IBM® WebSphere® Application Server V6

Application Server Java™ Class Loader

Examples

@business on demand.

© 2005 IBM Corporation
Updated May 11, 2005

This presentation will focus on Examples of the Application Server Java Class Loader.

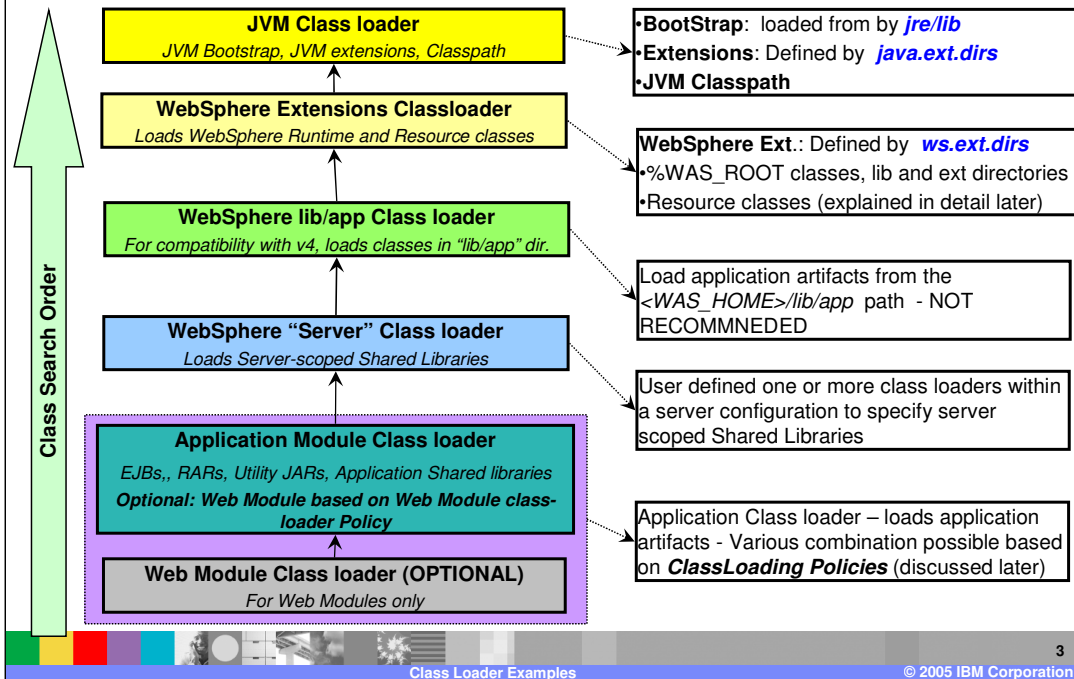

Goals

- Provide Class loaders examples with different policies and delegation modes

- Pre-requisite:
 - ▶ Understanding of WebSphere V6 Class loader Overview

The goal of this presentation is to provide some class loader examples with different policies and delegation modes.

Recap - Class Loader Hierarchy – At a Glance

Class loaders are organized in a hierarchy. This means that a child class loader can delegate class finding and loading to its parent should it fail to load a class.

This hierarchy was discussed in detail in the Class loader overview presentation.

This presentation will provide examples of some class loader scenarios.

Section

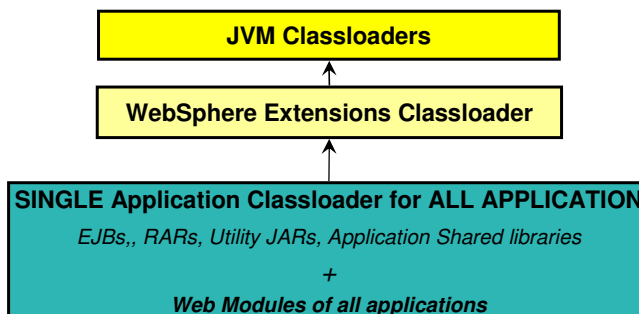

Class Loader Policies - Examples

This section will provide examples of Class Loader Policies.

