First Aid for Broken Databases

Rod Murchison

Miami Beach, FL

October 22-25, 2001

Contents

- ▶ How is a Database Broken
- ▶ The First Aid Kit
- ▶ The Danger Signs
- ▶ The Key Questions
- ▶ The First Aid Process
- ▶ Assess the Damage
- ▶ Assess the Affect
- ▶ Preserve the Evidence
- ▶ Recover The Database
- ▶ Pointers in the Prefix
- ▶ Control Fields
- ▶ The Bits in the Delete Byte
- ▶ Focus on the Damage
- ▶ Recovery Techniques
- ▶ Reorganization as a Recovery Tool
- ▶ A Few Last Words

How is a Database Broken?

▲ Control Information becomes incorrect

- ▶ Free Space
- ▶ RAPs
- ▶ VSAM CDF and RDF

▲ A pointer becomes incorrect

- ▶ Physical pointer
- ▶ Logical Pointer
 - Logical Relations
 - Secondary Indices
- ▶ Chain Pointer

▲ Data becomes incorrect

- ▶ Incorrect updates
 - Application logic
 - Double updates
 - Bad input
 - Mistaken backout

■ This presentation concentrates on Full Function pointer problems

The First Aid Kit

- ◆ **Image Copies**
- ◆ **Logs including Change Accumulations**
- ◆ **IDCAMS EXAMINE (and DIAGNOSE)**
- ◆ **Recovery Utility**
- ◆ **Reorganization Utilities**
- ◆ **Batch Backout Utility**
- ◆ **Pointer Checker**
- ◆ **IMASPZAP**
- ◆ **Application Programs**

The Danger Signs

▲ MSGDFSARL

- ▶ **DFS0931I** Invalid Index Relationship Between Index DBD and indexed DBD
- ▶ **DFS0934I** PSB psb Referenced SEGM seg in DBD dbd. SEGM has invalid Pointers.
- ▶ **DFS0953I** Logical Child in Database xxx has LP Pointer. LP is HISAM.
- ▶ **DFS0954I** Logical Parent in Database xxx has LC POINTER. LC is HISAM.
- ▶ **DFS2441W** SYMB Pointer from LC www in DBD xxx to LP yyy in DBD zzz is Non-unique.
- ▶ **DFS3098A** Partition Boundary

The Danger Signs...

▲ **ABENDUxxxx**

- ▶ ABENDU0302
- ▶ ABENDU0790
- ▶ ABENDU0803
- ▶ ABENDU0807
- ▶ ABENDU0808
- ▶ ABENDU0811
- ▶ ABENDU0832
- ▶ ABENDU085x
- ▶ ABENDU0860
- ▶ ABENDU0868
- ▶ ABENDU0931
- ▶ ABENDU0959
- ▶ ABENDU0960
- ▶ ABENDU0987

The Key Questions

- ▲ **1. What is broken?**
- ▲ **2. When was it last known to be good?**
- ▲ **3. When was it known to be broken?**
- ▲ **4. What happened between 2 and 3?**
- ▲ **5. When did it break?**
- ▲ **6. How did it break?**
- ▲ **7. Why did it break?**
- ▲ **8. How do we keep it from breaking again?**

The First Aid Process

- **Assess the Damage**
- **Assess the Effect of the damage**
- **Preserve the Evidence**
- **Recover the Database**

Assess the Damage

- **Check the messages and abend codes**
- **Refer to the Messages and Codes manual**
- **Refer to the Fast Manual**
- **Check the dump or snap**
- **Run Pointer Checker**

Assess the Effect

- **Importance of the data**
- **Impact on business process**
- **Availability of work-around**
- **Likelihood of repetition**
- **Impact of down time**
- **Effect on other work**
- **??? Recover immediately or wait until later**

Preserve the Evidence

▲ Save the damaged database

- ▶ Rename the data sets and save them
- ▶ Make copies of the data sets
- ▶ Do not forget logically related data set

▲ Keep the logs

▲ If VSAM, run EXAMINE and save the output

▲ Keep the dump

▲ Keep the output of the Pointer Checker

▲ Save the console log

▲ Start preparing answers to the key questions

Recover The Database

Pointers in the Prefix

▲ Prefix Without Logical Relationship

- ▶ PP only if a lower level segment is a logical parent

or

▲ Logical Child Prefix

- ▶ PP, LTF and LTB only present if virtual pairing

or

Pointers in the Prefix...

