## PREFACE

This manual describes the 32-bit run time library (RTL) mathematical functions. :

Chapter 1 introduces the RTL mathematical functions. Chapter 2 gives the needed information for all subprograms. Chapter 3 details elementary, min and max, and miscellaneous functions. The appendixes present information on error messages and the subprograms documented in the manual. Arithmetic tables are also included. :

The R03 revision of this manual provides more information on the exponentiation routines. :

For a survey of the Run Time Library and more information on the construction of programs in the Run Time Library, refer to the following Perkin-Elmer publication:

CHAPTER 1  
INTRODUCTION

This manual describes the mathematical subprogram Perkin-Elmer provides in the FORTRAN VII Run Time Library. Subprograms described include the Intrinsic and Basic External functions required by ANSI Standard X3J3/77 and the arithmetic routines which the compiler calls. See the FORTRAN VII Run Time Library Language Extensions Manual, Publication Number 29-580, for the subprograms which perform bit and byte manipulation and logical operations.

This manual provides the following information for each subprogram:

1. The purpose served by the subprogram.
2. The types of arguments and values.
3. The range of admissible arguments.
4. The accuracy (where relevant) of the result.
5. Error messages and possible interrupts.
6. A brief description of the algorithm.

The subprograms can be called by assembly language code. The user must be aware of which arguments are passed to subprograms and which values are returned. See the FORTRAN VII Run Time Library Introduction and Overview, Publication Number 29-578.

Chapter 2 contains information pertinent to all of the subprograms. Definitions are given to fix the terminology. Accuracy of the different subprograms, ranges of admissible values, and the generation of error messages are described.

The Run Time Library provides descriptions of the function subprograms. These descriptions include external functions called by explicit statements in FORTRAN, intrinsic functions which can be called explicitly or implicitly (e.g., type conversion), and the involution routines called as a result of compiler-generated code. The programs are grouped as follows:

Elementary functions

Square root:	SQRT, DSQRT, CSQRT, CDSQRT
Exponential:	EXP, DEXP, CEXP, CDEXP
Trigonometric:	SIN, DSIN, CSIN, CDSIN, COS, DCOS, CCOS, CDCOS, TAN, DTAN
Logarithm:	ALOG, ALOG10, DLOG, DLOG10, CLOG, CDLOG
Inverse Trigonometric:	ACOS, ASIN, ATAN, ATAN2, CACOS, DASIN, DATAN, DATAN2
Hyperbolic:	SINH, COSH, TANH, DSINH, DCOSH, DTANH

Min and Max functions:

AMAX0	AMAX1	AMIN0	MIN0	MAX1
AMIN1	DMAX1	DMIN1	MAX0	MIN1

Type conversion subprograms:

DBLE	FLOAT	IDINT	DFLOAT	
IFIX	INT	INT2	SNGL	REAL

Miscellaneous functions:

Remainder

AMOD	DMOD	MOD
------	------	-----

Manipulation of complex numbers

AIMAG	DIMAG	CMPLX	CONJG	DCONJG
-------	-------	-------	-------	--------

Absolute value

ABS	CABS	DABS	DCABS	IABS
-----	------	------	-------	------

Transfer of sign

DSIGN	ISIGN	SIGN
-------	-------	------

Positive difference

DIM	IDIM	DDIM
-----	------	------

Truncation and rounding

AINT	DINT	ANINT	DNINT	NINT	IDNINT
------	------	-------	-------	------	--------

Double-precision product of single-precision factors

DPROD

Involution (raising to powers):

.IXXI	.IXXR	.IXXD	.IXXC	.IXXCD
.RXXI	.RXXR	.RXXD	.RXXC	.RXXCD
.DXXI	.DXXR	.DXXD	.DXXC	.DXXCD
.CXXI	.CXXR	.CXXD	.CXXC	.CXXCD
.CDXXI	.CDXXR	.CDXXD	.CDXXC	.CDXCD

Complex arithmetic:

.CXMPY	.CDMPY	.CXDIV	.CDDIV
--------	--------	--------	--------

## CHAPTER 2

### GENERAL CONSIDERATIONS

#### 2.1 TERMS RELATED TO ACCURACY

Several methods describe the accuracy of a computation in floating-point arithmetic. In this manual, the following terms are used:

**Absolute Error:** is the absolute value of the difference between the true value of a desired number and the value as computed.

**Relative Error:** is the ratio between the absolute error and the true value.

Generally, the relative error is the more useful of the two and better adapted to floating-point representation of numbers. To refer to a result as accurate "to five decimal places" is actually saying that the relative error is  $1.0E-5$  or better.

A statement of the relative accuracy of a computation is based on the assumption that the numerical data, such as the argument of a function, is perfectly accurate.

In practice, numerical data generally has errors. Therefore, it is important to know the manner in which these errors can grow in the course of a computation. This is discussed for each function or group of functions under the heading "Propagation of Errors."

Extended discussions are available for accuracy and error-propagation qualities of floating point programs. The reader can consult:

Fike, C.T., Computer Evaluation of Mathematical Functions, Prentice-Hall, Inc., 1968

Hart, J.F., et al, Computer Approximations, Wiley, 1968

Sterbenz, P., Floating Point Computation, Prentice-Hall

#### 2.2 ACCURACY OF FUNCTION SUBPROGRAMS IN GENERAL

The subprograms in the Run Time Library can be classified by their use of integer or floating-point arithmetic and by the amount of computation they involve.

**Floating-point computations:** the function subprograms described under Elementary Functions generally return values with a relative accuracy better than  $1.0E-7$  for single-precision functions and better than  $1.0E-16$  for double-precision functions. There are exceptions to this rule, however, in the case of logarithms and trigonometric functions. See Paragraphs 3.2.3 and 3.2.4 for details.

The floating-point involution subprograms also have a relative accuracy of  $1.0E-7$  for single precision or  $1.0E-16$  for double precision. The other computational subprograms are accurate to a few units in the last significant bit (i.e., a relative error of  $1.0E-7$  or better in single precision and  $1.0E-16$  in double precision). The value  $1.0E-7$  also applies to the subroutines mentioned under Complex Arithmetic, Paragraph 3.7. An exception in the case of AMOD or DMOD is described under Remaindering, Paragraph 3.5.1.

Type conversion functions are accurate to one unit in the least significant bit. Those subprograms using only integer arithmetic are absolutely accurate. The same is true of subprograms which essentially do no arithmetic (such as AMIN1 and SIGN).

Ranges: The Basic External and Intrinsic function subprograms in the Run Time Library give meaningful results for all values of their arguments and are subject to the following range restrictions:

- Square root: The argument must be positive or zero.
- Exponential: The argument  $x$  must satisfy  $-65 \cdot \text{alog}(16) < x < 63 \cdot \text{alog}(16)$ , i.e.,  $-180.2 < x < 174.6$
- Logarithm: The argument must be positive.
- Trigonometric: The argument of SIN, COS, or TAN must have an absolute value no greater than  $16^{**6} = 16,777,216$ . The argument of DSIN, DCOS, or DTAN must have an absolute value no greater than  $16^{**14} = 72,057,594,037,927,936$ .
- Inverse trigonometric: The argument of ASIN, ACOS, DASIN, or DACOS must be between  $-1.0$  and  $1.0$ .
- Hyperbolic: The argument of SINH, COSH, DSINH, or DCOSH must have an absolute value no greater than  $175.0$ .
- Complex functions: Restrictions on the arguments of complex functions are described under the individual functions.
- Type conversion: The argument of IDINT, INT, or IFIX must be between  $-(2^{**31}-1)$  and  $2^{**31}-1$  ( $2^{**31} = 2,147,483,648$ ). The argument of INT2, must be between  $-32,768$  and  $32,767$ .

