

IBM Business Monitor
Version 8 Release 0

*IBM Business Monitor Installation
Guide*

Contents

Chapter 1. Installing IBM Business Monitor 1

Chapter 2. Planning to install IBM Business Monitor 3

Naming considerations for profiles, nodes, servers, hosts, and cells	3
Choosing appropriate topologies.	7
Single-server topology	7
High availability (network deployment) topology	7
Scalability	8
Four-cluster topology	11
Four-cluster topology with IBM Business Process Manager V8.0.1	12
Using existing software prerequisites	13
Profiles	13
Choosing the profile type.	13
Stand-alone profiles	14
Deployment manager profiles	14
Custom profiles	15
Database considerations	15
MONITOR database considerations for DB2	17
Cognos database considerations for DB2.	18
MONITOR database considerations for DB2 for z/OS	19
Cognos database considerations for DB2 for z/OS	21
MONITOR database considerations for Oracle.	22
Cognos database considerations for Oracle	24
MONITOR database considerations for Microsoft SQL Server	25
Cognos database considerations for Microsoft SQL Server	27
User registry considerations	27
Non-administrative user considerations	28
Topology considerations	28
Considerations for single-server topology	28
Considerations for network deployment topology using deployment environment patterns.	29
Considerations for custom network deployment topology	30
Considerations for IBM Business Process Manager in a four-cluster topology environment	30

Chapter 3. Preparing to install. 33

Hardware and software requirements.	33
Preparing operating systems for product installation	33
Preparing AIX systems for installation	33
Preparing Linux systems for installation.	34
Preparing Solaris systems for installation	36
Preparing Windows systems for installation	37

Chapter 4. Installing the IBM Business Monitor software 39

Installing from the product launchpad	39
Installing IBM Business Monitor interactively	41
Installing IBM Business Monitor silently.	44
Installing IBM Business Monitor silently using the command line	44
Installing IBM Business Monitor silently using a response file	49

Chapter 5. Creating the databases . . . 51

Creating or configuring database scripts using the database design tool	52
Configuring MONITOR database scripts manually	53
Configuring COGNOSCS database scripts manually	56
Installing the MONITOR database manually	57
Installing the COGNOSCS database manually	58
Creating messaging engine tables manually	59
Generating scripts for creating database objects in DB2 for z/OS.	60
Creating databases in the DB2 for z/OS subsystem	61
Setting up alias name definitions for connecting to the DB2 for z/OS server	62
Creating DB2 for z/OS database objects using the createDB2.sh script	63
Creating DB2 for z/OS database objects using the DB2 command line processor	65
Considerations for HADR setup and configuration	66
Configuring Oracle Real Application Cluster (RAC) for use with IBM Business Monitor	68
Configuring Oracle Data Guard for IBM Business Monitor	69

Chapter 6. Creating and augmenting profiles 73

Creating and augmenting profiles using the Profile Management Tool	73
Creating stand-alone profiles	74
Augmenting stand-alone profiles	80
Creating deployment manager profiles	82
Augmenting deployment manager profiles	87
Creating custom profiles for nodes	91
Augmenting custom profiles for nodes	93
Creating and augmenting profiles using the manageprofiles command	95

Chapter 7. Verifying the installation . . 97

Chapter 8. Determining port numbers 99

Chapter 9. Configuring the environment 101

Creating the deployment environment using a pattern	101
---	-----

Importing deployment environment definitions based on design documents	107
Adding an IBM Business Monitor deployment environment to an IBM Business Process Manager server deployment environment	113
Installing IBM Business Process Manager widgets into IBM Business Monitor Business Space	113
Installing IBM Business Monitor widgets into BPM Business Space	114
Creating the deployment environment using custom topology	114
Creating IBM Business Monitor clusters	115
Adding cluster members	116
Federating additional nodes	116
Configuring CEI event services	116
Configuring the environment using the configuration wizard	117
Configuring the environment using wsadmin commands	122
Configuring the environment manually.	124
Configuring the event emitter factory for IBM Business Monitor for z/OS	124
Installing the IBM Business Monitor action services application	125
Creating the Monitor action services group profile.	126
Installing Monitor scheduled services	126
Creating and configuring a scheduler resource	127
Installing dashboards for mobile devices	127
Installing event emitter services	128
Creating resources for manually installed event emitter services	128
Manually installing event emitter services	131
Using the configuration wizard to install event emitter services	132

Chapter 10. Configuring IBM Business Monitor components 133

Configuring IBM Cognos BI	133
Configuring a new IBM Cognos BI service	133
Generating an EAR file for IBM Cognos BI on a custom IBM Business Monitor node	136
Configuring IBM Business Monitor and Business Space to use an existing IBM Cognos BI service	137
Configuring IBM Cognos BI with WebSphere Portal	139
Configuring the reporting data source in IBM Cognos BI	140
Configuring IBM Business Monitor widgets for WebSphere Portal	141
Configuring how to receive events	141
Asynchronous event considerations	141
Configuring authorization for asynchronous event delivery	141
Receiving events from CEI	142
Receiving events using table-based event delivery	143
Configuring table-based event delivery in a single-cell environment	143

Configuring table-based event delivery in a multiple-cell environment	144
Receiving events using queue-based event delivery	145
Configuring queue-based event delivery in a single-cell environment	146
Configuring queue-based event delivery in a multiple-cell environment.	146
Configuring dashboards.	148
Configuring dashboards using the Profile Management Tool	149
Configuring dashboards as part of the Deployment Environment Configuration wizard.	150
Configuring dashboards for network deployment environments	151
Configuring REST services	152
Configuring all REST services on the administrative console	152
Configuring REST services using the command line	156
Configuring dashboards and registering REST endpoints on the administrative console	156
Configuring dashboards using the command line.	158
Creating a Business Space database design properties file	160
Configuring the Business Space database	161
Registering widget REST service endpoints using the command line.	163
Removing the virtual host from the primary cluster member.	164
Configuring a proxy server or load-balancing server to use with dashboards.	164
Configuring IBM HTTP Server for dashboards	166
Configuring a WebSphere Application Server proxy server for dashboards	167
Mapping dashboard URLs for a reverse proxy server.	168
Enabling widgets for cross-cell environments	169
Enabling widgets to work with multiple endpoints	171
Setting up specific widgets to work in dashboards	175
Installing the default dashboard space on z/OS	175
Setting up security for dashboards	176
Enabling security for dashboards	177
Selecting the user repository for dashboards	178
Setting up SSO and SSL for dashboards	182
Designating HTTP or HTTPS settings for dashboards	182
Setting up security for system REST services	183
Configuring Tivoli Access Manager WebSEAL to work with dashboards	184
Assigning the superuser role	187
Assigning the superuser by user group.	188
Preventing users from creating spaces	190
Enabling searches for user registries without wildcards.	191

Commands (wsadmin scripting) for configuring the Business Space component for dashboards	192
configureBusinessSpace command	193
getBusinessSpaceDeployStatus command	195
installBusinessSpace command	197
installBusinessSpaceWidgets command	199
registerRESTServiceEndpoint command	200
uninstallBusinessSpaceWidgets command	202
updateBusinessSpaceWidgets command	203
updateRESTGatewayService command	205
Updating templates and spaces after installing or updating widgets.	206
Configuring the Business Space Ajax proxy	207
Adding proxy policies to the Business Space Ajax proxy	207
Changing the timeout settings for the Business Space Ajax proxy	208
Blocking IP addresses using the Business Space Ajax proxy	209
Postmigration tasks for Business Space	209
Migrating dashboards	209
Configuring widgets to work with WebSphere Portal	210
Configuring SSO and SSL for widgets on WebSphere Portal	213
updateEndpointBindingsOnPortal command	214
Required entries for the proxy-config.xml file to configure widgets to work with WebSphere Portal	215

Configuring the global process monitor model	217
Installing the global process monitor model manually.	218
Enabling events for the global process monitor model	218
Configuring your dashboards for the global process monitor model	219

Chapter 11. Installing the showcase model. 221

Chapter 12. Updating IBM Business Monitor 223

Updating IBM Cognos BI	223
Installing fix packs and interim fixes interactively	224
Installing fix packs silently	226
Installing interim fixes silently.	227
Rolling back fix packs	228
Uninstalling interim fixes interactively	228
Uninstalling interim fixes silently.	229

Chapter 13. Uninstalling IBM Business Monitor 231

Uninstalling IBM Business Monitor interactively	231
Uninstalling IBM Business Monitor silently	232
Removing the showcase model	233

Chapter 1. Installing IBM Business Monitor

IBM® Business Monitor can be installed in multiple topologies. You can install all components on a single server, or you can distribute the components across multiple systems. To achieve a highly available environment with failover support, you can install IBM Business Monitor into a clustered environment that uses the clustering mechanism of WebSphere® Application Server or Process Server.

Important: IBM Business Monitor runs on multiple platforms. For details about supported operating systems, supported hardware, memory requirements, and disk space requirements, see the System requirements for IBM Business Monitor.

Chapter 2. Planning to install IBM Business Monitor

IBM Business Monitor has multiple components that can be installed on a single server or across multiple servers in the network. During the installation process, there are many options to consider. When planning to install IBM Business Monitor, you must consider the available options and how you want to deploy the components in your network.

Information is provided to help you to determine which topology is most appropriate for your environment and to understand the options that are available during the installation.

Review the following information before beginning your IBM Business Monitor installation:

Note: When you install IBM Cognos® Business Intelligence and IBM Business Monitor, ensure that IBM Cognos BI is installed using the same bit mode as WebSphere Application Server.

Naming considerations for profiles, nodes, servers, hosts, and cells

This topic discusses reserved terms and issues you must consider when naming your profile, node, server, host, and cell (if applicable). This topic applies to distributed platforms.

Profile naming considerations

The profile name can be any unique name with the following restrictions. Do not use any of the following characters when naming your profile:

- Spaces
- Special characters that are not allowed within the name of a directory on your operating system, such as *, &, or ?.
- Slashes (/) or back slashes (\)

Double-byte characters are allowed.

Windows **Directory path considerations:** The installation directory path must be less than or equal to 60 characters. The number of characters in the *profiles_directory_path\profile_name* directory must be less than or equal to 80 characters.

Note: Use a short path naming convention when you create a profile in a Windows environment to avoid the Windows 255 character path length limitation.

Node, server, host, and cell naming considerations

Reserved names: Avoid using reserved names as field values. The use of reserved names can cause unpredictable results. The following words are reserved:

- cells
- nodes
- servers
- clusters
- applications
- deployments

Descriptions of fields on the Node and Hosts Names and Node, Host, and Cell Names pages: Use the appropriate naming guidelines when you create profiles.

- Stand-alone server profiles
- Deployment manager profiles
- Custom profiles

Table 1. Naming guidelines for stand-alone server profiles

Field name	Default value	Constraints	Description
Node name	<div style="display: flex; justify-content: space-between; align-items: center;"> <div style="display: flex; align-items: center;"> <div style="background-color: #f4a460; padding: 2px 5px; margin-right: 5px;">Linux</div> <div style="background-color: #800040; color: white; padding: 2px 5px; margin-right: 5px;">UNIX</div> </div> <div style="margin-left: 20px;"> <p>Windows <i>shortHostName</i> Node <i>NodeNumber</i> where:</p> <ul style="list-style-type: none"> • <i>shortHost Name</i> is the short host name. • <i>NodeNumber</i> is a sequential number starting at 01. </div> </div>	Avoid using the reserved names.	Select any name you want. To help organize your installation, use a unique name if you plan to create more than one server on the system.
Server name	<div style="display: flex; justify-content: space-between; align-items: center;"> <div style="display: flex; align-items: center;"> <div style="background-color: #f4a460; padding: 2px 5px; margin-right: 5px;">Linux</div> <div style="background-color: #800040; color: white; padding: 2px 5px; margin-right: 5px;">UNIX</div> </div> <div style="margin-left: 20px;"> <p>Windows server1</p> </div> </div>	Use a unique name for the server.	The logical name for the server.
Host name	<div style="display: flex; justify-content: space-between; align-items: center;"> <div style="display: flex; align-items: center;"> <div style="background-color: #f4a460; padding: 2px 5px; margin-right: 5px;">Linux</div> <div style="background-color: #800040; color: white; padding: 2px 5px; margin-right: 5px;">UNIX</div> </div> <div style="margin-left: 20px;"> <p>Windows The long form of the domain name server (DNS) name.</p> </div> </div>	<p>The host name must be addressable through your network.</p> <p>If you are planning to use Business Space, use a fully qualified host name.</p>	Use the actual DNS name or IP address of your workstation to enable communication with it. See additional information about the host name following this table.

Table 2. Naming guidelines for deployment manager profiles

Field name	Default value	Constraints	Description
Node name	<div style="display: flex; justify-content: space-between; align-items: center;"> <div style="display: flex; align-items: center;"> <div style="background-color: #f4a460; padding: 2px 5px; margin-right: 5px;">Linux</div> <div style="background-color: #800040; color: white; padding: 2px 5px; margin-right: 5px;">UNIX</div> </div> <div style="margin-left: 20px;"> <p>Windows <i>shortHostName</i> Cell <i>ManagerNode Number</i> where:</p> <ul style="list-style-type: none"> • <i>shortHost Name</i> is the short host name. • <i>NodeNumber</i> is a sequential number starting at 01. </div> </div>	Use a unique name for the deployment manager. Avoid using the reserved names.	The name is used for administration within the deployment manager cell.
Host name	<div style="display: flex; justify-content: space-between; align-items: center;"> <div style="display: flex; align-items: center;"> <div style="background-color: #f4a460; padding: 2px 5px; margin-right: 5px;">Linux</div> <div style="background-color: #800040; color: white; padding: 2px 5px; margin-right: 5px;">UNIX</div> </div> <div style="margin-left: 20px;"> <p>Windows The long form of the domain name server (DNS) name.</p> </div> </div>	<p>The host name must be addressable through your network. Avoid using the reserved names.</p> <p>If you are planning to use Business Space, use a fully qualified host name.</p>	Use the actual DNS name or IP address of your workstation to enable communication with it. See additional information about the host name following this table.

Table 2. Naming guidelines for deployment manager profiles (continued)

Field name	Default value	Constraints	Description
Cell name	<p>> Linux UNIX</p> <p>> Windows <i>shortHostName</i> Cell <i>CellNumber</i> where:</p> <ul style="list-style-type: none"> • <i>shortHost Name</i> is the short host name. • <i>CellNumber</i> is a sequential number starting at 01. 	<p>Use a unique name for the deployment manager cell. A cell name must be unique in any circumstance in which the product is running on the same physical workstation or cluster of workstations, such as a Sysplex. Additionally, a cell name must be unique in any circumstance in which network connectivity between entities is required either between the cells or from a client that must communicate with each of the cells. Cell names also must be unique if their name spaces are going to be federated. Otherwise, you might encounter symptoms such as a <code>javax.naming.NameNotFoundException</code> exception, in which case, you need to create uniquely named cells.</p>	<p>All federated nodes become members of the deployment manager cell, which you name in the Node, Host, and Cell Names page of the Profile Management Tool.</p>

Table 3. Naming guidelines for custom profiles

Field name	Default value	Constraints	Description
Node name	<p>> Linux UNIX</p> <p>> Windows <i>shortHostName</i> Node <i>NodeNumber</i> where:</p> <ul style="list-style-type: none"> • <i>shortHost Name</i> is the short host name. • <i>NodeNumber</i> is a sequential number starting at 01. 	<p>Avoid using the reserved names.</p> <p>Use a unique name within the deployment manager cell.</p>	<p>The name is used for administration within the deployment manager cell to which the custom profile is added. Use a unique name within the deployment manager cell.</p>
Host name	<p>> Linux UNIX</p> <p>> Windows The long form of the domain name server (DNS) name.</p>	<p>The host name must be addressable through your network.</p> <p>If you are planning to use Business Space, use a fully qualified host name.</p>	<p>Use the actual DNS name or IP address of your workstation to enable communication with it. See additional information about the host name following this table.</p>

Host name considerations:

The host name is the network name for the physical workstation on which the node is installed. The host name must resolve to a physical network node on the server. When multiple network cards exist in the server, the host name or IP address must resolve to one of the network cards. Remote nodes use the host name to connect to and to communicate with this node.

IBM Business Monitor is compliant to both Internet Protocol version 4 (IPv4) and version 6 (IPv6). Wherever you can enter IP addresses in the administrative console, or elsewhere, you can do so in either format. Note that if IPv6 is implemented on your system you must enter the IP address in IPv6 format, and conversely, if IPv6 is not yet available to you, enter IP addresses in IPv4 format. For more information on IPv6 refer to the following description: IPv6.

