MADE IN USA

IDENTIFICATION

PRODUCT CODE: AC-7983B-MC

PRODUCT NAME: CEKBGB0 PDP-11/70-74MP System Power Fail Test

PRODUCT DATE: MAY, 1979

MAINTAINER: Diagnostic Engineering

DIAGNOSTIC ENGINEER: BILL SCHLITZKUS

CONTENTS

1.0 ABSTRACT

This diagnostic serves as a replacement to DEKBGA, the 11/70 Power Fail Test. It provides all of the coverage and features of the previous power fail test along with the added features of diagnostic support for multiprocessor systems using the KB11-CM Processor and the IIST interface.

The test is divided into two sections, Section 1 and Section 2. Section 1 completely replaces DEKBGA and basically serves as a test of CPU logic validity during a power Fail sequence. This section can be run on a standard unmodified 11/70 processor as it utilizes no multiprocessor resources. Section 2 is enabled by enabling console switch 6. This section will be executed directly after section 1. This section provides testing for proper functionality of the Interprocessor Interrupt and Sanity Timer (IIST) powerfail procedures, and memory system activity during a loss of power on the system or one of its subsystems.

This diagnostic also supports the use of the UNIBUS Exerciser (UBE) to perform simulated powerfail sequences during the execution of Section 1.

2.0 REQUIREMENTS

2.1 Equipment

This test is designed to support three types of systems.

1. Standard single processor 11/70 systems with the KB-11B/C processor.
2. Standard single processor 11/74 systems with the KB-11CM processor
3. Standard multiprocessor 11/74 systems with MKA11 memory using KB-11CM central processors connected with an IIST interprocessor interface.

At least one console terminal is required for message and error reporting on any of the above specified systems.

Optional equipment includes Unibus Exercisers for all system types and mass storage devices (RP0 5/6, massbus Exercisor) for type 3 systems.

2.2 Storage

The Power Fail test runs in 12K words of memory. The first 4K is used for stack areas and common access data. The second 4K contains the program itself. The only data elements that reside here are type and error messages, and execution flow and control variables that are used

(modified) when the processor runs in multiprocessor mode. The next 4K is used as buffer space for massbus transfers that occur during test 21.

2.3 Preliminary Procedures.

All standard 11/70-74 CPU diagnostics should first be run to insure proper operation under a secure power condition. Specifically, the IIST diagnostic and Unibus Exerciser diagnostics should be run. If massbus devices are to be used for test 21 it might be wise to insure that the devices are in proper working order. The power fail diagnostic may use all massbus drives and memory boxes accessible by the CPUs participating in this diagnostic. Therefore, it is important to switch offline to participating CPUs all data storage equipment that the operator does not want corrupted by this diagnostic. Before starting the power-fail diagnostic the operator should also be sure that the CPU power-up action switches (on the IIST front panel) are all "Run or Halt" for participating CPUs, the IIST enable switches are "online", and the IIST configuration switches are all at the same system for all participating CPUs. All participating memory boxes should be online to all participating CPUs.

The operator of this test should be familiar with the MKA11 and IIST boot/control panel.

3.0 LOADING PROCEDURE

This diagnostic can be loaded within the standard XXDP loading procedure. Note that if this diagnostic is being run as part of a chain that it must be the last element in that chain.

This diagnostic is loadable under the APT system but can only be run under APT in Uniprocessor mode with the UBE enabled.

4.0 STARTING PROCEDURE

4.1 Starting Address

The starting address for this diagnostic is 200. The restart address is 220.

4.2 Control Switch Settings

The switch settings are as follows (when set to 1):

SW15 - Halt on Error
SW14 - Loop on test (Section 1 only)
SW08 - Enable System Power Fail Test (Test 25)
SW07 - Disable Section 1 Tests (Multiprocessor mode only)

SW6	SW5	
0	0	Uniprocessor mode, manual powerfail. (this mode can be used a a replacement for previous powerfail diagnostic)
0	1	Uniprocessor mode, automatic (UBE) powerfail (uniprocessor mode that should be used under APT)
1	0	Multiprocessor mode, manual powerfail. Both sections (1 and 2) are executed.
1	1	Multiprocessor mode, automatic (UBE) powerfail. Only Section 1 will use the UBE. Each CPU must have a UBE.

Note that for the multiprocessor modes (SW6 enabled) the IIST "system" ID of each CPU participating in the test should be specified by setting the appropriate bit in Switches 0-3 in the switch register. For example, if all processors in a 4 processor system are to be tested then switches 0-3 should be enabled. If only CPU's 0 and 2 are to participate then only switches 0 and 2 should be enabled.

The switches are defined by the master CPU only (in multiprocessor mode), where the master is the CPU that starts or restarts the program. Each slave CPU uses the switch definitions of the master.

The Program will not interpret changes to the switches in multiprocessor mode while the program is running. The program must be restarted.

