

7. Practical trouble shooting

01. Poor print

Whenever you have a printing performance problem, check first if the carbon ribbon is suitable to the machine. Check the paper too, because some kind of paper are made of special material which repels the carbon ink.

1) Poor print impression

Adjust the volume resistor (located beneath 2 and 3 key) in the direction of A(X).

fig.1

fig.2

fig.3

If you make it too strong, the life of typewheel will be shortened. The adjustment position shown in fig.3 will be recommended.

Printing performance varies according to the type style.

With Pica: all letters should be printed completely in the middle position of the impression selector in the switch

With Elite or Micron: all letters should be printed completely in the low position of the impression selector

2) Bottom or top of letters too light

If the top or bottom of some letters are slightly light, check and adjust the volume resistor in the same manner as item 1).

Excite the selection motor by turning switch on while shorting the AUX D/C which is located on the right corner of the keyboard PCB. A small piece of aluminum foil will be suggested to use for shorting.

fig.4

fig.5

Loosen the hammer bracket set screws and position the hammer solenoid. Move the hammer solenoid backward if the top of prints is light. Move it forward if the bottom is light. Use two holes on the base as a guide for positioning. If the hammer is too far from the typewheel, it might cause click sounds. (see fig.5)

When fasten the screws, adjust the hammer solenoid sideways so that the notch of hammer fits to the prism on spokes exactly. If it does not fit, it might cause click sounds or poor printing. (see fig. 5)

fig.5

fig.6

This adjustment by excitation of motors should be completed in 10 minutes, or the motors will heat up.

3) Ring and cylinder

If the lightness of letters can not be fixed by above procedures, check the "Ring and cylinder" adjustment. Ring and cylinder means how the typefaces touch the platen roller when it is typed.

Step 1.

Check the distance in normal position between the typewheel and the platen roller in both right and left side. If it has the standard distance (approx. 3.5mm), go to the step 2. (see fig.7)

Adjustment of the distance will be made as follows.

At first, loosen the set screws A, C on the adjust plate. Insert the flat screw driver-like into the slit of the adjust plate and move it so that the distance between the type wheel and the platen will be 3.5mm by pivoting on the screw B. If the plate does not move at all, loosen the screw B slightly. Check the distance with a thickness gauge 3.5mm.

fig.7

view from inside frame

fig.8

view from outside frame

fig.9

Step 2.

Fasten the screw C. Loosen the screw B. Insert a flat screw driver-like into the slit again. Adjust the contact surface of the typewheel and platen by pivoting the adjust plate on the screw C so that the typeface will meet the platen surface evenly.

If the upper part of contact surface has some clearance, move the adjust plate in the direction of arrow X. And arrow Y for the lower part has some clearance. (see fig.8,9,10)

Some of longer typeface letters will be recommended to use. Fasten all the screws. Check the normal distance between the typewheel and the platen again. If the screw C is not fastened sufficiently, above adjustment might spoil the normal distance adjusted in step 1. In that case, take the step 1,2 again.

Step 3.

Do the same steps as step 1,2 in the other side of platen.

02. Ribbon problem

If the top of longer letters like \$, \$, #, (,) , ü, Ä etc. does not print, it might be caused by ribbon lifting being low.

fig.11

fig.12

Step 1.

Check the printed marks on the carbon ribbon. Open the slit on the right side of printer head chassis so that the clearance between the upper edge of the carbon ribbon and the printed marks on the carbon ribbon will be in 0.5-0.8mm.

Step 2.

After above adjustment, check if the overlapping amount of the carbon ribbon and the correction tape at the highest ribbon position is more than 1 mm. (see fig.13)

If the ribbon lifts too high, it might cause a ribbon jamming on the correction tape. (see fig.14)

About adjustment for correction tape height, see 03. Correction problem-item 3).

fig. 13

fig. 14

03. Correction problem

1) Correction tape does not transport

Step 1.

Check if the correction retainer spring is not missing.

fig. 15

fig. 16

Step 2.

Remove the correction tape spool right from the correct feed ratchet. Rotate the correct cam manually and check how the feed pawl and the retainer work.

