| SSI 22106 | Cross-point Switch | $8 \times 8 \times 1$, control memory, RCA second-source | 5 V | 28 DIP | $1-124$ |
| SSI 22301 | PCM Line Repeater | T1 carrier signal recondition | 5 V | 18 DIP | $1-132$ |

## SSI Telecommunications Capabilities

Silicon Systems offers a broad line of standard telecommunications circuits aimed at providing cost-effective solutions for common customer application problems. At the heart of SSi's efforts in the communications market is its pioneering work with CMOS switched capacitor filters. Our early success with the DTMF receiver has enabled us to develop a family of chips utilizing the switched capacitor filter technology.

As a trendsetter in the field, Silicon Systems is leading the way towards a whole new era of VLSI circuits for telecommunications. Our broad selection of DTMF receivers demonstrates not only technological leadership in our own semiconductor field but also our capability to anticipate the growing needs of the fastpaced telecommunications marketplace.

Here are a few completed circuits that demonstrate our broad telecommunications IC capability:

BIPOLAR

| Integrated Circuit Function | Application |
| :--- | :--- |
| Audio System Receiver | Telephone Answering <br> Machine |
| VHF/UHF Gain Mixer | Radio Receiver |
| Pulse Width Modulator | Switching Power Supply |
| Controller | Home Appliance |
| Digital Receiver | Remote Control |
| PCM Encoder/Decoder | Telecom System |
| Digital Correlator/ <br> Integrator | Radio Telescope |

## PROCESSES

Silicon Systems offers circuits in junction-isolated, bipolar, single and double-layer metal. Plus, SSi has a CMOS capability that includes not only a metal-gate process but also a silicon-gate process that produces circuits packed with more functions in a smaller size for high-speed, low-power performance. These are the most popular and reliable processes in the two basic technologies, and SSI's advanced ultra-clean wafer fab produces higher yields than ordinary facilities.

## PRODUCT QUALITY

Silicon Systems has made a major investment in product test and in-line quality control equipment. For example, a state-of-the-art LTX CP80 is used for functional and parametric testing of sophisticated analog, digital, and combination A/D circuits. In this way, SSi is dedicated to the delivery of complex VLSI circuits to meet the incoming quality level you require.

MOS

| Integrated Circuit Function | Application |
| :--- | :--- |

## CUSTOMER SERVICE

Silicon Systems provides individualized service for every customer. Our Customer Service Department is dedicated to responsive service and is staffed with personnel trained to consider our customers' needs as their most urgent requirement. Product quality and service are both viewed as cornerstones for SSi's continued growth.

## Data Sheet

SSI 201 Block Diagram

SSI 201 Pin Out
(Top View)

## FEATURES

- Central office quality
- NO front-end band-splitting filters required
- Single, low-tolerance, 12-volt supply
- Detects either 12 or 16 standard DTMF digits
- Uses inexpensive $\mathbf{3 . 5 7 9 5 4 5 - M H z}$ crystal for reference
- Excellent speech immunity
- 22-pin DIP package for high system density
- Output in either 4-bit hexadecimal code or binary coded 2 of 8
- Synchronous or handshake interface
- Three-state outputs

## DESCRIPTION

The SSI 201 is a complete Dual Tone Multiple Frequency (DTMF) receiver detecting a selectable group of 12 or 16 standard digits No front-end pre-filtering is needed. The only externally required components are an inexpensive $3.58-\mathrm{MHz}$ television "colorburst" crystal (for frequency reference) and two low-tolerance bypass capacitors. Extremely high system density is made possible by using the clock output of a crystal connected SSI 201 receiver to drive the time bases of additional receivers. The SSI 201 is a monolithic integrated circuit fabricated with lowpower, complementary symmetry MOS (CMOS) processing. It requires only a single low tolerance voltage supply and is packaged in a standard 22 pin DIP.

The SSI 201 employs state-of-the-art circuit technology to combine digital and analog functions on the same CMOS chip usıng a standard digital semıconductor process The analog input is pre-processed by $60-\mathrm{Hz}$ reject and band splitting filters and then hard-limited to provide AGC Eight bandpass filters detect the individual tones The digital post-processor tımes the tone durations and provides the correctly coded digital outputs Outputs interface directly to standard CMOS circuitry, and are three-state enabled to facilitate bus-oriented architectures

# Integrated DTMF Receiver <br> SSI 2 Ol 

## ANALOG IN (pin 12)

This pin accepts the analog input. It is internally biased so that the input signal may be AC coupled. The input may be DC coupled as long as it does not exceed the positive supply. Proper input coupling is illustrated below.

CRYSTAL OSCILLATOR
The SSI 201 contaıns an onboard inverter with sufficient gain to provide oscillation when connected to a low-cost television "color-burst" crystal The crystal oscillator is enabled by tying XEN (pin 16) high. The crystal is connected between XIN (pın 15) and XOUT (pın 14) A 1 MEG $\Omega 10 \%$ resistor is also connected between these pins in this mode, ATB ( $\mathrm{p} \cap 117$ ) is a clock frequency output. Other SSI 201's may use the same frequency reference by tying their ATB pins to the ATB of a crystal connected device XIN and XEN of the auxiliary devices must then be tied high and low respectively Twenty-five devices may run off a single crystal-connected SSI 201 as shown below.

## H/B28 (pin 2)

This pin selects the format of the digital output code When H/B28 is tied high, the output is hexadecimal When tied low, the output is binary coded 2 of 8 The table below describes the two output codes

|  | Hexadecimal |  |  |  |  | Binary Coded 2 of 8 |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Digit | D8 | D4 | D2 | D1 | D8 | D4 | D2 | D1 |  |
| 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |  |
| 2 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 |  |
| 3 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 |  |
| 4 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 |  |
| 5 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 |  |
| 6 | 0 | 1 | 1 | 0 | 0 | 1 | 1 | 0 |  |
| 7 | 0 | 1 | 1 | 1 | 1 | 0 | 0 | 0 |  |
| 8 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 1 |  |
| 9 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 0 |  |
| 0 | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 1 |  |
| $\star$ | 1 | 0 | 1 | 1 | 1 | 1 | 0 | 0 |  |
| $\#$ | 1 | 1 | 0 | 0 | 1 | 1 | 1 | 0 |  |
| A | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 1 |  |
| B | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 1 |  |
| C | 1 | 1 | 1 | 1 | 1 | 0 | 1 | 1 |  |
| D | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 |  |

## IN1633 (pin 5)

When tied high, this pin inhibits detection of tone pairs containıng the $1633-\mathrm{Hz}$ component For detection of all 16 standard digits, IN1633 must be tied low

## OUTPUTS D1, D2, D4, D8 (pins 1, 22, 21, 20) and EN

 (pin 3)Outputs D1, D2, D4, D8 are CMOS push-pull when enabled (EN high) and open cırcuited (high ımpedence) when disabled by pulling EN Iow These digital outputs provide the code corresponding to the detected digit in the format programmed by the H/B28 pin The digital outputs become valid after a tone pair has been detected and they are then cleared when a valid pause is timed

## DV (pin 18) and CLRDV (pin 19)

DV signals a detection by going high after a valid tone pair is sensed and decoded at the output pins D1, D2, D4, D8 DV remains high until a valid pause occurs or the CLRDV is raised high, whichever is earlier

## INTERNAL BYPASS PINS

## S1, S2 (pins 9, 10)

In order for the SSI 201 DTMF Receiver to function properly, these pins must be bypassed to $V_{N A}$ with $001 \mu \mathrm{~F} \pm 20 \%$ capacitors

## POWER SUPPLY PINS

$\mathbf{V}_{\mathrm{p}}$ (pin 6) $\mathbf{V}_{\mathrm{NA}}\left(\right.$ pin 13) $\mathbf{V}_{\mathrm{ND}}($ pin 4)
The analog $\left(\mathrm{V}_{\text {NA }}\right)$ and digital $\left(\mathrm{V}_{N D}\right)$ supplies are brought out separately to enhance analog noise immunity on the chip. $\mathrm{V}_{N A}$ and $\mathrm{V}_{\text {ND }}$ should be connected externally as shown below

## 12V SYSTEM

## N/C PINS (pins 7, 8, 11)

These pins have no internal connection and may be left floating.

## DTMF DIALING MATRIX

|  | Col 0 | Col 1 | Col 2 | Col 3 |

## Data Sheet

## DESCRIPTION

The SSI 202 and 203 are complete Dual Tone Multiple Frequency (DTMF) receivers detecting a selectable group of 12 or 16 standard digits. No front-end pre-filtering is needed. The only externally required components are an inexpensive $3.58-\mathrm{MHz}$ television "colorburst" crystal (for frequency reference) and a bias resistor. Extremely high system density is made possible by using the clock output of a crystal connected SSI 202 or 203 recerver to drive the time bases of addıtional receivers. Both are monolithic integrated circuits fabricated with low-power, complementary symmetry MOS (CMOS) processing. They require only a single low tolerance voltage supply and are packaged in a standard 18 pin plastic DIP.
The SSI 202 and 203 employ state-of-the-art circuit technology to combine digital and analog functions on the same CMOS chip using a standard digital semiconductor process. The analog input is pre-processed by $60-\mathrm{Hz}$ reject and band splitting filters and then hard-limited to provide AGC. Eight bandpass filters detect the individual
tones. The digital post-processor times the tone durations and provides the correctly coded digital outputs. Outputs interface directly to standard CMOS circuitry, and are three-state enabled to facilitate bus-oriented architectures.

## FEATURES

- Central office quality
- NO front-end band-splitting filters required
- Single, low-tolerance, 5 -volt supply
- Detects either 12 or 16 standard DTMF digits
- Uses inexpensive $3.579545-\mathrm{MHz}$ crystal for reference
- Excellent speech immunity
- Output in either 4-bit hexadecimal code or binary coded 2 of 8
- 18-pin DIP package for high system density
- Synchronous or handshake interface
- Three-state outputs
- Early detect output (SSI 203 only)

SSI 202/203 Block Diagram

CAUTION: Use handling procedures necessary for a static sensitive component

Pin Out
(Top View)

## ANALOG IN

This pin accepts the analog input. It is internally biased so that the input signal may be AC coupled. The input may be DC coupled as long as it does not exceed the positive supply. Proper input coupling is illustrated below.

The SSI 202 is designed to accept sinusoidal input wave forms but will operate satisfactorily with any input that has the correct fundamental frequency with harmonics greater than 20 dB below the fundamental

## CRYSTAL OSCILLATOR

The SSI 202 and 203 contain an onboard inverter with sufficient gain to provide oscillation when connected to a low-cost television "color-burst" crystal. The crystal oscillator is enabled by tying XEN high. The crystal is connected between XIN and XOUT A $1 \mathrm{M} \Omega 10 \%$ resistor is also connected between these pins. In this mode, ATB is a clock frequency output. Other SSI 202's (or 203's) may use the same frequency reference by tying their ATB pins to the ATB of a crystal connected device. XIN and XEN of the auxiliary devices must then be tied high and low respectively. Ten devices may run off a single crystal-connected SSI 202 or 203 as shown below.

## HEX /B28

This pin selects the format of the digital output code When HEX / B28 is tied high, the output is hexadecimal. When tied low, the output is binary coded 2 of 8 The table below describes the two output codes

|  |  |  |  |  |  | Hexadecimal |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Digit | D8 | D4 | D2 | D1 | D8 | D4 | D2 | D1 |  |
| 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |  |
| 2 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 |  |
| 3 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 |  |
| 4 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 |  |
| 5 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 |  |
| 6 | 0 | 1 | 1 | 0 | 0 | 1 | 1 | 0 |  |
| 7 | 0 | 1 | 1 | 1 | 1 | 0 | 0 | 0 |  |
| 8 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 1 |  |
| 9 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 0 |  |
| 0 | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 1 |  |
| $*$ | 1 | 0 | 1 | 1 | 1 | 1 | 0 | 0 |  |
| $\#$ | 1 | 1 | 0 | 0 | 1 | 1 | 1 | 0 |  |
| A | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 1 |  |
| B | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 1 |  |
| C | 1 | 1 | 1 | 1 | 1 | 0 | 1 | 1 |  |
| D | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 |  |

## IN1633

When tied high, this pin inhibits detection of tone pairs containing the $1633-\mathrm{Hz}$ component For detection of all 16 standard digits, IN1633 must be tied low

## OUTPUTS D1, D2, D4, D8 and EN

Outputs D1, D2, D4, D8 are CMOS push-pull when enabled (EN high) and open circuited (high impedence) when disabled by pulling EN Iow These digital outputs provide the code corresponding to the detected digit in the format programmed by the HEX/B28 pin The digital outputs become valid after a tone pair has been detected and they are then cleared when a valid pause is timed

DV and CLRDV
DV signals a detectıon by goıng high after a valıd tone pair is sensed and decoded at the output pins D1, D2, D4, D8. DV remains high until a valid pause occurs or the CLRDV is raised high, whichever is earlier

## ED (SSI 203 only)

The ED output goes high as soon as the SSI 203 begıns to detect a DTMF tone pair and falls when the 203 begıns to detect a pause. The D1, D2, D4, and D8 outputs are guaranteed to be valid when DV is high, but are not necessarily valid when ED is high

## N/C PINS

These pins have no internal connection and may be left floating

## Data Sheet

## DESCRIPTION

The SSI 204 is a complete Dual Tone Multiple Frequency (DTMF) receiver that detects all 16 standard digits. No front-end pre-filtering is needed. The only externally required components are an inexpensive $3.58-\mathrm{MHz}$ television "color-burst" crystal for frequency reference and a bias resistor. An Alternate Time Base (ATB) is provided to permit operation of up to 10 SSI 204's from a single crystal. The SSI 204 employs state-of-theart "switched-capacitor" filter technology, resulting in approximately 40 poles of filtering, and digital circuitry on the same CMOS chip. The analog input signal is pre-processed by $60-\mathrm{Hz}$ reject and band split filters and then zero-cross detected to provide AGC. Eight bandpass filters detect the individual tones. Digital processing is used to measure the tone and pause durations and to provide output timing and decoding. The outputs interface directly to standard CMOS circuitry and are three-state enabled to facilitate bus-oriented architectures.

## FEATURES

- Intended for applications with less requirements than the SSI 202
- 14-Pin plastic DIP for high system density
- NO front-end band splitting filters required
- Single low-tolerance 5 -volt supply
- Detects all $\mathbf{1 6}$ standard DTMF digits
- Uses inexpensive $\mathbf{3 . 5 7 9 5 4 5 - M H z}$ crystal
- Excellent speech immunity
- Output in 4-bit hexadecimal code
- Three-state outputs for microprocessor interface

SSI 204 Pin Out (Top View)

## ANALOG IN

This pin accepts the analog input. It is internally biased so that the input signal may be AC coupled. The input may be DC coupled as long as it does not exceed the positive supply. Proper input coupling is illustrated below.

The SSI 204 is designed to accept sinusoidal input wave forms but will operate satisfactorily with any input that has the correct fundamental frequency with harmonics greater than 20 dB below the fundamental.

## CRYSTAL OSCILLATOR

The SSI 204 contains an onboard inverter with sufficient gain to provide oscillation when connected to a low-cost television "color-burst" crystal. The crystal oscillator is enabled by tying XEN high. The crystal is connected between XIN and XOUT. A $1 \mathrm{M} \Omega 10 \%$ resistor is also connected between these pins. In this mode, ATB is a clock frequency output. Other SSI 204's (or 202's) may use the same frequency reference by tying their ATB pins to the ATB of a crystal connected device. XIN and XEN of the auxiliary devices must then be tied high and low respectively. Ten devices may run off a single crystal-connected SSI 204 (or 202) as shown below.

## OUTPUTS D1, D2, D4, D8, and EN

Outputs D1, D2, D4, D8 are CMOS push-pull when enabled (EN high) and open circuited (high impedance) when disabled by pulling EN low. These digital outputs provide the hexadecimal code corresponding to the detected digit. The digital outputs become valid after a tone pair has been detected and they are then cleared when a valid pause is timed. The table below describes the hexadecimal codes.

| OUTPUT CODE |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Digit | D8 | D4 | D2 | D1 |  |
| 1 | 0 | 0 | 0 | 1 |  |
| 2 | 0 | 0 | 1 | 0 |  |
| 3 | 0 | 0 | 1 | 1 |  |
| 4 | 0 | 1 | 0 | 0 |  |
| 5 | 0 | 1 | 0 | 1 |  |
| 6 | 0 | 1 | 1 | 0 |  |
| 7 | 0 | 1 | 1 | 1 |  |
| 8 | 1 | 0 | 0 | 0 |  |
| 9 | 1 | 0 | 0 | 1 |  |
| 0 | 1 | 0 | 1 | 0 |  |
| $*$ | 1 | 0 | 1 | 1 |  |
| $\#$ | 1 | 1 | 0 | 0 |  |
| A | 1 | 1 | 0 | 1 |  |
| B | 1 | 1 | 1 | 0 |  |
| C | 1 | 1 | 1 | 1 |  |
| D | 0 | 0 | 0 | 0 |  |

## DV

DV signals a detection by going high after a valid tone pair is sensed and decoded at the output pins D1, D2, D4, D8. DV remains high until a valid pause occurs.

N/C PIN
This pin has no internal connection and may be left floating.

## APPLICATION NOTES

The SSI 204 will tolerate total input rms noise up to 12 dB below the lowest amplitude tone. For most telephone applications, the combination of the high frequency attenuation of the telephone line and internal band-limiting make special circuitry at the input to the SSI 204 unnecessary. However, noise near the 56 kHz internal sampling frequency will be aliased (folded back) into the audio spectrum, so if excessive noise is present above 28 kHz , the simple RC filter as shown below may be employed to band limit the incoming signal.

Filter for use in extreme high frequency input noise environment

Noise will also be reduced by placing a grounded trace around XIN and XOUT pins on the circuit board layout when using a crystal. It is important to note that XOUT is not intended to drive an additional device. XIN may be driven externally; in this case leave XOUT floating.

## Preliminary Data Sheet

## GENERAL DESCRIPTION

The SSI 207 is a complete Multi-Frequency (MF) receiver that can detect all 15 tone-pairs, including ST and KP. This receiver is intended for use in equal access applications and thus meets Bell and CCITT R1 central office register signalling specifications.

No anti-alias filtering is needed if the input signal is bandlimited to 26 KHz . The only external component required is an inexpensive television "color burst" 3.58 MHz crystal.
The SSI 207 employs state-of-the-art switched capacitor filters in CMOS technology. The receiver consists of a bank of channel-separation bandpass filters followed by zero-crossing detectors and frequency-measurement bandpass filters, an amplitude check circuit, a timer and decoder circuit, and a clock generator. The device does not attempt to identify strings of digits by the KP (key pulse) and ST (stop) tone pairs.
The outputs interface directly with standard DMOS or TTL circuitry and are three-state enabled to facilitate bus-oriented architecture.

## FEATURES

- Meets Bell and CCITT R1 specifications.
- 20-pin plastic DIP.
- Single low-tolerance 5V supply.
- Detects all 15 tone-pairs including ST and KP
- Long KP capability
- Built-in amplitude discrimination.
- Excellent noise tolerance.
- Outputs in either " n of 6 " or hexadecimal code.
- Three-state outputs, CMOS-compatible and TTL. compatible.

SSI 207 Block Diagram

Pin Out (Top View)

## VIN

This pin accepts the analog input. It is internally biased to half the supply and is capacitively coupled to the channel separation filters. The input may be DC coupled as long as it does not exceed the positive supply. Proper input coupling is illustrated below.

## Crystal Oscillator

The SSI 207 contaıns an on-board inverter with sufficient gain to provide oscillation when connected to a low cost television "color-burst" crystal. The on-chip clock signals are generated based on the oscillator. The crystal is connected between X1 and X2. X-OUT is a 3.58 MHz square wave capable of driving other circuits as long as the capacitive load does not exceed 50 pF .
The digital output format is neither " $n$ of 6 " or 4 -bit hexadecimal.

| DV | : Data Strobe |
| :--- | :--- |
| DE | Data Error Strobe |
| DO to D5 | : Tristate Digital Outputs |

n of 6 MODE (HEX pulled low)
Whenever a valid 2 of 6 code has been recognized, the DV strobe rises. It remains high until the code goes away, or the CSTR* line is activated. It will not reactivate untıl a new code is detected. Whenever an invalid 2 of 6 code is recognized, ( 1 of 6,3 of 6 , etc.) the DE strobe rises to indicate a transmission error. The DE strobe remains high until all errors stop, a valid tone paır is detected, or the CSTR* line is activated. Once cleared by CSTR, it will not reactivate until a new invalid condıtion is detected. The DE and DV strobes will never be high simultaneously.
The off-chip output register can be clocked by either the rising or falling edge of the strobe. The outputs will be cleared to zero when no valid tone is present.
In the " $n$ of 6 " mode (HEX pulled low), each output represents one of the six frequencies according to the following table:

| Frequency | Output Pin |
| :---: | :---: |
| 700 | D0 |
| 900 | D1 |
| 1100 | D2 |
| 1300 | D3 |
| 1500 | D4 |
| 1700 | D5 |

HEX MODE (HEX pulled high)
In the "hex" mode, D0 to D3 provide a 4-bit code identifying one of the 15 valid tone combinations according to the following table:

| Channels | Tone Pair Freq. | Name | D3 | D2 | D1 | D0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $0-1$ | 700,900 | 1 | 0 | 0 | 0 | 1 |
| $0-2$ | 700,1100 | 2 | 0 | 0 | 1 | 0 |

NOTE In the hex mode, $\mathrm{D} 4=\mathrm{DE}$ and $\mathrm{D} 5=\mathrm{DV}$
The outputs will be cleared to zero when no valid tone pair is present.

## LKP

The KP timer control. When high, the KP pulse must be longer than the other tone pairs before it will be detected. When low, the KP pulse is treated as any other pulse.

## QUAL

Enables tone pair qualification. When low, the threshold detector outputs are passed to the data outputs (DO-D5), without validation, in the format selected by the HEX pin. These outputs, plus strobes DV and DE, are updated once per 2.3 ms frame. (DV and DE represent " 2 -of-6" indicators in this mode). Note that the strobes will cycle once per frame (even when the inputs are stable). As always, data changes only when both strobes are low.

## CSTR*

This input clears both the DV and DE strobes. After CSTR* is released, the strobes will remain low until a new detect (or error) occurs. The output data is latched by CSTR* and will not change while CSTR* is low, even in the event that a new detect is qualified internally. (Note that improper use of CSTR* may result in missed detects.

## EN*

The tristate enable control - When low, the DO-D5 outputs are in the low impedence state. In an interrupt oriented microprocessor interface, EN* and CSTR* will often be tied together to provide automatic reset of the strobes when the output data is enabled.

## Application Guide

for
SSi Monolithic Dual-Tone Multi-Frequency (DTMF) Receivers

The SSi integrated DTMF Receivers are complete Touch-Tone detection systems. Each can operate in a stand-alone mode for the majority of telecommunications applications, thereby providing the most economical implementation of DTMF signaling systems possible. Each combines precision active filters and analog circuits with digital control logic on a monolithic CMOS integrated circuit. SSi DTMF Receiver use is straightforward and the external component requirements are minimal. This application guide describes device operation, performance, system requirements, and typical application carcuits for the SSi DTMF Receiver circuits

## How the SSi DTMF Circuits Work

General Description of Operation
The task of a DTMF Receiver is to detect the presence of a valid tone pair on a telephone line or other transmission medium. The presence of a valid tone pair indicates a single dialed digit; to generate a valid digit sequence, each tone pair must be separated by a valid pause.

The following table gives the established Bell system standards for a valid tone pair and a valid pause:

| One Low-Group Tone <br> - and - | 697 or 770 or 852 or 941 Hz |
| :---: | :---: |
| One High-Group Tone | $\begin{gathered} 1209 \text { or } 1336 \text { or } 1477 \text { or } \\ 1633 \mathrm{~Hz} \end{gathered}$ |
| Frequency Tolerance Amplitude Range | $\begin{aligned} & \mathrm{f}_{\mathrm{O}} \pm(15 \%+2 \mathrm{~Hz}) \\ & -24 \mathrm{dBm} \leq \mathrm{A} \leq+6 \mathrm{dBm} @ 600 \Omega \\ & \text { (Dynamic Range } 30 \mathrm{~dB} \text { ) } \end{aligned}$ |
| Relative Amplitude (Twist) | $-8 \mathrm{~dB} \leq \frac{\text { Hıgh-Group Tone }}{\text { Low-Group Tone }} \leq+4 \mathrm{~dB}$ |

Duration
Inter-tone Pauses
40 ms or longer 40 ms or longer

The SSi DTMF Receivers meet or exceed these standards.
Similar device architecture is used in all the SSi DTMF Receivers. Figure 1 shows the SSI 202 Block Diagram. In general terms, the detection scheme is as follows: The input signal is pre-filtered and then split into two bands, each of which contains only one DTMF tone group. The output of each
band-split filter is amplified and limited by a zero-crossing detector. The limited signals, in the form of square waves, are passed through tone frequency band pass filters. Digital logic is then used to provide detector sampling and determıne detection validity, to present the digital output data in the correct format, and to provide device timing and control.

## Detailed Description of Operation

Noise and Speech Immunity
The two largest problems confrontıng a DTMF Receiver are:

1) Distinguishing between valid tone pairs (or pauses) and other stray signals (or speech) that contain valid tone pair frequencies.
2) Detecting valid tone pairs in the presence of noise, which is typically found in the telephone (or other transmission medium) environment.

Figure 1. SSi 202 Block Diagram
The SSi DTMF Receivers use several techniques to distinquish between valid tone pairs and other stray signals. These techniques are explained in later sections. Briefly, the techniques are:

1) Pre-filtering of audio signal. Removes supply noise and dial tone from input audio signal and emphasizes the voice frequency domain.
2) Zero-cross detection. Limits the acceptable level of noise during detection of a tone pair. Important for speech rejection.
3) Valid tone pair/pause sampling. Samples the detection filters and checks for consistency before determining that a received tone pair or pause is valid.

## Audio Preprocessor

The Audio Preprocessor is an analog filter that band limits the input analog signal between 500 Hz and 6 KHz . In addition, it emphasizes the 2 KHz to 6 KHz voice region.

Band limiting suppresses power supply and dial tone frequencies, and high frequency noise. The emphasized voice region helps to equalize the audio response since many phone lines tend to roll off at about 1 KHz . The upper voice frequencies are important in providing speech immunity.

## Tone Band Splitting

After the analog signal is preprocessed, it is then split into two bands, each of which contains only one DTMF tone group. The band-split filters are actually band-stop filters to maintain all frequencies except the other tone group, this is done to maintain all analog information to enhance speech immunity but not allow the other tone group to act as interfering noise for the band being detected. These band-stop filters have "floors" that limit the amount of tone pair twist which further enhances speech immunity. See device data sheets for acceptable twist limits

## Zero-Crossing Detectors

The output of each band-split filter is amplified and limited by a zero-crossing detector (limiter). The function of the zerocrossing detector is to produce a square wave at the prime frequency emanating from the band-split filter. If a pure tone is not present, as in the case of voice or other interfering noise, a rectangular wave with a variable period will result. Proportional to the interference, the limiter output power is spread over a broad frequency range as the zero crossings "dither". When a high level of noise (or speech) occurs, no single bandpass filter pair will contain significant power long enough to result in a tone detection. The zero-crossing detector also acts as AGC (Automatic Gain Control) in that the output amplitude is independent of input amplitude; this additionally establishes an acceptable signal-to-noise ratio not dependent on tone amplitude.

## Bandpass Filters and Amplitude Detectors

The bandpass filters perform tone frequency discrimination. Their responses are tailored so that if the frequency of the limited square wave from the zero-crossing detector is within the tone frequency tolerance, the filter output will exceed the amplitude detector threshold. The amplitude detectors are interrogated periodically by the digital control circuity to ascertain the presence of one and only one tone in each band for the required duration. In a similar fashion, valid pauses are measured by the absence of valid tone pairs for the specified time.

## Timing and Logic

The only precision external element needed for the SSi DTMF Receivers is a 3.58 MHz crystal (color-burst frequency) for the on-board oscillator. This generates the precise clock for the filters and for the logic timing and control of the receive.

## Circuit Implementation

Standard CMOS technology is used for the entire circuit. Logic functions use standard low-power circuitry while the analog circuits use precision switched-capacitor-filter technology.

## How to Use the SSi DTMF Receivers

## Precautions

Although static protection devices are provided on the highimpedance inputs, normal handling precautions observed for CMOS devices should be used.

A destructive high current latch-up mode will occur if pin voltages are not constrained to the range between VN - . 5 Volt and VP +.5 Volt (except AIN as described below). In applicatıons where voltage spikes may occur, protection must be provided to ensure that the maximum voltage ratings are not exceeded. This may require the use of clampıng diodes on the Analog Input to protect against ringer voltage, for example, or on the power supply to protect against supply spikes.

## Power Supply

Excessive power supply noise should be avoided and to aid the user in this regard, power supply hook-up options are provided on some devices.

Since the digital circuitry of the devices possess the high noise immunity characteristics of CMOS logic, limited power supply noise is required only for the analog section. On those SSi DTMF receivers that have separate Analog Negative and Digital Negative supply connections (grounds), namely VNA
and VND, an unfiltered supply may be used at VND. It is necessary that VND and VNA differ no more than 0.5 Volts

The analog circuitry of the devices require low power supply noise levels as specified on the device Data Sheet. Power supply noise effects will be slightly less if the analog input is referenced to VP. This is normally accomplished by connecting VP to ground and utilizing a negative power supply. The effects of excessive power supply noise will cause decreased tone amplitude sensitivity and less tone detection frequency bandwidth.

## Digital Inputs

The digital inputs are directly compatible with standard CMOS logic devices powered by VP and VN (or VND). The input logic levels should swing within $30 \%$ of VP or VN to insure detection. Any unused input must be tied to VN or VP. Figure 2 shows methods for interfacing TTL outputs to 12 Volt SSi DTMF Receivers.

## Analog Input

The Analog Input is the signal input pin for the devices, and is specially biased to facilitate its connection to external circuitry, as shown in Figure 3. The signal level at the Analog Input pin must not exceed or fall more than a few volts below the positive supply as stated on the device Data Sheets If this condition cannot be guaranteed by the external circuitry, the signal must be AC coupled into the chip with a $.01 \mu \mathrm{~F} \pm 20 \%$ capacitor.

Figure 2 Interface circuits for conversion from TTL output levels to 12 voit SSI DTMF input levels

Figure 3. Direct and AC coupled configurations

## Analog Input Noise

The SSi DTMF Receivers will tolerate wide-band input noise of up to 12 dB below the lowest amplitude tone fundamental during detection of a valid tone pair. Any single interference frequency (including tone harmonics) between 1 KHz and 6 KHz should be at least 20 dB below the lowest amplitude tone fundamental. Adherence to these conditions will ensure reliable detection and full tone detection frequency bandwidth Because of the internal band limiting, noise with frequencies above 8 KHz can remain unfiltered. However, noise near the 56 KHz internal switched-capacitor-filter sampling frequency will be alıased (folded back) into the audio spectrum, noise above 28 KHz therefore should be low-pass filtered with a circuit as shown in Figure 4 using a cut-off frequency (Fc) of 6.6 KHz.

A 1 KHz cut-off frequency filter can be used on "normal" phone lines for special applications. When a phone line is particularly noisy, tone pair detection may be unreliable. A 1 KHz low pass filter will remove much of the noise energy but maintain the tone groups; however, a decreased speech immunity will result. This usage should only be considered for applications where speech immunity is not important, such as control paths that carry no speech.

Some DTMF tone pair generators output distorted tones which the SSi DTMF Receivers may not detect reliably (inexpensive extension telephones are an example). Most of the interfering harmonics of these tones may be removed by the use of a 3 KHz Fow-pass filter as in Figure 4. Some speech immunity degradation will result, but not as bad as using the 1 KHz filter mentioned above.

## Telephone Line Interface

In applications that use an SSi DTMF Receiver to decode DTMF signals from a phone line, a DAA (Direct Access Arrangement) must be implemented. Equipment intended for connection to the public telephone network must comply with and be registered in accordance to FCC Part 68 For PBX applications refer to EIA Standard RS-464

Some of the basic guidelines are:

1) Maximum voltage and current ratıngs of the SSI DTMF Receivers must not be exceeded; this calls for protection from ringing voltage, if applicable, which ranges from 80 to 120 Volts RMS over a 20 to 80 Hz frequency range.
2) The interface equipment must not breakdown with highvoltage transient tests (including a 2500 Volt peak surge) as defined in the applicable document.
3) Phone line termınation must be less than 200 Ohms DC and approximately 600 Ohms AC $(200-3200 \mathrm{~Hz})$.
4) Termination must be capable of sustaıning phone line loop current (off-hook condition) which is typically 18 to 120 mA DC
5) The phone line termınation must be electrically balanced in respect to ground.
6) Public phone line termination equipment must be registered in accordance to FCC Part 68 or connected through registered protection circuitry. Registratıon typically takes about six months.

Ready made DAA devices are also available. One source is Cermetek Microelectronıcs, Sunnyvale, Californıa.

Figure 5 shows a simplified phone line interface using a 600 Ohm 1:1 line transformer. Transformers specially designed for phone line coupling are available from many transformer manufacturers.

Figure 5 Simplified Phone Line Interface

Figure 6 shows a more featured version of Figure 5. These added options include:

1) A 150 Volt surge protector to eliminate high voltage spikes.
2) A Texas Instruments TCM1520A ring detector, optically isolated from the supervisory circuitry.
3) Back-to-back Zener diodes to protect the DTMF (and optional multiplexer Op-Amp) from ringer voltage.
4) Audio multiplexer which allows voice or other audio to be placed on the line (a recorded message, for example) and not interfere with incoming DTMF tone detection.

Figure 6 Full Featured Phone Line Interface

An integrated voice circuit may also be implemented for line coupling, such as the Texas Instruments TCM1705A, however, this approach is typically more expensive than using a transformer as shown above.

## Outputs

The digital outputs of the SSi DTMF Receivers (except XOUT) swing between VP and VN (or VND) and are fully compatible with standard CMOS logic devices powered from VP and VN The 5 Volt DTMF devices will also interface directly to LSTTL. The 12 Volt DTMF devices can interface to TTL or low voltage MOS with the circuit in Figure 7.

Figure 7 SSI 12 Volt DTMF to TTL Level Interface
Data Outputs D8, D4, D2, and D1 are three-state enabled to facılitate interface to a three-state bus. Figure 8 shows the equivalent circuit for the data outputs in the high impedance state. Care must be taken to prevent either substrate diode in Figure 8 from becoming forward biased or damage may result.

Figure 8. Equivalent Circuit of SSı DTMF Receiver Data Output in High Impedance State

## Timing

Within 40 ms of a valid tone pair appearing at the DTMF Receiver Analog Input, the Data Outputs D8, D4, D2 and D1 will become valid. SSi 201 timing is shown in Figure 9 (refer to the device Data Sheet for other timing diagrams). Seven microseconds after the data outputs have become valid DV will be raised. DV will remain high and the outputs valid while the valid tone pair remains present. Within 40 ms after the tone pair stops, the DTMF will recognize a valid pause. DV is lowered approximately 45 ms following the end of the tone pair, and the data outputs all set to zero 4.56 ms following DV going low. DV will strobe at least for the same duration as the received tone pair.

## System Interface

Provision has been made on the SSi DTMF Receivers for handshake interface with an outside monitoring system. In this mode, the DV strobe is polled by the monitoring system at least once every 40 ms to determine whether a new valid tone pair has been detected. If DV is high, the coded data is stored in the monitoring system and then CLRDV is pulsed high. With some systems operating in the handshake mode, it may be desirable to know when a valid pause has occurred. Ordinarily this would be indicated by the falling edge of DV. However, in the handshake mode, DV is cleared by the monitoring system each time a new valid tone pair is detected and, therefore, cannot be used to determine when a valid pause is detected. The detection of a valid pause in this case may be observed by detecting the clearing of the Data Outputs. Since, in hexidecimal format (the mode normally used with a handshake interface), the all zero state represents a commonly unused tone pair (D), the detection of a valid pause may be detected by connecting a four-input NOR gate to the device outputs and sensing the all zero state.