Application/Web Module policies: Single &

Application Class-loader Policy	Web Module Class-loader Policy	Comments
Single	“Application” for all applications	<ul style="list-style-type: none"> Pros: Each Application EJBs, RARs, Dep. JARs can reference other classes in other Applications Cons: Cannot start and stop individual Applications without affecting others

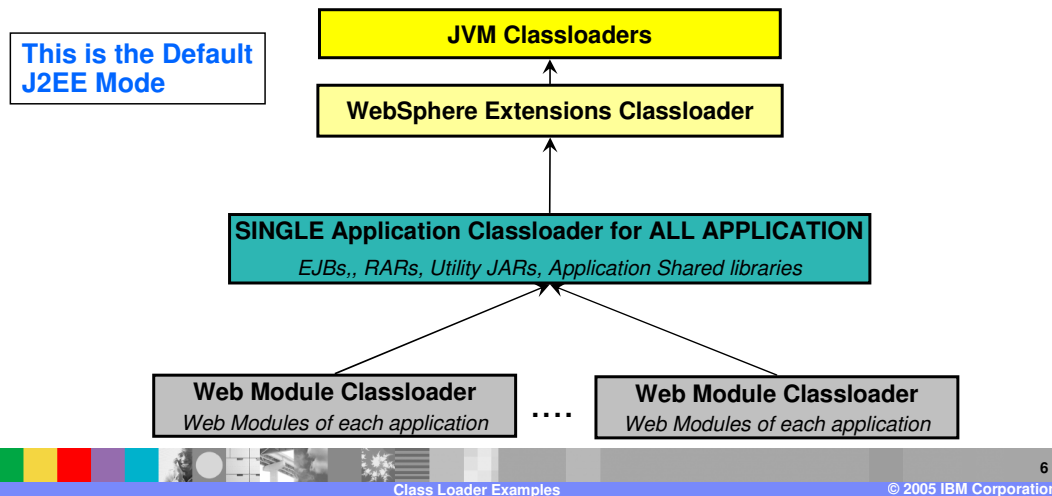

**Not Recommended to have Single Application Class loader
You loose isolation, dynamic reloading**

Shown here is an example hierarchy of an Application Class loader policy of **Single** and a Web module class loader policy of **Application** for all the J2EE applications. Using these class loader options sacrifices the isolation and dynamic reloading features.

Application/Web Module policies: Single &

Application Class-loader Policy	Web Module Class-loader Policy	Comments
Single	"Module" for all Applications	<ul style="list-style-type: none"> ▶ Pros: Each Application EJBs, RARs, Dep. JARs can reference other classes in other Applications ▶ Cons: Cannot start and stop individual Applications without affecting others

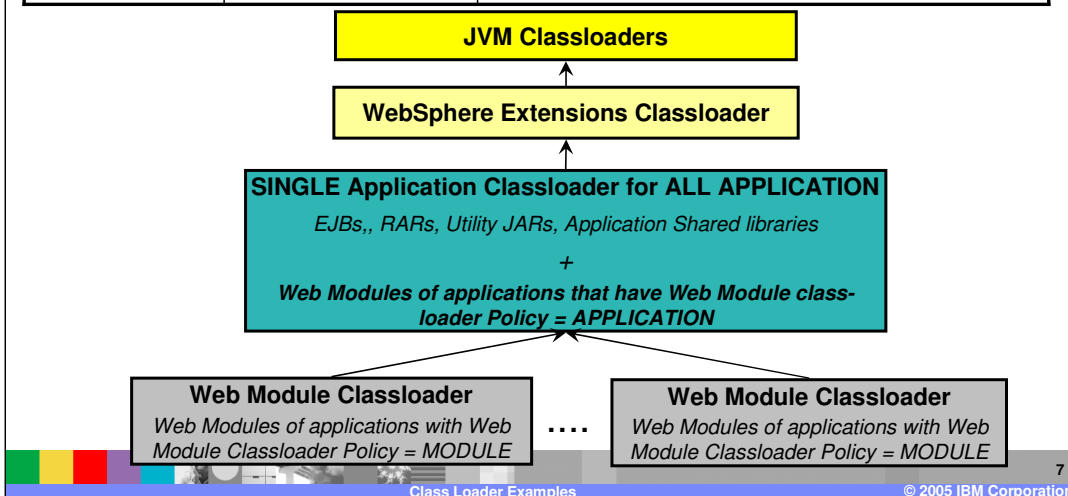

Shown here is an example hierarchy of an Application Class loader policy of **Single** and a Web module class loader policy of **Module** for all the J2EE applications.

With these policies, the Web module class loader is loaded by its own separate class loader. This is the default J2EE class loader mode.

