_{H(\text { nom })} \frac{I_{f}}{I_{0}}$
where: $\mathrm{V}_{1}=3.5 \mathrm{~V}$ and $\left|\mathrm{V}_{3}-\mathrm{V}_{1}\right|$ is the control voltage range.
The voltage at Pin 3 is limited by two clamping diodes at the voltage $V_{3 H}$ and $V_{3 L}$
When the PLL1 is synchronized and perfectly tuned, $\mathrm{V}_{3}=\mathrm{V}_{1}$.

Remark: The value of C 2 influences the horizontal oscillator free running frequency; it doesn't effect the pull-in range. If the horizontal frequency is changed by using R1, the pull-in range changes accordingly with the formula (A).

## Technical note 2

The internal pulse "t5", is generated by the current generator "Is" charging the external capacitor "C5", according with the formula (B):
$t_{5}=\frac{C 5 \cdot V_{5}}{I_{5}}$
$t_{5}=\frac{T_{H}}{12}$ is recommended.

## Technical note 3:

$\mathrm{K}_{9}=67.5$ degrees/volt represents the slope of the oscillator charging period of the waveform at
Pin 2:
$K_{9}=\frac{360 \times 0.75}{4} \quad \frac{\text { degree }}{V}$

## Technical note 4:

The second PLL can recover the storage of horizontal output stage maintaining a constant duty cycle till the trailing edge of the output pulse gets the trailing edge of the flyback pulse. From this point on, only the leading edge of the output pulse will be shifted covering a total phase shift of: 0.30T; overcoming this value, it will produce a notch in the output pulse ( $@ \mathrm{f}_{\mathrm{H}}=27 \mathrm{kHz}$ ).

## Technical note 5:

The voltage reference at Pin 19 can be used to polarize the DC operating point of the vertical booster. This voltage corresponds to the double of the mean value voltage of the vertical sawtooth at Pin 13.

## Technical note 6:

$\frac{V_{H}-V_{L}}{t_{s}}=\frac{V_{H}-V_{L L}}{1 / f_{V}}$
$t_{S}=\frac{\left(V_{H}-V_{L}\right)}{\left(V_{H}-V_{L L}\right)} \frac{1}{f_{V}}=\frac{K_{14}}{f_{V}}$

## PACKAGE MECHANICAL DATA

## 20 PINS - PLASTIC DIP

## CONTROL HEAD PLAYBACK \& RECORD AMPLIFIER AND SIGNALS INTERFACE

- CONTROL HEAD PLAYBACK AMPLIFIER WITH AGC
- CONTROL HEAD RECORD AMPLIFIER WITH SINK/SOURCE OUTPUT STAGE
- CONTROL PLAY-BACK SIGNAL INVERTER
- 4 COMPARATORS WITH INTERNAL 'FIXED THRESHOLD (2.5V)
- COMPARATORS WITH GROUND/Vs COMPATIBLE INPUTS AND OPEN COLLECTOR OUTPUTS

## DESCRIPTION

The TDA8118 is a bipolar integrated circuit for VCR application. It is intended to process the CTL-signal in record and playback mode. An internal AGC provides a wide range of input signal level. 5 further internal hysteresis comparators are intended to convert signals from optical and hall sensors to, TTL-level.

- VERY LOW DIFFERENTIAL ERROR
- VERY LOW PHASE ERROR
- INTERNAL AGC SWITCH (B/G - L)
- AGC TOP. SYNCH. FOR STANDARD B/G
- AGC TOP WHITE FOR STANDARD L
- QUASI SPLIT SOUND FOR STANDARD B/G
- SOUND DETECTOR FOR STANDARD L
- VIDEO MUTING FACILITY
- SEPARATED SOUND OUTPUT
- OPERATES WITHOUT EXTERNAL GATING PULSE

## DESCRIPTION

The TDA8120B is a monolithic IC for TV video IF and Sound IF amplification and demodulation that can operate with all the TV standards.
The Video IF section can handle negative $(B / G)$ or positive (L) modulated video signals by means of DC switching.

The Sound IF section acts as a Quasi Split Sound (QSS) subsystem in B/G transmission and allows a second Sound IF with high rejection of the video information.

The DC switch can modify the Sound IF configuration to process AM modulated Sound signals (L). The TDA8120B is assembled in a 24 pin dual in line power package.

DIP24
(Plastic Package)

## TEST CIRCUIT

## CIRCUIT OPERATION

The TDA8120B (see block diagram) consists of a video section and a sound section. The integration of both sections on the same chip requires a high isolation at IF frequencies. This is achieved by physically separating the two sections, with separate power supplies and ground pins. In addition, special care has been taken in the choice of pad positions for the IF inputs and sound/video outputs.
The video section consists of three AC-coupled IF stages with more than 60 dB AGC range, flat amplitude/frequency response from 10 to 85 MHz and linearized phase slope from 30 to 50 MHz . Video carrier regeneration is performed by a tuned limiter. The carrier is then applied to the video demodulator through a special circuit which switches the carrier phase from 0 to $180^{\circ}$ so that the video polarity can be maintained constant when the standard switches from $B / G$ to $L$. A noise inverter and a white spot inverter are included to eliminate ultra-black and white pulses.
A top sync or a top white clamping circuit and a minimum DC video component detector are implemented by two double comparators the characteristics of which may be controlled by an external control input to adapt to the modulation type for each standard. The voltage at the output of the two comparators is memorized by an external capacitor and used to drive the AGC network, which allows an input regulation of the video carrier from less than $100 \mu \mathrm{~V}$ to 100 mV . A delayed control storage with
current output for the turner AGC completes the video section.

The sound section consists of three IF stages with the same characteristics as the video IF stages and an identical network to control and set the gains of the three IF amplifiers. The output of the third IF stage feeds the AM/AGC detector and the QSS section.

The AM/AGC detector consists of a wideband limiter for AM sound regeneration or video carrier regeneration used to feed the synchronous multiplier and consequently to obtain the AM demodulated audio signal. In addition, a DC voltage proportional to the peak-to-peak value of the video carrier is produced. Two comparators complete the sound AGC loop.

The subsequent QSS section consists of a reference amplifier tuned to the video IF which buffers a wideband limiter to reject completely the video AM information without introducing incidental phase modulation (IPM).
Following the limiter there are a $90^{\circ}$ phase shifter and a linear-to-logarithmic converter which drives a linear multiplier as a demodulator for the intercarrier 2nd sound IF. This quadrature multiplier rejects all video components transmitted in DSB that is low frequency components of the video signal.

In addition to the sound and video sections, the TDA8120B includes a block for standard switching ( $\mathrm{B} / \mathrm{G}$ or L ) controlled by a TTL-compatible input.

PACKAGE MECHANICAL DATA : 24 PINS - PLASTIC DIP

## MULTISTANDARD VIDEO IF SYSTEM

ADVANCE DATA

- MULTISTANDARD VIDEO IF (POSITIVE AND NEGATIVE MODULATION)
- WHITE SPOT INVERTER AND NOISE SUPPRESSOR
- HIGH INPUT SENSITIVITY
- VERY LOW SENSITIVITY OF VISION OUTPUT AMPLITUDE VERSUS TEMPERATURE AND VCC
- VERY LOW DIFFERENTIAL PHASE AND GAIN
- VERY LOW SENSITIVITY TO THE DETUNING OF THE IF VIDEO CARRIER
- HIGH STABILITY OF THE TUNER AGC CURRENT

## DESCRIPTION

The TDA8123A is a multistandard $B / G$ and $L$ video IF demodulator consisting of three AC coupled IF stages with more than 60dB AGC range, flat amplitude/frequency response from 10 to 85 MHz and linearized phase slope from 30 to 50 MHz .
Video carrier regeneration is performed by a tuned reference amplifier and a wide band limiter increasing the linearity, the differential phase and gain and reducing the sensitivity to the detuning of the 38.9 MHz coil.

The carrier is then applied to the video demodulator through a special circuit which switches the carrier phase from $0^{\circ}$ to $180^{\circ}$ so that the video polarity can be maintained constant when the standard switches from $B / G$ to $L$.
A noise inverter and a white spot inverter are included in order to eliminate ultra-black and white pulses. The last one can be disabled applying a voltage higher than 2 V at Pin7.
The video output is applied also to the AGC circuit that performs a top sync or a top white clamp, implemented by two double comparators, and reconstructs the DC video components in accordance with the two different standards. The voltage at the output of the two comparators is memorized by an external capacitor and used to drive the AGC network, which allows an input regulation of the video carrier from less than $100 \mu \mathrm{~V}$ to 100 mV .
The integrated circuit is completed by a delayed
control storage with current output for the tuner AGC. This current has a very low sensitivity to temperature variations.
The TDA8123A includes also a block for the standard switching (standard $\mathrm{B} / \mathrm{G}$ or standard L ) controlled by a TTL compatible input.

## MULTISTANDARD VIDEO IF INTERFACE

PRELIMINARY DATA

- AUTOMATIC IDENTIFICATION OF PICTURECARRIER MODULATION POLARITY
- VIDEO SIGNAL IDENTIFICATION (FOR SOUND MUTING)
- ANALOG AND DIGITAL A.F.C. FOR STOP TUNING FUNCTION
- PICTURE CARRIER DETECTION IN A RANGE OF 1 MHz AROUND THE IF-PICTURE CARRIER VALUE

## DESCRIPTION

The TDA8124 has been developed in order to permit automatic standard switching and tuning when coupled with a multistandard VIDEO IF IC (for example TDA8120). It contains an A.F.C. synchronous demodulator and an A.F.C. comparator, a video polarity identification circuit with logic and a video signal identification system.

## GENERAL DESCRIPTION

The TDA8128 extracts the composite and verrtical sync signals from a video input signal with a negative going horizontal sync pulse.
By means of an internal monostable, the beginning of the vertical sync is triggered by the rising edge of the first serration in the vertical sync period.

The device also provides information when the input signal is not a true video signal or if its amplitude is below a certain limit.
The output stages are supplied by an internal reference voltage so that no external pull-up resistors are needed.

CIRCUIT DESCRIPTION (see the block diagram)

The infrared light received from D1 generates an AC signal that comes in to the device at pin 5 . The capacitor C 1 and the integrated $10 \mathrm{~K} \Omega$ resistor ( pin 4 ) filter out the low frequency noise.
The first stage shows a voltage gain of about 28 dB ; the second stage is a voltage to current converter
of $50 \mathrm{~mA} / \mathrm{V}\left(\mathrm{R}_{2}=\right.$ Zero $)$. A sensitive peak detector detects the amplifier signal ; one open collector output (pin 1) gives out the recovered pulses.

Figure 1: Recommended Application Circuit for the Drive of the IC M491 by Means of a Flash Mode IR. Transmitter only, in a TV 16 Station Memory Remote Control Subsystem.
The Above Shown IR Receiver Application must be Housed Inside a Metal Can Shield.

## INFRARED REMOTE CONTROL RECEIVER

ADVANCE DATA

- LOW SUPPLY VOLTAGE $\left(\mathrm{V}_{s}=5 \mathrm{~V}\right)$
- LOW CURRENT CONSUMPTION ( $1 \mathrm{~s}=4 \mathrm{~mA}$ )
- INTERNAL 5.5V SHUNT REGULATOR
- INPUT STAGE WITH GOOD REJECTION AT LOW FREQUENCY
- SELECTIVE AMPLIFIER
- LARGE INPUT DYNAMIC RANGE
- HIGH INPUT SENSITIVITY
- A.G.C. FACILITY

## DESCRIPTION

The TDA8162 is a monolithic integrated circuit in 14lead dual in line plastic package specially designed to amplify the infrared signals in remote controlled TV, Radio or VCR sets.
It is properly designed to work in "CARRIER" transmission mode and the open collector output allows direct operation with dedicated remote control circuit (for example M206) or microprocessor systems ST6 Family).

## PIN CONNECTION

## BLOCK DIAGRAM

The infrared light received from D1 generates an alternate current that, through the transistor T 1 , comes into the device at pin 7 .

The capacitor C1 and an internal network filter out the low frequency noise.
The first stage, the gain of which is controlled by AGC, shows a maximum voltage gain of about 30 dB .
The second stage is a selective amplifier (the frequency is generally included between 30 kHz and 40 kHz ), with an voltage gain of about 50 dB , loaded by Lo, Co.

A sensitive peak detector detects the amplified signal, two open collector outputs (pin 1, 2) allow positive and negative signals respectively.

The recovered signal drives the AGC block that controls the gain of the first stage when too strong signal is received.

This block (AGC) is a block at fast charge and slow discharge.

The detected information can be reshaped by connecting a suitable capacitor at pin 3 ; in such a way the carrier is integrated and the outputs become square wawes that can directly drive one microprocessor (avoiding a digital filter otherwise needed).

A voltage Regulator is also integrated, when you use a 5 V of alimentation, this regulator is automatically disabled.

## ELECTRICAL CHARACTERISTICS

Refer to the test circuit ; S1 to "a" ; Vss = 12V ; Vs $=5 \mathrm{~V}$; fo $=38.43 \mathrm{kHz}$,

| $\mathrm{~V}_{22}$ | Flyback Threshold Input |  |  | 5.7 |  | V |
| $\mathrm{I}_{22}$ | Flyback Current Input |  | 0.1 |  |  | mA |

Notes: 1. With $t_{\text {fly }}=12 \mu \mathrm{~s}$ and $\mathrm{t}_{\mathrm{t}}=29 \mu \mathrm{~s}$.
2. The TDA8185 may be operated on a 5 V supply directly. A 5.5 V shunt regulator is avalable internally for operation on higher supply voltage; in this case an external limiting resistor is required.
Without the external limiting resistor care must be taken to ensure that the supply voltage does not exceed 5.5 V or the regulator will intervene and the decice could be damaged.

## PACKAGE MECHANICAL DATA

## 24 PINS - PLATIC DIP

## TV SOUND CHANNEL WITH DC CONTROLS

- SEPARATE VCR INPUT AND OUTPUT PINS
- 4W OUTPUT POWER INTO $16 \Omega$
- NO SCREENING REQUIRED
- HIGH SENSITIVITY
- EXCELLENT AM REJECTION
- LOW DISTORTION
- DC TONE/VOLUME CONTROLS
- THERMAL PROTECTION

## DESCRIPTION

The TDA8190 is a complete TV sound channel with DC tone and volume controls plus separate VCR input and output connections. Mounted in a Powerdip $16+2+2$ package, the device delivers an output power of 4 W into $16 \Omega\left(\mathrm{~d}=10 \%, \mathrm{~V}_{\mathrm{s}}=24 \mathrm{~V}\right)$ or 1.5 W into $8 \Omega\left(\mathrm{~d}=10 \%, \mathrm{~V}_{\mathrm{s}}=12 \mathrm{~V}\right)$. Included in the TDA8190 are : IF amplifier limiter, active lowpass filter, AF pre-amplifier and power amplifier, turn-off muting, mute circuit and thermal protection. High output, high sensitivity, excellent AM rejection and low distortion make the device suitable for use in TVs of almost every type. Further, no screening is necessary because the device is free of radiation problems.

## APPLICATION INFORMATION (refer to the block diagram)

## IF AMPLIFIER-LIMITER

It is made by six differential stages of 15 dB gain each so that an open loop gain of 90 dB is obtained.
While a unity DC gain is provided, the AC closed loop gain is internally fixed at 70 dB that allows a typical input sensitivity of $50 \mu \mathrm{~V}$.
The differential output signal is single ended by a 20dB gain amplifier that through a buffer stage, feeds the detector system.
Internal diodes protect the inputs against overloads.

- Pin 2 is the IF non-inverting input
- Pin 3 is decoupled by a capacitor to open the AC loop
- Pin 4 grounded by a capacitor, allows a typical sensitivity of $50 \mu \mathrm{~V}$. (see VCR facility too).

