PRODUCT CODE: AC-9339F-MC

PRODUCT NAME: CZRXBF0 RX11 INTERFACE DIAGNOSTIC

DATE: APRIL 1979

MAINTAINER: DIAGNOSTIC ENGINEERING

AUTHOR: DAVID L. ADAMS
MODIFIED BY MIKE PAGE TO REV F

CONTENTS

1.0 GENERAL PROGRAM INFORMATION

1.1 Abstract

The RX11 interface diagnostic consists of a series of selectable tests that may be run individually, sequence through all tests, or start at a selected test and run through remaining tests, in order, then go back to the selected test.

These tests check out the basic functions of the RX11 interface such as:

1. Done flag
2. Interrupt level / address
3. Program initialize
4. Read status registers
5. Fill / empty buffer transfer verification
6. Fill / empty buffer with data patterns

It is necessary to insure that these functions work before a data reliability test is run.

Any errors are reported by the program, and it is possible to loop on the error or a particular test for scope testing.

1.2 System Requirements

1.2.1 Hardware Requirements

The following equipment is required:

1. PDP-11 series computer with minimum of 8k memory
2. RX11 floppy disk system, including a single or dual drive RX01 and a PDP-11 Interface card [m7846].

NOTE

A diskette must be included with each drive tested.

3. Console teleprinter

1.2.2 Software Requirements

No prerequisite software

2.0 OPERATING INSTRUCTIONS

2.0.1 Outline of Operating Procedure

The standard running procedure for the diagnostic (to run all tests on both drives with no operator intervention via the switch register) is as follows:

1. Load the program into memory

    1. If it is being loaded from a diskette replace the "library" diskette with a "scratch" diskette.

NOTE

If this step is forgotten and the program was loaded via RXDP (floppy monitor) on unit 0 with unit 0 selected by user to undergo testing the program will failsafe the operation and prompt the user as follows: "Caution - If you desire to test unit 0 replace load medium with a scratch diskette then press continue"

Caution again, however ----------

NOTE

When running this program on a Small 11 (e.g /04, LSI 11, etc.) Where there is no console switch register it is imperative to remember this setup.

NOTE

Before proceeding to Step B, ensure that the following modifiable locations contain the parameters you require for testing. The following table describes each location with respect to the default parameters which will be used if left unmodified by the user:

LOCATION	LABEL	CONTENTS	PROGRAM REACTION
1200	OD:	0	TRACKS 0,52,53,114(8)
1202	FIRST:	015001	SECTORS 1 THRU 32(8)
1204	KRXVEC:	264	ASSUMES PROPER DEVICE VECTOR
1206	RXCS:	177170	ASSUMES PROPER DEVICE STATUS REGISTER (CALCULATES 'RXDB' ADDRESS FROM)
1212	DTESTP:	0	TESTS BOTH UNITS AUTOMATICALLY SEQUENCES THRU ALL TESTS
1214	BRLEV:	5	ASSUMES PROPER DEVICE 'BR' LEVEL

Reference section 2 of this document for a more thorough description of each of these items and how to modify these locations if you desire to change the above mentioned default testing parameters.

2. Start the program at location 200.

3. The program will type out maindec number, a test parameter of 0 (use both drives and run all tests). Then type tracks to be accessed and sector limits. The program is now running all tests in sequence.

4. If there are no errors, at the end of the pass (approx. 50 seconds run time), a "D" will be typed and it will continue on for another pass.

5. To halt the test at any time (after or before completion of a pass) just halt the processor.

6. After completing a pass of the diagnostic, the RX11 reliability test may be run.

7. There are two types of error print out formats:

   1. Tests pretest, 1 - 17, and 21 - 23 use the format shown in section 3.1. The important address there is the "ERADR" (Error Address) go to the listing at that

location to get more information on the error condition

2. Test 20, and 24 - 26 use the format shown in section 3.3. In this case the "TEST PC" is the address of the test being run when the error occurred. Then the vital information of the error is printed (contents of all registers, address of where on the diskette the error occurred, and the type of error).