Application/Web Module policies: Single &

Application Class-loader Policy	Web Module Class-loader Policy	Comments
Single	“Application” for some and “Module” for others	<ul style="list-style-type: none"> Pros: Each Application EJBs, RARs, Dep. JARs can reference other classes in other Applications Cons: Cannot start and stop individual Applications without affecting others

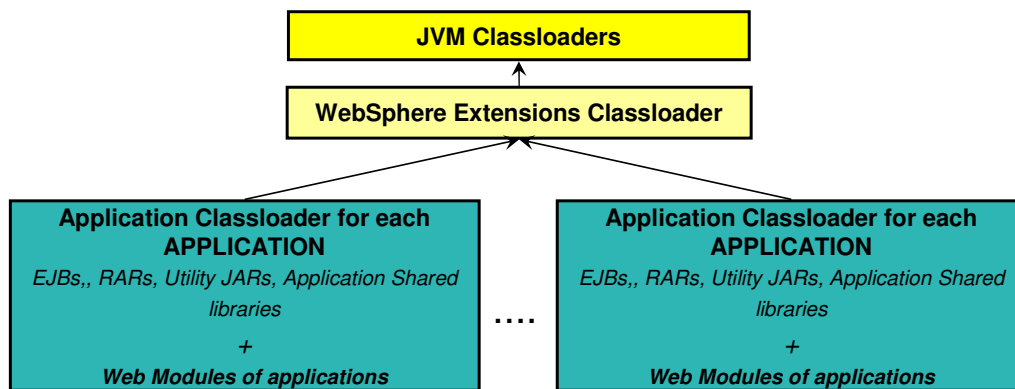

Shown here is an example hierarchy of the Application Class loader policy of **Single** and Web module class loader policy of **Module** for some of the J2EE applications and **Application** for the remaining applications.

With these policies, the Web module class loader for **Module** policy option is loaded by its own separate class loader. For a Web module class loader policy of **Application**, they are loaded by the Application Class loader.

Application/Web Module policies: Multiple &

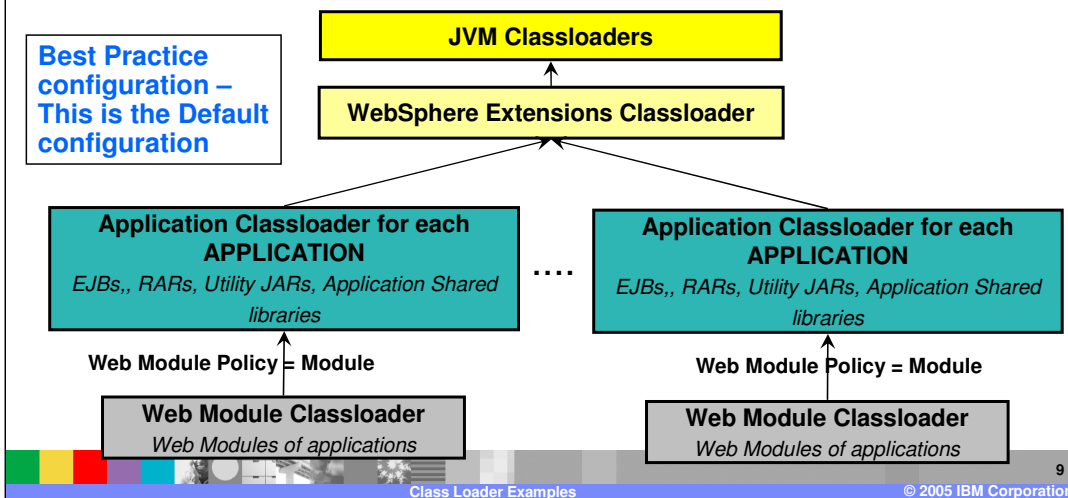

Application Class-loader Policy	Web Module Class-loader Policy	Comments
Multiple	“Application” for all applications	<ul style="list-style-type: none"> Pros: Can restart each application without affecting others Cons: Classes within one EAR cannot reference classes in another EAR

Shown here is an example hierarchy of an Application Class loader policy of **Multiple**. Each J2EE Application is loaded by its own class loader. Additionally, with the Web Module class loader policy of **Application**, the Web modules of those applications are loaded by the same class loader as the rest of the J2EE application classes.

Application/Web Module policies: Multiple &

Application Class-loader Policy	Web Module Class-loader Policy	Comments
Multiple	“Module” for all applications	<ul style="list-style-type: none"> ▶ Pros: Can restart each application without affecting others ▶ Cons: Classes within one EAR cannot reference classes in another EAR.