Miscellaneous functions: The second argument of AMOD, DMOD, or MOD, must be nonzero. The functions DSIGN, and SIGN require the second argument to be non-negative when the first argument is zero.

Involution routines: The integer, real, double-precision, and complex routines reject a zero base with a negative exponent. The real and double-precision routines reject a negative base.

### 2.3 GENERATION OF ERROR MESSAGES

Even if arguments satisfy the restrictions detailed under Ranges, they can lead to arithmetic underflow or overflow. When these conditions do occur, or when it is known that they will occur, the Run Time Library function subprograms cause an error message to be printed. The same happens if inadmissible arguments are passed to the subprogram. Details on specific error messages are given for each subprogram under Description of Function Subprograms. The error messages are of the form:

ERROR n IN m AT a: d

where: n identifies the diagnostic message,  
m is the name of the subprogram,  
a is the hexadecimal address of the point in the user's program from which the RTL is called, and  
d is a diagnostic message.

See Appendix 1 for operation of the error message facility and suggested response to error messages.

### 2.4 EXTERNAL AND INTRINSIC VERSIONS OF FUNCTIONS

Except for the involution and complex arithmetic routines, every mathematical function in the RTL exists in two versions, as an intrinsic function or as an external function. The external functions are identified by their purely alphabetical names. The arguments are passed via an argument list. The intrinsic functions have names preceded by an @. They also accept arguments via an argument list. Some intrinsic functions have argument passage in registers. Their names are preceded by a dot. Hence, certain functions in the RTL have 3 different versions, e.g. COS, @COS and .COS.

## DESCRIPTION OF FUNCTION SUBPROGRAMS

## 3.1 INTRODUCTION

This section contains information on each function subprogram and it covers these topics: the purpose served by each function, the range of argument values which it accepts, considerations of accuracy and propagation of errors, an explanation of run-time error messages, subprograms called by a function, and a brief description of the algorithm is included for the more complicated mathematical functions.

When a function is in both the intrinsic and the external versions, the external version calls the intrinsic version to perform the actual computation. Therefore, the references to the function subprograms use the names of the intrinsic versions. Usually, the algorithms for single precision and double precision are similar. To describe them concisely, the function name and its arguments written in lower-case letters are generic names. A reference for nearly all algorithms is the book by Hart, cited earlier in this manual. The largest number representable in floating-point notation is approximately  $16^{*}63$  or  $4.0E75$ . This number (whether in single or double precision) is referred to as "OMEGA". Small values of the argument are frequently a special case and dependent upon the level of precision. The notation "eps" denotes  $16^{*(-3)}$  in single precision and  $16^{*(-7)}$  in double precision:

EPS=Y`3E100000' in single precision

EPS=Y`3A100000', Y`00000000' in double precision.

The type Integer will always mean either Integer\*2 or Integer\*4.

## 3.2 ELEMENTARY FUNCTIONS

## 3.2.1 Square Root

	<u>Argument</u>	<u>Value</u>
Y=SQRT (X)	Real	Real
DY=DSQRT(DX)	Double precision	Double precision
CWW=CSQRT (CZZ)	Complex*8	Complex*8
CDWW=CDSQRT(CDZZ)	Complex*16	Complex*16

**Purpose:** To compute the square root of an argument of the appropriate type.

**Range of arguments:** For SQRT and DSQRT, the argument must not be negative. For CSQRT and CDSQRT, the argument may be any complex number.

**Accuracy:** SQRT and CSQRT are accurate to seven decimal places or better for all arguments. DSQRT and CDSQRT are accurate to 16 decimal places or better for all arguments.

Propagation of error: The relative error in  $\text{SQRT}(X)$  is approximately half the relative error in  $X$ . The only source of instability is the case where the absolute error in  $X$  is sizable compared to  $X$ .

Error messages: If a negative  $x$  is received, then  $\text{SQRT}$  and  $\text{DSQRT}$  print error messages "NEGATIVE ARGUMENT". The square root of the absolute value of  $x$  is returned to the called program.

Subroutines called:  $\text{.CSQRT}$  calls  $\text{.CABS}$  and  $\text{.SQRT}$   
 $\text{.CDSQRT}$  calls  $\text{.CDABS}$  and  $\text{.DSQRT}$

Algorithms:  $\text{.DSQRT}$  and  $\text{.SQRT}$  use the same basic algorithm. If  $x=0.0$ , then no processing is performed. If  $x<0.0$ , then an error message is printed and  $x$  is replaced by its absolute value.

Let  $x=(16**m)*u$ ,  $1/16 \leq u < 1$   
Let  $m=2*n+ip$ ,  $ip=0$  or  $1$   
 $u=v*(.25**iq)$ ,  $iq=0$  or  $1$ ,  $1/4 \leq v < 1$

A rational approximation,  $w_a$ , to  $\text{sqrt}(v)$  is found first (Hart, formulas 0291 or 0293). The approximation is improved by Heron's formula:

$w_a$  is replaced by  $(v/w_a + w_a)*.5$

In double precision, this formula is applied twice.

Let  $k=2*ip-iq$   
Then  $\text{sqrt}(x)=(16**n)*(2**k)*w_a$

The algorithm for  $\text{CSQRT}$  and  $\text{CDSQRT}$  makes use of  $\text{SQRT}$  and  $\text{DSQRT}$ , respectively. Let  $\text{sqrt}(x+iy)=a+ib$ . If  $x=y=0$ , no processing is performed.

If  $x=0$ , then  $a=\text{sqrt}(\text{abs}(y)/2)$   
 $b=(y/\text{abs}(y))a$

If  $y=0$ ,  $x>0$ , then  $a=\text{sqrt}(x)$   
 $b=0$

If  $y=0$ ,  $x<0$ , then  $a=0$   
 $b=\text{sqrt}(-x)$

Let  $r=\text{cabs}(x+iy)$

If  $x>0$ , then  $a=\text{sqrt}((x+r)/2)$   
 $b=y/(2a)$

If  $x<0$ , then  $b=(y/\text{abs}(y))\text{sqrt}((-x+r)/2)$   
 $a=y/(2b)$

### 3.2.2 Exponential Functions

	<u>Argument</u>	<u>Value</u>
Y=EXP(X)	Real	Real
DY=DEXP(DX)	Double precision	Double precision
CWW=CEXP(CZZ)	Complex*8	Complex*8
CDWW=CDEXP(CDZZ)	Complex*16	Complex*16

**Purpose:** To compute  $\exp(x)$  where  $x$  is a floating-point number of the appropriate type.

**Range of arguments:** For EXP and DEXP the argument must lie between  $-65 \cdot \log(16)$  and  $63 \cdot \log(16)$ . The interval from  $-180.0$  to  $+174.0$  is within these bounds. For CEXP and CDEXP, the real part must be between  $-180.0$  and  $+174.0$  and the imaginary part must have absolute value less than  $16^{**6}$ .

**Accuracy:** EXP and CEXP normally give results accurate to seven decimal places or better. When the imaginary part of a complex argument is very large, this accuracy degrades; see remarks in propagation of errors under Trigonometric Functions, Paragraph 3.2.3. DEXP and CDEXP give results accurate to 16 decimal places or better.