2.1 Loading The Program

Load the program into memory using the standard procedure for binary paper tapes. Make sure the total system is ready for operation. The diskettes inserted properly, doors closed on drives to be tested etc.

2.2 Starting Addresses

The program has two starting address locations as follows:

2.2.1 Initial Start [Loc.200]

This starting address tests for and selects the hardware, or software switch register, prints maindec name and revision, the test and drive selection, and tracks and sectors being used.

2.2.2 Restart [Loc.202]

This starting address directs the program to continue running using the drive and test selections specified in the previous initial start.

2.3 Operator Action Before Starting The Program

2.3.1 Device Address Selection

Like most options on the PDP-11 the RX11 Interface Card has jumperable register and vector addresses. This allows for devices with the same standard addresses to be jumpered to an other address so they will run without conflict.

The program must know what addresses are being used, as it is through these register and vector addresses that all communication between the

PDP-11 and the RX11 is handled.

If the RX11 system under test is jumpered for register addresses other than standard, which is RXCS = 177170 and RXDB = 177172 place in the memory location called "RXCS" [Loc.1206] its new address. The program assumes the next even address above that of RXCS, will be the address of RXDB, so setting that address is not necessary. If there is a nonstandard interrupt vector address (standard is Loc. 264) then place in memory location called "KRXVEC" [Loc. 1204] its new address.

If either of these locations is loaded with a wrong address, the program will get unpredictable errors and may halt.

NOTE

The program expects that the priority level jumpers are set for a normal 'BR' level of 5 (contents of program location 'BRLEV:' is set to 5). If the priority level jumpers are set to any other level tests 3 & 4 will report errors, unless program location 'BRLEV:' has been patched to contain the relevent 'BR' level before executing the program.

If this is being tested on a LSI 11, tests 3 and 4 will not be run as the LSI 11 has only 1 level of interrupt.

2.3.2 Non-Standard Diskette Address Selection

If it is desirable to test the diskette between track and sector address limits other than the preselected track addresses, and/or minimum (first) and maximum (last) sector addresses, this is done by the operator making changes to two memory locations before the program is started. One location is called "OD" [Loc. 1200] which contains the two bytes for inner and outer track addresses. The other location is called "FIRST" and it contains the two bytes for the first and last sector addresses.

1. Definitions
   OD = Address of track at outer diameter (min. 0)
   ID = Address of track at inner diameter (max. 114)
   FIRST = Address of first sector on a track (min. 1)
   LAST = Address of last sector on a track (max. 32)

2. Locations

   Tracks location 1200 bits 14----8 6----0
   ID OD

   Sectors location 1202 bits 12----8 4----0

LAST FIRST

3. Restrictions

The value of "OD" must be less than or equal to the value of "ID". The value of "FIRST" must be less than or equal to the value of "LAST".

If these locations are changed to new limits, then the program will access only those addresses inclusive of and between these limits. The exception to this is test 26 which always uses a special track sequence.

If the "OD" location is cleared or set to any illegal combination of tracks, the program will clear location "OD". The track sequence will then be tracks 0, 52, 53, and 114 (octal) only.

If the "FIRST" location is cleared or set to any illegal conbination of sector addresse limits then the program will set "FIRST" to 1 and "LAST" to 32 (octal).

2.3.3 Software Switch Register (Loc. 176)

For the PDP 11 processors that do not have a hardware switch register or if the operator wishes to select the software switch register, by putting all the switches up to a "1", (this must be done each time the program is started at location 200, otherwise the program will use the hardware SWR.) Location 176 is assigned as the switch register. Bits set to a "1" in this location have the same function as the corresponding switch in the hardware switch register. All references to the SWR are indirect and the program assigns the correct address of the SWR at "initial start". See Section 2.4.2 for the selection of operating conditions.

To change the software SWR. while the program is running, type "control G". Each time the SWR. is to be tested the program will check to see if the software SWR is selected, and the program is not running in auto mode of RXDP/ACT11. If both conditions exist then the program checks for the CTRL G in the keyboard buffer. If the CTRL G is there the contents of the software SWR. are printed and a "new =" is asked for. The operator may now type in the new switch register contents, terminated by a carriage return (CR), or if he doesn't want to change the SWR. just terminate with the (CR). Note see the character restrictions below.