The following guidelines can help in determining the appropriate host name for your workstation:

- Select a host name that other workstations can reach within your network.
- Do not use the generic identifier, localhost, for this value.
- Do not attempt to install IBM Business Monitor products on a server with a host name that uses characters from the double-byte character set (DBCS). DBCS characters are not supported when used in the host name.
- Avoid using the underscore (_) character in server names. Internet standards dictate that domain names conform to the host name requirements described in Internet Official Protocol Standards RFC 952 and RFC 1123. Domain names must contain only letters (upper or lower case) and digits. Domain names can also contain dash characters (-) as long as the dashes are not on the ends of the name. Underscore characters (_) are not supported in the host name. If you have installed IBM Business Monitor on a server with an underscore character in the server name, access the server with its IP address until you rename it.

If you define coexisting nodes on the same computer with unique IP addresses, define each IP address in a domain name server (DNS) look-up table. Configuration files for servers do not provide domain name resolution for multiple IP addresses on a workstation with a single network address.

The value that you specify for the host name is used as the value of the `hostName` property in configuration documents. Specify the host name value in one of the following formats:

- Fully qualified domain name servers (DNS) host name string, such as `xmachine.manhattan.ibm.com`
- The default short DNS host name string, such as `xmachine`
- Numeric IP address, such as `127.1.255.3`

The fully qualified DNS host name has the advantages of being totally unambiguous and flexible. You have the flexibility of changing the actual IP address for the host system without having to change the server configuration. This value for host name is particularly useful if you plan to change the IP address frequently when using Dynamic Host Configuration Protocol (DHCP) to assign IP addresses. A disadvantage of this format is being dependent on DNS. If DNS is not available, then connectivity is compromised.

The short host name is also dynamically resolvable. A short name format has the added ability of being redefined in the local hosts file so that the system can run the server even when disconnected from the network. Define the short name to `127.0.0.1` (local loopback) in the hosts file to run disconnected. A disadvantage of the short name format is being dependent on DNS for remote access. If DNS is not available, then connectivity is compromised.

A numeric IP address has the advantage of not requiring name resolution through DNS. A remote node can connect to the node you name with a numeric IP address without DNS being available. A disadvantage of this format is that the numeric IP address is fixed. You must change the setting of the `hostName` property in configuration documents whenever you change the workstation IP address. Therefore, do not use a numeric IP address if you use DHCP, or if you change IP addresses regularly. Another disadvantage of this format is that you cannot use the node if the host is disconnected from the network.

Choosing appropriate topologies

IBM Business Monitor can be installed in many different configurations. A few basic topologies are provided. You might need to customize these to fit your environment.

To help you understand some of the possible installation deployments, the following topologies illustrate some common installations:

Single-server topology

When you use the single-server topology, all supporting products and all IBM Business Monitor components are installed on the same physical server.

Installing IBM Business Monitor on a single server is ideal for development test environments, proof-of-concept environments, and simple deployments that do not require failover and high availability capabilities.

You can use the IBM Business Monitor installation program to install IBM Business Monitor and WebSphere Application Server. When you install IBM Business Monitor on a single server, the Cognos service is also installed. You can use an existing Cognos Server if you already have it installed. To view the monitored data, you can use either a business space or the portlet-based dashboards.

After you install IBM Business Monitor, create a stand-alone profile to define your runtime environment. All required IBM Business Monitor components are created when you create or augment a stand-alone profile.

High availability (network deployment) topology

IBM Business Monitor uses the high availability capabilities in WebSphere Application Server or Process Server Network Deployment (ND) environments. Network deployment provides the capacity, scalability, and robustness that is generally required of a production environment. In network deployment environments, a group of servers can be used collaboratively to provide workload balancing and failover. The servers are managed centrally, using a single administrative console.

IBM Business Monitor uses the same architecture model as WebSphere Application Server or Process Server. Using this model, you create environments that have cells, nodes, servers, and optionally clusters.

If you choose one of the available deployment environment patterns (single cluster or four-cluster), the deployment environment wizard helps you to configure the clusters, servers, and components that you need.

The cell is the main administrative domain. You can think of a cell as a logical grouping of servers, clusters, or a combination of both. (A cluster is a group of application servers that collaborate for the purposes of workload balancing and failover.) Using servers and clusters, you can install IBM Business Monitor into a single cell that is both highly available and scalable.

A managed node (a node within a cell) contains one or more servers. Each server provides a runtime environment. Managed servers are created within a managed node, which has been defined by a custom profile. Each of the managed nodes is federated to the same deployment manager, and the deployment manager manages all managed nodes in the cell. Servers can be grouped into clusters, which are also managed by the deployment manager. For a network deployment environment, you should cluster your applications so that the applications are protected from the failure of a single server (high availability), the workload of the applications is spread across a number of equivalent servers (workload balancing), or both.

For more information on high availability, see "High availability and workload sharing" in the related links.

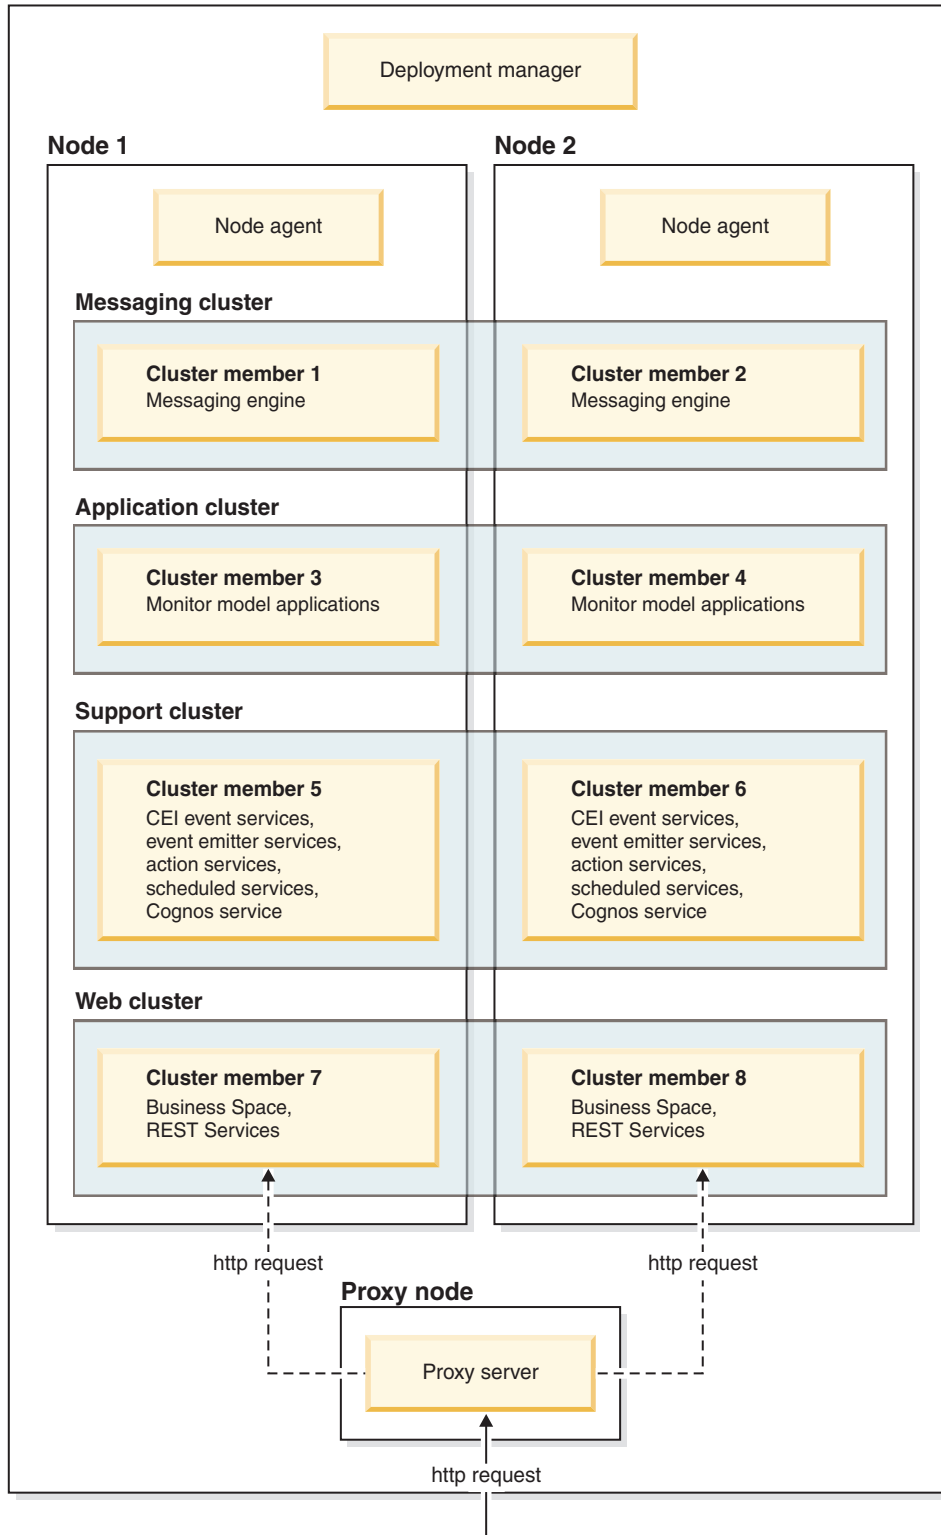

In an ND environment, you will normally set up a proxy server or an HTTP server for security reasons and for workload balancing. See the "Scalability" topic for more information about the proxy server.

Scalability

Installing IBM Business Monitor components and monitor models to a cluster enhances your ability to manage their workload. Distributing the components and monitor models across multiple clusters, grouping components based on common resource usage patterns, enables you to manage the individual workload of each cluster based on the resource usage pattern of the installed components. See the "Four-cluster topology" topic for a suggested starting point when planning for a scalable topology.

The following diagram shows a cell with two managed nodes.

Cell

Messaging engines

When deployed to a cluster, the messaging engine created for the IBM Business Monitor service integration bus is only active on one cluster member at a time. This behavior is specified by the default service integration bus policy. While the default service integration bus policy can be customized, the

policy must always be of type "One-of-N." A "One-of-N" policy allows only one instance of the messaging engine to become active in a cluster, providing high availability (protecting components and models from the failure of a single server), but not scalability (the ability to expand as resources are added).

You can minimize use of the messaging engine and enable better performance by using the feature that allows the common event infrastructure (CEI) event service to bypass the use of Java Messaging Service (JMS) queues and directly submit events into the IBM Business Monitor database. See "Receiving events using table-based event delivery" in the related task links for more information.

Support components

Support components include the CEI event service, IBM Cognos Business Intelligence service, action services, event emitter services, and scheduled services. Except for the scheduled services, add new cluster members for increased capacity.

Most of the workload for the scheduled services occurs on the database server. As the workload of the scheduled services increases, you should monitor, evaluate, and tune the database server as needed. The workload of the scheduled services can also be managed by either enabling or disabling the various scheduled services or by editing the service intervals associated with each scheduled service. See "Managing Monitor scheduled services" in the related tasks links for more information.

Web components

Web components include Business Space, widgets, and the IBM Business Monitor REST API service. Add new cluster members for increased capacity.

In an ND environment, you will normally set up a proxy server or an HTTP server for security reasons and for workload balancing. Instead of incoming HTTP requests going directly to a WebSphere Application Server, they go to a proxy server that can spread the requests across multiple application servers that perform the work. Create a proxy server in WebSphere Application Server. You can use other routing servers in place of or in front of the proxy server, for example IBM HTTP Server. The benefit of using the proxy server is that it is integrated with WebSphere Application Server and therefore easy to use and maintain.

Important: The proxy server (or an alternate routing server) is required for workload balancing HTTP requests across two or more cluster members. The proxy server allows clients to access the applications within this topology.

Monitor model applications

Monitor model applications are packaged as standard Java enterprise application archives (EARs). The monitor model application scales with the number of cluster members in the cluster.

Memory considerations

The amount of memory available to a single cluster member depends on the address space layout of the operating system and on whether the JVM that runs it is a 32-bit or 64-bit process. While a 64-bit JVM can access anywhere from 500 GB to 4 GB of memory, a 32-bit JVM might only have access to as little as 2 GB of memory (for example on 32-bit Windows).

As a general guideline, consider adding a second cluster for deploying monitor model applications when deploying more than ten monitor model applications if the cluster members are running on a 32-bit JVM. This is a guideline only, as individual workloads and models vary.

Four-cluster topology

You can install IBM Business Monitor into many topologies. You can use the four-cluster topology to set up a high performance environment.

The following four-cluster topology uses the Remote Messaging, Remote Support, and Web deployment environment pattern. This pattern groups the IBM Business Monitor applications into four clusters in a single cell.

Messaging Engine Cluster

WebSphere Business Monitor and CEI buses

Support Cluster

CEI event services, action services, services scheduler, event emitter services, Cognos service

Application Cluster

Monitor model applications

Web Cluster

Business Space application, Business Space widgets, REST services application

Messaging engine cluster

- Messaging engine for the IBM Business Monitor bus

- Messaging engine for the common event infrastructure (CEI) bus

Support cluster

- CEI event service

- Event emitter services

- Action services

- Monitor scheduled services

- IBM Cognos Business Intelligence service

Application cluster

- Monitor model applications

Web cluster

- Business Space application

- Business Space widgets

- Representational State Transfer (REST) services application

Note: For improved performance, place the event emitter services and CEI event service on the same cluster. Event emitter services includes both the REST event emitter and the JMS event emitter.

Related tasks:

“Considerations for IBM Business Process Manager in a four-cluster topology environment” on page 30
You can configure a Four cluster topology with IBM Business Process manager to create a combined IBM® Business Process Manager and IBM Business Monitor deployment environment using the Remote Messaging, Remote Support, and Web (four-cluster) pattern. Because one IBM Business Monitor deployment environment can monitor all applications in the cell, you should only create one IBM Business Monitor deployment environment in a given cell. The four-cluster topology combines IBM Business Monitor and IBM Business Process Manager messaging engine clusters into a single cluster.

Four-cluster topology with IBM Business Process Manager V8.0.1

You can create a combined IBM Business Process Manager and IBM Business Monitor deployment environment using the Remote Messaging, Remote Support, and Web (four-cluster) pattern. Because one IBM Business Monitor deployment environment can monitor all applications in the cell, you should only create one IBM Business Monitor deployment environment in a given cell.

Important: The information in this topic applies when you are setting up IBM Business Monitor V8.0.1 with IBM Business Process Manager V8.0.1. If you are using IBM Business Monitor V8.0.1 to monitor IBM Business Process Manager V8.5, see “Monitoring process applications with IBM Business Monitor 8.0.1” in the IBM Business Process Manager V8.5 information center.

The four-cluster topology combines IBM Business Monitor and IBM Business Process Manager messaging engine clusters into a single cluster. The following four-cluster topology uses the Remote Messaging, Remote Support, and Web deployment environment pattern.

Messaging engine cluster

- Messaging engine for the IBM Business Monitor bus
- Messaging engine for the common event infrastructure (CEI) bus
- Messaging engine for the Process Server bus
- Messaging engine for the Performance Data Warehouse bus
- (BPM Advanced only) Messaging engine for the Service Component Architecture (SCA) bus
- (BPM Advanced only) Messaging engine for the Business Process Execution Language (BPEL) bus

Support cluster

- CEI event service
- Event emitter services
- Action services
- Monitor scheduled services
- IBM Cognos Business Intelligence service
- Performance Data Warehouse
- (BPM Advanced only) Business rules manager

Application cluster

- Monitor model applications
- Process applications
- (BPM Advanced only) BPEL applications

Web cluster

- Business Space application
- Business Space widgets
- Representational State Transfer (REST) services application
- (BPM Advanced only) Business Process Choreographer tools

Using existing software prerequisites

You can install IBM Business Monitor on servers where the prerequisite software is installed.

Existing application servers

You can install the IBM Business Monitor server on a physical server where an application server platform is currently installed. The following application server platforms for IBM Business Monitor are supported:

- WebSphere Application Server
- IBM Business Process Manager

You can augment an existing profile, or you can create a new profile to contain the IBM Business Monitor server.

Note: Although you cannot install IBM Business Monitor V8.0.1 on IBM WebSphere Enterprise Service Bus, you can still monitor WebSphere Enterprise Service Bus applications.

Existing WebSphere Portal

IBM Business Monitor no longer provides portlet-based dashboards. However, your IBM Business Monitor widgets can still be displayed in WebSphere Portal. See the related task link for information.

