

Lotus Expeditor 6.1 Education

IBM® Lotus® Expeditor 6.1 Client for Desktop

Network awareness layer

Lotus software

@business on demand software

© 2006 IBM Corporation

This presentation explains the Network Awareness Layer in IBM Lotus Expeditor 6.1 Client for Desktop.

Goals

- Understand the network awareness layer support provided in IBM Lotus Expeditor Client for Desktop

The goal of this presentation is to understand the network awareness layer support provided in IBM Lotus Expeditor 6.1 Client for Desktop.

Agenda

- Network Layer
 - ▶ Overview
 - ▶ Extension point
 - ▶ Notification Model
 - ▶ Customized Handlers
 - ▶ Configuration
 - ▶ RCP HTTP URL handler
 - ▶ Serviceability
 - ▶ Summary

The agenda of this presentation is to explain the Network Layer capabilities that the client platform provides to you, the infrastructure and plug-ins that enable these capabilities, and details about the network layer supported by IBM Lotus Expeditor 6.1 Client for Desktop.

Section

Network layer

So, let's describe more details about the Network Layer

Network layer

Network layer

- The network layer provides a base framework to handle network errors and provides a network monitoring service

The network layer is a base network management layer in Expeditor Client that provides a framework to applications and platform components for network invocations and network error handling.

It provides users with the capability to determine the current status of the client platform as well as their connectivity to remote servers and HTTP resources including Web services. The application can choose to be notified of client status changes or check the client platform status by using the public APIs for offline manager. The application can handle the network error by using the public APIs for Net Faults. The application can also check the real network status by using the public APIs for network status. This layer also includes the Rich Client Platform (or RCP) version of HTTP URL Handler, which integrates with the account API and the offline manager.

Network layer functionality

Network layer

- Current network status of the client platform (online/offline)
- Connectivity status to remote servers
- Connectivity status to HTTP resources including Web services
- Application can be notified of client status changes
- Application can check the client platform status
 - ▶ Use the public APIs for Offline Manager
- Application can handle the network error
 - ▶ Use the public APIs for Net Faults
- Application can check the network adapter status
 - ▶ Use the public APIs for Network Status

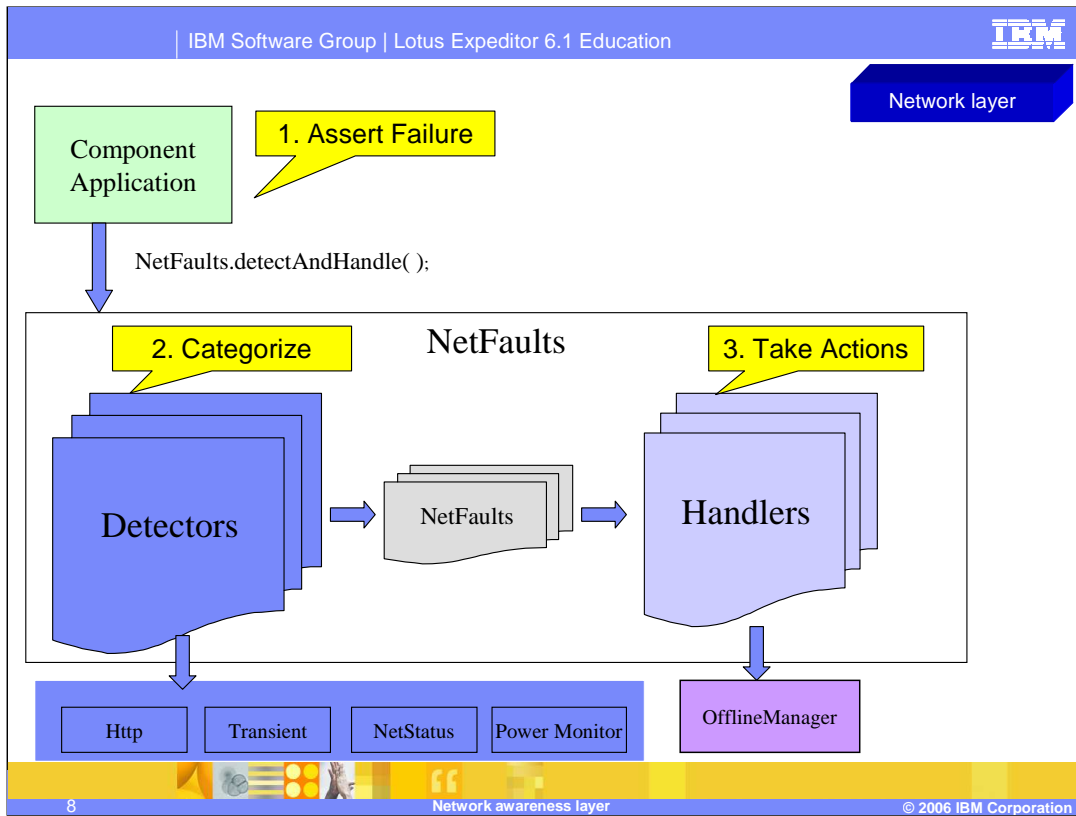

This slide describes the Network Layer functionality.