When the program detects the (CR) it will replace the contents of the software SWR., if a new one has been typed in, and return to the flow of the program.

NOTE

Character restrictions for changing the software SWR.

1. Only octal numbers 0 - 7 are accepted. Any other character typed will be printed as a ? and the whole SWR must be retyped.

2. To wipe out a "new" contents just typed in, type CTRL U. Now a new contents can be retyped.

3. Only 6 octal characters will be put into the SWR. If more than 6 characters are typed in only the last 6 will be put into the SWR.

2.3.4 Test Parameter Selection ("DTESTP" Loc. 1212)

The drive and test delection must be made before the program starts. Location "DTESTP" (Loc. 1212) is where the bits are set to tell the program what drives are wanted and what tests to run as indicated below. When the program starts it will print out the conditions under which it is running.

Bit 15 (1) Select Drive Unit 1
Bit 14 (1) Select Drive Unit 0

NOTE

If neither of the above bits are set to a 1, then the program expects both drives to be ready for operation (power on, diskettes inserted, and doors closed).

SEQ 0011

Then set the test selection in bits 4,3,2,1,and 0 as follows:

"DTESTP" BITS 15 14 13-----5 4 3 2 1 0
U1 U0 NOT USED TESTS

BITS 4	3	2	1	0	TESTS
0	0	0	0	0	(IF NO TEST SELECTED DEFAULTS TO TEST 1)
0	0	0	0	1	TEST 1
0	0	0	1	0	TEST 2
0	0	0	1	1	TEST 3
0	0	1	0	0	TEST 4
0	0	1	0	1	TEST 5
0	0	1	1	0	TEST 6
0	0	1	1	1	TEST 7
0	1	0	0	0	TEST 10
0	1	0	0	1	TEST 11
0	1	0	1	0	TEST 12
0	1	0	1	1	TEST 13
0	1	1	0	0	TEST 14
0	1	1	0	1	TEST 15
0	1	1	1	0	TEST 16
0	1	1	1	1	TEST 17
1	0	0	0	0	TEST 20
1	0	0	0	1	TEST 21
1	0	0	1	0	TEST 22
1	0	0	1	1	TEST 23
1	0	1	0	0	TEST 24
1	0	1	0	1	TEST 25
1	0	1	1	0	TEST 26

NOTE

Selection of tests 27 through 37 will cause the message "illegal test" to be printed.

NOTE

When a specified test is selected the program will start at that test and then run through all the following tests until it completes test 26, indicated by the EOP type out. Then it will go back to the test selected and start the next pass. (i.e. If test 24 is selected the program will rn test 24, 25, and 26, then go back to test 24.)

An expanded definition of the tests is in section 2.5

2.3.4.1 Prerequisite Of Tests: - The following tests must be run in order, as one test sets up for the next test.

Test 6 before tests 7 and test 10
Test 14 before test 15 and test 16
Test 16 before test 17
Test 21 before test 22 and test 23

See section 2.5 under the above tests for explanation

2.4 Operator Action To Run The Program

2.4.1 Starting the Program

Depending upon the starting address selected the program will do the following:

SA200 (Initial Start)

The selection of hardware or software switch register is made then the program will type its identification number, the test parameters selected in location "DTESTP", and tracks and sectors being tested. The program then proceeds to run under those conditions.

SA202 (Restart)

The program will type out the test parameters selected by the previous initial start, prints the diskette address limits, and starts running the tests. The only operator action required is to set the operating conditions as defined in Section 2.4.2, after depressing the "LOAD ADRS" switch and before depressing the start switch.

2.4.2 Operating Conditions

After the test selection has been made press the "CONT" switch. The program will then ask for operating conditions. Switches 0 and 8 through 15 are used as indicated below. Once they are set up again depress the "CONT" switch. The program is now running under the selected conditions.

SW15-SW0 (1) - Select Software Switch Register

NOTE

If there is a hardware switch register, and the operator wants the software switch register, put all switches up (1) befort starting the program at the initial start address.

