

IBM Enterprise2013 pOS585 - Using SVMON to Understand AIX Memory Usage

Grover Davidson – grover@us.ibm.com

© 2013 IBM Corporation

Objectives are to identify and understand:

- Segmented memory architecture
- System VMM segment types
- Virtual address space
- Effective address space
- Private and Shared memory segments
- File system cache

Segmented memory architecture

- Allows every process to function like it is the only process on the system
- Removes developer concerns about what is running on the system outside of their individual program
- Saves memory by allowing 'holes' in physical memory assigned
- 32 bit processes can have 16 segments: 0-F
- 64 bit processes can have up to 2^36 possible segments (note: this requires 64 bit hardware)
- AIX 5L supports multiple page sizes: 4k/64k/16M/16G
- 4k pages are supported on all platforms
- All other pages sizes are platform dependent
- A single segment references 256MB of address space

VMM Page sizes

- Physical memory pages are called Memory Frames.
- A frame consists of a specific amount of physically contiguous memory (the page size) aligned on a physical address boundary.
- The ability to support different page sizes is directly tied to the hardware memory management hardware.
- AIX maintains a free list of both 4k, 64k and 16M pages to be assigned as needed.
- All files are backed by 4k pages.
- Working storage can use all page sizes.

VMM page size selection

- AIX 6.1 supports dynamic page promotion. When 16 (4k) frames are *virtually* contiguous the VMM will attempt to migrate the pages to a single 64k page.
- The balance of 4k/64k pages is maintained by psmd (Page Size Management Damon).
- Page sizes can be explicitly chosen for a process by using the LDR_CNTRL environment variable or using the Idedit command on an executable. LDR_CNTRL is preferred in most cases.
- Using 64k pages CAN result in a larger memory footprint for an application due to memory holes.
- Using 64k pages reduces page faults and is more efficient for addressing memory.
- Do not set LDR_CNTRL to use all 64k pages in /etc/environment! There are many programs that will never need 64k pages and will waste memory!

Segment characteristics

- Addresses have a segment, page and page offset
 - Starting from the least significant digit of an address:
 Typical Address: F10006000 35A6C00
 - - 7 hex digits for page/page offset:

Segment Page/offset

4k pages: 4 hex digits for page number/3 hex digits for offset 64k pages: 3 hex digits for page number/4 hex digits for offset 16M pages: 1 hex digit for page number/6 hex digits for offset 16G pages: Handled completely different

- As of AIX 6.1 on POWER6 segments can have multiple page sizes
- Remaining digits are the effective segment id (ESID)
 - 1 hex digit for 32 bit applications
 - 9 hex digits for 64 bit applications
- The process address uses the ESID
- The system wide segment id is the VSID
- Translation is performed by hardware, VMM and the hypervisor
- The use of ESID/VSID depends on if the address is being referenced from the process space or kernel space

Assigning physical pages to a segment

- Segments are created as address space is needed by a process or kernel
- Initially have no physical pages in them
- Addressable pages are malloced/allocated
- As each address is referenced by the program, it is checked to be a valid address
- If the address is valid, the page frame table is checked for a reference to the frame
- If there is no reference, a page is assigned from the free list
- eXternal Page Tables (XPT) provide the tracking of pages on paging space devices
- File system pages are tracked though file system specific routines

Page Frame Table

- Used to translate between the virtual addresses and memory frames.
- Used to be part of AIX before virtualization.
- Now part of the hypervisor.
- Prevents an LPAR from changing it's own memory translations to access memory from another LPAR.
- Created based on the maximum amount of memory the LPAR can have assigned.
- These pages are part of the LPAR memory but not directly accessible by AIX.
- Part of the 'other' pages in symon output.

VMM Segment types

- Segments are classified by how they are being used
- The classification can change as the segment is used in different ways
- Processes that have the same VSID mapped into their address space are using the same memory
- Segments are classified to allow for memory management, security, and usage information

Basic Segment types

Working

- Kernel segment is used in kernel space and is addressable by all processes – kernel and application
- Text/shared library text Contain executable code
 - Not modifiable except through debuggers
 - Normally shared by multiple processes
- Data typically not shared and private to a single process
- mbuf Network memory segments
- Mmap/shmat'ed segments specifically setup to be mapped by 0 or more processes
 - Some applications use shmat segments to hold various data and are not normally attached to any process

Basic Segment types (cont'd)

- Persistent JFS file segment
 - Tightly integrated with the kernel
- Client Non-JFS file segment JFS2/NFS/Veritas/etc
 - Externalized from the kernel
- Multiple processes can map the segment by opening the same file
- All processes that map a segment have access to all pages referenced by that segment