Profiles

A profile defines the runtime environment and includes all of the files that the server processes in the runtime environment. In a high availability environment, you need multiple profiles to appropriately manage the complexity of the system. You can either create new profiles or augment existing profiles.

IBM Business Monitor has profile templates to enable functionality that is specific to IBM Business Monitor. After installing the product, you can create and augment profiles either using the Profile Management Tool wizard (in the WebSphere Customization Toolbox) or with the **manageprofiles** command. (If you are running Solaris in 64-bit mode, you must use the **manageprofiles** command.)

The IBM Business Monitor profile types are an extension of the similarly named profile types provided by WebSphere Application Server. The profile types provided by IBM Business Monitor are not the same as the profile types provided by WebSphere Application Server.

Using new profiles is more efficient and less prone to error than installing the product multiple times. Developers can use separate profiles for development and testing. By using profiles rather than multiple product installations, you gain the following advantages:

- You need to maintain only a single set of core product files.
- You save disk space.
- You can update the product more easily.

Choosing the profile type

A profile defines a unique runtime environment, with separate command files, configuration files, and log files. Profiles define three different types of environments: stand-alone single server, deployment manager, and managed node. Using profiles, you can have more than one runtime environment on a system, without having to install multiple copies of the product.

For a single-server environment, create a stand-alone profile.

For a network deployment environment, complete the following steps:

1. Create the deployment manager profile before creating the other profiles. If you created a deployment manager profile before installing IBM Business Monitor (for example, for WebSphere Application Server or Process Server) and you plan to use the same deployment manager profile to manage IBM Business Monitor nodes, augment the profile using the template that IBM Business Monitor provides.
2. Create a custom profile for each node that you plan to add to the server cluster. Alternatively, augment an existing custom profile for each node that you plan to add.

Note: If the database server contains multiple versions of DB2[®] installed, or multiple DB2 instances, the server's default DB2 version or instance is used for profile creation. To control which DB2 version or instance is used, use the "Installing databases manually" procedure so that the database administrator can ensure that the proper version or instance is used.

Templates for each profile are located in the `app_server_root/profileTemplates` directory. The following profile templates are available:

Profile	When to use
Stand-alone monitor server	For IBM Business Monitor single-server environments.
Monitor server deployment manager	If you are setting up a network deployment environment, create or augment this profile first. If you have created a deployment manager before installing IBM Business Monitor and you plan to use the same deployment manager profile to manage IBM Business Monitor nodes, augment the profile using the template provided by IBM Business Monitor.
Monitor server custom profile	If you are setting up a network deployment environment, create or augment custom nodes and later use the administrative console to install specific applications to the various custom nodes.

Stand-alone profiles

For IBM Business Monitor, use a stand-alone profile, also known as a stand-alone application server profile, for single-server environments.

Each stand-alone application server node has its own administrative console, which you use to manage the node. A stand-alone node can include more than one server.

A stand-alone server is easy to set up, and has a First steps console from which you can start and stop the server and install the Showcase sample. If you install the sample to the stand-alone server, you can explore the resources used for the sample in the administrative console.

You can deploy your own solutions to a stand-alone server, but a stand-alone server cannot provide the capacity, scalability, or robustness that is generally required of a production environment. For your production environment, it is better to use a network deployment environment.

Deployment manager profiles

A deployment manager is a server that manages operations for a logical group, or cell, of other servers. In network deployment environments, a group of servers are used collaboratively to provide workload balancing and failover. The deployment manager is the central location for administering the servers and clusters in the cell.

To create a deployment environment, the deployment manager profile is the first profile that you create or augment. . The deployment manager has a First steps console, from which you can start and stop the deployment manager and start its administrative console. You use the administrative console of the

deployment manager to manage the servers and clusters in the cell. This includes configuring servers and clusters, adding servers to clusters, starting and stopping servers and clusters, and deploying modules to them.

Although the deployment manager is a type of server, you cannot deploy modules to the deployment manager itself.

After creating or augmenting the deployment manager for IBM Business Monitor in a network deployment environment, you can then create or augment custom nodes and federate them into, or make them a part of, the deployment manager to create a cell, a group of nodes or clusters that are centrally administered.

Create or augment the deployment manager profile before creating or augmenting the custom profiles. If you created a deployment manager profile before installing IBM Business Monitor and you plan to use the same deployment manager profile to manage IBM Business Monitor nodes, augment the profile using the template provided by IBM Business Monitor.

Custom profiles

To configure a network deployment environment for IBM Business Monitor, create custom nodes and federate them into, or make them part of, the deployment manager cell that will manage them. Alternatively, you can augment an existing custom profile for each node that you plan to add to the cell. You can later use the administrative console to install specific applications to the various custom nodes.

A custom profile is an empty node that does not include the default applications or server that a stand-alone server profile includes. During the process of creating or augmenting a custom profile, you federate the node to identify the deployment manager profile that you plan to use to manage the node. After the custom profile has been federated to the deployment manager, the node becomes a *managed node*.

A managed node contains a node agent and can contain managed servers. In a managed node, you can configure and run managed servers. The servers that are configured on a managed node make up the resources of your deployment environment. These servers are created, configured, started, stopped, managed, and deleted using the administrative console of the deployment manager. Processes on the managed node can include cluster members that the deployment manager uses to balance the workload for heavily used applications.

A managed node can contain one or more servers, which are managed by a deployment manager. You can deploy solutions to the servers in a managed node, but the managed node does not have its own administrative console. The managed node is defined by a custom profile and has a First steps console.

Database considerations

The main MONITOR database stores the IBM Business Monitor configuration, monitor model metadata, and monitored data. The IBM Cognos Business Intelligence configuration is stored in a separate IBM Cognos BI content store database named COGNOSCS. Profile creation assumes that both the MONITOR and COGNOSCS database are created in the same database instance. If you already have the required level of IBM Cognos BI installed and running, you do not need to create an IBM Cognos BI content store database. The existing IBM Cognos BI server will have the content store database.

You can use a common database user name for the MONITOR and COGNOSCS databases. However, you might want to use separate names because IBM Cognos BI creates its own content store tables in the schema of the provided database name when IBM Cognos BI first starts.

The MONITOR database is also used to store schemas for the following components during stand-alone profile creation:

- Business Space

- Common event infrastructure (CEI) messaging engine message store
- IBM Business Monitor messaging engine message store

If you are not using a stand-alone profile, you can use the same database or different databases for these components, and additionally for the CEI data store, which is not required and therefore is not created or enabled by default.

For production environments, you can choose from the following supported database products:

- DB2
- DB2 for z/OS®
- Oracle
- Microsoft SQL Server

Multiple types of data are stored in the MONITOR database. When you create the IBM Business Monitor profile or run the database scripts, you create database tables that contain configuration data for IBM Business Monitor. Later, when each monitor model is installed, additional tables are created to store data for that monitor model. When events are processed, monitor model instance data is stored in these tables. The dashboards then refer to these tables.

Tip: In a network deployment environment, create the MONITOR and COGNOSCS databases before starting the deployment manager and creating other custom profiles.

Tip: If the COGNOSCS database is remote from the IBM Cognos BI server, you must install a database client on the IBM Cognos BI server machine. See the details in the database-specific database consideration topics.

Creating the databases

There are several ways to create the MONITOR and COGNOSCS databases.

- If the database software is installed on the same server as IBM Business Monitor, you can have the Profile Management Tool or the manageprofiles command create local databases when the profile is created.

Note:

- For DB2, the user who creates the profile must have credentials to create the database.
- For Oracle or SQL Server, a database administrator user ID and password must be provided to the Profile Management Tool or manageprofiles command so that database objects can be created in an existing database instance.
- You can have the profile management function generate database scripts, using the configuration values that were selected when the profile was created. Select the profile creation option to delay execution of database scripts and, at a later time, run the generated scripts to create the database objects on the database server.
- You can manually create the database using scripts provided on the installation media or in the IBM Business Monitor installation dbscripts directory. Variables in the scripts can be configured manually or by using the database design tool (DbDesignGenerator).

Important: Use this option with DB2 for z/OS.

In the MONITOR database, if you rename the table spaces for example data, then when you are creating the schema for monitor models, you must export the create schema scripts and change the table space names to match the names that were used during initial database creation.

Database size

The IBM Business Monitor database scripts for the MONITOR database create multiple table spaces to store data. The table space names and configuration can be altered depending on the enterprise standards and performance and sizing requirements. For development and test installations with minimal amounts of data, 1 GB of database storage should be sufficient. For production environments, size the database based on the amount of data that you intend to monitor.

Securing the databases

When the databases are created, the runtime database user is granted privileges to administer database objects by default, which simplifies the creation of the databases and enables the IBM Business Monitor server to automatically manage the monitor model database schema when models are deployed and removed. If you must secure the databases, see *Securing the MONITOR database environment and Configuring IBM Cognos BI security*.

MONITOR database considerations for DB2

There are specific recommendations for databases that are hosted on DB2.

Globalization considerations

DB2 must be installed using the UTF-8 Universal character set. Using this character set ensures that monitor model metadata and instance data containing native language characters can be saved to the database. Additionally, IBM Cognos Business Intelligence requires a UTF-8 database. The `createDatabase.sql` script creates the database as UTF-8 automatically.

The `createDatabase.sql` script creates the databases with the following default territory setting:

```
TERRITORY EN_US
```

To change the default language, change the `TERRITORY` to a supported territory setting from the DB2 Supported territory codes and code pages. Territory settings must use the UTF-8 code set. For example, to change the territory to French, you would use:

```
TERRITORY FR_FR
```

DB2 Express Edition considerations

DB2 Express Edition can use a maximum of 4 GB of instance memory, even if the system has more than 4 GB of memory. For more information about which version of DB2 to use, see the related reference links.

Currently, there is a known limitation in DB2 Express installer related to the inclusion of national language (NL) strings in properties passed to it from the IBM Business Monitor installer. The following values, which are passed to DB2 Express when it is being installed cannot have NL strings in them:

Linux Windows

- Linux Instance user name and password: `bpminst`
- Linux Fenced user name and password: `bpmfenc`
- Linux Administration server (DAS) user name: `bpmadmin`
- Windows Administrative user name: `bpmadmin`

DB2 catalog requirements

If the DB2 database is remote from the IBM Cognos BI server, then the MONITOR database must be cataloged by the DB2 client installed with the IBM Cognos BI server.

Important: Make sure that the alias name on the remote IBM Cognos BI server is the same as the cataloged database name of the MONITOR database. Otherwise cube creation will fail when a monitor model is deployed.

See the IBM Cognos BI database considerations topic for complete details.

MONITOR database security considerations

When you are using the Profile Management Tool (in the WebSphere Customization Toolbox) or the `manageprofiles` command to create the DB2 database, the administrative user creating the profile also attempts to create the database. The IBM Business Monitor runtime database user (`@DB_USER@`) that is specified during profile creation must already exist in the operating system.

By default, the IBM Business Monitor runtime database user is granted DBADM (database administrator) privileges as part of the database creation. This enables the IBM Business Monitor server to automatically manage the monitor model database schema when models are deployed and removed. To secure the database, you can create the database manually and grant the runtime database user only the privileges required for runtime operations. See “Installing the MONITOR database manually” on page 57 and Securing the Monitor database environment.

DB2 locking considerations

When there are a large number of events, the MONITOR database can deadlock on two or more different transactions waiting for the same database lock. When this happens, one of the transactions fails and is retried.

To eliminate deadlocks on DB2 LUW while maintaining concurrent processing under high volume, enter the following command in the DB2 command window:

```
db2set DB2_SKIPINSERTED=ON
db2set DB2_SKIPDELETED =ON
```

Multiple threads will not deadlock when the DB2 instance registry variables `DB2_SKIPINSERTED` and `DB2_SKIPDELETED` are set to `ON`.

Health Monitor considerations

If you are using DB2 Health Monitor (Automatic Maintenance), exclude the `SIBOWNER` from the automatic statistics collection. For more information, see the technote in related reference.

Cognos database considerations for DB2

IBM Cognos Business Intelligence uses the COGNOSCS (IBM Cognos BI content store) database for configuration and report specification information, and uses the MONITOR database for actual reporting data.

COGNOSCS database considerations for IBM Cognos BI

The IBM Cognos BI service creates tables in the IBM Cognos BI content store database the first time it is started. Because the database user provided for accessing the content store database must have privilege to create tables in the database, it is recommended that you create a new database user for the content store database only.

The COGNOSCS database must be used only for IBM Business Monitor data. You must not add data directly to the COGNOSCS database, or use the database with other databases to create reports against such data (combined or not with data created in IBM Business Monitor).

MONITOR database considerations for IBM Cognos BI

If your MONITOR database is remote from the server or cluster that the IBM Cognos BI service is deployed on, you must install a full database client such as the IBM Data Server Client on the IBM Cognos BI server to deploy cubes.

The remote database must be cataloged before you can publish IBM Cognos BI cube packages during monitor model deployment. The cataloged name must be the database name that you entered for the MONITOR database. Otherwise, you must change the WBMONITOR_DB data source in IBM Cognos BI to point to the correct cataloged name.

IBM Cognos BI needs access to DB2 client commands when publishing cube packages during model deployment.

-  The DB2 client must be in the server PATH.
-   The correct environment variables must be set for the DB2 user starting the IBM Business Monitor server.

32-bit client requirement

The database client that IBM Cognos BI uses to connect to the MONITOR database must be a 32-bit client. On a Windows system, DB2 makes available both 64-bit and 32-bit libraries without additional configuration. On a non-Windows system, IBM Cognos BI requires access to the following 32-bit DB2 libraries:

- Libraries in the /lib directory of the DB2 server install (for example, /opt/ibm/db2/V9.7/lib32)
- Libraries in the /lib directory in the instance directory (for example, /home/db2inst1/sqllib/lib32)

If you are using 64-bit DB2 and are not using Windows, complete the following steps to configure a path to the DB2 32-bit libraries:

1. In the administrative console, click **Servers > Server types > WebSphere application servers > server_name**. The Configuration panel is displayed.
2. Under **Server Infrastructure**, expand **Java and Process Management** and click **Process Definition**.
3. Under Additional Properties, click **Environment Entries**. Add the path to the 32-bit libraries as described below:

-  No change required.
-   Add the path to the DB2 32-bit server libraries to the following environment variable using a ":" as a delimiter.

For Linux and Solaris: LD_LIBRARY_PATH

For AIX: LIBPATH

MONITOR database considerations for DB2 for z/OS

There are specific recommendations for databases that are hosted on DB2 for z/OS. A dedicated storage group (STOGROUP) is recommended for IBM Business Monitor. The storage group must be created before the MONITOR database is created.

Globalization considerations

DB2 for z/OS must be installed using the UTF-8 Universal character set. Using this character set ensures that monitor model metadata and instance data containing native language characters can be saved to the database. The createDatabase_Monitor.sql and createTablespace_Monitor.sql scripts create the database as UTF-8 automatically.

The DIM_TIME table contains a column for populating dashboard reports with a translated month name. The location settings in z/OS are not used for creating the month names. There is an SQL statement in the createTable_Monitor.sql file that you can use to override the month name entries and define your own month names.

General database considerations

DB2 for z/OS requires the addition of two buffer pools. The following 32K buffer pools must be created by the database administrator before running the database scripts:

- BP32K
- TMPBP32

DB2 for z/OS requires a TEMP database for storing declared temporary tables.

- Create a dedicated STOGROUP to contain the IBM Business Monitor data.
- Create a TEMP database and a TEMP table space to contain the declared temporary tables for processing scrollable cursors. Examples are shown below.

For DB2 for z/OS version 8, a temp database and table space must be created if it does not already exist. The following code is a representative example of a TEMP database definition:

```
CREATE DATABASE TEMP AS TEMP STOGROUP SYSDEFLT;  
CREATE TABLESPACE TEMP IN TEMP  
USING STOGROUP SYSDEFLT  
BUFFERPOOL BP32K  
SEGSIZE 32;
```

For DB2 for z/OS version 9 and version 10 in a non-data-sharing environment, the TEMP database is DSNDB07 and is created during database installation. Temporary table spaces are added to the existing TEMP database. The following code is a representative example of a temporary table space:

```
CREATE TABLESPACE WBITEMP IN DSNDB07  
USING STOGROUP SYSDEFLT  
BUFFERPOOL BP32K  
SEGSIZE 32;
```

For DB2 for z/OS version 9 and version 10 in a data-sharing environment, a WORKFILE database must be created. Only one WORKFILE database can be created per subsystem. The following code is a representative example for creating a WORKFILE database and temporary table space:

```
CREATE DATABASE WORKTEMP AS WORKFILE STOGROUP SYSDEFLT;  
CREATE TABLESPACE WBITEMP IN WORKTEMP  
USING STOGROUP SYSDEFLT  
BUFFERPOOL BP32K  
SEGSIZE 32;
```

For detailed information about how the TEMP database and TEMP table spaces are set up, refer to DB2 for z/OS information center. See the related link.