## LOW-PASS FILTER, FM DETECTOR AND AMPLIFIER

The IF signal is detected by converting the frequency modulation into amplitude modulation and then detecting it.
Since the available modulated signal is a square wave, a $40 \mathrm{~dB} /$ decade low-pass filter cuts its harmonics so that a sine wave can feed the two-resonances external network L1, C8 and C9.
This network defines the working frequency value, the amplitude of the recovered audio signal and its distortion at the highest frequency deviations.
The two resonances f 1 (series resonance) and f 2 (parallel resonance) can be computed respectively by :
$X_{C 9}=\frac{X_{L 1} \cdot X_{C 8}}{X_{L 1}+X_{C 8}}$ and $X_{L 1}=X_{C 8}$
The ratio of these frequencies defines the peak-topeak separation of the " S " curve :
$\frac{\mathrm{f}_{2}}{\mathrm{f}_{1}}=\sqrt{1+\frac{\mathrm{C}_{9}}{\mathrm{C}_{8}}}$
A differential peak detector detects the audio frequency signal that amplified, reaches the deemphasis network R0; C11.
The AF amplifier can be muted (see turn-on and turn-off switch and VCR facility).

- Pin 7 is the output of the low-pass filter and one input of the differential peak detector
- Pin 8 is the other input of the differential peak detector
- $\operatorname{Pin} 9$ is used to provide the required deemphasis time constant by grounding it with C11. At this pin, the internal impedance of which is typically of 1.1 K , is available the recovered audio signal as auxiliary output.

## DC TONE CONTROL

The same signal available or applied to pin 10 , after a voltage to current converter, reaches, the DC Tone Control block. It operates, inside the 10 KHz bandwidth, by cutting the high audio frequencies with a variable slope of an RC network, by means of $P_{1}$.
The maximum slope of the RC network is of 20 dB per decade and its pole is defined by:
$X_{C 11}=6.8 \mathrm{~K}$, typically.
Pin 11 - At this pin is tied the tone capacitor.
Pin 12 - Is the DC Tone Control input.

## DC VOLUME CONTROL

After tone control regulation, the AF current signal reaches the DC volume control block that controls its intensity. The normal control, for which the block has been designed for a narrow spread, is produced by P2 ; however, without P2, a voltage control can be operated by forcing a voltage at pin 13 through R8.

- Pin 12, already seen as a DCTC input, is the reference voltage for the DCVC. Because of this, a small interface between tone and volume regulation can be expected.
- Pin 13 is the DC volume control input.
- Pin 14 after a current to voltage converter, the audio frequency signal comes out at this pin.

## AUDIO FREQUENCY POWER AMPLIFIER AND THERMAL PROTECTION

Through C12 the signal reaches the amplifier noninverting input. The closed loop gain is defined by the feedback at pin 19 (inverting input) or by the ratio

$$
\begin{equation*}
\mathrm{G}_{\mathrm{v}}=20 \log \overline{R 5+\mathrm{R} 4} \mathrm{R5} \tag{dB}
\end{equation*}
$$

The amplifier, thermally protected, can supply 4 W of power into a 16 load with 24 V of supply voltage. The power output stage is a class B type.

- Pin 20 is the non-inverting input
- Pin 19 is the inverting input
- Pin 17 is the output of the AFPA.

## TURN-ON AND TURN-OFF SWITCH

This block has been mainly designed to avoid, turning on the TV set, that transients, produced by the vision output, can reach the speaker.
Moreover this block, together an optimized rise time and full time of the supply voltage $\mathrm{V}_{\mathrm{s}}$, can avoid any pop generally produced during the turn-on and the turn-off transients.
Turninig on, pin 1 follows the supply voltage $\mathrm{V}_{\mathrm{s}}$ by means of C 7 ; a threshold is reached and the muting of the AFPA output (pin 17) is suddenly produced.
When $\mathrm{V}_{\mathrm{s}}$ reaches it stop, C 7 charges itself through the input impedance of pin 1 and the muting is removed with a time constant depending on the C7 value.
Turning off, the $\mathrm{V}_{\mathrm{s}}$ trend, in series to the voltage $\mathrm{V}_{\mathrm{s}}$ $V_{1}$ and which $C 7$ is charged, drives pin 1 at a low level threshold and a sudden muting is produced again.
Since the turn-off can be operated with high output
power, if the muting operates when the current through the inductance of the speaker is different from zero, a flyback is generated and then a small pop can be produced.
The flyback is clipped by integrated diodes.
The thresholds that produce the muting have been chosen in the way that 1 Vpp of ripple on the supply voltage does not produce any switching..

- Pin 1 is the turn-on and turn-off muting input.

## SUPPLY

An integrated voltage regulator with different output levels, supplies all the blocks operating with small signal.

- Pin 18 is the main supply of the device.
- Pin 5 ; pin 6 ; pin 15 and pin 16 are the ground of the supply. These pins are used to drain out from the device the heat produced by the dissipated power.

| Components | Units | Appl. 4.5 MHz | Appl. 5.5 MHz | Appl. 6 MHz |

## DESCRIPTION

The TDA8191 is a monolithic integrated circuit that includes all the functions needed for a complete TV sound channel. The TDA8191 is assembled in a 20 pin dual in line power package.

DIP20
(Plastic Package)
ORDER CODE : TDA8191

PIN CONNECTION

## ABSOLUTE MAXIMUM RATINGS

## MULTISTANDARD AM AND FM SOUND IF CIRCUIT FOR TV

The TDA8192 integrated circuit performs the following functions :

- A 2-STAGE GAIN CONTROLLED AMPLIFIER, PROVIDING COMPLETE IF GAIN ; (AM SECTION)
- A PEAK DETECTOR AND INTEGRATION WHICH PROVIDES AGC-VOLTAGE ; (AM SECTION)
- A 6-STAGE LIMITING AMPLIFIER FOLLOWED BY A SYNCHRONOUS DEMODULATOR AND DEEMPHASIS NETWORK ; (FM SECTION)
- AN AUDIO PREAMPLIFIER
- A CIRCUIT PROVIDING AM/FM SWITCHING AND MUTE FACILITIES
- AN EXTERNAL AUDIO INPUT CIRCUIT WITH SWITCHING FACILITIES TO DELIVER EITHER THE DEMODULATED IF, OR THE EXTERNAL AUDIO SIGNAL AT THE OUTPUTFULLY COMPATIBLE WITH THE SCART EUROPEAN NORM EN50 049
- A DC CONTROLLED VOLUME CIRCUIT

The demodulated IF signal is always available at a low impedance output.

PIN CONNECTIONS

## DESCRIPTION

The TDA8213 is a monolithic integrated circuit in DIP20 package for colour and black \& white television receivers using PNP tuners. It is intended to operate with a negatively modulated vision carrier and frequency modulated sound carrier. Used with TDA8214/15 (H/V deflection circuit) and TDA8217 (Pal decoder and video processor), this IC permits a complete low-cost solution for PAL applications.

| FG | Frame Saw-tooth Gain Between Pin 1 and non Inverting Input of the Frame Amplifier |  | -0.4 |  |  |
| $\frac{\Delta F}{\Delta \theta}$ | Vertical Frequency Drift with Temperature (see application) |  | $4.10^{-3}$ |  | $\mathrm{Hz}{ }^{\circ} \mathrm{C}$ |

## ELECTRICAL CHARACTERISTICS (continued)

$\mathrm{V}_{\mathrm{CC} 1}=10 \mathrm{~V}, \mathrm{~T}_{\mathrm{AMB}}=25^{\circ} \mathrm{C}$ (unless otherwise specified)

| Symbol | Parameter | Min. | Typ. | Max. | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: |
| FRAME POWER SUPPLY (Pın 9) |  |  |  |  |  |
| V9 | Operating Voltage (with flyback Generator) | 10 |  | 58 | V |
| 19 | Supply Current (V9 = 30V) |  | 11 | 22 | mA |
| FLYBACK GENERATOR SUPPLY (Pin 3) |  |  |  |  |  |
| $\mathrm{V}_{\mathrm{CC} 2}$ | Operating Voltage | 10 |  | 30 | V |
| FRAME OUTPUT (Pin 10) |  |  |  |  |  |
| Saturation Voltage to Ground (V9 = 30V) |  |  |  |  |  |
| LV10A | $110=0.1 \mathrm{~A}$ |  | 0.06 | 0.6 | V |
| LV10B | $110=1 \mathrm{~A}$ |  | 0.37 | 1 | V |
| Saturation Voltage to V9 (V9 = 30V) |  |  |  |  |  |
| HV10A | $110=-0.1 \mathrm{~A}$ |  | 1.3 | 1.6 | V |
| HV10B | $110=-1 \mathrm{~A}$ |  | 1.7 | 2.4 | V |
| Saturation Voltage to V9 in Flyback Mode (V10 > V9) |  |  |  |  |  |
| FV10A | $110=0.1 \mathrm{~A}$ |  | 1.6 | 2.1 | V |
| FV10B | $110=1 \mathrm{~A}$ |  | 2.5 | 4.5 | V |

FLYBACK GENERATOR (Pin 3 and Pin 4)

| Flyback Transistor on (output $=$ high state), $\mathrm{V}_{\mathrm{CC} 2}=30 \mathrm{~V} \mathrm{~V} 4 / 3$ with |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| F2DA | $\mathrm{I}_{4} \rightarrow 3=0.1 \mathrm{~A}$ | 1.5 | 21 | V |
| F2DB | $\mathrm{I}_{4 \rightarrow 3}=1 \mathrm{~A}$ | 3.0 | 4.5 | V |
| Flyback Transistor on (output = high state), $\mathrm{V}_{\mathrm{Cc} 2}=30 \mathrm{~V} \mathrm{~V} 3 / 4$ with |  |  |  |  |
| FSVA | $\mathrm{I}_{3 \rightarrow 4}=0.1 \mathrm{~A}$ | 0.8 | 1.1 | V |
| FSVB | $\mathrm{I}_{3 \rightarrow 4}=1 \mathrm{~A}$ | 2.2 | 4.5 | V |

Flyback Transistor off (output $=\mathrm{V} 9-8 \mathrm{~V}$ ), $\mathrm{V} 9-\mathrm{V}_{\mathrm{CC} 2}=30 \mathrm{~V}$

| FCl | Leakage Current Pin 3 |  |  | 170 | $\mu \mathrm{~A}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |

SUPER SANDCASTLE OUTPUT (Pin 19)

| Output Voltages ( R load $=2.2 \mathrm{k} \Omega$ ) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| SANDT2 | Frame blanking pulse level | 2 | 2.5 | 3 | V |
| SANDL2 | Line blanking pulse level | 4 | 4.5 | 5 | V |
| BG2 | Burst key pulse level | 8 | 9 |  | V |
| Pulses width and timing |  |  |  |  |  |
| SC3 | Delay between middle of sync pulse and leading edge of burst key pulse | 2.3 | 2.7 | 3.1 | $\mu \mathrm{s}$ |
| SC2 | Duration of burst key pulse Vertical blanking pulse width | 3.7 | $\begin{gathered} \hline 4 \\ \text { Note } 1 \\ \hline \end{gathered}$ | 5 | $\mu \mathrm{s}$ |

LINE FLYBACK INPUT (Pin 18)

|  | Switching level | 2 |  | V |
| :---: | :--- | :---: | :---: | :---: |
|  | Maxımum imput current at VPEAK $=800 \mathrm{~V}$ | 8 |  | mA |
|  | Limiting voltage at maximum current |  | 4.3 |  |
| $\tau$ | RC network tıme constant (Note 2) | 6 |  |  |

Notes : 1 Width of vertical blanking pulse on SSC output is proportional to the frame flyback tıme, the switching level is $V_{C C} 2-2 V_{B E}$ and the other input of the comparator is tied to the frame amplifier output Applicatıon circuit uses the frame flyback generator.
2 An RC network is connected to this input Typical value for the resistor is $27 \mathrm{k} \Omega$ and 220 pF for the capacitor A different time constant for RC changes the delay between the middle of the line synchro pulse and the leading edge of the burst key pulse but also the duration of the burst key pulse

## GENERAL DESCRIPTION

The TDA8214A performs all the video and power functions required to provide signals for the line driver and frame yoke.
It contains:

- A synchronization separator
- An integrated frame separator without external components
- A saw-tooth generator for the frame
- A power amplifier for direct drive of frame yoke (short circuit protected)
- An open collector output for the line driver
- A line phase detector and a voltage control oscillator
- A super sandcastle generator
- Video identification output.

Figure 1 : Synchronization Separator Circuit

The slice level of sync-separation is fixed by value of the external resistors R1 and R2. $\mathrm{V}_{\mathrm{R}}$ is an internally fixed voltage.
Figure 2 : Frame Separator

The sync-pulse allows the discharge of the capacitor by a $2 \times I$ current. A line sync-pulse is not able to discharge the capacitor under $\mathrm{V}_{\mathrm{z}} / 2$. A frame
sync-pulse permits the complete discharge of the capacitor, so during the frame sync-pulse $Q_{3}$ and Q4 provide current for the other parts of the circuit.

Figure 3: Line Oscillator

The oscillator thresholds are internally fixed by resistors. The discharge of the capacitor depends on the internal resistor R4. The control voltage is applied on resistor R5.
Figure 4: Phase Comparator

The sync-pulse drives the current in the comparator. The line flyback integrated by the external net work gives on pin 13 a saw tooth, the DC offset of this saw tooth is fixed by VC. The comparator output provides a positive current for the part of the signal on pin 13 greater than to VC and a negative current for the other part. When the line flyback and
the video signal are synchronized, the output of the comparator is an alternatively negative and positive current. The frame sync-pulse inhibits the comparator to prevent frequency drift of the line oscillator on the frame beginning.

Figure 5

## Line output (Pin 17)

It is an open-collector output. The output positive pulse time is $29 \mu$ s for a $64 \mu$ s period.

Figure 6: Frame Oscillator

The oscillator thresholds are internally fixed by resistors. The oscillator is synchronized during the last half free run period. The input current during the charge of the capacitor is less than 100 nA .

Frame output amplifier
This amplifier is able to drive directly the frame yoke. Its output is short circuit and overload protected; it contains also a thermal protection.

Figure 7: Super sandcastle generator

The frame blanking is detected by the frame flyback generator. When the output voltage of the frame amplifier exceeds $V_{C C} 2-2 V_{B E}$, the pulse is detected. The line flyback detection is provided by
a comparator which compares the input line flyback pulse to an internal reference. The burst gate pulse position is fixed by the external RC network (pin 14). It is referenced to the middle of the line flyback.

Figure 8 : Video Identification Circuit (Pln 8).

This stage will detect the coincidence between the line sync pulse (if present) and a $2 \mu$ s sampling pulse. This $2 \mu$ s pulse is positionned at the center of line sync pulse when the phase loop is locked. This sampled detection is stored by an external
capacitor Pin 8.
The identification output level is high when video signal is present.
Important remark : minimum saw-tooth amplitude on Pin 13 has to be 2VPP (typ. : $2.5 \mathrm{~V}_{\mathrm{PP}}$ ).