Paging activity

- Used mainly for working storage pages, there are some rare exceptions
- Pages can be stolen and their contents are copied to paging space on a page by page basis
- If the page is referenced, a page fault occurs and the page is copied back into memory from paging space
- The page can be allocated just in real memory, just on paging space OR both
- These details are handled by the XPT
- Applications have no direct control over paging

"svmon –S" – A system wide view

Vsid	Esid Type Description	PSize	Inuse	Pin	Pgsp V	irtual
2c6d6	<pre>- pers /dev/testcase2_lv:20</pre>	S	84243	0	-	-
cb26	- pers /dev/hd1:2079	S	38274	0	-	-

1c00e	- work misc kernel tables	S	17322	0	0	17322
12c29	- clnt /dev/j2_test2:5	S	14667	0	-	-

- Vsid unique system segment ID.
- Esid effective segment only applies from process view
- Type Segment type: work/persistent/client
- Desc Any additional information like device: inode or details of how the segment is being used.
- PSize Page size: s=4k m=64k L=16M S=16G
- Inuse actual number a memory frames in use
- Pin pages that cannot be stolen by lrud
- Pgsp paging space usage
- Virtual total number of virtual pages created. This indicates how many pages would be needed for all the accessed pages to be in memory.

"symon –P" – View from the process

svmon -P 43818

Pid	Command		Inuse	Pin	Pgsp	Virt	ual 64-	bit M	thrd	16MB	
43818	less		25520	9293	0	25	478	Ν	Ν	Ν

46a2	_	pers	/dev/hd	2:221186		S	1	0	_	_	

The first summary line of page counts for the process is always in units of 4k pages.

- Vsid System wide segment number. 2 processes with the same Vsid mapped are sharing the same memory
- Esid Effective segment based on the address the process addresses the segment at. Esid's are different in 64 and 32 bit *processes*.

Esid's of '-' here indicate a file the is open by the process. The file is found with: 'find /usr -inum 221186 -xdev'. This segment is shared by all processes accessing this file.

Note that Vsid 0 is mapped to all processes. This is how the processes access the kernel. Vsid 3601b is also shared by all non-kernel processes on the system. This is the shared library code. Any other instances of the 'less' command will use the same VSID. The exact segment numbers will vary from system to system.

All other segments here are private to this process.

symon with multiple page sizes

Many lines have been deleted to save space.

- Note here that the kernel segment is using 16MB pages (PSize=L). To compute the pages added to in use multiply by 4096 (16 * 1024 * 1024 / 4096).
- The medium pages add 3269 * 16 = 52304 (4k) pages.
- Remember that the summary in use is in units of 4k pages. The Inuse for each SEGMENT is in the page size for that segment.

Segments with multiple page sizes

Pid	Command		Inuse	Pin	Pgsj	p Vir	tual	64-bit	Мt	chrd	16MB

- Page size column showing 'sm' for the page size indicates multiple pages sizes are being used in this segment.
- Unable to determine details of how many of each pages sizes is in use.
- The Inuse/Pin/Pgsp/Virtual page counts are adjusted to display all in 4k units.

Segments with multiple page size details

svmon -O pgsz=on, segment=on, mpss=on -P 36372852

Unit: page

			_								
Pid	Command		Inuse	Pın		Pgsp	Vırt	ual			
36372852	kdb		42164	14080		0	30	887			
Page	eSize		Inuse		Pin		Pgs	p Vi	irtual		
S	4 KB		16788 0				0 551				
m	64 KB		1586		880			0	1586		
Vsid	Esid	Туре	Descriptior	1		I	PSize	Inuse	Pin	Pgsp	Virtual
20002	0	work	kernel segn	nent			m	937	877	0	937
a10021	90000000	work	shared libr	cary te	ext		m	644	0	0	644
85a604	-	clnt	remote				S	9079	0	-	-
50005	9fffffd	work	shared libr	rary			S	2019	0	0	2899
							m	55	0	0	0
flce71	11	work	text data E	BSS hea	ap		S	636	0	0	1772
							m	71	0	0	0

• Each page size is lised and the number of pages in each catagory.

■When using 'svmon –S' use 'svmon –O mpss=on –S' to see the segement page size details.

For segment 50005 we have 2019 (4k) pages + 55 (64k) pages = 2019 + 55(16 4k pages per 64k page) = 2899 (64k) pages. This correctly matches the output from the previous slide.