## Time Base

The SSi DTMF Receivers contain an on-chip oscillator for a 3.5795 MHz parallel resonant quartz crystal or ceramic resonator. The crystal (or resonator) is placed between XIN and XOUT in parallel with a 1 Mohm resistor, while XEN is tied high. Since the switched-capacitor-filter time base is derived from the oscillator, the tone detect band frequency tolerance is proportional to the time base tolerance. The SSI DTMF Receiver frequency response and timing is guaranteed with a time base accuracy of at least $\pm .01 \%$. To obtain this accuracy the CTS Part No. MP036 or Workman Part No. CY1-C or equivalent quartz crystal is recommended. In less critical applications a suitable ceramic resonator may be implemented.

Figure 9. SSI 201 Timing Diagram and Specifications
For the SSi 201, a muRata Part No. FX-5135 is recommended which will provide an accuracy of approximately $\pm 0.3 \%$. The use of a ceramic resonator requires the addition of two $30 \mathrm{pF} \pm 10 \%$ capacitors; one between XIN and VN (or VND)
and the other between XOUT and VN (or VND). Extra caution should be used to avoid stray capacitance on the resonant circuit when using a ceramic resonator instead of a quartz crystal.

When the oscillator connected as above and XEN tied high, the ATB (alternate time base) pin delivers a square wave output at one-eighth the oscillator frequency $(447.443 \mathrm{KHz}$ nominal). The ATB pin can be converted to a time base input by tying XEN low; ATB can then be externally driven from another device such as the ATB output of another DTMF. No crystal is required for the ATB input device; XIN must be tied high if unused. Several SSi DTMF Receivers can be driven with a single crystal (refer to device data sheet for fan-out limit).

XOUT is designed to drive a resonant circuit only and is not intended to drive additional devices. If a 3.58 MHz clock is needed for more than one device and it is desirable to use only one resonant device, an outside inverter should be used for the time base, buffered by a second inverter or buffer. The buffer output would then drive XIN of the SSi DTMF Receiver as well as the other device(s); XOUT must be left floating and XEN tied high.

## Dial Tone Rejection

The SSi DTMF Receivers incorporate enough dial tone rejection circuitry to provide dial tone tolerance of up to 0 dB . Dial tone tolerance is defined as the total power of precise dial tone ( 350 Hz and 440 Hz as equal amplitudes) relative to the lowest amplitude tone in a valid tone pair. The filter of Figure 10 may be used for further dial tone rejection. This filter exhibits an elliptic highpass response that provides a minimum of 18 dB rejection at 350 Hz and 24 dB rejection at 440 Hz so long as the component tolerances indicated are observed. The DTMF on-chip filter rejects 350 Hz at least 6 dB more than 440 Hz . Therefore, employing the filter of Figure 10 yields a dial tone tolerance of +24 dB .

Figure 10. Dial Tone Reject Filter

## Printed Circuit Board Implementation

The SSi DTMF Receivers are analog in nature and should be treated as such; circuit noise should be kept to a minimum. To be certain of this, all input and output lines should be kept away from noise sources (high frequency data or clock lines); this is especially true for the Analog Input. Noise in the ground or power supply lines can be avoided by running separate traces to supportive logic circuits or by running thicker (lower resistance) busses. Capacitance power supply bypassing should be performed at the device. Refer to the Power Supply section above.

## Performance Data

A portion of the final SSi DTMF Receiver device characterization uses the Mitel CM7290 tone receiver test tape. The evaluation circuit shown in Figure 11 was used to characterize the SSI 201. The speed and output level of the tape deck must be adjusted so that the calibration tone at the beginning of the tape is at exactly 1000 Hz and 2 V rms.

The Mitel tape tests yield similar results on all of the SSI DTMF Receivers. Test results for the SSI 201 are summarized in Table 1. In short, the measured performance data demonstrates that the SSi DTMF Receivers are monolithic realizations of a full "central office quality" DTMF Receiver.

Table I Mitel \#CM7290 Tape Test Results for SSI 201 (Averaged for 10 parts)

## Applications

Creating Hexadecimal " 0 " Output upon Digit " 0 " Detection
To be consistent with pulse-dialing systems, the SSi DTMF Receivers provide a hexadecimal " 10 " output upon the detection of a digit 0 tone pair when in the hexadecimal code format. However, some applications may instead require a hexadecimal " 0 " with a digit " 0 " detection. The circuit of

The 4514 raises one of its 16 outputs in response to the 4 -bit output code from the DTMF. The output at the 4514 will remain high until the next button is depressed.

## 2-of.8 Output Decode

The circuit shown in Figure 14 can be used to convert the binary coded $2-$ of 8 to the actual 2 of 8 code (or 2 of 7 if detection of 1633 Hz tone is inhibited). The output data will be valid while DV is high. If it is desired to force the eight outputs to zero when a valid tone is not present, DV should be inverted and connected to both E-NOT inputs of the 4555.

Figure 14 Touch Tone to $2 \cdot 0 \mathrm{f}$-8 Output Converter

## DTMF to Rotary Dial Pulse Converter

The 2-of-8 output of Figure 14 can be modified to interface with a pulse dialer as shown in Figure 15 If a 12 Volt DTMF is used the 4049 will translate the 12 Volt outputs to the 5 Volt swings required for the MK5099 pulse dialer

Figure 16 shows the interface for adding pulse detection and counting to a SSi DTMF Receiver.

The loop detector provides a digıtal output representıng the telephone loop circuit "make" and "break" condition assocıated with rotary pulse dialing. For the circuit of Figure 16, Ground represents a "make" and $\mathrm{V}_{\mathrm{p}}$ a "break".
The loop detector feeds dial pulses to IC-1, a binary counter, and to IC-2A, a re-triggerable "one-shot'. When a dial pulse appears the Q1-NOT output of IC-2A immediately goes low, resetting IC-1. The clock input to IC-1 is delayed by R1-C1 so that reset and count input do not overlap The binary outputs of IC-1 will reflect the pulse count and 02 seconds after the last pulse the Q1-NOT output will go high. C3-R3 differentiate this pulse and clock the output latch, IC-3, holding the output pulse untıl the next digit.

#### Abstract

 $\qquad$   

^[  ]

 都
 SSı DTMF Receivers

The 0.2 second timeout of IC-2A indicates the end of dial pulsing since even a slow ( 8 pps ) dial would input another pulse every 0125 seconds. The binary outputs of IC-1 are paralleled with those of the SSi DTMF Receiver circuit through diodes to the inputs of IC-3 A pulldown resistor is necessary on each IC-3 input pin IC- 1 must be a binary, not BCD, counter.
With a 4175 for IC-3 the output data is latched until the next valid input, whether from a rotary dial or dual tone instrument A unique situation exists, however, when going on-hook. The loop detector will output a continuous level of VP which would trigger IC-2A and put a single count into IC-1 A high level from the loop detector also turns on Q1, pulling the clock input of IC-3 to ground Since the loop detector output will be low at the completion of dialing, all outputs are valid even when the telephone is placed on-hook, an important consideration if output data is recorded.

## Data Sheet

## GENERAL DESCRIPTION

Silicon Systems' new SSI 20C89 is a complete Dual Tone Multiple Frequency (DTMF) Transceiver that can both generate and detect all 16 standard Touch-Tone digits. The SSI 20C89 circuit integrates the performance proven SSI 202 DTMF Receiver with a new DTMF generator circuit.
The DTMF Receiver electrical characteristics are identical to the standard SSI 202 device characteristics. The DTMF generator provides performance similar to the Mostek MK5380, but with an improved (tighter) output amplitude range specification and with the addition of independent latch and reset controls.

The only external components necessary for the SSI 20 C 89 are: a 3.58 MHz "colorburst" crystal with a parallel $1 \mathrm{M} \Omega$ resistor. This provides the time base for digital functions and switched capacitor filters in the device. No external filtering is required.

FEATURES

- DTMF Generator and Receiver on one chip
- 22-Pin plastic DIP
- Low-power 5 Volt CMOS
- DTMF Receiver exhibits excellent speech immunity
- Three-state outputs (4-bit hexadecimal) from DTMF Receiver
- AC coupled, internally biased analog input
- Latched DTMF Generator inputs
- Analog input range from - $\mathbf{3 2}$ to $\mathbf{- 2 d B m}$ (ref $600 \Omega$ )
- DTMF output typ. - $8 \mathbf{d B m}$ (Low Band) and $\mathbf{- 5 . 5 ~ d B m}$ (High Band)
- Uses inexpensive 3.579545 MHz crystal for reference
- Easily interfaced for microprocessor dialing

Block Diagram

## CIRCUIT OPERATION

## Receiver

The DTMF Receiver in the SSI 20C89 detects the presence of a valid tone pair (indicating a single dialed digit) on a telephone line or other transmission medium. The analog input is pre-processed by 60 Hz reject and band splitting filters, then hard-limited to provide Automatic Gain Control. Eight bandpass filters detect the individual tones. The digital post-processor times the tone durations and provides the correctly coded digital outputs. The outputs will drive standard CMOS circuitry, and are three-state enabled to facilitate bus-oriented architectures.

## DIN

This pin accepts the analog input. It is internally biased so that the input signal may be AC coupled. The input may be DC coupled as long as it does not exceed the positive supply. Proper input coupling is illustrated below.

The SSI 20C89 is designed to accept sinusoidal input wave forms but will operate satisfactorily with any input that has the correct fundamental frequency with harmonics greater than 20 dB below the fundamental.

## Crystal Oscillator

The SSI 20C89 contains an onboard inverter with sufficient gain to provide oscillation when connected to a low-cost television "color-burst" crystal. The crystal is placed between XIN and XOUT in parallel with a 1 Mohm resistor, while XEN is tied high. Since the switched-capacitor-filter time base is derived from the crystal oscillator, the frequency accuracy of all portions of the 20 C 89 depends on the time base tolerance. The SSI DTMF Receiver frequency response and timing is
specified for a time base accuracy of at least $\pm 0.005 \%$. ATB is a clock frequency output. Other devices may use the same frequency reference by tying their ATB pins to the ATB of a crystal connected device. XIN and XEN of the auxiliary devices must then be tied high and low respectively, XOUT is left floating. XOUT is designed to drive a resonant circuit only and is not intended to drive additional devices. Ten devices may run off a single crystal-connected SSI 20 C 89 as shown below.

Receiver Outputs and the $\overline{\mathrm{DE}}$ Pin
Outputs D0,D1,D2,D3 are CMOS push-pull when enabled ( $\overline{\mathrm{DE}}$ low) and open-circuited (high impedance) when disabled ( $\overline{\mathrm{DE}}$ high). These digital outputs provide the I hexadecimal code corresponding to the detected digit. The table below shows that code.

| Digit | Input: Output: | Hexadecimal code |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | D7 | D6 | D5 | D4 |
|  |  | D3 | D2 | D1 | D0 |
| 1 |  | 0 | 0 | 0 | 1 |
| 2 |  | 0 | 0 | 1 | 0 |
| 3 |  | 0 | 0 | 1 | 1 |
| 4 |  | 0 | 1 | 0 | 0 |
| 5 |  | 0 | 1 | 0 | 1 |
| 6 |  | 0 | 1 | 1 | 0 |
| 7 |  | 0 | 1 | 1 | 1 |
| 8 |  | 1 | 0 | 0 | 0 |
| 9 |  | 1 | 0 | 0 | 1 |
| 0 |  | 1 | 0 | 1 | 0 |
| * |  | 1 | 0 | 1 | 1 |
| \# |  | 1 | 1 | 0 | 0 |
| A |  | 1 | 1 | 0 | 1 |
| B |  | 1 | 1 | 1 | 0 |
| C |  | 1 | 1 | 1 | 1 |
| D |  | 0 | 0 | 0 | 0 |

The digital outputs become valid and DV signals a detection after a valid tone pair has been sensed. The outputs and DV are cleared when a valid pause has been timed.

## Generator

The DTMF generator on the SSI 20 C 89 responds to a hexadecimal code input with a valid tone pair. Pins D4-D7 are the data inputs for the generator. A high to low transition on LATCH causes the hexadecimal code to be latched internally and generation of the appropriate DTMF tone pair to begin. The DTMF output is disabled by a high on RESET and will not resume until new data is latched in.

## Digital Inputs

The D4,D5,D6,D7, $\overline{\text { LATCH, RESET inputs to the DTMF }}$ generator may be interfaced to open-collector TTL with a pull-up resistor or standard CMOS. These inputs follow the same hexadecimal code format as the DTMF receiver output. Table 1 shows the code for each digit. The dialing matrix and detection frequency table below list the frequencies of the digits.

## DTMF DIALING MATRIX

## Data Sheet

## GENERAL DESCRIPTION

Silicon Systems' new SSI 20 C 90 is a complete Dual Tone Multiple Frequency (DTMF) Transceiver that can both generate and detect all 16 standard Touch-Tone digits. The SSI 20C90 circuit integrates the performance proven SSI 202 DTMF Receiver with a new DTMF generator circuit.

The DTMF Receiver electrical characteristics are identical to the standard SSI 202 device characteristics. The DTMF generator provides performance similar to the Mostek MK5380, but with an improved (tighter) output amplitude range specification and with the addition of independent latch and reset controls.

An additional feature of the 20 C 90 is "imprecise" call progress detector. The detector detects the presence of signals in the $305-640 \mathrm{~Hz}$ band.

The only external components necessary for the SSI 20 C 90 are a 3.58 MHz "colorburst" crystal with a parallel $1 \mathrm{M} \Omega$ resistor. This provides the time base for digital functions and switched capacitor filters in the device. No external filtering is required.

FEATURES

- DTMF Generator and Receiver on one chip
- 22-Pin plastic DIP
- Low-power 5 Volt CMOS
- DTMF Receiver exhibits excellent speech immunity
- Three-state outputs (4-bit hexadecimal) from DTMF Receiver
- AC- coupled, internally-biased analog input
- Latched DTMF Generator inputs
- Analog input range from -32 to $\mathbf{- 2 d B m}$ (ref $600 \Omega$ )
- DTMF output typ. $\mathbf{- 8} \mathbf{d B m}$ (Low Band) and $\mathbf{- 5 . 5 d B m}$ (High Band)
- Uses inexpensive 3.579545 MHz crystal for reference
- Easily interfaced for microprocessor dialing
- Call progress detection

Pin Out (Top View)

CAUTION: Use handling procedures necessary for a static sensitive component

## CIRCUIT OPERATION

## Receiver

The DTMF Receiver in the SSI 20C90 detects the presence of a valid tone pair (indicating a single dialed digit) on a telephone line or other transmission medium. The analog input is pre-processed by 60 Hz reject and band splitting filters, then hard-limited to provide Automatic Gain Control. Eight bandpass filters detect the individual tones. The digital post-processor times the tone durations and provides the correctly coded digital outputs. The outputs will drive standard CMOS circuitry, and are three-state enabled to facilitate bus-oriented architectures.

## DIN

This pin accepts the analog input. It is internally biased so that the input signal may be AC coupled. The input may be DC coupled as long as it does not exceed the positive supply. Proper input coupling is illustrated below.

The SSI 20C90 is designed to accept sinusoidal input wave forms but will operate satisfactorily with any input that has the correct fundamental frequency with harmonics greater than 20 dB below the fundamental.

## Crystal Oscillator

The SSI 20 C 90 contains an onboard inverter with sufficient gain to provide oscillation when connected to a low-cost television "color-burst" crystal. The crystal is placed between XIN and XOUT in parallel with a 1 Mohm resistor, while XEN is tied high. Since the switched-capacitor-filter time base is derived from the crystal oscillator, the frequency accuracy of all portions of the

20C90 depends on the time base tolerance. The SSI DTMF Receiver frequency response and timing is specified for a time base accuracy of at least $\pm 0.005 \%$. ATB is a clock frequency output. Other devices may use the same frequency reference by tying their ATB pins to the ATB of a crystal connected device. XIN and XEN of the auxiliary devices must then be tied high and low respectively, XOUT is left floating. XOUT is designed to drive a resonant circuit only and is not intended to drive additional devices. Ten devices may run off a single crystal-connected SSI 20 C 90 as shown below.

## Receiver Outputs and the $\overline{\mathrm{DE}}$ Pin

Outputs D0,D1,D2,D3 are CMOS push-pull when enabled ( $\overline{\mathrm{DE}}$ low) and open-circuited (high impedance) when disabled ( $\overline{D E}$ high). These digital outputs provide the hexadecimal code corresponding to the detected digit. The table below shows that code.

| Digit | Input: Output: | Hexadecimal code |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | D7 | D6 | D5 | D4 |
|  |  | D3 | D2 | D1 | D0 |
| 1 |  | 0 | 0 | 0 | 1 |
| 2 |  | 0 | 0 | 1 | 0 |

| 5 |  | 0 | 1 | 0 | 1 |
| 6 |  | 0 | 1 | 1 | 0 |
| 7 |  | 0 | 1 | 1 | 1 |
| 8 |  | 1 | 0 | 0 | 0 |
| 9 |  | 1 | 0 | 0 | 1 |
| 0 |  | 1 | 0 | 1 | 0 |
| $\star$ |  | 1 | 0 | 1 | 1 |
| \# |  | 1 | 1 | 0 | 0 |
| A |  | 1 | 1 | 0 | 1 |
| B |  | 1 | 1 | 1 | 0 |
| C |  | 1 | 1 | 1 | 1 |
| D |  | 0 | 0 | 0 | 0 |

The digital outputs become valid and DV signals a detection after a valid tone pair has been sensed. The outputs and DV are cleared when a valid pause has been timed.

## Generator

The DTMF generator on the SSI 20C90 responds to a hexadecimal code input with a valid tone pair. Pins D4-D7 are the data inputs for the generator. A high to low transition on LATCH causes the hexadecimal code to be latched internally and generation of the appropriate DTMF tone pair to begin. The DTMF output is disabled by a high on RESET and will not resume until new data is latched in.

## Digital Inputs

The D4,D5,D6,D7, $\overline{\text { LATCH, RESET inputs to the DTMF }}$ generator may be interfaced to open-collector TTL with a pull-up resistor or standard CMOS. These inputs follow the same hexadecimal code format as the DTMF receiver output. Table 1 shows the code for each digit. The dialing matrix and detection frequency table below list the frequencies of the digits.

## DTMF DIALING MATRIX

Note Column 3 is for special applications and is not normally used in telephone dialing

## DETECTION FREQUENCY

| Low Group $\mathbf{f}_{\mathbf{o}}$ | High Group f. |
| :---: | :---: |
| Row $0=697 \mathrm{~Hz}$ | Column $0=1209 \mathrm{~Hz}$ |
| Row $1=770 \mathrm{~Hz}$ | Column $1=1336 \mathrm{~Hz}$ |
| Row $2=852 \mathrm{~Hz}$ | Column $2=1477 \mathrm{~Hz}$ |
| Row $3=941 \mathrm{~Hz}$ | Column $3=1633 \mathrm{~Hz}$ |

## DTMF OUT

The output amplitude characteristics listed in the specifications are given for a supply voltage of 5.0 V . However, the output level is directly proportional to the supply, so variations in it will affect the DTMF output. A recommended line interface for this output is shown below.

## Call Progress Detection

The Call Progress Detector consists of a bandpass filter and an energy detector for turning the on/off cadences into a microprocessor compatible signal.

## LIN Input

This analog input accepts the call progress signal and should be used in the same manner as the receiver input DIN.

## DET Output

This output is TTL compatible and will be of a frequency corresponding to the various cadences of Call Progress signals such as, on $0.5 \mathrm{sec} / 0 \mathrm{ff} 0.5 \mathrm{sec}$ for a busy tone, on $0.25 \mathrm{sec} / \mathrm{off} 0.25 \mathrm{sec}$ for a reorder tone and on 0.8-1.2 $\mathrm{sec} / \mathrm{off}$ 2.7-3.3 sec for an audible ring tone.

## Data Sheet

## GENERAL DESCRIPTION

The SSI 957 combines switched-capacitor and digital frequency measuring techniques to decode Dual-Tone Multifrequency (DTMF) signals to four bit binary data. Dial tone rejection and 60 Hz noise rejection filters are built in. Fabricated as a monolithic integrated circuit using low power CMOS processing, the SSI 957 is packaged in a 22 -pin DIP and operates from a single 5 through 12 volt DC supply. An inexpensive 3.58 MHz television crystal and a resistor are the only external components required. High system density may be achieved by using the clock output of one crystal connected receiver to drive the time bases of additional receivers.

The SIGNAL IN input to the SSI 957 interfaces readily to telephone lines, radio receivers, tape players, and other DTMF signal sources. Inputs A and B control sensitivity to a maximum of -38 dBm , while the $12 / \overline{16}$ input determines the signals to be detected. The preprocessing stages of the SSI 957 filter out dial tone and noise, split the signal into its high frequency group and low frequency group components, and hard limit each component to provide automatic gain control. Four discriminators in each group then detect the individual
tones. Post-processing stages of the SSI 957 time the tone durations and store binary data for outputting as determined by the HEX input. The STROBE output is activated by the presence of valid data in the output register and cleared by the detection of a valid end-ofsignal pause or by the CLEAR input. An early signal presence indicator, $B D$, facilitates applications requiring tone blocking. The data outputs operate with simple logic circuits or microprocessors, and are tristate enabled to facilitate bus-oriented architectures.

## FEATURES

- Complete DTMF receiver in 22-pin DIP
- Decodes all 16 DTMF digits
- Excellent dial tone and speech immunity
- Meets telephone impulse noise immunity standards
- Digitally selectable sensitivity to -38 dBm
- Selectable 4-bit hexadecimal or binary-coded 2-of-8 output
- Fabricated using low-power CMOS technology
- Operates on single DC supply
- Uses inexpensive 3.58 MHz crystal
- Second source of Teltone M-957

Pin Out (Top View)

# SSI 957 DTMF Receiver with Dial Tone Reject Filter 

Table 1:Pin Functions

| Pin | Function |
| :---: | :---: |
| SIGNALIN | DTMF input. Timings are shown in Figure 1. Internally biased so that the input signal may be AC coupled. SIGNAL IN also permits DC coupling as long as the input voltage does not exceed the positive supply. Proper coupling is shown in Figure 3 . See Table 3 for the frequency pairs associated with each DTMF signal. |
| 12/16 | DTMF signal detection control. When $12 / 16$ is at logic " 1 ", the SSI 957 detects the 12 most commonly used DTMF signals ( 1 through \#). When $12 \sqrt{16}$ is at logic " 0 ", the SSI 957 detects all 16 DTMF signals ( 1 through D). |
| A, B | Binary DTMF signal sensitivity control inputs. A and B select the sensitivity of the SIGNAL IN input to a maximum of -38 dBm . |
| D3, D2, D1, D0 | Data outputs. When enabled by the OE input, the data outputs provide the code corresponding to the detected digit in the format programmed by the HEX pin. See Table 3. The data outputs become valid after a tone pair has been detected and are cleared when a valid pause is timed. Timings are shown in Figure 1. |
| OE | Output enable. When OE is at logic " 1 ", the data outputs are in the CMOS push/pull state and represent the contents of the output register. When OE is driven to logic " 0 ", the data outputs are forced to the high-impedance or "third" state. Timings are shown in Figure 1. |
| HEX | Binary output format control. When HEX is at logic " 1 " the output of SSI 957 is full, 4 -bit binary. When HEX is at logic " 0 ", the output is binary coded 2 -of-8. Table 3 shows the output codes. |
| STROBE | Valid data indication. STROBE goes to logic " 1 " after a valid tone pair is sensed and decoded at the data outputs. STROBE remains at logic " 1 " until a valid pause occurs or the CLEAR input is driven to logic " 1 ", whichever is earlier. Once cleared, STROBE will not rise to a logic " 1 " until a new valid tone (preceded by a valid pause) is detected. Timings are shown in Figure 1. |
| CLEAR | STROBE control. Driving CLEAR to logic " 1 " forces the STROBE output to logic " 0 ". When CLEAR is at Iogic " 0 ", STROBE is forced to logic " 0 " only when a valid pause is detected. Tie to VNA or VND when not used. |
| BD | Button Down - A logic " 1 ' BD indicates a signal has been detected and is being validated. BD precedes STROBE and Data outputs. |
| XIN, XOUT | Crystal connections. When an auxiliary clock is used, XIN should be tied to logic "1". See Figure 4. |
| OSC/CLK | Time base control. WHen OSCICLK is at logic " 1 ", the output of the SSI 957's internal oscillator is selected as the time base. When OSC/CLK is at logic " 0 " and XIN is at logic " 1 ", the AUXCLK input is selected as the time base. |
| AUXCLK | Auxiliary clock input. When OSC/CLK is at logic " 0 " and XIN is at logic " 1 ", the AUXCLK input is selected as the SSI 957 's time base. The auxiliary input must be 3.58 MHz divided by 8 for the SSI 957 to operate to'specifications. If unused, AUXCLK should be left open. |
| VNA, VND | Negative analog and digital power supply connections. Separated on the chip for greater system flexibility, VNA and VND should be at equal potential. |
| VP | Positive power supply connection. |
| N/C | Not connected. These pins have no internal connection and may be left floating. |

## Notes

1 With an ambient temperature of $25^{\circ} \mathrm{C}$, the signal duration and signal interval at minimum, and the signal frequency deviation and twist at maximum The unit "dBm" refers to decibels above or below a reference power of one milliwatt into a 600 -ohm load (For example, - 24 dBm equals 49 mVrms )

2 Twist is defined as the ratio of the level of the high-frequency DTMF component to the level of the low-frequency DTMF component
3 With an ambient temperature of $25^{\circ} \mathrm{C}$, the signal level at $\mathrm{A}+5$, the signal frequency deviation and twist at 0 , and the signal applied 50
ms off and 50 ms on The A level is the minımum detect level selected
4 With the signal duration and signal interval at mınımum, and the signal frequency deviation and twist at maximum The A level is the mınımum detect level selected
5 Logic levels shown are referenced to VND
6 For an ambient temperature of $25^{\circ} \mathrm{C}$
7 Power supply excursions above this value can cause device damage

## Data Sheet

## DESCRIPTION

The SSI 980 Call Progress Tone Detector circuit allows automatic equipment to monitor tones in dial telephone systems that relate to the routing of calls. Such tones commonly include dial tone, circuits-busy tone, station-busy tone, audible ringing tones, and others. By sensing signals in the range of 305 to 640 Hz , the SSI 980 does not require the use of precision tones to function. This means that tones which vary with location or call destination can be detected regardless of their exact frequency. The SSI 980 is sensitive to signals from 0 dBm to -40 dBm .

The low power CMOS switched capacitor filters used in the SSI 980 derive therr accuracy from a 3.58 MHz clock, which in turn may be derived from other devices in the system being designed. The SSI 980 is available in plastic and ceramic DIP 8-pin packages.

FEATURES

- Detects tones throughout the telephone progress supervision band ( $\mathbf{3 0 5}$ to $\mathbf{6 4 0 ~ H z}$ )
- Sensitivity to - $\mathbf{4 0} \mathbf{d B m}$
- Dynamic range over 40 dB
- 40 ms minimum detect ( 50 ms to output)
- Single supply CMOS (low power)
- Supply range 4.5 to 5.5 V DC
- Uses 3.58 MHz crystal or external clock,
- 8-pin DIP
- Second source of Teltone M-980.

 SSI 981/982 Precise Call Progress Tone Detector
## Data Sheet

## DESCRIPTION

The SSI 981 and 982 Precise Call Progress Tone Detector circuits enable automatic monitoring of tones in dial telephone systems for the purpose of routing calls. Built using CMOS switched capacitor technology, each has four independent channels for detecting precise tones in the 305 to 640 Hz range. The outputs of the channels have a response related to the respective tone durations.
The SSI 981 and 982 are identical except for the tones detected. The SSI 981 will decode $350 \mathrm{~Hz}, 400 \mathrm{~Hz}, 440 \mathrm{~Hz}$ and 480 Hz . The SSI 982 will decode $350 \mathrm{~Hz}, 440 \mathrm{~Hz}$, 480 Hz and 620 Hz tones.

## FEATURES

- Detects \& decodes precise tones throughout $305-640 \mathrm{~Hz}$ telephone progress band
- 35dB dynamic range
- Single supply CMOS (low power)
- Adjustable gain sensitivity
- Supply range 4.5 to 5.5 VDC
- Uses 3.58 MHz crystal
- Three-state outputs
- Standard 22-pin DIP
- Second source to Teltone M981 and M982

SSI 981/982 Block Diagram

Pin Out (Top View)

Figure 1

## CIRCUIT OPERATION

The functional block diagram is shown in figure 1. Channels 1 and 2, and 3 and 4 are multiplexed, respectively as shown. Each channel starts with a 4-pole band-pass filter that reduces the amplitude of out-of-band signals. The output of the front-end filter is fed into two circuits, one being a zero-crossing detector which functions as a limiter-AGC, and the other being a circuit that controls the level of the interference floor based on the level of the incoming signal. The output of the ZCD, an energy-limited signal, is fed into a peak-to-peak detector that determines if the precise frequency is present by checking the amplitude of the signal from the back-end filter. Pulses from the peak-to-peak detector, which indicate the presence of the precise tone, are counted to time the duration of the input pulsed-tone. If the criteria of the specifications are met, the appropiate detect output goes to the high state. As shown in figure 1, all circuitry after the front-end filters is multiplexed. A digital demultiplexer follows the P-P detector to provide the four distinct outputs.
SIGIN
The input signal is applied to the SIGIN pin and is ACcoupled into the front-end filters. The SSI 981 and 982 can amplify a low level signal by 10 dB when the $\overline{\text { XRANG }}$ pin is held low.

## DET OUTPUTS \& OE

Outputs DET1-4 are CMOS push-pull when enabled
( $O E=$ " 1 ") and high impedance when disabled
( $O E=$ " 0 '). A " 1 '" on a Det pin indicates that the appropiate valid tone pulse was detected (see table 2). Detect timing is shown is figure 2.

## STROBE \& EN

The STROBE pin is the logical OR of the DETn outputs and will indicate when any one of the four call progress tones has been detected. STROBE is unaffected by OE but goes to a high impedance state when $\mathrm{EN}=$ '" 0 '".

## XIN, XOUT \& X358

Internal timing and clocks are derived from the 3.58 MHz clock. The SSI 981 and 982 contain an on-board inverter with sufficient gain to provide oscillation when connected to a low cost "colorburst" crystal. The crystal is connected between XIN an XOUT. A 1Mohm 10\% resistor is also connected between these pins. In this mode, X358 is a clock frequency output available to drive other parts requiring the same frequency.
The part will also operate with an external digital clock (duty cycle $40 \%$ to $60 \%$ ).

## VREF

Internal analog signal reference voltage. Noise or interference coupled onto this pin may degrade chip functionality.
TST1 \& TST2
Manufacturer's special test pins.

## Notes

(1) All parameters are specified at VDD $=5$ volts and XRANG at a logical "hi" state, which implies unity front-end gain Power levels in dBm are referenced to $600 \Omega$
(2) A post-filter AGC is employed to enhance end-of-tone detection for high-level signals A drop in amplitude of the input tone may cause an end-of-tone (interval) indication
(3) Large input voltage transients may cause excessive ringing in the highly selective filter, causing spurious detection The detects are not considered as incorrect circuit operation
(4) Any tone $40 \mathrm{~Hz}-1 \%$ from fo must adhere to this specification, where fo is defined in Table 1

## INTRODUCTION

The SSI K212 is a true single-chip modem device that provides the functions needed to construct a typical Bell 212A standard full-duplex modem. Using an advanced CMOS process that integrates analog, digital, and switched-capacitor array functions on a single substrate, the SSI K212 offers excellent performance and a high level of functional integration in a single 28 pin DIP configuration. The K212 provides the basic PSK and FSK modulator/demodulator functions, call progress and handshake tone monitors, test modes, and a DTMF dialer. This device supports all Bell 212A modes of operation, allowing both synchronous and asynchronous communication. The K212 is designed to appear to the systems designer as a microprocessor peripheral, and will easily interface with popular one-chip microprocessors (80C51 typical) for control of modem functions through its 8-bit multiplexed address/data bus or via an optional serial command bus. An ALE control line simplifies address demultiplexing. Data communication occurs through a separate serial port only.
The K212 is ideal for use in either freestanding or inte-gral-system modem products where full-duplex 1200 BPS data communications over the 2 -wire switched telephone network is desired. Its high functionality, low power consumption, and efficient packaging simplify design requirements and increase system reliability. A complete modem requires only the addition of the phone line interface, a control microprocessor, and RS-232 level converters for a typical system The use of coherent demodulation techniques also assures the user of optimum performance when communicating over degraded lines.

## FEATURES

- One-chip fully Bell 103/212A compatible modem
- Full duplex operation at 0-300 and 1200 BPS
- FSK (300 BPS) or PSK (1200 BPS) encoding
- Compatible with standard microprocessors (8048, 80C51 typical)
- Serial (22 Pin DIP) or parallel microprocessor bus interface (28 Pin DIP)
- Maskable interrupts
- Serial port for data transfer
- Selectable asynch/synch and scrambler/descrambler functions
- Coherent demodulation technique provides optimal performance
- Call progress, carrier, and long-loop detect monitor
- DTMF tone generator
- Test modes available - ALB, DL, RDL, Mark, Space, Alternating bit patterns
- Space efficient 22-pin DIP, 28-pin DIP and Quad packages
- CMOS technology for low power consumption ( 120 mW )
- Low power IDLE mode uses $<10 \mathrm{~mW}$
- Single +12 V supply
- TTL and CMOS compatible inputs and outputs

BLOCK DIAGRAM

## OPERATION

## General

The SSI K212 was designed to be a complete Bell 212A compatible modem on a chip. As many functions as deemed economically feasible were included in order to simplify implementation into typical modem designs. In addition to the basic 1200 BPS PSK and 300 BPS FSK modulator/demodulator sectıons, the device also includes synch/asynch converters, scrambler/descrambler, call progress tone detect, and DTMF tone generator capabilities. All Bell 212A modes are supported (synchronous and asynchronous) and test modes are provided for diagnostics. Most functions are selectable as options and logical defaults are provided when override modes are selected. The device can be directly interfaced to a microprocessor via its 8-bit multiplexed address/data bus, or a serial command interface can be used (22-pin version) reducing the number of control lines required. Data communication takes place through a serial port.

## PSK Modulator/Demodulator

The K212 modulates a serial bit stream into dibit pairs that are represented by four possible phase shifts as prescribed by the Bell 212A standard. The baseband signal is then filtered to reduce intersymbol interference on the bandlimited 2-wire PSTN line. Transmission occurs on either a 1200 Hz (Originate mode) or 2400 Hz carrier (Answer mode). Demodulation is the reverse of the modulation process, with the incoming analog signal eventually decoded into dibits and converted back to a serial bit stream The demodulator also recovers the clock which was encoded into the analog signal during modulatıon. Demodulatıon occurs using either a 1200 Hz carrier (Answer mode or ALB Originate mode) or a 2400 Hz carrier (Originate mode or ALB Answer mode) The K212 uses a phase-locked-loop coherent demodulation technique that offers inherently better performance than typical DPSK demodulators used by other manufacturers

## FSK Modulator/Demodulator

The FSK modulator frequency modulates the analog output signal using two discrete frequencies to represent the binary data. The Bell 103 standard frequencies of 1270 Hz and 1070 Hz (originate mark and space) and 2225 and 2025 (answer mark and space) are used. Demodulation involves detecting the received frequencies and decoding them into the appropriate binary value. The rate converter and scrambler/descrambler are bypassed in the 103 mode.