**Propagation of errors:** The relative error of EXP(X) is equal to the absolute error of X.

**Error conditions:** If the argument of EXP or DEXP is greater than the maximum acceptable value, then a message to that effect is put out and the number OMEGA is returned. If the argument of EXP or DEXP is less than the least acceptable value, then a different message is put out and 0.0 is returned. The same messages are put out if the real part of the argument of CEXP or CDEXP is out of the acceptable range. If the imaginary part of the argument of CEXP or CDEXP is unacceptable, another message is put out. CEXP returns the value (0,0) if the real part of the argument is less than the lower limit or the imaginary part is too large. If the imaginary part is acceptable, but the real part is above the upper limit, a large complex number is returned.

**Subroutines called:** .CEXP calls .EXP, .SIN, and .COS  
.CDEXP calls .DEXP, .DSIN, and .DCOS

Algorithm:

1. EXP and DEXP.

If  $\text{abs}(x) < \text{eps}$ , then  $1+x$  is returned.  
If  $\text{abs}(x) > 256$  then it is treated as an error. Otherwise, let  $y = x*r$ , where  
 $r = 2.0 / \text{alog}(2.0)$   
 $y = n+f$ ,  $0 \leq f < 1$

If  $n > 504$  then  $x$  is above the upper limit;  
if  $n < -520$  then  $x$  is below the lower limit. Otherwise,  $\text{exp}(x)$  can be evaluated without overflow as follows:

Let  $g = f - 0.5$   
Let  $z = 2^{g/2}$

$z$  is found by a rational approximation (Hart, formulas 1080 or 1082).

Let  $n = 8*m+k$ ,  $0 \leq k \leq 7$   
 $s = 2^{(0.5*k+0.25)}$   
 $s$  is found from a table

Finally:  
 $\text{exp}(x) = (16^m) * s * z$

2. CEXP and CDEXP

Let the two parts of the argument be  $(x_r, x_i)$

If  $-180.0 \leq x_r \leq 174.0$ , let  $u = \text{exp}(x_r)$

If  $x_r < -180.0$ , let  $u = 0$

If  $x_r > 174.0$ , let  $u = \text{OMEGA}$

If  $\text{abs}(x_i) > 16^6$ , let  $s = c = 0$ .  
Otherwise,  $s = \text{sin}(x_i)$ ,  $c = \text{cos}(x_i)$

Then:  
 $\text{cexp}(x_i, x_r) = (u*c, u*s)$

3.2.3 Trigonometric Functions

	<u>Argument</u>	<u>Value</u>
Y = SIN(X)	Real	Real
Y = COS(X)	Real	Real
Y = TAN(X)	Real	Real
DY = DSIN(DX)	Double precision	Double precision
DY = DCOS(DX)	Double precision	Double precision
DY = DTAN(DX)	Double precision	Double precision
CWW = CSIN(CZZ)	Complex*8	Complex*8
CWW = CCOS(CZZ)	Complex*8	Complex*8
CDWW = CDSIN(CDZZ)	Complex*16	Complex*16
CDWW = CDCOS(CDZZ)	Complex*16	Complex*16

**Purpose:** To compute the trigonometric sine, cosine, or tangent (assuming radian measure) of an argument of the appropriate type.

**Range of arguments:** For SIN, COS, and TAN, the argument must have an absolute value less than  $16^{**}6$ . For DSIN, DCOS, and DTAN the argument must have an absolute value less than  $16^{**}4$ . For CSIN, CDSIN, CCOS, and CDCOS, the argument must have a real part less in absolute value than  $16^{**}6$  and an imaginary part between -175 and +175.

**Accuracy:** Normally, SIN, COS, TAN, CSIN, and CCOS return values which are accurate to seven decimal places or better. DSIN, CDSIN, DCOS, and CDCOS return values accurate to 16 decimal places or better.

**Propagation of errors:** The absolute error in SIN(X), COS(X), DSIN(X), and DCOS(X) is no greater on absolute value than the error in X. The absolute error in TAN(X) or DTAN(X) is the absolute error in X times  $\text{COS}(X)^{**}(-2)$ . Thus when COS(X) is small, TAN(X) is large and its evaluation can be unstable. For the complex functions, when the imaginary part of the argument differs from 0.0, the relative error in the value is proportioned to the absolute error in the argument.

**Error conditions:** If the argument of SIN, COS, or TAN is greater in absolute value than  $16^{**}6$ , then an error message is put out and 0.0 is returned. If the argument of DSIN, DCOS, or DTAN is greater in absolute value than  $16^{**}14$ , then the same error message is put out and 0.0 is returned. If the argument of TAN or DTAN is such that function evaluation would lead to division by zero, then a different error message is put out and OMEGA is returned. If the real part of the argument of CSIN or CCOS has absolute value greater than  $16^{**}6$ , a message is put out and (0.0, 0.0) is returned. If the real part is acceptable, but the imaginary part is greater in absolute value than 175.0, a message is put out and a large complex number is returned.

**Subroutines called:** .CSIN and .CCOS call .SIN, .COS, .SINH, and .COSH  
.CDSIN and .CDCOS call .DSIN, .DCOS, .DSINH, and .DCOSH

Algorithms:

1. Real and double-precision functions

If  $\text{abs}(x) < \text{eps}$ , then  
 $\sin(x) = x$ ,  $\cos(x) = 1$ ,  $\tan(x) = x$

If  $\text{abs}(x)$  is too large (see "Error Conditions"), then 0.0 is returned.

Otherwise let

$ya = x^2 * c$  where  $c = 2/\pi$   
Set  $ya = k + u$  where  $-1 \leq u < 1$ .

Depending on  $k$ , the evaluation of the function of  $x$  reduces to one of these forms:

$pm * \sin(u * \pi / 4)$   
 $pm * \cos(u * \pi / 4)$   
 $\tan(u * \pi / 4)$   
 $\cot(u * \pi / 4)$

where  $pm = 1$  or  $-1$

Polynomial or fractional approximations are used (Hart, formulae 3040, 3603, 3820, 3823, 4242, and 4245) to evaluate the above 4 formulas. If  $u = 0$  and  $\cot(u * \pi / 4)$  is required, then an error message is put out and OMEGA is returned.

2. Complex functions

Let the argument be  $cz = (x, y)$ .

If  $\text{abs}(x) < 16^{**}6$ , let  
 $rc = \cos(x)$ ,  $rs = \sin(x)$ ,  
Otherwise  $rc = rs = 0$

If  $\text{abs}(y) < 175.0$ , let  
 $hc = \cosh(y)$ ,  $hs = \sinh(y)$ ;

If  $y > 175.0$ , let  
 $hc = \text{OMEGA}$ ,  $hs = \text{OMEGA}$ ;

If  $y < -175.0$ , let  
 $hc = \text{OMEGA}$ ,  $hs = -\text{OMEGA}$

Then:

$c\cos(cz) = (rc * hc, -rs * hs)$   
 $c\sin(cz) = (rs * hc, rc * hs)$

### 3.2.4 Logarithmic Functions

	<u>Argument</u>	<u>Value</u>
Y=ALOG(X)	Real	Real
Y=ALOG10(X)	Real	Real
DY=DLOG(DX)	Double precision	Double precision
DY=DLOG10(DX)	Double precision	Double precision
CWW=CLOG(CZZ)	Complex*8	Complex*8
CDWW=CDLOG(CDZZ)	Complex*16	Complex*16

**Purpose:** To compute the logarithm of a floating-point number of the appropriate type. ALOG10 and DLOG10 compute logarithms to the base 10; the others, to the base e (natural logarithms).