Differences between svmon –S and -P

■ -S

- No segment is listed more than 1 time
- Segments not associated with a process are listed
- Unable to tell how many processes are referencing a segment

■ -P

- Segment is listed for every process using it
- Segments not associated with a process are not listed
- Most kernel segments are not shown
- Files not opened by a process but that are cached are not listed

/u	sr/bin/s	vmon -G					
		size	inuse	free	pin	virtual	mmode

m	64 KB	_	182582	0	110333	182582	

- All segments are counted and classified.
- 'Other pages' summarize pages in use but do not have a VMM segment, like the page frame table in the hypervisor.
- Memory mode is listed, in this case it is traditional dedicated mode.
- Paging space usage is summarized.
- The total number of memory frames needed for working segments (everything except file cache) is the value under 'virtual'. This is the number of 4k pages needed for working storage. This should be approximately equal to AVM column of vmstat.
- File system cache in use is determined by adding pers and clnt in use values.
- Memory page usage by page size is also summarized here.

find /tmp -inum 300

/tmp/errorlog.grover

The pages used by segment 12ce9 are SHARED by both processes. It does not matter which process causes the pages to be read, they are available to all processes accessing the segment.

NOTE: Not all file systems provide this level of detail! Encrypted file systems may add additional complications.

Shared Memory Segments

svmon	-Pns
-------	------

Shared segments are identified as shmat'ed or mmap'ed. Any processes that have these segments mapped are in fact accessing the same memory.

Please note that these segments are fully populated with pages! 65536 * 4k = 256MB.

Shmat'ed memory segments are not deleted when they are not mapped to a process. These segments must be explicitly deleted. Segments marked for deletion will not be deleted until no processes are attached to them.

Correlating ipcs with svmon

# i]	ocs -aS								
IPC	status f	from /dev/me	em as of Mon	Aug 28 16:	:21:17 MS	т 2006			
Т	ID	KEY	MODE	OWNER	GROUP	CREATOR	CGROUP	NATTCH	SEGSZ
Sha	red Memoi	cy:							
m	1048576	0x00004dbe	rw-rw-rw-	root	sapsys	root	sapsys	1	1845702
SID	:								
0xe	084f								
m	5242881	Oxfffffff	rw	rctadm	sapsys	rctadm	sapsys	0	2147483648
SID	:								
0x9	0548 0x1k	05da 0x601	0x107e0 0x18	07b9 0x160)5b7 0x1c	05dd			

'svmon –U' will NOT add these segments in because they are not attached to a process. Note that this

information looks more like file information.

NATTCH indicates how many process have the segment mapped into their address space.

The SID listed is the VSID that can be examined with symon

The second shared memory segment listed here is larger than a single memory segment and as a result, multiple segments are allocated.

The first segment will appear in both the process and system output for symon since it is mapped by a process.

Since the second segment is not mapped, it will not appear as a shared memory segment in symon!

Identifying shared segments

Execute several instances of the program and select 1 instance of the program and examine each segment to see how many processes are using it:

#	svmon -P	29180 -1	
	Vsid	Esid Type Description PSize Inuse Pin Pgsp Virtual	
	3601b	d work shared library text s 13538 0 0 13538	
		Shared library text segment	
	0	0 work kernel segment s 11833 9293 0 11833	
		System segment	
	164ab	1 pers code,/dev/hd2:32977 s 18 0	
		pid(s)=30730, 30468, 29700, 29434, 29180, 26144, 25574	
		pid(s)=24790, 24534, 24282, 24014, 23768, 23246, 23020,	
		pid(s)=22742, 22516, 17372, 16342, 13764	
	344fa	2 work process private s 18 2 0 18	
		parent=264f3	
		pid(s)=29180	
	384fc	f work shared library data s 5 0 0 5	
		parent=2a4f5	
		pid(s)=29180	

Here we see that segment 164ab is shared because it is mapped to multiple processes. Shared library text segments do not list each process they are mapped into.

File system cache

- The file system cache will grow to use all free pages by default
- All processes accessing a file share access to all the pages of the file in the cache
- Pages for a file remain in memory even after the file is closed until they are stolen or the file is unlinked or the file system is unmounted
- File system segments (pers or clnt) that are marked as unused by symon are files that are not currently open but have pages in the file cache
- Executables are reclassified from file pages to working pages in most cases

How much memory does the file cache need?

- Depends on the type of application:
 - Databases that have internal caches like db2 can use CIO to disable AIX caching – use application statistics to determine the cache hit ratio to determine the effectiveness of the application cache
 - Databases without caches and other applications that rely on the operating system to cache will need more memory that can be used for caching
- Every system needs some file system cache
- Applications that access file systems will fill available memory with cached files
- Many backup utilities can be configured to use CIO/DIO to avoid flushing the active cache
- This is all normal and expected

What does AVM size really mean?