Sw 5 (1) - Halt on Error

The program halts on detecting an error, after printing the error message. Pressing "CONT" restores the normal operation of the program.

Sw14 (1) Halt at End of Pass

At "end of pass" the program types a bell then an EOP indicator.

"D" means no errors during the pass
"-" means had errors during the pass

If SW14 is set the program will halt. If SW14 is off the program goes back to the test selected and recycles through to the last test, at which time another EOP indicator is printed. If the program halts due to SW14 then press "CONT" will restore the normal flow of the program. If it halts at the end of a pass it will type out the number of passes completed.

Sw13 (- Inhibit Error Typeout

At the detection of an error if SW13 is set no error print out will occur. If SW13 is off the error information is printed as described in section 3.0 error detection.

Sw12 (1) - Loop on Test

At the completion of a test the program checks SW12. If set the program will go back to the beginning of that test and rerun it. This produces a scope loop on a particular test. The program will stay in this test until:

1. Halt on end of test switch is set

2. Loop on test switch is turned off

At which time the program will go on to the next test.

NOTE

If SW12 is set and no test specified (0) the program will loop on test 1.

NOTE

To loop on a test that requires a previous test to be run first (Section 2.3.4), select the prerequisite test and set the "HALT AT END OF TEST" switch. Start the program and when it halts, select the desired test and set the "LOOP ON TEST" switch. The program will now stay in that test.

SW11 (1) - Lock on Error

In some tests errors can occur in several places throughout the test. When the error has been reported the program sets a PC flag to indicate where the error occurred. If SW11 is set the program goes back to the beginning of the test running, and goes through the test until:

1. It finds a different error in an earlier part of the test in which case it will lock onto that error.

2. It detects the PC flag indicating this is where the error occurred. It then goes back to the beginning of the test again.

This loop will continue until halt on error switch is set or the lock on error switch is turned off.

SW10 (1) - Halt at End of Test

When set it will halt the program at the end of the test presently running.

SW 9 - Limit Data Error Print Outs

(0) - When off only the first 10 data byte errors will be printed on a read check test, for each sector. Any more errors will be tabulated but not printed. An error on a different sector will allow 10 more data byte errors to be printed.

(1) - When set all data byte errors for all sectors will be printed on an error.

SW 8 (1) - Inhibit Recalibration

No recalibration of the drives will occur upon the detection of a seek error if this switch is set.

SW 0 (1) - Inhibit Bell at Error

If SW0 is off the error routine will ring the teleprinter bell at each error detected. With SW0 set no bell will ring.

2.5 Test Definitions

2.5.1 Pretest - Initialize [Key] Part 1

Each time the program is started, by either starting address, it runs through a pretest.

Key initialize should set the done flag because any initialization of the RX01 microprocessor is an implied [read sector] of track 1 sector 1. Therefore any error, except parity, that may occur from a normal [read sector] command may occur during an initialize, causing the error flag to set.

Pretest insures that:

1. Done is set
2. Error flag is cleared
3. TR flag is cleared
4. Init done is set

2.5.2 Test 1 - RXCS Test Part I / Interrupt Test Part I

The purpose of this test is to verify that writing all RXCS writable bits to a 0 are not written to a 1.

The program writes the RXCS = 0

No interrupts should occur

The RXCS should remain unchanged = 40 (done)

The RXDB should = 0

2.5.3 Test 2 - Interrupt Test Part II / Vector Address Verification

The purpose of this test is to verify that writing the RXCS interrupt enable bit (bit 6) to a 1, does indeed write it to a 1, therefore because done is set an interrupt should occur (the PDP 11 priority is 0)

2.5.4 Test 3 - Interrupt Test Part III / Priority Level Test Part I

The purpose of this test is to verify the priority of the interrupt request line. The program sets the PDP-11 priority to 4

An RX01 interrupt should occur on priority level 5

If no interrupt occurs then the priority level of the RX11 is not 5, but maybe levels 4,3.2,or 1

2.5.5 Test 4 - Interrupt Test Part IV / Priority Test Part II

The purpose of this test is to verify the priority of the RX11 interrupt request line. The program sets the PDP-11 priority to 5.