## Passband Filters and Equalizers

A high and low band filter is included to shape the amplitude and phase response of the transmit signal and provide compromise delay equalization and rejection of out of band signals in the receive channel. Amplitude and phase equalization is necessary to compensate for distortion of the transmission line and to reduce intersymbol interference in the bandlimited receive signal. The transmit signal filtering corresponds to a 75\% square root of raised Cosine frequency response characteristic.

## Asynchronous Mode

The asynchronous mode is used for communication with asynchronous terminals which may communicate at 1200 BPS $+1 \%,-2.5 \%$ even though the modem's output is limited to 1200 BPS $\pm 001 \%$. When transmitting
in this mode the serial data on the TXD input is passed through a rate converter which inserts or deletes stop bits in the serial bit stream in order to output a signal that is $1200 \mathrm{BPS} \pm 0.01 \%$. This signal is then routed to a data scrambler (following the CCITT V. 22 algorithm) and into the analog PSK modulator where dibit encoding results in a Bell 212A standard PSK output signal. Both the rate converter and scrambler can be bypassed for handshaking, FSK, and synchronous operation. The device recognizes a break signal and handles it in accordance with Bell 212A specifications. Received data is processed in a similar fashion except that the rate converter now acts to reinsert any deleted stop bits and output data to the terminal at no greater than 1219 BPS. An incoming break signal will be passed through without incorrectly inserting a stop bit.

## Synchronous Mode

The Bell 212A standard defines synchronous operation only at 1200 BPS. Operation is similar to that of the asynchronous mode except that data must be synchronized to a provided clock and no variation in data transfer rate is allowable. Serial input data appearing at TxD must be valid on the rising edge of TxCLK. Receive data at the RxD pin is clocked out on the falling edge of RxCLK. The asynch/synch converter is bypassed when synchronous mode is selected and data is transmitted out at essentially the same rate as it is input

## Parallel Bus Interface

Four 8-bit registers are provided for control, option select, and status monitoring. These registers are addressed with the A0 and A1 multiplexed address lines (latched by ALE) and appear to a control microprocessor as four consecutive memory locations. Two control registers and the DTMF register are read or write memory. The status detect register is read only and cannot be modified except by modem response to monitored parameters.

## Serial Command Interface

The serial command mode allows access to the K212 control and status registers via a serial command port (22 pin version only). In this mode the A0 and A1 lines provide register addresses for data passed through the data pin under control of the $\overline{R D}$ and $\overline{W R}$ lines. A read operation is initiated when the RD line is taken low. The next eight cycles of ExCLK will then transfer out eight bits of the selected address location LSB first. A write takes place by shifting in eight bits of data LSB first for eight consecutive cycles of ExCLK. WR is then pulsed low and data transfer into the selected register occurs on the rising edge of $\overline{W R}$.

## Special Detect Circuitry

The special detect circuit monitors carrier, call-progress tones, answer tone, long loop (weak received signal), and remote-digital-loopback-request bit pattern. The appropriate status bit is set when one of these conditions changes and an interrupt is generated.

## DTMF Generator

The DTMF generator will output one of 16 standard dualtones determined by the 4-bit binary value previously loaded into the DTMF register. Dialing is initiated when the DTMF mode is selected and the transmit enable bit is changed from a 1 to a 0 .

## HARDWARE INTERFACE

|  | I/O | Signal Label | $\mathbf{2 8}$ Pin | $\mathbf{2 2}$ Pin | Description |
| :--- | :---: | :---: | :---: | :---: | :--- | :--- |
| POWER |  |  |  |  |  |
| \begin{tabular}{\|l|c|c|c|c|l|}
\hline
\end{tabular} |  |  |  |  |  |
|  | I | GND | 28 | 1 | System ground. |
|  | O | Vref | 26 | 21 | An internally generated reference voltage for test use. Bypass <br> with .1 $\mu$ F cap. to ground. |
|  | I | ISET | 24 | 19 | Chip current reference. Sets bias current for op-amps. Programmed <br> by connecting to Vcc through 2 Meg $\Omega$ resistor. Power dissipation/ <br> performance tradeoff results from varying this value. |

MICROPROCESSOR INTERFACE

| I | ALE | 12 | - | Address latch enable. The falling edge of ALE latches the address on AD0-AD2. |
| :---: | :---: | :---: | :---: | :---: |
| 1/O | AD0-AD7 | 4-11 | - | Address/data bus. This is a bidirectional, tri-state, multiplexed address and data bus. |
| 1 | $\overline{\mathrm{CS}}$ | 20 | - | Chip select Allows access to device data and address bus. ADO-AD7 will be in a high impedance state unless $\overline{\mathrm{CS}}$ is low. $\overline{\mathrm{CS}}$ is latched on the falling edge of ALE. |
| 0 | CLK | 1 | 2 | Clock output. This pin outputs either the crystal frequency (for use as a processor clock) or a $16 \times 1200 \mathrm{~Hz}$ signal for use as a baud clock. |
| 0 | $\overline{\text { INT }}$ | 17 | 13 | Interrupt flag to processor When low, indicates that a detect condition has occurred. Reset when the detect register is read or a reset is performed. |
| 1 | $\overline{\mathrm{RD}}$ | 14 | - | Read control When low puts addressed register into a read condition. $\overline{\mathrm{CS}}$ must also be low. |
| 1 | Reset | 25 | 20 | Resets device when in high state, setting all register bits to zero and CLK to Xtal frequency. An internal pulldown resistor allows power on reset by connecting a $1 \mu \mathrm{f}$ capacitor between reset and Vcc. |
| 1 | $\overline{\mathrm{WR}}$ | 13 | - | Write control. A low indicates that data is available Data is latched on the rising edge of $\overline{W R}$. $\overline{C S}$ must be active. |

## RS-232 INTERFACE

|  | 1 | ExCLK | 19 | 15 | External clock input. Used in synchronous modes when external <br> timing is selected. ExCLK becomes the phase-lock reference <br> for TxCLK. |
| :---: | :---: | :---: | :---: | :---: | :--- |
|  | O | RxCLK | 23 | 18 | Receive clock output. Carrier derived synch clock. Falling edge <br> coincides with received data output transitions. Rısing edge can be <br> used to latch valid output data. Active when carrier present. |
|  | O | RxD | 22 | 17 | Received digital data output. In synchronous or asynchronous <br> mode, data is valıd on rising edge of RxCLK. |
|  | O | TxCLK | 18 | 14 | Transmit clock output. Used in synchronous mode to latch nnput data <br> on the TxD pin. Data must be valid on the rising edge of TxCLK. <br> TxCLK is an internally generated 1200 Hz reference in internal mode, <br> phase locked to ExCLK in external mode, and derived from RxCLK <br> in slave mode. TxCLK is always active. |
|  | 1 | TxD | 21 | 16 | Transmit digital data input. In synch modes the data must be valid on <br> the rising edge of TxCLK. In Asynch modes no clocking is necessary. <br> High speed data must be 1200 +1\%, $-2.5 \%$. |

HARDWARE INTERFACE
Pin No.

|  | 1/0 | Signal Label | 28 Pin | 22 Pin | Description |
| :---: | :---: | :---: | :---: | :---: | :---: |
| ANALOG INTERFACE |  |  |  |  |  |
|  | 1 | RxA | 27 | 22 | Received modulated analog signal input. |
|  | 0 | TxA | 16 | 12 | Transmit analog output. |
|  | 1 | Xtal 1 | 2 | 3 | Connection for external 11.0592 MHz crystal or CMOS level clock signal. |
|  | 1 | Xtal 2 | 3 | 4 | Connection for external 11.0592/ MHz crystal |

SERIAL INTERFACE

|  | I | A0-A1 | - | $5-6$ | Register address selection. These lines should be valid during any <br> read or write operation. |
| :---: | :---: | :---: | :---: | :---: | :--- |
|  | I/O | Data | - | 8 | Serial control data. Data for a read/write operation is clocked in or <br> out on the falling edge of the ExCLK pin. The direction of data flow is <br> controlled by the $\overline{\mathrm{RD}}$ pin. $\overline{\mathrm{RD}}$ low outputs data. $\overline{\mathrm{RD}}$ high inputs data. |
|  | 1 | $\overline{\mathrm{RD}}$ | - | 10 | Read data control. A low enables a read operation from the <br> addressed register. Data is clocked out on transitions of the ExCLK <br> (LSB first) while the $\overline{\mathrm{RD}}$ line is low. Eight cycles of ExCLK are needed <br> to transfer the full 8 bits of data contained in one register. |
|  | I | $\overline{\mathrm{WR}}$ | - | 9 | Write data control. A low to high transition on this line causes 8 bits <br> of data previously shifted in (LSB first) to be transferred to the <br> addressed register. |

Operating Limits - Absolute Maximums - SSI K212

| Parameter | Max | Unit |
| :--- | :---: | :---: |
| VDD supply voltage | 14 | V |
| Storage temperature | -65 to 150 | ${ }^{\circ} \mathrm{C}$ |
| Lead temperature (10 sec.) | 260 | ${ }^{\circ} \mathrm{C}$ |
| TTL compatible inputs | 0 to VDD | V |
| TTL compatible outputs | -0.3 to <br> VDD | V |
| TTL compatible outputs | $\pm 3$ | mA |

Notes: 1. All inputs and outputs are protected from static charge using builtin industry standard protection devices.
2. All outputs are short-circuit protected.

## BUS INTERFACE

Four 8-bit internal registers are accessible for control and status monitoring. The registers are accessed in read or write operations by addressing the A0 and A1 address lines (latched by ALE in parallel mode). Control and status bits are identified below:

| A0 | A1 | Register | Function |
| :---: | :---: | :---: | :--- |
| 0 | 0 | CR0 | Control register 1 |
| 0 | 1 | CR1 | Control register 2 |
| 1 | 0 | DR | Detect register (read only) |
| 1 | 1 | DTMF | DTMF transmit tones |

| Detect off | - | - | - | -48 | $\mathrm{dBm0}$ |

[^4]Application
The SSI K212 is designed to be used in conjunction with a microprocessor and RS-232 serial lines or parallel bus interface, and a DAA phone line interface to function as a typical intelligent modem. The K212 interfaces directly with 8048/8051 family microprocessors for this purpose. Figure 1 shows the components making up the typical intelligent modem and that portion of the system contained in the K212. Figure 2 shows a basic modem circuit for the stand-alone modem (self-contained box), which functions as described in the following section.

A typical intelligent modem consists of the mod/demod block, phone line and terminal interfaces, and a dedicated control microprocessor as shown in the block diagram. The SSI K212 has two busses - a parallel or serial bus for control or status monitoring, and a serial bus for data transfer. Either a serial or parallel interface can be used to transfer data (and commands) between the modem and terminal, but the actual data path is through
the serial port. A dedicated microprocessor monitors the TXD line from the terminal, interprets commands in the data stream, and takes control action in response to these commands by using the K212's control bus to access its four internal registers. The received data path is monitored by passing received data through the control processor to allow sending messages back to the terminal for status indication. The mod/demod block performs the actual Bell 212A communications link, which includes asynchronous buffer/debuffer functions, scrambler/descramber, and 1200 and 0-300 BPS modulation/demodulation. DTMF dialing capability allows the modem to dial its own calls. Call progress detection expands this capability by giving the modem the ability to detect dial tone, busy signal, or ringback, and to change its calling action in response to these detected signals. An FCC approved DAA section completes the modem by providing a connection to the dial-up phone line.

## Preliminary Data Sheet

## PRODUCT DESCRIPTION

The SSI K214 is a complete analog front end for digital signal processor based V. 22 bis and Bell 212A compatible modems. The K214 provides bandsplit filters, fixed compromise equalization, signal path, programmable gains, and the clocks for transmit and receive activities. An 8-bit A/D convertor is available for receive signal processing, and on-chip modulators provide the QAM, PSK, and FSK transmit signals, making it unnecessary for the DSP to perform the transmit functions. A tone generator is used to produce DTMF, answer, and guard tones while an analog loopback mode allows system testing. Level detectors indicate carrier answer tone and call progress tone detection.
All functions on the device can be accessed easily using two control busses. A 4-bit parallel bus designed to work with standard micro-processors is used to pass transmit data, control, and status information to the K214. A serial bus which interfaces with popular DSP's (7720 typical) is used for the demodulator section.

The SSI K214 is ideal for use in self-contained or integral intelligent modem products requiring the benefits of 2400 BPS full duplex operation while maintaining compatibility with existing standards at speeds down to 300 BPS . By
integrating the majority of functions needed on a single CMOS I.C., system complexity and cost is reduced without compromising performance or features.

## FEATURES

- Analog front end for DSP-based V. 22 bis modems
- Complete modulators for QAM/DPSK (V. 22 bis, V. 22 Bell 212) and FSK (Bell 103)
- Programmable receive gain/transmit attenuation
- 8 bit ADC with reference
- Band split filters with compromise equalization
- Analog loopback test mode
- Serial interface for receive processing
- Parallel 4-bit interface for transmitter and control
- Receive/transmit bit rate clocks
- Programmable timer for receiver data clock recovery
- Carrier, call progress, and answer tone detector
- DTMF, guard tone, and answer tone generation
- Crystal oscillator with echo
- Audio output for audible call monitoring
- Low power CMOS ( $\pm 5 \mathrm{~V} @ 300 \mathrm{~mW}$ )
- 28-pin plastic DIP or quad surface mount package

## Preliminary Data Sheet

## INTRODUCTION

The SSI K222 is a highly integrated single-chip modem I.C. which provides the functions needed to construct a V. 22 compatible modem capable of 1200 BPS full-duplex operation over dial-up lines. The K222 is an enhancement of the SSI K212 single-chip modem with performance characteristics suitable for European telephone systems. The K222 also produces both 550 Hz and 1800 Hz guard tones, recognizes and generates a 2100 Hz answer tone, and allows V. 21 fallback for 300 Hz FSK operation. The K222 integrates analog, digit, and switched-capacitor array functions on a single substrate, offering excellent performance and a high level of functional integration in a single 28 pin DIP configuration.
The K222 provides the PSK and FSK modulator/ demodulator functions, call progress and handshake tone monitors, test modes, and a tone generator capable of producing DTMF, answer, and simulataneous 550 and 1800 Hz guard tones required for European applications. This device supports all V. 22 and V. 21 modes of operation, allowing both synchronous and asychronous communication. The K222 is designed to appear to the systems designer as a microprocessor peripheral, and will easily interface with popular one-chip microprocessors ( 80 C 51 typical) for control of modem functions through its 8 -bit mulitplexed address/data bus or via an optional serial command bus. An ALE control line simplifies address demultiplexing. Data communications occurs through a separate serial port only. The K222 is pin and software compatible with the SSI K212 and K224 one-chip modem I.C.'s allowing systems to be configured for either U.S. or European operation with only a single component change.
The K222 is ideal for use in either free standing or integral system modem products where full-duplex 1200 BPS data communications over the 2 -wire switched telephone network is desired. It's high functionality, low
power consumption, and efficient packaging simplify design requirements and increase system reliability. A complete modem requires only the addition of the phone line interface, a control microprocessor, and RS-232 level convertors for a typical system. Coherent demodulation techniques and efficient switched-capacitor filters provide optimum performance over all line conditions when operating in the PSK mode.

FEATURES

- One-chip V. 22 standard compatible modem
- Full duplex operation at 0-300, 600, and 1200 BPS
- FSK (300 BPS), or PSK (1200 BPS) encoding
- Pin and software compatible with SSI K212 and K224 1-chip modems
- Interfaces directly with standard microprocessors (8048, 80C51 typical)
- Serial (22 Pin DIP) or parallel microprocessor bus (28 pin DIP) for control
- Serial port for data transfer
- Maskable interrupts
- Selectable asynch/synch and scrambler/descrambler functions
- Both synchronous and asynchronous operating modes
- Notch filters for elimination of 550 Hz and 1800 Hz guard tones
- Call progress, carrier, answer tone, and long loop monitors
- DTMF and guard tone generators
- Test modes available - ALB, DL, RDL, Mark, Space, Alternating bit patterns
- Space efficient 22 and 28 pin DIP packages
- CMOS technology for low power consumption ( 120 mW ) with power down mode ( 30 mW )
- Single +5 volt supply
- TTL and CMOS compatible inputs and outputs

HARDWARE INTERFACE

|  | I/O | Signal Label | 28 Pin | 22 Pin | Description |
| :--- | :---: | :---: | :---: | :---: | :--- |
| POWER |  |  |  |  |  |
| \begin{tabular}{\|l|c|c|c|c|l|}
\hline
\end{tabular} |  |  |  |  |  |
|  | I | GND | 28 | 1 | System ground |
|  | O | Vref | 26 | 21 | An internally generated reference voltage for test use. Bypass <br> with 0.1 $\mu$ F cap. to ground. |
|  | I | ISET | 24 | 19 | Chip current reference Sets bias current for op-amps Programmed <br> by connecting to Vcc through 2 M $\Omega$ resistor. Power dissipation/ <br> performance tradeoff results from varying this value. Connecting ISET <br> to ground selects the power down mode. |

## MICROPROCESSOR INTERFACE

|  | 1 | ALE | 12 | - | Address latch enable. The falling edge of ALE latches the address on AD0-AD2. |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1/0 | AD0-AD7 | 4-11 | - | Address/data bus. This is a bidirectional, tri-state, multiplexed address and data bus. |
|  | 1 | $\overline{\mathrm{CS}}$ | 20 | - | Chip select. Allows access to device data and address bus. AD0-AD7 will be in a high impedance state unless $\overline{\mathrm{CS}}$ is low. $\overline{\mathrm{CS}}$ is latched on the falling edge of ALE. |
|  | O | CLK | 1 | 2 | Clock output This pin outputs either the crystal frequency (for use as a processor clock) or a $16 \times 1200 \mathrm{~Hz}$ signal for use as a baud clock. |
|  | O | INT | 17 | 13 | Interrupt flag to processor. When low, indicates that a detect condition has occurred. Reset when the detect register is read or a reset is performed |
|  | 1 | $\overline{\mathrm{RD}}$ | 14 | - | Read control. When low puts addressed register into a read condition. $\overline{\mathrm{CS}}$ must also be low. |
|  | 1 | Reset | 25 | 20 | Resets device when in high state, setting all register bits to zero and CLK to Xtal frequency. An internal pulldown resistor allows power on reset by connectıng a $1 \mu \mathrm{~F}$ capacitor between reset and Vcc. |
|  | 1 | $\overline{\mathrm{WR}}$ | 13 | - | Write control. A low indicates that data is available. Data is latched on the rising edge of $\overline{\mathrm{WR}}$. $\overline{\mathrm{CS}}$ must be active |

## RS-232 INTERFACE

|  | I | ExCLK | 19 | 15 | External clock input. Used in synchronous modes when external <br> timing is selected. ExCLK becomes the phase-lock reference <br> for TxCLK. |
| :---: | :---: | :---: | :---: | :---: | :--- |
|  | O | RxCLK | 23 | 18 | Receive clock output. Carrier derived synch clock. Falling edge <br> coincides with received data output transitions. Risıng edge can be <br> used to latch valid output data Active when carrier present |
|  | O | RxD | 22 | 17 | Received digital data output. In synchronous or asynchronous <br> mode, data is valid on rising edge of RxCLK. |
|  | O | TxCLK | 18 | 14 | Transmit clock output. Used in synchronous mode to latch input data <br> on the TxD pin. Data must be valid on the rising edge of TxCLK. <br> TxCLK is an internally generated 1200 Hz reference in internal mode, <br> phase locked to ExCLK in external mode, and derived from RxCLK |
| in slave mode. TxCLK is always active. |  |  |  |  |  |\(\left|\begin{array}{l}Transmit digital data input. In synch modes the data must be valid on <br>

the rising edge of TxCLK. In Asynch modes no clocking is necessary. <br>
High speed data must be 1200 +2.3\%, -2.5\%.\end{array}\right|\)

## HARDWARE INTERFACE

Pin No.

|  | I/O | Signal Label | 28 Pin | 22 Pin | Description |
| :---: | :---: | :---: | :---: | :---: | :--- |
| ANALOG INTERFACE |  |  |  |  |  |
|  | 1 | RxA | 27 | 22 | Received modulated analog signal input. |
|  | O | TxA | 16 | 12 | Transmit analog output. |
|  | 1 | Xtal 2 | 2 | 3 | Connection for external 11.0592 MHz crystal or CMOS level <br> lock signal. |
|  | 1 | Xtal 1 | 3 | 4 | Connection for external 11.0592 MHz crystal or CMOS level <br> lock signal. |

## SERIAL INTERFACE

|  | I | AO-A1 | - | $5-6$ | Regıster address selection. These lines should be valid during any <br> read or write operation |
| :---: | :---: | :---: | :---: | :---: | :--- |
|  | I/O | Data | - | 8 | Serial control data. Data for a read/write operation is clocked in or <br> out on the falling edge of the ExCLK pin. The direction of data flow is <br> controlled by the $\overline{\mathrm{RD}}$ pin. $\overline{\mathrm{RD}}$ low outputs data. $\overline{\mathrm{RD}}$ high inputs data. |
|  | 1 | $\overline{\mathrm{RD}}$ | - | 10 | Read data control. A low enables a read operation from the <br> addressed register. Data is clocked out on transitions of the ExCLK <br> (LSB first) while the $\overline{\mathrm{RD}}$ line is low. Eight cycles of ExCLK are needed <br> to transfer the full 8 bits of data contained in one register. |
|  | I | $\overline{\mathrm{WR}}$ | - | 9 | Write data control. A low to high transition on this line causes 8 bits <br> of data previously shifted in (LSB first) to be transferred to the <br> addressed register. |

Operating Limits - Absolute Maximums - SSI K222

| Parameter | Max | Unit |
| :--- | :---: | :---: |
| VDD supply voltage | 14 | V |
| Storage temperature | -65 to 150 | ${ }^{\circ} \mathrm{C}$ |
| Lead temperature (10 sec.) | 260 | ${ }^{\circ} \mathrm{C}$ |
| TTL compatible inputs | 0 to $\mathrm{VDD}_{\mathrm{DD}}$ | V |
| TTL compatible outputs | -0.3 to <br> VDD | V |
| TTL compatible outputs | $\pm 3$ | mA |

Notes• 1. All inputs and outputs are protected from statıc charge using builtin industry standard protection devices
2 All outputs are short-circuit protected

## BUS INTERFACE

Four 8-bit internal registers are accessible for control and status monitoring. The registers are accessed in read or write operations by addressing the A0 and A1 address lines (latched by ALE in parallel mode) Control and status bits are identified below:

| A0 | A1 | Register | Function |
| :---: | :---: | :--- | :--- |
| 0 | 0 | CR0 | Control register 1 |
| 0 | 1 | CR1 | Control register 2 |
| 1 | 0 | DR | Detect regıster (read only) |
| 1 | 1 | DTMF | DTMF transmit tones |

## Preliminary Data Sheet

## DESCRIPTION

The SSI 223 modem device receives and transmits, serial, binary data over existing telephone networks using Frequency Shift Keying (FSK). It provides the filtering, modulation, and demodulation to implement a serial, asynchronous data communication channel. The SSI 223 employs the CCITT V. 23 signaling frequencies of 1302 and 2097 Hz , operating at 1200 baud, and is intended for half duplex operation over a single line system or full duplex operation over a two line system.

The SSI 223 provides a cost effective alternative to existing modem solutions. It is ideally suited for R.F. data links, credit verification systems, point-of-sale terminals, and remote process control.

CMOS Technology ensures small size, low power consumption and enhanced reliability.

FEATURES

- Low cost FSK Modem
- 1200 Baud operation
- CMOS switched capacitor technology
- Simultaneous transmit and receive
- Built-in self-test feature
- On-chip filtering, Mod/Demod.
- Uses CCITT V. 23 Frequencies
- On chip crystal oscillator
- Pin/function compatible with SSI 180
- Low power/High reliability
- 16-pin plastic package

## Circuit Operation

The SSI 223 has four main functional sections: timing, transmit, receive, and test. Each section of the chip will be individually described below.

## TIMING

The timing section contains the oscillator (OSC) and random logic which generates digital timing signals used throughout the chip. The time base can be derived from 3.18 MHz crystal or an external digital input. The modem will operate with clock inputs from 330 KHz to 3.3 MHz . Back channel is supplied by selecting the lower frequency clock rate. The digital timing logic divides the oscillator frequency to give a 1200 HZ output that can be used for system timing.

## TRANSMITTER

The SSI 223 transmitter consists of a programmable divider that drives a programmable coherent phase frequency synthesizer. The programmable divider is digitally controlled via the Data Input pin (TXD). The output of the divider clocks a 16 segment phase coherent frequency synthesizer. A sine wave is constructed by eight weighted capacitors which are the inputs to a high pass filter. Proper matching of the capacitors is important in order to suppress the second thru fourteenth harmonics. The synthesized signal is output directly to the transmit pin TXA. The transmit signal can be disabled by using the digital control pin TX.

## RECEIVER

The SSI 223's receiver is comprised of three sections: the input bandpass filter, the synchronization loop, and the demodulator.

The input bandpass filter is a four pole Butterworth filter, implemented using switched capacitor technology. This filter reduces wideband noise which significantly improves data error rates. the SSI 223 can be configured with the bandpass filter in series with the receiver by setting FIL $=1$ and inserting the received signal at RXF, or the bandpass filter can be deleted from the system by setting FIL $=0$ and inputting the received signal thru RXA.

The demodulator is used to detect a received mark or space.

The synchronization for sampling the digital output at RXD derived from a digital phase locked loop. The phase locked loop is clocked at 16 times the bit rate with a maximum lock period of 8 clocks and locks on the data output signal.

## SELF TEST MODE

The SSI 223 features an autotest mode which provides easy field test capability of the chip's funtionality. The modem is placed in the test mode by taking the test pin
high. In the test mode the Data Input pin is disconnected and the programmable divider is driven by a pseudo random PN sequence generator and the transmitter's output is connected to the receiver's input. The input data to the programmable divider is delayed by the system delay time and compared to the digital output on sync transitions. If the detected data matches the delayed input data from the PN sequence counter, the SSI 223 is properly functioning as indicated by RXD low. A high on the RXD pin indicates a functional problem on the SSI 223.

## Preliminary Data Sheet

## INTRODUCTION

The SSI K224 is a highly integrated single-chip modem I.C. which provides the functions needed to construct a V. 22 bis compatible modem, capable of 2400 BPS fullduplex operation over dial-up lines. Using an advanced CMOS process that integrates analog, digital signal processing, and switched-capacitor array functions on a single substrate, the SSI K224 offers excellent performance and a high level of functional integration in a single 28 pin DIP configuration. The K224 provides the QAM, PSK and FSK modulator/demodulator functions, call progress and handshake tone monitors, test modes, and a tone generator capable of producing DTMF answer, and simultaneous 550 and 1800 Hz guard tones required for European applications. This device suppofts all V. 22 bis, V.22, V.21, Bell 212 A , and Bell 103 modes of operation, allowing both synchronous and asyn chronous communication. The K224 is designed to appear to the systems designer as microprocessor peripheral, and will easily interface with popular onethip microprocessors ( 80051 typical) for control of modem" functions through its 8 -bit mưtiplexed address/data bus or via an optional serial command bus. An ALE control line simplifies address demultiplexing. Data communications occurs through a separate serial port only. The K224 is pin and software compatible with the SSI K212 and K222 one-chip modem I.C.'s, allowing system upgrades with a single component change.

The K224 is ideal for use in either free standing or integral system modem products where full-duplex 2400 BPS data communications over the 2 -wire switched telephone network is desired. It's high functionality, low power consumption, and efficient packaging simplify design requirements and increase system reliability. A complete modem requires only the addition of the phone line interface, a control microprocessor, and RS-232 level
convertors for a typical system. Adaptive equalization assures the user of optimum periormance over all line conditions when operating in the QAM and PSK modes.

FEATURES

- One-chip multi-mode V. 22 bis/Bell 212A compatible modem
- Full duplex operation at 0-300, 1200, and 2400 BPS
- FFK (300 BPS), PSK (1200 BPS), or QAM (2400 BPS) encodîng
Pin and software compatible with SSI K212 and K222 1-chip modems
Interfaces directly with standard microprocessors (8048), 80C51 typical)
- Serial (22 Pin DIP) or paralle microprocessor bus (28 pin DIP) for control
- Serial port for data transfer
- Maskable interrupts
- Selectable asynch/synch and scrambler/descrambler functions
- All synchronous and asynchronous operating modes
- Adaptive equalization for optimum performance over all lines
- Programmable transmit gain (15dB, 1 dB steps), selectable receive boost (+12dB)
- Call progress, carrier, answer tone, and signal quality monitors
- DTMF and guard tone generators
- Test modes available - ALB, DL, RDL, Mark, Space, Alternating bit patterns
- Space efficient 22 and 28 pin DIP packages
- CMOS technology for low power consumption (120 MW) with power down mode ( 30 mW )
- Single +12 volt supply
- TTL and CMOS compatible inputs and outputs

## OPERATION

## General

The SSI K224 was designed to be a complete V. 22 bis compatible modem on a chip. It requires only the addition of a control microprocessor, RS-232, and a phone line interface to design a complete modem. As many functions as possible were included in order to simplify implementation into typical modem designs. In addition to the basic 2400 BPS QAM, 1200 BPS PSK and 300 BPS FSK modulator/demodulator sections, the device also includes synch/asynch converters, scramber/descrambler, call progress tone detect, and DTMF tone generator capabilities. All V. 22 bis and Bell 212A modes are supported (synchronous and asynchronous) and test modes are provided for diagnostics. Most functions are selectable as options and logical defaults are provided when override modes are chosen. The device can be directly interfaced to a microprocessor via its 8 -bit multiplexed address/data bus for control and status monitoring. Datacommunication takes place through a separate serial port.

## QAM Modulator/Demodulator

The SSI K224 encodes incoming data into quadbits represented by 16 possible signal points with specific phase and amplitude levels. The baseband signal is then filtered to reduce intersymbol interference on the bandlimited telephone network. The modulator transmits this encoded data using either a 1200 Hz (originate mode) or 2400 Hz (answer mode) carrier. The demodulator reverses this procedure but also recovers a data clock from the incoming signal. Adaptive equalization corrects for varying line conditions by automatically changing filter parameters to compensate for those line characteristics.

## PSK Modulator/Demodulator

The K224 modulates a serıal bit stream into dibit pairs that are represented by four possible phase shifts as prescribed by the Bell 212A/V. 22 standard. The baseband signal is then filtered to reduce intersymbol interference on the bandlimited 2-wire PSTN line.
Transmission occurs on either a 1200 Hz (originate mode) or 2400 Hz carrier (answer mode). Demodulation is the reverse of the modulation process, with the incoming analog signal eventually decoded into dibits and converted back to a serial bit stream. The demodulator also recovers the clock which was encoded into the analog signal during modulation. Demodulation occurs using ether a 1200 Hz carrier (answer mode or ALB originate mode) or a 2400 Hz carrier (originate mode or ALB answer mode). The K224 uses a phase locked loop coherent demodulation technique that offers inherently better performance than typical DPSK demodulators used by other manufacturers. Adaptive equalization is also used in PSK modes for optimum operation with slowly varying line conditions.

## FSK Modulator/Demodulator

The FSK modulator frequency modulates the analog output signal using two discrete frequencies to represent the binary data. The Bell 103 standard frequencies of 1270 Hz and 1070 Hz (originate mark and space) and 2225 Hz and 2025 Hz (answer mark and space) are used when this mode is selected. V. 21 frequencies are used when this mode is selected. Demodulation involves detecting the
received frequencies and decoding them into the appropriate binary value. The rate converter and scrambler/descrambler are bypassed in the FSK modes.

## Passband Filters and Equalizers

A high and low band filter is included to shape the amplitude and phase response of the transmit signal and provide compromise delay equalization and rejection of out of band signals in the receive channel. Amplitude and phase equalization is necessary to compensate for distortion of the transmission line and to reduce intersymbol interference in the bandlimited receive signal. The transmit signal filtering corresponds to a $75 \%$ square root of raised Cosine frequency response characteristic.

## Asynchronous Mode

The asynchronous mode is used for communication with asychronous terminals which may communicate at 1200 BPS $+1 \%,-2.5 \%$ even though the modem's output is limited to 1200 BPS $\pm .01 \%$. When transmitting in this mode the serial data on the TxD input is passed through a rate convertor which inserts or deletes stop bits in the serial bit stream in order to output a signal that is exactly 1200 BPS $\pm .01 \%$. This signal is then routed to a data scrambler (following the CCITT V. 22 algorithm) and into the analog PSK modulator where dibit encoding results in a V. 22 bis or Bell 212A standard output signal. Both the rate convertor and scrambler can be bypassed for handshaking, FSK, and synchronous operation. The device recognizes a break signal and handles it in accordance with Bell 212A specifications. Received data is processed in a similar fashion except that the rate convertor now acts to reinsert any deleted stop bits and output data to the terminal at no greater than 1219 BPS. An incoming break signal will be passed through without incorrectly inserting a stop bit.

## Synchronous Mode

Synchronous operation is possible only with the QAM or PSK modes. Operation is similar to that of the asynchronous mode except that data must be synchronized to a provided clock and no variation in data transfer rate is allowable. Serial input data appearing at TxD must be valid on the falling edge ot TxCLK. Receive data at the RxD pin is clocked out on the rising edge of RxCLK. The asynch/synch convertor is bypassed when synchronous mode is selected and data is transmitted out at essentially the same rate as it is input.

## Parallel Bus Interface

Six 8 -bit registers are provided for control, option select, and status monitoring. These registers are addressed with the A0, A1, and A2 multiplexed address lines (latched by ALE) and appear to a control microprocessor as six consecutive memory locations. Five control registers are read or write memory. The status detect register is read only and cannot be modified except by modem response to monitored parameters.

## Serial Command Interface

The serial command mode allows access to the K224 control and status registers via a serial command port (22 pin version only). In this mode the A0 and A1 lines provide register addresses for data passed through the data pin under control of the RD and WR lines. A read
operation is initiated when the RD line is taken low. The next eight cycles of ExCLK will then transfer out eight bits of the selected address location LSB first. A write takes place by shifting in eight bits of data LSB first for
eight consecutive cycles of ExCLK. WR is then pulsed low and data transfer into the selected register occurs on the rising edge of WR.

## Preliminary Pin Configuration

Pin out

SSI 291/213 Modem 1200 BPS Full Duplex

## Preliminary Data Sheet

## GENERAL DESCRIPTION

The SSI 291/213 is a CMOS I.C. device set that forms the basis for a 1200 bps Bell 212A compatible modem. The SSI 213 is a modem filter that provides the channel separation, equalization, and answer/originate steering logic needed for Bell 212A operation. The 291 contains the Bell 212 modulator and demodulator, AGC, scrambler/descrambler, and carrier detect monitor. Clock generator and undedicated low pass filter functions are also included to minimize the requirement for external components. Using TTL and CMOS compatible I/O, the device set is designed to provide a low-cost modem when integrated with a onechip control microprocessor.
The 291/213 device set is ideal for use in either free standing, or integral system modem products, where full-duplex 1200 bps data communications over the 2-wire switched telephone network is desired. Its high functionality, reduced power consumption, and low-cost simplify design requirements and increase system reliability. A complete modem can be implemented by adding a phone line interface, a control microprocessor, and RS-232 level converters for a typical system. The use of coherent demodulation techniques assures the user of optimum performance when communicating over degraded lines.