TYPICAL APPLICATION

Note. Pins 5-6 : Frame oscillator ground
Pins 15-16. Frame and line power ground

## HORIZONTAL AND VERTICAL DEFLECTION CIRCUIT

- DIRECT LINE DARLINGTON DRIVE
- DIRECT FRAME-YOKE DRIVE ( $\pm 1 \mathrm{~A}$ )
- COMPOSITE VIDEO SIGNAL INPUT CAPABILITY
- FRAME OUTPUT PROTECTION AGAINST SHORT CIRCUITS
- PLL
- VIDEO IDENTIFICATION CIRCUIT
- SUPER SANDCASTLE OUTPUT
- VERY FEW EXTERNAL COMPONENTS
- VERY LOW COST POWER PACKAGE

## DESCRIPTION

The TDA8215A is an horizontal and vertical deflection circuit with super sandcastle generator and video identification output. Used with TDA8213 (Video \& Sound IF system) and TDA8217 (Pal decoder and video processor), this IC permits a complete low-cost solution for PAL applications. THe TDA8215A has been specially designed for direct drive of line DARLINGTON transistors.

| :---: | :---: | :---: | :---: | :---: |
| FSVA | $\mathrm{l}_{3 \rightarrow 4}=0.1 \mathrm{~A}$ | 0.8 | 1.1 | V |
| FSVB | $\mathrm{I}_{3 \rightarrow 4}=1 \mathrm{~A}$ | 2.2 | 4.5 | V |

| Flyback Transistor off (output $=\mathrm{V} 9-8 \mathrm{~V}$ ), V9 $-\mathrm{VCC}_{\mathrm{C} 2}=30 \mathrm{~V}$ |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| FCl | Leakage Current Pin 3 |  | 170 | $\mu \mathrm{~A}$ |  |

SUPER SANDCASTLE OUTPUT (Pin 19)

| Output Voltages (R load $=2.2 \mathrm{k} \Omega$ ) |  |  |  |  |  |  |
| :---: | :--- | :---: | :---: | :---: | :---: | :---: |
| SANDT2 | Frame blanking pulse level | 2 | 2.5 | 3 | V |  |
| SANDL2 | Line blanking pulse level | 4 | 4.5 | 5 | V |  |
| BG2 | Burst key pulse level | 8 | 9 |  | V |  |
|  |  |  |  |  |  |  |
| SC3 | Pulses width and timing | Delay between middle of sync pulse and leading edge of burst key pulse | 2.3 | 2.7 | 3.1 |  |
| SC2 | Duration of burst key pulse <br> Vertical blanking pulse width | 3.7 | 4 <br> Note 1 | 5 | $\mu \mathrm{~s}$ |  |

LINE FLYBACK INPUT (Pin 18)

|  | Switching level |  | 2 |  | V |
| :---: | :--- | :---: | :---: | :---: | :---: |
|  | Maximum imput current at V PEAK $=800 \mathrm{~V}$ |  | 8 |  | mA |
|  | Limiting voltage at maximum current |  | 4.3 |  | V |
| $\tau$ | RC network time constant (Note 2) |  | 6 |  | $\mu \mathrm{~s}$ |

Notes: 1. Wıdth of vertical blanking pulse on SSC output is proportional to the frame flyback tıme, the switching level is $V_{C C} 2-2 V_{B E}$ and the other input of the comparator is tied to the frame amplifier output. Application circuit uses the frame flyback generator.
2. An RC network is connected to this input. Typical value for the resistor is $27 \mathrm{k} \Omega$ and 220 pF for the capacitor. A different time constant for RC changes the delay between the middle of the line synchro pulse and the leading edge of the burst key pulse but also the duration of the burst key pulse.

## GENERAL DESCRIPTION

The TDA8215A performs all the video and power functions required to provide signals for the line driver and frame yoke.

It contains:

- A synchronization separator
- An integrated frame separator without external components
- A saw-tooth generator for the frame
- A power amplifier for direct drive of frame yoke (short circuit protected)
- An open collector output for the line darlington drive
- A line phase detector and a voltage control oscillator
- A super sandcastle generator
- Video identification output.

Figure 1 : Synchronization Separator Circuit

The slice level of sync-separation is fixed by value of the external resistors R1 and R2. VR is an internally fixed voltage.
Figure 2 : Frame Separator

The sync-pulse allows the discharge of the capacitor by a $2 \times I$ current. A line sync-pulse is not able to discharge the capacitor under $\mathrm{V}_{\mathrm{z}} / 2$. A frame
sync-pulse permits the complete discharge of the capacitor, so during the frame sync-pulse $Q_{3}$ and Q4 provide current for the other parts of the circuit.

Figure 3: Line Oscillator

The oscillator thresholds are internally fixed by resistors. The discharge of the capacitor depends on the internal resistor R4. The control voltage is applied on resistor R5.
Figure 4: Phase Comparator

The sync-pulse drives the current in the comparator. The line flyback integrated by the external net work gives on pin 13 a saw tooth, the DC offset of this saw tooth is fixed by VC. The comparator output provides a positive current for the part of the signal on pin 13 greater than to VC and a negative current for the other part. When the line flyback and
the video signal are synchronized, the output of the comparator is an alternatively negative and positive current. The frame sync-pulse inhibits the comparator to prevent frequency drift of the line oscillator on the frame beginning.

Figure 5

## Line output (Pin 17)

It is an open-collector output. The output negative pulse time is $22 \mu$ s for a $64 \mu \mathrm{~s}$ period.

Figure 6: Frame Oscillator

The oscillator thresholds are internally fixed by resistors. The oscillator is synchronized during the last half free run period. The input current during the charge of the capacitor is less than 100 nA .

## Frame output amplifier

This amplifier is able to drive directly the frame yoke. Its output is short circuit and overload protected; it contains also a thermal protection.

Figure 7: Super sandcastle generator

The frame blanking is detected by the frame flyback generator. When the output voltage of the frame amplifier exceeds $\mathrm{V}_{\mathrm{CC}} 2-2 \mathrm{~V}_{\mathrm{BE}}$, the pulse is detected. The line flyback detection is provided by
a comparator which compares the input line flyback pulse to an internal reference. The burst gate pulse position is fixed by the external RC network (pin 14). It is referenced to the middle of the line flyback.

Figure 8 : Video Identification Circuit (Pln 8).

This stage will detect the coincidence between the line sync pulse (if present) and a $2 \mu$ s sampling pulse. This $2 \mu$ s pulse is positionned at the center of line sync pulse when the phase loop is locked. This sampled detection is stored by an external
capacitor Pin 8.
The identification output level is high when video signal is present.
Important remark : minimum saw-tooth amplitude on Pin 13 has to be $2 \mathrm{~V}_{\mathrm{PP}}$ (typ. : $2.5 \mathrm{~V}_{\mathrm{PP}}$ ).

TYPICAL APPLICATION

## PACKAGE MECHANICAL DATA

20 PINS - POWER DIP $16+2+2$

## PAL DECODER AND VIDEO PROCESSOR

- RGB OUTPUTS
- SINGLE CHIP CHROMA AND LUMINANCE PROCESSOR
- DC CONTROL BRIGHTNESS, CONTRAST, AND SATURATION
- FEW EXTERNAL COMPONENTS
- FAST BLANKING INPUT FOR OSD INSERTION
- SUPER SANDCASTLE INPUT

## DESCRIPTION

The TDA8217 is a monolithic integrated color decoder for the PAL standard. It includes in a 20 pins IC all the functions required for the identification and demodulation of PAL signals, and all the videoprocessor functions up to the drive of the video stages. Used with TDA8213 (video \& sound IF system) and TDA8214A (H/V deflection circuit), this IC permits a complete low-cost solution for PAL applications.

| F2DB | $\mathrm{I}_{4 \rightarrow 3}=1 \mathrm{~A}$ |  | 3.0 | 4.5 | V |  |  |  |  |  |

Flyback Transistor on (output $=$ high state), $\mathrm{V}_{\mathrm{CC} 2}=30 \mathrm{~V}, \mathrm{~V} 3 / 4$ with

| FSVA | $I_{3} \rightarrow 4=0.1 \mathrm{~A}$ |  | 0.8 | 1.1 | V |
| :--- | :--- | :--- | :--- | :--- | :---: |
| FSVB | $\mathrm{I}_{3} \rightarrow 4=1 \mathrm{~A}$ | 2.2 | 4.5 | V |  |
| Flyback Transistor off (output $=\mathrm{V} 9-8 \mathrm{~V}$ ), V9 $-\mathrm{V}_{\mathrm{CC} 2}=30 \mathrm{~V}$ |  |  |  |  |  |
| FCI | Leakage Current Pin 3 |  | 170 | $\mu \mathrm{~A}$ |  |

SUPER SANDCASTLE OUTPUT (Pin 19)

| Output Voltages ( $\mathrm{Rload}=2.2 \mathrm{k} \Omega$ ) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| SANDT2 | Frame blanking pulse level | 2 | 2.5 | 3 | V |
| SANDL2 | Line blanking pulse level | 4 | 4.5 | 5 | V |
| BG2 | Burst key pulse level | 8 | 9 |  | V |
| Pulses width and timing |  |  |  |  |  |
| SC3 | Delay between middle of sync pulse and leading edge of burst key pulse | 2.3 | 2.7 | 3.1 | $\mu \mathrm{S}$ |
| SC2 | Duration of burst key pulse <br> Vertical blanking pulse width : Defined by external R.C. Pin 8 | 3.7 | 4 | 5 | $\mu \mathrm{s}$ |

LINE FLYBACK INPUT (Pin 18)

|  | Switching level | 2 |  | V |
| :---: | :--- | :---: | :---: | :---: |
|  | Maximum imput current at $\mathrm{V}_{\text {PEAK }}=800 \mathrm{~V}$ |  | 8 |  |
|  | Limiting voltage at maximum current | mA |  |  |
| $\tau$ | RC network time constant (Note 1) for the burst key pulse | 4.3 |  | V |

Note: 1. An RC network is connected to this input. Typical value for the resistor is $27 \mathrm{k} \Omega$ and 220 pF for the capacitor. A different time constant for RC changes the delay between the middle of the line synchro pulse and the leading edge of the burst key pulse but also the duration of the burst key pulse.

## GENERAL DESCRIPTION

The TDA8218 performs all the video and power functions required to provide signals for the line driver and frame yoke.
It contains:

- A synchronization separator
- An integrated frame separator without external components
- A saw-tooth generator for the frame
- A power amplifier for direct drive of frame yoke (short circuit protected)
- An open collector output for the line driver
- A line phase detector and a voltage control oscillator
- A super sandcastle generator.

Figure 1 : Synchronization Separator Circuit

The slice level of sync-separation is fixed by value of the external resistors $R 1$ and $R 2 . V_{R}$ is an internally fixed voltage.

Figure 2 : Frame Separator

The sync-pulse allows the discharge of the capacitor by a $2 \times 1$ current. A line sync-pulse is not able to discharge the capacitor under $\mathrm{V}_{\mathrm{z}} / 2$. A frame
sync-pulse permits the complete discharge of the capacitor, so during the frame sync-pulse $Q_{3}$ and $Q_{4}$ provide current for the other parts of the circuit.

Figure 3: Line Oscillator

The oscillator thresholds are internally fixed by resistors. The discharge of the capacitor depends on the internal resistor R4. The control voltage is applied on resistor R5.
Figure 4: Phase Comparator

The sync-pulse drives the current in the comparator. The line flyback integrated by the external net work gives on pin 13 a saw tooth, the DC offset of this saw tooth is fixed by VC. The comparator output provides a positive current for the part of the signal on pin 13 greater than to VC and a negative current for the other part. When the line flyback
and the video signal are synchronized, the output of the comparator is an alternatively negative and positive current. The frame sync-pulse inhibits the comparator to prevent frequency drift of the line oscillator on the frame beginning.

Figure 5

## Line output (Pin 17)

It is an open-collector output. The output positive pulse time is $29 \mu \mathrm{~s}$ for a $64 \mu \mathrm{~s}$ period.

Figure 6: Frame Oscillator

The oscillator thresholds are internally fixed by resistors. The oscillator is synchronized during the last half free run period. The input current during the charge of the capacitor is less than 100nA.

## Frame output amplifier

This amplifier is able to drive directly the frame yoke. Its output is short circuit and overload protected; it contains also a thermal protection.

Figure 7: Super sandcastle generator

The line flyback detection is provided by a comparator which compares the input line flyback pulse to an internal reference. The burst gate pulse position is fixed by the external RC network (pin 14). It is referenced to the middle of the line flyback.
The frame blanking generator is a monostable with external R.C. The start blanking pulse is triggered by the falling edge of the frame saw-tooth (Pin 2). The reset is provided by a comparator which compares the capacitor voltage during its charge to an
internal threshold fixed by resistors.
The frame blanking time is defined by :

$$
\mathrm{T}_{\mathrm{fb}}=0.613 \cdot R . C .
$$

This pulse is available on Super Sand Castle output (Pin 19).

Remark : For compatability with TEA5640, frame blanking time must be larger than 1.15 ms with centered value @ 1.35ms ( $\mathrm{R}=100 \mathrm{k} \Omega \pm 1 \%$, $\mathrm{C}=22 \mathrm{nF} \pm 5 \%$ )

TYPICAL APPLICATION

## PACKAGE MECHANICAL DATA

20 PINS - POWER DIP $16+2+2$

## VIDEO \& SOUND IF SYSTEM WITH VIDEO AND SOUND SWITCHES

- VERY LOW CURRENT ABSORPTION
- 3 STAGE IF GAIN CONTROLLED AMPLIFIER
- SYNCHRONOUS VIDEO DEMODULATOR
- WHITE SPOT AND NOISE INVERTER
- AGC CIRCUIT WITH NOISE GATING
- TUNER AGC OUTPUT FOR PNP TUNERS
- FM DETECTOR
- AF AMPLIFIER WITH DC VOLUME CONTROL
- AFC
- AUDIO AND VIDEO SWITCHES COMPATIBLE WITH SCART EUROPEAN NORM
- MUTE FUNCTION

## DESCRIPTION

The TDA8222 is a monolithic integrated circuit in Shrink DIP24 package for color and black \& white television receivers using PNP tuners. It is intended to operate with a negatively modulated vision carrier and frequency modulated sound carrier.

SHRINK DIP24
(Plastic Package)
ORDER CODE : TDA8222

 TDA9102B TDA9102C

## H/V PROCESSOR FOR TTL V.D.U

PRELIMINARY DATA

## HORIZONTAL SECTION

- SYNCHRONIZATION INPUT : TTL COMPATIBLE, NEGATIVE EDGE TRIGGERED
-SYNCHRONIZATION INDEPENDENT FROM DUTY CYCLE TIME
- OSCILLATOR : FREQUENCY RANGE FROM 15 kHz to 100 kHz
- HORIZONTAL OUTPUT PULSE SHAPER AND SHIFTER
- PHASE COMPARATOR BETWEEN SYNCHRO AND OSCILLATOR (PLL1)
- PHASE COMPARATOR BETWEEN FLYBACK AND OSCILLATOR (PLL2)
- INTERNAL VOLTAGE REGULATOR
- DC COMPATIBLE CONTROLS FOR PHASE AND FREQUENCY
- DUTY CYCLE : 34\% FOR TDA9102B

43\% FOR TDA9102C

## VERTICAL SECTION

- SYNCHRONIZATION INPUT : TTL COMPATIBLE, NEGATIVE EDGE TRIGGERED
- SYNCHRONIZATION INDEPENDENT FROM DUTY CYCLE TIME
- OSCILLATOR : FREQUENCY RANGE FROM 30 Hz to 120 Hz
- RAMP GENERATOR WITH VARIABLE GAIN STAGE
- VERTICAL RAMP VOLTAGE REFERENCE
- INTERNAL VOLTAGE REGULATOR

## DESCRIPTION

The TDA9102B, C is a monolithic integrated circuit for horizontal and vertical sync processing in monochrome and color video displays driven by input TTL compatible signals.

The TDA9102B, C is supplied in a 20 pin dual in line package with pin 11 connected to ground and used for heatsinking.

## VIDEO AND AUDIO SIGNALS SWITCHING FOR THE PERI-TELEVISION PLUG

- VIDEO CROSSTALK : 60 dB TYPICAL
- LOW IMPEDANCE VIDEO OUTPUT $75 \Omega$
- SHORT-CIRCUIT PROTECTION OF INPUTS AND OUTPUTS
- INTERNAL HORIZONTAL PLL TIME CONSTANT SWITCHING IN CASE OF VIDEO RECORDER RECEPTION

## DESCRIPTION

This integrated circuit provides both video and sound switching allowing connections between the peri-TV plug and video, sound sections in the TV set. Input and output signal characteristics follow the NFC 92250/EN 50049 norms.

## CIRCUIT DESCRIPTION

The main functions of the I.C. are following :

## VIDEO SWITCHING

2 electronically switched inputs :

- one 2.5 Vpp input for internal video.
- one 1 Vpp input for signal coming from the peri-TV plug.
2 outputs :
- 1 Vpp output (low impedance $75 \Omega$ ) for periTV plug.
- 1 Vpp output low impedance for video section of the TV set.

Each input and output is protected from ground short-circuit. The $75 \Omega$ output is protected through a $75 \Omega$ resistor.

## AUDIO SWITCHING

Two electronically switched inputs :

- 300 mV rms input coming from internal audio.
- 100 mV rms input coming from the peri-TV plug one low impedance output 300 mV rms.

Inputs and outputs are also protected against ground short-circuit.

## SWITCHING LOGIC

The logic takes into account the information on 3 pins.

- Internal or external video and sound (pin 8 peri TV plug)
- Band III information
- Video recorder key.

External Video and Audio signals are selected in two cases.

- When there is a voltage information coming from peri-TV plug.
- When the video recorder key is selected (on TV front panel) and programmed on band III.

This I.C. includes an internal switch (open collector transistor) which commutes the time constant of the horizontal PLL circuit in case of video recorder reception.