No interrupt should occur. If an interrupt does occur then the priority level of the RX11 is not level 5, but maybe level 6, or 7.

2.5.6 Test 5 - Init [Programmed] B / Read Status

The purpose of this test is to verify that setting the RX11 bit 14 causes a RX01 programmed subsystem initialize.

The RXCS should = 40 (done)
The RXDB should = 4, or 104, or 204, or 304

Test 5 cont'd - RXCS test part II / RST

The purpose of this test is to verify the read status command (Function #12)., and that done bit is cleared by the function.

2.5.7 Test 6 - Fill Buffer Transfer Length Test

The purpose of this test is to verify the transfer length of the function "fill buffer" of the RX01 microcontroller

NOTE

This test loads the sector buffer for test 7 and 10, and must be run previous to them.

2.5.8 Test 7 - Empty Buffer Transfer Length and Content Verification Part 1

The purpose of this test is to verify the transfer length of the function "empty buffer" and to verify the contents of the sector buffer.

2.5.9 Test 10 - Empty Buffer Transfer Length and Content Verification Part 11

The purpose of this test is to verify the previous empty buffer test did not empty and destroy the contents of the sector buffer.

2.5.10 Test 11 - Fill / Empty Buffer With All 0"s

During the empty buffer function this test verifies that all 0's are in fact in the sector buffer.

2.5.11 Test 12 - Fill / Empty Buffer With All 1's

During the empty buffer function this test verifies that all 1's are in fact in the sector buffer.

2.5.12 Test 13 - Drive Ready Verification

Tests that the drive ready (RDY) bit will set for all selected drives. The RDY bit will be set after a read status function directed to the the selected drive.

2.5.13 Test 14 - Error Flag and B-Code Verification Part 1

The purpose of this test is to verify that trying to read a non-existant sector will cause an error and the correct error code will be put into the RXDB when the status B is read.

NOTE

This test checks for parity error on the read status B function, the next two tests (T15 & T16) do not. This test must be run before tests 15 & 16.

2.5.14 Test 15 - Error Flag and B-Code Verification Part II

This test verifies that trying to write deleted data on an illegal sector will produce an error and the correct B-code is produced. The deleted data bit should be set after this test.

2.5.15 Test 16 - Error Flag and B-Code Verification Part III

Verifies that a write function to a nonexistant sector will produce an error and the correct B-code is produced. The deleted data bit will also be cleared.

NOTE

Test 16 must be run before test 17 as test 16 clears the deleted data bit and test 17 tests that it is cleared.

2.5.16 Test 17 - Illegal Track Error Verification

This test verifies that if a track address larger than 114(octal) is accessed, an error condition will occur, and the B-code will = 40. It also expects the deleted data bit to be cleared.

2.5.17 Test 20 - Seek Verification Via Read Function

This test does a read function on the selected tracks testing for seek errors on various sections of the diskette.

2.5.18 Test 21 - Write Test

The purpose of this test is to write all ones on sector 1, track 1, and to verify that the data in the sector buffer is not changed.

NOTE

This test must be run before tests 22 & 23 as they check for data written on track 1 sector 1.

2.5.19 Test 22 - Initialize Implied Read

After previously writing data on track 1 sector 1, this test changes the contents of the sector buffer and does a programmed initialize. At the end of an init. (recal.) the sector buffer must contain the data from track 1 sector 1.

NOTE

Unit 0 must be on-line for this test to work.

2.5.20 Test 23 - Read Test

This test verifies that a read function does infact load the sector buffer with data read from the selected address.

2.5.21 Test 24 - Data Transfer and Verification

The purpose of this test is to write then read and check data on all sectors of the selected tracks. The test alternates between drives, if both drives are selected, before changing tracks. The data pattern used is a floating 0 pattern.

2.5.22 Test 25 - Data Verification Via Deleted Data Mode.

This test is the same as Test 24 except it checks for deleted data indicators and uses a data pattern of floating 1.