Network layer – Notification model

Network layer

- Applications use the Notification Model to be notified when
 - ▶ Platform network connection status change (online/offline)
 - ▶ Listening to remote server status change
- When an error occurs the application calls
 - ▶ `com.ibm.rcp.net.faults.DetectAndHandle.detectAndHandle()`
- `DetectAndHandle()`
 - ▶ Walk through the detectors, which generate the Faults
 - ▶ The Faults are passed to the handlers
 - ▶ The application component can also contribute customized handlers
- Handlers can then perform actions based on the Fault type

When an application throws a network error and calls `NetFaults.detectAndHandle()`, the `NetFaults` component will walk through the detectors and handlers in the order specified by the default configuration or its customized configuration. The detectors will categorize the fault and pass the fault to the handler. The handler can then take action based on the fault type. The platform provides all the detectors in a predefined order. The application component can contribute its customized handlers.

When a failure occurs, `detectAndHandle` is called by an application. The fault is categorized by the detectors and then passed to the Handlers where various actions can be done based on the fault occurring.

Network layer - Detectors

Network layer

▪ Default Detectors

- ▶ `com.ibm.rcp.net.faults.default.detectors.TransientFaultDetector` – This detector evaluates other fault types and determines if a transient Fault has occurred.
- ▶ `com.ibm.rcp.net.faults.default.netstatus.NetStatusFaultDetector` - This detector detects the physical network adaptor's availability.
- ▶ `com.ibm.rcp.net.faults.default.power.PowerMonitor` - This detector detects power related faults that may occur if a system transitions to standby or hibernate.
- ▶ `com.ibm.rcp.net.http.faults.HttpFaultDetector` - This detector recognizes errors at the HTTP level.
- ▶ `com.ibm.rcp.net.faults.default.handlers.AdvancedHandler` - This handler handles the `PowerFault` and `NetStatusFault`.

The Network Layer provides a handler extension point for applications to provide their own custom network faults handler.

The Network Layer also provides the following default detectors:

- The `TransientFaultDetector` evaluates other fault types and determines if a transient Fault has occurred.
- The `NetStatusFaultDetector` detects the physical network adaptor's availability.
- The `PowerMonitor` detector detects power related faults that may occur if a system transitions to standby or hibernate.
- The `HttpFaultDetector` recognizes errors at the HTTP level.
- The `AdvancedHandler` handles `PowerFaults` and `NetStatusFaults`

Network layer – Customized handlers

Network layer

- Extension Point
 - ▶ `com.ibm.rcp.net.faults.handler` – Create customized handler to handle the network faults
- Adding and configuring customized handlers
 - ▶ First create the handler
 - ▶ Then add the handler to the platform
 - ▶ Configure the platform to use the customized handler
 - ▶ See *Developing Applications for Lotus Expeditor* for details about adding and configuring customized handlers.

You can create customized handlers and configure the platform to use the customized handlers. First, you must create the handler. Then add the handler to the platform. See *Developing Applications for Lotus Expeditor* for information about creating a handler and adding the extension to the `plugin.xml`.

Network layer – Errors

Network layer

- If you have a networking error, the NetStatusFaultDetector will generate a NetStatusFault by the NetStatusDetector
- When you use the HTTP plug-in, if the server is down or if there are networking errors, use one of these exception types:
 - ▶ SocketException
 - ▶ ConnectException
 - ▶ NoRouteToHostException
- Will generate a ConnectFault by the HTTPDetector

Let's discuss an example of Handling Faults. If you have a networking error, the NetStatusFaultDetector will generate a NetStatusFault by the NetStatusDetector. When you use the HTTP plug-in, if the server is down or if there are networking errors, the exception type SocketException, ConnectException, or NoRouteToHostException will generate a ConnectFault by the httpDetector.