## SAFETY INFORMATION FOR CRITICAL APPLICATIONS

## Typical Connection Between Peritel Plug and TEA1014.

Voltage on pin 9 must not exceed the $V_{c c}$ voltage on pin 13. In case of risk of over voltage, use the protection as described as below s:

All connections to Peritel plug are terminated by low impedance loads ( $75 \Omega$ ), except the external sound input.

## PACKAGE MECHANICAL DATA

14 PINS - PLASTIC DIP

- 1 VIDEO OUTPUT $75 \Omega$ - 1 Vpp NOTSWITCHED
- 1 SWITCHED VIDEO OUTPUT 2 VPP
- VIDEO CROSSTALK : 50 dB TYPICAL
- SHORT CIRCUIT PROTECTION OF INPUTS AND OUTPUTS
- CLAMPED VIDEO INPUTS

## DESCRIPTION

This integrated circuit provides all video switching allowing connections between the peri TV plug and video sections in the TV set. The TEA2014A is supplied in a DIL8.

## PACKAGE MECHANICAL DATA

8 PINS - PLASTIC DIP

## COLOR TV SCANNING AND POWER SUPPLY PROCESSOR

## DEFLECTION :

- CERAMIC 500 kHz RESONATOR FREQUENCY REFERENCE
- NO LINE AND FRAME OSCILLATOR ADJUSTMENT REFERENCE
- DUAL PLL FOR LINE DEFLECTION
- HIGH PERFORMANCE SYNCHRONIZATION
- SUPER SANDCASTLE OUTPUT
- FRAME BLANKING WITH SAFETY CIRCUIT
- VIDEO IDENTIFICATION CIRCUIT
- AUTOMATIC 50/60Hz STANDARD IDENTIFICATION
- EXCELLENT INTERLACING CONTROL
- SPECIAL PATENTED FRAME SYNCHRO DEVICE FOR VCR OPERATION
- FRAME SAW-TOOTH GENERATOR

SMPS CONTROL:

- ERROR AMPLIFIER AND PHASE MODULATOR
- SYNCHRONIZATION WITH HORIZONTAL DEFLECTION
- SECURITY CIRCUIT AND START-UP PROCESSOR
- OUTPUT PULSES ARE SENT TO THE PRIMARY SMPS IC (TEA2260 or TEA2164) THROUGH A LOW COST SYNCHRO PULSE TRANSFORMER

## DESCRIPTION

The TEA2028B is a complete (horizontal and vertical) deflection processor with secondary to primary SMPS control for color TV sets.

## GENERAL DESCRIPTION

## INTRODUCTION

This integrated circuit uses $I^{2} \mathrm{~L}$ bipolar technology and combines analog signal processing with digital processing.
Timing signals are obtained from a voltage-controlled oscillator (VCO) operating at 500 kHz by means of a cheap ceramic resonator. This avoids the frequency adjustment normally required with line and frame oscillators.
A chain of dividers and appropriate logic circuitry produce very accurately defined sampling pulses and the necessary timing signals.
The principal functions implemented are :

- Horizontal scanning processor.
- Frame scanning processor.
- BClass Power stage using an external power amplifier with fly back generator such as the TDA8170.
- Secondary switch mode power regulation.
- The SMPS output synchronize a primary I.C. (TEA2260 or TEA2164) at the mains part.
- This concept allows ACTIVE STANDBY facilities.
- Line and frame synchronization separation.
- Dual phase-locked loop horizontal scanning.
- High performance frame and line synchronization with interlacing control.
- Video identification circuit.
- Super sandcastle.
- Automatic $50-60 \mathrm{~Hz}$ standard identification.
- VCR input for PLL time constant and frame synchro switching.
- Frame saw-tooth generator.
- Frame blanking output.
- Switching mode regulated power supply comprising error amplifier and phase modulator.
- Security circuit and start-up processor.
- 500 KHz VCO.

The circuit is supplied in a 28 pin DIP case.
$V_{C C}=12 \mathrm{~V}$.

## SYNCHRONIZATION SEPARATOR

Line synchronization separator is clamped to black level of input video signal with synchronization pulse bottom level measurement.

The synchronization pulses are divided centrally between the black level and the synchronization pulse bottom level, to improve performance on video signals in noise conditions.

## FRAME SYNCHRONIZATION

Time constant of Frame Separator can be adjusted by adding a capacitor pin 20.
The frame timing identification logic permits automatic adaptatio to $50-60 \mathrm{~Hz}$ standards or noninterlaced video.

An automatic synchronization window width system provides:

- fast frame capture ( 6.7 ms wide window),
- good noise immunity ( 0.4 ms narrow window).

The internal generator starts the discharge of the saw-tooth generator capacitor so that it is not disturbed by line fly-back effects.
Thanks to the logic control, the beginning of the charge phase does not depend on any disturbing effect of the line fly-back.
A $32 \mu \mathrm{~s}$ timing is automatically applied on standardized transmissions, for perfect interlacing.
In VCR mode, the discharge time is controlled by an internal monostable independent of the line frequency and gives a direct frame synchronization.

## HORIZONTAL SCANNING

The horizontal scanning frequency is obtained from the 500 KHz VCO .
The circuit uses two phase-locked loops (PLL) :
the first one controls the frequency, the second one controls the relative phase of the synchronization and line fly-back signals.
The frequency PLL has two switched time constants to provide :

- capture with a short time constant,
- good noise immunity after capture with a long time constant.
The output pulse has a constant duration of $29 \mu \mathrm{~s}$ (with $\mathrm{C}\left(\right.$ pin 1) $=3.3 \mathrm{nF}$ ), independent of $\mathrm{V}_{\mathrm{Cc}}$ and delay in switching off the scanning transistor.

## VIDEO IDENTIFICATION

The horizontal synchronization signal is sampled by a $2 \mu \mathrm{~s}$ pulse within the synchronization pulse. The signal is integrated by an external capacitor.
The identification function provides three different levels:

- OV : no video identification
- $6 \mathrm{~V}: 60 \mathrm{~Hz}$ video identification
- $12 \mathrm{~V}: 50 \mathrm{~Hz}$ video identification

This information may be used for timing research in the case of frequency or voltage synthetizer type receivers and for audio muting.
SUPER SANDCASTLE with 3 levels : burst, line flyback, frame blanking.
In the event of vertical scanning failure, the frame blanking level goes high to protect the tube.
Frame blanking time (start with reset of frame divider) is 21 lines.

## VCR INPUT

This provides for continuous use of the short time constant of the first phase-locked loop (frequency). In VCR mode, the frame synchronization window widens out to a search window and there is no delay of frame fly-back (direct synchronization).
FRAME SAW-TOOTH GENERATOR.
The current to charge the capacitor is automatically switched to 60 Hz operation to maintain constant amplitude.

## SWITCH MODE POWER SUPPLY (SMPS) SECONDARY TO PRIMARY REGULATION

This power supply uses a differential error amplifier with an internal reference voltage of 1.26 V and a phase modulator operating at the line frequency. The power transistor is turned off by the falling edge of the horizontal saw-tooth.
The "soft start" device imposes a very small conduction angle on starting up, this angle progressively increases to its nominal regulation value.
The maximum conduction angle may be monitored by forcing a voltage on pin 15. This pin may also be used for current limitation.
The output pulse is sent to the primary I.C. (TEA2260 or TEA2164) via a low cost synchro transformer.

## SECURITY CIRCUIT AND START UP PROCESSOR

When the security input (pin 28) is at a voltage below 1.26 V the two outputs are simultaneously cut off until this voltage reaches the 1.26 V threshold again. In this case the switch mode power supply is restarted by the "soft start" system.
If this cycle is repeated three times, the two outputs are cut off definitively. To reset the safety logic circuits, $\mathrm{V}_{\mathrm{Cc}}$ must be lower than 3.5 V .
This circuit eliminates the risk to switch off the TV receiver in the event of a flash affecting the tube.
On starting up the horizontal scanning function comes into operation at $\mathrm{V}_{c \mathrm{C}}=6 \mathrm{~V}$. The power supply then comes into operation progressively.
On shutting down, the two functions are interrupted simultaneously after the first line fly back.

## FRAME BLANKING SAFETY (pin 2)

The frame blanking safety checks the normal of frame scanning.
In case of any problem pin 4 and pin 11 is at a high level (frame blanking) in order to protect the tube.

## ELECTRICAL OPERATING CHARACTERISTICS

$\mathrm{T}_{\text {amb }}=25^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{CC}}=12 \mathrm{~V}$ (unless otherwise noted) Pulse duration at $50 \%$ of the ampl.

## PACKAGE MECHANICAL DATA

28 PINS - PLASTIC DIP

## COLOR TV SCANNING AND POWER SUPPLY PROCESSOR

DEFLECTION :

- CERAMIC 500 KHz RESONATOR FREQUENCY REFERENCE
- NO LINE AND FRAME OSCILLATOR ADJUSTMENT
- DUAL PLL FOR LINE DEFLECTION
- HIGH PERFORMANCE SYNCHRONIZATION
- SUPER SANDCASTLE OUTPUT
- VIDEO IDENTIFICATION CIRCUIT
- AUTOMATIC $50 / 60 \mathrm{~Hz}$ STANDARD IDENTIFICATION
- EXCELLENT INTERLACING CONTROL
- SPECIAL PATENTED FRAME SYNCHRO DEVICE FOR VCR OPERATION
- FRAME SAW-TOOTH GENERATOR
- FRAME PHASE MODULATOR FOR THYRISTOR

SMPS CONTROL:

- ERROR AMPLIFIER AND PHASE MODULATOR
- SYNCHRONIZATION WITH HORIZONTAL DEFLECTION
- SECURITY CIRCUIT AND START UP PROCESSOR
- OUTPUT PULSES ARE SENT TO THE PRIMARY SMPS IC (TEA2164 OR TEA2260/61) THROUGH A LOW COST SYNCHRO PULSE TRANSFORMER

## DESCRIPTION

The TEA2029C is a complete (horizontal and vertical) deflection processor with secondary to primary SMPS control for color TV sets.

DIP28 (Plastic Package)

## THERMAL DATA

$R_{\text {th ( }}$ (-a) $\quad$ Junction-ambient Thermal Resistance

## GENERAL DESCRIPTION

This integrated circuit uses $\left.\right|^{2} L$ bipolar technology and combines analog signal processing with digital processing.

Timing signals are obtained from a voltage-controlled oscillator (VCO) operating at 500 KHz by means of a cheap ceramic resonator. This avoids the frequency adjustment normally required with line and frame oscillators.
A chain of dividers and appropriate logic circuitry produce very accurately defined sampling pulses and the necessary timing signals.
The principal functions implemented are :

- Horizontal scanning processor.
- Frame scanning processor. Two applications are possible :
- DClass

Power stage using an external thyristor.
Power stage using an external power amplifier with fly-back generator such as the TDA8170.

- Secondary switch mode power regulation.

The SMPS output synchronize a primary I.C. (TEA2164 or TEA2260/61) at the mains part. This concept allows ACTIVE STANDBY facilities.

- Dual phase-locked loop horizontal scanning.
- High performance frame and line synchronization with interlacing control.
- Video identification circuit.
- Super sandcastle.
- AGC key pulse output.
- Automatic $50-60 \mathrm{~Hz}$ standard identification.
- VCR input for PLL time constant and frame synchro switching.
- Frame saw-tooth generator and phase modulator.
- Switching mode regulated power supply comprising error amplifier and phase modulator.
- Security circuit and start-up processor.
- 500 KHz VCO

The circuit is supplied in a 28 pin DIP case.
$V_{C C}=12 \mathrm{~V}$.

## SYNCHRONIZATION SEPARATOR

Line synchronization separator is clamped to black level of input video signal with synchronization pulse bottom level measurement.
The synchronization pulses are divided centrally between the black level and the synchronization pulse bottom level, to improve performance on video signals in noise conditions.

## FRAME SYNCHRONIZATION

Frame synchronization is fully integrated (no external capacitor required).
The frame timing identification logic permits automatic adaptation to $50-60 \mathrm{~Hz}$ standards or non-interlaced video.
An automatic synchronization window width system provides:

- fast frame capture ( 6.7 ms wide window),
- good noise immunity ( 0.4 ms narrow window).

The internal generator starts the discharge of the saw-tooth generator capacitor so that it is not disturbed by line fly back effects.
Thanks to the logic control, the beginning of the charge phase does not depend on any disturbing effect of the line fly-back.
A $32 \mu$ s timing is automatically applied on standardized transmissions, for perfect interlacing.
In VCR mode, the discharge time is controlled by an internal monostable independent of the line frequency and gives a direct frame synchronization.

## HORIZONTAL SCANNING

The horizontal scanning frequency is obtained from the 500 kHz VCO .
The circuit uses two phase-locked loops (PLL) :
the first one controls the frequency, the second one controls the relative phase of the synchronization and line fly-back signals.
The frequency PLL has two switched time constants to provide :

- capture with a short time constant,
- good noise immunity after capture with a long time constant.
The output pulse has a constant duration of $26 \mu \mathrm{~s}$, independent of $\mathrm{V}_{\mathrm{CC}}$ and any delay in switching off the scanning transistor.

## VIDEO IDENTIFICATION

The horizontal synchronization signal is sampled by a $2 \mu \mathrm{~s}$ pulse within the synchronization pulse. The signal is integrated by an external capacitor.
The identification function provides three different levels:

- OV : no video identification
- $6 \mathrm{~V}: 60 \mathrm{~Hz}$ video identification
- $12 \mathrm{~V}: 50 \mathrm{~Hz}$ video identification

This information may be used for timing research in the case of frequency or voltage synthetizer type receivers, and for audio muting.

SUPER SANDCASTLE with 3 levels : burst, line flyback, frame blanking.
In the event of vertical scanning failure, the frame blanking level goes high to protect the tube.
Frame blanking time (start with reset of Frame divider) is 24 lines.

## VCR INPUT

This provides for continuous use of the short time constant of the first phase-locked loop (frequency).
In VCR mode, the frame synchronization window widens out to a search window and there is no delay of frame fly-back (direct synchronization).

## FRAME SCANNING

FRAME SAW-TOOTH GENERATOR. The current to charge the capacitor is automatically switched to 60 Hz operation to maintain constant amplitude.
FRAME PHASE MODULATOR (WITH TWO DIFFERENTIAL INPUTS). The output signal is a pulse at the line frequency, pulse width modulated by the voltage at the differential pre-amplifier input.
This signal is used to control a thyristor which provides the scanning current to the yoke. The sawtooth output is a low impedance, however, and can therefore be used in class B operation with a power amplifier circuit.

## SWITCH MODE POWER SUPPLY (SMPS) SECONDARY TO PRIMARY REGULATION

This power supply uses a differential error amplifier with an internal reference voltage of 1.26 V and a phase modulator operating at the line frequency. The power transistor is turned off by the falling edge of the horizontal saw-tooth.
The "soft start" device imposes a very small conduction angle on starting up, this angle progressively increases to its nominal regulation value.
The maximum conduction angle may be monitored by forcing a voltage on pin 15. This pin may also be used for current limitation.
The output pulse is sent to the primary S.M.P.S. I.C. (TEA2164) via a low cost synchro transformer.

## SECURITY CIRCUIT AND START UP PROCESSOR

When the security input (pin 28) is at a voltage exceeding 1.26 V the three outputs are simultaneously cut off until this voltage drops below the 1.26 V threshold again. In this case the switch mode power supply is restarted by the "soft start" system.

If this cycle is repeated three times, the three outputs are cut off definitively. To reset the safety logic circuits, Vcc must be zero volt.
This circuit eliminates the risk to switch off the TV receiver in the event of a flash affecting the tube.

On starting up, the horizontal and vertical scanning functions come into operation at $\mathrm{V}_{c c}=6 \mathrm{~V}$. The power supply then comes into operation progressively.
On shutting down, the three functions are interrupted simultaneously after the first line fly-back.

## ELECTRICAL OPERATING CHARACTERISTICS

$\mathrm{T}_{\mathrm{amb}}=25^{\circ} \mathrm{C} \mathrm{V}_{\mathrm{cc}}=12 \mathrm{~V}$ (unless otherwise noted) Pulse duration at $50 \%$ of the ampl.