Note: If you are using DB2 for z/OS and you intend to use SPUFI for running the database scripts, use FTP to transfer the files to the z/OS database server. The IBM Business Monitor database scripts end with a line-feed character. The FTP server on z/OS will correctly map the line feed to an end-of-line character for the database script.

DB2 for z/OS version 8 also requires work file database storage for SQL statements that require working storage, such as sorts. This requires the addition of a table space to support sorting operations in addition to the TEMP database for version 8. In DB2 for z/OS version 9 and 10, the work file database and TEMP databases are combined. See the DB2 for z/OS information center for the procedures and sizing recommendations for creating work file databases.

Set the **RRULOCK** subsystem parameter to **YES** for greater concurrency.

If data movement service is to be enabled, increase the number of locks per user, NUMLKUS, to at least 100,000.

JDBC driver

IBM Business Monitor uses the JDBC 4.0 driver. By default, the Profile Management Tool points to the `db2jcc4.jar` file supplied in `app_server_root\jdbcdrivers\DB2`. For DB2 for z/OS installations, it is recommended that you use the JDBC 3.0 driver `db2jcc.jar` that is shipped with DB2.

Database substitution variables

Monitor model schema generation for DB2 for z/OS requires the database name and storage group variables to be provided. To minimize the manual substitution of variables, the following file is created when you create a profile:

```
profile_root/properties/monitor_database.properties
```

This file contains the following properties:

```
databaseName  
db2zOSStorageGroup
```

Set the **databaseName** to the database name used in the Profile Management Tool or **manageprofiles** command for creating the database. Set the **db2zOSStorageGroup** to the DB2 storage group for the MONITOR database. If the variable names are left empty, the values are not substituted for the variables in the create schema scripts for the monitor models.

Cognos database considerations for DB2 for z/OS

IBM Cognos Business Intelligence uses the COGNOSCS (IBM Cognos BI content store) database for configuration and report specification information, and uses the MONITOR database for actual reporting data.

COGNOSCS database considerations for IBM Cognos BI

The IBM Cognos BI service creates tables in the IBM Cognos BI content store database the first time it is started. Because the database user provided for accessing the content store database must have privilege to create tables in the database, it is recommended that you create a new database user for the content store database only.

The COGNOSCS database must be used only for IBM Business Monitor data. You must not add data directly to the COGNOSCS database, or use the database with other databases to create reports against such data (combined or not with data created in IBM Business Monitor).

For DB2 on z/OS, you must manually create the database and table spaces. Update the table create scripts used by DB2 during startup with the database and table space names used when they were created.

MONITOR database considerations for IBM Cognos BI

If your MONITOR database is remote from the server or cluster that the IBM Cognos BI service is deployed on, you must install a full database client such as DB2 Connect on the IBM Cognos BI server to deploy cubes.

The remote database must be cataloged before you can publish IBM Cognos BI cube packages during monitor model deployment. The cataloged name must be the database name that you entered for the MONITOR database. Otherwise, you must change the `WBMONITOR_DB` data source in IBM Cognos BI to point to the correct cataloged name.

IBM Cognos BI needs access to DB Connect client commands when publishing cube packages during model deployment.

-  The DB2 Connect client must be in the server PATH.
-   The correct environment variables must be set for the DB2 user starting the IBM Business Monitor server.

32-bit client requirement

The database client that IBM Cognos BI uses to connect to the MONITOR database must be a 32-bit client. On a Windows system, DB2 Connect makes available both 64-bit and 32-bit libraries without additional configuration. On a non-Windows system, IBM Cognos BI requires access to the following 32-bit DB2 Connect libraries:

- Libraries in the /lib directory of the DB2 Connect server install (for example, /opt/ibm/db2/V9.7/lib32)
- Libraries in the /lib directory in the instance directory (for example, /home/db2inst1/sqllib/lib32)

If you are using 64-bit DB2 Connect and are not using Windows, complete the following steps to configure a path to the DB2 Connect 32-bit libraries:

1. In the administrative console, click **Servers > Server types > WebSphere application servers > server_name**. The Configuration panel is displayed.
2. Under **Server Infrastructure**, expand **Java and Process Management** and click **Process Definition**.
3. Under Additional Properties, click **Environment Entries**. Add the path to the 32-bit libraries as described below:

-  No change required.
-   Add the path to the DB2 Connect 32-bit server libraries to the following environment variable using a ":" as a delimiter.
For Linux and Solaris: LD_LIBRARY_PATH
For AIX: LIBPATH

MONITOR database considerations for Oracle

There are specific recommendations for databases that are hosted on Oracle.

Globalization considerations

Oracle must be installed using the UTF-8 Universal character set (AL32UTF8) instead of the default database character set (WE8ISO8859P1 - ISO 8859-1 West European). Using this character set ensures that monitor model metadata and instance data containing native language characters can be saved to the database. Additionally, IBM Cognos BI requires a UTF-8 database.

Oracle manages the language and locale settings with two database parameters:

NLS_LANGUAGE
NLS_TERRITORY

To change the default language for the databases, change the NLS_LANGUAGE parameter to a supported language for Oracle. Territory settings define the defaults for data formatting, currency, and so on. Set the NLS_TERRITORY parameter to change the Oracle instance.

The DIM_TIME table contains a column for populating dashboard reports containing time dimensions with a translated month name. By default, the locale code for the NLS_LANGUAGE setting is used for populating the DIM_TIME table entries. To change the default language, change the NLS_LANGUAGE for the Oracle instance or for the current session before running the createTables.sql script. There is also

an SQL statement in `createTables.sql` that you can use to override the month name entries and define your own month names.

MONITOR security considerations

When you are using the Profile Management Tool (in the WebSphere Customization Toolbox) or the `manageprofiles` command to create the Oracle database objects, the database administrative user specified in the profile creation creates the database objects and a MONITOR schema. On Oracle, a schema is both a collection of database objects and a user ID that can log into the database.

By default, the MONITOR schema owner is also the runtime database user, and is granted privileges to create other schemas and database objects as part of the database creation. This enables the IBM Business Monitor server to automatically manage the monitor model database schema when models are deployed and removed. To secure the database, you can create the database manually. The MONITOR schema owner, or a different user, can be used as the IBM Business Monitor runtime database user. In a secured environment, you can grant the runtime database user only the privileges required for runtime operations. See the topics "Installing the database manually" and "Securing the MONITOR database environment" in the related links.

JDBC driver

JDBC support is provided by the Oracle JDBC drivers for JVM 1.6. The `ojdbc6.jar` JDBC driver file is the Oracle-supported JDBC driver for use with WebSphere Application Server version 7. The `ojdbc6.jar` file can be used for both Oracle 10g and Oracle 11g. For information about minimum required settings for Oracle, see the related link.

By default, the Profile Management Tool points to the `ojdbc6.jar` file supplied in `app_server_root\jdbcdrivers\Oracle`. Alternatively, you can download another Oracle `ojdbc6.jar` JDBC driver file and point to it when you run the Profile Management Tool or the `manageprofiles` command.

XA recovery

You must apply special grants for Oracle's XA recovery to work correctly. Run the following commands as user SYS:

```
grant select on pending_trans$ to <user>;
grant select on dba_2pc_pending to <user>;
grant select on dba_pending_transactions to <user>;
grant execute on dbms_system to <user>;
```

where `<user>` is the user name for the MONITOR database that is configured during profile creation.

Materialized Views

Dashboard page loading performance can degrade as you build up large volumes of monitoring data in your database. After you have more than approximately 10 million monitoring context instances, you might want to enable your database vendor's option to precompute the data.

You can use materialized views in Oracle to improve query performance. A materialized view can precompute the values of key performance indicators (KPIs) and of IBM Cognos BI cube measures on Oracle. When the dashboard requests the value, the precomputed value is returned almost immediately, instead of the aggregation, such as an average, being computed against every monitoring context instance.

To define a materialized view, the Oracle database administrator (DBA) specifies the following settings:

ON COMMIT

Automatically refreshes the materialized view whenever a transaction that changes data in the table is committed (that is, when the data movement services runs).

FAST Incrementally updates data during a refresh.

Tip: Before the materialized views are created, make sure that the data movement service (DMS) is enabled for the monitor model so that the materialized view is updated on each DMS cycle, not on each event that is processed.

You can find an example script that defines a FAST, ON COMMIT materialized view for the Showcase (Better Lender) sample in the following directory: `app_server_root\installableApps.wbm\showcase\OracleMaterializedViews_Sample`.

Cognos database considerations for Oracle

IBM Cognos Business Intelligence uses the COGNOSCS (IBM Cognos BI content store) database for configuration and report specification information, and uses the MONITOR database for actual reporting data.

COGNOSCS database considerations for IBM Cognos BI

The IBM Cognos BI service creates tables in the IBM Cognos BI content store database the first time it is started. The database user provided for accessing the IBM Cognos BI content store database must have full access to Oracle to create tables, views, sequences, triggers, and so on. In IBM Cognos BI, you cannot specify a separate schema name; the IBM Cognos BI objects are created in the default schema and default table space of the database user. It is recommended that you create a new database user for the content store database only.

Important: Do not use the SYSTEM user for this purpose, because you do not want the IBM Cognos BI database objects to be created in the system area.

The COGNOSCS database must be used only for IBM Business Monitor data. You must not add data directly to the COGNOSCS database, or use the database with other databases to create reports against such data (combined or not with data created in IBM Business Monitor).

MONITOR database considerations for IBM Cognos BI

If your MONITOR database is remote from the server or cluster that the IBM Cognos Business Intelligence service is deployed on, you must install a full database client or the Oracle Instant Client on the IBM Cognos BI server to deploy cubes.

The Oracle instance for IBM Cognos BI must be addressable by a TNSNAMES entry in the Oracle client on the IBM Cognos BI server. The entry in TNSNAMES must use the same name as the database instance name that you entered for the MONITOR database during profile creation (for example, ORCL). Otherwise, you must change the WBMONITOR_DB data source in IBM Cognos BI to point to the correct TNSNAMES entry.

If you are using Oracle Instant Client, the path to the client must be in the system path. A TNSNAMES.ORA file must also be included with an entry for the Oracle database server, and the TNS_ADMIN environment variable must be set to point to the directory containing the TNSNAMES.ORA file.

Important: Install the SQLPlus command utility with Oracle Instant Client for troubleshooting purposes.

The following example shows the contents of a valid TNSNAMES.ORA file. (The uppercase ORCL is the alias for the database connection.)

```

ORCL =
(DESCRIPTION =
(AADDRESS = (PROTOCOL = TCP)(HOST = 127.0.0.1)(PORT = 1521))
(CONNECT_DATA =
(SERVER = DEDICATED)
(SERVICE_NAME = orcl)
)
)

```

IBM Cognos BI needs access to Oracle client commands when publishing cube packages during model deployment.

-  The Oracle client must be in the server PATH.
-   The user starting the IBM Business Monitor server must be profiled as an Oracle user profile.

Oracle Instant Client

To use Oracle Instant Client, you must download and install the following libraries:

- Instant Client Package - Basic Instant Client Package
- SQL*Plus (useful for connection troubleshooting)

Add the installation directory to the server path and create a TNSNAMES.ORA file as described in the previous section. Add a TNS_ADMIN environment variable and specify the path to the directory containing the TNSNAMES.ORA file.

32-bit client requirement

An Oracle 32-bit client must be installed for IBM Cognos BI cube deployment. If Oracle is installed on a separate server, the 32-bit Oracle Instant Client is recommended. If Oracle is installed on the same server as IBM Cognos BI and 64-bit Oracle is installed, the 32-bit Oracle Instant Client must be installed as well.

If you are using 64-bit Oracle, complete the following steps to configure a path to the Oracle 32-bit libraries:

1. In the administrative console, click **Servers > Server types > WebSphere application servers > *server_name***. The Configuration panel is displayed.
2. Under **Server Infrastructure**, expand **Java and Process Management** and click **Process Definition**.
3. Under Additional Properties, click **Environment Entries**. Add the path to the Oracle Instant Client as described below:
 -  Add the path to the 32-bit Oracle Instant Client to the PATH environment variable using a ";" as a delimiter:
 -   Add the path to the 32-bit Oracle Instant Client to the following environment variable using a ":" as a delimiter.
 - For Linux and Solaris: LD_LIBRARY_PATH
 - For AIX: LIBPATH

MONITOR database considerations for Microsoft SQL Server

There are specific recommendations for databases that are hosted on Microsoft SQL Server.

Important: When you are installing SQL Server, you must select mixed mode (Windows Authentication or SQL Server Authentication) as the authentication mode.

Important: To use SQL Server with IBM Business Monitor, you must configure SQL Server for XA transactions. SQL Server is not pre-configured for XA transactions. The XA support is delivered as part of

the Microsoft JDBC driver distribution and contains a dynamic link library (sqljdbc_xa.dll) and an installation script (xa_install.sql). Because XA transactions are not enabled by default, you must change the configuration in the Microsoft Windows Distributed Transaction Coordinator (MSDTC). For instructions to enable XA support for SQL Server, see "Understanding XA Transactions" in the Microsoft SQL Server online documentation.

When you are using the Profile Management Tool (in the WebSphere Customization Toolbox) or the `manageprofiles` command to create the SQL Server database, the database administrative user specified in the profile creation creates the database. The IBM Business Monitor runtime database user (@DB_USER@) that is specified during profile creation should already exist as an SQL Server login and database user. You can use the following command to create the database login and database user:

```
CREATE LOGIN @DB_USER@ WITH PASSWORD = '@DB_PASSWORD@', DEFAULT_DATABASE=@DB_NAME@
CREATE USER @DB_USER@ FOR LOGIN @DB_USER@
```

where DB_USER is the IBM Business Monitor runtime database user, DB_PASSWORD is the runtime database password, and DB_NAME is the IBM Business Monitor database name.

By default, the IBM Business Monitor runtime database user is granted `db_owner` privileges as part of the database creation. This enables the IBM Business Monitor server to automatically manage the monitor model database schema when models are deployed and removed. To secure the database, you can create the database manually and grant the runtime database user only the privileges required for runtime operations. See the topics "Installing the database manually" and "Securing the MONITOR database environment" in the related links.

The SQL Server JDBC drivers for JVM 1.6 provide JDBC support. IBM Business Monitor uses the Microsoft JDBC 2.0 driver `sqljdbc4.jar` file. By default, the Profile Management Tool points to the `sqljdbc4.jar` file supplied in `app_server_root\jdbcdrivers\SQLServer`. Alternatively, you can download another Microsoft `sqljdbc4.jar` JDBC driver file and point to it when you run the Profile Management Tool or the `manageprofiles` command. For information about minimum required settings for SQL Server, see the related link.

Globalization considerations

SQL Server manages the locale settings with the `COLLATE` option when creating the database. The create database statement for the MONITOR and COGNOSCS databases contains the following option:

```
COLLATE SQL_Latin1_General_CP1_CS_AS
```

To change the locale settings, change the collation parameter to a supported collation for the language you want. For example, to change the collation to French, you would use:

```
COLLATE French_100_CS_AS
```

SQL Server manages the default language based on the login user. To change the default language, in the `createDatabase.sql` file, add the `DEFAULT_LANGUAGE` option to the create login with a different default language. For example, to create the login with a default language of French, you would use:

```
IF NOT EXISTS (SELECT * FROM syslogins WHERE NAME = '@DB_USER@')
CREATE LOGIN @DB_USER@ WITH PASSWORD = '@DB_PASSWORD@',
DEFAULT_DATABASE=@DB_NAME@, DEFAULT_LANGUAGE=French;
```

The `DIM_TIME` table contains a column for populating dashboard reports containing time dimensions with a translated month name. By default, the locale code for `DEFAULT_LANGUAGE` setting is used for populating the `DIM_TIME` table entries. To change the default language, change the `DEFAULT_LANGUAGE` for the database user before running the `createTables.sql` script. There is also an SQL statement in `createTables.sql` that you can use to override the month name entries and define your own month names.

Cognos database considerations for Microsoft SQL Server

IBM Cognos Business Intelligence uses the COGNOSCS (IBM Cognos BI content store) database for configuration and report specification information, and uses the MONITOR database for actual reporting data.

Important: The IBM Cognos BI database requires collation that is not case-sensitive, while the IBM Business Monitor database requires a case-sensitive collation. If the default collation is changed for the IBM Cognos BI database, the collation must NOT be case-sensitive.