**Range of arguments:** ALOG, ALOG10, DLOG, and DLOG10 require positive (non-zero) arguments. CLOG and CDLOG require a non-zero complex argument.

**Accuracy:** ALOG, ALOG10, and CLOG return values with an absolute error of 1.0E-7 or less. DLOG and DLOG10 return values with an absolute error of 1.0E-16 or less.

**Propagation of error:** The absolute error of ALOG(X) equals the relative error of X. The absolute error of ALOG10(X) equals the relative error of X multiplied by ALOG10(e)=.434.

**Error conditions:** When the argument of a real or double-precision function is 0, an error message is printed and -OMEGA is returned. When the argument is negative, a different error message is printed and the logarithm of the absolute value is returned. When the argument of CLOG or CDLOG is (0.0, 0.0) an error message is printed and (-OMEGA 0.0) is returned.

**Subroutines called:** .ALOG1 branches to .ALOG, and .DLOG1 branches to .DLOG.  
 .CLOG calls .CABS, .ALOG1, and .ATAN2.  
 .CDLOG calls .CDABS, .DLOG1, and .DATN2.

**Algorithms:** 1. ALOG, ALOG10, DLOG, DLOG10.

After stage (A) in the algorithm, the computation for base 10 is identical to that for base e. Therefore, .ALOG1 passes control to .ALOG, and .DLOG1 passes control to .DLOG.

(A) The error conditions are checked. The constant  $c$  is set to  $\text{alog}(2)$  in the programs `.ALOG` and `.DLOG` and to  $\text{alogl0}(2)$  in the programs `.ALOGl` and `.DLOGl`.

(B) Let the argument be  $x$

$$x = (16^{**m}) * f, \quad 1/16 < f < 1$$

Let  $g = (2^{**j}) * f, \quad 0 \leq j \leq 3, \quad .5 \leq g \leq 1$

If  $g > \text{sqrt}(.5)$ , let  
 $n = 4 * m - j$   
 $h = (g - 1) / (g + 1)$ ;

If  $g > \text{sqrt}(.5)$ , let  
 $n = 4 * m - j - 1$   
 $h = (g - .5) / (g + .5)$

The rational function of  $h$  (Hart's formula 2701 or 2705) is found; the result is the logarithm to the base 2 of either  $g$  or  $2 * g$ , depending on whether  $g$  is greater or less than  $\text{sqrt}(.5)$ . If this number is  $u$ , then  $v = n + u$  is the logarithm of  $x$  to the base 2. Multiplication by  $c$  gives the logarithm of  $x$  to the desired base.

## 2. CLOG and CDLOG

The error case  $(0.0, 0.0)$  is eliminated. If the argument  $(x, y)$  is not zero, let

$u = \text{alog}(\text{cabs}(x, y))$   
 $v = \text{atan2}(y, x)$

Then  $(u, v)$  is returned

## 3.2.5 Inverse Trigonometric Functions

	<u>ARGUMENT</u>	<u>VALUE</u>
Y=ACOS(X)	Real	Real
Y=ASIN(X)	Real	Real
Y=ATAN(X)	Real	Real
Y=ATAN2(X1, X2)	Real	Real
Y=DACOS(X)	Double precision	Double precision
Y=DASIN(X)	Double precision	Double precision
Y=DATAN(X)	Double precision	Double precision
Y2=DATAN2(X1, X2)	Double precision	Double precision

**Purpose:** To compute the inverse sine, cosine, or tangent of a number of the given type. The routines ATAN2 and DATAN2 compute the angle between an upward vertical line and the point with coordinates (x1,x2). When x2>0, this is atan(x1/x2). In general, the value of ATAN2 is between  $-\pi$  and  $\pi$ .

**Programming note:** The definition of the value of ATAN2 is that which the ANSI standard requires. To get a value between 0 and  $2*\pi$ , one can take:

$$\pi + \text{atan2}(-x1, -x2) \text{ when } x1 < 0$$

**Range of arguments:** ATAN and DATAN accept any argument of the correct type. ATAN2 and DATAN2 accept any pair of arguments other than (0.0, 0.0). ASIN, ACOS, DASIN, and DACOS accept any arguments between -1.0 and 1.0.

**Accuracy:** The single-precision functions are accurate to seven places. The double-precision functions are accurate to 16 places.

**Propagation of error:** Both absolute and relative errors are decreased by ATAN and DATAN. When X is large, the absolute error in ATAN (X) is very small. For ATAN2 and DATAN2, it is convenient to define the relative error of a pair of arguments as:

$$\text{sqrt} ((\text{er1}^2 + \text{er2}^2) / (x1^2 + x2^2))$$

where er1 and er2 are the errors in x1 and x2. Then, the absolute error in ATAN2 or DATAN2 is no greater than the relative error in the arguments. The functions ASIN, ACOS, DASIN, and DACOS increase the relative error; they become unstable as the argument nears 1.0 or -1.0.

**Error conditions:** If ATAN2 and DATAN2 receive (0.0, 0.0) as arguments, they put out an error message and return  $+\pi/4$ . If ASIN, DASIN, ACOS, and DACOS receive an argument greater than 1.0 in absolute value, they put out an error message and return the value 0.0.

**Subroutines called:** .ASIN and .ACOS call .SQRT. .DASIN and .DACOS call .DSQRT.

Algorithms:

1. ASIN, ACOS, DASIN, DACOS

If  $\text{abs}(x) < \text{eps}$ , then  
 $\text{asin}(x) = x$ ,  $\text{acos}(x) = \pi / 2 - x$

If  $-.5 \leq x \leq .5$ , then  $\text{asin}(x)$  is found by a  
rational approximation (Hart,  
formula 4693 or 4698);  
 $\text{acos}(x) = \pi / 2 - \text{asin}(x)$ .

If  $-1 < x < -.5$ , let

$y = \text{sqrt}(0.5 * x + 0.5)$   
 $u = \text{asin}(y)$   
 $\text{asin}(x) = -\pi / 2 + 2 * u$   
 $\text{acos}(x) = \pi / 2 - 2 * u$

If  $.5 < x \leq 1$ , let

$y = \text{sqrt}(-0.5 * x + 0.5)$   
 $u = \text{asin}(y)$   
 $\text{asin}(x) = \pi / 2 - 2 * u$   
 $\text{acos}(x) = 2 * u$

2. ATAN, DATAN

If the argument is so large that the  
value of the function is  $+\pi / 2$  to the  
limit of precision involved, then that  
value is returned. Otherwise, the range  
is reduced by the following process. The  
argument belongs to one of seven  
intervals, the dividing points being:

$-\tan(75^\circ)$ ,  $-\tan(45^\circ)$ ,  $-\tan(15^\circ)$ ,  
 $\tan(15^\circ)$ ,  $\tan(45^\circ)$ ,  $\tan(75^\circ)$ . The  
argument is shifted to the range  
 $-\tan(15^\circ) < w < \tan(15^\circ)$  by setting:

$$w = (x - a) / (1 + ax)$$

where  $a = \tan((30^\circ)m)$ , with  $-3 \leq m \leq 3$  (in the  
extreme cases, the transformation is  
 $w = -1/x$ ). Then  $\text{atan}(w)$  is evaluated; it  
is equal to  $w$  if  $\text{abs}(w) < \text{eps}$ , and  
otherwise  $w * P(w * w)$  where  $P$  is a  
polynomial. The coefficients of  $P$  are  
taken from Hart (No. 4940 for ATAN, No.  
4945 for DATAN). Then,

$$\text{atan}(x) = \text{atan}(w) + m * (\pi / 6).$$

The algorithms for ATAN2 and DATAN2 are like those for ATAN and DATAN with the exception of the following: the case (0.0,0.0) generates an error message as mentioned above; in the case (x1, 0.0), the value  $+\pi/2$  is returned if  $x1 > 0.0$  and  $-\pi/2$  if  $x1 < 0$ ; in the case (0.0,x2), the value 0.0 is returned if  $x2 > 0$  and  $\pi$  if  $x2 < 0$ .