## FEATURES

- Two-chip set compatible with 2-wire PSTN phone lines
- Available in $\mathbf{4 0}$ - or $\mathbf{2 8}$-pin DIP (SSI 291) and 16-pin DIP (SSI 213)
- Full duplex operation at 1200 bps
- PSK encoding in Bell 212A format
- Will interface with standard microprocessors through serial control lines
- Serial port for data transfer
- Selectable answer/originate, clock frequencies
- Support functions on-chip: clock generator, low-pass filter, receive clock flag
- Coherent demodulation technique provides optimal performance
- CMOS technology for low power consumption ( 100 mW typical)
- $\pm 5 \mathrm{~V}$ supplies
- TTL and CMOS compatible inputs and outputs

SSI 291/213 Block Diagram

## General

The SSI 291/213 is designed to serve as a low-cost 1200 bps full-duplex modem that offers Bell 212A 1200 bps compatibility when used with a control microprocessor. The modulator/demodulator, as well as various support functions needed to integrate the function with a microprocessor in a minimum cost system, were included in the device set. In addition to the basic 1200 bps PSK modulator/demodulator, the product also includes a carrier detect monitor, scrambler/descrambler, clock generator, and a DTMF low-pass filter for eliminating distortion from microprocessor-generated dual-tones. A zero-crossing detector simplifies the design of the 300 bps FSK demodulator function, and signal control logic is included to ease the addition of this operating mode to the device set. An included "receive signal flag" can be used as an interrupt, reducing the load on the system processor when operating in Bell 212A mode. The 1200 bps Bell 212A mode is supported (synchronous operation) and test modes are provided for chip diagnostics. The device set can be directly interfaced to a microprocessor using serial lines for data transfer, control, and status monitoring.

## PSK Modulator/Demodulator

The 291/213 modulates a serial bit stream into dibit pairs that are represented by four possible phase shifts as prescribed by the Bell 212A standard. The baseband signal is then filtered to reduce intersymbol interference on the bandlimited 2 -wire PSTN line. Transmission occurs on either a 1200 Hz (Orginiate mode) or 2400 Hz carrier (Answer mode). Demodulation is the reverse of the modulation process, with the incoming analog signal eventually decoded into dibits and converted
back to a serial bit stream. Demodulation occurs using either a 1200 Hz (Answer mode) or a 2400 Hz carrier (Originate mode). The 291/213 uses a phase locked loop coherent demodulation technique that offers inherently better performance than typical DPSK demodulators used by other manufacturers.

## Passband Filters and Equalizers

A high and low band filter is included in the SSI 213 to shape the amplitude and phase response of the transmit signal and provide compromise delay equalization and rejection of out of band signals in the receive channel. Amplitude and phase equalization is necessary to compensate for distortion of the transmission line and to reduce intersymbol interference in the bandlimited receive signal.

## Signal Control Logic

Signal control logic is provided that allows addition of the 300 bps mod/demod function to a system using the SSI 291/213 device set. This logic (see diagram) allows single pin routing of externally provided 300 bps digital signals to the $\overline{\mathrm{LSTX}}$ and $\overline{\mathrm{RX}}$ outputs for either full or half-duplex operation.

## Synchronous Operation

The SSI 291/213 is designed to provide synchronous operation at the 1200 bps rate. In this mode, data is synchronized to a provided clock, and no variation in data transfer rate is allowable. Proper transmit action requires that serial input data appearing at TxD be valid on the falling edge of SCT. A receive data flag acts as a synchronization device for microprocessor interfacing. Received data at the RxD pin may be read after the RXFLG goes low, and this flag is reset after a read operation by externally setting CLRFLG.

Pin Descriptions - SSI 291

## Design Considerations

The SSI 213 uses SCF sampled data techniques. To avoid signal aliasing problems the input signal should not contain significant energy within 3 KHz of any multiple of the 52.36 KHz sampling clock. An anti-aliasing filter may be needed to meet this requirement.
When the alternate clock input is selected, a rate multiplier is inserted in the normal clock divider circuit. This
shifts the SCF clock frequency to 52.30 KHz and the CLK out pin output to 104.6 KHz . In addition, a low level modulation tone at approximately 23 KHz will be generated with a typical amplitude of less than $600 \mu \mathrm{~V}$ RMS. Normal applications will not be affected by these changes.

## Application

The SSI 291/213 chip set is typically used in conjunction with a microprocessor and supporting external components to form a cost-effective intelligent modem system. This type of modem communicates asynchronously by interpreting ASCII commands passed through the serial data stream, and controls the modem functions accordingly by using serial port lines to switch various control lines on the 291/213. A basic version of this design would include 1200 bps communications capability, answer/originate logic to answer incoming calls, and an auto dial function using pulse dialing. The 291/213 provides the mod/demod function, while the microprocessor performs the command interpretation, control, and the handshaking needed to originate and answer calls. The microprocessor must also perform the asynch to synch conversion needed to generate a synchronous data stream using the variable data rate coming from a terminal or processor bus.

A more elaborate system uses the additional features of the 291 I.C. to form a complete low-cost system, providing 1200 bps PSK and 300 bps FSK communication, smart calling functions with DTMF or pulse dialing, and call progress detection. In this system, the microprocessor performs the 300 bps mod/demod function using the partial demod block (zero crossing detector) on the 291 and an external D/A for waveform generation and DTMF tones.
A third version provides higher quality DTMF generation, call progress detection, and 300 bps operation by using external components. While not as economical as the basic 291/213 only design, the advantage of this approach is a reduction in the software requirement for the processor, making code available for providing more sophisticated features or multiple command sets.

## Data Sheet

## GENERAL DESCRIPTION

The SSI 3522 is a 16 pin CMOS integrated circuit that provides the channel filtering and equalization functions required for Bell 212A and C.C.I.T.T. V. 22 modem applications. Employing switched capacitor filter techniques, the 3522 includes channel separation filters optimized for 1200 and 2400 Hz operation, while maintaining the bandshape necessary to reject 550 and 1800 Hz guard tones typical for V. 22 standard modems. Fixed compromise equalization and group delay correction is distributed between the two channels as prescribed by V. 22 recommendations. Dual multiplexers provide channel steering action for answer/orginate control using a single pin.
The 3522 is designed to provide the front end for a Bell 212A or V. 22 modulator/demodulator I C such as the SSI 291. Optimized for PSTN lines, the 3522 offers an economical solution to the filter requirements of medium speed modem designs.

FEATURES

- Performs Bell 212A/V. 22 channel filter functions
- High performance/low cost filter for medium speed modems
- Compromise equalization
- Single pin originate/answer steering logic
- Selectable clock divider-2.304 MHz or 3.5795 MHz color burst frequency
- +-5V operation at 50 mW typical power consumption
- CMOS technology and I/O compatibility
- 16 pin DIP configuration
- CMOS latch-up protected

## CIRCUIT OPERATION

## GENERAL:

The SSI 3522 is designed to act as a low cost filter for use in conjunction with Bell 212A or V. 22 modem I C's such as the SSI 291. The device consists of a high and low band filters, split compromise equalizers for the two channels, and dual multiplexer logic for originate/answer channel steering. The unbuffered filter outputs are brought out to pins LBF and HBF before the signals have been processed by the equalizer section, and may be used for test purposes or in applications where the equalizer must be bypassed. Output impedance of these pins is $100 \mathrm{k} \Omega$, requiring buffering if significant loads are to be driven. A clock generator provides the switched capacitor clock sampling frequency of 52.36 kHz from a 2.304 MHz buffered input signal. Tying pins 10 and 11 together changes the internal scaling rate to allow use of a 3.5795 MHz input, which can be generated from a standard color burst crystal. Filter response is essentially flat for a passband centered around the 1200 and 2400 Hz center frequencies, while notch filters located at 550 and 1800 Hz insure excellent rejection of C.C.I.T.T. guard tones.

## DESIGN CONSIDERATIONS

The SSI 3522 uses SCF sampled data techniques. To avoid signal aliasing problems the input signal should not contain significant energy within 3 kHz of any multiple of the 52.36 kHz sampling clock. An anti-aliasing filter may be needed to meet this requirement.

When the alternate clock input is selected, a rate multiplier is inserted in the normal clock divider circuit. This shifts the SCF clock frequency to 52.30 kHz and the CLK out pin output to 104.6 kHz . In addition, a low level modulation tone at approximately 23 kHz will be generated with a typical amplitude of less than $600 \mu \mathrm{~V}$ RMS. Normal applications will not be affected by these changes.

SSI 263A Phoneme Speech Synthesizer

## Data Sheet

## DESCRIPTION

The SSI 263A is a versatile, high-quality, phonemebased speech synthesizer circuit contained in a single monolithic CMOS integrated circuit. It is designed to produce an audio output of unlimited vocabulary, music and sound effects at an extremely low data input rate.

Speech is synthesized by combining phonemes, the building blocks of speech, in an appropriate sequence. The SSI 263A contains five eight-bit registers that allow software control of speech rate, pitch, pitch movement rate, amplitude, articulation rate, vocal tract filter response, and phoneme selection and duration.

FEATURES

- Single low-power CMOS integrated circuit
- 5 Volt supply
- Extremely low data rate
- 8 -bit bus compatible with selectable handshaking modes
- Non-dedicated speech, ideal for text-to-speech programming
- Programmable and hard powerdown/reset mode
- Switched-capacitor-filter technology

CAUTION: Use handling procedures necessary for a static sensitive component

SSI 263A Pin Out
(Top View)

## SSI 263A Operation Description

This short description is intended to provide SSI 263A feature and capability information only. Refer to the SSI 263A USERS GUIDE for complete information on application and phonetic programming.

## The Production of Speech

To produce different speech phonemes (sounds) the SSI 263A uses a model of the human vocal tract. Within the device this analog tract is modeled with five cascaded programmable low pass filter sections. The filter sections are programmed internally by a digital controller. Either a glottal (pitch) or a pseudo-random noise source is used to excite the vocal tract, depending on whether a voiced or non-voiced phoneme is selected. During speech production the phonemes will typically last between 25 and 100 mS .

## The Speech Attribute Registers

Speech is produced by programming speech attribute (characteristic) data into five eight-bit registers. These internal registers allow selection of phonemes and speech characteristics. Refer to the Register Input Formats for the functional allocations.

## Device Response to Attribute Register Data

The SSI 263A has two general classes of attribute data: "control" data (speech rate, filter frequency, phoneme articulation rate, phoneme duration, immediate inflection setting, and inflection movement rate) and "target" data (phoneme selection, audio amplitude, and transitioned inflection). The SSI 263A responds immediately upon loading "control" data; upon loading "target" data the device will begin to move towards that target at the prescribed transition rates. This fully internal linear transitioning between target values, done in a manner as is found in normal speech, is a key factor in reducing control data rate without sacrificing speech quality.

## Attribute Register Writing

The eight bit data bus D7-D0 loads the particular attribute register selected by the three bit address bus RS2-RS0. To write the data, R/W (Read/Write), CS0 (Chip Select 0 ), and $\overline{\mathrm{CS} 1}$ pins must first be in the $0,1,0$ state, respectively. The data is then written when at least one of these pins changes state. Refer to the Write Timing Diagram. Writing is accomplished by changing preferably CS0 or $\overline{\mathrm{CS} 1}$. Following device power up, nominal values should be loaded into the attribute registers as described below.

## Approximate Data Transfer Rate

For speech production using the SSI 263A, the actual data rate depends on the amount of speech attribute manipulation. For example, the production of monotonic speech, where phoneme and duration are the only attribute manipulations, requires a data rate less than 100 bits-per-second. A higher data rate of
about 500 bits-per-second is required for high quality speech due to the associated full attribute manipulation.

## Selectable Operation Modes

The state of the Duration/Phoeme Register bits DR1 and DRO determine the operating mode of the device when the Control bit (CTL) is changed from a logic one to a logic zero. The four modes of operation include choice of timing response between "frame" or "phoneme" timing (as explained below), transitioned or immediate inflection response, and setting the $A / \bar{R}$ (Acknowledge/Request Not) pin active or disabled. Refer to the Mode Selection Chart.

## Phoneme Selection

The SSI 263A can produce the 64 phonemes listed on the Phoneme Chart. Bits P5-P0 are used for phoneme selection. The relative phoneme duration is set by bits DR1 and DR0.

## Phoneme Articulation Adjustment

A particular phoneme is produced by the combination of vocal-tract low-pass filter settings, excitation source type, and source amplitude. When a new phoneme is selected, the device performs a linear transition to the new set of characteristics. The rate of this transition is controlled by the articulation setting, bits TR2-TRO. This rate is relative in that articulation is not affected by speech rate bits R3-R0. A typical articulation register setting is " 5 ".

## Programming Inflection (Pitch)

When the SSI 263A is in the mode of immediate inflection, bits I11-IO provide immediate adjustment with seven octaves of pitch on an even tempered scale. With the device in the transitioned inflection mode, bits $\mathrm{I} 10-\mathrm{I} 6$ select the target pitch and bits $15-13$ determine the inflection rate of change. Bits $111,12,11$, and 10 always provide immediate adjustment. A typical value used for speech production is 90 Hz where:

$$
\begin{aligned}
& \text { Inflection Frequency }=\frac{\text { XCK frequency }}{8 \times(4096-I)} \\
& I=\text { decimal equivalent of Inflection Register setting }
\end{aligned}
$$

## Filter Frequency Setting

Data bits FF7-FF0 set the clock frequency for the switched-capacitor vocal tract filters. This determines overall filter frequency response. Inflection pitch is not affected by these bits. Typically this is set to give a clock frequency of about 20 KHz (see formula below), but may be manipulated to fine-tune speech quality or to change "voice type"; bass, baritone, etc.

$$
\text { Filter Frequency }=\frac{\text { XCK frequency }}{2(256-\mathrm{FF})}
$$

FF = decimal equivalent to the Filter Frequency Register setting.

## Speech Rate

Rate of speech is controlled by bits R3-R0, the Speech

Rate Register. In Frame Timing Mode new attribute data is requested at the end of a "frame" where:

$$
\text { Frame Duration } \quad=\quad \frac{4096 \times(16-\mathrm{R})}{\text { XCK frequency }}
$$

$R=$ decimal equivalent of Rate Register setting In the Phoneme Timing Mode the frame duration is modified by the phoneme duration bits DR1 and DR0 where:

Phoneme Duration $=$ (Frame Duration) $X$ (4-D)
$D=$ decimal equivalent of Duration Register setting All internal attribute transitioning is performed relative to the Speech Rate Register setting. Speech rate does not effect inflection or filter frequency. A typical rate setting is hexadecimal " $A$ ".

## Amplitude Adjustment

The overall Audio Output level is set with register bits A3-A0. Since each phoneme has a preset amplitude relative to other phonemes, it is not necessary to program the amplitude of each phoneme; however, amplitude changes may be used to enhance the speech quality and add emphasis. Amplitude is transitioned linearly at rate dependent on the phoneme duration setting. A typical amplitude setting is hexadecimal " C ".

## Control Bit and Power Down Mode

Setting the Control bit (CTL) to a logic one puts the device into Power Down mode, a sort of "standby". This bit is also set high when the $\overline{\mathrm{PD}} / \overline{\mathrm{RST}}$ pin is brought low and also upon power up. The Power Down mode turns off the excitation sources and analog circuits to reduce power consumption, but maintains the present register settings. Upon a Control bit logic one-to-zero transition, the present settings of DR1 and DR0 determine the operation mode as described above.

## Register Reading

Device pin D7 becomes an output, as the inverted state of $A / \bar{R}$, when the device is put into Read ( $R / \bar{W}$ is a logic 1 and the chip is selected, $\overline{C S 1}=0, C S 0=1$ ). Refer to the Read Timing Diagram. The register address bits are ignored.

## Time Base

Many different time bases may be utilized (see external clock input specifications). It is desirable to establish a stable crystal controlled time base from 800 to 1000 KHz when DIV2 is set low, or twice the frequency when DIV2 is set high. A good time base can be easily accomplished with an inexpensive colorburst 3.5795 MHz crystal in conjunction with a divide-by-two circuit. The actual device timing and output frequencies are directly related to the time base frequency used.

## Microprocessor Interfacing

Either the A/R line, or D7 as an output, are used as an interrupt to indicate when the duration of a frame or phoneme has been exceeded. No detectable degradation to speech quality results when several milliseconds occur between data request and load.

PHONEME CHART

| Hex Code* | Phoneme Symbol | Example Word (or Usage) |
| :---: | :---: | :---: |
| 00 | PA | (pause) |
| 01 | E | MEET |
| 02 | E1 | BENT |
| 03 | Y | BEFORE |
| 04 | YI | YEAR |
| 05 | AY | PLEASE |
| 06 | IE | ANY |
| 07 | 1 | SIX |
| 08 | A | MADE |
| 09 | AI | CARE |
| OA | EH | NEST |
| OB | EH1 | BELT |
| OC | AE | DAD |
| 0D | AE1 | AFTER |
| OE | AH | GOT |
| OF | AH1 | FATHER |
| 10 | AW | OFFICE |
| 11 | 0 | STORE |
| 12 | OU | BOAT |
| 13 | 00 | LOOK |
| 14 | IU | YOU |
| 15 | IU1 | COULD |

| 3F | LB | LUBE |

PIN ASSIGNMENT DESCRIPTIONS

| Pin No. | Symbol | Active Level | Description |
| :---: | :---: | :---: | :---: |
| 1 | AO |  | Analog Audio Output biased @ VDD/2 requires an external audio amp for speaker drive |
| 2 | AGND |  | Analog Ground |
| 3 | TP1 |  | Do not use |
| 4 | A/ $\bar{R}$ |  | Acknowledge/Request Not - open collector output changes from high to low level after phoneme is generated. May be used as an interrupt request for new phoneme data. (See Pin 17 also.) |
| 5 | TP2 |  | Do not use |
| 6 | RS2 |  | Register Select Input - used to select one of five internal registers in conjunction with RS1 and RS0 |
| 7 | RS1 |  | Register Select (See pin 6) |
| 8 | RS0 |  | Register Select (See pin 6) |
| 9 | D0 |  | LSB of 8-bit data bus input only |
| 10 | D1 |  | Data Input (only) |
| 11 | D2 |  | Data Input (only) |
| 12 | DGND |  | Digital Ground |
| 13 | D3 |  | Data Input (only) |

| Pin No. | Symbol | Active Level | Description |
| :---: | :---: | :---: | :---: |
| 14 | D4 |  | Data Input (only) |
| 15 | D5 |  | Data Input (only) |
| 16 | D6 |  | Data Input (only) |
| 17 | D7 |  | MSB of 8-bit data bus. Bidirectional, inverse of pin 4 when read is high |
| 18 | $\overline{\mathrm{PD}} / \overline{\mathrm{RST}}$ | Low | Power Down Control Input Silences audio output and retains DC bias without disturbing register contents. Disables $A / \bar{R}$ output. |
| 19 | CS0 | High | Chip Select Input |
| 20 | $\overline{\mathrm{CS} 1}$ | Low | Chip Select Input |
| 21 | R/ $\bar{W}$ |  | Read/Write Control Input Write is active low for loading internal registers. Read is active high but enables D7 only. |
| 22 | XCK |  | Clock Input ( $\simeq 11$ or 2 MHz ) |
| 23 | DIV2 | High | Clock Divide by Two - used when external clock is $\simeq$ 2 MHz |
| 24 | VDD |  | Positive Voltage Supply |

## REGISTER INPUT FORMATS

| Register Address |  | Register Name |  |  |  |  |  |  | Bus Input Bit Position |  |  |  |  |  |
| :---: | :---: | :---: | :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| RS2 | RS1 | RS0 |  | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |  |  |  |
| LO | LO | LO | Duration/Phoneme (DR/P) | DR1 | DR0 | P5 | P4 | P3 | P2 | P1 | P0 |  |  |  |
| LO | LO | HI | Inflection (I) | I10 | I9 | I8 | I7 | I6 | I5 | I4 | I3 |  |  |  |
| LO | HI | LO | Rate/Inflection (R/I) | R3 | R2 | R1 | R0 | I11 | I2 | I1 | I |  |  |  |
| LO | HI | HI | Control/Articulation/Amplitude (C/A/A) | CTL | T2 | T1 | T0 | A3 | A2 | A1 | A0 |  |  |  |
| HI | X | X | Filter Frequency (F) | F7 | F6 | F5 | F4 | F3 | F2 | F1 | F0 |  |  |  |

DR1, DR0 . . Define the phoneme duration.
P5 - P0 . . Address the phoneme required.
111-10.... Define inflection target frequencies and rate of change.
R3-R0 ... Define the rate or speed of speech. CTL . . . . . . . Define the mode of $A / \bar{R}$ response in conjunction with DR1 and DR0. Also directly set by PD/RST.

T2 - T0 . . . Define the rate of movement of the formant position for articulation purposes.
A3 - A0 ... Define the amplitude of the output audio.
F7-F0 ... Define the frequency of all vocal tract filters.

## TYPICAL MICROPROCESSOR IMPLEMENTATION

# User's Guide <br> for <br> Phonetic Programming Using the SSI 263A 

## Phonetics

Every speech sound (phoneme) in any language may be represented by a special symbol (phonetic symbol). These symbols are used in WRITING precisely the sound sequence (phonetic transcription) of a word according to the way it is pronounced. There are many different phonetic symbol sets (phonetic alphabets). Each would contain a mınimum number of symbols to represent the basic sounds (phonemes) required to pronounce any word in the language. Additional symbols are usually included which represent sounds with slight to great variations in the basic sounds (allophones). These symbols are used to assist in the transcription of words that reflect a regional, dialectıc, or foreign pronunciation.

The process of transcribing a spoken word into its phonetıc components begins with identifying the number of sounds in the word, then tagging each with a label to specify its type. Consonants and vowels are the most familiar labels but these may be broken down into subtypes (e.g., stop consonants, back vowels, etc.) as the need for more specificity arises. Once the sounds have been identified, their symbols are selected, then written in sequence. The resulting transcription should allow another person to identify the pronunciation without having heard the word spoken.

Note that when using a phonetic alphabet to transcribe words into their sound sequences, there is not a one-to-one correspondence between the alphabet characters (orthographics) used to spell words and the phonetic symbols (phonetics) used to represent their pronunciations. For example, in the word "phones" there are 6 letters but only 4 sounds. Conversely, the word " $l$ " has 1 letter but 2 sounds. It may be of some assistance to keep a dictionary handy for reference. Dictionaries use their own phonetic system to describe the pronunciations of every word entry. It will be necessary to learn at least one phonetic alphabet in order to engage in phonetıc transcription. The SSI 263A Phonetıc Alphabet is the referent used in this manual. However, if another system is already known, it is easily translated into the referent.

When transcribıng vocabulary from orthography (standard alphabet spelling) to phonetics, it is common to place the phonetic sequence between right slash marks when the transcription appears in running text. The word "phones," for example, would be transcribed as /F O N Z/ when using SSI 263A phonetic symbols. This allows the reader easier identification of phonetic segments.

## SSI 263A Phonetic Alphabet

The phonetic alphabet used to represent the SSI 263A phonemes is the SSI 263A PHONETIC ALPHABET. Refer to the Phoneme Chart for a complete listing of the phoneme symbols.

Of the 64 alphanumeric symbols in the SSI 263A Phonetic Alphabet, 34 represent sound BASIC to the pronunciation of American English. The remaining 30 symbols fall into 2 groups: the ALLOPHONE group and the NO-SOUND group. The BASIC sound symbols are:

A, AE, AH, AW, B, D, E, EH, ER, F, HF, I, J, K, KV, L, M, N, NG, O, OO, P, R, S, SCH, T, TH, THV, U, UH, V, W, Y, Z.

Symbols in the ALLOPHONE group represent speech sounds that vary in pronunciation from one of the basic sounds. They may be used in transcribing words or word segments (syllables or morphemes) whose pronunciations are not satisfied by the basic phonemes alone (words rooted in a foreign language, words adapted by a regional dialect, etc.). The ALLOPHONE symbols are:

A1, AE1, AH1, AY, E1, E2, EH1, HN, HV, IE, IU, IU1, L1, LB, LF, OU, R1, R2, U1, UH1, UH2, UH3, YI,:A,: OH,:U,:UH.

The NO-SOUND symbols represent silent states. One of these symbols represents a "pause" state. It is used to separate phoneme sequences into phrase-like segments which assist in more closely imitating the natural pausing in human speech for breathing or for delayed emphasis. The "pause" is treated as a phoneme when it is selected for a transcription and will be subject to phoneme parameter programming. It has the ability to maintain the parametric levels of duration, inflection, amplitude, etc., during its silence, thus audibly affecting the movement of the preceding and following phonemes. Other NO-SOUND symbols represent "hold" states. They are used in combination with BASIC phonemes or ALLOPHONEs to generate articulation variations on their pronunclations. The NO-SOUND symbols are.
HFC, HVC, PA.
Now that there is a tool to use for writing the sounds that are heard, the next stage is to identify the sounds that are produced by the SSI 263A speech synthesizer

## SSI 263A Phoneme Review

Thus far in this program, it has been established that: (1) spoken words are made up of a series of sounds; (2) each speech sound in a language may be represented by an identifying symbol; and (3) the spoken word may be written according to its sound sequence using these special symbols. Before a word may be written phonetically, however, users may wish to study further the SSI 263A speech sounds. What makes one sound different from another and how these differences may be helpful to phonetic programmıng will be essential informatıon for phonetic programmers.

The sound that is represented by each phonetic symbol in the SSI 263A Phonetic Alphabet must be audibly learned. The easiest way to approach this task is to start with the sounds already known and associate a symbol with them. For example, from spelling we have already learned that vowels may be "long" or "short" and are often differentiated by their particular spelling formats. Every tıme a word with a "short a" sound is heard (sat, fat, cat, bat, happy, plaster, ankle, Saturday, amplify, contaminate, etc.) the symbol /AE/ should come to mind. A "long a" sound (fate, state, bait, lace, maybe, stable, arrangement, etc.) is actually a diphthong (two sounds combined into a single unit) and may be represented by the symbols/A AY/.

In standard orthography, there are only 5 vowel letters to represent 17 vowel sounds. In phonetics, each vowel sound will be represented by its own symbol or symbol combination.

Again, from spelling, we have learned that the letter " $c$ " may have a hard sound as in "cat" or a soft sound as in "city." The hard sound is actually a $/ \mathrm{K} /$ as in "kite" and the soft sound is an $/ \mathrm{S} /$ as in "sing." Users must identify which sound (/K/ or /S/) is used in the transcriptıon of a "c." You will not find a symbol $C$ in a phonetıc alphabet. Like " $C$ ", the letters " $Q$ " and " $X$ " will not be found in phonetic alphabets. They are transcribed into the sound sequences /K W/ and /K PA S/. Refer to the Phoneme Chart during this learnıng period. It provides example words to describe the pronunciations corresponding to each symbol.

Users may add more words to the examples above to continue identifying the symbol-sound relationship for/AE/ and /A AY/. Follow this technique for each symbol in the alphabet. For auditory verification, enter the sound that is being reviewed into the device. Speak aloud your example word for the SSI 263A
sound in an attempt to match that which the synthesizer is emitting.

$$
\begin{aligned}
\text { Example: } / E /= & \text { "long e" vowel sound } \\
= & \text { meat, read, need, repair, before, phoneme, } \\
& \text { erase, brief, people, timeliness, seniority, } \\
& \text { receive, catastrophe. }
\end{aligned}
$$

## Example: /F/ = "voiceless fricative" consonant

= farm, false, aft, feet, finger, phrase, phone, Africa, alphabet, cough.

Once you have reviewed auditorily the sounds you already have a familiarity with from spelling, proceed to the BASIC sound list in the above text and continue the review. Be aware that several consonant sounds will not provide output unless they have another sound following. This is the case with/B/, /D/,/P/, /T/, and /K/. When one of these sounds is entered into the SSI 263A, follow it by a vowel and listen to both in sequence.

Users who already have a familiarity with phonetics and SSI 263A synthetic sounds, may wish to follow the sound review procedures in order to auditorily determıne the difference between two sounds or identify new ones. For example, enter the $/ \mathrm{UH} /$ phoneme into the device. Then enter/UH1/, /UH2/, and /UH3/. Listen to each sound noting the pronunciation variations. Be aware that there are no duplicate sounds resident on the SSI 263A chip.

Whenever a SSI 263A sound is audited that cannot be readily identified as to its appropriate usage, do not be concerned. The review is designed only to provide a method for establishing an auditory memory for each sound and a visual memory for its symbol. Phonetic programming may begın anytime after the initial review. Return to the review later as your familiarity with the BASIC sounds increases and as your need for sound alternatives to those BASIC sounds becomes more apparent.

If there is a question as to which symbols should be chosen to transcribe a word into its sound sequence, make a written note of the word by circling the letter(s) that present the problem. Later, when phonetic programming has begun, a phoneme sequence may be created for the word and users may verify auditorily which phonetic selection produces the most appropriate translation.

## SSI 263A Phoneme Discussion

The SSI 263A Phonetic Alphabet is divided into 3 groups for the purpose of differentiating between phonemes and allophones. Another way of dividing the Alphabet is according to usage. The most familiar division is a two sections split: CONSONANT sounds and VOWEL sounds. Within each of these sections, sounds may be further subdivided according to the distinctive features that best describe the sounds phonetically or acoustically. The more that is known about a sound, the easier it is to determine how it may be used in transcribing and phonetically programming a word.

## Consonant Sounds

There are 22 Consonant Phonemes, subdivided according to their manner of production in the human speech mechanism. Some are characterized by the noise emitted when the articulators obstruct the arr flow (Fricatives like/S/). Vowel-like consonants have the least amount of obstruction and may occasionally be used as a vowel substitute. Stop consonants are obstructed completely, release of air flow occuring at the onset of the next sound. Notice that Affricates are a sequence of 2 sounds (a Stop followed by a Fricative) spoken as a single unit. Unlike vowels, which always have a vocal source during production, consonants may be voiced (V) or unvoiced (U) (no vocal source during air flow). When listening to the manner in which a consonant is produced during speech, note its special characteristics that distinguish it from all other consonants. The figure below displays all of the consonant sounds within their production groups.

|  | Stops | Fricatives | Affricates |
| :--- | :---: | :---: | :---: |
| Voiced | B, D, KV | $Z, \mathrm{~V}, \mathrm{~J}, \mathrm{THV}$ | $(\mathrm{D}, \mathrm{J})$ |
| Voiceless | P, T, K | S, F, SCH, | $(T$, SCH $)$ |
|  |  | TH, HF, |  |

|  | Semi-vowels | Glides | Nasals |
| :--- | :---: | :---: | :---: |
| Voiced | R, L | $\mathrm{W}, \mathrm{Y}$ | $\mathrm{M}, \mathrm{N}, \mathrm{NG}$ |
| Voiceless |  |  |  |

## Consonant Chart

Voiced and voiceless consonants are subdivided into 6 categories according to the manner in which they are produced in the human vocal tract: i.e., how the air flow is obstructed by the articulators to make each sound different.

Consonant sounds are selected for a sequence in much the same manner as an alphabet character would be selected for the spelling of a word. Users must be alert, however, to identify the exceptions. Occasionally, a consonant appears in the spelling of a word but not in its sound sequence: the " b " in "comb" is not pronounced and the sound sequence reflects the absence of the "b": /K OU M/. Some exceptions have grammatical rules that may be used in determining the appropriate sound. For example, a consonant may have 2 pronunciations according to its sound environment. The " $s$ " used to pluralize the two words that follow are pronounced differently based on whether the sound that precedes it is voiced or unvoiced. An "s" pronunciation will match the voicing characteristics of the sound it follows.

$$
\begin{aligned}
\text { Examples: tips } & =/ \mathrm{T} \text { I P S/ } \\
\text { tabs } & =/ \mathrm{T} \mathrm{AE} \mathrm{~B} \mathrm{Z/}
\end{aligned}
$$

There are other types of consonantal exceptions. For example, the " t " in a word like "nation" is pronounced/SH/ and the program might look like this: nation $=/ \mathrm{N}$ A AY SH UH3 N/. Users must listen to each word's pronunciation to determine the appropriate phoneme selection.

There are 7 Consonant Allophones, each noted in the table below. The/L/ consonant is used in the initial position of a sequence for words beginning with "L", while the /LF/ allophone will occupy a medial or final position in a sequence: e.g., lull =/LUH LF/. The /LB/ and the /LI/ allophones would be used when a most constricted pronunciation of an " L " was required, as would occur for some words of foreign languages.

| Consonant <br> Phoneme | Consonant <br> Allophones | Consonant <br> Phoneme | Vowel <br> Allophone |
| :---: | :---: | :---: | :---: |
| L | $\mathrm{L} 1, \mathrm{LB}, \mathrm{LF}$ | R | ER |
| R | $\mathrm{R} 1, \mathrm{R} 2$ | Y | YI |

Allophone Listing for/L/, /R/, \& /Y/
The/R/ is an initial position phoneme. Both /R1/ and/R2/ have more constricted pronunciations than /R/ and may be used in sequence with soundless interrupts to create a trilled/R/. Often when the $/ R /$ is required in a medial or final position, it is vowelized and the /ER/ is used. Listening to the production of all four of these sounds will auditorily show that they may, occasionally, be used interchangeably.

$$
\begin{aligned}
\text { Examples: } & \text { red }=/ \text { R EH D } / \\
\text { bird } & =/ B E R D / \\
& \text { motor }=/ M O U T E R /
\end{aligned}
$$

The / $\mathrm{Y} /$ consonant, used as the final sound in words ending with "y", has a vowel allophone that may be used as the initial sound of words starting with " y ." Note that both $/ \mathrm{Y} /$ and $/ \mathrm{Y} \mathrm{I} /$ are auditorily very close to the /E/ and the/IE/ vowels and may be considered interchangeable.

## Vowel Sounds

There are 12 BASIC Vowel Phonemes. Vowels are subdivided according to the manner in which they are produced. All vowels are voiced sounds but each has a different output based on the degree of obstruction created by the opening of the mouth and the tongue position. Lip positions, another obstructing articulator, may range from spread flat to round. While the lips are in any of these positions, the jaw may be simultaneously dropped from a closed to an open position.

|  | Front Vowels | Medial Vowels |
| :---: | :---: | :---: |
|  | Back Vowels |  |
|  | Spread | Rounded |
| Closed | E | U |
|  | I |  |
|  | A | UH |
|  | EH | OO |
|  | AE | O |

## Vowel Quadrilateral

Vowels begin their production with the same voiced energy. Changes in the position of the tongue (front or back), the shape of the lips (from spread flat to rounded), and the position of the lower jaw (from closed to open) determine the final characteristics that allow listeners to distinguish between vowel sounds.

Refer to the SSI 263A Phoneme Chart for the pronunciation reference on each BASIC vowel sound. Utilize the sound review techniques on the previous pages to practice identifying the vowel sounds in words and associating them with therr phonetic symbols.

The allophonic varıations of vowels, 20 in number, are used in a phonetic program to enhance the pronunciation of a word. There are some cases where the allophone is required for articulate pronunciations. This is true for $/ \mathrm{AY} /, / \mathrm{YI} /$ and $/ / \mathrm{IU} /$, which are integral components in the phonetic sequences for the "long a" and the varied "long $u$."

$$
\begin{gathered}
\text { Examples: } \begin{array}{c}
\text { same }=/ S \text { A AY M/ } \\
\text { you }=/ Y \mid I \cup U /
\end{array}
\end{gathered}
$$

The table below places each allophone into the vowel quadrilateral to demonstrate approximately how they might relate to the BASIC vowels. Users are in no way restricted to traditional phonetic transcriptions that use only the BASIC vowel phonemes. Be encouraged to experiment with allophones. Place them in different positions in a sequence to auditorly check how they effect the overall pronunciation of a word.

|  | Front Vowels | Medial Vowels | Back Vowels |
| :---: | :---: | :---: | :---: |
|  | Spread |  | Rounded |
| Closed | $\mathrm{YIE1IE}$ |  | U 1 |
|  | AY | E 2 | IU IU1 |
|  | A 1 | UH 1 | OU |
|  | EH 1 | UH 2 |  |
|  | AE 1 | UH 3 | AH 1 |

Allophone Placement in Vowel Quadrilateral
Vowel allophones are placed in the vowel quadrilateral according to their production features. The sounds they emit vary slightly from the BASIC vowels that occupy the same positions.

Four vowel allophones-/:A/, /:OH/, $/: \mathrm{U} /$, and $/: \mathrm{UH} /$ - are adapted pronunciations of four of the BASIC vowels. These sounds are most commonly used for phonetically programming a foreign word. They may also be used as transitory sounds to link phonemes with opposite production features such as a round, open vowel with a very constricted, narrow consonant.