COGNOSCS database considerations for IBM Cognos BI

The IBM Cognos BI service creates tables in the IBM Cognos BI content store database the first time it is started. Because the database user provided for accessing the content store database must have privilege to create tables in the database, it is recommended that you create a new database user for the content store database only.

The COGNOSCS database must be used only for IBM Business Monitor data. You must not add data directly to the COGNOSCS database, or use the database with other databases to create reports against such data (combined or not with data created in IBM Business Monitor).

MONITOR database considerations for IBM Cognos BI

If your MONITOR database is remote from the server or cluster that the IBM Cognos Business Intelligence service is deployed on, you must install a full Microsoft SQL Server database client on the IBM Cognos BI server to deploy cubes.

Microsoft offers a SQL Server Native Client that can be used in place of the full SQL Server client installation. This minimal installation includes all of the required native drivers. Along with the native client, you should also download and install the SQL Server command line utilities. Both items are available from the Microsoft SQL Server 2008 Feature Pack, August 2008 page.

IBM Cognos BI needs access to SQL Server client commands when publishing cube packages during model deployment. The SQL Server client must be in the server PATH.

User registry considerations

The user registry stores information that is used to authenticate users using basic authentication. Your choice of user registry is an essential consideration when planning your environment. You must configure WebSphere Application Server to use the user registry in your environment.

The user registry stores information that is used to authenticate users requesting access to IBM Business Monitor. You can configure multiple user registry types under federated repositories. Most production deployments use a Lightweight Directory Access Protocol (LDAP) server. For small deployments that are contained on a single server, you can use a file-based user registry.

You can select any of the following registry for your user account repository:

- Federated Repositories
- Local operating system
- Standalone Lightweight Directory Access Protocol (LDAP) registry
- Standalone custom registry

Note: For fine-grained security, the supported user registries are federated repositories (file-based), federated repositories (LDAP), and standalone LDAP registry.

Non-administrative user considerations

If you are installing IBM Business Monitor as a non-administrative or non-root user and you want to create a test profile during installation, you must have the DB2 server installed before you begin the installation. Remember the database details so that you can enter them during the installation.

The considerations described in this topic apply to any install scenario where you choose to install using the **Typical** install option. Profiles are created automatically when you install using the **Typical** option.

To install as a non-administrative user, you have the following choices:   

- Before installing the product, install a DB2 server separately. For information about installing DB2 as a non-administrative or non-root user, see   
 -   Non-root installation overview (Linux and UNIX)
 -  Required user accounts for installation of DB2 server products (Windows)
- Logon as an administrator and use the product installer to install the DB2 server alone. Grant special permission to the non-administrative user. Then logon as the non-administrative user and install the product using the installed DB2 server.

Alternatively, instead of creating a test profile, you can create a profile after installation . Use these steps:

1. Install the product without creating a profile. When you install as a non-administrative user, on the Install Packages page, you must clear the check box for DB2 Express. On Windows, if you have the option to install IBM Cognos Business Intelligence, you must clear that check box as well.
2. On the Features page, expand the servers and make sure that none of the test profiles are selected.
3. Use the Profile Management Tool to create a stand-alone profile, or to create the deployment manager and the custom profiles. If you do not have a database installed, use the **Advanced** path for all. Do not use the **Typical** path. Select the option to delay the execution of the database scripts during profile creation.
4. If the databases were not created in advance, have the database administrator create the databases and tables after profile creation or augmentation.
5. For a network deployment:
 - a. Federate the custom profiles to the deployment manager.
 - b. Using the administrative console, create the required deployment environment

Topology considerations

In IBM Business Monitor, you can select from several different configuration paths to create your deployment environment.

A cross-cell environment is one in which IBM Business Monitor receives events from a server that is in a different cell from the IBM Business Monitor server. A cross-cell environment can involve either network deployment (ND) or single-server topology. In either case, you must perform several steps to enable communication between the common event infrastructure (CEI) server and the IBM Business Monitor server. For information on how to enable cross-cell communication, see "Configuring how to receive events." For an example of a cross-cell topology, see the "Monitoring events from an SAP enterprise information system (EIS) without mediation" scenario.

Considerations for single-server topology

When you use the single-server topology, IBM Business Monitor and all required components are installed on the same physical server.

To install the IBM Business Monitor server and all required components on the same server, use the following high-level steps:

1. Complete the pre-installation steps found in Chapter 3, “Preparing to install,” on page 33.
2. Install IBM Business Monitor, following the steps in Chapter 4, “Installing the IBM Business Monitor software,” on page 39. When you install the product, you are given the option of creating a development profile, which provides a test environment but cannot be used in a production environment.
3. If you did not create a development profile, create a stand-alone profile using either the Profile Management Tool or the `manageprofiles` command, following the steps in Chapter 6, “Creating and augmenting profiles,” on page 73.

All required IBM Business Monitor components are installed and configured for you.

You can optionally check the status of the components and make updates using the configuration wizard in the administrative console.

Considerations for network deployment topology using deployment environment patterns

Network deployment (ND) in IBM Business Monitor builds upon network deployment functions implemented in WebSphere Application Server Network Deployment. If you choose one of the available deployment environment patterns, use the deployment environment wizard to configure the clusters, servers, and components that you need.

If you are familiar with network deployment in WebSphere Application Server Network Deployment, the concepts are the same. For IBM Business Monitor, two patterns are available: the Single Cluster pattern and the Remote Messaging, Remote Support, and Web (four-cluster) pattern.

To install the IBM Business Monitor server and all required components using the single cluster or four-cluster deployment environment, use the following high-level steps:

1. Complete the pre-installation steps found in Chapter 3, “Preparing to install,” on page 33.
2. Install IBM Business Monitor, following the steps in Chapter 4, “Installing the IBM Business Monitor software,” on page 39. Do not create a development profile.
3. Create a deployment manager profile using either the Profile Management Tool or the `manageprofiles` command, following the steps in Chapter 6, “Creating and augmenting profiles,” on page 73.
4. Unless you created the MONITOR database as part of creating the profile, run the scripts to create the database, following the instructions in Chapter 5, “Creating the databases,” on page 51.
5. Start the deployment manager.
6. Create custom nodes that are federated into the deployment manager cell, following the steps in Chapter 6, “Creating and augmenting profiles,” on page 73.
7. Create the deployment environment, choosing either the Single Cluster pattern or the Remote Messaging, Remote Support, and Web (four-cluster) pattern. Follow the steps in “Creating the deployment environment using a pattern” on page 101.
8. Configure additional components such as Business Space and IBM Cognos BI, following the instructions in Chapter 10, “Configuring IBM Business Monitor components,” on page 133.

The clusters are created and all required IBM Business Monitor components are installed and configured for you.

You can optionally check the status of the components and make updates using the configuration wizard in the administrative console.

Considerations for custom network deployment topology

Rather than use the deployment environment wizard to create a single-cluster or four-cluster topology for network deployment (ND), you can create any topology you choose using the configuration wizard or the wsadmin task.

To install the IBM Business Monitor server and all required components in a custom ND topology, use the following high-level steps:

1. Complete the pre-installation steps found in Chapter 3, “Preparing to install,” on page 33.
2. Install IBM Business Monitor, following the steps in Chapter 4, “Installing the IBM Business Monitor software,” on page 39. Do not create a development profile.
3. Create a deployment manager profile using either the Profile Management Tool or the `manageprofiles` command, following the steps in Chapter 6, “Creating and augmenting profiles,” on page 73.
4. Unless you created the MONITOR database as part of creating the profile, run the scripts to create the database, following the instructions in Chapter 5, “Creating the databases,” on page 51.
5. Start the deployment manager.
6. Create custom nodes that are federated into the deployment manager cell, following the steps in Chapter 6, “Creating and augmenting profiles,” on page 73.
7. Use the administrative console to create the clusters, following the instructions in “Creating IBM Business Monitor clusters” on page 115.
8. Configure the required common event infrastructure (CEI) event services, following the instructions in “Configuring CEI event services” on page 116.
9. Use the configuration wizard or the wsadmin command to configure the environment, following the instructions in “Configuring the environment using the configuration wizard” on page 117 or “Configuring the environment using wsadmin commands” on page 122. For the required shared components, however, you must follow the manual steps provided in “Configuring the environment manually” on page 124.
10. Configure additional components such as Business Space and IBM Cognos BI, following the instructions in Chapter 10, “Configuring IBM Business Monitor components,” on page 133.

Considerations for IBM Business Process Manager in a four-cluster topology environment

You can configure a Four cluster topology with IBM Business Process manager to create a combined IBM® Business Process Manager and IBM Business Monitor deployment environment using the Remote Messaging, Remote Support, and Web (four-cluster) pattern. Because one IBM Business Monitor deployment environment can monitor all applications in the cell, you should only create one IBM Business Monitor deployment environment in a given cell. The four-cluster topology combines IBM Business Monitor and IBM Business Process Manager messaging engine clusters into a single cluster.

Complete the following procedure to configure a four-cluster topology with IBM Business Process manager to create a combined IBM Business Process Manager and IBM Business Monitor deployment environment:

1. Complete the pre-installation steps found in the section Preparing to install.
2. Install IBM BPM product. Do not create a development profile.
3. Install IBM Monitor on the BPM WAS environment.
4. Create a deployment manager profile using either the Profile Management Tool or the **manageprofiles** command, following the steps in the section Creating and augmenting profiles.
5. Augment it to MONITOR deployment manager
6. Create CUSTOM profile of BPM which will be federated later
7. Augment it to MONITOR CUSTOM profile.

8. Start the deployment manager profile
9. Run the **AddNode** command to create custom profiles that are federated to deployment manager profile.
10. Configure the deployment environment step by step choosing the four-cluster pattern. Follow the steps in *Creating the deployment environment using a pattern*.

The clusters are created and all required IBM Business Monitor and IBM BPM components are installed and configured for you.

You can optionally check the status of the components and make updates using the configuration wizard in the administrative console.

Related concepts:

“Four-cluster topology” on page 11

You can install IBM Business Monitor into many topologies. You can use the four-cluster topology to set up a high performance environment.

Chapter 3. Preparing to install

Before installing IBM Business Monitor, ensure that you have the required hardware and software prerequisites. Some operating platforms also require special preparation before you can install.

Hardware and software requirements

IBM Business Monitor runs on AIX®, Windows, Linux, Linux on zSeries, Solaris, and z/OS operating systems.

For the most current software and hardware requirements, see the System requirements for IBM Business Monitor.

These links include supported LDAP servers. Stand-alone LDAP registries are also supported by IBM Business Monitor. All of the following current realm definitions are available for your current user account repositories:

- Federated Repositories
- Local operating system
- Standalone LDAP registry
- Standalone custom registry

Preparing operating systems for product installation

Before you can install IBM Business Monitor, you must prepare your operating system. The configuration depends on the type of operating system you are using.

Before preparing the installation environment, complete the following tasks:

- Disable the firewall if you have a firewall running on the system where you plan to install IBM Business Monitor.
- Ensure that your user login provides access to your DB2 or Oracle database commands.
- Complete additional tasks specific to your operating system.

Preparing AIX systems for installation

Before you can install IBM Business Monitor, you must prepare your AIX operating system.

Because WebSphere Application Server is a prerequisite of IBM Business Monitor, you must complete the required preparation steps in the Preparing AIX systems for installation topic in the WebSphere Application Server information center.

Because certain steps are specific to a version of the operating system, all steps might not apply to your environment. If no qualifier is provided for a particular step, complete the step for all versions of the operating system.

Refer to the following technote for additional preparation information for configuring Installation manager to run on 64-bit AIX systems: <https://www-304.ibm.com/support/docview.wss?uid=swg21330190&wv=1> .

Complete the following steps on your AIX system before installing IBM Business Monitor:

1. Increase the maximum number of open files. The default setting is usually not enough. You can check your current maximum number of open files by using **ulimit -n**. The following example shows the

maximum number of open files being increased to 8800, which is large enough for most systems. The ulimit requirement is dynamically calculated at installation time and might need to be larger based on the options you select.

Before installing, run the following command:

```
ulimit -n 8800
```

Alternatively, you can use the following steps to edit the resource limits file:

- a. Open `/etc/security/limits`.
- b. Edit or add the **default** section and include this line:

```
nofiles = 8800
```

- c. Save and close the file.
 - d. Log off from the operating system and log in again.
2. Set the **umask** value to 077 using the following command:

```
umask 077
```

The value 077 is the most restrictive value that IBM Business Monitor will tolerate. You can optionally choose to set a less restrictive **umask** value for the following access levels:

- 037 for read-only access for a group of human administrators and tools
- 027 for read and write access for a group of human administrators and tools
- 007 for read, write, and execute access for a group of human administrators and tools

3. Ensure that you have Mozilla Firefox installed at version 3.5.x.x or higher.
4. Before starting the data movement service, increase the number of processes configured in the AIX operating system to avoid a connection reset error. You can increase the number of processing using a command, or using the AIX interface.
 - Run the command:

```
chdev -l sys0 -a maxuproc='256'
```
 - In the AIX interface, enter **smitty**, then select **System Environments > Change / Show Characteristics of Operating System > Number of processes allowed per user(Num.)**.
5. Complete the steps in Tuning AIX systems.
6. Ensure all servers involved are set to the same time. Use the same network time protocol for all servers on all cluster nodes, including application, support, and database clusters. A time mismatch will cause erratic behavior, including duplicate system tasks.

Preparing Linux systems for installation

Before you can install IBM Business Monitor, you must prepare your Linux operating system.

Because WebSphere Application Server is a prerequisite of IBM Business Monitor, you must complete all the required preparation steps in the Preparing Linux systems for installation topic in the WebSphere Application Server information center.

Ensure that you have Mozilla Firefox installed at version 3.5.x.x or higher.

Because certain steps are specific to a version of the operating system, all steps might not apply to your environment. If no qualifier is provided for a particular step, complete the step for all versions of the operating system. To install Installation Manager on Red Hat Enterprise Linux 6.0 (64-bit), see Unable to install Installation Manager on RHEL 6.0 (64-bit).

Note: Cognos bundles an alternate version of the `libfreebl3.so` library for Red Hat Enterprise Linux 6.0 (64-bit). Ensure that you preinstall this system library that is required for other utilities.

Complete the following steps on your Linux system before installing IBM Business Monitor:

1. Increase the allowable stack size, number of open files, and number of processes by adding the following lines to the end of the `/etc/security/limits.conf` file:

```
# - stack - max stack size (KB)
* soft stack 32768
* hard stack 32768
# - nofile - max number of open files
* soft nofile 65536
* hard nofile 65536
# - nproc - max number of processes
* soft nproc 16384
* hard nproc 16384
```

Save and close the file, and log off and log in again. You can check the current maximum number of open files by using `ulimit -n`. The `ulimit` requirement is dynamically calculated at installation time and might need to be larger based on the options you select. For more information about this setting, run `man limits.conf` or see the topic `Preparing the operating system for product installation` in the WebSphere Application Server information center.

2. Check for the existence of a file named `/etc/security/limits.d/90-nproc.conf`, which overrides the `nproc` value set in the `limits.conf` file. If the `90-nproc.conf` file exists, edit it and set the `nproc` values that are specified in the previous step.
3. If you are planning to install DB2 Express as part of the installation process, ensure that you have administrative (root) privileges. As a root user, you must also ensure that all kernel requirements are met before the DB2 Express installation begins. You can locate the current values by parsing the output of the `ipcs -l` command. To change the values, add the following lines, in the following order, to the `/etc/sysctl.conf` file:

```
kernel.shmmni=4096
kernel.shmmax=4294967296
kernel.shmall=8388608
#kernel.sem=<SEMMS><SEMMNS><SEMOPM><SEMMNI>
kernel.sem=250 256000 32 4096
kernel.msgmni=16384
kernel.msgmax=65536
kernel.msgmnb=65536
```

Reboot the system

4. Install the following packages for your operating system:

Option	Description
Red Hat Enterprise Linux 5	libXp-1.0.0-8 rpm-build-4.4.2-37.el5
Red Hat Enterprise Linux 6	ksh-version.rpm Korn shell

You can also install a later release of any of these packages if there are new packages as errata. If you have additional packages that are specific to your hardware, install them.

The following command example shows how to use the default package manager on supported Linux distributions.