▲ Logical Parent Prefix

- ▶ PP only if a lower level segment is a logical parent
- ▶ Counter is used if no LC pointers are generated

or

Control Fields

▲ Free Space Anchor Point

- ▶ Two 2-byte fields
 - First the offset from in bytes to first FSE
 - Second is a flag indicating if this block is a bitmap
0 = this is **not** a bitmap

▲ Anchor Point Area

- ▶ Contains one or more 4-byte Root Anchor Points (RAP)
 - 1 RAP in HIDAM if the root has PTF or HF pointer
 - RMNAME parameter specifies number of RAPs in HDAM

▲ Each RAP contains the address of a root segment or 0s or Fs

▲ Free Space Element

The Bits in the Delete Byte

- ▲ **0 - Segment marked for delete**
 - ▶ Used in HISAM and index database

- ▲ **1 - Database Record marked for delete**
 - ▶ Used in HISAM and index database

- ▲ **2 - Segment Processed by Delete**

- ▲ **3 - Reserved**

- ▲ **4 - Prefix and Data are Separated**

- ▲ **5 - Segment marked for delete on Physical path (PD)**

The Bits in the Delete Byte....

- ▲ **6** - Segment marked for delete on Logical path (LD)
- ▲ **7** - Segment marked for delete on Logical Twin chain
 - ▶ Only set if bits 5 and 6 are set

- ★ FF means that this is the separated data

- ★ 27 is a thoroughly deleted HD segment
C0 is a thoroughly deleted HISAM or
Index segment

Focus on the Damage

▲ Look at the Source and the Target of the Bad Pointer

- ▶ The source is the prefix where the pointer is located
- ▶ The target is the prefix where it is pointing

▲ Is the error in the Source or the Target

- ▶ If in the source, it may be possible to correct it
- ▶ If the Target is bad, it will usually need recovery

Recovery Techniques

▲ Backout

- ▶ Ideal when reversing data errors
- ▶ May backout pointer errors
 - Usually hits the same problem in trying to process
- ▶ Subsequent processing may make this impossible

▲ Forward Recovery

- ▶ Only recover to the point at which the error occurred
- ▶ Will lose some processing
- ▶ Can be hard to find a recovery point
 - May have to persuade DBRC to accept your choice
- ▶ This will get you a clean database

Reorganization as a Recovery Tool

▲ HD Unload - The Poor Man's Pointer Checker

- ▶ Uses unqualified GN calls to read the database
 - Checks all PCF and PTF pointers
 - If it runs clean, the PCF and PTF are good
 - Will **not** correct bad PCF or PTF pointer

- ▶ May use LP pointers during unload
 - If LPCK in the LC is not physically stored
 - If it runs clean, LP pointers are good
 - Will **not** correct a bad LP pointer

Reorganization as a Recovery Tool...

▲ HD Reload - Reconstruction

- ▶ Rebuilds all physical pointers
 - can correct bad backward pointers
- ▶ Prepares to resolve Logical Pointers
 - DBR will cause unload to save the old LP pointer
 - **DBIL** will use concatenated keys to resolve relations

▲ Prefix Resolution and Update

- ▶ Rebuild the LP and LT pointers

▲ HISAM Reload

- ▶ Rebuilds the Indices

▶ If you can reorg your database, it will be good

A Few Last Words

- ★ **Don' take heroic measures unless you have to**

- ★ **Use extreme Care in Repairing Pointers**

- ★ **It may be better to ZAP a delete byte than a pointer**

- ★ **Discuss what you are about to do with somebody else**

- ★ **Activate the Emergency Care System - Dial 911**
 - **IMS Level 2**
 - **PSS Group**