- AVM (Active Virtual Memory) column of vmstat or the Virtual value of svmon represents how much memory in 4k pages are needed for non-filesystem cache. This is all of the memory needed to execute the programs on the system.
- If Virtual/AVM exceeds the real memory on the system, paging cannot be prevented.

How much memory is a process using?

- Identify:
 - Private data
 - Code
 - Shared library
 - Process Shared memory
 - System segments (these are generally not included)
- Total memory = (N * private_data_pages) + Code + shared_libraries + process_shared_memory
- N= number of instances of the process

A real example

Find all the instances of the program:

# ps -ef	grep]	kdb_64						
grover	692314	1073586	0	14:53:06	pts/128	0:02	./kdb_64	./dump ./unix
sivar	950408	966850	0	15:12:19	pts/80	0:04	./kdb_64	dump unix
raghavan	1589418	716976	0	15:15:46	pts/99	0:08	./kdb_64	./dump ./unix
asulu	917900	1851674	0	Dec 27	pts/108	0:03	./kdb_64	dump unix

- Note that just because the names are the same it does not mean the executables are the same
- Select 1 instance and collect 'svmon –P XXX –I' and catagorize the segment based on the number of PIDs is it mapped to:

Adding it up!

- Process private segments are f2f8c, f022e, b0248, c2faf, 1a3079 and 1b2f78. These add up to 3322 pages of memory needed for EACH instance of this executable. Check several instances of this executable and average them.
- Keep in mind that there can be variations in memory usage in private segments depending on the execution path of each instance. Each instance should be examined!
- Shared text segments are 1ea55c, a01ab and 1b01ba. The first instance of this executable also needs 500 pages. Of the 500 pages, 202 are shared with other programs (segments a01ab and 1b01ba).
- The files are using 7051 pages in the file cache for these specific files. Depending on the specific files, they may or may not need to be completely cached.
- Man pages have additional flags for symon read them very carefully to understand the flags

AIX 6.1/7.1 updates/changes

- 'rmss' pages are also listed on the 'svmon –G' output as 'stolen' pages.
- New segment type of 'rmap' is used to indicate Real Mode Memory Mapping for accessing adapter IO space from memory.

Things that don't work like you may expect

- A number of things go into pinned memory and they are hidden from symon because of how they are configured. Adding up the pinned column of 'symon –S' will not match 'symon –G'.
- LPARs allocate certain structures based on the maximum memory and processors allowed. Adapters may also add/use addressable memory that is dedicated. These systems will have more pinned pages than can be identified in 'svmon –S' output. This can be partly accounted for by the difference between 'memory pages' and 'Iruable pages' in 'vmstat –v' output. Not all of the pinned pages will be accounted for. This is normal and expected.
- Both of these issues are resolved by accounting for the pages in the 'other' category. The 'other' category is defined as:
 - Number of frames managed by the operating system that are not attached to a VMM segment.

Finding growing segments

- Growing segments are only important for working segments
- Use 'symon –S' and collect 2 samples separated by some time.
- Now, determine which work segments have changed size with:

egrep –v " clnt | pers " before after | sort +1 | cut –f2-99 –d: | uniq –c | awk '\$1==1 {print}' before and after are the 2 svmon files.

Indentifying growing segments

Count	Vsid	Esid	Туре	Descriptio	n	PSize	Inuse	Pin	Pgsp	o Virtu	ıal

1	9002	-	work k	ernel heap		S	65482	0	5531	65536	

• The count should always be 1. Otherwise, this line is not unique.

 Please note that segment 826f is a segment created Or deleted between the before and after samples.

Summary

- By understanding the classification of memory segments in AIX, we can understand how memory is used by the kernel, processes and the file system cache
- svmon shows how AIX has classified a memory segment, the page size of the segment, and the processes using the segment
- Not all segments can be associated with a process
- If AVM exceeds real memory, paging is unavoidable
- Working storage pages can be in memory, on paging space, or in both places at the same time
- Note: svmon in kdb/KDB is different

Notes:

Performance is in Internal Throughput Rate (ITR) ratio based on measurements and projections using standard IBM benchmarks in a controlled environment. The actual throughput that any user will experience will vary depending upon considerations such as the amount of multiprogramming in the user's job stream, the I/O configuration, the storage configuration, and the workload processed. Therefore, no assurance can be given that an individual user will achieve throughput improvements equivalent to the performance ratios stated here.

IBM hardware products are manufactured from new parts, or new and serviceable used parts. Regardless, our warranty terms apply.

All customer examples cited or described in this presentation are presented as illustrations of the manner in which some customers have used IBM products and the results they may have achieved. Actual environmental costs and performance characteristics will vary depending on individual customer configurations and conditions.

This publication was produced in the United States.