- **Red Hat Enterprise Linux 5:**

```
yum install libXp rpm-build
```

5. Set the `umask` value to `077` using the following command:

```
umask 077
```

The value `077` is the most restrictive value that IBM Business Monitor will tolerate. You can optionally choose to set a less restrictive `umask` value for the following access levels:

- `037` for read-only access for a group of human administrators and tools
- `027` for read and write access for a group of human administrators and tools
- `007` for read, write, and execute access for a group of human administrators and tools

6. On Red Hat Enterprise Linux 5 systems, disable SELinux, or set it to a permissive mode.
7. Restart the computer.
8. Complete the steps in Tuning Linux systems.
9. Ensure all servers involved are set to the same time. Use the same network time protocol for all servers on all cluster nodes, including application, support, and database clusters. A time mismatch will cause erratic behavior, including duplicate system tasks.

Preparing Solaris systems for installation

Before you can install IBM Business Monitor, you must prepare your Solaris operating system.

Because WebSphere Application Server is a prerequisite of IBM Business Monitor, you must complete the required preparation steps in the Preparing Solaris systems for installation topic in the WebSphere Application Server information center.

The HotSpot Java JVM was developed by Sun Microsystems for the Solaris operating system. The Java heap structure and management for the HotSpot JVM is different from those of other JVMs. In your environment, you might need to tune the heap management of the JVM to avoid any **java.lang.OutOfMemoryError: PermGen** errors during profile creation or server runtime. You might need to update the value for the **MaxPermSize** JVM parameter.

Because certain steps are specific to a version of the operating system, all steps might not apply to your environment. If no qualifier is provided for a particular step, complete the step for all versions of the operating system.

Complete the following steps on your Solaris systems before installing IBM Business Monitor:

1. Increase the maximum number of open files. The default setting is usually not enough. You can check your current maximum number of open files by using **ulimit -n**. The following example shows the maximum number of open files being increased to 8800, which is large enough for most systems. The **ulimit** requirement is dynamically calculated at installation time and might need to be larger based on the options you select.

Before installing, run the following command:

```
ulimit -Hn 8800
```

Alternatively, you can use the following steps to edit the resource limits file:

- a. Open `/etc/system`
- b. Add the following line to the end of the file:

```
set rlim_fd_max=8800
```

- c. Save and close the file.
- d. Log off from the operating system and log in again.

2. Set the **umask** value to 077 using the following command:

```
umask 077
```

The value 077 is the most restrictive value that IBM Business Monitor will tolerate. You can optionally choose to set a less restrictive **umask** value for the following access levels:

- 037 for read-only access for a group of human administrators and tools
- 027 for read and write access for a group of human administrators and tools
- 007 for read, write, and execute access for a group of human administrators and tools

3. Complete the steps in Tuning Solaris systems.
4. Ensure all servers involved are set to the same time. Use the same network time protocol for all servers on all cluster nodes, including application, support, and database clusters. A time mismatch will cause erratic behavior, including duplicate system tasks.

Before creating or augmenting IBM Business Monitor profiles on your Solaris system, change the **MaxPermSize** JVM parameter, following the steps in Eliminating profile creation OutOfMemoryErrors on Solaris

Preparing Windows systems for installation

Before you can install IBM Business Monitor, you must prepare your Windows operating system.

Because WebSphere Application Server is a prerequisite product for IBM Business Monitor, you must complete all of the preparation tasks for WebSphere Application Server before installing IBM Business Monitor.

Complete the following steps on your Windows system before installing IBM Business Monitor:

1. Complete the steps in the Preparing Windows systems for installation topic in the WebSphere Application Server information center.
2. Complete the steps in Tuning Windows systems.

Chapter 4. Installing the IBM Business Monitor software

You can install IBM Business Monitor interactively or silently. You can use IBM Business Monitor with other software in your monitoring environment, including WebSphere Portal or Process Server.

When you install IBM Business Monitor interactively, you must use the Installation Manager, whether you are installing all IBM Business Monitor components on a single server or installing the components to clusters in a network deployment environment.

Alternatively, you can set up a response file in advance and install IBM Business Monitor silently from a command line without interacting with the IBM Business Monitor installation program.

Note: When you install IBM Cognos Business Intelligence and IBM Business Monitor, ensure that IBM Cognos BI is installed using the same bit mode as WebSphere Application Server.

Installing from the product launchpad

The IBM Business Monitor product launchpad program provides you with a single location to view release information for IBM Business Monitor, install WebSphere Application Server if required, and start the installation process.

Complete the preinstallation tasks described in Chapter 3, “Preparing to install,” on page 33, if you have not done so already.

For the default installation locations, see the related reference.

Windows To install or run IBM Business Monitor on Windows 7, Windows Vista, or Windows Server 2008, you must elevate your Microsoft Windows user account privileges. Whether you are an administrative user or a non-administrative user, right-click `launchpad.exe` and select **Run as administrator**.

Tip: For Windows installations, keep the path as short as possible. Otherwise, you might run into problems later when the paths of other components, when added to this path, exceed the 255-character path limit.

Use the product launchpad program to start the installation of IBM Business Monitor in the following cases:

- Installing from the product DVDs
- Installing from an electronic installation image on your local file system
- Installing from an electronic installation image on a shared drive

To start the launchpad program and install WebSphere Application Server if you have not already done so, complete the following steps. You can run only one launchpad at a time.

1. Insert the first IBM Business Monitor DVD into your DVD drive.

Linux **UNIX** Ensure that you have mounted the DVD drive.

2. If auto-run is enabled on your system, the IBM Business Monitor launchpad program automatically opens. If auto-run is not enabled on your system:
 - Run `launchpad.sh` located in the root directory of the DVD.
 - Run `launchpad.exe`, or `launchpad64.exe` for a 64-bit system, located in the root directory of the DVD.

3. Optional: If you see a message that prompts you to update the launchpad, click **Update** to receive the latest updates. The updates are installed and your launchpad is restarted automatically.

If you do not have access to the Internet and want updates to the launchpad to be installed from a local directory, you can use a properties file to tell the Installation Manager where to find the updates. Create the following file:

-   /home/user/bpm_updates.properties
-  C:\HOMEPATH\bpm_updates.properties

On Windows 7, Windows Vista, or Windows Server 2008, the HOMEPATH environment variable points to C:\Users\user_name\

For more information about Installation Manager updates, see Installation Manager updates.

Note: Ensure that you have read/write access to the folders specified in the bpm_updates.properties file.

The file uses a launchpad prefix, followed by a dot. The part of the name after the prefix and the dot can be anything you want, which enables you to point to multiple locations for launchpad upgrades. The locations can be either local directories or URLs. For example:

```
launchpad.1=http://test/launchpad
launchpad.2=C:\launchpad_updates
```

4. Optional: Click **Help System installation** to install the product Help System and documentation on your computer. The Help System is an Eclipse framework for displaying the documentation.
5. If you are in the Administrator group on Windows, or if you are a root user on a Linux or UNIX system, ensure that **Install as administrative user** is selected. Clear this check box only if you are not an administrative user, or if you want to install to your own user name without giving privileges to other users.
6. **If you do not yet have WebSphere Application Server installed**, click the **Install** button to start the installation of IBM Business Monitor.

Important: If you are on a 64-bit system, you might receive the following message:

Your operating system failed the launchpad prerequisites check. The following 32-bit GTK Library for running IBM Installation Manager is not available in underlying OS:
list_of_missing_files. Please install the 32-bit GTK Library and restart your installation.

If you see this message, your server does not have the 32-bit version of the GTK library installed, or the library is an incorrect version. Update your server with the correct version of the 32-bit GTK library, using the DVD or official website of your operating system, before you continue the installation.

The Installation Manager is started and configured for you. Go to “Installing IBM Business Monitor interactively” on page 41 for the remainder of the installation instructions.

7. **To install IBM Business Monitor on an existing installation of WebSphere Application Server**, click **Installation on existing WebSphere Application Server**.
 - a. If you are in the Administrator group on Windows, or if you are a root user on a Linux or UNIX system, ensure that **Install as administrative user** is selected. Clear this check box only if you are not an administrative user, or if you want to install to your own user name without giving privileges to other users.
 - b. Click **Import or Update**.
 - If the Open file window displays, click **Run**. The Installation Manager opens.
 - Click **Import** to import WebSphere Application Server into Installation Manager. You must import WebSphere Application Server if it has never previously been imported or if it has been updated with the Update Installer after it was last imported.
 - Click **Browse** and select the directory where WebSphere Application Server was installed, for example, **app_server_root**.

- Click **Next**, and then click **Import**.
- Click **Finish**.
- From the Installation Manager window, click **Update**.
- Select the package group **IBM WebSphere Application Server - ND**.

Tip: On the Update Packages page, select **Show All** to display available updates.

- Click **Next** and follow the instructions on each page, accepting the defaults.
 - Close the Installation Manager and return to the launchpad application.
- c. Click **Install** to start the installation of IBM Business Monitor. If the Open file window displays, click **Run**.

Important: If you are on a 64-bit system, you might receive the following message:

Your operating system failed the launchpad prerequisites check. The following 32-bit GTK Library for running IBM Installation Manager is not available in underlying OS: *list_of_missing_files*. Please install the 32-bit GTK Library and restart your installation.

If you see this message, your server does not have the 32-bit version of the GTK library installed, or the library is an incorrect version. Update your server with the correct version of the 32-bit GTK library, using the DVD or official website of your operating system, before you continue the installation.

- d. Click **Install IBM Business Monitor**. The Installation Manager is started and configured for you. Go to “Installing IBM Business Monitor interactively” for the remainder of the installation instructions.

If your operating system supports it, you can click **Help System Installation** on the launchpad to install the information center.

Installing IBM Business Monitor interactively

You can install IBM Business Monitor interactively using the Installation Manager, whether you are installing all the components on a single server or installing the components to clusters in a network deployment environment.

Launch the Installation Manager from the product launchpad. For the default installation locations, see the related reference link.

To install IBM Business Monitor, complete the following steps:

1. From the Installation Manager Start page, click **Install Packages** and click **Next** to continue. The following packages are selected for you:

IBM Cognos Business Intelligence

Clear this check box if you are using Microsoft Windows and you are not an administrative user.

WebSphere Application Server - ND

Clear this check box if the package is already installed.

DB2 Express®

Clear this check box if you already have a database that you intend to use or if you are not an administrative user.

IBM Business Monitor

If you receive the following warning message during the prerequisite checking, use the platform-specific steps below to increase the **ulimit** number.

Current system has detected a lower level of ulimit than the recommended value of *recommended_value*. Please increase the ulimit number to minimum value of *recommended_value* and re-start the installation.

Shutdown your installer. If you are a root user open a command prompt and issue `ulimit -n recommended_value` and then restart the installer. If you are a non-root user, work with your system administrator to increase your `ulimit -n recommended_value` and then restart the installer.

The required value is calculated based on the version of WebSphere Application Server and the configuration that you are installing.

- a. Set the maximum number of open files using the following steps: 
 - 1) Open `/etc/security/limits.conf`.
 - 2) Locate the **nofile** parameter and increase the value. If a line containing the **nofile** parameter does not exist, add the following lines to the file:
 - * **hard nofile recommended_value**
 - * **soft nofile recommended_value**
 - 3) Save and close the file.
 - 4) Log off and log in again.
 - b. Restart the computer.
 - c. Restart the installer.
2. On the Licenses page, read the license agreement for the selected package.

If you selected more than one package to install, there might be a license agreement for each package. On the left side of the **License** page, click each package version to display its license agreement. The package versions that you selected to install (for example, the base package and an update) are listed under the package name.

 - a. If you agree to the terms of all of the license agreements, click **I accept the terms of the license agreements**.
 - b. Click **Next**.
 3. If IBM Business Monitor is the first package installed using Installation Manager, enter the path for the *shared resources directory* in the **Shared Resources Directory** field on the Location page, or accept the default path. The shared resources directory contains resources that can be shared by one or more package groups.

Important:

- a. You can specify the shared resources directory only the first time that you install a package. Use your largest disk for this to ensure adequate space for the shared resources of future packages. You cannot change the directory location unless you uninstall all packages.
- b. Ensure that your installation path does not contain parentheses.
- c.   Ensure that your installation path does not contain spaces.
- d.  Keep the installation path as short as possible. Otherwise, you might run into problems later when the paths of other components, when added to this path, exceed the 255-character path limit.

Click **Next**.

4. On the next Location page, create a *package group* to install the IBM Business Monitor package into. To create a new package group use the following steps:
 - a. Select **Create a new package group**.
 - b. Type the path for the installation directory for the package group. Ensure that your installation path does not contain parentheses.   Do not include any spaces in the directory path. The name for the package group is created automatically.
 - c. Click **Next**.
5. On the Features page, select the package features to install.

- a. Optional: To see the dependency relationships between features, select the **Show Dependencies** check box.
 - b. Optional: Click a feature to view its brief description under **Details**.
 - c. Select or clear features in the package. Installation Manager automatically enforces any dependencies with other features and display updated download size and disk space requirements for the installation.
 - If you do not select any features, Business Space and the IBM Business Monitor license files are installed.
 - If you expand **Business Monitor Server** and select one or more stand-alone development profiles, the profiles are created for you during installation. To create Process Server or WebSphere Enterprise Service Bus development profiles, you must have those packages already installed.

A stand-alone development profile is a default development profile that provides a IBM Business Monitor test environment. The Process Server development profile also comes with Business Process Rules Manager enabled. To create a stand-alone development profile, you must supply the administration security credentials (user name and password) for the server that you are creating.

A stand-alone development profile cannot be used in a production environment. If you choose not to install a default stand-alone development profile, you can install one later by launching the Installation Manager and clicking **Modify** on the first page.

If you are installing **Business Monitor Server 8.0**, and you have profiles that were previously created, those profiles are automatically preserved. You do not need to re-create them.
 - d. Required: Select the WebSphere Application Server feature **EJBDeploy tool for pre-EJB 3.0 modules**. This feature is selected by default. If it is not selected, some **Business Monitor Server 8.0** components may not work correctly.
 - e. When you are finished selecting features, click **Next**.
6. If you selected a stand-alone development profile, on the Profiles page, enter the credentials for your profile. The default user name is admin and the default password is admin.
 7. On the Common Configurations page, if you already have a database, enter the credentials for the database. If you selected DB2 Express, enter a user name and password for DB2. The default administrative user name is bpmadmin. Choose a password that complies with the password policy of your system (for example, Windows 2008).

Restriction: User names must not contain National Language Strings (NLS).
Click **Next**.

8. On the Summary page, review your choices before installing the IBM Business Monitor package.
 - If you want to change the choices that you made on previous pages, click **Back** and make your changes.
 - If you are satisfied with your installation choices, click **Install** to install the package

A progress indicator shows the percentage of the installation completed.

9. When the installation process is complete, a message confirms the success of the process. If you chose to create a stand-alone development profile during installation and it failed or did not fully succeed, you see an error message informing you of the failure and giving you the location of the profile creation error log at `app_server_root/logs/manageprofiles/profilename_create.log`. You must resolve the profile creation problem and create a profile using the Profile Management Tool or the **manageprofiles** command.
 - a. Optional: Click **View log file** to open the installation log file for the current session in a new window. You must close the Installation Log window to continue.
 - b. Under **Which program do you want to start?**, select whether you want the Profile Management Tool to start when you exit. If you have already created a stand-alone development profile, you

can select **None**. For production, you must define a stand-alone server profile or a deployment manager using the Profile Management Tool or the **manageprofiles** command. See the information about *Creating and Augmenting profiles*.

- c. Click **Finish** to close the Installation Manager.

For production, you must create a stand-alone server profile or a deployment manager using the Profile Management Tool or the **manageprofiles** command.

Restriction: If you created a stand-alone development profile during installation, remember that it does not work in a production environment. It is intended to help you gain familiarity with IBM Business Monitor without having to create a working production profile. You can start the profile from its First steps console.

- Open a command window. Go to **profile_root/firststeps.wbm** and run the **firststeps.sh** command.
- Go to **Start > All Programs > IBM > Business Monitor 8.0 > Profiles > profile_name > First Steps**.
- Go to **profile_root\firststeps.wbm** and run the **firststeps.bat** command.

Important: To install or run First Steps on Microsoft Windows 7, Microsoft Windows Vista, or Microsoft Windows Server 2008, you must elevate your Microsoft Windows user account privileges by right-clicking **firststeps.bat** and selecting **Run as administrator**. This is required for both administrative and nonadministrative users.

Installing IBM Business Monitor silently

You can install the IBM Business Monitor product package in *silent* installation mode. When you install in silent mode, the user interface is not available.

Important: Only one IBM Installation Manager is required to install multiple instances of IBM Business Monitor.

Installing IBM Business Monitor silently using the command line

You can install IBM Business Monitor using the command line.

Before you install IBM Business Monitor, review the system requirements for the product.

Operating system and software prerequisite levels are particularly important. Although the installation process automatically checks for prerequisite operating system patches, review the system requirements if you have not already done so. The system requirements link lists all supported operating systems and the operating system fixes and patches that you must install to have a compliant operating system. It also lists the required levels of all prerequisite software.