## PACKAGE MECHANICAL DATA

## 28 PINS - PLASTIC DIP

- 2 VIDEO OUTPUTS WITH $150 \Omega$ LOAD DRIVE CAPABILITY
- DYNAMIC OUTPUT AMPLITUDE 4 VPP ON EACH OUTPUT
- BANDWIDTH 18MHz TYP
- FULL PROTECTION AGAINST ESD

## DESCRIPTION

This integrated circuit provides general video switches. It is particularly intended for switching between the peri TV plug and video section of the sets. Its electrical performances make it suitable for wide bandwidth applications (Teletext, D2MAC).

PIN CONNECTIONS

## BLOCK DIAGRAM

## PACKAGE MECHANICAL DATA

8 PINS - PLASTIC DIP

## COLOR TV SCANNING AND POWER SUPPLY PROCESSOR

ADVANCE DATA

## DEFLECTION

- AUTOMATIC VCR MODE RECOGNITION FOR TIME CONSTANT SWITCHING
- VIDEO IDENTIFICATION CIRCUIT
- DEFLECTION 500kHz RESONATOR OSCILLATOR
- NO LINE AND FRAME OSCILLATOR ADJUSTMENT
- DUAL PLL FOR LINE DEFLECTION
- SUPER SANDCASTLE OUTPUT
- INTERNAL SYNCHRO INHIBITION FOR OSD MODE
- AUTOMATIC $50 \mathrm{~Hz} / 60 \mathrm{~Hz}$ STANDARD IDENTIFICATION
- EXCELLENT INTERLACING CONTROL
- FRAME SAFETY INPUT
- FRAME SAWTOOTH GENERATOR

## S.M.P.S. CONTROL

- ERROR AMPLIFIER AND PHASE MODULATOR
- SYNCHRONIZATION WITH HORIZONTAL DEFLECTION
- START UP PROCESSOR
- MASTER/SLAVE CONCEPT FACILITIES

## DESCRIPTION

The TEA2128 is a complete (horizontal and vertical) deflection processor with secondary to primary S.M.P.S. control for color TV sets.

SHRINK24
(Plastic Package)
ORDER CODE: TEA2128S

## PIN CONNECTIONS

## GENERAL DESCRIPTION

## Introduction

This integrated circuit uses high density I2L bipolar technology and combines analog signal processing with digital processing.
Timing signals are obtained from a voltage-controlled oscillator (VCO) operating at 500 kHz by means of a cheap ceramic resonator. This avoid the frequency adjustment normally required with line and frame oscillators.
A chain of dividers and appropriate logic circuitry produces very accurate defined sampling pulses and the necessary timing signals.

## Internal Functions

- Horizontal scanning processor
- Frame scanning processor
- B class frame output stage using an external power amplifier with flyback generator
- Line and frame synchronization separation
- Dual phase-locked loop horizontal scanning
- High performance frame and line synchronization with interlacing control.
- Supersandcastle generator
- Automatic $50 \mathrm{~Hz} / 60 \mathrm{~Hz}$ standard identification
- Frame saw-tooth generator
- Video identification circuit
- Very steady free running mode of the line and frame oscillator in OSD mode. This allows on screen display without phase Jitter in research mode of the tuner
- Automatic VCR mode recognition for time constant switching
- Switching mode regulated supply comprising error amplifier and phase modulator. This allowed a secondary switch mode power regulation with a master slave concept and provides active standby facilities
- Line and S.M.P.S. start-up processor
- Frame safety input

## WORKING DESCRIPTION

## Synchronization Separator

Line synchronization separator is clamped to black level of input video signal with synchronization pulse bottom level measurement.
The synchronization pulses are divided centrally between the black level and the synchronization pulse bottom level, to improve performance on video signal in noise conditions.

## Frame Synchronization

Frame synchronization is fully integrated (no external capacitor required).
The frame timing identification logic permits automatic adaptation to $50-60 \mathrm{~Hz}$ standards or non-interlaced video.
An automatic synchronization window width system provides:

- Fast frame capture ( 7.3 ms wide window)
- Good noise immunity ( 0.4 ms narrow window)

The internal generator starts the discharge of the sawtooth generator capacitor, so that it is not disturbed by line flyback effects.
Thanks to the logic control, the beginning of the charge phase does not depend on any disturbing effect of the line flyback. A $32 \mu \mathrm{~s}$ timing is automatically applied on standardized transmissions for perfect interlacing.
In VCR mode, the discharge time is controlled by an internal monostable independent of the line frequency and gives a direct frame synchronization.

## Horizontal Scanning

The horizontal scanning frequency is obtained from the 500 kHz VCO.
The circuit uses two PLL:

- The first one controls the frequency
- The second one controls the relative phase of the synchronization and the line flyback signals.

The output pulse has a constant duration of $29 \mu \mathrm{~s}$, independent of $\mathrm{V}_{\mathrm{cc}}$ and of any delay in switchingoff the scanning transistor.

## Supersandcastle Generator

This output delivers a 3 level synchronization signal:

- Burst level
- Line blanking level
- Frame blanking level

In the event of vertical scanning failure, the frame blanking level goes high to protect the tube.

## Frame Scanning

The current to charge the frame sawtooth generator is automatically switched to 60 Hz operation to maintain constant amplitude.

## Automatic VCR Mode Recognition for Time Constant Switching

- A third phase comparator is used to detect VCR signals and to switch the $\phi 1$ short time constant.
- A noise level measurement is realized on the video synchronization pulse to inhibit the short time constant if the noise level is superior to an adjustable threshold.
- VCR signals are detected if peak to peak signal on Pin 7 is superior to an internal threshold.

This threshold is depending on the noise level. So with a no noisy video signal, the auto VCR switch sensitivity is maximum, and it decreases when the noise increases.

- The sensitivity of the noise gate and the auto VCR switch is adjustable by external resistance.
- Long and short time constants can be selected manually by Pin 5 .

## Video Identification

The horizontal synchronization signal is sampled by a $2 \mu \mathrm{~s}$ pulse within the synchronization pulse. The signal is integrated by an external capacitor.

## Identification Output

The identification function provides three different levels:

- OV : No video identification
- 6 V : 60 Hz video identification
- $12 \mathrm{~V}: 50 \mathrm{~Hz}$ video identification

This information may be used for timing research in the case of frequency or voltage synthetizer type receivers and for audio muting.

## O.S.D. Mode

The O.S.D. (On Screen Display) function is available when Pin 14 is switch to ground. This function fixes line and frame frequencies to standard deflection frequencies ( $\mathrm{f}_{\mathrm{H}}=15.6 \mathrm{kHz}, \mathrm{fV}_{\mathrm{V}}=50 \mathrm{~Hz}$ ) and inhibits $\Phi 1$ PLL. This allows to have a stable text display when no signal is coming from antenna.

## Switch Mode Power Supply Secondary to Primary Regulation

This power supply uses a differential error amplifier with an internal reference voltage of 1.3 V and a phase modulator operating at the line frequency. The power transistor is turned-off during the line retrace by the falling edge of the horizontal sawtooth.
The maximum conduction angle may be monitored by forcing a voltage at Pin 9 . This pin can also be used for current limitation.
The output pulse is sent to the primary IC (TEA2260/61 via a low cost synchro transformer).

## S.M.P.S. Start-up Processor

The "soft-start" device imposes a very small conduction angle on starting-up. This angle progressively increases to its nominal regulation value.
On starting-up the horizontal scanning function comes into operation at $\mathrm{V}_{\mathrm{Cc}}=7 \mathrm{~V}$. The power supply then comes into operation progressively.

## Frame Blanking Safety Input (Pin 15)

The frame blanking safety checks the normal frame scanning. In the event of vertical scanning failure, the frame blanking level goes high to protect the CRT.

## PACKAGE MECHANICAL DATA

24 pins - PLASTIC SHRINK
Dimensions in mm

## COLOR TV SCANNING PROCESSOR

ADVANCE DATA

- AUTOMATIC VCR MODE RECOGNITION FOR TIME CONSTANT SWITCHING
- DIGITAL VIDEO IDENTIFICATION CIRCUIT
- 500kHz RESONATOR OSCILLATOR
- NO LINE AND FRAME OSCILLATOR ADJUSTMENT
- DUAL PLL FOR LINE DEFLECTION
- SUPER SANDCASTLE OUTPUT
- AUTOMATIC $50 \mathrm{~Hz} / 60 \mathrm{~Hz}$ STANDARD IDENTIFICATION
- EXCELLENT INTERLACING CONTROL
- FRAME SAFETY INPUT
- FRAME SAWTOOTH GENERATOR

## GENERAL DESCRIPTION

## Introduction

This integrated circuit uses high density I2L bipolar technology and combines analog signal processing with digital processing.
Timing signals are obtained from a voltage-controlled oscillator (VCO) operating at 500 kHz by means of a cheap ceramic resonator. This avoid the frequency adjustment normally required with line and frame oscillators.
A chain of dividers and appropriate logic circuitry produces very accurate defined sampling pulses and the necessary timing signals.

## Internal Functions

- Horizontal scanning processor
- Frame scanning processor
- B class frame output stage using an external power amplifier with flyback generator
- Line and frame synchronization separation
- Dual phase-locked loop horizontal scanning
- High performance frame and line synchronization with interlacing control.
- Supersandcastle generator with reduced burst gate pulse for 60 Hz
- Automatic $50 \mathrm{~Hz} / 60 \mathrm{~Hz}$ standard identification
- Frame saw-tooth generator
- Digital video identification circuit
- Very steady free running mode of the line and frame oscillator when no video is detected. This allows on screen display without phase Jitter in research mode of the tuner
- Automatic VCR mode recognition for time constant switching
- Frame safety input

## WORKING DESCRIPTION

## Synchronization Separator

Line synchronization separator is clamped to black level of input video signal with synchronization pulse bottom level measurement.
The synchronization pulses are divided centrally between the black level and the synchronization pulse bottom level, to improve performance on video signal in noise conditions.

## Frame Synchronization

Frame synchronization is fully integrated (no external capacitor required).
The frame timing identification logic permits automatic adaptation to $50-60 \mathrm{~Hz}$ standards or non-interlaced video.
An automatic synchronization window width system provides:

- Fast frame capture ( 7.3 ms wide window)
- Good noise immunity ( 0.4 ms narrow window)

The internal generator starts the discharge of the sawtooth generator capacitor, so that it is not disturbed by line flyback effects.
Thanks to the logic control, the beginning of the charge phase does not depend on any disturbing effect of the line flyback. A $32 \mu \mathrm{~s}$ timing is automatically applied on standardized transmissions for perfect interlacing.
In VCR mode, the discharge time is controlled by an internal monostable independent of the line frequency and gives a direct frame synchronization.

## Horizontal Scanning

The horizontal scanning frequency is obtained from the 500 kHz VCO .

The circuit uses two PLL:

- The first one controls the frequency
- The second one controls the relative phase of the output line pulse and the line flyback signals.
The output pulse has a constant duration of $29 \mu \mathrm{~s}$, independent of $V_{C C}$ and of any delay in switchingoff the scanning transistor.

## Supersandcastle Generator

This output delivers a 3 level synchronization signal:

- Burst level
- Line blanking level
- Frame blanking level

In the event of vertical scanning failure, the frame blanking level goes high to protect the tube.

## Frame Scanning

The current to charge the frame sawtooth generator is automatically switched to 60 Hz operation to maintain constant amplitude.

## Automatic VCR Mode Recognition for Time Constant Switching

- A third phase comparator is used to detect VCR signals and to switch the $\phi 1$ short time constant.
- A noise level measurement is realized on the video synchronization pulse to inhibit the short time constant if the noise level is superior to an adjustable threshold.
- VCR signals are detected if peak to peak signal on pin 2 is superior to an internal threshold.

This threshold is depending on the noise level. So with a no noisy video signal, the auto VCR switch sensitivity is maximum, and it decreases when the noise increases.

- The sensitivity of the noise gate and the auto VCR switch is adjustable by external resistance.
- Long and short time constants can be selected manually by Pin 20.

## Digital Video Identification

A digital circuit controls the identification signal. When identification signal is low, the line oscillator is set on a reference frequency. When identification signal is high, $\phi 1$ is locked and the catching phase can start. So that, the TEA2130 allowed on screen displays in a steady way even without video signal (during tuner research for example).

## Identification Output

The identification function provides three different levels:

- OV : No video identification
- $6 \mathrm{~V}: 60 \mathrm{~Hz}$ video identification
- $12 \mathrm{~V}: 50 \mathrm{~Hz}$ video identification

This information may be used for timing research in the case of frequency or voltage synthetizer type receivers and for audio muting.

## O.S.D. Mode

The O.S.D. (On Screen Display) function is available when video signal is not present on Pin 19. This function fixes line and frame frequencies to standard deflection frequencies ( $\mathrm{f}_{\mathrm{H}}=15.6 \mathrm{kHz}$, $\mathrm{f}_{\mathrm{V}}=50 \mathrm{~Hz}$ ) and inhibits $\Phi 1 \mathrm{PLL}$. This allows to have a stable text display when no signal is coming from antenna.

## Frame Blanking Safety Input (Pin 6)

The frame blanking safety checks the normal frame scanning. In the event of vertical scanning failure, the frame blanking level goes high to protect the CRT.

## TYPICAL APPLICATION

## PACKAGE MECHANICAL DATA

20 pins - PLASTIC DIP

## WIDE BAND VIDEO PROCESSOR

- DIGITAL CONTROL OF BRIGHTNESS, SATURATION AND CONTRAST ON TV SIGNALS AND R, G, B INTERNAL OR EXTERNAL SOURCES
- BUS DRIVE OF SWITCHING FUNCTIONS
- DEMATRIXING OF R, G, B SIGNALS FROM Y, R-Y, B-Y, TV MODE INPUTS
- MATRIXING OF R, G, B SOURCES INTO Y, R-Y, B-Y SIGNALS
- AUTOMATIC DRIVE AND CUT-OFF CONTROLS BY DIGITAL PROCESSING DURING FRAME RETRACE
- PEAK AND AVERAGE BEAM CURRENT LIMITATION
- ON-CHIP SWITCHING FOR R, G, B INPUT SELECTION
- ON-CHIP INSERTION OF INTERNAL OR EXTERNAL R, G, B SOURCES

## DESCRIPTION

The TEA5040 is a serial bus-controlled videoprocessing device which integrates a complex architecture fulfilling multiple functions.

(Plastic Package) ORDER CODE: TEA5040S

## PIN CONNECTIONS

BLOCK DIAGRAM (simplified)

## GENERAL DESCRIPTION

## Brief Description

This integrated circuit incorporates the following features:

- a synchro and two video inputs
- a fixed video output
- a switchable video output
- normal Y, R-Y, B-Y TV mode inputs
- double set of R, G, B inputs
- brightness, contrast and saturation controls as well on a R, G, B picture as on a normal TV picture
- digital control inputs by means of serial bus
- peak beam current limitation
- average beam current limitation
- automatic drive and cut-off controls

## Block Diagram Description

BUS DECODER.
A 3 lines bus (clock, data, enable) delivered by the microcontroller of the TV-set enters the videoprocessor integrated circuit (pins 13-14-15). A control system acts in such a way that only a 9 -bit word is taken into account by the videoprocessor. Six of the bits carry the data, the remaining three carry the address of the subsystem.

| Function | +Address | +Number of Bits |
| :--- | :---: | :---: |
| Brightness Control | 0 | 5 |
| Contrast Control | 1 | 5 |
| Colour on/off Selection | 2 | 1 |
| Insertion Allowed | 3 | 1 |
| Sync/Async Mode | 4 | 1 |
| Int/Ext Video Switching | 5 | 1 |
| B-Y Saturation Control | 6 | 6 |
| R-Y Saturation Control | 7 | 6 |

Table below depicts 9-bit words required for various functions.

| Subsystem's Configuration | Data Bits <br> LSB....MSB | Add. Bits <br> LSB....MSB |  |
| :--- | :--- | :--- | :---: |
| BRIGHTNESS | Min. <br> Max. | X00000 <br> X11111 | 000 |
| CONTRAST | Min. <br> max. | X00000 <br> X11111 | 100 |
| COLOUR ON/OFF | Off <br> On | XXXXX0 <br> XXXXX1 | 010 |
| INSERTION | Allowed <br> Not Allowed | XXXXX0 | XXXXX1 |

A demultiplexer directs the data towards latches which drive the appropriate control. More detailed information about serial bus operation is given in the following chapter.