2.5.23 Test 26 - Head "Home" Test

This test checks for the "home found before the desired track was reached" error code. The head is moved out 10 tracks then decremented back to track 0. It tests all selected drives, and uses a data pattern of random data.

3.0 ERRORS

Pretest and tests 1 - 17, and tests 21 - 23 handle errors as indicated in Section 3.1. For the most part these tests do not rely on an interrupt to indicate the function is completed. Whereas the other tests (tests 20, and 24 - 26) do read, write and read check functions over the selected track, sectors, and drives. These require the interrupt service and error detection that was used in the data reliability test. This is described in Section 3.3.

NOTE

If loop on error switch is up then the program will loop on the shortest set of instructions that will keep it in the failing loop. Otherwise after reporting the error the program will continue running through the remaining addresses and tests.

3.1 Error Heading For Tests 1 - 17, And 21 - 23 Plus Pretest.

The error heading is as follows:

ERADR FAST FAPT [BLANK] GOOD BAD

Under each column the error routine prints pertinent information.

ERADR = Error address
Address of the error trap instruction where the error was detected.

FAST = First address of selected test
Address of the test selected and running

FAPT = First address of present test
Address of the test or subtest presently running, or address of the scope loop.

[BLANK]
Additional general information supplied by some tests on an error.

GOOD = Expected results of the test
Test results of what should have happened if there was no error.

BAD = Actual test results
The data that was received from the RX01, that caused the error.

PASS = Number of passes made up to this error

3.2 Error Output Per Test

The following are the types of print outs under the columns [blank], good, and bad for the various tests, using this errror format.

TEST (SECTION)	[BLANK] (R2)	GOOD (R0)	BAD (R1)
PRETEST (1)	N/A	40	(RXCS)
PRETEST (2)	(RXCS) INCL.DD BIT	4 OR 204	(RXCS) NO DD BIT
TEST 1 (1)	N/A	40	(RXCS)
TEST 1 (2)	N/A	0	(RXCS)
TEST 1 (3)	(KRXVEC)	N/A	N/A
TEST 2 (1)	(KRXVEC)	N/A	N/A
TEST 2 (2)	(KRXVEC)	140	(RXCS)
TEST 2 (3)	(KRXVEC)	40	(RXCS)
TEST 2 (4)	(KRXVEC)	40	(RXCS)
TEST 2 (5)	(KRXVEC)	40	(RXCS)
TEST 3 (1)	(KRXVEC)	N/A	N/A
TEST 4 (1)	(KRXVEC)	N/A	N/A
TEST 5 (1)	N/A	40	(RXCS)
TEST 5 (2)	(RXDB) INCL.DD BIT	4 OR 204	(RXDB) NO DD BIT
TEST 5 (3)	N/A	0	(RXCS)
TEST 5 (4)	N/A	40	(RXCS)
TEST 5 (5)	(RXCS) INCL.DD BIT	200	(RXCS) NO DD BIT
TEST 6 (1)	NO. OF XFERS	N/A	N/A
TEST 7 (1)	NO. OF XFERS	EXPEC. DATA	ACTUAL DATA

TEST 10 (1)	NO. OF XFERS	EXPEC. DATA	ACTUAL DATA
TEST 11&12 (1)	[USES TEST 6 & 7 TO FILL / EMPTY BUFFER]		
TEST 13 (1)	(RXDB)	200	(RXDB) NO DD BIT
TEST 13 (2)	(RXDB)	200	(RXDB) NO DD BIT
TEST 14 (1)	NO. OF TR'S	100040	(RXCS)
TEST 14 (2)	(RXDB)	0	(RXDB) NO DD BIT
TEST 14 (3)	(RXDB)	40	(RXCS)
TEST 14 (4)	N/A	70	(RXDB) ERROR CODE
TEST 15 (1)	NO. OF TR'S	100040	(RXCS)
TEST 15 (2)	N/A	100	(RXDB)
TEST 15 (3)	N/A	70	(RXDB) ERROR CODE
TEST 16 (1)	NO. OF TR'S	100040	(RXCS)
TEST 16 (2)	N/A	0	(RXDB)
TEST 16 (3)	N/A	70	(RXDB) ERROR CODE
TEST 17 (1A)	(RXDB)	0	(RXCS)
TEST 17 (1B)	N/A	100040	(RXCS)
TEST 17 (2)	N/A	0	(RXDB)
TEST 17 (3)	(RXDB)	40	(RXCS)
TEST 17 (4)	N/A	40	(RXDB) ERROR CODE
TEST 21 (1)	(RXES) STATUS A	NO. OF BYTE	(RXDB) STATUS B
TEST 21 (2)	[USES TEST 7 TO EMPTY BUFFER]		
TEST 22	[USES TEST 6 & 7 TO FILL AND EMPTY BUFFER]		
TEST 23	[USES TEST 6 & 21 TO FILL AND CHECK BUFFER]		