If you are planning to install IBM Business Monitor using DB2 Express with Red Hat Enterprise Linux 6, ensure that the user has administrative privileges (root user). As a root user, you must also ensure that all kernel requirements are met before the DB2 Express installation begins. You can locate the current values by parsing the output of the **ipcs -l** command.

If you do not have the prerequisite base products necessary for IBM Business Monitor installation, you must install them as part of the silent installation. The required base products are:

- Installation Manager
- WebSphere Application Server Network Deployment, including the `ejbdeploy` and `thinclient` features

The silent installation performs the following tasks:

- Installs Installation Manager if it is not already installed or updates it to the appropriate level if it is installed.

- Installs the required base products and IBM Business Monitor.

To silently install IBM Business Monitor, complete the following steps:

1. Run the following command to generate encrypted passwords using IBM Installation Manager to securely connect to DB2 and the WebSphere administrative console.

Important: If you are running Windows 7, Windows Vista, or Windows Server 2008, start your command prompt by right-clicking and selecting **Run as administrator**.

Windows

```
IM_location\eclipse\tools\imutilsc -silent -nosplash encryptString password_to_encrypt
```

Linux

```
IM_location/eclipse/tools/imutilsc -silent -nosplash encryptString password_to_encrypt
```

2. Read and accept the license terms before installing. Adding **-acceptLicense** to the command line means that you accept all licenses.
3. Run the following command:

Important: If you are running Windows 7, Windows Vista, or Windows Server 2008, start your command prompt by right-clicking and selecting **Run as administrator**.

Windows

```
extract_directory\IM\tools\imcl install list_of_product_IDS -acceptLicense
-installationDirectory location -repositories repository
-properties key=value,key=value -showVerboseProgress -log logName.log
```

UNIX Linux

```
extract_directory/IM/tools/imcl install list_of_product_IDS -acceptLicense
-installationDirectory location -repositories repository
-properties key=value,key=value -showVerboseProgress -log logName.log
```

Important: If your system does not have a graphical user interface, you will not be able to use the **showVerboseProgress** as shown on the sample invocation.

where:

- *list_of_product_IDS* is a list of the IDs for the products you want to install, separated by spaces.

Table 4. Product IDs

Product	Product ID	Feature	Description
IBM Business Monitor	com.ibm.websphere.MON.V80	core.feature	Required. IBM Business Monitor core runtime content.
		wbm.server.feature	Required. IBM Business Monitor server runtime content.
		wbm.profile.feature	Stand-alone development IBM Business Monitor profile (qmwasp).
		wbm.wps.profile.feature	Stand-alone development IBM Business Monitor on Process Server profile (qmbpmaps).
		wbm.esb.profile.feature	Stand-alone development IBM Business Monitor on WebSphere ESB profile (qmesb).

Table 4. Product IDs (continued)

Product	Product ID	Feature	Description
WebSphere Application Server Network Deployment	com.ibm.websphere.ND.v80	core.feature	Required. WebSphere Application Server core content.
		ejbdeploy	Required. Pre-Enterprise JavaBeans (EJB) 3.0 modules.
		thinclient	Required. Stand-alone thin clients and resource adapters.
		embeddablecontainer	Embeddable EJB container.
		samples	Sample applications feature.
		com.ibm.sdk.6_32bit	32-bit software development kit (SDK). You must specify either this feature or com.ibm.sdk.6_64bit.
		com.ibm.sdk.6_64bit	64-bit SDK This feature can only be selected on a 64-bit system. You must specify either this feature or com.ibm.sdk.6_32bit.
Installation Manager	com.ibm.cic.agent	agent_core	Installation Manager core content.
		agent_jre	Installation Manager Java Runtime Environment (JRE).
DB2 Express for Linux 32-bit	com.ibm.ws.DB2EXP97.linuxia32	n/a	DB2 must match the operating system and bit version.
DB2 Express for Linux 64-bit	com.ibm.ws.DB2EXP97.linuxia64	n/a	DB2 must match the operating system and bit version.
DB2 Express for Windows 32-bit	com.ibm.ws.DB2EXP97.winia32	n/a	DB2 must match the operating system and bit version.
DB2 Express for Windows 64-bit	com.ibm.ws.DB2EXP97.winia64	n/a	DB2 must match the operating system and bit version.
IBM Cognos Business Intelligence for Windows x86 (32-bit)	com.ibm.ws.cognos.v1011.winia32	n/a	IBM Cognos BI must match the operating system and the WebSphere Application Server bit version.
IBM Cognos BI for Windows x64 (64-bit)	com.ibm.ws.cognos.v1011.winia64	n/a	IBM Cognos BI must match the operating system and the WebSphere Application Server bitnes
IBM Cognos BI for AIX PPC 32-bit	com.ibm.ws.cognos.v1011.aix32	n/a	IBM Cognos BI must match the operating system and the WebSphere Application Server bitnes

Table 4. Product IDs (continued)

Product	Product ID	Feature	Description
IBM Cognos BI for AIX PPC 64-bit	com.ibm.ws.cognos.v1011.aix64	n/a	IBM Cognos BI must match the operating system and the WebSphere Application Server bitnes
IBM Cognos BI for Linux x86 (32-bit)	com.ibm.ws.cognos.v1011.linuxia32	n/a	IBM Cognos BI must match the operating system and the WebSphere Application Server bitnes
IBM Cognos BI for Linux x86-64 (64-bit)	com.ibm.ws.cognos.v1011.linuxia64	n/a	IBM Cognos BI must match the operating system and the WebSphere Application Server bitnes
IBM Cognos BI for Solaris SPARC (32-bit)	com.ibm.ws.cognos.v1011.solaris32	n/a	IBM Cognos BI must match the operating system and the WebSphere Application Server bitnes
IBM Cognos BI for Solaris SPARC (64-bit)	com.ibm.ws.cognos.v1011.solaris64	n/a	IBM Cognos BI must match the operating system and the WebSphere Application Server bitnes
IBM Cognos BI for Linux on System z	com.ibm.ws.cognos.v1011.zlinux64	n/a	IBM Cognos BI must match the operating system and the WebSphere Application Server bitnes

- *location* is the path to the directory where you want to install the products.
- *repository* is the path to the repository where you have extracted the files, one of the following directories:

```
extract_directory/repository/repos_32bit
extract_directory/repository/repos_64bit
```

For more than one repository, separate the repository locations with commas.

- *key=value* is a list of the keys and values you want to pass to the installation, separated by commas. Do not put spaces between the commas. Create encrypted passwords using the IBM Installation Manager.

Table 5. Keys

Key	Description
user.select.64bit.image	If you are installing on a 64-bit operating system, add the following line exactly: user.select.64bit.image,,com.ibm.websphere.ND.v80=true The default value is false.
user.db2.admin.username	Windows only. User name with authority to access the DB2 database. The default value is bpmadmin.
user.db2.admin.password	Windows only. Password for the user name. Choose a password that complies with the password policy of your system (for example, Windows 2008).

Table 5. Keys (continued)

Key	Description
user.bpm.admin.username	User name for the administrative console. The default value is admin. This property is needed only if you are creating a profile.
user.bpm.admin.password	Password for the user name. The default value is admin. This property is needed only if you are creating a profile.
user.db2.port	Port for the DB2 database. The default value is 50000.
user.db2.instance.username	Linux only. DB2 instance user name. The default value is bpminst.
user.db2.instance.password	Linux only. Password for the user name.
user.db2.fenced.username	Linux only. Fenced user name. The default value is bpmfenc.
user.db2.fenced.password	Linux only. Password for the user name.
user.db2.das.username	Linux only. Administration server (DAS) user name. The default value is bpmadmin.
user.db2.das.password	Linux only. Password for the user name.

- *logName* is the name of the log file to record messages and results.

Running this command installs the product with the default features. If you want to install specific features or make other changes, see the reference link for the command-line arguments for `imcl`.

Installation Manager installs the list of products and writes a log file to the directory that you specified.

The following example installs IBM Business Monitor.

Windows

```
imcl install com.ibm.websphere.MON.V80 com.ibm.websphere.ND.v80,core.feature,ejbdeploy,thinclient,
embeddablecontainer,samples,com.ibm.sdk.6_32bit com.ibm.ws.cognos.v1011.winia32
com.ibm.ws.DB2EXP97.winia32 -acceptLicense
-installationDirectory C:\IBM\MON80 -repositories D:\temp\MonServer\repository\WBM
-properties user.db2.admin.username=bpmadmin,user.db2.admin.password=Vvrs88V/a9BUdxwodz0nUg==
-showVerboseProgress -log silentinstall.log
```

Linux

```
imcl install com.ibm.websphere.MON.V80 com.ibm.websphere.ND.v80,core.feature,ejbdeploy,thinclient,
embeddablecontainer,samples,com.ibm.sdk.6_32bit com.ibm.ws.cognos.v1011.linuxia32
com.ibm.ws.DB2EXP97.linuxia32 -acceptLicense
-installationDirectory /usr/IBM/MON80 -repositories usr/tmp/MonServer/repository/WBM
-properties user.db2.instance.username=bpmadmin,user.db2.instance.password=Vvrs88V/a9BUdxwodz0nUg==
-showVerboseProgress -log silentinstall.log
```

AIX

```
imcl install com.ibm.websphere.MON.V80 com.ibm.websphere.ND.v80,core.feature,ejbdeploy,thinclient,
embeddablecontainer,samples,com.ibm.sdk.6_32bit com.ibm.ws.cognos.v1011.aix32 -acceptLicense
-installationDirectory /usr/IBM/MON80 -repositories usr/tmp/MonServer/repository/WBM
-showVerboseProgress -log silentinstall.log
```

Solaris

```
imcl install com.ibm.websphere.MON.V80 com.ibm.websphere.ND.v80,core.feature,ejbdeploy,thinclient,
embeddablecontainer,samples,com.ibm.sdk.6_32bit com.ibm.ws.cognos.v1011.solaris32 -acceptLicense
-installationDirectory /usr/IBM/MON80 -repositories usr/tmp/MonServer/repository/WBM
-showVerboseProgress -log silentinstall.log
```

You must define a stand-alone server profile or a deployment manager in the Profile Management Tool or using the `manageprofiles` command. Only profiles created with the Profile Management Tool or `manageprofiles` command can be used in production.

Installing IBM Business Monitor silently using a response file

You can install IBM Business Monitor by creating a response file and then running a command to use that response file to install the product.

Before you install IBM Business Monitor, review the system requirements for the product.

Operating system and software prerequisite levels are particularly important. Although the installation process automatically checks for prerequisite operating system patches, review the system requirements if you have not already done so. The system requirements link lists all supported operating systems and the operating system fixes and patches that you must install to have a compliant operating system. It also lists the required levels of all prerequisite software.

If you are planning to install IBM Business Monitor using DB2 Express with Red Hat Enterprise Linux 6, ensure that the user has administrative privileges (root user). As a root user, you must also ensure that all kernel requirements are met before the DB2 Express installation begins. You can locate the current values by parsing the output of the `ipcs -l` command.

If you do not have the prerequisite base products necessary for IBM Business Monitor installation, you must install them as part of the silent installation. The required base products are:

- Installation Manager
- WebSphere Application Server Network Deployment, including the `ejbdeploy` and `thinclient` features

The silent installation performs the following tasks:

- Installs Installation Manager if it is not already installed or updates it to the appropriate level if it is installed.
- Installs the required base products and IBM Business Monitor.

To silently install IBM Business Monitor, complete the following steps:

1. Run the following command to generate encrypted passwords using IBM Installation Manager to securely connect to DB2 and the WebSphere administrative console.

Important: If you are running Windows 7, Windows Vista, or Windows Server 2008, start your command prompt by right-clicking and selecting **Run as administrator**.

> Windows

```
IM_location\eclipse\tools\imutilsc -silent -nosplash encryptString password_to_encrypt
```

> Linux

```
IM_location/eclipse/tools/imutilsc -silent -nosplash encryptString password_to_encrypt
```

2. Read and accept the license terms before installing. Adding **-acceptLicense** to the command line means that you accept all licenses.
3. Create the response file that will install the required base products and IBM Business Monitor. Copy a sample response file, suitable for your bit version and user access level, from the following directory:

```
extract_directory/responsefiles/WBM/
```

Alternatively, you can create a response file by recording your actions in Installation Manager. When you record a response file, the selections that you make in Installation Manager are stored in an XML file. When you run Installation Manager in silent mode, Installation Manager uses the data in the XML response file to perform the installation.

- The default values provided in the sample response files will perform a basic install, but you should review the file and its comments, and modify the parameters as needed for your environment.

Important: Verify that the repository locations in your response file point to the correct location in your environment and that other parameter values are also appropriate.

- Run the following command:

Important: If you are running Windows 7, Windows Vista, or Windows Server 2008, start your command prompt by right-clicking and selecting **Run as administrator**.

Administrator or Root user: 

```
extract_directory\IM\installc.exe -acceptLicense input
  extract_directory\responsefiles\BusMon\response_file_name.xml
  -log preferred_log_location\silent_install.log
```

 UNIX

 Linux

```
extract_directory/IM/installc -acceptLicense input
  extract_directory/responsefiles/BusMon/response_file_name.xml
  -log preferred_log_location/silent_install.log
```

Non-administrator or non-root user: 

```
extract_directory\IM\userinstc.exe -acceptLicense input
  extract_directory\responsefiles\BusMon\response_file_name.xml
  -log preferred_log_location\silent_install.log
```

 UNIX

 Linux

```
extract_directory/IM/userinstc -acceptLicense input
  extract_directory/responsefiles/BusMon/response_file_name.xml
  -log preferred_log_location/silent_install.log
```

Installation Manager installs any required prerequisites and IBM Business Monitor, and writes a log file to the directory you specified.

You must define a stand-alone server profile or a deployment manager in the Profile Management Tool or using the `manageprofiles` command. Only profiles created with the Profile Management Tool or `manageprofiles` command can be used in production.

Chapter 5. Creating the databases

IBM Business Monitor requires two databases, one for the IBM Business Monitor configuration and one for the IBM Cognos Business Intelligence content store.

MONITOR and COGNOSCS databases

By default, the database for IBM Business Monitor is named MONITOR and the database for the IBM Cognos BI content store is named COGNOSCS.

You can create the MONITOR and COGNOSCS databases as part of creating a stand-alone or deployment manager profile, you can use the database design tool (dbDesignGenerator), or you can manually create the databases by running the database script files before or after profile creation. In a network deployment environment, it is best to create the databases before starting the deployment manager and creating custom profiles.

Important: If you are using DB2 for z/OS, create the database using the database design tool (dbDesignGenerator) or manually create the database.

If you have an existing IBM Cognos BI server, you do not need to create a COGNOSCS database because the content store is already defined.

Tip: If the COGNOSCS database is remote from the IBM Cognos BI server, you must install a database client on the IBM Cognos BI server machine. See the details in the database-specific database consideration topics.

The MONITOR and COGNOSCS databases can be located on the same server as the IBM Business Monitor server or on a different server. For profile creation to create the databases automatically, your database server must be local to the machine where you run the Profile Management Tool or the **manageprofiles** command. Otherwise, use the database script files to create the databases. Also use the database script files to create the databases if you are using z/OS, or if the database server contains multiple versions of the database or multiple database instances.

Database scripts

When you create a stand-alone or deployment manager profile, database scripts are generated that match the values entered during profile creation, ensuring that names are consistent between the IBM Business Monitor server and the IBM Business Monitor database.

You can also create the database scripts yourself using one of the following methods:

- Configure the values using the database design tool (DbDesignGenerator) that is installed with the IBM Business Monitor server. One advantage of using the database design tool is that you can design the MONITOR database, the IBM Cognos BI database, the Business Space database, and the databases for the messaging engines for IBM Business Monitor and the common event infrastructure (CEI) all at the same time. See “Creating or configuring database scripts using the database design tool” on page 52 for instructions.
- Configure the values manually. See “Configuring MONITOR database scripts manually” on page 53 for instructions.

After the database scripts are generated or customized, run the scripts using the procedures described in “Installing the MONITOR database manually” on page 57.

Messaging engine tables

The messaging engines for the IBM Business Monitor service integration bus and the common event infrastructure (CEI) bus require database tables. Except on z/OS, these tables can be created automatically by WebSphere Application Server if the IBM Business Monitor database user has sufficient privileges and the option to create tables automatically is set in the service integration bus message store options. This option is set to true by default unless you are using DB2 for z/OS.