## Video Switch

The video switch has three inputs :

- an internal video input (pin 37),
- an external video input (pin 35),
- a synchro input (pin 39),
and two outputs :
- an internal video output (pin 38),
- a switchable video output (pin 40)

The 1 Vpp composite video signal applied to the internal video input is multiplied by two and then appears as a 2 Vpp low impedance composite video signal at the output. This signal is used to deliver a $1 \mathrm{Vpp} / 75 \Omega$ composite video signal to the peri-TV plug.
The switchable video output can be any of the three inputs. When the Int/Ext one active bit word is high (address number 5), the internal video input is selected. If not, either a regenerated synchro pulse or the external video signal is directed towards this output depending on the level of the Sync/Async one active bit word (address number 4). As this output is to be connected to the synchro integrated circuit, RGB information derived from an external source via the Peri-TV plug can be displayed on the screen, the synchronization of the TV-set being then made with an external video signal.
When RGB information is derived from a source integrated in the TV-set, a teletext decoder for
example, the synchronization can be made either on the internal video input (in case of synchronous data) or on the synchro input (in case of asynchronous data).

## R, G, B Inputs

There are two sets of R, G, B inputs : one is to be connected to the peri-TV plug (Ext R, G, B), the second one to receive the information derived from the TV-set itself (Int R, G, B).
In order to have a saturation control on a picture coming from the $R, G, B$ inputs too, it is necessary to get $R-Y, B-Y$ and $Y$ signals from $R, G, B$ information : this is performed on the first matrix that receives the three 0.9 Vp ( $100 \%$ white) R, G, B signals and delivers the corresponding $\mathrm{Y}, \mathrm{R}-\mathrm{Y}, \mathrm{B}-\mathrm{Y}$ signals. These ones are multiplied by 1.4 in order to make the $R-Y$ and $B-Y$ signals compatible with the $R-Y$ and B-Y TV mode inputs. The desired R, G, B inputs are selected by means of 3 switches controlled by the two fast blanking signal inputs. A high level on FB external pin selects the external RGB sources. The three selected inputs are clamped in order to give the required DC level at the output of this first matrix. The three not selected inputs are clamped on a fixed DC level.

## Y, R-Y, B-Y Inputs

The 2Vpp composite video signal appearing at the switchable output of the video switch (pin 40) is driven through the subcarrier trap and the luminance delay line with a 6 dB attenuation to the Y input (1Vpp ; pin 12). In order to make this 1Vpp (synchro to white) Y signal compatible with the 1 Vpp (black
to white) Y signal delivered by the first matrix, it is necessary to multiply it by a coefficient of 1.4.

## R, G, B Insertion Pulse (fast blanking)

A R, G, B source has also to provide an insertion pulse. Since this integrated circuit can be directly connected to two different sources, it is necessary then to have two separate insertion pulse inputs (pin $8-9)$. Fast blanking can be inhibited by a one active bit word. The two fast blanking inputs carry out an OR function to insert R, G, B sources into TV picture. The external fast blanking (FB ext.) selects the appropriate R, G, B source.

## Controls

The four brightness, contrast and saturation control functions are direct digitally controlled without using digital-to-analog converters.
The contrast control of the $Y$ channel is obtained by means of a digital potentiometer which is an attenuator including several switchable cells directly controlled by a 5 active bit word (address number 1). The brightness control is also made by a digital potentiometer ( 5 active bit word, address number 0 ). Since a + 3dB contrast capability is required, the $Y$ signal value could be up to 0.7 Vpp nominal. For both functions, the control characteristics are quasi-linear.
In each R-Y and B-Y channel, a six-cell digital attenuator is directly controlled by a 6 active bit word (address number 6 and 7). The tracking needed to keep the saturation constant when changing the contrast has to be done externally by the microcontroller. Furthermore, colour can be disabled by blanking $R-Y$ and $B-Y$ signals using one active bit word (address number 2) to drive the one-chip colour ON/OFF switch.

## Second Matrix, Clamp, Peak Clipping, Blanking

The second matrix receives the $Y, R-Y$ and $B-Y$ signals and delivers the corresponding R, G, B signals. As it is required to have the capability of +6 dB saturation, an internal gain of 2 is applied on both $\mathrm{R}-\mathrm{Y}$ and $B-Y$ signals.
A low clipping level is included in order to ensure a correct blanking during the line and frame retraces. A high clipping level ensures the peak beam current limitation. These limitations are correct only if the DC bias of the three $\mathrm{R}, \mathrm{G}, \mathrm{B}$ signals are precise enough.

Therefore a clamp has been added in each channel in order to compensate for the inaccuracy of the matrix.

## Sandcastle Detector And Counter

The three level supersandcastle is used in the circuit to deliver the burst pulse (CLP), the horizontal pulse $(\mathrm{HP})$, and the composite vertical and horizontal blanking pulse (BLI). This last one is regenerated in the counter which delivers a new composite pulse (BL) in which the vertical part lasts 23 lines when the vertical part of the supersandcastle lasts more than 11 lines.
The TEA5040 cannot work properly if this minimum duration of 11 lines is not ensured.
The counter delivers different pulses needed circuit and especially the line pulses 17 to 23 used in the automatic drive and cut-off control system.

## Automatic Drive And Cut-off Control System

Cut-off and drive adjustments are no longer required with this integrated circuit as it has a sample and hold feedback loop incorporating the final stages of the TV-set. This system works in a sequential mode. For this purpose, special pulses are inserted in G, $R$ and $B$ channels. During the lines 17, 18 and 19, a "drive pulse" is inserted respectively in the green, red and blue channels. The line 20 is blanked on the three channels. During the lines 21, 22 and 23, a "quasi cut-off pulse" is inserted respectively in the green, red and blue guns.
The resulting signal is then applied to the input of a voltage controlled amplifier. In the final stages of the TV-set, the current flowing in each green, red and blue cathode is measured and sent to the videoprocessor by a current source.
The three currents are added together in a resistor matrix which can be programmed to set the ratio between the three currents in order to get the appropriate colour temperature. The output of the matrix forms a high impedance voltage source which is connected to the integrated circuit (pin 32). Same measurement range between drive and cut-off is achieved by internally grounding an external low impedance resistor during lines 17, 18 and 19.
This is due to the fact that the drive currents are about one hundred times higher than the cut-off and leakage currents.

Each voltage appearing sequentially on the wire pin 32 is then a function of specific cathode current :

- When a current due to a drive pulse occurs, the voltage appearing on the pin 32 is compared within the IC with an internal reference, and the result of the comparison charges or discharges an external appropriate drive capacitor which stores the value during the frame. This voltage is applied to a voltage controlled amplifier and the system works in such a way that the pulse current drive derived from the cathode is kept constant.
- During the line 20 , the three guns of the picture tube are blanked. The leakage current flowing out of the final stages is transformed into a voltage which is stored by an external leakage capacitor to be used later as a reference for the cut-off current measurement.
- When a current due to a cut-off pulse occurs, the voltage appearing on the pin 32 is compared
within the IC to the voltage present on the leakage memory. An appropriate external capacitor is then charged or discharged in such a way that the difference between each measured current and the leakage current is kept constant, and thus the quasi cut-off current is kept constant.

## Average Beam Current Limitation

The total current of the three guns is integrated by means of an internal resistor and an external capacitor (pin 34) and then compared with a programmable voltage reference (pin 36). When $70 \%$ of the maximum permitted beam current is reached, the drive gain begins to be reduced ; to do so, the amplitude of the inserted pulse is increased.
In order to keep enough contrast, the maximum drive reduction is limited to 6 dB . If it is not sufficient, the brightness is suppressed.

## SPECIFICATION FOR THE THOMSON BI-DIRECTIONAL DATA BUS

This is a bi-directional 3 -wire (ENABLE, CLOCK, DATA) serial bus. The DATA line transmission is bidirectional whereas ENABLE and CLOCK lines are
only microprocessor controlled. The ENABLE and CLOCK lines are only driven by the microcomputer.

Figure 1 : Peripheral Connections on Bus.

It is possible to select several IC from the microprocessor via the bus. The identification of each particular IC is achieved by the length of the word (number of data bits/clock pulses), meaning that each IC responds with its own particular word length.
The number is determined while ENABLE is low and by counting the negative clock edges. As soon as the high edge of the ENABLE signal is applied, the number is fixed (see figure 2).
The reply word lenght from any of the IC on the bidirectional line is four bits. If it is found insufficient then the reply word can be expanded to include two
repetitive reply sequences one after the other.

The bi-directional transmission is enabled if :

- the IC has been previously addressed at the positive going edge of the enable pulse.
- ENABLE remains high, and DATA is available only during the period when the clock remains low.
- number of identification bits : n
1...n: data from the microcomputer
- number of bi-directional clocks : 4

1 ...M : data to the microcomputer

Figure 2.

The four bit reply word (synchronized with the clock coming from the microcontroller) from the addressed IC to the microcontroller is sent only once. Subsequent clock pulses present on the clock line will be ignored by the IC in question. The data sent to the microcontroller can generally be suppressed completely or partially, but in the case of the videoprocessor, a minimum reply word lenght of 1 has to be maintained (see figure 3).

This implies that a bi-directional bus that incorporates other IC's together with a videoprocessor IC is then also limited by the minimum reply word restric-
tion of 1.
The data word from the microcompter is divided into :

- addresses within the IC
- data

The data word to the microcomputer is divided into

- two data bits,
- two address bits

After the operating voltage is applied, the first transmission will be used as a reset command, i.e. the data word will not be detected.

Figure 3.

- number of identification bits : n
1...n : data from the microcomputer
- number of bi-directional clocks : $1 \quad 1$ : data the microcomputer
(which is the minimum number for the videoprocessor)

TEST DIAGRAM

TYPICAL R, G, B SWITCHING APPLICATION
$\begin{array}{ll}V_{C C}=12 V & Z_{L} \geq 300 \Omega . \\ V_{C C}=10 V & Z_{L} \geq 150 \Omega .\end{array}$

Peritelevision plug standard input value 1 Vpp

## PACKAGE MECHANICAL DATA

16 Pins - Plastic DIP

## 5 CHANNELS VIDEO SWITCH

- EACH CHANNEL EXCEPT FAST BLANKING HAS 6dB GAIN
- R, G, B AND VIDEO SIGNALS ARE CLAMPED TO THE SAME REFERENCE VOLTAGE IN ORDER TO HAVE NO OUTPUT DIFFERENTIAL VOLTAGE WHEN SWITCHING
- ALL INPUT LEVELS COMPATIBLE WITH NFC 92250 AND EN 50049 NORMS
- 30MHz BAND WIDTH FOR R, G, B SIGNALS
- INTERNAL 6.7V SHUNT REGULATOR FOR :
- LOW IMPEDANCE LOADS,
- POWER DISSIPATION LIMITATION

INDEPENDANT VIDEO OR SYNCHRONIZING SIGNAL SELECTION

- SIMULTANEOUS SWITCHING OF R, G, B AND FB SIGNALS BY FB1 INPUT (internal)

## PIN CONNECTION

## PACKAGE MECHANICAL DATA

18 PINS - PLASTIC DIP

## MULTISTANDARD COLOR TV DECODER

- FULLY AUTOMATIC MULTISTANDARD SWITCHING : THE CIRCUIT INCLUDES A SCANNING CONTROL SYSTEM USED FOR THE AUTOMATIC STANDARD RECOGNITION
- NO CRYSTALS REQUIRED : ALL THE FREQUENCIES ARE SYNTHESIZED FROM THE EXTERNAL REFERENCE FREQUENCY OF 62.5 kHz , AND FROM SPECIFIED DATA STORED IN AN INTERNAL ROM
- AUTOMATIC BELL FILTER ADJUSTMENT
- ONLY ONE DELAY LINE COMPENSATION ADJUSTMENT
- AUTOMATIC INTERNAL PAL AND NTSC OSCILLATOR ADJUSTMENT
- AUTOMATIC ADJUSTMENT FOR FOB AND FOR IN SECAM
- POSITIVE R-Y AND B-Y OUTPUTS

## DESCRIPTION

The TEA5640E is a multistandard TV decoder for PAL-SECAM NTSC1 ( 3.58 MHz ) and NTSC2 $(4.43 \mathrm{MHz})$. The circuit automatically selects the standard corresponding to the input signal. It produces all the reference frequencies required for decoding, which is achieved by a digital frequency syn-
thesizer. Included on the chip are four numerical frequency locked loops that allow the elimination of PAL and NTSC crystals. The circuit uses an external reference frequency of 62.5 kHz generally provided by the frequency synthesis tuner of the TV set.

DIP28 (Plastic Package)

ORDER CODE : TEA5640E

PIN CONNECTIONS

BLOCK DIAGRAM (simplified)

## FEATURES

- FULL AUTOMATIC MULTISTANDARD SWITCHING :
THE CIRCUIT INCLUDES A SCANNING CONTROL SYSTEM THAT PROVIDES ALL THE SWITCHINGS REQUIRED FOR THE AUTOMATIC STANDARD RECOGNITION. THIS SYSTEM IS SYNCHRONIZED BY THE FRAME PULSE.
- NO CRYSTAL REQUIREMENT:

THE PAL AND NTSC FREQUENCIES ARE SYNTHESIZED ORIGINALLY BY THE EXTERNAL REFERENCE FREQUENCY OF 62.5 kHz AND DATA STORED IN THE ROM.

- AUTOMATIC ADJUSTMENT OF THE BELL FILTER : BY SWITCHING AN INTERNAL CAPACITOR NETWORK INCLUDED IN A DIGITAL LOOP.
- AUTOMATIC GAIN ADJUSTMENT OF THE DELAY LINE COMPENSATIONS :
THIS ADJUSTMENT IS MADE ON THE BURST AND IS REFRESTED EVERY LINE RETRACE
- AUTOMATIC ADJUSTMENT FOR PAL AND NTSC OSCILLATOR :
THIS OSCILLATOR HAS A DIGITAL AND AN ANALOGIC LOOP. THE PAL AND NTSC FREQUENCIES ARE MEMORIZED IN A ROM CONNECTED TO THE DIGITAL LOOP. THE DIGI-

TAL LOOP GIVES THE RIGHT FREQUENCY AND THE ANALOGIC ONE HOLDS THE PHASE.

- AUTOMATIC ADJUSTMENT OF FoR AND FoB IN SECAM : THESE FREQUENCIES ARE PROGRAMMED IN THE ROM AND ARE SENT TO TWO OTHER DIGITAL LOOPS WHEN SECAM STANDARD IS SELECTED.
AUTOMATIC DIFFERENCE PHASE ERROR COMPENSATION IN PAL MODE.
THE PAL VCO IS LOCKED ON THE BURST AND DURING THE LINE, ON THE BLUE PICTURE CONTENT ( $0^{\circ}$ axis color vector).

## STANDARD SWITCHING AND INHIBITION

NTSC inhibition
NTSC 1 and 2 standards can be inhibited by connecting pin 6 to the ground.
3.58 MHz filter switching :

Pin 26 can be used to switch external filters when NTSC 1 is selected (For example luma filter).

SECAM recognition :

- When SECAM on, pin 12 and pin 17 DC voltages are lower than 5 V .
- For other standards, pin 12 and pin 17 DC voltages are regulated $\mathrm{V}_{\mathrm{CC}}$ (typical 8 V ).

28 PINS - PLASTIC DIP

## PAL/SECAM COLOR TV DECODER

- FULLY AUTOMATIC MULTISTANDARD SWITCHING : THE CIRCUIT INCLUDES A SCANNING CONTROL SYSTEM USED FOR THE AUTOMATIC STANDARD RECOGNITION
- NO CRYSTALS REQUIRED : ALL THE FREQUENCIES ARE SYNTHESIZED FROM THE EXTERNAL REFERENCE FREQUENCY OF 62.5 kHz , AND FROM SPECIFIED DATA STORED IN AN INTERNAL ROM
- AUTOMATIC BELL FILTER ADJUSTMENT
- ONLY ONE DELAY LINE COMPENSATION ADJUSTMENT
- AUTOMATIC INTERNAL PAL OSCILLATOR ADJUSTMENT
- AUTOMATIC ADJUSTMENT FOR FOB AND FOR IN SECAM
- POSITIVE R-Y AND B-Y OUTPUTS

## DESCRIPTION

The TEA5640F is a multistandard TV decoder for PAL-SECAM. The circuit automatically selects the standard corresponding to the input signal. It produces all the reference frequencies required for decoding, which is achieved by a digital frequency synthesizer. Included on the chip are four numerical
frequency locked loops that allow the elimination of PAL crystal. The circuit uses an external reference frequency of 62.5 kHz generally provided by the frequency synthesis tuner of the TV set.