3.3 Error Heading for Tests 20, 24 - 26

As previously stated these tests access all the selected sectors. tracks, and drives, and rely on the interrupt service routine to indicate that a function is completed or an error occurred. All errors, with the exceptions where noted, will type as its first or second line of the message "error conditions test PC = XXXX PASS = x". The test PC number is the starting address of the test running, and the pass number is the number of passes made up to the error.

On most errors the program will type out the contents of "Status A" and "Status B".

Status A is the contents of the RXES (error and status register) at the time the error was detected. It shows the CRC, PAR, etc. errors.

Status B is the "definitive error codes" that the RX01 detected, that may have caused the error condition. These error codes are defined in Section 3.3.4

There are three categories of errors as listed and described below.

3.3.1 No Error Flag Errors

These are errors that can occur but the error flag in the RXCS will not be set.

1. Unexpected or missing deleted data bit

   This error results when the program expects and doesn't see the DD bit ("D D mark missing"), or doesn't expect and finds the deleted data bit set ("unexpected D D mark"). The program will type out at what diskette address this occurred then continue testing.

   NOTE

   See Section 3.3.3 for other causes of this error.

2. Data no status error

   This error occurs during a read check when the data read does not match the data in the memory data buffer, and there was no CRC error indicated. This means that the data was probably read off the diskette correctly but the transfer between the sector buffer and the RXDB in the RX11 produced bad data.

The error message will include the diskette address, "byte" number in the sector, the data read from the sector buffer "bad", and the expected data from the memory buffer "good".

Byte # Bad Good
(The data patterns are formatted as shown)

0 (Track address; bits 6 - 0)
1 (Unit number bit 7)
(Sector address bits 4 - 0)

Bytes 2 - 125 contain the selected data pattern.

126 (The sum of all bytes 0 - 125)
127 (The negative of 2 times byte 125)

The program detects a checksum errror by summing all the data read from the sector buffer and comparing that sum to 0.

At the end of the data error typeout the program prints if the checksum accumulated was "good" or "bad". If bytes 0 or 1 have data errors the operator must check the results of the checksum. If it is also bad, then there was a true data error. If the checksum was good, then it might be that the head is not over the track expected, and there is a positioning error.

If switch 9 is down then only 10 data errors will be printed, and at the end of the sector the "total read check errors =" will be typed. If switch 9 is up then all the data errors for that sector will be typed out.

3. Power failure

The program tests for two types of power failure, total system power loss, and RX11 power loss resulting in a recalibration of the drives.

The total system power failure is detected by "SYSMAC" subroutine ".$POWER". When the power is detected to be going down, the registers are saved. When the power comes back up the registers are restored and the message "power" is printed. The program then restarts.

Loss of power in the RX11 causes a recalibration of all drives. When this happens the "init done" bit is set in the RXES register along with the normal done flag At each interrupt the program tests for the init done bit. If it is found set, the function was not completed and a power loss must have been detected. When this happpens the program types out "RX11 Power" and restarts. The error heading is not typed on this error.

4. Unknown interrupt

   If an interrupt occurs through the RX11 interrupt vector address and none of the status bits are set (done, error, etc.) the program will type "unknown interrupt" and return back to the program to continue the function. The error heading is not printed.