The exponents of the floating-point numbers x1 and, x2 are checked; and, if they differ by more than 6, the smaller is treated as 0.0 according to the previous paragraph. The exception is the case when  $x1=0.0$  and  $x2 > 0$ ; then  $x1/x2$  is returned.

In the general case, the argument pairs are partitioned into sectors depending on the signs of the arguments and the size of their ratio. The evaluation is reduced to finding  $\text{atan}(w)$  where  $w < \tan(15^\circ)$ . The value of  $\text{atan}(w)$  is computed exactly as in ATAN or DATAN.

### 3.2.6 Hyperbolic Functions

	<u>ARGUMENT</u>	<u>VALUE</u>
Y=SINH(X)	Real	Real
Y=COSH(X)	Real	Real
Y=TANH(X)	Real	Real
Y=DSINH(X)	Double precision	Double precision
Y=DCOSH(X)	Double precision	Double precision
Y=DTANH(X)	Double precision	Double precision

Range of arguments: SINH, COSH, DSINH, and DCOSH accept arguments between -175.0 and +175.0. TANH and DTANH accept all values.

Accuracy: The single-precision functions are accurate to seven decimal places; the double-precision functions are accurate to 16 decimal places.

Propagation of error: SINH multiplies the absolute error in X by COSH(X) and COSH multiplies it by SINH(X). When X is greater than 1 in absolute value, the relative error in SINH(X) or COSH(X) is close to the absolute error in X. TANH decreases both relative and absolute errors.

Error conditions: If the argument is greater than 175.0, then SINH and COSH put out an error message and return OMEGA. If the argument is less than -175.0, then SINH and COSH put out an error message and return, respectively, -OMEGA and OMEGA.

Subroutines called: .SINH and .COSH call .HYEXP and .TANH calls .EXP.  
.DSINH and .DCOSH call .HYDEX, and .DTANH calls .DEXP.

Algorithms:

1. SINH and DSINH

If  $\text{abs}(x) < \text{eps}$  then  $\sinh(x) = x$

If  $\text{abs}(x) > 175.0$  then an error condition exists as described above.

If  $-175.0 < x < -.5$ , let

$xa = -x - a \log(2)$   
 $u = -\exp(xa)$

If  $u < -16^{**}3$  in single precision or  $u < -16^{**}7$  in double precision,

then

$\sinh(x) = u,$

otherwise

$\sinh(x) = u - .25/u$

If  $-.5 < x < .5$ , a rational approximation is used (Hart, formula 2023 or 2028).

If  $.5 < x < 175.0$ , let

$xa = x - a \log(2)$   
 $u = \exp(xa)$

If  $u > 16^{**}3$  in single precision or  $u > 16^{**}7$  in double precision,

then

$\sinh(x) = u,$

otherwise

$\sinh(x) = u - .25/u$

2. COSH and DCOSH

If  $x < 0$ , replace  $x$  by  $-x$   
If  $x > 175.0$ , an error condition exists as described above. If  $x < \text{eps}$ ,

Then

$$\cosh(x) = 1.0$$

Otherwise let

$$\begin{aligned} x_a &= x - \text{alog}(2) \\ u &= \exp(x_a) \end{aligned}$$

If  $u > 16^{**3}$  in single precision or  $u > 16^{**7}$  in double precision,

Then

$$\cosh(x) = u$$

Otherwise

$$\cosh(x) = u + .25u$$

3. TANH and DTANH

Let  $\text{top} = 8.5$  in single precision and  $21.0$  in double precision.

If  $x > \text{top}$ ,  $\tanh(x) = 1$   
If  $x < -\text{top}$ ,  $\tanh(x) = -1$   
If  $.5 * \text{alog}(2) < x < \text{top}$ , let

$$\begin{aligned} u &= \exp(2 * x) \\ \tanh(x) &= (u - 1) / (u + 1) \end{aligned}$$

If  $\text{abs}(x) < \text{eps}$ , then  $\tanh(x) = x$

If  $\text{eps} < \text{abs}(x) < .5 * \text{alog}(2)$ , a rational approximation is used.

If  $-\text{top} < x < -.5 * \text{alog}(2)$ , let

$$\begin{aligned} u &= \exp(-2 * x) \\ \tanh(x) &= (1 - u) / (1 + u) \end{aligned}$$

3.3 MIN AND MAX FUNCTIONS:

	<u>ARGUMENT</u>	<u>VALUE</u>
I=MAX0 (I1,...,In)	Integer	Integer*4
I=MIN0 (I1,...,In)	Integer	Integer*4
X=AMAX0 (I1,...,In)	Integer	Real
X=AMIN0 (I1,...,In)	Integer	Real
I=MAX1 (X1,...,Xn)	Real	Integer*4
I=MIN1 (X1,...,Xn)	Real	Integer*4
X=AMAX1 (X1,...,Xn)	Real	Real
X=AMIN1 (X1,...,Xn)	Real	Real
DX=DMAX1 (DX1,...,DXn)	Double	Double
DX=DMIN1 (DX1,...,DXn)	Double	Double

where  $2 < n < 256$

Purpose:

To find the algebraic minimum or maximum of a collection of arguments of a given type and (in some cases) to convert to a different type. Types of arguments and values are shown in Table 3-1.

TABLE 3-1 TYPES OF MIN AND MAX ARGUMENTS

VALUE	ARGUMENT		
	INTEGER	REAL	DOUBLE PRECISION
INTEGER*4	MAX0 MIN0	MAX1 MIN1	
REAL	AMAX0 AMIN0	AMAX1 AMIN1	
DOUBLE PRECISION			DMAX1 DMIN1

Range of arguments: Unrestricted, except for MAX1 and MIN1, which convert real numbers to integers. MAX1 and MIN1 require the chosen value to be between -2,147,483,648 and +2,147,483,647.

Accuracy: Absolute.

Propagation of error: Any error in the argument chosen as minimum or maximum is passed through unchanged.

Error messages: If MAX1 or MIN1, try to convert a number too large for the appropriate type to fixed point, they print 'OVERFLOW' and return the largest integer of the appropriate sign and type.