When the correct cam comes to the highest position (fig. 16), there should be some clearance (approx. 0.5mm) between the retainer and the ratchet after being fed. (see fig. 17)

When the correct cam returns to the neutral position after a transportation of the correction tape, there should be some clearance between the feed pawl and feed ratchet. Adjustment will be made by bending the pawl holder on the ribbon base. (fig. 17, 18)

fig. 17

fig. 18

2) Top of letters is not correctable

Step 1

Check if the windows of line locator does not prevent the correct rollers from going up. (fig.19,20)

If a correct roller leans forward to the line locator, straighten up the roller. If the line locator is too far from the platen roller, align the line locator.

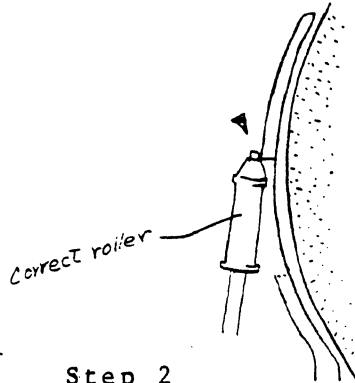

fig.19

fig.20

Step 2

Check if the correction ribbon goes up high enough in its lifting stroke. (see fig.21) If the correction tape

is too low, bend the cam follower bracket of the right correction arm. However, there should be some clearance between the cam and the cam follower before it starts cam function (point A in fig 22)

fig.21

fig.22

3) Underscore does not print

This problem is mostly caused by the height of correction tape being too high in its normal position.

The normal height of correction tape will be adjusted by the stopper on the ribbon base (fig.23) or on the line locator base right (fig.24)

fig.23

fig.24

Adjusting by the line locator base might affect the line locator alignment.

4) Part of letters is not correctable

fig.25

Check if the correction tape touches the edge of window on the line locator and correctable material is sticking on it. (see fig.26)

fig.26

Bend the correct roller in the direction of arrow so that the correct tape does not touch the edge of line locator. (This problem tends to appear when a customer inserts many papers at one time for making carbon copies.) However, if the tape is too close to the carbon ribbon, it might cause some difficulty in setting the cassette. On the other hand, if the line locator is too far from the platen, align the line locator.

5) Poor correction performance

When you have any correction problem, check first if the customer is using a proper carbon ribbon and suitable correction tape. And the type of paper is also very important for the printing and correction performance.

Step 1.

Check the adjustment on the carrier drive gear and the drive pulley. There should not exist any backlash or tightness in mesh.(fig.27)

fig.27

Loosen the set screw(upper one) and move the carrier drive motor.

Step2.

Check the tension of the drive wire. The tension should be 16mm by 500g as in fig.28. It will be adjusted by the tension pulleys which have eccentric set screws. Two tension pulleys should be adjusted equally(symmetrically) in the direction of arrow A so that the wire will be parallel to the base platen. Before the final positioning of the tension pulleys, align the wire around the drive pulley and pull the wire in order to take up the slack in the wire on the drive pulley.

fig.28

Step 3.

Check if there is a lateral play on the hammer. There should be no play. Adjustment will be made by fastening screw, however, do not make it too tight and make sure that the hammer works free.

fig.29

Step 4.

Check if the line locator is not pressing the paper too tightly. The line locator moves the paper when the carrier makes backspace in its correction movement and causes poor correction. For the adjustment see 04.Line locator adjustment.

Step 5.

Check if the tension pulley set nuts, the carrier drive motor set screws and the drive wire set screws are not loose.

fig.30

fig.31

fig.32

Step 6.

Check if the correct brake spring beneath the correct tape spool has not excessive tension. Adjustment will be made by making the diameter of spring wider.

fig.33

Step 7.

Check if the impression by the volume resistor is not too high. For the adjustment, see 01.

04. Line locator adjustment

1) Guide for typing letters

Adjust horizontally so that the bottom line of "l" and "i" meet the dash scale on the line locator.

Adjust vertically so that the center mark "┆" and triangle marks "▽" will meet the "l" and "i".