5. No interrupt at done

   The program expects an interrupt at done on the functions of these tests. if an interrupt does not occur at done time then the program will type out "no interrupt at done error" then go into the interrupt service routine as if an interrupt did occur. At this point other errors may be printed if any are detected.

3.3.2 Error Flag Errors

These errors are detected as the results of the error bit being set in the RXCS at an interrupt.

1. Parity error

   A parity error results from an incorrect transfer of a command word from the RX11 interface to the RX01 micro-processor controller. The program will type out the contents of the command status register (RXCS) showing the function that failed, the address of the error, contents of status A (RXES) with the parity bit set, contents of status B (RXDB) with the definitive error code of 210 set. Then a "read, write, fill buffer or empty buffer parity error" will be printed. If a parity error occurs on a "read definitive error code" function, then the contents of the RXCS and "parity error" will be typed out.

2. CRC errors

   On all data transfers between the sector buffer and the diskette, a CRC word is generated and checked. If an error is detected by the micro-processor in this CRC word then a CRC error is generated. The program again types out the contents of the registers (RXCS contains function, status A with "CRC ERR" bit set, status B with an error code of 200). Then if it is a read only function, or a read check function and there were data errors it will type out "data CRC errors" then print the bad bytes if any. If it was a read check function and there were no data errors it will print "CRC error no data error".

3. Seek errors

Any error that produces a definitive error code but does not set an error bit in status A (RXDB at end of function) is labeled a seek error. See Section 3.3.4 for error codes and meanings. The same information is printed for these errors as in parity, or CRC errors, except it states that it is a "write or read seek error". If switch 8 is down then at each seek error found the program does an initialize of the RX01 so it will recalibrate to a known (home) position. The program then goes on to the next sector or track and continues testing, if the loop on error switch is off. (See Section 3.3.3. for errors caused by previous errors.) If the loop on error switch is up it will retry the function at the same address. If switch 8 is up then no "initialize" is done and the program looks at the other switches for operating conditions. Seek errors also print the track address that the head moved from at the time of the error.

4. Error flag error

If the error flag is not set in the RXCS and an error bit is set in status A or an error code is set in status B then there was an error but the error flag was not set. The message "error flag error" is printed then the program continues to type out the type of error.

3.3.3 Errors Resulting From Previous Errors

If there is a "write seek error" the program will go on to the next address without writing on the address where the error occurred. (Unless the loop on error switch 11 is up and the seek error is recovered.) If the write function is followed by a read check function and the read does not have a seek error at the same address, then there may be data errors, or unexpected or missing deleted data bit errors resulting from no data being written on that address by the previous write function.

3.3.4 Definitive Error Codes

The RX01 micro-processor has defined the error codes and meanings which are available to the program by issuing command #7 "read definitive error code"
The following are the codes and their meanings:

10 - Drive 0 failed to see home from initialize
20 - Drive 1 failed to see home from initialize
30 - Home found when stepping out 10 tracks for init.
40 - Tried to access a track greater then 76
50 - Home found before desired track was reached
60 - Self diagnostic error
70 - Desired sector not found after sampling 52 headers
100 - Write protect error
110 - More then 40 us and no sep clock detected
120 - A preamble could not be found
130 - Preamble found but no ID mark found in time
140 - CRC error on a header, no error flag
150 - Good header (no CRC error) but track compare error
160 - ID address mark not found in time
170 - Data mark not found in time
200 - Data CRC error
210 - Parity errors

3.4 Program Hung

If there is no response from the RX11 while waiting for the transfer request (TR) flag or the done flag, the program will type "device test hung @ PC" (only if SW13 is off) and then go on to the next test, or the beginning of the present test.

4.0 HALTS

The only halts in the program are the selectable halts (EOP, EOT, at error), the illegal vector halts, and the illegal test selection halt.

NOTE

One additional 'halt' exists in the program. It occurs when the user has loaded his program via the 'RXDP' monitor (on unit 0) and also requires testing of unit 0. A prompt message is typed reminding the user to replace his load medium with a scratch diskette before going on. The program will wait for the 'continue' switch to be depressed.