Network layer – Check network status

Network layer

- Applications can use the NetStatus API to detect if the network is on or off.
 - ▶ The following is an example of how to use the API
 - `hasAnyLinkConnector()` – the system has any link level connection
 - `hasChanged()` – indicates the network adapter has changed
 - `update()` – update to get the latest status of the network adapter

```
//call update() to get latest status, before checking status
private static final NetStatusMonitor _monitor=new NetStatusMonitor();
_monitor.update();
If (!_monitor.hasAnyLinkConnection())
{
    //network is off
}
```

Applications can use the Netstatus API to detect if the network is on or off.

This slide provides an example of how to use the API. Ensure you call the `update()` method first to get the latest status.

Network layer – HTTP URL handler

Network layer

- The Http plug-in within the network layer replaces the default VM implementation of HTTP and HTTPS URLStreamHandler's to be based on the Apache HTTP client.
 - ▶ No special coding is required to use the replacement URLStreamHandlers/URLConnections for HTTP and HTTPS.
- Simply create a URL object and then open the connection (with openConnection or openStream)
 - ▶ The HTTP URLConnection is a subclass of java.net.HttpURLConnection.
 - ▶ The HTTPS URL Connection is a subclass of javax.net.ssl.HttpsURLConnection.
- The URLConnection subclasses will always consult the Accounts API to locate login credentials for the subject URL.
 - ▶ If credentials are present for the URL, then those credentials will be used to authenticate access to the URL.
- See "Using enhanced HttpClient" in *Developing Applications for Lotus Expeditor*

The network layer also includes the RCP version of HTTP URL Handler which integrates with the account API and the offline manager.

The Http plug-in within the network layer replaces the default VM implementation of HTTP and HTTPS URLStreamHandler's to be based on the Apache HTTP client.

No special coding is required to use the replacement URLStreamHandlers and URLConnections for HTTP and HTTPS. Simply create a URL object and then open the connection (with openConnection or openStream)

The HTTP URLConnection is a subclass of java.net.HttpURLConnection.

The HTTPS URL Connection is a subclass of javax.net.ssl.HttpsURLConnection but the methods introduced by javax.net.ssl.HttpsURLConnection are not implemented. Otherwise, the HTTPS URLConnection subclass operates normally.

The URLConnection subclasses will always consult the Accounts API to locate login credentials for the subject URL. If credentials are present for the URL, then those credentials will be used to authenticate access to the URL.

Network layer - Serviceability

Network layer

- The Network Layer leverages JSR47 logging to log all messages
- JSR47 logging is the Expeditor platform runtime logging framework
 - ▶ Default Settings
 - Logging turned on, default level is INFO
 - Tracing turned off
- Runtime Logging and Tracing levels can be modified by updating `rcpinstall.properties`

The Network Layer has logging and tracing facilities. The Network Layer leverages the JSR47 logging framework to log all messages. This is the Expeditor Client platform runtime logging framework. The default configuration of the platform logging framework is stored in the user's `workspace/.config/rcpinstall.properties` file. This is further documented in the guide *Developing Applications for Lotus Expeditor*.

Network layer - Summary

Network layer

- The Network layer is a framework for handling network faults
 - ▶ It provides a handler extension point, and default detectors
- API
 - ▶ `com.ibm.rcp.net.faults` – applications use to create its own Fault and Handler
 - ▶ `com.ibm.rcp.net.offline` – applications can use to query the client status
 - ▶ `com.ibm.rcp.net.status` – applications can use to query the real network status: network is on or off.
 - ▶ `com.ibm.rcp.locationmanager` – transition the client between online and offline states and notification of a switch to a new location.
- Extension Point
 - ▶ `com.ibm.rcp.net.faults.handler` – handlers to handle the faults
- Target feature:
 - ▶ Network Layer
- Reference:
 - ▶ “Developing Network Aware Applications” in *Developing Applications for Lotus Expeditor*
 - ▶ “Using the Network Layer” in *Assembling and Deploying Lotus Expeditor Applications*

In summary, the Network Layer provides a framework for handling network faults. Further documentation on the API and Extension point can be found in *Developing Applications for Lotus Expeditor* in the section “Developing Network Aware Applications” and in *Assembling and Deploying Lotus Expeditor Applications* in the section “Using the Network Layer”.

Performance is based on measurements and projections using standard IBM benchmarks in a controlled environment. All customer examples described are presented as illustrations of how those customers have used IBM products and the results they may have achieved. The actual throughput or performance that any user will experience will vary depending upon considerations such as the amount of multiprogramming in the user's job stream, the I/O configuration, the storage configuration, and the workload processed. Therefore, no assurance can be given that an individual user will achieve throughput or performance improvements equivalent to the ratios stated here.