See fig.34-39.

fig.34

2) Distance from the platen.

The clearance between the line locator and the platen roller is critical for proper ribbon function.

The clearance should be equal from side to side on the line locator. The adjustment will be made by loosening 2 set screws or forming the line locator base on the carrier chassis.

fig.35

fig.36

fig.37

If the clearance between the line locator and the platen ^{is too much}, the line locator might push the correction tape and make it jam with the carbon ribbon. In that case, you can see some scratches on the carbon ribbon made by the edge of the correction tape like in fig.38. You may also find that the ribbon does not get in between the correction tape and the typewheel when setting the cassette. (see fig.39)

Note: At the end of line locator adjustment, be sure to fasten the set screws firmly.

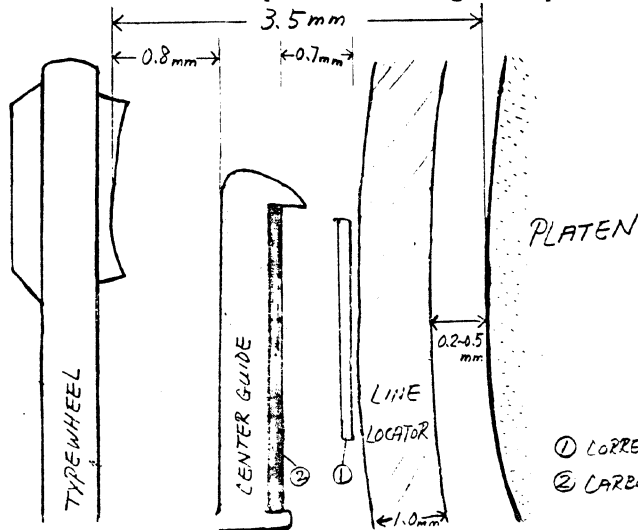

fig.38

05. Standard position of parts

(platen, line locator, correction tape, carbon ribbon, ribbon center guide, typewheel)

The standard positioning of printing parts is shown below.

* It is preferable that the center guide is positioned in the middle of the line locator and the typewheel.

- ① CORRECTION TAPE
- ② CARBON RIBBON

fig.39

You can also adjust the positioning of the center guides by filing it and putting a plastic washer.

fig.40

fig.41

06. Carbon ribbon does not transport

Step 1.

Check if the cassette is not defective by replacing it.

Step 2.

Check if the referring springs are all in the proper position and all referring parts work free. (see fig.42)

Step 3.

Check if the surface of the feed pulleys and feed spring are not greasy with excessive oil. (see fig.42 ① ⑦ ⑧)

fig.42

- ① ribbon feed spring
- ② feed finger spring
- ③ feed torsion spring
- ④ stop finger spring
- ⑤ stop finger
- ⑥ feed finger
- ⑦ ribbon feed pulley (small)
- ⑧ ribbon feed pulley (large)

Revise

July, 1982

05. Standard position of parts

Dimension of the ribbon center guide left and right have been changed in order to make the adjustment and service easier. Instead of filing the ribbon center guides, use new ones with 4 plastic washers each.

The position of center guides will be adjusted by placing those washers in suitable position-behind or in front of the ribbon center guides.

*Example

If you want to get the ribbon guides forward, move a washer(front) to between the ribbon guides and printer head chassis

New parts number etc. will be informed later officially.

Installation of ribbon feed spring. ①→②→③

fig.43

07. Platen adjustment

1) Right side of the platen

Adjustment will be made by loosening 2 set screws. When fastening the screws, make sure that the screws meet the flat part of the platen shaft.

fig.44

2) Left side of the platen (Installation of platen knob shaft)

fig.45

fig.46

fig.47

* Check the lateral play of platen, after completion of installation. (approx.0.07mm)

3) Detent spring adjustment

Fit the 3 tips of the detent spring on to grooves of the platen pulley after the excitation of the index motor.

(see fig.4,5 in 01. Poor print)

fig.48

Turn the platen knob shaft manually and check where the 3 tips of the detent spring will remain stationary. (with the index motor excited)