## PIN CONNECTIONS

BLOCK DIAGRAM (simplified)

## FEATURES

- FULL AUTOMATIC MULTISTANDARD SWITCHING:
THE CIRCUIT INCLUDES A SCANNING CONTROL SYSTEM THAT PROVIDES ALL THE SWITCHINGS REQUIRED FOR THE AUTOMATIC STANDARD RECOGNITION. THIS SYSTEM IS SYNCHRONIZED BY THE FRAME PULSE.
- NO CRYSTAL REQUIREMENT:

THE PAL FREQUENCIES ARE SYNTHESIZED ORIGINALLY BY THE EXTERNAL REFERENCE FREQUENCY OF 62.5 kHz AND DATA STORED IN THE ROM.

- AUTOMATIC GAIN ADJUSTMENT OF THE BELL FILTER : BY SWITCHING AN INTERNAL CAPACITOR NETWORK INCLUDED IN A DIGITAL LOOP.
- AUTOMATIC GAIN ADJUSTMENT OF THE DELAY LINE COMPENSATIONS :
THIS ADJUSTMENT IS MADE ON THE BURST AND IS REFRESTED EVERY LINE RETRACE
- AUTOMATIC ADJUSTMENT FOR PAL OSCILLATOR :
THIS OSCILLATOR HAS A DIGITAL AND AN

ANALOGIC LOOP. THE PAL FREQUENCIES ARE MEMORIZED IN A ROM CONNECTED TO THE DIGITAL LOOP. THE DIGITAL LOOP GIVES THE RIGHT FREQUENCY AND THE ANALOGIC ONE HOLDS THE PHASE.
AUTOMATIC ADJUSTMENT OF FoR AND FoB IN SECAM : THESE FREQUENCIES ARE PROGRAMMED IN THE ROM AND ARE SENT TO TWO OTHER DIGITAL LOOPS WHEN SECAM STANDARD IS SELECTED.
AUTOMATIC DIFFERENCE PHASE ERROR COMPENSATION IN PAL MODE.
THE PAL VCO IS LOCKED ON THE BURST AND DURING THE LINE, ON THE BLUE
PICTURE CONTENT ( $0^{\circ}$ axis color vector).

## STANDARD SWITCHING AND INHIBITION

SECAM recognition :

- When SECAM on. pın 12 and pın 17 DC voltages are lower than 5 V .
- For PAL standard, pin 12 and pin 17 DC voltages are regulated $\mathrm{V}_{\mathrm{Cc}}$ (typical 8 V ).

## 3 CHANNEL, LARGE BAND HEAD AMPLIFIER FOR VCR

THE TEA5701 IS AN ADVANCED ONE CHIP 3 HEADS RECORD AND PLAY-BACK AMPLIFIER FOR VCR
PLAY-BACK MODE

- LOW NOISE PERFORMANCE
- LARGE BANDWIDTH (SVHS PROCESSING CAPABILITY)
- AUTOMATIC OFFSET CANCELLER BETWEEN TWO SELECTED HEADS
- RECORD AMPLIFIER INHIBITION DURING PLAY-BACK
- DIRECT DRIVE OF COAXIAL CABLE (500 $\Omega$ $100 \mathrm{pF})$ OF PLAY-BACK OUTPUT
RECORD MODE
- INTEGRATED I/I CONVERTER WITH AUTOMATIC CONTROL OF TRANSCONDUCTANCE
- AUTOMATIC RECORD PLAY-BACK SWITCHING
- PLAY-BACK INHIBITION DURING RECORD MODE
- AUTOMATIC PROTECTION OF RECORD AMPLIFIER AGAINST SHORT CIRCUIT

## PIN CONNECTIONS

## BLOCK DIAGRAM

## DESCRIPTION

TEA5701 is intended for 3 heads VCR applications. It includes all the electrical functions necessary to achieve play-back and record processing for VHS and SVHS applications ( 9 MHz ).
High performance technology allows very low noise levels (current and voltage). In play-back mode a special feature suppresses the DC offset when switching two channels. Optimized play-back output stage gives to the TEA5701 large capability to drive directly a coaxial cable in order to reduce number of external components.

An automatic scanning of recording supply voltage permits that TEA5701 switches automatically in play-back or in record mode. The switching threshold voltage from play-back to record and record to play-back is fixed to a value which forbids high current peaking through the heads.
The recording amplifier includes a protection system which protects the IC and the application board against overheating in case of short circuit on the recording transconductance components.
The TEA5701 is fully protected against ESD.

## DESCRIPTION

The TEA5702 is an advanced two head record and play-back amplifier for VCR.

PIN DESCRIPTION

91DSTEA5702-01

## BLOCK DIAGRAM

## FUNCTIONAL DESCRIPTION

TEA5702 is intended for 2 heads VCR applications. It includes all the electrical functions necessary to achieve play-back and record processing for VHS applications.
High performance technology allows very low noise levels (current and voltage). In play-back mode a special feature suppresses the DC offset when switching two channels. Optimized play-back output stage gives to the TEA5702 large capability to drive directly a coaxial cable in order to reduce number of external components.
Three play-back outputs are availabe : one, dedicated to Chroma processing, is a 60 dB voltage amplifier output, the two others, dedicated to Luma processing, are phase opposite signals with a constant $A C$ output level of 200 mV PP at 3.8 MHz signal.

A tracking information for video signal (TRIV) is Luma amplitude proportional and allows automatic phase correction.
An automatic scanning of record supply voltage permits TEA5702 automatically switching either in play-back or in record mode. The switching threshold voltage is fixed to a value which forbids high current peaking through the heads.
During play-back mode, record output is grounded via an internal transistor and during record mode preamplifiers are turned off.
There is one output current for the two heads, the DC current and the AC characteristics can be very precisely controlled with accurate external resistors. If recommended resistances are used, $a \pm 3 \%$ transconductance accuracy is guaranteed.
TEA5702 is fully protected against ESD.

ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter | Value | Unit |
| :---: | :--- | :---: | :---: |
| $V_{C C}$ | Power Supply Voltage | 6 | V |
| $V_{\text {REC }}$ | Power Supply Voltage Record | 15 | V |
| $\mathrm{~T}_{J}$ | Junction Temperature | 150 | ${ }^{\circ} \mathrm{C}$ |

## THERMAL DATA

| Symbol | Parameter | Value | Unit |
| :---: | :---: | :---: | :---: |
| $\mathrm{R}_{\mathrm{th}}(\cdot-\mathrm{a})$ | Junction-ambient Thermal Resistance (Typ.) | 70 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

ELECTRICAL OPERATING CHARACTERISTICS $\left(T_{A}=25^{\circ} \mathrm{C}\right.$ unless otherwise specified)
Power Consumption

| Parameter |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Typ. | Max. | Typ. | Max. |
| VCC |  | 35mA | 45mA | 25mA | 35mA |
| $V_{\text {REC }}$ |  | 0 mA | 0 mA | 45 mA | 55 mA |
| Total Consumption (2) | $\mathrm{V}_{\mathrm{CC}}=5, \mathrm{~V}_{\text {REC }}=10$ | 175 mW |  | 530 mW |  |
|  | $V_{\text {CC }}=5.25, \mathrm{~V}_{\text {REC }}=10.5$ |  | 240mW |  | 760 mW |

Notes: 1. $\mathrm{R} 1=10 \Omega$
2. Taking in account only the consumption through the IC.

A great care should be taken to the maximum power consumption. $\mathrm{V}_{\text {REC }}$ can be increased to 12.6 V if the DC current flowing through the head is reduced. This can be done by increasing R1 value

## Play-back Mode

## FUNCTIONAL DESCRIPTION

TEA5703 is intended for 3 heads VCR applications. It includes all the electrical functions necessary to achieve play-back and record processing for VHS and S-VHS applications.
High performance technology allows very low noise levels (current and voltage). In play-back mode a special feature suppresses the DC offset when switching two channels. Optimized play-back output stage gives to the TEA5703 large capability to drive directly a coaxial cable in order to reduce number of external components.
Two play-back outputs are availabe : one, dedicated to Chroma processing, is a 60 dB volfage amplifier output, the other one, dedicated to Luma processing, is phase opposite signal with a constant AC output level of 200 mVPP at 3.8 MHz signal. A tracking information for video signal (TRIV) is Luma amplitude proportional and allows automatic phase correction.

An automatic scanning of record supply voltage permits TEA5703 automatically switching either in play-back or in record mode. The switching threshold voltage is fixed to a value which forbids high current peaking through the heads.
During play-back mode, record output is grounded via an internal transistor and during record mode preamplifiers are turned off.
There is one output current for the two recording heads, the DC current and the AC characteristics can be very precisely controlled with accurate external resistors. If recommended resistances are used, a $\pm 5 \%$ transconductance accuracy is guaranteed.
Against short circuit on the recording transconductance components, the recording amplifier includes an overheating protection system for the IC and the application board.
TEA5703 is fully protected against ESD.

## DESCRIPTION

The TEA5704 is an advanced four head record and play-back amplifier for VCR.

SO28
(Plastic Micropackage)
ORDER CODE : TEA5704

PIN DESCRIPTION

## BLOCK DIAGRAM

## FUNCTIONAL DESCRIPTION

TEA5704 is intended for 4 heads VCR applications. It includes all the electrical functions necessary to achieve play-back and record processing for VHS and S-VHS applications ( 10 MHz bandwidth).
High performance technology allows very low noise levels (current and voltage), which are frequency dependant in all the frequency range. In play-back mode a special feature suppresses the DC offset when switching two channels. Optimized play-back output stage gives to the TEA5704 large capability to drive directly a coaxial cable in order to reduce number of external components.
Three play-back outputs are availabe : one, dedicated to Chroma processing, is a 60 dB voltage amplifier output, the two others, dedicated to Luma processing, are phase opposite signals with a constant $A C$ output level of 200 mV Pp at 3.8 MHz signal. A tracking information for video signal (TRIV) is Luma amplitude proportional and allows automatic phase correction.
An automatic scanning of record supply voltage permits TEA5704 automatically switching either in play-back or in record mode. The switching threshold voltage is fixed to a value which forbids high
current peaking through the heads.
During play-back mode, record output is grounded via an internal transistor and during record mode preamplifiers are turned off.
There is one output current for two recording heads, the DC current and the AC characteristics can be very precisely controlled with accurate external resistors. If recommended resistances are used, $a \pm 5 \%$ transconductance accuracy is guaranteed.
Feedback loop gains of SP channel and LP channel can be different.
The recording amplifiers include a protection system which protexts the IC and the application board against overheating in case of short circuit on the recording transconductance components.
A particular feature is the SP/LP envelope comparator and detector. This system can be used in search mode, still mode, slow mode... The output signal is an output current feeding a capacitor. When the input signals are too low, the output is forced high (corresponding to SP Signal amplitude greater than the LP one) by an hysteresys comparator. This output is high in record mode.
TEA5704 is fully protected against ESD.

## Power Consumption

| Parameter |  | Play-Back |  | Record (1) |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Max. | Typ. | Max. |  |
| $\mathrm{V}_{\mathrm{CC}}$ |  | 50 mA | 65 mA | 35 mA | 45 mA |
| $\mathrm{~V}_{\text {REC }}$ |  | 0 mA | 0 mA | 45 mA | 55 mA |
| Total <br> Consumption (2) | $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~V}_{\text {REC }}=9 \mathrm{~V}$ | 250 mW |  | 535 mW |  |
|  | $\mathrm{~V}_{\mathrm{CC}}=5.25 \mathrm{~V}, \mathrm{~V}_{\text {REC }}=9.45 \mathrm{~V}$ |  | 340 mW |  | 700 mW |

Notes: 1. R1 $=5.6 \Omega$
2. Taking in account only the consumption through the IC

A great care should be taken to the maximum power consumption : $V_{\text {REC }}$ can be increased to 12.6 V if the DC current flowing through the head is reduced. This can be done by increasing R1 value. Vaec can be reduced as long as voltage on Pins lour-SP, lout-LP is not going under 1 V (to forbid output stage saturation).

Play-back Mode
VCc = 5V, no load on Pins CHROMA, LUMA+, LUMA-

## ADVANCED FM AUDIO PLAY-BACK AND RECORD AMPLIFIER FOR VCR

ADVANCE DATA

## PLAY-BACK MODE

- LOW NOISE 70dB AMPLIFIERS FOR 2 HEADS
- AUTOMATIC OFFSET CANCELLATION BETWEEN THE 2 SELECTED HEADS
- ONE PLAY-BACK OUTPUT
- MODE SELECTION BY LOGIC INPUT

## RECORD MODE

- ONE INTEGRATED I/I CONVERTER WITH ACCURATE CONTROL OF TRANSCONDUCTANCE
- RECORD AMPLIFIER WITH AUTOMATIC PROTECTION AGAINST SHORT CIRCUIT
- 5V SUPPLY VOLTAGE

## DESCRIPTION

The TEA5712 is an advanced two head FM audio record and play-back amplifier for VCR.

PIN DESCRIPTION

|  |  |
| :---: | :---: |
|  | 91DSTEA5712-01 |

## BLOCK DIAGRAM

91DSTEA5712-02

## FUNCTIONAL DESTCRIPTION

TEA5712 is intended for 2 heads FM audio VCR applications.
High performance technology allows very low noise levels (current and voltage). In play-back mode a special feature suppresses the DC offset when switching two channels. Optimized play-back output stage gives to the TEA5712 large capability to directly drive a coaxial cable in order to reduce number of external components.
Only one power supply is necessary for play-back and record modes. The mode can be chosen through a logic input. A special care has been taken to avoid current peaks through the rotary trans-
formers.
During play-back mode, record output is grounded via an internal transistor and during record mode preamplifiers are turned off.
There is one output current for the two heads, the DC current and the AC characteristics can be very precisely controled with accurate external resistors. If recommended resistances are used, $a \pm 5 \%$ transconductance accuracy is guaranted.
The recording amplifier includes a protection system which protects the IC and the application board against overheating in case of short circuit on the recording transconductance components.
TEA5712 is fully protected against ESD.

## PACKAGE MECHANICAL DATA

16 PINS - PLASTIC MICROPACKAGE

## BUS-CONTROLLED VIDEO MATRIX SWITCH

- 15MHz BANDWIDTH
- 8 INPUTS (CVBS, RGB, MAC, chroma...)
- 6 OUTPUTS
- POSSIBILITY OF MAC OR CHROMA SIGNAL FOR EACH INPUT BY SWITCHING-OFF THE CLAMP WITH AN EXTERNAL RESISTOR BRIDGE
- BUS CONTROLLED
- 6.5dB GAIN BETWEEN ANY INPUT AND OUTPUT
-     - 50dB CROSSTALK AT 5 MHz
- FULLY PROTECTED AGAINST ESD

## DESCRIPTION

The main function of the TEA6414A is to switch 8 video input sources on the 6 outputs.
Each output can be switched to only one of the inputs whereas any same input may be connected to several outputs.
All the switching possibilities are changed through the 3-Wire Bus (THOMSON BUS).

## GENERAL DESCRIPTION

The main function of the IC is to switch 8 video input sources on 6 outputs.
Each output can be switched on only one of each input. On each input an alignment of the lowest level of the signal is made (bottom of synch. top for CVBS or black level for RGB signals).
Each nominal gain between any input and output is 6.5 dB . For D2MAC or Chroma signal the alignment is switched off by forcing, with an external resistor bridge, $5 \mathrm{~V}_{\mathrm{DC}}$ on the input.
Each input can be used as a normal input or as a MAC or Chroma input (with external resistor
bridge).
All the switching possibilities are changed through the BUS.
Driving $75 \Omega$ load needs an external transistor.
It is possible to have the same input connected to several outputs.
The starting configuration (power supply from 0 to 10 V ) is undetermined. In this case, 6 words of 8 bits are necessary to determine one configuration. In other case, one word of 8 bits is necessary to determine one configuration.