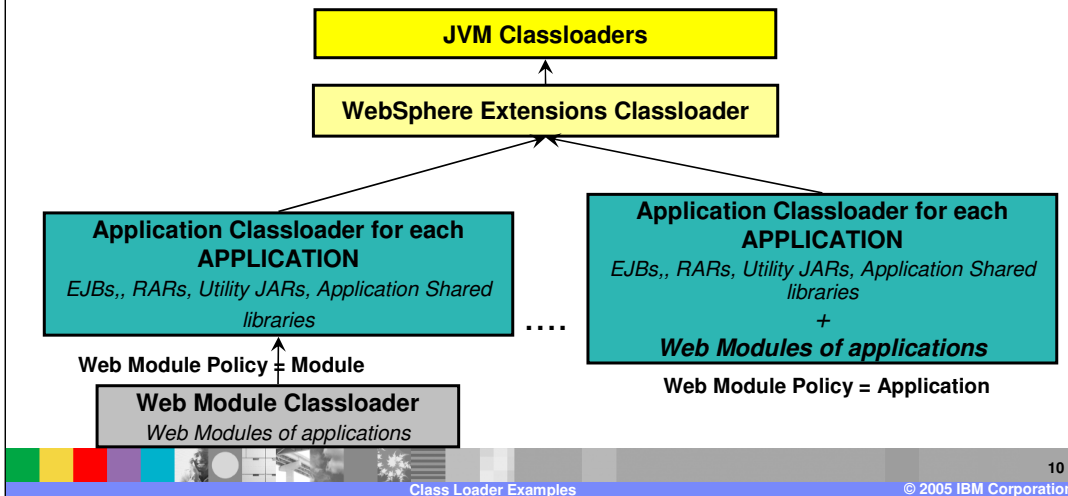

Shown here is an example hierarchy of an Application Class loader policy of **Multiple**. Each J2EE Application is loaded by its own class loader. However, note that the Web Module class loader policy is **Module**. As a result, each Web module is loaded by separate class loader, lower in the class loader hierarchy.

This is the default class loader configuration of WebSphere Application Server V6.

Application/Web Module policies: Multiple &

Application Class-loader Policy	Web Module Class-loader Policy	Comments
Multiple	“Application” for some and “Module” for others	<ul style="list-style-type: none"> Pros: Can restart each application without affecting others Cons: Classes within one EAR cannot reference classes in another EAR

Class Loader Examples

10

Shown here is an example hierarchy of an Application Class loader policy of **Multiple**. Each J2EE Application is loaded by its own class loader. However, some of the Applications have Web Module class loader policy is **Module**. As a result, for those applications, the Web module is loaded by a separate class loader, lower in the class loader hierarchy.

For the remaining applications that have a Web module class loader policy of **Application**, those Web module classes are loaded by the same class loader that loads the J2EE application.

Example 1

- Application class-loader policy: **Single**
- *Application 1*
 - ▶ Module: **EJB1.jar**
 - ▶ MANIFEST Class-Path: **Dependency1.jar**
 - ▶ Module: WAR1.war
 - ▶ Web Module Classloader Policy = **Module**
- *Application 2*
 - ▶ Module: **EJB2.jar**
 - ▶ MANIFEST Class-Path: **Dependency2.jar**
 - ▶ Module: **WAR2.war**
 - ▶ Web Module Classloader Policy = **Application**

The example shown here has the Application class loader policy at the server level set to **Single**.

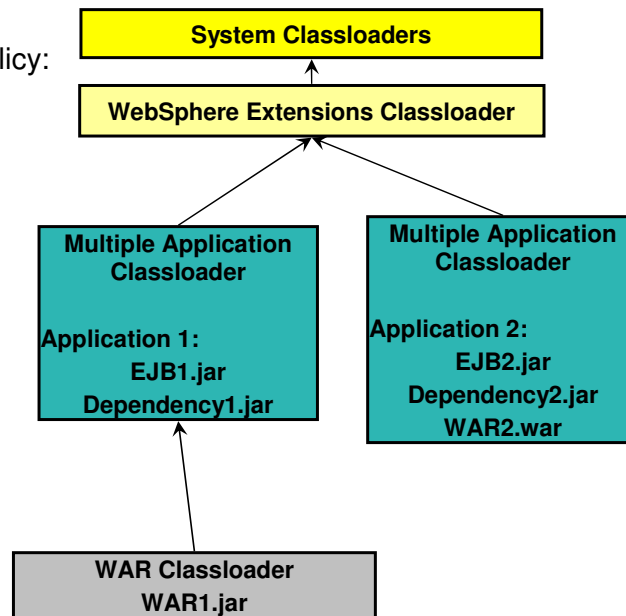

As a result, the classes for both the applications are loaded by the Single class loader. However, the Web module class loader policy defines how the Web modules will be loaded.

For Application 1, the Web module class loader policy is Module. As a result, each Web module of application 1 will have its own separate class loader, as shown by the WAR1 Web module.

For Application 2, the Web module class loader policy is Application. As a result, all Web modules of application 2 will be loaded by the same class loader that loaded Application 2 classes, as shown by the WAR2 Web module.