There are five vowels that require two or more vowel sounds in sequence in order to achieve their pronunciations. These are generally referred to as diphthongs. Refer to the Diphthong Conversion Chart.

The vowel quadrilateral is a handy tool to use for selecting vowel phonemes for diphthongs and other multi-phoneme units. For example, the diphthong in the word "I" starts with an /AH/ and ends with an /E/. In order to move smoothly from the first sound to the second (transition), another vowel may be inserted between these two sounds in sequence. The most likely choice would be a vowel that falls somewhere between $/ \mathrm{AH} /$ and $/ E /$ in the quadrilateral: e.g., /UH/, /EH/, /I/, etc. The sequence may look like
this: /AH EH E/ or /AH1 UH3 IE/ or /AH1 EH3 AY/. In their fullest durations, a three-sound sequence would over articulate the diphthong. Shortening the first and last sounds by 1 duration and the medial sound by 2 durations will produce a more acceptable pronunciation (see SSI 263A Phoneme Parameters).

## SS1 263A Phoneme Parameters (Attributes)

To achieve an accurate pronunciation of a word produced by the SSI 263A synthesizer requires more than a selection of the appropriate phonemes. Like human speech sounds, synthesized sounds are further defined by the rate at which they are emitted (duration), the level of pitch at which they are emitted (inflection or frequency), and the intensity with which they are produced (amplitude). These are considered the three major speech parameters which give the overall production of a word its linguistic character, transforming simple speech into more complex language. Inflection, amplitude, and duration are only three of the parameters that users have control of during the programming process. The rate at which one sound moves into another (articulation) is also a controllable parameter. Other parameters are: the slope of the inflection (slope), the rate of each selected duration (rate), and the extended inflection frequencies (extension). Users may also select the base frequency at which speech may be produced (filter frequency). Refer to SSI 263A Phoneme Parameters, for the range of each and typical default values selected.

Every phoneme selected for a sequence must be accompanied by assignments for each of the eight parameters. As users become more aware of their need to create different language effects with their synthesized speech output, they will require the flexiblity and choice that comes with programmable parameters. For example, with 4 selectable durations per phoneme, each actual pronunciation of each sound may be changed. Thus, every sound has four possible outputs increasing the users' choice from 64 phonemes and allophones to 256 . Each of the 256 may be effected differently by each of the 32 possible inflection assignments. Add to these possibilities 16 variations in amplitude and 16 variations in rate. The possible combinations are not limitless, of course, but they are very great and users are encouraged to experiment with as many as possible.

Several of the parameters effect synthetic speech output as a whole. These are articulation, pitch extension, and filter frequency. Users may select a single level at which to set the filter frequency, for example, and maintain that level throughout the programming process.

## Phonetic Programming Methodology

Due to the great variety of phonemes and parameter choices, as well as the different effects the parameter selections have on the speech sounds, a systematic approach to selecting the variables is advised. The approach described below is only one of several that might be used. It may be adjusted to accommodate the user's special programming style or to accommodate later implementation of automatic control techniques.

The first step is to transcribe the target word, phrase, etc., into its basic phonetic components. Next, enter these sounds into the SSI 263A and auditorily check the output. Use the default values suggested in the Nominal Phoneme Parameter Table. The results should be a bit stilted if not misarticulated for the first trial program. Phoneme adjustment is next. Continue to make changes in the phoneme sequence, auditorily monitoring the changes, until an adequate pronunciation of the target is established.

Begin parameter adjustments. First, maintain articulation, pitch extension and filter frequency at nominal values. The device should be kept in the transitioned inflection mode. Make adjustments in the levels of only one of the remaining 4 parameters at a time, beginning with the duration and moving on to the inflection, rate, and amplitude (in that order) once the specific effect that the parameter can make has been made. Return to a previously adjusted parameter at any time based on need.

PHONEME CHART

| Hex Code* | Phoneme Symbol | Example Word (or Usage) |
| :---: | :---: | :---: |

## Data Sheet

## DESCRIPTION

The SSI 80C50 is a CMOS digital IC that provides all the formatting to T-1, D2 or T-1, D3 specifications. The IC is functionally identical and pin compatible with the Rockwell R8050, but offers reduced power consumption and provides greater output current drive (fully $T \mathrm{~T}$ ). The data rate is 1.544 MHz .

The IC performs 8-bit parallel to serial conversion channel data is received and then serially transmitted in two formats: binary and as a pair of unipolar outputs. Inputs control the formatting features available - alarm reporting, highway signalling, zero data suppression, and framing. Several timing signal outputs are provided to indicate channel, frame, and multiframe boundaries.

## FEATURES

- Second source, Rockwell R8050
- TTL compatible
- CMOS low power dissipation
- Single 5V supply
- Provides formatting, timing and control for T-1, D2 or T1, D3
- Provides timing signals to synchronize channel and framing data

SSI 80C50 Block Diagram

## Pin Description

| Pin No. | Name | Description |
| :---: | :---: | :---: |
| 1 | B70PTN | Provides bit 7 as an alternate bit position for "1" stuffing |
| 2 | TEST | Used only for device testing, otherwise this pin should be grounded or open (on chip pulldown resistor to ground). In test mode (TEST = 1) the bit/channel counters count 13, not 193 bits per frame - shortening test throughout time. |
| 3 | FRSYNC | Frame sync allows external synchronization of the transmitter's frame counter. When FRSYNC becomes " 1 ", the frame counter is set to frame 1. If FRSYNC is held high and does not return to " 0 " before the rising edge of CLOCK, BINOUT will " 1 " and UNPLRA \& UNPLRB will toggle each CLOCK cycle. |
| 4 | S-BIT | In conjunction with CCIS, provides an alternate way to control the multiframe signalling bit (FS) transmission. The S-BIT input is transmitted at the multiframe signalling bit (FS) if CCIS is " 1 ". |
| 5 | CCIS | Common Channel Interoffice Signalling strap. Provides optional control for replacing the automatic FS bit pattern with a 4-kilobit common channel signalling path. When CCIS is high, the S-BIT input replaces the FS pattern and the insertion of ACH and BCH is suspended. The CCIS input may also be used to provide the alternate method of alarm reporting. |
| 6 | SSTB | 4 kHz multiframe strobe. SSTB is the least significant bit of the frame counter. Unless it is directly set by FRSYNC, SSTB will be " 1 " as each FT bit is serially transmitted, and will be " 0 " as each multiframe alignment signal FS is transmited. |
| $\begin{aligned} & 7 \\ & 8 \end{aligned}$ | UNPLRA UNPLRB | Serial data unipolar outputs. Two paired unipolar outputs are provided for the purpose of creating a single serial data transmission in bipolar format. |
| 9 | GROUND | Ground |
| 10 | BINOUT | Serial data output, binary formatted. |
| 11 | SYNOUT | Channel sync output. Provides a means to synchronize to the internal bit/channel (mod 193) counters. SYNOUT is high one bit time, beginning just prior to the first data bit of a frame being serially transmitted. SYNOUT is the only output determined by the falling edge of CLOCK. |
| 12 | LOOP | Loop strap. Intended Used for user testing, otherwise this pin should be grounded or open (on chip pulldown resistor to ground). When enabled to " 1 ", LOOP forces the unipolar outputs to transmit, alternating ones and zeros, regardless of input conditions, while BINOUT still provides normal data outputs. |
| 13 | SYNCIN | SYNCIN allows external sychronization of the bit/channel counters (modulo 193). When SYNCIN becomes " 1 ", the counters are set to the state corresponding to the output of the framing (FT or FS) bit. The first bit of channel one will be output on BINOUT (and UNPLRA or UNPLRB) as a result of the first rising edge of CLOCK following the return of SYNCIN to "0". |
| 14 | BCH | " $B$ " channel highway signalling allows the user to transmit one bit of signalling per channel data sample in frame 12 only. |
| 15 | ACH | "A" channel highway signalling allows the user to transmit one bit of signalling per channel data sample in frame 6 only. |
| $\begin{gathered} 16 \\ 20-25 \\ 27 \end{gathered}$ | $\begin{aligned} & \hline \text { BITS } \\ & 1-8 \end{aligned}$ | Bit 1, the sign bit, will be serially transimitted first, followed by bits 2 through 8 . The falling edge of CHCLKF indicates input channel data has been clocked into the input register and always occurs during the final bit (bit 8) of each sample. |
| 17 | ALARM | Used for reporting alarm conditions. If the ALARM signal is " 1 ", bit 2 of every channel is transmitted as " 0 ". |
| 18 | CLOCK | 1.544 MHz clock. |
| 19 | VDD | Power. |
| 26 | CHCLKF | Channel clock false. The falling edge of CHCLKF, occurring as bit 8 of any channel is being serially transmitted, indicates input data has been clocked into the input register. With the exception of an extra bit period extending the low level duration at frame bit time, CHCLKF is a divide-by-eight of CLOCK. |
| 28 | INH | Inhibit zero channel monitor. |

## Counters -

Channel data (BIT1-BIT8) is parallel loaded into an input register and is then serially transmitted out at BINOUT at the clock rate of 1.544 MHz . Bit1 is the sign bit, bit 2 the MSB and bit 8 the LSB. When the last bit (bit 8) is being transmitted, the next channel is loaded into the register, latched by CHCLKF. Three counters control the transmission of data. The bit counter (modulo 8) decodes which bit is being transmitted, generates CHCLKF, and increments the channel counter at the end of each channel. The channel counter (modulo 24) outputs a pulse for frame synchronization which is one clock period wide (SYNOUT), and increments the frame counter. The frame counter (modulo 12) signals odd or even frames (SSTB). External synchronization is available with pins SYNCIN, which initializes the bit and channel counters, and FRSYNC which initializes the frame counter.

## Transmit Ouputs -

The device provides two types of transmit formats a binary ouput (BINOUT) and a pair of unipolar outputs (UNPLRA and UNPLRB). BINOUT is the binary formatted serial conversion of the parallel input channel data. The unipolar outputs toggle for each " 1 " to be serially transmitted, and are complements of each other. For example, if the current BINOUT is " 1 ", UNPLRA is " 1 " and UNPLRB is " 0 ", the next output of " 1 " on BINOUT
will toggle UNPLRA to " $O$ " and UNPLRB to " 1 ". Whenever BINOUT is " O ", both unipolar outputs are forced to "O".

## Alarm reporting and Signalling -

The device provides control for alarm reporting and highway signalling with inputs ALARM, ACH and BCH - all three are latched in by CHCLKF. In remote alarm signalling bit2 of every channel is transmitted as "O". Alternate remote alarm signalling may be used with signals CCIS and S-BIT. In highway signalling ACH replaces bit 8 of every channel in frame 6 only; likewise BCH replaces bit 8 in frame 12.

## Bit Stuffing -

The device provides for automatic bit stuffing for all zero channel samples. Input INH inhibits the zero channel monitor ( zcm ) while input B70PTN controls whether bit 7 or bit 8 is stuffed. If INH is high, bits 7 and 8 are transmitted as normal, i.e., bits 7 and 8 are transmitted as received unless the frame is a signalling frame (6 or 12) - in which case the highway signalls replace bit 8 as previously described. If INH is low, the zcm is enabled and the following applies. For signalling frames, if the first seven channel bits and the signalling highway are all " O ", bit 7 will be forced to " 1 ". For the other frames, if all the channel bits are " $O$ ", then bit 7 will be " 1 " if B70PTN is " 1 ", otherwise bit 8 will be forced to " 1 " if B70PTN is " 0 ".

## Framing -

The device automatically inserts frame information at the beginning of each frame. An FT bit is inserted before the sign bit (bit1) of channel 1 in odd frames, stretching
the channel to 9 bits, an FS bit likewise is inserted in even frames. Alternatively, the FS bit insertion can be externally controlled by pins CCIS and S-BIT.

| FRAME NUMBER | FT <br> FRAME <br> ALIGNMENT <br> SIGNAL | FS <br> MULTIFRAME ALIGNMENT <br> SIGNAL |  | BIT NUMBERS IN CHANNELS |  | SIGNALLING CHANNEL |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | CHARACTER BITS | SIGNALLING BIT |  |
|  |  | CCIS $=0$ | CCIS $=1$ |  |  |  |
| 1 | 1 |  |  | 1-8 |  |  |
| 2 |  | 0 | S-BIT | 1-8 |  |  |
| 3 | 0 |  |  | 1-8 |  |  |
| 4 |  | 0 | S-BIT | $1-8$ |  |  |
| 5 | 1 |  |  | 1.8 |  |  |
| 6 |  | 1 | S-BIT | 1.7 | 8 | A |
| 7 | 0 |  |  | 1.8 |  |  |

## Data Sheet

## GENERAL DESCRIPTION

The SSI 80C60 is a CMOS digital IC that receives and deserializes serial unipolar data in a T-1, D2 or T-1, D3 format. The IC is functionally identical and pin compatible with the R8060 but offers reduced power consumption and provides greater output current drive (fully TTL).
The IC receives $1.544 \mathrm{MBit} / \mathrm{s}$ unipolar data and an extracted clock. The data pattern is in 193 bit frames, each frame consisting of a frame bit (FT) or a signaling bit (FS) followed by 192 bits of data representing 24 channels of 8 bit words. $F$ frames and $S$ frames alternate. The receiver synchronizes by locking to (FT) which occurs every 386 bits and which continually alters between 1 and 0 , and deserializes the data stream into 24 eight bit wide channels which are clocked out of the 8 data bit pins at a 192,000 channel/s rate with each channel repeated at a 8000 frame/s rate. Signaling bits (FS), which are positioned 193 bits behind the frame bit, are outputed at the SBIT pin.

Remote alarm reporting is monitored and an alarm is indicated at the B2ALRM pin if 255 consecutive bit 2 zeros are received. The incoming data is monitored for loss of carrier and an alarm is indicated at the CALRM pin if 31 consecutive zero bits are received.

## FEATURES

- Second source, Rockwell R8060
- TTL compatible
- CMOS low power dissipation
- Single 5V supply
- Locks onto and deserializes incoming T-1, D2 and T-1, D3 data in 5 ms
- Generates timing signals to synchronize channel and frame information
- Monitors and detects
- FS bit
- Frame sync
- Carrier
- Remote alarm reporting

Block Diagram

Pin Out (Top View)

| Pin | Name | Description |
| :---: | :---: | :---: |
| 1 | TCLK | Data clock. Nominal clock frequency is 1.544 MHz . Data bits are clocked into the chip on the falling edge of the clock. |
| 2 | VDD | Power |
| 3 | WIHBT | Write inhibit clock. Strobes high once every channel for two TCLK periods and is used to load the 8 -bit parallel channel output data into external circuitry. |
| 4 | B2ALRM | Bit 2 alarm signal, active high. Goes high indicating a remote alarm when 255 consecutive 0's are received in the bit 2 position. Resets low after bit 2 becomes 1. |
| 5 | TESTI | Test input, when low puts the circuit in its test mode. Must be high or left open during normal operation. |
| 6 | FRALRM | Frame alarm, active high. Goes high when frame sync is lost. |
| 7 | CHCLK | Output data channel clock, going high signals new parallel data output. |
| 8 | MAXCNTB | Strobes low once every two frames for one TCLK period during the expected input of FT. |
| 9 | CHSYNCB | Channel sync clock, strobes low once every frame for six TCLK periods during channel 1. |
| 10 | SYNCEN | Frame synchronization enable. When low, disables the automatic resync search initiated by a frame alarm condition. |
| 11 | MRB | Master Reset, active low resets the circuit. |
| 12 | GND | Ground |
| 13 | CALRM | Carrier alarm signal, active high. Goes high if 31 consecutive zeros are received in the TDATA input. Resets low when TDATA becomes 1. |
| 14 | SBALRM | FS alarm signal, active high. Signals an FS alarm when the previous FS bits have been a 0 followed by 1111. SBALRM is reset low when the FS bit pattern 10001 occurs. The SBALRM transition occurs during channel 1 of FS frame. |
| 15 | TESTO | Test mode output. |
| 16 | SBIT | Signaling bit, outputs the FS received 2 frames before the current FS. |
| 17 | CDINH | Channel data inhibit, when high forces CDB1 through CDB7 pins high. CDB8 is not affected. |
| 18-25 | CDB1-8 | Bit 1, the sign bit, will be serially received first, followed by bits 2 (MSB) through bit 8 (LSB). The rising edge of CHCLK indicates output channel data has been clocked out and occurs as the final bit (bit 8) is received. |
| 26 | TDATA | Serial data input. |
| 27 | SBCLK | 4 kHz signal that is low during even frames and high during odd frames. |
| 28 | SIGFRB | Signal frame clock, strobes low during frame 6 and 12. |

Timing - Timing signals for channel and frame synchronization.
WIHBT
CHCLK
MAXCNTB
SIGFRB
CHSYNCB
SBCLK
SBIT

Alarms - Alarm conditions reported.
SBALRM
B2ALRM
CALRM
FRALRM

FRAME ALARM
FRALRM goes high indicating an out-of-frame condition when:
(1) The frame sinchronization algorithm is in progress.
(2) MRB is low.
(3) The current FT is in error and a previous FT error occurred in the past four frames.
(4) CALRM is low.

FRALRM returns low when:
(1) Frame synchronızation is complete.
(2) CALRM is high.

During frame sync output signals CHCLK, CHSYNC, and WIHBT will continue normally for 2 frame periods - afterwards they will be high. For most data patterns frame sync requires less than 5 milliseconds to acquire frame lock.

## Absolute Maximum Ratings

SBALRM

## Data Sheet

## GENERAL DESCRIPTION

The SSI 22100 combines a $4 \times 4$ array of crosspoints (transmission gates) with a 4-line-to-16 decoder and 16 latch circuits. Any one of the sixteen transmission gates (crosspoints) can be selected by applying the appropriate four line address. The selected transmission gate can be turned ON or OFF by applying a logical ONE or ZERO respectively to DATA IN and strobing the STROBE input to a logical ONE. Any number of the transmission gates can be ON simultaneously. When the device is "powered up', the states of the 16 switches are indeterminate. Therefore, all switches must be turned OFF by setting the STROBE high and DATA IN low, then addressing all switches in succession.
The SSI 22100 is supplied in 16-lead hermetic dual-in-line ceramic packages and 16-lead dual-in-line plastic packages.

## FEATURES

- Low ON resistance-75 $\Omega$ typ. at $\mathrm{V}_{\mathrm{DD}}=\mathbf{1 2 V}$
- "Built-In" control latches
- Large analog signal capability- $\pm$ VDD/2
- $\mathbf{1 0 - M H z}$ switch bandwidth
- Matched switch characteristics $-\Delta$ RON $=18 \Omega$ typ. at $V_{D D}=12 \mathrm{~V}$
- High linearity-0.5\% distortion (typ.) at $f=1 \mathrm{kHz}$, $V_{I N}=5 V_{\text {p-p }}, V_{D D}=10 \mathrm{~V}$, and $R_{L}=1 \mathrm{k} \Omega$
- Standard CMOS noise immunity
- 100\% tested for maximum quiescent current at 20 V
- Second source for RCA CD22100

## Data Sheet

## GENERAL DESCRIPTION

The SSI 22101 and 22102 crosspoint switches consist of $4 \times 4 \times 2$ arrays of crosspoints (transmission gates), 4 -line to 16 -line decoders, and 16 latch circuits. Any one of the sixteen crosspoint pairs can be selected by applying the appropriate four-line address, and any number of crosspoints can be ON simultaneously. Corresponding crosspoints in each array are turned on and off simultaneously, also.
In the SSI 22101, the selected crosspoint pair can be turned on or off by applying a logical ONE or ZERO, respectively, to the DATA input, and applying a ONE to the STROBE input. When the device is "powered up', the states of the 16 switches are indeterminate. Therefore, all switches must be turned off by putting the STROBE high, DATA low, and then addressing all switches in succession.

The selected pair of crosspoints in the SSI 22102 is turned on by applying a logical ONE to the $\mathrm{K}_{\mathrm{a}}$ (set) input while a logical ZERO is on the $K_{b}$ input, and turned off by applying a logical ONE to the $K_{b}$ (reset) input while a logical ZERO is on the $K_{a}$ input. In this respect, the control latches of the SSI 22102 are similar to SET/RESET
flip-flops. They differ, however, in that the simultaneous application of ONEs to the $\mathrm{K}_{\mathrm{a}}$ and $\mathrm{K}_{\mathrm{b}}$ inputs turns off (resets) all crosspoints. All crosspoints in both devices must be turned off as VDD is applied.
The SSI 22101 and SSI 22102 are supplied in 24-lead hermetic dual-in-line ceramic packages and 24-lead dual-in-line plastic packages.

## FEATURES

- Low ON resistance-75 typ. at $V_{D D}=12 \mathrm{~V}$
- "Built-In" latched inputs
- Large analog signal capability $- \pm \mathrm{V}_{\mathrm{DD}} / 2$
- $\mathbf{1 0 - M H z}$ switch bandwidth
- Matched switch characteristics- $\Delta$ RON $=8 \Omega$ typ. at $V_{D D}=12 \mathrm{~V}$
- High linearity-0.25\% distortion (typ.) at $\mathbf{f}=\mathbf{1 k H z}$, $\mathrm{V}_{\mathbf{I N}}=5 \mathrm{~V}_{\mathrm{p}-\mathrm{p}}, \mathrm{V}_{\mathrm{DD}}-\mathrm{V}_{\mathbf{S S}}=10 \mathrm{~V}$, and $\mathrm{R}_{\mathrm{I}}=1 \mathrm{k} \Omega$
- Standard CMOS noise immunity
- Second source for RCA CD22101 \& CD22102

## Data Sheet

## GENERAL DESCRIPTION

The SSI 22106 is an $8 \times 8 \times 1$ analog switch array of CMOS transmission gates designed using high-speed CMOS technology. It offers high noise immunity and has very low static power consumption.
At power up all switches are automatically reset. A "low" on the Master Reset turns OFF all switches and clears the control latches. A 6-bit address through a 6-line-to-64-line decoder selects the transmission gate which can be turned ON by applying a logical ONE to the DATA INPUT and a logical ZERO to the STROBE. Similarly, any transmission gate can be turned OFF by applying a logical ZERO to the DATA INPUT while strobing the STROBE with a logical ZERO.

A $\overline{C E}$ allows the crosspoint array to be cascaded for matrix expansion in both the X and Y direction. The SSI 22106 is supplied in a 28 -lead hermetic dual-in-line ceramic package and 28 -lead dual-in-line plastic packages.

## FEATURES

- 64 crosspoint switches in an $8 \times 8$ array
- $\mu \mathbf{P}$ compatible control inputs
- On chip line decoder and control latches
- Ron resistance $95 \Omega$ max @ 4.5V
- $\Delta$ Ron $25 \Omega$ typical @ 4.5V
- Operation voltage 2-10V
- Analog signal capability Vdd/2
- Automatic power up reset
- Parallel data input
- Second source for RCA CD 22106
- Address latches on-chip
- CMOS or TTL ("T" suffix) compatible inputs

SSI 22106 Block Diagram

PIN DESCRIPTION

| Pin No. | Symbol | Description |
| :---: | :---: | :---: |
| $\begin{aligned} & 24,25, \\ & 26,27, \\ & 28,1, \end{aligned}$ | A0-A5 | 6 bit address control inputs |
| 2 | $\overline{\text { STROBE }}$ | Strobe input. A "low" of $\overline{\text { STROBE }}$ input permits DATA input to turn on or off the switch specified to connect $X$ 's and $Y$ 's |
| 3 | $\overline{\mathrm{CE}}$ | Chip Enable input. A "low" of $\overline{\mathrm{CE}}$ allows the crosspoint array to be cascaded for matrix expansions in both the $X$ and $Y$ directions. |
| 4 | DATA | Data Input. With a "zero" of STROBE, a "one" of DATA turns on the switch and a "zero" of DATA input turns off the switch. |
| 5 | Vss | Ground |
| $\begin{aligned} & 6,23 \\ & 7,22, \\ & 8,21, \\ & 19,20 \end{aligned}$ | $\mathrm{X}_{0}-\mathrm{X}_{7}$ | 8 lines in X direction |
| 10 | $\overline{M R}$ | Master Reset input. A "low" of $\overline{M R}$ turns off all switches and clears the control latches. |
| 18-11 | $\mathrm{Y}_{0}-\mathrm{Y}_{7}$ | 8 lines in Y direction. |
| 19 | VDD | Positive Power Supply. |

Maximum Ratings, Absolute - Maximum Values:
DC Supply - Voltage (Vcc)
(Voltages referenced to ground) . . . . . . . . . . . . -0.5 to 11 V
DC Input Diode Current, IIK

DC Output Current, IOK

| SSI 22301 | PCM Line Repeater | T1 carrier signal recondition | 5 V | 18 DIP |

## Data Sheet

## GENERAL DESCRIPTION

The SSI 22301 monolithic PCM repeater circuit is designed for T1 carrier systems operating with a bipolar pulse train of $1.544 \mathrm{Mb} / \mathrm{s}$. It can also be used in the T148 carrier system operating with a ternary pulse train of 2.37 $\mathrm{Mb} / \mathrm{s}$. The circuit operates from a $5.1 \mathrm{~V} \pm 5 \%$ externally regulated supply.
The SSI 22301 provides active circuitry to perform all functions of signal equalization and amplification, automatic line buildout (ALBO), threshold detection, clock extraction, pulse timing, and buffered output formation.

The SSI 22301 is supplied in an 18-lead dual-in-line plastic package.

FEATURES

- Automatic line buildout
- 5.IV supply voltage
- Buffered output
- Second source for RCA CD22301

Notes.

1. No signal input Measure voltage between pins 7 and 8

2 Measure clock lımiter input impedance at pın 15.
3 Adjust potentımeter for 0 volts. Measure ALBO off impedances from pins 2,3 and 4 to pin 1
4 Increase potentıometer until voltage at pin $17=2 \mathrm{Vdc}$ Measure ALBO on impedances from pins 2,3 and 4 to pin 1
5 Adjust potentiometer for $\Delta \mathrm{V}=0$ volts Then slowly increase $\Delta \mathrm{V}$ in the positive direction until pulses are observed at the DATA terminal
6 Contınue increasing $\Delta V$ untıl the $D C$ level at the clock termınal drops to 4 volts
7 Contınute increasing $\Delta V$ until the ALBO terminal rises to 1 volt
8 Turn potentıometer in the opposite dırection and measure negative threshold voltages by repeatıng tests outlined in notes 5,6 , and 7
9 Set $e_{\mathrm{In}}=275 \mathrm{mV}(\mathrm{rms})$ at $f=1185 \mathrm{MHz}$. Adjust frequency untıl maxımum amplitude is obtaıned at pın 15 Observe output pulses at pins 10 and 11
10 Adjust input signal amplitude until pulses just appear in outputs Increase input amplitude by three dB

## Data Sheet

Block Diagram

SSI 122 Pin Out

## FEATURES

- IBM 3350 compatible performance.
- IBM compatible power supply voltages and logic levels.
- Four read/write channels.
- Safety circuits

## DESCRIPTION

The SSI 104 is a monolithic bipolar integrated circuit for use in high performance disk drive systems where it is desirable to locate the control circuitry directly on the data arm. Each circuit controls four heads and has three modes of operation: Read, Write and Idle.

The 104 L is a low-noise version of the 104 with all
other parameters identical. Both are packaged in a 24 pin flat pack.

The SSI 108 and 122 are identical in performance to the 104. The 108 is packaged in a 24 pin dip package while the 122 is packaged in a 22 pin dip.

## 4-Channel Read/Write Circuit SSI 104, 1O4L, 1O8, 122

## WRITE MODE

In the write mode, the circuit functions as a current gate. Externally supplied write current is gated by the state of the head select and data inputs to one side of one head. Head voltage swings are monitored by the head transition detect circuit. Absence of proper head voltage swings, indicating an open or short on either side of the head or absence of write current, will cause a fault current to flow into the unsafe pin.

## READ MODE

In the read mode, the circuit functions as a low noise differential amplifier. The state of the head select inputs determines which amplifer is active. Data is differentially read from one of four heads and an open collector differential signal is put across the Data $X$ and Data $Y$ pins. If a fault condition exists such that
write current is applied to the chip when the chip is in read mode, the write current will be drawn from the unsafe pin and the fault will be detected.

## ABSOLUTE MAXIMUM RATINGS

Positive Supply Voltage VCC . . . . . . . . . . . . . . . . . . . . . 7.0 V
Negative Supply Voltage, VEE . . . . . . . . . . . . . . . . . . 5.5 V

## Preliminary Data Sheet

SSI 114 Block Diagram

SSI 114 Pin Out

FEATURES

- Thin film head compatible performance
- Four Read/Write Channels
- TTL - compatible logic levels
- Operates on standard +5 volt and -5 volt power supplies

## DESCRIPTION

The SSI 114 is an integrated read/write circuit designed for use with non-center tapped thin film heads in disk drive systems. Each chip controls four heads and has three modes of operation: read, write, and idle. The circuit contains four channels of read amplifiers and write drivers and also has an internal write current source.

A current monitor (IMF) output is provided that
allows a multichip enable fault to be detected. An enabled chip's output will produce one unit of current. An open collector output, write select verify (WSV), will go low if the write current source transistor is forward biased. The circuit operates on +5 volt, and -5 volt power and is available in a 24 pin flatpack.

# Thin Film - 4-Channel Read/Write Circuit SSI 114 

## CIRCUIT DESCRIPTION

## WRITE MODE

In the write mode ( $R / \bar{W}$ and CE low) the circuit functions as a differential current switch. The Head Select inputs (HS1 and HS2) determine the selected head. The Write Data Inputs (WD, $\overline{W D}$ ) determine the polarity of the head current. The write current magnitude is adjustable by an external $1 \%$ resistor, $\mathbf{R}_{\mathbf{X}}$ from VWC to VCC, where

$$
I_{W}=\frac{K_{W}}{R_{X}\left(1+\frac{R_{h}}{R_{d}}+\frac{R_{h}}{1 k}\right)}-0.7 m A
$$

Where $\mathrm{K}_{\mathrm{W}}=$ Current Gain Factor $=130$ Amp-Ohms
$R_{h}=$ Head plus External Wire Resistance
$R_{d}=$ Damping Resistance

## READ MODE

In the Read Mode, (R/W high and CD low), the circuit functions as a differential amplifier. The amplifier input terminals are determined by the Head Select inputs.

## Data Sheet

SSI 115 Block Diagram

SSI 115 Pin Out (Top View)

* Do not connect to any etch or any part of any circuit

## FEATURES

- Electrically compatible with 8 inch and 5-1/4 inch Winchester disk drive magnetic recording heads.
- Supports up to five recording heads per circuit.
- Detects and indicates unsafe write conditions.
- On-chip current diverter eliminates the need for
external write current switching.
- Control signals are TTL compatible.
- Operates on standard +5 volt and -5 volt (or -5.2 volt) power sources.

## DESCRIPTION

The SSI 115 is a monolithic bipolar integrated circuit designed for use with 8 inch and 5-1/4 inch Winchester disk drive magnetic recording heads. The circuit interfaces with up to five magnetic recording heads providing the required read/write electronic functions as well as various control and data protect functions. The
circuit operates on +5 volt and -5 volt (or -5.2 volt) power and is available in a variety of packages. The $115 / 24$ is a 5 channel circuit available in both flatpack and dip packages. The $115 / 22$ is a 4 channel circuit packaged in a 22 pin dip and the $115 / 18$ is a 2 channel circuit offered in a 18 pin dip package.

## CIRCUIT OPERATION

## WRITE MODE

With both the chip enable and write select signals actıvated, the SSI 115 is switched to the write mode and the circuit operates as a differential current switch. The center tap head voltage (VCT) is turned on, the unsafe circuit detector is activated, and the current diverter is disabled. The head select signals (HS1, HS2, HS3) select one of five differential current switches. The selected current switch senses the polarity of the data input signal ( $\mathrm{Dx}-\mathrm{Dy}$ ) and gates write current to the corresponding side of the head (HN1 or HN2). Head overshoot voltages that occur during normal write operation are sensed to determıne safe or unsafe head circuit conditions. The detector senses the following unsafe conditions - no data transitions, head open, or no write current.

## READ MODE

With chip enable actıve and write select disabled, the SSI 115 is switched to the read mode and the circuit operates as a differential amplifier. The center tap head voltage is turned off, the unsafe circuit detector is deactivated, and the write current diverter is enabled. The differential head input sıgnal (HN1-HN2), selected by the head select signals, is amplified by a differential read amplifier and appears as a differential output signal on the data lines ( $D x, D y$ ).

During the read and idle modes, the on-chip current diverter circuit prevents write current from flowing in the head circuits. Therefore, external gating of the write current source is not required.

## Data Sheet

## GENERAL DESCRIPTION

The SSI 117 devices are bipolar monolithic integrated circuits designed for use with center-tapped ferrite recording heads. They provide a low noise read path, write current control, and data protection circuitry for as many as six channels. The SSI 117 requires +5 V and +12 V power supplies and is available in 2,4 , or 6 channel versions with a variety of packages.
The SSI 117R differs from the SSI 117 by having internal damping resistors.

FEATURES

- +5V, + 12V power supplies
- Single- or multi-platter Winchester drives
- Designed for center-tapped ferrite heads
- Programmable write current source
- Available in 2, 4, or 6 channels
- Easily multiplexed for larger systems
- Includes write unsafe detection
- TTL compatible control signals

SSI 117 Block Diagram

## Circuit Operation

The SSI $117^{\prime}$ functions as a write driver or as a read amplifier for the selected head. Head selection and mode control are described in Tables $2 \& 3$. Both $R \bar{W}$ and $\overline{C S}$ have internal pull up resistors to prevent an accidental write condition.

## WRITE MODE

The Write mode configures the SSI 117A as a current switch and activates the Write Unsafe Detector. Head current is toggled between the $X$ - and $Y$-side of the recording head on the falling edges of WDI, Write Data Input. Note that a preceding read operation initializes the Write Data Flip Flop, WDFF, to pass current through the X -side of the head. The magnitude of the write current, given by
Iw $=$ K/Rwc, where $K=$ Write Current Constant is set by the external resistor, Rwc, connected from pin WC to GND.

## TABLE 1: PIN DESCRIPTIONS

| Symbol | Name - Description |
| :--- | :--- |
| HSO - HS2 | Head Select: selects up to six heads |
| $\overline{\mathrm{CS}}$ | $\overline{\text { Chip Select: a low level enables device }}$ |
| R $\overline{\mathrm{W}}$ | Read/ $\overline{\text { Write: a high level selects Read }}$ <br> mode |
| WUS | Write Unsafe: a high level indicates an <br> unsafe writing condition |
| WDI | Write Data In: a negative transition <br> toggles the direction of the head <br> current |
| H0X - H5X <br> HOY - H5Y | X, Y head connections |
| RDX, RDY | X, Y Read Data: differential read signal <br> out |
| WC | Write Current: used to set the <br> magnitude of the write current |
| VCT | Voltage Center Tap: voltage source for <br> head center tap |
| VCC | +5 V |
| VDD1 | +12 V |
| VDD2 | Positive power supply for the Center <br> Tap voltage source |
| GND | Ground |

Any of the following conditions will be indicated as a high level on the Write Unsafe, WUS, open collector output.

- Head open
- Head center tap open
- WDI frequency too low
- Device in Read mode
- Device not selected
- No write current

After the fault condition is removed, two negative transitions on WDI are required to clear WUS.

## READ MODE

In the Read mode the SSI 117A is configured as a low noise differential amplifier, the write current source and the write unsafe detector are deactivated, and the write data flip flop is set. The RDX and RDY outputs are driven by emitter followers and are in phase with the " $X$ " and " $Y$ " head ports. They should be AC coupled to the load.
Note that the internal write current source is deactivated for both the Read and the chip deselect mode. This eliminates the need for external gating of the write current source.