### 3.4 TYPE CONVERSIONS

- Purpose:** To convert a number from one type to another. The types of arguments and values are shown in Table 3-2.
- Range of arguments:** The functions with INTEGER\*2 value require arguments between -32,768 and 32,767. The functions with INTEGER\*4 value require arguments between -2,147,483,648 and +2,147,483,647.
- Accuracy:** SNGL truncates the least significant 32 bits of the fraction in a double-precision number. The functions which convert floating point to integer all truncate those bits which represent values less than one. For large arguments, FLOAT also truncates some bits; the result is accurate to the least significant bit in a floating point number.
- Propagation of error:** A small error in the argument can be entirely lost or it can result in a large error in the value, depending on whether or not it moves the argument from below an integer to above that integer. If the true value of X is 2.93, then INT(X)=2. If X is computed as 2.85 (an error of .08), then INT(X) is correctly computed as 2. But if X is computed as 3.01 (also an error of .08), then INT(X) is computed as 3.
- Error messages:** If the functions with integer values receive an argument which is too large, they print "OVERFLOW" and return the largest integer of the appropriate sign and type.
- Remarks:** The name INT2, INT, REAL, DBLE, and CMPLX are generic names for FORTRAN VII O and FORTRAN VII D. This means that INT2, INT, REAL, DBLE, and CMPLX can take any of the following types of arguments:
- Integer\*2
  - Integer\*4
  - Real\*4
  - Double Precision (Real\*8)
  - Complex\*8
  - Complex\*16

Table 3-2 lists their names, types of arguments, and return values.

TABLE 3-2 TYPE CONVERSION ROUTINE NAMES, TYPES OF ARGUMENTS AND VALUES

Generic Name	Specific RTL Name	FORTRAN User Name	TYPE OF INPUT ARGUMENT		TYPE OF FUNCTION
			Arg 1	Optional Arg 2	
INT2	@@II2 @INT2 @@DI2 @@CI2 @@CDI2	INT2	Integer Real Double Complex*8 Complex*16		Integer*2 Integer*2 Integer*2 Integer*2 Integer*2

CMPLX	@@ICX @CMPLX @@DCX @@CCX @@CDCX	CMPLX	Integer Real Double Complex*8 Complex*16	Integer Real Double Complex*8	Complex*8 Complex*8 Complex*8 Complex*8 Complex*16
DCMPLX	@@ICD @@RCD @DCMPL @@CXCD @@CDCD	DCMPLX	Integer Real*4 Real*8 Complex*8 Complex*16	Integer Real*4 Real*8	Complex*16 Complex*16 Complex*16 Complex*16 Complex*16

CMPLX or DCMPLX takes 2 arguments of the same type, if the type is not complex. CMPLX or DCMPLX will accept only 1 argument of the complex type, in which case CMPLX just returns that argument.

A complex number CZ is stored as two real numbers (Z1, Z2) signifying  $(Z1) + (Z2) * \text{SQRT}(-1)$ . The statement  $\text{CZ} = \text{COMPLX}(A1, A2)$  for A1, A2 of the same type which is not complex, results in making A1, A2 into 2 real numbers Z1, Z2 (by floating or truncation) and setting  $\text{CZ} = (Z1, Z2)$ .

### 3.5 MISCELLANEOUS FUNCTIONS

#### 3.5.1 Remaindering

	<u>ARGUMENT</u>	<u>VALUE</u>
Y=AMOD(X1, X2)	Real	Real
DY=DMOD(DX1, DX2)	Double precision	Double precision
K=MOD(I1, I2)	Integer	Integer*4

- Purpose:** To find the remainder as a result of dividing the first argument by the second.
- Range of arguments:** The second argument must not be zero. In the functions AMOD and DMOD, if the second argument is very small compared to the first, then a floating point overflow can occur.
- Accuracy:** MOD is precise. AMOD is accurate to about  $1.0E-7$  times the value of X2 and DMOD to about  $1.0E-16$  times the value of DX2. These accuracies can be degraded when X1/X2 becomes large. When X1/X2 is greater than  $16^{**}6$ , the returned result is meaningless.
- Propagation of error:** Absolute error in the first argument of AMOD or DMOD is passed through unchanged, unless it changes the integer part of X1/X2. In that case, it leads to an error of the same size as X2. Absolute error in the second argument is multiplied by the integer part of X1/X2; if it also causes a shift in that number, then an error the size of X2 is introduced.
- Examples:**
- Let the true value of x be 10.0 and the true value of y, 91.0. Then amod(y,x)=1.0. If y is computed as 92.1, then amod(y,x)=2.1; the error is passed along. If y is computed as 89.9 (same error in opposite direction), then amod(y,x)=9.9; a large error is introduced. If y is computed as 91.0 and x is computed as 10.1, then amod(y,x)=0.1; the error in x has been multiplied by y/x. If x is computed as 10.2, then amod(y,x)=9.4; a large error is introduced.
- Error messages:** If the second argument is 0, then an error message is printed and the value of the first argument is returned.

### 3.5.2 Manipulation of Complex Numbers

	<u>ARGUMENT</u>	<u>VALUE</u>
Y=AIMAG(CZ)	Complex*8	Real
R=CABS(CZ)	Complex*8	Real
CW=CONJG(CZ)	Complex*8	Complex*8
CDWW=DIMAG(CDZZ)	Complex*16	Complex*16
CDWW=CDABS(CDZZ)	Complex*16	Complex*16
CDWW=DCONJG(CDZZ)	Complex*16	Complex*16

**Purpose:** The complex number CZ is stored as two real numbers (Z1, Z2), signifying (Z1)+(Z2)SQRT(-1). AIMAG and DIMAG return Z2. CABS and CDABS return SQRT((Z1)\*(Z1)+(Z2)\*(Z2)). CONJG and DCONJG return (Z1, -Z2) as its value.

**Range of arguments:** Unrestricted.

**Accuracy:** Not applicable except to CABS, which is accurate to seven decimal places; and CDABS to sixteen decimal places.

**Error messages:** CABS and CDABS can cause arithmetic overflow.

**Subroutines called:** CABS calls .SQRT  
CDABS calls .DSQRT

### 3.5.3 Absolute Values

	<u>ARGUMENT</u>	<u>VALUE</u>
Y=ABS(X)	Real	Real
DY=DABS(DX)	Double precision	Double precision
I=IABS(J)	Integer	Integer*4

**Purpose:** To return the absolute value of an appropriate argument.

**Range of arguments:** Unrestricted, except IABS return +2,147,483,647 for full scale negative number -2,147,483,648.

**Accuracy:** Not applicable.

**Propagation of error:** Not applicable.

**Error messages:** Not applicable.

**Subroutines called:** None.

### 3.5.4 Transfer of Sign

	<u>ARGUMENTS</u>	<u>VALUE</u>
K=ISIGN(I,J)	Integer	Integer*4
Z=SIGN(X,Y)	Real	Real
DZ=DSIGN(DX,DY)	Double precision	Double precision

Purpose: The second argument sign is applied to the absolute value of the first.

Range of arguments: The only restriction is the first argument must not be 0 if the second argument is negative.

Accuracy: Does not apply.

Propagation of error: Does not apply.

Remark: Zero is a positive number for these routines.

Error messages: If the first argument is 0 and the second argument is negative, then an error message is printed and 0 is returned.

Subroutines called: None.

### 3.5.5 Positive Difference

	<u>ARGUMENT</u>	<u>VALUE</u>
K=IDIM(I,J)	Integer	Integer*4
Z=DIM(X,Y)	Real	Real
DZ=DDIM(DX,DY)	Double precision	Double precision

Purpose: To give the value 0 or the value of the first argument minus the second, whichever is greater.

Range of arguments: Unrestricted.

Accuracy: To one bit in the least significant place.

Propagation of error: Not applicable.