4.3 Restarting Procedures

The restart address for this diagnostic is 220. A restart should be considered a completely new session therefore be sure the proper switches are enabled for the features that you want.

4.4 Program And/Or Operator Action

NOTE

Be sure to isolate the CPU's that are to participate in the powerfail test from other CPU's that are to remain functional. Participating CPU's should have the IIST configuration switches found on the IIST panel switched to the SYSTEM B position (if this is the default position for the installation then the SYSTEM A position could be used).

5.0 OPERATING PROCEDURES

5.1 Modes Of Operation

This diagnostic is designed to run in four basic modes specified by the selection of bits 5 & 6 in the console switch register. It should be noted that if a multiprocessor mode is chosen (SW6 enabled) that the first CPU started will become the "master" and successively start the remaining participating CPU's, the "Slaves".

5.2 Common Procedures

Load address 200 and then enable the switches for the test mode that is desired. Remember to enable the appropriate CPU mask bit if you are running a multiprocessor mode. When this has been done insure that all slaves are powered up and have their halt switches in the "enable" state if MP mode is to be used. Hit start - the program name will be typed followed by the mode the diagnostic is running in (uniprocessor or multi-processor) followed by the contents of the switch register and whether the Unibus Exerciser will be used to simulate power fails.

5.3 Notes And Warnings

1. Power failures in section 1 are only allowed when expected. Therefore in manual mode do not remove the power until the test number appears in the display register.

2. Power failures are not allowed during the execution of the End of Pass (EOP) routines. Note that the number displayed during the End of Pass is the Pass number NOT the test number.

3. When running the diagnostic in uniprocessor mode on a single CPU that is part of a multiprocessor system make sure that the IIST configuration switch for the respecitve CPU is in the STAND ALONE position and the IIST ENABLE switch is in the

OFF LINE position.

4. When running in multiprocessor mode insure that the subsystem under test is isolated from any system that is still running by switching the CPU's under test to an alternate postion with the IIST CONFIGURATION swtiches. For example, if the default system normally runs on the "SYSTEM A" postion, switch the subsystem under test to the "SYSTEM B" position.

5.4 Uniprocessor Mode, No UBE

The diagnostic will instruct you to "interrupt the power after the test number appears on the display". Interrupt the power only at this time. If the test is successful then the next test number should appear in the display. When the End of Pass is reached the Pass count will be typed. There are no error reports in Section 1 (except for unexpected traps to 4 and 114.) Normally, an error results in a processor halt.

5.5 Uniprocessor Mode, With UBE

In this mode the UBE is used to perform the power Fail procedure. No "interrupt the power..." message is typed before the UBE takes action. The test number and pass number however do appear in the display register. An EOP message is typed equivalent to that of Section 5.4. Note that in this mode only the CPU logic involved in the power-fail sequence is tested. Failures that may occur because of problems in the Power system will go undetected.

5.6 Multiprocessor Mode, No UBE

In multiprocessor mode the CPU that is initially started becomes the 'MASTER" CPU. What this means is that all error messages and typeouts will appear on this CPU's console. This CPU is also responsible for startup of "slave" CPU's. Slave CPU's are the remaining CPU's that are scheduled to participate in the test by their appropriate bit being set in switches 0-3 of the master CPU's SWR. When start is depressed and multi-processor mode is specified the program name, test mode, and switch register setting will be typed upon the master CPU console. The remaining CPU's will then be booted and then interrupted through the masters IIST. This will be followed by an "interrupt the power..." message.

The ID of the processor responsible for typeouts and error messages will precede the message:

0>
1>

n>

Run each processor through section 1 one at a time. After power-failing the last test in Section 1 (Test 16) on one CPU go on to the next CPU, etc. After the last test on the last CPU has been completed in Section 1, the operator will receive instructions at console.

Whereas there are no prompts printed at the console in Section 1, all power fails in Section 2 must be done in exact agreement with the typed-out instructions.

Section 2 prompts the operator to remove the power from a particular element of the system. If the expected results occur then the next element is tried. When all relevant elements have been tried then the diagnostic precedes to the next test. Section 2 contains tests 17 through 25.

5.7 Multiprocessor Mode, With UBE

This mode is the same as "multiprocessor mode, no UBE" except that Section 1 will be done without manual intervention. ALl CPUs that are to participate must have a UBE module.

6.0 ERRORS AND ERROR REPORTING

Error reports are always typed out on the console of the CPU that was first started. This is the "master" CPU in multiprocessor mode. All error messages are preceded by a tag as follows 'n>' where n's the IIST self-ID of the CPU encountering the error. Typing in multiprocessor mode is always done by the master. If the master is without power when typing is required, the messages will be queued and printed when power has been restored.

7.0 TEST DESCRIPTIONS

The tests that are found in section I are simple power fail tests that guarantee that the proper machine states are entered on power fail and power up. The test names are self- explanatory.