## Data Sheet

## GENERAL DESCRIPTION

The SSI 117A devices are bipolar monolithic integrated circuits designed for use with center-tapped ferrite recording heads. They provide a low noise read path, write current control, and data protection circuitry for as many as six channels. The SSI 117A requires +5 V and +12 V power supplies and is available in 2,4 , or 6 channel versions with a variety of packages.

The SSI 117AR differs from the SSI 117A by having internal damping resistors.

FEATURES

- $+5 \mathrm{~V},+12 \mathrm{~V}$ power supplies
- Single- or multi-platter Winchester drives
- Designed for center-tapped ferrite heads
- Programmable write current source
- Available in 2, 4, or 6 channels
- Easily multiplexed for larger systems
- Includes write unsafe detection
- TTL compatible control signals

SSI 117A Block Diagram

## Circuit Operation

The SSI 117A functions as a write driver or as a read amplifier for the selected head. Head selection and mode control are described in Tables 2 \& 3. Both R $\bar{W}$ and $\overline{\mathrm{CS}}$ have internal pull up resistors to prevent an accidental write condition.

## WRITE MODE

The Write mode configures the SSI 117A as a current switch and activates the Write Unsafe Detector. Head current is toggled between the X - and Y -side of the recording head on the falling edges of WDI, Write Data Input. Note that a preceding read operation initializes the Write Data Flip Flop, WDFF, to pass current through the X -side of the head. The magnitude of the write current, given by
Iw = K/Rwc, where K = Write Current Constant is set by the external resistor, Rwc, connected from pin WC to GND.

## TABLE 1: PIN DESCRIPTIONS

| Symbol | Name - Description |
| :---: | :---: |
| HSO - HS2 | Head Select: selects up to six heads |
| $\overline{\mathrm{CS}}$ | Chip Select: a low level enables device |
| R/ $\bar{W}$ | Read/Write: a high level selects Read mode |
| WUS | Write Unsafe: a high level indicates an unsafe writing condition |
| WDI | Write Data In: a negative transition toggles the direction of the head current |
| $\begin{aligned} & \text { HOX - H5X } \\ & \text { HOY - H5Y } \end{aligned}$ | $\mathrm{X}, \mathrm{Y}$ head connections |
| RDX, RDY | X, Y Read Data: differential read signal out |
| WC | Write Current: used to set the magnitude of the write current |
| VCT | Voltage Center Tap: voltage source for head center tap |
| VCC | +5V |
| VDD1 | + 12V |
| VDD2 | Positive power supply for the Center Tap voltage source |
| GND | Ground |

Any of the following conditions will be indicated as a high level on the Write Unsafe, WUS, open collector output.

- Head open
- Head center tap open
- WDI frequency too low
- Device in Read mode
- Device not selected
- No write current

After the fault condition is removed, two negative transitions on WDI are required to clear WUS.

## READ MODE

In the Read mode the SSI 117A is configured as a low noise differential amplifier, the write current source and the write unsafe detector are deactivated, and the write data flip flop is set. The RDX and RDY outputs are driven by emitter followers and are in phase with the " $X$ " and " $Y$ " head ports.

Note that the internal write current source is deactivated for both the Read and the chip deselect mode. This eliminates the need for external gating of the write current source.

## Preliminary Data Sheet

## GENERAL DESCRIPTION

The SSI 188 is a high-performance, bipolar integrated read/write circuit for use with center tapped, ferrite heads. It provides a low noise read path, write control circuitry and data protection circuitry for 4 channels. The SSI 188 requires +6.5 V and -5.2 V power supplies. It is available in a 24 pin flat pack.

FEATURES

- Fast switching characteristics
- TTL compatible control signals
- Four head capacity
- Designed for center-tapped ferrite heads
- Includes write unsafe detection
- Easily multiplexed

## Circuit Operation

The SSI 188 has 3 selectable modes of operation as illustrated in Table 2. The R/W and $\overline{\mathrm{CS}}$ inputs which determine these modes have internal resistor pullups to prevent an accidental write condition. Depending on the mode selected, the chip performs as a write gate or read amplifier for the selected head. Table 3 shows proper head addressing. In the Idle mode all inputs and outputs are in a high-impedance state, except the WC pin which is diverted to GND.

## Write Mode

In this mode, externally supplied write current is gated to the " X " side of the chosen head when the DX input is low and to the " Y " side when DY is low. The write unsafe detector is activated when the SSI 188 is in the write mode. A low on the WUS pin indicates one of the following unsafe conditions:

- Head open or shorted
- No write current
- No write data transitions

During a normal write cycle the pin is initially low and then goes high after the differential input makes two transitions. Two transitions are also needed to clear $\overline{\text { WUS }}$ after a fault condition.

## Read Mode

The SSI 188 amplifies the differential signal on the addressed head when in the read mode. The amplified signal is output on the open-collector DX and DY pins, with a gain dependent on external resistors tied from each pin to ground. The nominal values listed in this data sheet were obtained with 50 ohm resistors and can be doubled by using 100 ohm resistors. Polarity is such that the DX output is more positive when the " $X$ " side of the head is more positive. External gating of the write current source is not necessary because an on-chip diverter circuit prevents the write current from flowing in the head circuits during the read and idle modes.

Table 1: Pin Descriptions

## Temperature Monitoring

Two sets of series diodes are included on the chip for junction temperature monitoring. Between both the HSO and HS1 pads to GND, two diodes are connected in series as shown in the figure below.

To calibrate the diodes remove power from the SSI 188, pull down on the HSO or HS1 pin with a constant current and measure the diode forward bias voltage as the temperature is varied. To monitor temperature measure the diode forward bias voltage in either read or write

mode and compare to the previously determined calibration curve.

## Applications

These circuits are suggested for interfacing the differential DX and DY lines and either ECL or TTL data.

## Data Sheet

GENERAL DESCRIPTION
The SSI 501/501R devices are bipolar monolithic integrated circuits designed for use with center-tapped ferrite recording heads. They provide a low noise read path, write current control, and data protection circuitry for eight channels. The SSI 501/501R requires +5 V and +12 V power supplies and is available in a variety of packages. The SSI 501R differs from the SSI 501 by having internal damping resistors.

FEATURES

- +5 V , +12 V power supplies
- Single- or multi-platter Winchester drives
- Designed for center-tapped ferrite heads
- Programmable write current source
- Easily multiplexed for larger systems
- Includes write unsafe detection
- TTL compatible control signals

SSI 501/501R Block Diagram

## Circuit Operation

The SSI 501/501R functions as a write driver or as a read amplifier for the selected head. Head selection and mode control are described in Tables 2 \& 3. Both R $\bar{W}$ and $\overline{\mathrm{CS}}$ have internal pull up resistors to prevent an accidental write condition.

## WRITE MODE

The Write mode configures the SSI 501/501R as a current switch and activates the Write Unsafe Detector. Head current is toggled between the X - and Y -side of the recording head on the falling edges of WDI, Write Data Input. Note that a preceding read operation initializes the Write Data Flip Flop, WDFF, to pass current through the X -side of the head. The magnitude of the write current, given by
Iw $=$ K/Rwc, where $\mathrm{K}=$ Write Current Constant
is set by the external resistor, Rwc, connected from pin WC to GND.

TABLE 1: PIN DESCRIPTIONS

| Symbol | Name - Description |
| :---: | :---: |
| HSO - HS2 | Head Select |
| $\overline{\mathrm{CS}}$ | Chip Select: a low level enables device |
| $R / \bar{W}$ | Read/Write: a high level selects Read mode |
| WUS | Write Unsafe: a high level indicates an unsafe writing condition |
| WDI | Write Data In: a negative transition toggles the direction of the head current |
| $\begin{aligned} & \text { HOX - H7X } \\ & \text { HOY }-\mathrm{H} 7 \mathrm{X} \end{aligned}$ | $\mathrm{X}, \mathrm{Y}$ head connections |
| RDX, RDY | X, Y Read Data: differential read signal out |
| WC | Write Current: used to set the magnitude of the write current |
| VCT | Voltage Center Tap: voltage source for head center tap |
| VCC | $+5 \mathrm{~V}$ |
| VDD1 | + 12V |
| VDD2 | Positive power supply for the Center Tap voltage source |
| GND | Ground |

Any of the following conditions will be indicated as a high level on the Write Unsafe, WUS, open collector output.

- Head open
- Head center tap open
- WDI frequency too low
- Device in Read mode
- Device not selected
- No write current

After the fault condition is removed, two negative transitions on WDI are required to clear WUS.

## READ MODE

In the Read mode the SSI 501/501R is configured as a low noise differential amplifier, the write current source and the write unsafe detector are deactivated, and the write data flip flop is set. The RDX and RDY outputs are driven by emitter followers and are in phase with the " $X$ " and " $Y$ '" head ports. They should be AC coupled to the load.
Note that the internal write current source is deactivated for both the Read and the chip deselect mode. This eliminates the need for external gating of the write current source.

Note 2 A ferrite bead (Ferroxcube 5659065/4A6) can be used to suppress write current overshoot and ringing induced by flex cable parasitics Note 3 Limit DC current from RDX and RDY to 100 uA and load capacitance to 20pF
Note 4 Damping resistors required on SSI 501 only

## SSI 501/501R Pin Assignments

No responsibility is assumed by SSi for use of this product nor for any infringements of patents and trademarks or other rights of third parties resulting from its use No license is
granted under any patents, patent rights or trademarks of SSI SSi reserves the right to make changes in specifications at any time and without notice

## Preliminary Data Sheet

## GENERAL DESCRIPTION

The SSI 510 devices are bipolar monolithic integrated circuits designed for use with center-tapped ferrite recording heads. They provide a low noise read path, write current control, and data protection circuitry for as many as four channels. The SSI 510 requires +5 V and +12 V power supplies and is available in a variety of packages.

The SSI 510R differs from the SSI 510 by having internal damping resistors.

## FEATURES

- $+5 \mathrm{~V},+12 \mathrm{~V}$ power supplies
- Single- or multi-platter Winchester drives
- Designed for center-tapped ferrite heads
- Programmable write current source
- Easily multiplexed for larger systems
- Includes write unsafe detection
- TTL compatible control signals

SSI 510 Block Diagram

## Circuit Operation

The SSI 510 functions as a write driver or as a read amplifier for the selected head. Head selection and mode control are described in Tables 2 \& 3. Both R/W and $\overline{\mathrm{CS}}$ have internal pull up resistors to prevent an accidental write condition.

## WRITE MODE

The Write mode configures the SSI 510 as a current switch and activates the Write Unsafe Detector. Head current is toggled between the X - and Y -side of the recording head on the falling edges of WDI, Write Data Input. Note that a preceding read operation initializes the Write Data Flip Flop, WDFF, to pass current through the X -side of the head. The magnitude of the write current, given by
Iw $=$ K/Rwc, where $K=$ Write Current Constant is set by the external resistor, Rwc, connected from pin WC to GND.

A Voltage Fault detection circuit assures Data Security by preventing application of Write Current during power sequencing or power loss.

## TABLE 1: PIN DESCRIPTIONS

| Symbol | Name - Description |
| :--- | :--- |
| HSO - HS1 | Head Select |
| $\overline{\text { CS }}$ | $\overline{\text { Chip Select: a low level enables device }}$ |
| R/ $\overline{\text { W }}$ | Read/Write: a high level selects Read <br> mode |
| WUS | Write Unsafe: a high level indicates an <br> unsafe writing condition |
| WDI | Write Data In: a negative transition <br> toggles the direction of the head <br> current |
| H0X - H3X <br> H0Y - H3Y | X, Y head connections |
| RDX, RDY | X, Y Read Data: differential read signal <br> out |
| WC | Write Current: used to set the <br> magnitude of the write current |
| VCT | Voltage Center Tap: voltage source for <br> head center tap |
| VCC | $+5 V$ |
| VDD1 | $+12 V$ |
| VDD2 | Positive power supply for the Center <br> Tap voltage source |
| GND | Ground |

Any of the following conditions will be indicated as a high level on the Write Unsafe, WUS, open collector output.

- Head open
- Head center tap open
- WDI frequency too low
- Device in Read mode
- Device not selected
- No write current

After the fault condition is removed, two negative transitions on WDI are required to clear WUS.

## READ MODE

In the Read mode the SSI 510 is configured as a low noise differential amplifier, the write current source and the write unsafe detector are deactivated, and the write data flip flop is set. The RDX and RDY outputs are driven by emitter followers and are in phase with the " $X$ " and "Y" head ports. They should be AC coupled to load.
Note that the internal write current source is deactivated for both the Read and the chip deselect mode. This eliminates the need for external gating of the write current source.

## Preliminary Data Sheet

## DESCRIPTION

The SSI 520 is an integrated read/write circuit designed for use with non-center tapped thin film heads in disk drive systems. Each chip controls four heads and has three modes of operation: read, write, and idle. The circuit contains four channels of read amplifiers and write drivers and also has an internal write current source.

A current monitor (IMF) output is provided that allows a multichip enable fault to be detected. An enabled chip's output will produce one unit of current. An open collector output, write select verify (WSV), will go low if the write current source transistor is forward biased. The circuit operates on +5 volt, and -5 volt power and is available in a 24 pin flatpack. The SSI 520R differs from the SSI 520 by having internal damping resistors.

## FEATURES

- Thin film head compatible performance
- Four Read/Write Channels
- TTL - compatible logic levels
- Operates on standard +5 volt and $\mathbf{- 5}$ volt power supplies

SSI 520 Block Diagram

## CIRCUIT DESCRIPTION

## WRITE MODE

In the write mode ( $\mathrm{R} / \bar{W}$ and CE low) the circuit functions as a differential current switch. The Head Select inputs (HS1 and HS2) determine the selected head. The Write Data Inputs (WD, $\overline{W D}$ ) determine the polarity of the head current. The write current magnitude is adjustable by an external $1 \%$ resistor, Rwe, to VEE, where:

$$
I_{w}=\frac{V_{w c}}{R_{w c}\left(1+\frac{R_{h}}{R_{d}}\right)}
$$

Where $V_{\text {WC }}=$ Write Current Pin Voltage $=1.65 \pm 5 \%$
$R_{h}=$ Head plus External Wire Resistance
$\mathrm{R}_{\mathrm{d}}=$ Damping Resistance

## READ MODE

In the Read Mode, (R/W̄ high and CD low), the circuit functions as a differential amplifier. The amplifier input terminals are determined by the Head Select inputs.

## Data Sheet

## GENERAL DESCRIPTION

The SSI 521R is a bipolar monolithic integrated circuit designed for use with non-center tapped thin film recording heads. It provides a low noise read path, write current control, and data protection circuitry for up to six channels. The SSI 521R requires $+5 v$ and $+12 v$ power supplies and is available in a variety of packages.

FEATURES

- Designed for thin film heads
- +5V,+12V power supplies
- Ideal for multi-platter Winchester applications
- Programmable write current source
- Easily multiplexed for larger systems
- Includes write unsafe detection
- LSTTL compatible control signals

SSI 521R Block Diagram

CAUTION: Use handling procedures necessary for a static sensitive component

## CIRCUIT OPERATION

The SSI 521R functions as a write driver or as a read amplifier for the selected head. Head selection and mode control are described in Tables 2 \& 3. The inputs R/W, CS and WP have internal pull up resistors to prevent an accidental write condition.

## WRITE MODE

The Write mode configures the SSI 521R as a current switch and activates the Write Unsafe Detector. Head current is toggled between the X - and Y -direction of the recording head on the falling edges of WDI, Write Data Input. Note that a preceding read operation initializes the Write Data flip flop to pass current in the X-direction of the head. The magnitude of the write current, given by

$$
I w=\frac{V w c}{R w c}
$$

is controlled by an external resistor, Rwc, connected from pin WC to GND.
Head Current $\mathrm{lx}, \mathrm{y}=\frac{\mathrm{I} w}{1+\mathrm{Rh} / \mathrm{Rd}}$
Any of the following conditions will be indicated as a high level on the Write Unsafe, WUS, open collector output.

- Head open-only when Iw $\geq=30 \mathrm{ma}$
- WDI frequency too low
- Device in Read mode
- Chip disabled
- No write current

After fault condition is removed, two negative transitions on WDI are required to clear WUS. The current monitor output (IMF) sinks one unit of current when the device is selected. This allows a multichip enable fault to be detected.
READ MODE
In the Read mode, the SSI 521R is configured as a low noise differential amplifier, the write current source and the write unsafe detector are deactivated, and the write data flip flop is set. The RDX and RDY outputs are driven by emitter followers. They should be AC coupled to the load.
Note that the internal write current source is deactivated for both the Read and the chip deselect mode.

## Data Sheet

GENERAL DESCRIPTION
The SSI 101A is a two stage differential amplifier applicable for use as a preamplifier for the magnetic servo head circuit of Winchester technology disk drives.

## FEATURES

- Very narrow gain range
- 30MHz bandwidth
- Electrically characterized at two power supply voltages: IBM Model 3340 compatible (8.3V) and standard OEM industry compatible (10V)
- Mechanically compatible with Model 3348 type head arm assembly
- SSI 101A-2 available to operate with a 12V power supply
- Packages include 8 pin DIP and custom 10-pin flatpack

SSI 101A Pin Configuration (Top View)

Plastic Dip

NOTE 1 Pin must be left open and not connected to any circuit etch

## Recommended Load Conditions

1. Input must be AC coupled
2. CC's are AC coupling capacitors
3. RL's are DC bias and termination resistors (recommended $130 \Omega$ )
4. REQ represents equivalent load resistance
5. For gain calculations $R P=\frac{R_{L} \cdot R_{E Q}}{R_{L}+R_{E Q}}$
6. Differential gain $=0.72 R p( \pm 18 \%)(R p$ in $\Omega)$
7. Ceramic capacitors $(0.1 \mu \mathrm{f})$ are recommended for good power supply noise filtering

## Absolute Maximum Ratings

## Data Sheet

## GENERAL DESCRIPTION

The SSI 116 is a high performance differential amplifier applicable for use as a preamplifier for the magnetic servo thin film head in Winchester disk drives.

FEATURES

- Narrow gain range
- 50 MHz bandwidth
- IBM 3370/3380-compatible performance
- Operates on either IBM-compatible voltages (8.3V) or OEM-compatible (10V)
- Packages include 8-pin CERDIP or Plastic DIP and custom 10-pin flatpack.
- SSI 116-2 available to operate with a 12V power supply

## Preliminary Data Sheet

## GENERAL DESCRIPTION

The SSI 531 Data Separator performs data synchronizatıon and write precompensation of encoded data. The interface of the SSI 531 is optimum for use with Western Digital's WD1010/WD2010 controller family.
The SSI 531 contains a high performance Phase Locked Loop for read data synchronization, a crystal controlled reference oscillator for write data synchronization, and write precompensation circuitry.
The SSI 531 employs an advanced bipolar technology which affords precise bit cell control without the need for external active components.
The SSI 531 requires a single +5 V power supply and is available in 24-pin DIP and 28-pin PLCC packages.

## FEATURES

- MFM \& RLL Data Synchronization.
- Optimized for use with the WD1010/WD2010 controller family.
- Fast acquisition Phase Locked Loop.
- 1F detection.
- Write precompensation.
- Write data resynchronized for reduced jitter.
- No external delay line or varactor diode required.
- Single +5 V power supply.

SSI 531 Block Diagram

## CIRCUIT DESCRIPTION

## Data Synchronization

Read Data synchronization is accomplished with a high performance, fast acquisition Phase Locked Loop (PLL). The input from the disk drive, ENCODED READ DATA, is phase locked with the VCO clock. The synchronized Read Data and the VCO clock divided by two are made available for external data extraction at the SYNCH READ DATA and READ CLOCK pins respectively.
The synchronized Read Data is synchronized in a jitterfree manner such that leading edge transitions occur at the center of READ CLOCK half cycles. This is accomplished by internally decoding and re-encoding using the READ CLOCK as a reference.
When READ GATE changes state, the VCO is stopped and restarted in phase with the PLL input which can be etther the internal Crystal Oscillator or ENCODED READ DATA. In this manner the lock time is reduced due to small angles of phase error. Limiting the phase error by restarting the VCO in phase with the input prevents the PLL from locking to harmonics and short lock times are assured. The correct phase of READ CLOCK is also ensured by resetting the N/2 Divider at the same time as the VCO restart.
When READ GATE is high, the $1 / 4$ CELL DELAY allows the Phase Detector to be enabled prior to when an edge of the encoded input is to occur This updates the PLL on a sampled basis and corrects for any phase error with each subsequent input pulse. When READ GATE is low the Phase Detector is contınuously enabled and the PLL is both phase and frequency locked to the reference oscillator. By locking the VCO to the reference oscillator it is virtualiy at the correct frequency when the PLL is switched to track ENCODED READ DATA
The following waveforms are a graphic representation of the PLL alternately locking to ENCODED READ DATA and the Crystal Oscillator.

With an ENCODED READ DATA input of 5 MHz , the final DC level of the VCO waveform is constant as shown with transients occurring at each edge of the READ GATE. The amplitude and duration of the VCO locking transient
is dependent on the initial phase error on switching (max is 0.5 rad.) as well as the damping factor and natural frequency of the loop. The lower two waveforms are an expansion of the ENCODED READ DATA and VCO IN signals showing the effect of disabling the VCO during reference switching and the subsequent stairstep characteristic of the VCO waveform as the PLL locks to the new input.
The synchronizer circuit separates the data and clock pulses using windows derived from the VCO output. The window edges are aligned with the opposite edge from that used to phase lock the VCO. Using a VCO running at twice the expected input frequency allows accurate centering of these windows about the expected bit positions.

## 1F Data Detection

The 531 provides a flag, 1F DETECT, that indicates a continuous stream of " 1 ' $s$ " or " 0 ' $s$ ".
The period of the 1F Detect Retriggerable One-Shot is set so that the sum of the $1 / 4$ Cell Delay and the One-Shot is nominally $1-1 / 4$ times the $2 F$ frequency data period. This results in the 1F DETECT output remaining high during a continuous high frequency input representing a field of " 1 's" and " 0 's". External components R1F and C1F at the 1F DETECT SET pin are used to set the One-Shot delay.
A Latch operates in conjunction with the One-Shot to guarantee a minimum 1F DETECT output pulse width of one data period.

## Write Precompensation

Write precompensation reduces the effect of intersymbol interference caused by magnetic transition proximity in the disk media. Compensation consists of shifting written data pulses in time to counteract the read back bit shifting caused by such interaction. The severity of the intersymbol interference is a function of radial velocity of the media, the magnitude of the write pulse and the data pattern. Typically, write precompensation is enabled at the same time as the write current level is reduced.
The COMP WRITE DATA output is a re-synchronized version of the MFM WRITE DATA input that has been time shifted, if needed, to reduce intersymbol interference. Re-synchronization, to the internal crystal oscillator, is performed to minimize bit jitter in the output waveform. The magnitude of the time shift, TC, is determined by the RC network at the PRECOMP SET pin and is applied as noted in Table 1 according to the states of EARLY, $\overline{\text { LATE }}$ and PRECOMP ENABLE. Figure 2 is a further illustration of these timing relationships.

Table 1: Write Precompensation Truth Table

| PRECOMP <br> Enable | EARLY | LATE | Delay |
| :---: | :---: | :---: | :---: |
| 0 | X | X | Constant |
| 1 | 0 | 0 | Illegal State |
| 1 | 0 | 1 | TN-TC |
| 1 | 1 | 0 | TN+TC |
| 1 | 1 | 1 | TN |

TN=Nominal Pulse Delay
TC=Magnitude of Time Shift

## Reference Oscillator

The crystal controlled oscillator serves as the system master clock for the write functions. Its frequency divided by two provides a WRITE CLOCK for an external MFM encoder. It is also used to re-synchronize the MFM WRITE DATA for precise timing control when writing data to the disk. A series resonant crystal should be used.

Additionally, the oscillator output is used as a standby reference for the PLL when READ GATE is low. This enables the PLL to lock rapidly to incoming data when required.
When an external system clock, is available it may be connected to XTAL1 and XTAL2 should be left open.

| Pin Name | Description |
| :---: | :---: |

Input Pins

| MFM WRITE <br> DATA | Write data to be resynchronized <br> and precompensated. Syn- <br> chronous with WRITE CLOCK. |
| :--- | :--- |
| PRECOMP <br> ENABLE | Enables precompensatıon to be <br> controlled by -EARLY or -LATE. |
| $\overline{\text { EARLY }}$ | When low causes the MFM <br> WRITE DATA pulses to be written <br> early. |
| $\overline{\text { LATE }}$ | When low causes the MFM <br> WRITE DATA pulses to be written <br> late. |
| ENCODED | MFM encoded read data pulses <br> from the read amplifier circuits. |
| READ DATA | Selects the reference input to the <br> PLL. Selects ENCODED READ <br> DATA when high, crystal oscillator <br> when low. |
| VCC | $+5 V$ |
| GND | Power and signal ground <br> connection. |

## Output Pins

| WRITE CLOCK | Crystal-controlled reference <br> oscillator frequency divided by <br> two. Used by the controller to <br> generate MFM WRITE DATA. |
| :--- | :--- |

$|$| Pin Name | Description |
| :--- | :--- |
| Output Pins (cont.) | Re-synchronized and precompen- <br> sated write data. |
| COMP WRITE <br> DATA | Voltage-controlled oscillator output <br> divided by two. SYNC READ DATA <br> is synchronized to this signal. |
| READ CLOCK |  |
| SYNC READ <br> DATA | Synchronized read data output. <br> Leading-edge transitions occur at <br> center of READ CLOCK half <br> cycles. |
| 1F DETECT | Flag used to locate strings of <br> MFM-encoded 1's or 0's in the <br> ENCODED READ DATA input. |

External Component Connection Pins

| XTAL1, XTAL2 | Connections for oscillator crystal. <br> If oscillator is not required, XTAL1 <br> may be driven by TTL logic signal <br> at twice the data rate and XTAL2 <br> left open. |
| :--- | :--- |
| PRECOMP SET | Pin for R-C network to control <br> write precompensation early and <br> late times. |
| 1F DETECT SET | Pin for R-C network to control the <br> 1F detect period. Component <br> values are dependent on the <br> minimum data period that will <br> keep 1F DETECT high. |
| 1/4 CELL DELAY | Pin for R-C network to control the <br> $1 / 4$ CELL DELAY. This allows the <br> Phase Detector to be enabled 1/4 <br> of the data period prior to receiv- <br> ing an MFM data input. |
| SET | Pins for the capacitor used in con- <br> junction with RF and RS to set the <br> VCO center frequency. |
| CF1, CF2 | Pin for resistors used in conjunc- <br> tion with capacitor to set the VCO <br> center frequency. |
| RF, RS | Output of phase detector, input to <br> loop filter |
| PD OUT | Control input of the VCO, for con- <br> nection of the loop filter output. |
| VCO IN |  |

## Applications Information

In a typical application the, SSI 531 is used with a Western Digital WD1010-05 Winchester Disk Controlier as shown in Figure 3.

Fig. 3 - Typical System Connections

Interface to the disk drive consists of the Read data input signal from the drive and the Write data output signal
from the SSI 531. All the other connections are with the WD1010 and external components.

## Loop Filter

The low pass filter serves several purposes, it attentuates high frequency components of the phase error signal from the phase detector and modifies the dynamics of the PLL.

In lock mode, the PLL can be approximately by the linear model shown in Figure 4.

Fig. 4 - Phase Locked Loop

Standard linear system analysis methods can then be used for analysis. The transfer functions of each of the blocks is as follows:
$K D=$ conversion factor for phase detector in $\mu \mathrm{A} /$ radian KVCO = VCO gain factor in radians/second volt
$F(s)=$ Low pass filter transfer function
Thus the closed loop transfer function is

$$
\begin{aligned}
& H(s)=\frac{\text { KDKVCO } F(s)}{N} \\
& S+\frac{K D K V C O ~ F(s)}{N}
\end{aligned}
$$

5 M bit/sec and $\mathrm{f}_{\text {in }}$ (i.e. for
preamble $\mathrm{N}=1$, for crystal reference $\mathrm{N}=0.5$ )

The transient performance and frequency response is highly dependent on the filter transfer function $F(s)$.
To obtain a zero phase error, a type 2 or higher system must be used. This necessitates the use of a filter transfer function with at least one pole at the origin to obtain two poles at the loop gain origin. A detailed analysis supporting this choice can be found in Phaselock Techniques by Gardner¹. The filter shown in Figure 5 can be used which will give independent control of the damping factor and natural frequency of the closed loop function. Proper choice of capacitors C1 and C2 will effect loop settling time and stability. More complex filters can be used that give finer control over loop parameters and enhance performance even further.

[^13]

Fig. 5 - Loop Filter Example

## $\mathbf{V}_{\mathbf{C O}}$ Free Running Frequency

The external components RF, RS and CF, are chosen to set the VCO frequency at twice the ENCODED READ DATA bit rate. For a symmetrical window, equal values of RF and RS are used. Increasing the ratio RF/RS causes the detection window to occur earlier in time with respect to ENCODED READ DATA. Decreasing the ratıo has the opposite effect, the value of the time shift is:

$$
\mathrm{T}=\mathrm{TVCO}(\mathrm{RF}-\mathrm{RS}) /(\mathrm{RF}+\mathrm{RS})
$$

# silicon sustems INNOVATORS IN INTEGRATION 

## Preliminary Data Sheet

## GENERAL DESCRIPTION

The SSI 540 is a bipolar integrated circuit that provides all data processing necessary for detection and qualification of MFM read signals from rigid media. ST506 compatible interfacing is provided for write data signals, head select lines and recovered read data as applicable.
In read mode the SSI 540 provides amplification, differentiation and time domain qualification of head preamplifier outputs. The recovered data is available at the output of a differential line driver that conforms to the ST506 interface specification. In write mode the SSI 540 provides a differential line receiver conforming with ST506 requirements. Schmitt Trigger inputs on head select lines and an open collector output for voltage fault indication are provided for interface compatibility. All other logic inputs and outputs are TTL compatible.
The SSI 540-2 is a dual ground version for use in noisier environments. In order to provide this feature the number of head select lines is reduced to 2.
Two other versions of the SSI 540 are available that offer subsets of the above configurations. The SSI 540-3 has dual grounds and an open-collector RD output instead
of a differential line-driver output. The SSI 540-4 has the same features as the SSI 540-3 but also deletes the head select buffers. The SSI 540-4 is available in a 22 -Pin dip.
When used with a read/write preamplifier (i.e. SSI 117 or SSI 501), the SSI 540 or SSI 540-2 and required external passive components perform all read/write signal processing necessary between the heads and the interface connector of an ST506 compatible Winchester disk drive. With the SSI 540-3 and SSI 540-4 a line driver is required.

## FEATURES

- Differential Read and Write Ports
- Schmitt Trigger Head Select Inputs for Higher Noise Immunity
- Programmable Gain
- Time Domain Pulse Qualification Supports MFM Encoded Data Retrieval
- Supply Voltage Fault Detection
-     + 12 Volt and +5 Volt Power Supplies
- I/O Meets ST506 Requirements
- Dual-In-Line and Surface Mount Packages Available
- Adjustible Time Domain Filter and Output Pulse Width Settings

## Circuit Operation

In both read and write modes, Schmitt Trigger inputs are used to buffer the three head select lines providing the increased noise immunity required of a ST506 interface. A power supply monitoring function, VFLTB, is provided to flag a low voltage fault condition if either supply is low. A low voltage fault condition results in a low level output on the VFLTB pin.

## READ MODE

In the read mode (MODE input high) the read signal is detected, time domain qualified and made available at RD + and RD - as differential MFM encoded data, or at the RD + open collector output. This is accomplished by the on-board Amplifier, Differentiator, Zero Crossing Detector, Time Domain Filter, Output One Shot and Line Driver circuits.
The amplified and filtered read back sıgnal, which contaıns pulses corresponding to magnetıc transitions in the media is AC coupled into the input amplifier. A resistor, Rg, connected between pins G + and G-is used to adjust the 1st stage amplifier gain accordıng to the following expression

$$
A v_{1}=\frac{680}{17+R x} \quad \text { Where } R x=\frac{94 x(R g+42)}{230+R g}
$$

First stage gain can be monitored at the DIF + and DIF - pins.
The amplifier is followed by an active differentiator whose external network serves to transform peaks in the input signal into zero-crossings while maintaining the time relationship of the original input peaks. Differentiator response is set by an external capacitor or more complex series LRC network between the DIF + and DIF - pins. The transfer function with such a network is:

$$
\mathrm{Av}_{2}=\frac{-1420 \operatorname{Cexs}}{\text { LexCex s}{ }^{2}+(\operatorname{Rex}+46) \operatorname{Cex} s+1}
$$

where: $\quad$ Cex $=$ external capacitor ( 50 pf to 250 pf )
Rex = external resistor

$$
\text { Lex }=\text { external inductor }
$$

$$
s=j w=j 2 \pi f
$$

Total gain from $\mathrm{IN}+$ and IN - to OUT + and OUT - is: $A v=A v_{1} \times A v_{2}$
To reduce pulse pairing (bit shift), it is essential that the input to the zero-crossing detector be maximized to reduce the effect of any comparator offset. This means that the above gains should be chosen such that the differential voltage at OUT + and OUT - approaches 5 Vpp at max input and frequency.

The Differentiator output is AC coupled into a zerocrossing detector that provides an output level change at each positive or negative zero transition on its input. The zero-crossing detector output is coupled to a Time Domain Filter that eliminates false triggering of the output one-shot by spurious zero-crossings. The validity decision is based on a minimum duration between zero crossings that can be set externally by an RC network on the TD pin.
The output of the Time Domain Filter triggers a one-shot that defines the output pulsewidth based on an external RC network on the PW pin. These output pulses are fed into a line driver that provides a high-current differential output at RD + and RD - , or are made available as an open-collector output at RD + .

## Write Mode

In the write mode (MODE input low) the differential line receiver is enabled. This receiver accepts the differential data from the ST506 interface and outputs a TTL signal for the write data input of an external R/W amplifier. A low on the MODE input also puts the read outputs in a high impedance state, allowing several 540 's to be multiplexed on a bus.

## Layout Considerations

The SSI 540 is a high gain wide bandwidth device thatrequires care in layout. The designer should keep analog signal lines as short as possible and balanced. Analog test points should be provided with a probe ground in the immediate vicinity. Do not run digital signals under the chip or next to analog inputs. Use of a ground plane is recommended along with supply bypassing and separation of the SSI 540 ground from other circuits on the disk drive PCB.

## SSI 540 Series <br> Read Data Processor

## Design Example

As a design example a system using a 4-channel SSI 117 Read/Write preamplifier will be used.

Assumptions-coding scheme is MFM
-data rate is $5 \mathrm{Mbits} /$ second
-Ferrite head output is 1 mVpp min . and 2 mVpp max.
The output from the SSI 117 is 80 mVpp to 240 mVpp . Assuming a 6 dB loss through the external low pass filter the input to the SSI 540 at $I N+, I N-i s:$

40 mVpp to 120 mVpp differential voltage.
For this analysis the $\pm 37 \%$ tolerance on gain from IN + , IN - to OUT + , OUT - will be equally divided between the gain stage and the differentiator, so each will contribute a $\pm 17 \%$ variance from nominal values. The objective is to get a 5 Vpp signal at OUT + ,OUT - at max input and max frequency. For MFM the $2 f$ frequency in a $5 \mathrm{Mbit} / \mathrm{sec}$ data rate is $2.5 \mathrm{MHz}, 1 \mathrm{f}$ is 1.25 MHz .

## Gain Setting

Maximum gain from the amplifier occurs when $\mathrm{Rg}=0$. So calculating for nominal gain:

$$
\begin{aligned}
& \mathrm{Rx}=\frac{94 \times 42}{230}=17.17 \\
& \mathrm{Av}_{1}=\frac{680}{17+17.17}=19.9 \text { nominal or } 16.52 \mathrm{~min} \text { to } \\
& 23.28 \mathrm{max}
\end{aligned}
$$

The voltage swing at the DIF + , DIF - pins is:
$120 \mathrm{mVpp} \times 22.25=2.79 \mathrm{Vpp}$ max
$40 \mathrm{mVpp} \times 17.55=0.661 \mathrm{Vpp} \mathrm{min}$
This is within the 3.2 Vpp max guaranteed by this specification, so max gain will be used.