Error messages: Not applicable.

Subroutines called: None.

### 3.5.6 Truncation and Rounding

	<u>Argument</u>	<u>Value</u>	<u>Function</u>
Y=AINT(X)	Real	Real	Truncation
Y=ANINT(X)	Real	Real	Rounding
DY=DINT(DX)	Double precision	Double precision	Truncation
DY=DNINT(DX)	Double precision	Double precision	Rounding
J=NINT(X)	Real	Integer	Rounding
J=IDNINT(DX)	Double precision	Integer	Rounding

To obtain integer values with truncation, use the type conversion routines IDINT, INT, or INT2.

**Purpose:** The Truncation functions remove the fractional part of a number; the result is equal to or smaller in absolute value. The Rounding functions return the nearest integer value. A fractional part of .5 is rounded up in absolute value; thus, NINT(1.5)=2 and NINT(-1.5)=-2.

**Range:** Unrestricted for AINT, ANINT, DINT, and DNINT.

For NINT and IDNINT, the value must be no greater than  $2^{*}31-1$  in absolute value.

**Accuracy:** Not applicable.

**Propagation of error:** Not applicable.

**Error messages:** An overflow condition can be incurred by NINT or IDNINT.

### 3.5.7 Double-Precision Product of Single-Precision Factors

	<u>Argument</u>	<u>Value</u>
DY=DPROD(X1,X2)	Real	Double-precision

**Purpose:** The argument's product is computed as a double-precision number.

**Range of Arguments:** That of floating-point multiplication.

**Accuracy:** No error is introduced.

**Propagation of error:** The relative error in the product is the sum of the relative errors in the factors.

Error messages: Multiplicative overflow or underflow results in error messages.

Subroutines called: None.

### 3.6 INVOLUTION (RAISING TO POWERS)

<u>Program</u>	<u>Base</u>	<u>Exponent</u>	<u>Value</u>
.IXXI	Integer	Integer	Integer*4
.IXXR	Integer	Real	Real
.IXXD	Integer	Double Precision	Double Precision
.IXXC	Integer	Complex	Complex
.IXXCD	Integer	Complex*16	Complex*16
.RXXI	Real	Integer	Real
.RXXR	Real	Real	Real
.RXXD	Real	Double Precision	Double Precision
.RXXC	Real	Complex	Complex
.RXXCD	Real	Complex*16	Complex*16
.DXXI	Double Precision	Integer	Double Precision
.DXXR	Double Precision	Real	Double Precision
.DXXD	Double Precision	Double Precision	Double Precision
.DXXC	Double Precision	Complex	Complex*16
.DXXCD	Double Precision	Complex*16	Complex*16
.CXXI	Complex	Integer	Complex
.CXXR	Complex	Real	Complex
.CXXD	Complex	Double Precision	Complex*16
.CXXC	Complex	Complex	Complex
.CXXCD	Complex	Complex*16	Complex*16
.CDXXI	Complex*16	Integer	Complex*16
.CDXXR	Complex*16	Real	Complex*16
.CDXXD	Complex*16	Double Precision	Complex*16
.CDXXC	Complex*16	Complex	Complex*16
.CDXCD	Complex*16	Complex*16	Complex*16

Purpose: To evaluate expressions of the form  $a^{**}b$ , (for complex involutions  $a^{**}b$  is defined as the principal value determined by  $EXP(b*LOG(a))$ ). All arithmetic types are permissible as bases and exponents. The interpretation of exponentiation operations on mixed mode data types is described in the FORTRAN VII Reference Manual.

Range of arguments: These following conditions are not acceptable: zero base with negative exponent; negative base with non-integer exponent.

Accuracy: .IXXI introduces no error. .RXXI, .RXXR, and .CXXI are accurate to six decimal places. .DXXI, .DXXD, and .CDXXI are accurate to 14 decimal places.

Propagation of error: The relative error includes: the relative error of the base multiplied by the exponent and the absolute error of the exponent multiplied by the natural logarithm of the base.

Interfaces: Arguments and values are passed by loading them into registers as follows:

<u>Program</u>	<u>Base</u>	<u>Exponent</u>	<u>Value</u>	
.IXXI	G13	G12	G13	
.IXXR	G13	F14	F14	
.IXXD	G13	D14	D14	
.IXXC	G13	(F12,F14)	(F12,F14)	⋮
.IXXCD	G13	(D12,D14)	(D12,D14)	⋮
.RXXI	F14	G13	F14	
.RXXR	F14	F12	F14	
.RXXD	F14	D14	D14	
.RXXC	F14	(F10,F12)	(F12,F14)	⋮
.RXXCD	F14	(D12,D14)	(D12,D14)	⋮
.DXXI	D14	G13	D14	
.DXXR	D14	F14	D14	
.DXXD	D14	D12	D14	
.DXXC	D14	(F12,F14)	(D12,D14)	⋮
.DXXCD	D14	(D10,D12)	(D12,D14)	⋮
.CXXI	(F12,F14)	G13	(F12,F14)	
.CXXR	(F12,F14)	F10	(F12,F14)	⋮
.CXXD	(F12,F14)	D14	(D12,D14)	⋮
.CXXC	(F12,F14)	(F8,F10)	(F12,F14)	⋮
.CXXCD	(F12,F14)	(D12,D14)	(D12,D14)	⋮
.CDXXI	(D12,D14)	G13	(D12,D14)	
.CDXXR	(D12,D14)	F14	(D12,D14)	⋮
.CDXXD	(D12,D14)	D10	(D12,D14)	⋮
.CDXXC	(D12,D14)	(F12,F14)	(D12,D14)	⋮
.CDXCD	(D12,D14)	(D8,D10)	(D12,D14)	⋮

Error conditions: Unacceptable combinations of arguments are detected and error messages are put out. For a zero base and a negative exponent, the largest positive number is returned. For a negative base and floating-point exponent, 0.0 is returned. The routines .IXXI, .RXXR, and .DXXD can anticipate certain occurrences of arithmetic underflow or overflow; .IXXI detects all such occurrences internally. The routines other than .IXXI can suffer exponential

underflows or overflows that cause arithmetic fault interrupts. In these cases, the user sees error messages from both the operating system and the Run Time Library.

If either a fixed-point overflow or a floating-point exponential overflow is detected, the value returned is the largest number of the appropriate sign. If an exponential underflow is detected, the value returned is 0.0.

Algorithm:

If the exponent is of integer type, the subroutine repeatedly squares the base and multiplies together those iterated squares that correspond to '1' bits in the binary expression of the exponent. The routines which receive real exponents of a single or double precision use the formula  $x^{**}y = \exp(y * \text{alog}(x))$ . If the exponent is 0, then the result 1 or 1.0 is invariably returned, whatever the value of the base.

Remarks:

These routines are called by the FORTRAN compiler to evaluate expressions of the form  $a^{**}b$ . User can access these routines via assembly code.

APPENDIX 1  
ERROR MESSAGES

If a mathematical RTL program detects an error, it calls a routine .ERR to print out an error message in this form:

ERROR n IN m AT a: d

where: n is the error message number,  
m is the name of the RTL function,  
a is the hexadecimal return address in the user's program, and  
d is either a number or a diagnostic message.

The messages are listed by number in the error messages list in this appendix. The following comments are intended to help interpret the messages and correct their causes.