Section 1

1. Simple Down/Up test (Kernal node)
2. Program Voltility Test
   Verify that the memory bank containing the program will not be corrupted by CPU power fails.
3. Simple Down/Up test (Supervisor mode)
4. Simple Down/Up Test (User mode)
5. Power fail with odd address
6. Power Fail in the Red Zone
7. Power Fail with memory timeout (kernai)
10. Power Fail in the yellow zone.
11. Power Fail with resets.
12. Power Fail with odd address (Supervisor).
13. Power Fail with Timeout (Supervisor)
14. Power Fail with odd address (User)
15. Power Fail with timeout (User)
16. Memory Management Abort Test

Section 2

After all CPUs reach the beginning of Section 2, each CPU sizes for RP04/5/6 massbus devices. If no devices are found the following message is printed:

No Massbus Device Available On CPU #n

If the only massbus device found has its PGM bit set, the following message is printed:

Warning: Drive #n
On CPU #n
Is accessible over Ports A and B

and will be used later in this diagnostic.

17. Check "BRK" & "DCF" FLAGS during power fail. Insure that the IIST's of functioning CPU's receive BRK & DCF signals corresponding to the CPU that performed a Power Fail.

The operator will be prompted with messages of the following type:

Power Fail CPU #n

After restoring power, each of the other CPUs should report:

CPU Interrupt As Expected

20. Check power fail during high memory activity. Insure that power down sequences can be performed by a CPU while other CPU's are contending for the memory bus.

The operator will be prompted with messages of the following type:

Power Fail CPU #n

There is no report from the other CPUs after restoring power.

21. Check power fail during massbus transfer. Insure that power down sequences can be performed by a CPU while other CPU's are performing massbus read operations. Also verify that the read operations don't experience any loss of data due to the power condition of an uninvolved CPU.

The operator will be prompted with messages of the following type:

Power Fail CPU #n

If there are no massbus devices for the other CPUs to use, then the following messages are printed instead of the above message:

No Massbus Device Available On CPU #n Proceeding
To Next CPU.

There is no report from the other CPUs after restoring power.

22. Insure that a loss of AC power on a MKA11 semiconductor memory box does not cause a power fail sequence to occur on any processor that has a disabled part to that box.

    The operator will be prompted with messages of the type:

        Get Set To Power Fail Mem Box #n

    Put battery backup on all memory boxes
    Make all memory ports offline only on mem box to be power failed
    Make all CPU power-up switches "Run or Halt"

    Now Power Fail The Mem Box

    Restore power 5 seconds after power fail
    Restore all memory ports online
    Then type any character at the master console
    No CPU should report a power fail

    The master should report "OK".

23. Check AC power fail on memory box. Insure that a loss of AC power on a MKA11 semiconductor memory box causes a power fail sequence to occur on any processor that has an enabled port to that box.

    The operator will be prompted with message of the type:

        Get Set To Power Fail Mem Box #n

    Put battery backup on all memory boxes
    Make all memory ports online
    Make all CPU power-up switches "Run or Halt"

    Now power fail the mem box

    Restore power 5 seconds after power fail then type any character at the master console. Each CPU should report a power failure.

    Each CPU should report the following message:

        Power Failure On CPU As Expected

24. Check DC Power Loss on a memory box. Insure that the slave CPU(s) specified through the IIST Boot/control panel perform a boot operation when AC & DC power are restored to the memory box.

    The operator will be prompted with message of the type:

        Get Set To Power Fail Mem Box #n

Disable battery backup on mem box to be power-failed. Put all slave CPU mem ports online. Make master CPU mem port offline only on box to be power-failed. Make all CPU power-up switches 'RUN OR Boot'.

Now Power Fail The Mem Box

Restore power 5 seconds after power fail
Restore all mem ports online
Restore all CPU power-up switches to 'Run or Halt''
Then type any character at the master console
Each slave should report an interrupt

Each slave CPU should report the following message:

CPU Interrupt As Expected

25. Check system recovery on power fail. Insure that a total momentary loss of AC power on a system level is recoverable without operator intervention.

The operator will be prompted with the following message:

Get Set to Power Fail Entire System...

Put battery backup on all mem boxes
Make all memory ports online
Make all CPU power-up switches 'Run or Halt''

Now Power Fail the Entire System
Restore power 5 seconds after power fail

Each CPU should report the following:

8.0 MISCELLANEOUS

Test 24 will not be done on the memory box with base address 0. Therefore, in order to fullY test all system elements the operator should restart this diagnostic a second time and switch the box with base address 0 with another box (using the thumbwheels to switch base addresses). The operator should also switch master CPUs on the restart.

SEQ 0013

Test 22 will be skipped if there is only one MKA11 memory box. Power Failing through Section 1 with the UBE will not necessarily test power fail during odd address trap, timeout, etc. (it depends on when the UBE starts the power down). Therefore, it is recommended to manually power fail Section 1!