## Differentiator Design

The differentiator can be as simple as a capacitor or as complex as a series RLC network. In order not to violate
the 5 Vpp max spec at OUT + ,OUT - the maximum differential voltage gain is:

$$
\frac{5}{2.79}=1.79 \max \text { gain }
$$

which is nominally a gain of 1.53
For Cex only:

$$
\text { Cex }=\frac{1.53}{2 \pi f \sqrt{(1420)^{2}-(1.53 \times 46)^{2}}}=68 \mathrm{pf}
$$

check for current saturation:
Ic $=$ Cex $\times V p \times 2 \pi f$ must be less than 1.9 mA
For Cex, Rex network:
The following two formulas are used:

$$
\begin{aligned}
1.53 & =\frac{j 1420 \operatorname{Cex} 2 \pi f}{j(\operatorname{Rex}+46) \operatorname{Cex} 2 \pi f+1} \\
\operatorname{Rex}+46 & =\frac{1}{\operatorname{CexA} 2 \pi f \text { max }}
\end{aligned}
$$

where $A$ is chosen for position of corner frequency to reduce high frequency noise gain from the single capacitor network.
Graphically the method is as follows:

Check for current saturation using the following formula.

$$
\mathrm{Ip}=\frac{\mathrm{jVp} 2 \pi \mathrm{fCex}}{1+\mathrm{j} 2 \pi \mathrm{f} \operatorname{Cex}(\mathrm{R}+46)}
$$

For $R_{\text {ex }}, C_{\text {ex }}$, Lex networks, the following formulae are used ${ }^{\text {• }}$

$$
\text { Gain } \begin{aligned}
G= & \frac{-j 1420 C_{e x} 2 \pi f}{1-L_{e x} C_{e x}} \frac{(2 \pi f)^{2}+j\left(R_{e x}+46\right)}{} C_{e x} 2 \pi f \\
= & \frac{1420 C_{e x} 2 \pi f}{\left.\sqrt{\left[1-L_{e x} C_{e x}(2 \pi f)^{2}\right]^{2}+\left[\left(R_{e x}+46\right)\right.} C_{e x} 2 \pi f\right]^{2}} \\
& {\left[-\frac{\pi}{2}-\tan ^{-1}\left[\frac{\left(R_{e x}+46\right)\left(C_{e x} 2 \pi f\right.}{1-L_{e x} C_{e x}(2 \pi f)^{2}}\right]\right.}
\end{aligned}
$$

$$
\text { Center Freq } f_{n}=\frac{1}{2 \pi \sqrt{L_{e x} C_{\mathrm{ex}}}}
$$

$$
\text { Damping Factor } \zeta=\frac{\left(\mathrm{Rex}_{\mathrm{ex}}+46\right) \mathrm{C}_{\mathrm{ex}}}{2 \sqrt{\mathrm{Lex}_{\mathrm{ex}} \mathrm{C}_{\mathrm{ex}}}}
$$

Group Delay $\frac{d Q}{d f}=\frac{2 \zeta}{2 \pi f_{n}}\left[\begin{array}{c}1+\left(\frac{f}{f_{n}}\right)^{2} \\ 1+\left(4 \zeta^{2}-2\right)\left(\frac{f}{f_{n}}\right)^{2}+\left(\frac{f}{f_{n}}\right)^{4}\end{array}\right]$
This technique adds another pole to the differentiator response to attenuate high frequency noise. The center frequency damping ratio and group delay are chosen to meet system requirements. Values for the center frequency are usually from 2 to $10 f m a x$ and the damping factor may be from 03 to 1.

Graphically the method is as follows

As with the previous Rex, Cex example, care must be taken to insure a $90^{\circ}$ phase shift at the frequencies of interest ( 1 f and 2 f or 1.25 MHz and 2.5 MHz ). This requirement is modified by any need to compensate for phase distortion caused by preceeding signal processing.

## Effect of Gain Tolerance

At minimum gain the $1 \mathrm{~m} V_{P P}$ input at 1.25 MHz frequency has the following effects:

Using the capacitor only results with $\mathrm{C}_{\mathrm{ex}}=68 \mathrm{pf}$
Diff gain $=\frac{1420 \mathrm{C}_{\mathrm{ex}} 2 \pi f}{\sqrt{1+\left(46 \mathrm{C}_{\mathrm{ex} 2} 2 \pi \mathrm{f}\right)^{2}}}=0.758$ nominal
Using $\pm 17 \%$ tolerance, min gain $=0.629$
so with a 661 mV PP input the min voltage @ OUT + /OUT is 416 mV PP.

Thus, with all tolerances considered, a 1 m Vpp to 2 m Vpp input to the SSI 117 will result in a 5 Vpp to 416 mVpp input to the zero-crossing detector.

## ONE-SHOT CONSIDERATIONS

The timing for both one shots conform to the same equation: $\quad t=0.184 \times C \times R$

Setting of the time domain one-shot reflects the expected base line shouldering effect at the $1 f$ frequecy and is set accordingly. In this example the output pulse width has been set at approximately 30 nsec and the time domain filter at approximately 80 nsec .

## EXTERNAL FILTER

The filter on the output of the read/write amplifier, limits the bandwidth of the input to the SSI 540. This reduces the noise input to the differentiator which can produce spurious zero-crossings. The design of this filter is not discussed here, but general aspects of its transfer function will be discussed.
On the outer tracks of an ST506 compatible drive using a MFM coding technique, the output pulses return to baseline or exhibit shouldering.

This waveform has a high third harmonic content. In order to preserve this waveform the filter must not add any distortion to this harmonic. For this reason, the most common filter type used is a Bessel Filter which has a constant group delay ( $\frac{d \phi}{d t}$ ) or linear phase shift. Thus for a $5 \mathrm{Mbit} / \mathrm{sec}$ MFM waveform a Bessel Filter with constant group delay and a -3 dB point of 3.75 MHz is required. This is the type of filter used in the design example.

## Bit Shift or Pulse Pairing

Theoretical consideration of this aspect of pulse replication relative solely to the SSI 540 indicates that comparator offset is the major contributing parameter. For sinusoidal inputs the offset produces a nonsymetric waveform as shown.

The RD + ,RD - output pulses have been offset from true position (zero-crossing) by an amount $\Delta t$, that is dependent on Voffset and OUT + ,OUT - amplitude.

This relationship is

$$
\begin{aligned}
& \Delta t=\frac{1}{\mathrm{w}} \sin ^{-1}\left(\frac{\text { Voff }}{V p}\right) \text { (radians) } \\
& \text { So, referring to previous results: } \\
& \text { when OUT }+ \text {,OUT }-=5 \mathrm{Vpp} @ 2.5 \mathrm{MHz} \\
& \quad \Delta t=0.13 \mathrm{nsec} \\
& \text { when OUT }+ \text {,OUT }-=416 \mathrm{mVpp} @ 1.25 \mathrm{MHz} \\
& \quad \Delta t=3.1 \mathrm{nsec}
\end{aligned}
$$

As can be seen above the center pulse has been shifted from its true position by $2 \Delta t$. So for this example the Bit

Shift contributed by the SSI 540 is:
0.26 nsec at maximum input and frequency
6.2 nsec at minimum input and frequency

In some literature this effect is called Pulse Pairing. If the RD + ,RD - waveform is displayed on an oscilloscope with the trigger holdoff adjusted to fire on succeeding pulses the following waveform is observed:

where $\mathrm{t}_{2}-\mathrm{t}_{1},=4 \Delta \mathrm{t}$ or $2 \times$ (Bit Shift)
Using this technique and a sinusoidal input to $\mathrm{D}_{I N} \pm$ of varying amplitude at 1.25 MHz and 2.5 MHz , the following results were obtained.

| $D_{1 N} \pm$ Input |  |  |
| :---: | :---: | :---: |
| $\mathbf{V}_{\mathbf{p}-\mathbf{p}}$ | $R D \pm$ Pulse Jitter (4.t) nsec |  |

infringements of patents and trademarks or other rights of third parties resulting from its use No license is granted under any patents, patent rights or trademarks of SSI SSı reserves the right to make changes in specifications at any time and without notice.

SSI 541 Read Data Processor

## Preliminary Data Sheet

## DESCRIPTION

The SSI 541 is a bipolar integrated circuit that provides all data processing necessary for detection and qualification of MFM or RLL encoded read signals. The circuit will handle data rates up to 15 Megabits/sec.

In read mode the SSI 541 provides amplification and qualification of head preamplifier outputs. Pulse qualification is accomplished using level qualification of differentiated input zero crossings. An AGC amplifier is used to compensate for variations in head preamp output levels, presenting a constant input level to the pulse qualification circuitry.

The AGC loop can be disabled so that a constant gain can be used for embedded servo decoding or other processing needs.
In write mode the circuitry is disabled and the AGC gain stage input impedance switched to a lower level to allow fast setting of the input coupling capacitors during a write to read transition.

The SSI 541 requires +5 V and +12 V power supplies and is available in a 24 pin DIP and 28 pin PLCC.

## FEATURES

- Level qualification supports high resolution MFM and RLL encoded data retrieval
- Wide bandwidth AGC input amplifier
- Supports data rates up to 15 megabits/sec
- Standard $12 \mathrm{~V} \pm 10 \%$ and $5 \mathrm{~V} \pm 10 \%$ supplies
- Supports embedded servo pattern decoding
- Write to read transient suppression
- Fast and slow AGC attack regions for fast transient recovery

## SSI 541 Block Diagram

## CIRCUIT OPERATION Read Mode

In the read mode (R/WB input high or open) the input read signal is amplified and qualified using an AGC amplifier and pulse level qualification of the detected signal peaks.
The amplified head signals are AC coupled to the $\mathrm{IN}+$ and IN - pins of the AGC amplifier that is gain controlled by full wave rectifying and amplifying the (DIN+ - DIN - ) voltage level and comparing it to a reference level at the AGC pin. A fast attack mode, which supplies a 1.5 mA charging current for the capacitor at the BYP pin, is entered whenever the instantaneous DIN $\pm$ level is more than 125\% of set level. Between $100 \%$ and $125 \%$ the slow attack mode is invoked, providing 0.17 mA of charging current. The two attack modes allow rapid AGC recovery from a write to read transition while reducing zero crossing distortion once the amplifier is in range.
The level at the AGC pin should be set such that the differential voltage level at the DIN+, DIN- pins is 1.00 Vpp at nominal conditions. The circuit can swing 3.0 Vpp at the OUT+, OUT- pins which allows for up to 6 dB loss in any external filter connected between the OUT+, OUT- outputs and the DIN+, DIN- inputs.

Gain of the AGC section is nominally

$$
\frac{\mathrm{Av} 2}{\mathrm{Av} 1}=\exp \frac{\mathrm{V}_{2}-\mathrm{V} 1}{5.8 \times \mathrm{Vt}}
$$

Where: Av1 and Av2 are initial and final amplifier gains. V1, V2 are initial and final voltages on the BYP pin.
$\mathrm{Vt}=(\mathrm{Kx} \mathrm{T}) / \mathrm{q}=26 \mathrm{mV}$ at room temperature.
One filter for both data (DIN+, DIN - input) and clock (CIN+, CIN - input) paths, or a separate filter for each path may be used. If two filters are used, care must be exercised to control time delays so that each path is timed properly. A multi-pole Bessell filter is typically used for its linear phase or constant group delay characteristics.

The filtered data path signal is fed into a hysteresis comparator that is set at a fraction of the input signal level by using an external filter/network between the LEVEL and Hys pins. Using this approach allows setting the AGC slow attack and decay times slow enough to minimize distortion of the clock path signal. This "feedforward" technique, utilizing a fraction of the rectified data path input available at the LEVEL pin as the hysteresis threshold, is especially useful in the slow decay mode of the AGC loop. By using a short time constant for the hysteresis level, the qualification method can continue as the AGC amplifier gain is slowly ramped up. This level will also shorten the write to read transient recovery time without affecting data timing as the circuit will be properly decoding before the AGC gain has settled to its final value. The comparator output is the "D" input of a D type flip-flop. The DOUT pin provides a buffered test point for monitoring this function.

The filtered clock path signal is differentiated to transform signal peaks to zero-crossings which clock an edgetrigger circuit to provide output pulses at each zerocrossing. The pulses are used to clock the D type flipflop. The COUT pin is a buffered test point for monitoring this function.
The differentiator function is set by an external network between the DIF+, DIF- pins. The transfer function is:

$$
A V=\frac{-2000 C s}{L C s^{2}+(R+92) C s+1}
$$

Where: $\mathrm{C}=$ external capacitor (20pf to 150 pf )
$\mathrm{L}=$ external inductor
$R=$ external resistor
$s=j w=j 2 \pi f$
During normal operation the differentiator circuit clocks the D flip-flop on every positive and negative peak of the signal input to $\mathrm{CIN}+, \mathrm{CIN}-$. The D input to the flip-flop only changes state when the signal applied to the DIN+, DIN - inputs exceeds the hysteresis comparator threshold opposite in polarity to the previous peak that exceeded the threshold.
The clocking path, then, determines signal timing and the data path determines validity by blocking signal peaks that do not exceed the hysteresis comparator threshold.
The delays from CIN+, CIN- inputs to the flip-flop clock input and from the DIN+, DIN - inputs to the flip-flop $D$ input are well matched.

## WRITE (DISABLED) MODE

In the write or disabled mode (R/WB input low) the digital circuitry is disabled and the AGC amplifier input impedance is reduced. In addition the AGC amplifier gain is set to maximum so that the loop is in its fast attack mode when changing back to Read Mode. The lowered input impedance facilitates more rapid settling of the write to read transient by reducing the time constant of the network between the SSI 541 and a read/write preamplifier, such as the SSI 510.
Internal SSI 541 timing is such that this settling is accomplished before the AGC loop is activated when going to read mode. Coupling capacitors should be chosen with as low a value as possible, consistant with bandwidth requirements, to allow more rapid settling.

## LAYOUT CONSIDERATIONS

The SSI 541 is a high gain wide bandwidth device that requires care in layout. The designer should keep analog signal lines as short as possible and well balanced. Use of a ground plane is recommended along with supply bypassing and separation of the SSI 541 and associated circuitry grounds from other circuits on the disk drive PCB.

## PIN DESCRIPTION

| Pin Name | Description |
| :--- | :--- |
| VCC | 5 volt power supply |
| VDD | 12 volt power supply |
| AGND, DGND | Analog and Digital ground pins |
| R/WB | TTL compatible read/write control pin |
| IN+, IN- | Analog signal input pins |
| OUT+, OUT- | AGC Amplifier output pins |
| BYP | The AGC timing capacitor is tied between <br> this pin and AGND |
| HOLDB | TTL compatible pin that holds the AGC <br> gain when pulled low |
| AGC | Reference input voltage level for the AGC <br> circuit |
| DIN+, DIN- | Analog input to the hysteresis comparator |

## Preliminary Data Sheet

## DESCRIPTION

The SSi 545 is an integrated circuit which consolidates functions in a Winchester Disk Drive normally performed by a variety of LSTTL SSI and MSI devices. Varıous gates, comparators and flip-flops are used to format signals compatible with the ST 506 interface requirements. All ST 506 connections have the necessary output drive or input hysteresis consistent with bus signal needs. The SSi 545 uses a single +5 volt supply and is available in 40 pin DIP and 44 pin QUAD packages.

## FEATURES

- Reduces package count in $51 / 4^{\prime \prime}$ and smaller Winchester Disk Drives.
- Replaces bus interface and combinatorial logic devices between the ST 506 bus and on board processor and mechanical interfaces.
- Surface mount package available for further real estate reduction.

## Preliminary Data Sheet

## GENERAL DESCRIPTION:

The SSI 590 is a motor controller IC designed to provide all timing and control functions necessary to start, drive and brake a two-phase, four-pole, brushless DC spindle motor. The IC requires two external power transistors (such as Darlington power transistors), three external resistors, and an external frequency reference. The motor Hall sensor is directly driven and decoded by the device. The controller is optimized for a 3600 rpm disc drive motor using a 2 MegaHertz clock. Motor protection features include stuck rotor shutdown, coil over-current detection and control, and supply fault detection. The device's linear control loop controls the power drivers using Pulse Amplitude Modulation.

FEATURES:

- Available in 8 pin DIP (SSI 590-1) or 14 pin DIP (SSI 590-2).
- CMOS with single +12 volt power supply.
- All motor START, DRIVE, AND STOP timing and control.
- Includes Hall-Effect sensor drive and input pins.
- Highly accurate speed regulation of $+/-.035 \%$.
- Active braking function (590-2 only).
- On-chip digital filtering requires no external compensation or adjustments.
- Provides protection against stuck rotor, coil over-current, and supply fault.
- Regenerative braking with shutdown.

CAUTION: Use handling procedures necessary for a static sensitive component.

## SSI 590

## CONTROL LOOP DESCRIPTION:

The device incorporates both analog and digital circuit techniques to utilize the advantages of each. The analog portion of the loop uses switched capacitor filter technology to eliminate external components. The control loop uses a Pulse Amplitude Modulation (PAM) control scheme to avoid the switching transients and torque ripple inherent in Pulse Width Modulation (PWM) schemes.

A binary counter is preset once per motor revolution by an index signal generated by the hall position sensor. On the next index pulse, the remaining least significant bits are loaded into the proportional D/A and accumulated by a saturating accumulator. The most significant bits are loaded into the integral D/A. The size of the accumulator and the bit locations determine the major scaling (within a factor of two) for the gain and zero location of the filter. To prevent overflow in the proportional D/A the counter is decoded to detect overflow, and the proportional D/A is saturated as needed. The overflow also generates a boost signal used in the summer. The range of the accumulator is larger than the linear range of the proportional channel to help filter small load disturbances that tend to saturate the proportional channel. The entire counter is also used to provide a time-out feature to protect the motor and external circuitry.

## INPUT/OUTPUT PIN DESCRIPTION:

* FREF (frequency reference input)

A TTL compatible input used by the device to set and maintain the desired motor speed and operate circuit blocks.

* HALLOUT

Provides a regulated bias voltage for the Hall effect sensor inside the motor.

* HALLIN (Hall sensor input)

The TTL open-collector type output of the motor's Hall switch feeds this input which has a resistor pullup to the HALLOUT bias voltage. Refer to figure 1 for input timing.

* OUTA, OUTB (driver outputs)

These two driver outputs drive the external power transistors, such as TIP120 NPN darlington power transistors as shown in the typical application. The power transistors control the motor current through the current setting resistor Re. The motor current is V (sense)/Re. During normal operation, the drive voltages are adjusted as necessary to maintain the proper motor speed and drive current. Regenerative braking is accomplished with self biasing of the power transistors thru resistors Rb with power shutdown. Refer to figure 1 for output timing.

* SENSE (coil current sense line)

Senses the coil current and limits the sense voltage to the threshold by limiting the drive to the external power transistors.

* START (active brake control, only available on 14 pin package)
The active brake is enabled by applying a logic " 0 " to the START pin. During active braking the output phasing is reversed to apply a reverse torque to the motor until the motor period drops below the reverse shutdown speed at which time the drivers turn off the external power transistors to deny power to the motor. Active braking is shown in figure 1.
* N/C (no connection, 14 pin package only)

These pins must remain unconnected and floating.

## PROTECTION FEATURES:

## * LOW VOLTAGE DETECTION

If the supply drops below the detect threshold the device will turn off all of the external power transistors to prevent damage to the motor and the power devices.

## * STUCK ROTOR SHUTDOWN

If the delay from power onset to a positive Index transition or the time interval between successive Index transitions is greater than the prescribed time, the device interprets this delay as a stuck rotor and reduces the motor current to zero until such time as one positive HALLIN transition is detected or until power is removed and reapplied.

## * MOTOR COIL OVER-CURRENT

Refer to SENSE input description. Sense voltage is generated by current through Re shown in the typical application. The SENSE input threshold limits the maximum coil current.

## Preliminary Data Sheet

## General Description

The SSI 591 is a motor controller IC designed to provide all timing and control functions necessary to start, drive and brake a three-phase brushless DC spindle motor. The IC requires three external power transistors (such as Darlington power transistors), one external power resistor, and an external frequency reference. The three motor Hall sensors are directly driven and decoded by the device. The controller is optimized for a 3600 rpm disc drive motor using a 2 Mega-Hertz clock. Motor protection features include stuck rotor shutdown, supply and clock fault detection, all of which are indicated by a FAULT signal, and coil over-current detection and control. A LOCK signal is provided to indicate that the motor is at speed. The device's linear control loop controls the power drivers using Pulse Amplitude Modulation.

## FEATURES:

- CMOS with TTL/LSTTL compatible control functions
- Single +12 volt power supply
- All motor START, DRIVE, AND STOP timing and control.
- Includes Hall-Effect sensor drive and input pins.
- Highly accurate speed regulation of $+I-.05 \%$.
- Active braking function.
- On-chip digital filtering requires no external compensation of adjustments.
- Provides protection against stuck rotor, motor coil over-current, supply fault, or clock fault.
- At speed indication provided.

CAUTION: Use handling procedures necessary
for a static sensitive component.

TYPICAL APPLICATION

## CONTROL LOOP DESCRIPTION

The device incorporates both analog and digital circuit techniques to utilize the advantages of each. The analog portion of the loop uses switched capacitor filter technology to eliminate external components. The control loop uses a Pulse Amplitude Modulation (PAM) control scheme to avoid the switching transients and torque ripple inherent in Pulse Width Modulation (PWM) schemes.

A binary counter is preset once per motor revolution by an index signal generated by Hall position sensor 1. On the next index pulse, the remaining least significant bits are loaded into the proportional D/A and accumulated by a saturating accumulator. The most significant bits are loaded into the integral D/A. The size of the accumulator and the bit locations determine the major scaling (within a factor of two) for the gain and zero location of the filter. To prevent overflow in the proportional D/A, the counter is decoded to detect overflow and the proportional D/A is saturated as needed. The overflow also generates a boost signal used in the summer. The range of the accumulator is larger than the linear range of the proportional channel to help filter small load disturbances that tend to saturate the proportional channel. The entire counter is also used to provide a time-out feature to protect the motor and external circuitry.

## INPUT/OUTPUT PIN DESCRIPTION

* FREF (frequency reference input)

A TTL compatible input used by the device to set and maintain the desired motor speed and operate circuit blocks.

* HALLOUT (Hall sensor bias output)

Provides a regulated bias voltage for the Hall effect sensors inside the motor.

* HALL1, HALL2, HALL3 (Hall sensor inputs) The TTL open-collector type outputs of the motor's Hall switches feed these inputs which have a resistor pullup to the HALLOUT bias voltage. The HALL1 input is used to index the control loop counter. Refer to figure 1 for input timing.
* OUTA, OUTB, OUTC (driver outputs)

These three driver outputs drive the external power transistors, such as TIP120 NPN darlington power transistors shown in typical application. The power transistors control the motor current through the current setting resistor Re. The motor current is V (sense)/Re. During normal operation, the drive voltages are adjusted as necessary to maintain the proper motor speed and drive current. Refer to figure 1 for output timing.

* SENSE (coil current sense input)

Senses the coil current and limits the sense voltage to the threshold by limiting the drive to the external power transistors.

* LOCK (at speed indicator output)

An open drain LSTTL compatible output that indicates with an active low that the period of the motor is within the controllers linear range. Because of the accuracy of the loop, the LOCK pin is a good "at speed" indicator.

* START (active brake control input) The active brake is enabled by appling a logic " 0 " to the START pin. During active braking the Hall sensor's phasing is changed to apply a reverse torque to the motor until the motor period drops below the reverse shutdown speed at which time the drivers turn off the external power transistors to deny power to the motor. Active braking is shown in figure 1.
* FAULT (fault indicator output)

Goes high when the motor is determined to be stalled, $V_{D D}$ is low, or FREF clock is too slow.

* N/C (no connection)

These pins must be left unconnected and floating.

## PROTECTION FEATURES:

## * LOW VOLTAGE DETECTION

If the supply drops below the detect threshold, the device will turn off all of the external power transistors to prevent damage to the motor and the power devices. The FAULT pin goes high in this condition.

* STALLED ROTOR SHUTDOWN

If the delay from power onset to a positive Index transition or the time interval between successive index transitions is greater than the prescribed time, the device interprets this delay as a stalled rotor and reduces the motor current to zero until such time as one positive Index transition is detected or until power is removed and reapplied. The FAULT output goes high when the motor is determined to be stalled.

* MOTOR COIL OVER-CURRENT

Refer to SENSE input description. Senses voltage is generated by current through Re shown in the typical application. The SENSE input threshold limits the maximum coil current.

* FREF CLOCK FAULT

If the FREF frequency drops below the specified minimum frequency, the driver will shut down and the FAULT pin will go high.

## *CONTROL LOOP NOTES:

Running current limits refer to capabilities during speed correction.
The motor control loop consists of counters, logic, and digital-to-analog converters that provide loop time constants The continuous time transfer function of the on chip control can be modeled as follows.

$$
\mathrm{H}(\mathrm{~s})=\frac{\mathrm{Vc}(\mathrm{~s})}{\mathrm{Fm}(\mathrm{~s})}=\frac{\mathrm{K}_{1}}{\mathrm{~s}}+\mathrm{Kp}
$$

$\mathrm{Vc}(\mathrm{s})$ is the voltage applied to the external current setting resistor (RE) by the modulator. By adjusting the value of Re the gain the motor sees can be adjusted, as can the starting current

## Preliminary Data Sheet

## GENERAL DESCRIPTION

The SSI 570 is an integrated circuit which performs the functions of generating write signals and amplifying and processing read signals required for a double sided floppy disk drive. The write data circuitry includes switching differential current drivers and erase head drive with programmable delay and hold times. The read data circuitry includes low noise amplifiers for each channel as well as a programmable gain stage and necessary equalization and filtering capability using external passive components. All logic inputs and outputs are TTL compatible and all timing is externally programmable for maximum design flexibility. The circuit operates on +12 volt and +5 volt power supplies and is available in 28 pin plastic DIP and QUAD packages.

## FEATURES

- Single chip read/write amplifier and read data processing function.
- Compatible with $8^{\prime \prime}, 51 / 4^{\prime \prime}$, and $31 / 2^{\prime \prime}$ drives.
- Internal write and erase current sources, externally set.
- Internal center tap voltage source.
- Control signals are TTL compatible.
- Schmitt trigger inputs for higher noise immunity on bussed control signals.
- TTL selectable write current boost.
- Operates on +12 volt and +5 volt power supplies.
- High gain, low noise, low peak shift ( $0.3 \%$ Typ) read processing circuits.

SSI 570 Block Diagram

CAUTION: Use handling procedures necessary for a Static Sensitive Component.

## Circuit Operation

## WRITE MODE CIRCUITRY

In Write Mode ( $\mathrm{R} / \overline{\mathrm{W}}$ low), the circuit provides controlled write and erase currents to either of two magnetic heads. The Write-Erase circuitry consists of two differential Write Current Drivers, a Center Tap Voltage Reference, two Erase Current Switches and control circuits for head selection and erase timing.

Write current is toggled between opposing sides of the head on each negative transition of the Write Data Input (WDI) and is set externally by a single resistor, RW, connected between the $\mathrm{R}_{\mathrm{W}}$ terminal and ground. Since driver output impedance is large, proper damping resistors must be provided across each head. A signal at the CB terminal provides write current boost.

Erase current is also set externally through resistors $\mathrm{R}_{\mathrm{EC}}$ connected in series with each erase coil. Erase can be activated by, but delayed from, selection of the write mode, and is held active after mode deselection. The turn-on delay is determined by the charging of $C_{E}$ through $R_{E D}$, while the hold time is determined by the discharge of $C_{E}$ through the series combination of $R_{E D}$ and REH (see connection diagram). The $R_{E} C_{E}$ node may be driven directly by a logic gate, with external resistors per fig. 4, if the erase period is to be controlled separately from the write mode selection. For applications where no delays are required, $\mathrm{C}_{\mathrm{E}}$ is omitted.

The Center Tap Voltage Reference supplies both write and erase currents. A Power Turn-On protection circuit prevents undesired writing or erasure by holding the voltage reference off until the supply voltages are within their operating ranges.

## READ MODE CIRCUITRY

In the Read Mode ( $R / \bar{W}$ high), the circuit performs the functions of amplifying and detecting the selected head output pulses which correspond to magnetic transitions in the media. The Read circuitry consists of two differential Preamplifiers, a Summing Amplifier, a

Postamplifier, an Active Differentiator, a Zero-Crossing Detector, a Time Domain Filter, and an Output One-Shot. The selected Preamplifier drives the Summing Amplifier whose outputs are AC coupled to the Postamplifier through an external filter network. The Postamplifier adjusts signal amplitudes prior to application of signals to the Active Differentiator. Postamplifier gain is set as required by connecting a resistor across the gain terminals, G 1 and G 2 . If desired, an additional frequency/phase compensation network may also be connected across these gain terminals.

The Differentiator, driven by the Postamplifier, provides zero-crossing output voltages in response to input signal peaks. Differentiator response characteristics are set by an external capacitor or more complex series network connected between the D1 and D2 terminals.

The Zero-Crossing Detector provides a unipolar output for each positive or negative zero-crossing of the Differentiator output. To enhance signal peak detection, the Time Domain Filter inhibits the detection of zerocrossings if they are not sufficiently separated in time. The filter period is set by an external RC network connected to the TD pin.

The Time Domain Filter drives the output One-Shot which generates uniform output data pulses. The pulse width is set by an external RC network connected to the PW pin. The Output One-Shot is inhibited while in the Write Mode.

## NOTES:

1 Voltage below which center tap voltage reference is dısabled
2 Threshold Differentıal Input Voltage can be related to peak shift by the following formula
Peak Shift $=\frac{37 \mathrm{mV}}{\pi \mathrm{Vin}} \times 100 \%$
where $V_{ı n}$ = peak to peak input voltage at post amplifier
Note that this formula demonstrates an inverse relationship between the input amplitude and the Peak Shift

The "PRELIMINARY" designation on an SSi data sheet indicates that the product is not yet released for production. The specifications are subject to change, are based on design goals or preliminary part evaluation, and are not guaranteed SSi should be consulted for current information before using this product. No responsibility is assumed by SSi for Its use; nor for any
infringements of patents and trademarks or other rights of third parties resulting from its use. No license is granted under any patents, patent rights or trademarks of SSI. SSi reserves the right to make changes in specifications at any time and without notice.

## Preliminary Data Sheet

## GENERAL

The SSI 575 device is a bipolar monolithic integrated circuit used in floppy disk systems for head control and write, erase, and read select functions. The device has either two or four discrete read, write, and erase channels. Channel select inputs are TTL compatible. The SSI 575 device requires +5 V and +12 V power supplies and is available in 18-pin (2-channel version) or 24 -pin (4-channel version) dual inline packages.

## FEATURES

- Operates on $+5 \mathrm{~V},+12 \mathrm{~V}$ power supplies
- Two or four channel capability
- TTL compatible control inputs
- Read/Write functions on one chip
- Internal center tap voltage source
- Supports all disk sizes
- Applicable to tape systems

## SSI 575 Block Diagram

## CIRCUIT OPERATION

The SSI 575 functions as a write and erase driver or as a read amplifier for the selected head. Two TTL compatible inputs are decoded to select the desired read/write and erase heads. Head select logic is indicated in Table 2. Both the erase gate (EG) and write gate ( $\overline{\mathrm{WG}}$ ) lines have internal pull up resistors to prevent an accidental write or erase condition.

## MODE SELECTION

The read or write mode is determined by the write gate (WG) line. The input is open collector TTL compatible. With the input low, the circuit is in the write mode. With the input high (open), the circuit is in the read mode. In the read mode, or with the +5 V supply off the circuit will not pass write current.

## ERASE

The erase operation is controlled by an open collector TTL compatible input. With erase gate (EG) input high (open) or the +5 V supply off, the circuit will not pass erase current. With $\overline{\mathrm{EG}}$ low, the selected open collector erase output will be low and current will be pulled through the erase heads.

## READ MODE

With the $\overline{W G}$ line high, the read mode is enabled. In the read mode the circuit functions as a differential amplifier. The state of the head select input determines which amplifier is active. When the mode or head is switched, the read output will have a voltage level shift. External reactive elements must be allowed to recover before proper reading can commence. A current diverting circuit prevents any possible write current from appearing on a head line.

## WRITE MODE

With the $\overline{W G}$ line low, externally generated write current is mirrored to the selected head and is switched between head windings by the state of the write data (WD) signal.

## Preliminary Data Sheet

## DESCRIPTION

The SSi 580 device is a bipolar integrated circuit that serves as an input/output port expander for an 8048 type microprocessor based floppy disk drive system. The device consolidates functions normally performed by a variety of LSTTL, SSI, and MSI devices. The combination of an SSI 570 (read, write, and erase device), an 8048 type microprocessor, and the SSI 580 provides the majority of electronics required for a SA400 type floppy disk drive system, including host interface bus driver and receiver. In addition to its port expansion function, the SSI 580 processes system data and provides both pulse width and delay control (adjustable by external elements) for the INDEX SENSOR input. The device requires a single +5 V power supply and is available in a 28-pin package.

## FEATURES

- Reduces package count in flexible disk drive systems
- Replaces bus interface and combinational logic devices between the SSI 570, on board microprocessor and mechanical interfaces.
- Surface mount available for further real estate reduction.
- Provides drive capability for mechanical and system interfaces

## PIN ASSIGNMENT DESCRIPTIONS

| Pin Name | Description |
| :---: | :---: |
| P20-P23 | 4-bit bidirectional port, referred to as Port 2. |
| $\overline{\text { WGATE IN }}$ | This input command to write is asserted by the host interface bus. |
| $\overline{\text { MOTOR ON }}$ | This input command to turn on the spindle motor comes from the host interface bus. |
| $\overline{\text { DIR }}$ | Input from the host interface bus selecting the direction in which the stepper motor should move the head. |
| $\overline{\text { DS }}$ | Drive select |
| INDEX SENSOR | Input from the photodiode that indicates the index marker in the diskette. |
| WR PROT SENSOR | Input from the photodiode that indicates if the diskette is write protected. |
| TRACK 0 SENSOR | Input from the photodiode that detects when the head is positioned over track 0. |
| $\overline{\text { STEP }}$ | Input from the host interface bus indicating that the head should be moved. |
| T1 | This pin changes state when a $\overline{\text { STE }} \bar{P}$ command is received from the host interface bus. |
| $\begin{aligned} & \text { RD DATA IN } \\ & \frac{\text { and } \overline{\text { RD }}}{\text { DATA OUT }} \end{aligned}$ | Read data path |
| WGATE | Output to the disk drive's read/write circuitry. |
| INDEX | Output to the host interface bus indicating index sensor status. |
| TRACK 0 | Output to the host interface bus indicating track 0 sensor status. |
| $\overline{\text { READY }}$ | Output to the host interface bus indicating track 0 sensor status. |
| $\overline{\text { WR PROT }}$ | Output to the host interface bus indicating write protect sensor status. |
| PROG | Input from the 8048 microprocessor for I/O control of the 580. |
| INTR | Output to the interrupt pin of the 8048 microprocessor. |
| R/C D and R/C W | The external resistor and capacitor networks tied to these pins determines the delay and width of the output pulse to the $\overline{\text { NDEX }}$ pin. |
| Vcc | + 5 V supply |
| GND | Ground |

Table 1

## CIRCUIT OPERATION

## PORTS

The SSI 580 has two 4-bit input ports, Port A and Port B. Port a receives data from the host interface bus for conveyance to the drive's read/write circuitry and to the microprocessor. Three sensors report the status of the drive to the 580 via Port B. Common to both ports is a drive select ( $\overline{\mathrm{DS}}$ ) signal from the host interface bus. This allows the host to address separate disk drives. There is also a 4-bit bidirectional port on the SSI 580. This is port 2 and it can be used by the microprocessor to write to or read from the 580.