Messages Pertaining to the Argument List

When a mathematical RTL program is called by giving it an argument list with argument checking turned on, a series of messages can be put out as a result of errors in the list. Please refer to FORTRAN VII Run Time Library Introduction and Overview, Publication Number 29-578 for argument checking.

The error messages may be one of the following:

1. ILLEGAL CALL (72).  
A function has been called as a subroutine, e.g.

CALL SQRT (....).

The solution is to revise the text of the source program or, if the user means to call an external subroutine of that name, to ensure that it is brought in at linkage time.

2. INCORRECT TYPE OF VALUE OF FUNCTION (73).  
A function supplied in the RTL has been called as an external function and the user program has specified a value type that is incorrect. Example:

IMPLICIT INTEGER (A-H)  
EXTERNAL COS  
A=COS(X)

Check implicit and explicit types or include a user-written program of the appropriate name.

## APPENDIX 1 (Continued)

3. ARGUMENT OF INCORRECT CLASS (75).  
An argument has been classified as an array or external function and not a number. Check for the presence or absence of a DIMENSION statement, a misnamed argument, or an incorrect EXTERNAL statement.
4. AN ARGUMENT OF INCORRECT TYPE (45).  
The argument supplied is of the wrong type for this function. Check implicit and explicit type statements and types of expressions passed as arguments.
5. INCORRECT NUMBER OF ARGUMENTS (76).  
Check argument lists in source program and for the presence or absence of commas.

### Arguments Outside Acceptable Ranges

These messages can occur whether or not a program is called with arguments in registers or by giving it a list.

1. ARGUMENT TOO LARGE (49)  
REAL PART TOO LARGE (52)  
IMAGINARY PART TOO LARGE (55)

The absolute value of the number is too large if the number is positive or negative. Check the numerical stability of the computation being performed. Check if variables have been initialized. Consider building error-checking logic into the program.

2. ARGUMENT OUT OF RANGE: POSITIVE (50)  
ARGUMENT OUT OF RANGE: NEGATIVE (51)  
REAL PART OUT OF RANGE: POSITIVE (53)  
REAL PART OUT OF RANGE: NEGATIVE (54)  
IMAGINARY PART OUT OF RANGE: POSITIVE (56)  
IMAGINARY PART OUT OF RANGE: NEGATIVE (57)

The number is greater than its maximum permissible value or less than its minimum permissible value. Remedies are as in #1.

3. OVERFLOW ON CONVERSION (58)

The absolute value of a floating-point number was too large to be converted to an integer. Besides the messages listed in 1 above, consider if this conversion is really appropriate.

APPENDIX 1 (Continued)

- 4. ZERO ARGUMENT (46)
- NEGATIVE ARGUMENT (47)
- ARGUMENTS (0,0) (48)
- ZERO DIVISOR (62)
- ARGUMENTS (ZERO, NEGATIVE) (63)

These cases must be averted by building appropriate logic into the source code. Numerical instability should be closely checked; the difference of two numbers may be quite inaccurate.

- 5. NEGATIVE EXPONENT (64)
- NEGATIVE BASE (74)
- ZERO BASE, NEGATIVE EXPONENT (65)

These are conditions that can arise in computing powers. Check the validity of the computations which determined the base and exponent; consider building in logic to avoid these erroneous conditions.

- 6. EXPONENTIAL OVERFLOW (60)
- EXPONENTIAL UNDERFLOW (61)

These are conditions that can arise when the computation of a number raised to a power has led to arithmetic faults. To safeguard against these conditions, build logic into the program to handle extreme values of either base or exponent.

APPENDIX 1 (Continued)

RTL PROGRAM ERROR MESSAGES

ERROR MESSAGES THAT MAY BE INVOKED FROM MATHEMATICAL RTL PROGRAMS.

<u>NUMBER</u>	<u>DIAGNOSTIC MESSAGE</u>
45	AN ARGUMENT OF INCORRECT TYPE
46	ZERO ARGUMENT

INDEX (Continued)

Function

- Absolute Value Function, 1-2, 3-19
- Complex Arithmetic Function, 1-1, 3-24
- Double-Precision Product of Single-Precision
  - Factors Function, 1-2, 3-21
- Exponential Function, 3-3, 3-4
- External Versions of Functions, 2-3/2-4
- Hyperbolic Functions, 3-11, 3-12, 3-13
- Internal Versions of Functions, 2-3/2-4
- Inverse Trigonometric Functions, 3-8, 3-9, 3-10, 3-11
- Logarithm Function, 3-7, 3-8
- Manipulation of Complex Number Function, 1-2, 3-19
- Min and Max Functions, 1-2, 3-14, 3-15
- Positive Difference Function, 1-2, 3-20
- Remaindering Function, 1-2, 3-18
- Single Precision Function, 2-1
- Square Root Function, 3-1, 3-2
- Trigonometric Function, 3-4, 3-5, 3-6
- Truncation and Rounding Function, 1-2, 3-21

Generation of Error Messages, 2-3/2-4

Hyperbolic, 2-2

Hyperbolic Function, 3-11, 3-12, 3-13

Imaginary Part, 3-3, 3-5, 3-7, 3-24

Internal Versions of Functions, 2-3/2-4

Intrinsic Function, 2-3/2-4

Intrinsic Version, 2-3/2-4, 3-1

Inverse Trigonometric Functions, 3-8, 3-9, 3-10, 3-11

Involution (Raising to Powers), 3-22

Logarithm Function, 3-7, 3-8

Manipulation of Complex Number Function, 1-2, 3-19

Min and Max Functions, 1-2, 3-14

Miscellaneous Functions

- Absolute Value Function, 1-2, 3-19

- Double-Precision Product of Single-Precision

- Factors Function, 1-20, 3-21

- Manipulation of Complex Number Function, 1-2, 3-19

- Positive Difference Function, 1-2, 3-20

- Remaindering Function, 1-2, 3-18

- Transfer of Sign Function, 1-2, 3-20

- Truncation and Rounding Function, 1-2, 3-21

Number, Complex, 3-1, 3-3, 3-5, 3-19, 3-24

Overflow, 2-3/2-4, 3-4, 3-15, 3-18, 3-19, 3-21, 3-22, 3-23, 3-24

INDEX (Continued)

Positive Difference Function, 1-2, 3-20

Raising to Powers (Involution), 3-22

Range Restrictions of Subprograms in the RTL, 2-2, 2-3

Real Part, 3-3, 3-5

Relative Accuracy, 2-1

Relative Error, 2-1, 3-2, 3-3, 3-9, 3-11, 3-21

Remaindering Function, 1-2, 3-18

Routines, Complex, 2-3/2-4

Single-Precision Functions, 2-1

Square Root Function, 3-1, 3-2

Subprograms

- Accuracy of Function Subprograms, 2-1
- Description of Function Subprograms, 3-1
- Range Restrictions of Subprograms in the RTL, 2-2, 2-3
- Transfer of Sign Function, 1-2, 3-20
- Type Conversion Subprogram, 1-2

Terms Related to Accuracy, 2-1

Transfer of Sign Function, 1-2, 3-20

Trigonometric Function, 3-4, 3-5, 3-6

Truncation and Rounding Functions, 1-2, 3-21

Type Conversion Subprogram, 1-2, 2-2

Type Conversions, 2-2, 3-16, 3-21

Underflow, 2-3/2-4, 3-23, 3-24

Value, Absolute, 2-1, 3-2, 3-5, 3-7, 3-9, 3-11, 3-20, 3-21