Example 2

- Application class-loader policy: **Multiple**
- *Application 1*
 - ▶ Module: **EJB1.jar**
 - ▶ MANIFEST Class-Path: **Dependency1.jar**
 - ▶ Module: WAR1.war
 - ▶ WAR Classloader Policy = **Module**
- *Application 2*
 - ▶ Module: **EJB2.jar**
 - ▶ MANIFEST Class-Path: **Dependency2.jar**
 - ▶ Module: **WAR2.war**
 - ▶ WAR Classloader Policy = **Application**

The example shown here has the Application class loader policy at the server level set to **Multiple**.

As a result, the classes for both the applications are loaded by their own separate class loader, as shown by the class loaders of Application 1 and 2.

However, the Web module class loader policy defines how the Web modules will be loaded.

For Application 1, the Web module class loader policy is **Module**. As a result, each Web module of application 1 will have its own separate class loader, as shown by the WAR1 Web module.

For Application 2, the Web module class loader policy is **Application**. As a result, each Web modules of application 2 will be loaded by the same class loader that loaded Application 2 classes, as shown by the WAR2 Web module.

Section

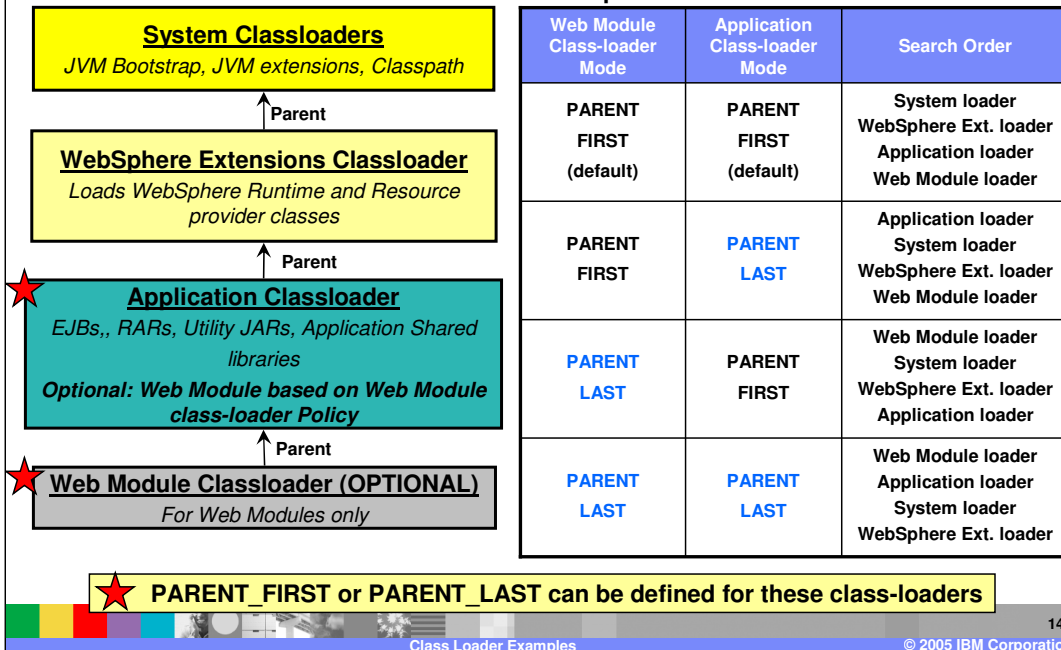

Class Loader Delegation - Example

This section will provide some examples of Class Loader Delegation.

Class-loader Delegation Mode: Example

Example: Web Module wants to load a class

Delegation or search mode is defined at the Application class loader and at the Web module class loader levels. Based on the different delegation modes, the table shows the search order path. At each level, if the delegation mode is PARENT_FIRST, the search goes to the parent. If the delegation mode is PARENT_LAST, the current class loader is searched before the parent. These delegation modes help when an application requires classes loaded from its own class loader rather than having it loaded by WebSphere supplied classes. This provides flexibility.

The default mode is the PARENT_FIRST for both the application class loader and the Web module class loader.

Section

Summary and References

This section will provide a summary of the concepts covered by this presentation.

Summary

- Provided some examples of Class-loader options with different policies and delegation modes

In summary, this presentation has provided some examples of class loader options with different policies and delegation modes.

Performance is based on measurements and projections using standard IBM benchmarks in a controlled environment. All customer examples described are presented as illustrations of how those customers have used IBM products and the results they may have achieved. The actual throughput or performance that any user will experience will vary depending upon considerations such as the amount of multiprogramming in the user's job stream, the I/O configuration, the storage configuration, and the workload processed. Therefore, no assurance can be given that an individual user will achieve throughput or performance improvements equivalent to the ratios stated here.