## READ MODE

Ports A and B can be read by a microprocessor via Port 2. This allows the microprocessor to obtain data from the host interface bus and the status sensors. The PROG signal from the microprocessor provides the timing for the operation. First an OP code and a port address must be placed on Port 2 (see Table 2), then latched in on the falling edge of PROG. When the OP code and addresses have been decoded, the desired input port is selected and output on Port 2. The operation is terminated by the rising edge PROG, which returns Port 2 to the input mode.

## WRITE MODE

In the write mode the microprocessor passes system parameters to the SSI 580 for logic processing and outputting. Table 3 shows how each bit of Port 2 affects the 580. A logic one on the zero bit of Port 2 will reset the index latch. P21, qualified by the $\overline{\mathrm{DS}}$ signal, sends a "this drive ready" signal from the microprocessor to the host interface bus. Similarly P22 is $\overline{\mathrm{DS}}$ qualified and sent to the host as a signal that the head is positioned over track $0 . \mathrm{P} 23$ is used in the logic that sends a $\mathrm{R} / \overline{\mathrm{W}}$ signal to the drive's read/write circuitry. The write mode occurs when the proper OP code and address is placed on Port 2 and latched in on the falling edge of PROG (see Table 3). The microprocessor writes in the data on PROG's rising edge.

## INDEX PULSE

An optical sensor connected to the INDEX SENSOR pin detects the diskette's index marker. The state of the index sensor is latched into the 580 and is available to be read by the microprocessor on P22. The latch may be reset by writing a one to P 20 from the microprocessor. The pulse received from the sensor also drives the host interface signal INDEX, the width and delay of which can be controlled by external R/C circuits. The time constant attached to the R/C D pin determines the delay from the INDEX SENSOR input to the INDEX signal on the host interface bus. The equation for the delay is Td $=0.59 \mathrm{Rd} \times \mathrm{Cd}$ (seconds). The width of the INDEX signal is determined by the circuit attached to the R/C W pin and the equation $\mathrm{Tw}=0.59 \mathrm{Rw} \times \mathrm{Cw}$ (seconds).

## INTERRUPT

The INTR signal is asserted every time a step command is issued to the drive on the host interface bus. Thus when INTR is tied to the interrupt pin of 8048 type
microprocessor, an interrupt service routine will be executed on each step command. This routine typically obtains information on the direction the heads should move and the status of the track 0 sensor to use for generating the stepper motor control signals. The interrupt signal is cleared (set high) by first placing the proper OP code and address on Port 2 (see Table 3). This is latched in on the falling edge of PROG, then on its rising edge logic ones on P20 and P21 will be latched in to set INTR back to a high state. Note that an indeterminate operation will result from holding the INDEX SENSOR latch reset (holding P20 high).

## T1 PIN

This signal changes state with the STEP command of the host interface bus when the drive is selected. It drives the T1 pin on an 8048 type microprocessor which is an input to a counter. The 8048 can use this count and the DIR signal read from Port 2 of the SSI 580 to monitor the head position and issue a CB (current boost) command to the SSI 570 when a specific track is reached.

TABLE 2. READ MODE

| Input to Port 2 | Read From Port 2 |  |  |  |  | 4-Bit |

# Preliminary Data Sheet 

## GENERAL DESCRIPTION

Silicon Systems' SSI 550 combines magnetic tape head read signal amplification and processing onto a single integrated circuit. The device accepts up to 4 centertapped magnetic read heads connected directly to the head inputs; head center tap voltage is provided by an on-chip reference. The device architecture permits system design flexibility by providing the external connections between the Preamplifier/Multiplexer, Postamplifier, Signal Level Detector, and Data Detector; this allows the implementation of many suitable filtering combinations. Low noise amplifiers are used throughout the device. The SSI 550 operates on +5 and +12 Volt supplies and has TTL compatible control signals.

## FEATURES

- 4-Channel Multiplexer with differential-input Preamplifiers
- Postamplifier has component-adjustable and programmable gain
- On-chip Signal Level Detector with programmable threshold and adjustable delay
- Data Detection Circuit includes spurious signal rejection (adjustable time domain filter) and provides an adjustable uniform Data Pulse output
- Available in 40 pin DIP or 44 pin Quad plastic packages

(shown with typical external circuitry)

## DEVICE DESCRIPTION AND OPERATION

## 4-Channel Preamplifier and Multiplexer

The device contains four low level differential-input Preamplifiers. The differential output of a single Preamplifier is selectively connected to the Preamplifier output terminals by means of two logical CHANNEL SELECT signals, S 0 and S1. The selected Preamplifier number is the binary value of the logical SELECT signals for active high voltage levels.

The Preamplifier inputs are intended for connection to center-tapped magnetic read heads. An appropriate Preamplifier input bias voltage level is obtained by connecting the head center taps to the circuit C.T. VOLT terminal.

The C.T.VOLT terminal is the output of a voltage reference which has a value to center the Preamplifier inputs within their operating range.

## Postamplifier

The Postamplifier is a differential-input, differentialoutput circuit which has two means of gain adjustment. A continuously-variable gain adjustment is obtained by use of an external resistor or potentiometer. Discrete values of gain setting are additionally obtained by applying combinations of logical signal levels to the three GAIN SELECT terminals, G0, G1, and G2.

The Postamplifier receives the output signals of the Preamplifier after frequency selection by an external filter network. The input characteristics of the Postamplifier are such that the inputs may have DC coupling to the Preamplifier output, or may be AC coupled with proper bias of 3 V nom.

A suitable coupling capacitor must be connected between the GAIN1, GAIN2 terminals independent of the use of a gain setting resistor.

## Signal Level Detect Circuits

The Signal Level Detect circuits consist of detector circuits which compare the amplitude of the signal envelope of the Postamplifier output with a selectable threshold and provide a logical output level which indicates the presence of Postamplifier signal greater than the threshold. AC coupling is required between the Postamplifier output and the Signal Level Detect circuits input. The Signal Level Detect input has internal bias connections so that no external bias network is required.

The threshold to which the Postamplifier signals are compared is selected by means of two THRESHOLD SELECT logical inputs T0 and T1. The result of the comparison is delayed from appearing at the circuit SIGNAL DETECT output terminal by means of a delay circuit which is adjustable by means of external components.

The delay associated with signal detection is set by combinations of capacitor CDS and resistor RDS1. The delay associated with signal loss is set by combinations of CDS and resistors RDS1 plus RDS2.

## Data Detection Circuits

The Data Detection circuits are AC coupled to the Postamplifier outputs through an (optional) external filter network and provide logical output pulse signals in
response to positive and negative input signal amplitude peaks. This function is performed by differentiating input signals to obtain zero-crossing voltages at points of inflection and detecting these crossings to provide output signals.

To enhance the signal peak detection, spurious inflection points which occur inpairs between true signal peaks are suppressed by means of the Time Domain Filter. The filter inhibits the propagation of detected zero-crossings if they are not sufficiently separated in time. This time period is set by external capacitor CTD and resistor RTD.

Uniform DATA PULSE output signals are provided by the One-Shot Multivibrator which is triggered by outputs of the Time Domain Filter. The time duration of the DATA PULSE signals is set by external capacitor CDP and RDP.

DC paths through the external filter network to the Signal Level Detect circuits inputs are required to properly bias the Data Detection circuits. The resistance of each path is not critical and may be as large as 10 Kohm.

The "PRELIMINARY" designation on an SSI data sheet indicates that the product is not yet released for production The specifications are subject to change, are based on design goals or preliminary part evaluation, and are not guaranteed. SSi should be consulted for current information before using this product No responsibility is assumed by SSi for its use; nor for any
infringements of patents and trademarks or other rights of third parties resulting from its use No license is granted under any patents, patent rights or trademarks of SSi. SSi reserves the right to make changes in specifications at any tıme and without notice.

## Preliminary Data Sheet

## GENERAL DESCRIPTION

The SSI 67C401/402 devices are high speed, expandable memories operating as a First-In, First-Out, (FIFO) asynchronous register of either 64 words by 4-bit (SSI67C 401) or 64 words by 5 -bit (SSI 67C 402). The SSI 67C401/402 are CMOS devices. A 10 MHz shift rate provides the fast transfer of data necessary for applications in high speed tape or disc controllers and communication buffers. A single +5 V power supply is required.

## FEATURES

- 10 MHz shift in, shift out rates
- Choice of 4 -bit or 5 -bit width
- TTL compatible inputs and outputs
- Readily expandable in word and bit dimensions
- Output pins directly opposite corresponding input pins
- Asynchronous operation
- Pin compatible with MMI 67401 Series
- Low power consumption
- HCT input and output characteristics

## CIRCUIT DESCRIPTION

## Data Input

When the FIFO is reset, the Master Reset is pulsed Iow to prepare the device for data input. Data is entered at the $D_{X}$ inputs as controlled by the Input Ready (IR) and Shift In (SI) logic. With IR high, data can be accepted. Data present at the data inputs is entered into the first position on the rising edge of SI . As SI is taken high, IR goes low indicating the FIFO is busy. When SI is set low, IR goes high if the memory is not full. In the FIFO, data is shifted towards the output progressively until a full memory position is encountered. Thus, the memory is filled with the first data word at the output position and subsequent data words in order behind it. If the memory is full, that is all 64 word positions contain valid data, IR remains low after SI is set low.

## Data Transfer

After data input, transfer of a data word from a memory position to an adjacent empty memory position is automatic, activated by on-chip control. Thus, data stacks up at the output end of the FIFO while memory positions that are emptied as data is unloaded are moved to the input end. The time for data (or emptied positions) to move the entire length of the memory is defined as the throughput, or fall through, time (tpT).

## Data Output

Data outputs at the $Q_{X}$ pins are controlled by the Output Ready (OR) and Shift Out (SO). When valid data is shifted to the outputs, OR goes high. With OR high, data
may be shifted out by bringing SO high. The rise of SO causes OR to go low. Valid data is maintained while SO is high. When SO is brought low, the upstream data (providing the next stage contains valid data) is shifted to the output stage and OR goes high. If the FIFO is emptied, OR stays low and the $Q_{X}$ data remains as before.

## Application Notes

The Input Ready (IR) and Output Ready (OR) may be used as status signals indicating that the FIFO is completely full (IR stays low for at least fall through time $t_{p t}$ ) or that the FIFO is completely empty (OR stays low for at least $t_{p t}$ ).
Since the high speed FIFO is particularly sensitive to small glitches as might be caused by long reflective lines, high capacitances, or poor supply decoupling and grounding, circuit design should account for these potential problems ensuring that adequate ground planes and decoupling measures are taken. For example, it is recommended that a $0.1 \mu \mathrm{f}$ ceramic capacitor be connected directly between $\mathrm{V}_{\mathrm{CC}}$ and ground with a very short lead length.

Absolute Maximum Ratings* (All voltages referenced to GND)

infringements of patents and trademarks or other rights of third parties resulting from its use. No license is granted under any patents, patent rights or trademarks of SSi . SSi reserves the right to make changes in specifications at any time and without notice.

## Section 3 CUSTOM/ SEMICUSTOM

## SILICON SYSTEMS -LEADING THE WAY IN CUSTOM/SEMICUSTOM IC’S

At SSI, we've been in a leadership role in custom circuits, first with superior IC design capabilities, and then with one of industry's finest wafer fabrication facilities Today we're still pacing the field in the burgeoning market for "applicatıon specific" custom/semıcustom IC's. We've maıntaıned our position by carefully monitoring evolving market requirements and providıng cost-effective, quality solutions for even the most specialized applications

In both engineering and technology, we offer versatility with design capabilities for digital, analog, and combined digital/analog ICs along with a wafer fabrication capability that includes both Bipolar and CMOS technologies

|  | Specification Approval |
| :---: | :---: |
|  | Design \& Layout |
| CUSTOM | Mask <br> Fabrication |
| SEMICUSTOM ABEAYS | Wafer Fabrication |
| STANDARD | Wafer Testıng |
|  | Production Assembly |
| $y$ | Final Test |

Custom/Semicustom Approach to Integrated Circuits
Custom IC's are not just a side line at SSI; they've always been our prımary business We provide the full range of custom IC design with such practical semıcustom optıons as pre-built standard cells and switched capacitor filter arrays. With a top engineerıng staff supported by our unique Integrated Design Methodology (IDM), and with a fully automated wafer

fabricatıon facility designed especially for custom and "Application-Specific" IC's, we can cut custom design time down to readily acceptable lımits

## Integrated Solution for You

So whether your requirements fall in our specialty areas of telecommunications and rotatıng memories, or other application areas appropriate for custom/semıcustom IC's, we offer the advantages of a complete IC development and production operation; single-point accountability, smooth progress through all phases of a project, and a high level of quality assurance. The result reduced time and cost to produce the best custom/semicustom IC's available.

## VERSATILITY - THE OPTIMUM APPROACH FOR EACH CUSTOMER

Silicon Systems has focused on the ASIC (Application Specific Integrated Circuit) market for over 10 years and has developed a versatile offering of customized components that covers the design spectrum.

The digital market can be satısfied by our Mask Programmed Logıc Arrays (MPLA) for implementation of complex logic functions and by our full custom or standard cell library for large scale system designs

Table 1
The analog market is served by our Bıpolar analog array for moderate complexity needs, by switch capacitor arrays for filter needs and by full custom or standard cell library for higher levels of sophistication. All four design technologies also accommodate full analog and digital integration on the same chip for total system solutions.

Desıgn engıneering, semıconductor processing and testing are all housed in the same facility
at Silicon Systems which allows quick turnaround from design concept to working silicon The ultra-clean wafer fab supports both Bipolar and CMOS technologies with high and low voltage optıons as well as single or double layer metal interconnections. These variations permit us to select the optımum process when fabricatıng a new circuit

## DIGITAL APPLICATION SPECTRUM

No. of Gates

Our standard cell library is implemented on the CC process ( $3 \mu \mathrm{~m}$ silicon gate CMOS) allowing high density, low power digital and analog functions to be integrated, while operating with standard 5-volt levels The proprietary "CD" process extends operatıon from 35 V to 14 V for higher performance analog or analog/digital functions while our proprietary Bipolar "BJ" process offers extremely high density and performance combined with very low noise.

Silicon Systems also offers full capability for supportıng Customer Owned Tooling (COT) with any of our industry standard processes.

Table 2A

Table 2B

## INTEGRATED DESIGN METHODOLOGY - THE IDM" ${ }^{\text {™ }}$ ADVANTAGE

When deciding to convert a system or subsystem design to silicon the user can choose etther a fully customized approach or a semı-customized approach, each with its own benefits For these designs SSi offers the alternatives of fully "handcrafted" custom design in CMOS and Bıpolar or standard cell design in CMOS As seen in Table 3, the fully individualized custom gives the advantages of chip size (lower production cost) and highest

With Computer Aıded Design (CAD) playıng a major role in our product development cycle, SSi has developed an Integrated Design system that accommodates an interlocking set of design methods all supported by a single CAD system. This Integrated Design Methodology (IDM ${ }^{m \mathrm{~m}}$ ) allows the user to design at the transistor level (ether composite or symbolic), at a procedural macro level (silicon compiler), with

INTEGRATED DESIGN METHODOLOGY

|  | PERFORMANCE | COST |
| :--- | :---: | :---: |
| TRANSISTOR |  |  |
| LEVEL DESIGN |  |  |$\quad$ HIGHEST

performance (speed, input offset, etc.) while semicustom, using a pre-characterızed standard cell library, offers the advantages of lower NRE, faster turnaround and somewhat higher first article success rate. SSı adds to the flexibility of the standard cell concept by its willingness to develop special cells as needed to satisfy design requirements that lie between the two custom design technologies.

MACRO IC USING IDM

Table 3
Parameterızed Building Blocks (PBB), or with conventional standard cells. Each of these design levels has a unique set of attributes, as shown in Figure 2, accessible in a "mix or match" manner under IDM. This enables an efficient performance/design-time tradeoff.

Silicon Systems offers experienced staffing throughout its organization along with state-of-the-art CAD and processing facilities to efficiently develop customized products.

We start with a large, expert staff of design engineers to help define the product from both the system and silicon aspects The design is then developed using our advanced CAD tools and programs including ALICE (Automated Layout for Integrated Circuit Engıneerıng), which accurately handles chip design from schematic input to pattern generator output, all within one system. SSi engineers utilize an advanced version of "SPICE" to simulate DC, transient, noise, distortion, and AC response for CMOS and Bipolar. It accurately models such second order effects as weak-Inversion, high-level injection, temperature dependent mobility, etc

SSı has adapted a special program called "SWITCAP" for switched-capacitor filter frequency domain analysis which accurately predicts the frequency response of switchedcapacitor filters. Our Automatic Network Intertrace Algorithm (ANITA"') compares the network description generated from the captured circuit to the layout as it proceeds This guarantees that no interconnection errors exist and that all component sizes and tolerances match those used in the design analysis. The completed design goes through a masking procedure and the wafers are run in our ultramodern class 10 (10ppm particulate count) wafer fabrication facility it is a "paperless"

Table 4
environment accomplished by downloading process information to in-place terminals and processing equipment The PROMIS (Process Management Information Systems) program that accomplishes this control provides work-in-process tracking, engineering data collection,

and continuous facility monitoring
After the wafer prototype is fabricated, SSI packages a few representative chips using in-house assembly for design verification. The units are tested in-house by one of our advanced analog or digital tester We can test your circuit with your existing test program or help you create a test program from your specificatıon.

After approval of prototypes or characterization lots (If needed) the final step is off-shore assembly for volume production

We can also perform hi-rel screenıng and burn-in, if desired.

Table 8

Table 11

Table 9

Table 10
The above tables show some of our demonstrated high performance design capabilities in Bipolar and CMOS. These analog/ digital chips cover a wide range of challenging circuit functions that were designed for a diversity of system applications.
As part of a total capability SSI offers commercial, industrial, and hi-rel product flows, as well as packaging optıons that include Dual-inLine, Flatpacks, and plastic Quads For further detalled information on product flow and packagıng call SSi or refer to our Quality and Reliability Brochure.

## Section 4 STANDARD CELLS

## STANDARD CELL LIBRARY - ANALOG AND DIGITAL

Table 5

The standard cells shown in Table 5 represent the basic buildıng blocks or "prımitives" of our present library. In addition to these cells, macros are already scheduled for functions such as RAM, ROM, PLA etc Others can be generated and added to the library on an "as needed" basis. As part of the SSi flexibility in custom we will design new cells to accommodate any feasıble "special" requirements.

Table 6

Table 7
The characterıstics shown in Table 6 are indicatıve of our cell library in 5 Volt $3 \mu \mathrm{~m} \mathrm{Si}$ gate CMOS (CC process). An additional library of higher performance analog cells will be made avalable on our CD process.

## SECTION 1

## A MESSAGE FROM SILICON SYSTEMS' PRESIDENT AND CEO

Quality is the secret to long term success It literally overshadows the short term emphasis on price, delivery, or any other measure of performance
At Silicon Systems, we have based our quality philosophy on the development of a "state of mind" in each employee, related to job performance and to its reflection in the overall level of quality and reliability of our product

You won't hear very many cliches about quality in our environment But we do strive for "zero defects" for "just in time service" and for "doing it right the

FIGURE 1.1 ORGANIZATION CHART

CARMELO J SANTORO
Chairman, President \& CEO
first tıme " We think constant remınders of tired phrases can serve more as an ırritant than a stımulant Our quality ethic is based on settıng examples for others and by intuitive "high quality" job performance propagatıng the quality ethic throughout the organization to each employee
To be sure, we have programs related to quality and reliability They are the subject of this brochure We are dedicated to process control, overall product reliability and outstanding outgoing quality Rapid analysis of failures and returns providing responsive service to our customers also generates quick solutions to our own problems We believe that the high levels which we achieve in quality, reliability and service are directly attributable to belief in the basic tenets of quality within our corporate culture

### 1.1 INTRODUCTION

This brochure presents the basic quality and reliability philosophy used by Sillcon Systems
Silicon Systems' management philosophy is the manufacture of a quality product consistent with company policy and customer requirements It is the goal of the Quality Assurance and Reliability departments to ensure that these requirements are met

Included in this brochure is Silicon Systems' ongoing program for controlling and improving the quality of devices manufactured

The data clearly illustrates that Silicon Systems is working diligently to maintain its position as a leader in the industry The use of highly specialized equipment, test programs and test procedures allows us to determine product reliability under extreme conditions

Quality is bult into Silicon Systems' parts from rigid incoming inspection of piece parts and materials to stringent outgoing quality verification The assembly process flow is encompassed by an elaborate system of test and inspection gates and monitors These gates and monitors ensure a step-by-step adherence to prescribed procedure In this manner, a high level of quality and reliability is produced in all Sillicon Systems' products

### 1.2 QUALITY ASSURANCE AND RELIABILITY

The quality of a semiconductor device is defined by its conformance to specification, the reliability of a semiconductor device is defined by how well it continues to conform to spec,fication over time while under stress This relatıonship between quality and reliability requires a program that encompasses both Included in this brochure are outlines of our process control program and our PPM (parts-permillion) program These programs assure conformance to specification throughout the manufacturing process

### 1.2.1 ORGANIZATION PHILOSOPHY

To facilitate the close cooperation and coordinatıon required of the Quality and Reliability functions, a combined organization has been established This organization must have access to and support from the top of the organization The R \& Q A organization is shown in Figure 11

## SECTION 2 QUALITY ASSURANCE

### 2.1 QUALITY PROGRAM

Quality Assurance has the ultimate responsiblity for the reliable performance of our products This is accomplished through the administration of formal systems which assure that our products meet the requirements of customer purchase orders, and specifications for design, from raw materials through finished product

Quality Assurance supports formal qualifications of suppliers, materıals, processes, and products, administration of system and production monitors to assure that our products do meet the desired specifications, and the liaison between Silicon Systems and the customer for all product-related problems

It is the practice of Silicon Systems to have the Quality and Reliability Program encompass all of its activities, starting with a strong commitment of support for the program from the corporate level, and continuing with customer support after the product has been shipped

Silicon Systems firmly believes that quality must be "built into" all of its products by ensuring that employees are trained in the quality philosophy of the company Some of the features built into Silicon Systems' Quality Program include
1 Structured traınıng programs directed at Wafer Fabrication, Test, and Process Control personnel
2 Stringent in-process inspection gates and monitors
3 Total evaluation of designs, materials, and processing procedures
4 Stringent electrical testing ( $100 \%$ and redundant QA AQL testıng)
5 Ongoing reliablity monitors and process verificatıons

These structured quality methods result in products which deliver superior performance in the field

### 2.1.1 LOT ACCEPTANCE TESTING

At Silicon Systems, all sampling for Lot Acceptance Testing is based upon MIL-STD-105D

1 Commercial Testing includes resistance to solvents, Solution A, plus external Visual Inspection to strict SSI standards

2 Industrial Testing includes hermetic-only Destructive Physical Analysis (DPA), as well as Resistance to Solvents, Solutions A and B, plus Solderability, Electrical @ $25^{\circ} \mathrm{C}$, and external Visual Inspection to SSi standards

3 Extended Reliability covers hermetic-only DPA and Burn-in, as well as Resistance to Solvents, Solutions A, B, and C, plus Solderability, Fine and Gross Leak Hermeticity, Electrıcal @ $25^{\circ} \mathrm{C}$, and external Visual Inspection to SSi standards

4 High Reliability includes Destructive Physical Analysis and Burn-ın, as well as Resistance to Solvents, Solutions A, B, C, and D, plus SolderabilIty, Fine and Gross Leak Hermeticity, Electrical @ max/min temperature limits as well as $25^{\circ} \mathrm{C}$, and external Visual Inspection to SSi standards

### 2.2 PROCESS CONTROL

Silicon Systems' process control program is designed to provide continuous visibility of the performance of manufacturing processes and ensures that corrective action is taken before problems develop

The princıpal areas of process control which assess the quality of processed product against quality standards are incoming materials inspection and process control monitoring

### 2.2.1 Incoming Inspections

Incoming inspection plays a very important role in Silicon Systems' quality program Small deviations from material specifications can transverse the entire production cycle before being detected by outgoing quality control By paying strict attention to quality at this early stage, the possibility of failures occurring further down the line is greatly minimized

### 2.2.2 In-Process Inspections

Every major manufacturing step is followed by an appropriate in-process quality control inspection gate Silicon Systems has established inspection gates in areas such as Wafer Fabricatıon, Wafer Probe, Prep for Assembly, Assembly, and Final Test areas

In addition to these established gates, Silicon Systems also has established monitors during various stages in the manufacturing process It is this builtin quality that ensures fallure-free shipment of Sillicon Systems' products
Quality control monitors have been placed throughout the manufacturing flow, so that data may be collected and analyzed to verify the results of intermediate manufacturing steps This data is used to determine quality trends or long term changes in

FIGURE 2.1 AOQ TRENDS

the quality of specific operations A general description of the product flow and QC inspection points are shown in Figure 22

### 2.3 PPM PROGRAM

The main purpose of employing a PPM program is to eliminate defects The action portion of this program is accomplished in three stages
1 Identify all defects by fallure mode
2 Identify defect causes and initiate corrective action

3 Measure results and set improved goals
The data generated from an established PPM program is statistically compiled as a ratio of units rejected/tested This ratio is then expressed in terms of parts per million (PPM) with a confidence limit attached The eventual reported PPM result therefore allows proper significance to be attached to every defect found The final aim or goal is to achieve and maintaın zero defects

Based on significantly large volumes of PPM data and an established five-year strategic plan identifying industry-wide competitive PPM goals, Silicon Systems has progressively achieved excellent quality standards and will contınue to measure the results and, therefore, improve on PPM standards as set by the industry

## FIGURE 2.2

## PROCESS CONTROL GATES AND MONITORS

### 2.4 COMPUTER AIDED MANUFACTURING CONTROL

Computer Aided Manufacturing (CAM) requires the identificatıon, control, collectıon and dissemination of vast amounts of data for logistics control. Silicon Systems uses this type of computerized system for statistical process control and manufacturing monitoring

PROMIS (Process Management and information System) displays document control-released recipes, processes, and procedures, tracks work-inprocess, contains accurate inventory information, allows continuous recording of facilities data, contains performance analysis capabilities, and much more PROMIS allows for a paperless facillty, which assists in keeping contamination out of the wafer fab clean room

The configuration of PROMIS has been tallored to meet the requirements of Silicon Systems

### 2.5 GUARANTEED AQL

Silicon Systems currently offers a guaranteed AQL level of $005 \%$ and has a written plan to implement a guaranteed AQL of $001 \%$ in 1987
Our PPM program, which allows us to guarantee the AQLs, is key to the contınuing improvement in our average outgoing quality AOQ, see Figure 21 This program encompasses the ongoing analysis of our product and process performance to continually reduce our process defect densities The ultimate goal of this program is improvement toward zero defects, rather than the acceptance of a given defect density level as an ultimate goal

## SECTION 3 RELIABILITY

### 3.1 RELIABILITY PROGRAM

Silicon Systems' reliability is ensured through continuous monitoring of generic product families

The reliability program includes several highly specialized areas which are equipped with a variety of analytical capabilities
a Scannıng Electron Microscope (SEM)

- Energy Dispersive X-Ray (EDX)
- Voltage Contrast
- Electron Beam Induced Current (EBIC)
b Electrical Characterizatıon
c Metallurgıcal Cross-Sectıonıng
d Ion Chromatograph
e Mıcromanıpulator Probe Statıon
f Wet Chemıcal and Plasma Technıques
g Macro/Microphotography
h X-Ray Technıques
These capabilites allow the prompt and accurate analysis of fallure mechanisms

### 3.2 RELIABILITY METHODS

Various stress tests are utilized that define performance levels of our products Many of these stress tests are per MIl-883 as shown in Table 31.

### 3.3 FAILURE ANALYSIS PROGRAM

A highly visible comprehensive fallure reporting, analysis, and corrective action program is extremely important to the continued achievement of high reliability in components produced by Silicon Systems

This detailed fallure analysis program is an integral part of every phase of device technology from initial product design review to analysis of our product under actual field use conditions

## TABLE 3.1 RELIABILITY STRESS TESTS

| TEST | METHODS |
| :--- | :---: |

The fallure analysis data generated is used to help our customers implement improved device applications and to allow Silicon Systems to identify and implement product or process improvements

Conclusively, this in-house testing and analysis allows Silicon Systems to monitor all aspects of manufacturing to ensure that a product of highest quality is shipped to our customers

TABLE 3.2
RELIABILITY DATA BASE
Failure Rates in \%/1000 Hours ${ }^{1}$

| 2 | Device <br> Product Type <br> Hours (10) | Number <br> Falled | $55^{\circ} \mathrm{C}^{2}$ <br> $60 \%$ Conlidence Level | FIrs |
| :--- | :---: | :---: | :---: | :---: |
| Bipolar | 5.424 | 28 | .006 | 60 |
| CMOS | 3.720 | 89 | .029 | 290 |
| Computer Product | 5.424 | 28 | .006 | 60 |
| Telecom Product | 3.720 | 89 | .029 | 290 |

## Note

1. $01 \% / 1000$ hours $=1000$ FIT, fallure rates are quoted with $60 \%$ confidence level
2. $55^{\circ} \mathrm{C}$ number assume an actıvation energy of 071 eV

TABLE 3.3 ACTIVATION ENERGIES OF MAJOR FAILURE MECHANISMS

| Fallure Mechanisms | Activation <br> Energy $(\mathrm{eV})$ |
| :--- | :---: |
| Surface Inversion Failures | 1.02 |
| Au-Al Intermetallic Bond Failures | $1.02-1.04$ |
| MOS $V_{\text {TH }}$ Shift | $1.0-1.6$ |
| Aluminum Electro Migration | $0.4-0.8$ |
| MOS Surface Charge Accumulation | $1.2-1.35$ |
| Corrosion of Metallization | $0.3-0.6$ |
| Ion Migration | 1.4 |
| Slow Trapping | 1.0 |
| Die Surface Charge Spread | $0.5-1.0$ |
| Oxide Defects | 0.3 |

### 3.4 RELIABILITY PREDICTION METHODOLOGY

It has been established through Reliability Engineering principles that the fallure rate of a group of devices as a function of time will endorse a life curve as shown in Figure 31

Basically, the bath tub curve in Figure 31, implies that the useful life of the product extends until some basic design or material limitation is experienced At Silicon Systems, the Arrhenius model is used to extrapolate a fallure rate at an accelerated temperature test condition to a normal use temperature condition

Silicon Systems uses the Arrhenius equation concept to determine unique fallure mechanisms and as a base line for defining the reliability of integrated circuits

The Arrhenius equation for validity requires the following
1 The stress remain constant
2 Activation energy remain constant with temperature
3 The mass remain constant
The model basically states $R=A e^{-E_{a} / K T}$ where $R=$ Reaction rate constant

A = Constant
$\mathrm{E}_{\mathrm{a}}=$ Activation energy ( eV )
$K=$ Boltzmann's constant $863 \times 10^{-5}$ $\mathrm{eV} /{ }^{\circ} \mathrm{K}$
$\mathrm{T}=$ Absolute temperature $\left({ }^{\circ} \mathrm{K}\right)$

## SECTION 4 ELECTROSTATIC DISCHARGE PROGRAM <br> 4.1 ESD PREVENTION

Silicon Systems recognizes that procedures for the protection of Electrostatic Discharge (ESD) sensıtive devices from damage by electrical transients and static electricity must be incorporated throughout all operations which come in contact with these devices

Silicon Systems' quality program incorporates varıous protection measures for the control of ESD Some of these preventive measures include handling of parts at static safe-guarded work stations, the wearing of wrist straps durıng all handlıng operations, the use of conductive lab coats in all test areas and areas which handle parts, and the packaging of components in conductive and anti-static containers

RELATIONSHIP BETWEEN FAILURE CAUSES AND ANALYTICAL TEST METHODS

# Quality Assurance Flow Chart 

Although full compliance with MIL-STD-883 is not implied, all processes are in accordance with or derived from the methods indicated

## LOT ACCEPTANCE TESTING

At Silicon Systems, all sampling for Lot Acceptance Testing is based upon MIL-STD-105D.

Commercial Testing includes resistance to solvents, Solution A, plus external Visual Inspection to strict SSi standards.

Industrial Testing includes hermetic-only Destructive Physical Analysis (DPA), as well as Resistance to Solvents, Solutions A and B, plus Solderability, Electrical @ $25^{\circ} \mathrm{C}$, and external Visual Inspection to SSi standards.

Extended Reliability covers hermetic-only DPA and Burn-in, as well as Resistance to Solvents, Solutions A, B, and C, plus Solderability, Fine and Gross Leak Hermeticity, Electrical @ max/min and $25^{\circ} \mathrm{C}$, and external Visual Inspection to SSi standards.

High Reliability includes Destructive Physical Analysis and Burn-in, as well as Resistance to Solvents, Solutions A, B, C, and D, plus Solderability, Fine and Gross Leak Hermeticity, Electrical @ max/min and $25^{\circ} \mathrm{C}$, and external Visual Inspection to SSi standards.

[^0]:    Note All SSI 204 unused inputs must be connected to $V_{p}$ or Gnd as appropriate

[^2]:    *Operation above absolute maxımum ratıngs may damage the device

[^3]:    Note dBm is referenced to $600 \Omega$

[^4]:    Note dBm 0 refers to an output level of 0 dBm at the line side of the DAA specified in the following section The DAA introduces a +90 dB receive gain and a -100 dB loss on the transmit side The K212 transmits nomınally at $00 \mathrm{dBm}(775 \mathrm{Vrms})$ at its TXA pin with $-100 \mathrm{dBm0}$ output from the DAA to the phone line It receives a nomınal +90 dBm signal ( 218 Vrms ) at its RXA pin with a 0 dBm 0 signal input from the phone line

[^5]:    Note dBm 0 refers to an output level of 0 dBm at the line side of the DAA specified in the following section The DAA introduces a +90 dB receive gain and a -100 dB loss on the transmit side The K212 transmits nominally at 00 dBm ( 775 Vrms ) at its TXA pin with -100 dBm 0 output from the DAA to the phone line it receives a nominal +90 dBm sıgnal ( 218 Vrms ) at its RXA pin with a $0 \mathrm{dBm0}$ signal input from the phone line

[^6]:    * Note The SSI 223 RXF input is AC coupled internally, but the DC value of the input must be between the two supplies VDD \& VSS

[^7]:    - Peak-to-peak voltage symmetrical about $\frac{\mathrm{V}_{\mathrm{DD}}}{2}$

[^8]:    *Peak-to-peak voltage symmetrical about $\mathrm{V}_{\mathrm{DD}} / 2$

[^9]:    *Determıned by mınımum feasıble leakage measurements for automatıc testıng
    $\dagger$ Values at $-55,+25,+125$, apply to $D$ package Values at $-40,+25,+85$, apply to $P$ package

[^10]:    - Peak-to-peak voltage symmetrical about $\mathrm{V}_{\mathrm{DD}}$ unless otherwise specified.

[^11]:    The "PRELIMINARY" designation on an SSi data sheet indicates that the product is not yet released for production. The specifications are subject to change, are based on design goals or prelımınary part evaluation, and are not guaranteed. SSi should be consulted for current informatıon before using this product No responsibility is assumed by SSi for its use; nor for any

[^12]:    $0=$ Low level
    $1=$ High level
    $X=$ Don't care

[^13]:    1 Gardner FM Phaselock Technıques, Wiley NY, Second Ed, 1967

[^14]:    *Operatıon above absolute maximum ratıngs may damage the device.

[^15]:    Notes [1] The motor parameters given are for a typical motor The device will work for a range of motors near this nominal motor
    [|2] The motor must have a back EMF less than 10 volts peak (measured from center tap to drive transistor collector/drain) at speed to insure linear operatıon of drive transistors and a coil resistance small enough to insure adequate start current

[^16]:    $\dagger$ Not more than one output should be shorted at a time and duration of the short-circuit should not exceed one second