BUS SELECTIONS (THOMSON BUS)

## SPECIFICATION FOR THE THOMSON BIDIRECTIONAL DATA BUS

The bidirectional data bus has three lines (DATA, CLOCK, ENABLE) and operates serially. Transmission on the DATALINE is effected bidirectionally,
whilst the ENABLE- and CLOCKLINES are driven only by the microprocessor. It is possible to select several ICs from the $\mu \mathrm{P}$ via the THOMSON BUS.

90DSTEA6414A-07

The identification or address of each particular IC is achieved by the length of the word (number of clock pulses), and each IC responds with its own particular word length. The address length is determined only while ENABLE is low, by counting the clock pulses. The rising edge of the ENABLE signal indicates the end of the address sequence.
Normally, there are several locations within the same chip, which must be selected individually, the datastream may, therefore be split into subaddress and data. In the case where an IC is not using the complete specified subaddress range it is possible to employ the unused subaddress range with a second or third IC with the same word length. The bitnumber of the subaddress is flexible.

The reply word length from any of the ICs to the $\mu \mathrm{P}$ is also flexible. This bidirectional transmission is possible from the last addressed IC after the positive going edge of the ENABLE signal if the ENABLE signal remains high and the CLOCK impulses are present on the line. The $\mu \mathrm{P}$ in effect clocks out the data from the chip. When an IC is able to send information in the bidirectional way, the $\mu \mathrm{P}$ decides whether to take all information, to suppress completely the information or to stop the transfer after any bit.
This reply word, synchronized to the clock from $\mu \mathrm{P}$, is sent only once. Should a subsequent clock impulse be present on the clock line, it will switch the IC in question to high impedance.

The register, from which the bidirectional information comes, is addressed with the IC address. When more than one bidirectional register exists,
the selection is made by the previously selected subaddress.
Data from $\mu \mathrm{p}$

## USE WITH AN OTHER TEA6415B

The programmation input (PROG) permits to operate with two TEA6415B in parallel and to select them independantly through the $I^{2} \mathrm{C}$-BUS without
modifying the adress byte. Consequently, the switch capabilities are doubled or IC1 and IC2 can be cascaded.

TYPICAL APPLICATION

## CROSSTALK IMPROVEMENT

1 - When any input is not used, it must be bypassed to ground through a 220 nF capacitor.

2-An important improvement can be achieved considering the input crosstalk by means of the application (see technical note).

## PACKAGE MECHANICAL DATA

[^15]Example: 01001100 connects outputs 3 with input 4 at a gain of 4 dB
The following are selected after power-on reset . input 4 selected for all outputs; gain $=0 \mathrm{~dB}$.

## TYPICAL APPLICATION

### 1.3 GHz PLL AND PRESCALER CIRCUIT

PRELIMINARY DATA

- FULLY SERIAL BUS-CONTROLLED ( $I^{2} \mathrm{C}$-BUS)
- SEVEN PROGRAMMABLE OUTPUT BAND BUFFERS (CAN DRIVE UP TO 10 mA )
- PROGRAMMABLE REFERENCE COUNTER
- SELECTABLE DIVIDE-BY-8 PRESCALER (ACCEPTS INPUT FREQUENCIES > 1.3GHz)
- 15-BIT PROGRAMMABLE COUNTER (ACCEPTS INPUT FREQUENCIES > 160MHz)
- TRI-STATE PHASE/FREQUENCY COMPARATOR
- OPERATIONAL AMPLIFIER FOR DIRECT TUNING VOLTAGE OUTPUT (33V)
- 62.5 kHz OUTPUT
- CHIP ADDRESS PROGRAMMABLE BY APPLICATION

## DESCRIPTION

The TEA8805 is a PLL and prescaler circuit for TV applications using frequency synthesis tuning principle. It can handle frequencies up to 1.3 GHz and is fully serial bus controlled ( $\mathrm{I}^{2} \mathrm{C}$-Bus).

HF CHARACTERISTICS

|  | HF in/Ref DC Bias |  | 2 |  | V |
| :--- | :--- | :--- | :--- | :--- | :---: |
|  | HF Voltage Range Prescaler "OFF" $10-180 \mathrm{MHz}$ | 20 |  | 300 | $\mathrm{mV} \mathrm{V}_{\mathrm{RMS}}$ |
|  | HF Voltage Range Prescaler "OFF" $80-900 \mathrm{MHz}$ | 20 |  | 300 | $\mathrm{mV} V_{\mathrm{RMS}}$ |
|  | HF Voltage Range Prescaler "ON" $900-1300 \mathrm{MHz}$ | 50 |  | 300 | mV RMS |

Note : When prescaler "OFF", typical supply current is decreased by 10 mA

## GENERAL DESCRITION

Bus Decoder - Data Format
The circuit receives the information for tuning and control via the Bus ( $\mathrm{I}^{2} \mathrm{C}$-Bus).
The incomming information consisting of a chip address byte followed by two or four data bytes, is created in the bus decoder. The definition of the permissible bus protocol is shown below :
1- STA CA CO BA STO
2- STA CA FM FL STO
3- STA CA CO BA FM FL TO
4- STA CA FM FL CO BA STO
STA = Start condition
STO = Stop condition
CA = Chip address byte
CO = Data byte for control information
FM = Data byte for frequency information (MSB'S)
FL = Data byte for frequency information (LSB'S)

BA = Band Information
Frequency information is predeeded by a logic " 0 ". If the function bit is logic " 1 " the two following bytes contain control and band information where the bits have the following functions:

- Bit R0 and R1 : define the reference divider division ratio. Four ratios are available (see Table 1).
- Blt R2 and R3 : are used to switch internal signals to the buffer outputs. Pins 10 and 11 (see Table 2).
- Bit R2 and T : are used to control the phase comparator output stage (see Table 3)
- Blt P : switches the prescaler in and out. At logic "1" The prescaler is bypassed and the power supply of the prescaler is switched off.

COMPLETE DATA TRANSFER PROCESS

Figure 1 shows the five bytes of information that are needed for circuit operation : there is the chip address, two bytes of control and band information and two bytes of frequency information.
After the chip address, two or four data bytes may be received: if three data bytes are received the third data byte is ignored.
If five or more data bytes are received the fifth and following data bytes are ignored and the last acknowledge puise is sent at the end of the fourth data byte.
The first and the third data bytes contain a function bit which allow the IC to distinguish between fre-
quency information and control plus band information.

| Chip address (CA) with Pin 7 to ground | 1 | 1 | 0 | 0 | 0 | 1 | 1 | 0 | ACK |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Chip address (CA) with Pin 7 not grounded | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | ACK |
|  |  |  |  |  |  |  |  |  |  |
| Control INFO (CO) | (1) | R6 | T | $P$ | R3 | R2 | R1 | R0 | ACK |
| Band INFO (BA) | B7 | B6 | B5 | B4 | X | B2 | B1 | B0 | ACK |
|  |  |  |  |  |  |  |  |  | A |
| Frequency INFO (FM) | (0) | N14 | N13 | N12 | N11 | N10 | N9 | N8 | ACK |
| Frequency INFO (FL) | N7 | N6 | N5 | N4 | N3 | N2 | N1 | NO | ACK |
|  |  |  |  |  |  | 91D | TE | 880 | 5-05 |

## Table 1

| Input Data |  | Reference |
| :---: | :---: | :---: |
| R1 | R0 | Division Ratio |
| 0 | 0 | 2048 |
| 0 | 1 | 1024 |
| 1 | 0 | 512 |
| 1 | 1 | 256 |

## Table 2

| Input Data |  | Test Output on Buffers |  |
| :---: | :---: | :---: | :---: |
| R2 | R3 | Pln10 | Pln11 |
| 0 | 0 |  |  |
| 0 | 1 | 62.5 kHz |  |
| 1 | 0 | Fref | FpC2 |
| 1 | 1 |  |  |

Bit B4 has to be "zero" when Pin 10 is used to output 62.5 kHz frequency.

Bit B4 and B5 have to be "zero" to output internal IC signals : reference frequency (Fref) or programmable counter output frequency divided by 2 (FpC2) on PIns 10 and 11.

## Table 3

| Input Data |  |  | Output State of the Phase Comparator |
| :---: | :---: | :---: | :---: |
| R2 | R6 | T |  |
| 0 | 0 | 0 | Normal operation |
| 0 | 0 | 1 | Off (high impedance) |
| 0 | 1 | 0 | High |
| 0 | 1 | 1 | Low |
| 1 | 0 | 0 | Normal operatıon |
| 1 | 0 | 1 | Off |
| 1 | 1 | 0 | Normal operation |
| 1 | 1 | 1 | Off |

BAND BUFFERS

| Band INFO (BA) | B7 | B6 | B5 | B4 | X | B2 | B1 | B0 | ACK |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

The band buffers are open collector transistors and are active "low" at $\mathrm{Bn}=1$. They are designed for 10 mA with a typical on-resistance of $70 \Omega$. These buffers are designed to withstand relative high output voltage in the off-state.
B4 and B5 buffers (Pins 10 and 11 or Pins 11 and 12) may also be used to output internal IC signals (reference frequency and programmable divider
output frequency divided by 2) for tests purposes. Buffer B4 may also be used to output a 62.5 kHz frequency for an intermediate stage of the reference divider. The bit B4 and/or B5 have also to be zero if the buffers are used for these additional functions.

## PROGRAMMABLE COUNTER

The programmable counter is a presentable down counter. When it has counted to zero it takes its required division ratio out of latches.
The division ratio definition is given by :
$\mathrm{N}=16384 \times \mathrm{N} 14+8132 \times \mathrm{N} 13+\ldots+4 \times \mathrm{N} 2+2 \times \mathrm{N} 1+\mathrm{N} 0$ Max. Ration 32767
Min. Ratio 1024
Where N0...N14 are thedifferent bits for frequency information.
The counter may be used for any ratio between 1024 and 32767 and reloads correctly as long as its output frequency does not exceed $1 / 0 \mathrm{MHz}$.
At power-on the whole bus receiver is reset and the programmable counter is set to a counting ratio of $N=1024$ or higher.

## PRESCALER

THe prescaler has a preamplifier which guarantees high input sensitivity. The prescaler may by-passed (Bip P).

## PHASE COMPARATOR

The phase comparator is phase and frequency sensitive and has very low output leakage current in the high impedance state.

## OPERATIONAL AMPLIFIER

The operational amplifier is designed for very low noise, low input bias current and high power supply rejection. The positive input is biased internally. The operational amplifier needs 33 V supply ( $\mathrm{V} C \mathrm{C} 2^{2}$ ) as minimum voltage for a guaranteed maximum tuning voltage of 28 V .
Block Diagram shows a possible filter arrangement. The component values depend very much on the application (tuner characteristic, reference frequency, etc).

## OSCILLATOR

The oscillator uses a 4.0 MHZ crystal tied to ground or $\mathrm{V}_{\mathrm{Cc}}$ through a capacitor, used in the series resonance mode.
The voltage at Pin 16 or Pin 18, "crystal", has low amplitude and low harmonic distortion.

## SYSTEM APPLICATION

Table 4 is summary of the circuit applications using a 4.0 MHz crystal.
Table 4

| Input Data |  | Ref. Dlvider Div. Ratio | Reference Frequency (Hz) (1) | With int. Prescaler P = 0 |  | With int. Prescaler P = 1 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| R1 | R0 |  |  | Frequency <br> Steps (kHz) | Max. Input Frequency (MHz) | Frequency <br> Steps (kHz) | Max. Input Frequency (MHz) |
| 0 | 0 | 2048 | 1953.125 | 15.625 | 512 | 1953125 | 64 |
| 0 | 1 | 1024 | 3906.25 | 31.25 | 1024 | 3.90625 | 128 |
| 1 | 0 | 512 | 7812.5 | 62.5 | 1300 (2) | 7.8125 | 165 (3) |
| 1 | 1 | 258 | 15525.0 | 125 | 1300 (2) | 15.625 | 165 (3) |

Notes: 1. With 4.0MHz crystal
2. Limit of prescaler

3 Limit of programmable divider

## TYPICAL APPLICATION

## PACKAGE MECHANICAL DATA

18 PINS - PLASTIC DIP

20 PINS - PLASTIC MICROPACKAGE (SO LARGE)

## REMOTE CONTROL TRANSMITTER

- ULTRASONIC OR INFRA-RED TRANSMISSION
- DIRECT DRIVE FOR ULTRASONIC TRANSDUCER
- DIRECT DRIVE OF VISIBLE LED WHENUSING INFRA-RED
- VERY LOW POWER REQUIREMENTS
- PULSE POSITION MODULATION GIVES EXCELLENT IMMUNITY FROM NOISE AND MULTIPATH REFLECTIONS
- SINGLE POLE KEY MATRIX
- SWITCH RESISTANCE UP TO $1 \mathrm{~K} \Omega$ TOLERATED
- FEW EXTERNAL COMPONENTS
- ANTI-BOUNCE CIRCUITRY ON CHIP

## QUICK REFERENCE DATA

- POWER SUPPLY: 9 V , STANDBY $6 \mu \mathrm{~A}$, OPERATING 8 mA
- MODULATION : PULSE POSITION WITH OR WITHOUT CARRIER
- CODING : 5 BITS WORD GIVING A PRIMARY COMMAND SET OF 32 COMMANDS
- KEY ENTRY : $8 \times 4$ SINGLE POLE KEY MATRIX
- DATE RATE : SELECTABLE 1 BIT/SEC TO 10 K BIT/SEC
- CARRIER FREQUENCY : SELECTABLE 0 HZ (no carrier) TO 200 KHz

## DESCRIPTION

The UAA4000 is an easily expandable, 32 command, pulse position modulation transmitter drawing zero standby current.

DIP18
(Plastic Package)
ORDER CODE : UAA4000

## PIN CONNECTIONS

## BLOCK DIAGRAM

88DSUAA4000-02

[^0]:    - Under development

[^1]:    * Darlington
    - Typical Value
    - Also Ideal for SMPS

[^2]:    Notes: *. Valid only at the beginning of the cycle
    \#. Valid only untit 18 of the cycle

[^3]:    TDOT $=2$ /fosc

[^4]:    Notes:
    abc. 12-bit address;
    *. Not Affected

[^5]:    Note: The value left hand two columns show the formula used to calculate the timıng minimum or maximum from the oscillator clock perıod, prescale value and number of wat cycles inserted.
    The value right hand two columns show the timing mınımum and maximum for an external clock at 24 MHz divided by 2 , prescale value of zero and zero wait status

[^6]:    ## Legend:

    $N=8$ bit Value
    NN $=16$ bit Value or Address
    $r=$ Working Register
    R = Directly Addressed Regıster
    ( ) = Indirect Addressing
    ( ) $+=$ Indirect with Post-Increment
    -()$=$ Indirect with Pre-Decrement
    b $=$ Bit Number ( 0 to 7 )

[^7]:    Legend :
    $0=$ Bit set to zero
    = Bit set to one
    = Bit affected
    ? $=$ Bit status undefined
    $-\quad=$ Bit not affected

[^8]:    Note: The value left hand two columns show the formula used to calculate the timıng minımum or maximum from the oscillator clock perıod, prescale value and number of wait cycles inserted.
    The value right hand two columns show the tımıng mınımum and maxımum for an external clock at 24 MHz divided by 2 , prescale value of zero and zero wait status

[^9]:    Note : $1 \mathrm{~S} / \mathrm{N}=\frac{\mathrm{V}_{0} \text { (black to white) }}{\left.\mathrm{V}_{\mathrm{N}} \text { (RMS at } \mathrm{B}=5 \mathrm{MHz}\right)}$ (dB)

[^10]:    * Obtaıned with the GND pins soldered to printed circuit with minimized copper area.

[^11]:    教

[^12]:    X = don't care
    $\mathrm{Ax}=2 \mathrm{~dB}$ steps
    $B x=10 \mathrm{~dB}$ steps
    $\mathrm{Cx}=2.5 \mathrm{~dB}$ steps

[^13]:    $A x=1.25 \mathrm{~dB}$ steps; $B x=10 \mathrm{~dB}$ steps; $C x=2 d B$ steps; $G x=6.25 d B$ steps

[^14]:    * Progressive starting by decreasing $\mathrm{V}_{15}$

[^15]:    X = don't care
    MSB is transmitted first