The database scripts for the messaging engine tables can also be generated using one of the following options:

- Create the script using the database design tool (DbDesignGenerator). See “Creating or configuring database scripts using the database design tool” for instructions.
- Create the tables manually. See “Creating messaging engine tables manually” on page 59 for instructions.

Business Space tables

For dashboards, you must also configure the Business Space tables, using either the scripts that were generated during stand-alone profile creation or the database design tool. For more information, see Configuring Business Space database tables.

Database security

When the databases are created, the runtime database user is granted privileges to administer database objects by default, which simplifies the creation of the databases and enables the IBM Business Monitor server to automatically manage the monitor model database schema when models are deployed and removed. If you must secure the databases, see Securing the MONITOR database environment and Configuring IBM Cognos BI security.

Creating or configuring database scripts using the database design tool

The database design tool (DbDesignGenerator) installed with the IBM Business Monitor server can be used to generate database scripts that can be executed before or after IBM Business Monitor profile creation.

One advantage of using the database design tool is that you can design the databases for IBM Business Monitor, IBM Cognos BI, Business Space, and the messaging engine all at the same time. Database scripts are generated for each component, and a dbdesign file is generated that can later be passed into the deployment environment wizard, to automatically configure the data sources when creating a complex IBM Business Monitor topology.

Important: Make sure you use the database design tool when you are creating databases for DB2 for z/OS.

If you choose the **Advanced** path through the Profile Management Tool, you can choose **Configure the database using a design file** and select a design file that you have already created.

For more information about the database design tool, see the related links.

To edit the database script files using the database design tool, complete the following steps:

1. Change directory to the **app_server_root/util/dbUtils** directory.
2. Run the command to start the utility.
 - DbDesignGenerator.bat

- DbDesignGenerator.sh.
3. From the main menu, select option **(1) Create a database design for Standalone profile or Deployment Environment**.
 4. At the **Please pick one of the following db designs that are supported** prompt, select either option **(1)monitor.nd.topology** or option **(2)monitor.standalone**. The monitor.nd.topology option provides more flexibility for distributing the database components across multiple databases.
 5. At the **Please pick one of the following [database component(s)]** prompt, select option **(1)[Monitor] MONITOR : [master] [status = not complete]**.
 6. At the **Edit this db component?** prompt, enter **y**.
 7. At the **Please pick one of the following DB types that are supported** prompt, select the number of your database platform.
 8. Respond to the series of prompts or press Enter to accept the defaults where applicable. You are asked to enter your database name, schema name, user name and password, and table space location directory prefix.
 9. At the **To skip data source properties, enter 's'; or enter anything else to continue** prompt, enter **c** (or any character except **s**) to continue entering information.
 10. Respond to the series of prompts or press Enter to accept the defaults where applicable. You are asked to enter the properties for your data source.
 11. Verify that the IBM Business Monitor database component is complete before configuring the other components. The IBM Cognos BI database is shown as not complete and requires a database user and password. You can accept the defaults for the other settings.
 12. When you see the **Please pick one of the following [database component(s)]** prompt again, you have finished entering properties if all the lines display **[status = complete]**, for example **(1)[Monitor] MONITOR : [master] [status = complete]**. Enter **5 [save and exit]** and press Enter to save the database design.
The **[Cognos] COGNOSCS** database component requires additional configuration after completing the MONITOR configuration. The COGNOSCS status is **[status = not complete]** until this component is fully configured.
 13. At the **Please enter the output directory** prompt, press Enter to accept the default (**app_server_root/util/dbUtils**) or enter the location to write the database design files.
 14. At the **Please enter the output filename** prompt, press Enter to accept the default (**monitor.standalone.dbdesign**) or enter the name for the file.
 15. At the **Generate db script?** prompt, enter **y** and keep pressing Enter to accept the default locations. Subdirectories are created for the MONITOR and COGNOSCS database scripts, messaging engine datastore script, and Business Space database scripts.

Configuring MONITOR database scripts manually

The database scripts required for creating the MONITOR database are shipped on the installation media and are copied to the application server during IBM Business Monitor server installation. These database scripts can be customized manually so that you can create the databases before server installation or profile creation.

To edit the database script files manually, complete the following steps:

1. Using a text editor, open the database script files for your database software.
The scripts create the databases and required tables for IBM Business Monitor.
 - **For DB2 for z/OS:**
 - **createDatabase_Monitor.sql**
 - **createTablespace_Monitor.sql**
 - **createTable_Monitor.sql**
 - **For all other databases:**

- **createDatabase.sql**
- **createTables.sql**

By default, the files are located in the following directories:

(distributed only) *DVD_root/scripts/database/Monitor/platform*

app_server_root/dbscripts/Monitor

app_server_root/profiles/profile_name/dbscripts/Monitor (stand-alone)

app_server_root/profiles/profile_name/dbscripts.wbm (deployment manager)

where

DVD_root is the directory where you extracted the DVD or downloadable image

platform is the operating system of the database (for example DB2, Oracle, or SQL Server)

app_server_root is the directory where IBM Business Monitor is installed

2. Edit the following variables in the database script files for your database software:

- **For DB2**, edit the following variables:

@DB_NAME@

Represents the name of the IBM Business Monitor database (for example, MONITOR).

@SCHEMA@

Represents the name of the IBM Business Monitor schema (for example, MONITOR).

@TSDIR@

Represents the table space directory.

If **@TSDIR@** is omitted from data file specification of a table space, the data file is created in the database manager directory.

@DB_USER@

Represents the runtime IBM Business Monitor database user.

- **For DB2 for z/OS**, edit the following variables:

@STOGRP@

Represents the DB2 storage group name (for example, SYSDEFLT).

@DB_NAME@

Represents the name of the IBM Business Monitor database.

@SCHEMA@

Represents the name of the IBM Business Monitor schema qualifier.

@DB_USER@

Represents the runtime IBM Business Monitor database user.

- **For SQL Server**, edit the following variables:

@DB_NAME@

Represents the name of the IBM Business Monitor database (for example, MONITOR).

@SCHEMA@

Represents the name of the IBM Business Monitor schema (for example, MONITOR).

@DB_USER@

Represents the runtime IBM Business Monitor database user.

@DB_PASSWORD@

Represents the password of the runtime IBM Business Monitor database user. You can create the database user and password before running the script, or you can design the script to create the database user and password for you. If the script will create the database user and password, you must specify **@DB_PASSWORD@** in the script.

- **For Oracle**, edit the following variables:

@SCHEMA@

Represents the name of the database user that owns the IBM Business Monitor database tables.

@DB_PASSWORD@

Represents the password for the database user identified by \$SCHEMA\$.

@TSDIR@

Represents the table space directory.

If @TSDIR@ is omitted from the data file specification of a table space, the data file is created in the database manager directory. If a fully qualified path is specified for @TSDIR@, the directory must exist before you invoke this script.

@DB_USER@

Represents the runtime IBM Business Monitor database user.

The table spaces are created in the **createDatabase.sql** file. If you decide to replace the default table space names with your own table space names, when models are deployed you must export the model schema scripts and modify them to refer to your chosen table space names.

Important: If you are configuring an additional monitoring instance in one Oracle installation, you must also replace the string **DEFAULTTS** in createDatabase.sql with a unique identifier for this additional monitoring instance in the following four lines:

```
CREATE TABLESPACE MONDSTS
  DATAFILE 'DEFAULTTS_MONDSTS.dbf' SIZE 500M AUTOEXTEND ON
  NEXT 100M MAXSIZE UNLIMITED LOGGING;
```

```
CREATE TABLESPACE MONDMSTS
  DATAFILE 'DEFAULTTS_MONDMSTS.dbf' SIZE 100M AUTOEXTEND ON
  NEXT 20M MAXSIZE UNLIMITED LOGGING;
```

```
CREATE TABLESPACE MONIDXTS
  DATAFILE 'DEFAULTTS_MONIDXTS.dbf' SIZE 250M AUTOEXTEND ON
  NEXT 50M MAXSIZE UNLIMITED LOGGING;
```

```
CREATE TABLESPACE MONLOBTS
  DATAFILE 'DEFAULTTS_MONLOBTS.dbf' SIZE 200M AUTOEXTEND ON
  NEXT 40M MAXSIZE UNLIMITED LOGGING; ;
```

For example, if the unique identifier of the additional monitoring instance was **MONDEV1_MONDSTS**, the edited lines would look like this:

```
CREATE TABLESPACE MONDSTS
  DATAFILE 'MONDEV1_MONDSTS.dbf' SIZE 500M AUTOEXTEND ON
  NEXT 100M MAXSIZE UNLIMITED LOGGING;
```

```
CREATE TABLESPACE MONDMSTS
  DATAFILE 'MONDEV1_MONDMSTS.dbf' SIZE 100M AUTOEXTEND ON
  NEXT 20M MAXSIZE UNLIMITED LOGGING;
```

```
CREATE TABLESPACE MONIDXTS
  DATAFILE 'MONDEV1_MONIDXTS.dbf' SIZE 250M AUTOEXTEND ON
  NEXT 50M MAXSIZE UNLIMITED LOGGING;
```

```
CREATE TABLESPACE MONLOBTS
  DATAFILE 'MONDEV1_MONLOBTS.dbf' SIZE 200M AUTOEXTEND ON
  NEXT 40M MAXSIZE UNLIMITED LOGGING;
```

Repeat this procedure for each additional monitoring instance.

Note: Version 6.2 of IBM Business Monitor used different table spaces from previous versions. This means that if you are using Oracle and intend to deploy a 6.1 model to IBM Business Monitor 8.0, you must choose one of the following options:

- Run the 6.1 table space statements during the installation of the 8.0 database.
- When you deploy a monitor model, export the model database script and manually change the table space references to point to the 7.0 table space names. If you choose the second option, you must do this each time you deploy a 6.1 model to the 7.0 server.

A simple way to avoid this issue is to migrate from 6.1 to 8.0 with existing models deployed, and then generate new models in 6.2 or 8.0 IBM Business Monitor development toolkit.

The map of table space names is shown in the table below.

Table 6. Map of table space names from previous versions of IBM Business Monitor

Current Table Space	6.1.x Table Space
MONDSTS	INSTANCE
MONDMSTS	DMSTS
MONIDXTS	INDEXTS
MONLOBTS	LOBTS

3. Save and close the file.

Configuring COGNOSCS database scripts manually

The database scripts required for creating the COGNOSCS database for IBM Cognos Business Intelligence are shipped on the installation media and are copied to the application server during IBM Business Monitor server installation. These database scripts can be customized manually so that you can create the databases before server installation or profile creation.

To edit the database script files manually, complete the following steps:

1. Using a text editor, open the database script file for your database software.
 - For DB2 for z/OS, the createDatabase_Cognos.sql script creates the database.
 - For all other databases, the createDatabase.sql script creates the database.

By default, the file is located in the following directories:

```
app_server_root/dbscripts/Cognos
app_server_root/profiles/profile_name/dbscripts/Cognos
```

where

app_server_root is the directory where IBM Business Monitor is installed

2. Edit the following variables in the database script files for your database software:
 - **For DB2 for z/OS**, the default schema for the database user will be used. Edit the following variables:
 - @STOGRP@**
Represents the DB2 storage group name (for example, SYSDEFLT).
 - @COG_DB_NAME@**
Represents the name of the IBM Business Monitor database (for example, COGNOSCS).
 - **For all other databases**, the default schema and table space for the database user will be used. Edit the following variables:
 - @COG_DB_NAME@**
Represents the name of the IBM Business Monitor database (for example, COGNOSCS).
 - @DB_USER@**
Represents the runtime IBM Business Monitor database user.
3. Save and close the file.
4. **For DB2 for z/OS only:**

- a. On DB2 for z/OS, you must create the table spaces using the IBM Cognos BI scripts `tablespace_db2z0S.sql` and `NC_TABLESPACES.sql`. See the full instructions in the IBM Cognos BI information center:

Suggested Settings for Creating the Content Store in DB2 on z/OS

Create Tablespaces for a DB2 Content Store on z/OS

- b. The first time IBM Cognos BI starts, it creates the tables using the following scripts:

`COGNOS_location/configuration/schemas/content/db2z0S/dbInitTest_db2z0S.sql`

`COGNOS_location/configuration/schemas/content/db2z0S/dbInitScript_db2z0S.sql`

`COGNOS_location/configuration/schemas/content/db2z0S/dbInitLock_db2z0S.sql`

`COGNOS_location/configuration/schemas/content/db2z0S/dbInitMeta_db2z0S.sql`

`COGNOS_location/configuration/schemas/delivery/zosdb2/NC_CREATE_DB2.sql`

For network deployment (ND) environments, the initial server startup will first copy these files from the master IBM Cognos BI installation location to the server location. Make sure that you have replaced the environment-specific variables in these files before the IBM Cognos BI server starts; otherwise the table creation scripts will fail when the server starts. To determine your `COGNOS_location`, see *Locating your runtime IBM Cognos BI root directory*.

Installing the MONITOR database manually

You can use database scripts to install the IBM Business Monitor database manually, either on the same server as the IBM Business Monitor server or as a remote database on another server. Before running the scripts, ensure that the environment-specific variables in the scripts have been configured, either manually or using the database design tool.

Before you complete this task, make sure that you have read "Database considerations" and any prerequisites for your specific database product. For example, if you are using DB2 for z/OS, a dedicated storage group (STOGROUP) is recommended for IBM Business Monitor. The storage group must be created before the database is created.

Complete the following steps on the server where the database software is installed:

1. Log in to the database server as a user with authority to create table spaces and database objects.
2. Locate the DDL scripts.
 - If you are using the scripts that are delivered when IBM Business Monitor is installed, they are found in the `app_server_root/dbscripts/Monitor` directory.
 - If you used DbDesignGenerator to generate the scripts with your variable values substituted, they are in the output directory you chose while running the utility (by default `app_server_root/util/dbUtils`).
 - If you had profile creation generate the scripts with your variable values substituted, they are in the output directory that you chose when creating the profile (by default `app_server_root/profiles/<profile>/dbscripts/Monitor`).
3. From the command line interface, run the script, using the following command for your database software. The script creates the database for IBM Business Monitor.
 - **DB2:** `db2 -tf createDatabase.sql`
 - **DB2 for z/OS:**
 - `db2 -tf createDatabase_Monitor.sql`
 - `db2 -tf createTablespace_Monitor.sql`

The database scripts can be run using either the SPUFI or the DSNTEP2 utility.

 - **Oracle:** `sqlplus dbadmin/password @ database_name @createDatabase.sql` where
 - `dbadmin` is an Oracle user with administrative authority
 - `database_name` is the Oracle ID (for example, `orcl`)

- **Microsoft SQL Server:** `sqlcmd -U dbadmin -P password -e -i createDatabase.sql` where *dbadmin* is a SQL Server user with administrative authority
4. Run the script to create tables using one of the following commands:
 - **DB2:**

```
db2 connect to MONITOR
db2 -tf createTables.sql
db2 connect reset
```

Note: While running the DDL file, you might see the following warning message: **SQL0347W The recursive common table expression "MON023.WBITIME" may contain an infinite loop. SQLSTATE=01605.** You can safely ignore this message.
 - **DB2 for z/OS :**

```
db2 connect to MONITOR
db2 -tf createTable_Monitor.sql
db2 connect reset
```

Note: While running the DDL file, you might see the following warning message: **SQL0347W The recursive common table expression "MON023.WBITIME" may contain an infinite loop. SQLSTATE=01605.** You can safely ignore this message.
 - **Oracle:** `sqlplus user/password@database_name @createTables.sql`
 - **Microsoft SQL Server:** `sqlcmd -U user -P password -e -i createTables.sql`
 5. Start WebSphere Application Server.

Installing the COGNOSCS database manually

You can use the `createDatabase` script, or, for DB2 for z/OS, the `createDatabase_Cognos` script, to install the IBM Cognos Business Intelligence content store database manually, either on the same server as the IBM Business Monitor server or as a remote database on another server. Before running the script, ensure that the environment-specific variables in the script have been configured, either manually or using the database design tool.

Before you complete this task, make sure that you have read "Database considerations" and any prerequisites for your specific database product.

Complete the following steps on the server where the database software is installed:

1. Log in to the database server as a user with authority to create table spaces and database objects.
2. Locate the DDL scripts.
 - If you are using the scripts that are delivered when IBM Business Monitor is installed, they are found in the `app_server_root/dbscripts/Cognos` directory.
 - If you used DbDesignGenerator to generate the scripts with your variable values substituted, they are in the output directory you chose while running the utility (by default `app_server_root/util/dbUtils`).
 - If you had profile creation generate the scripts with your variable values substituted, they are in the output directory that you chose when creating the profile (by default `app_server_root/profiles/<profile>/dbscripts/Cognos`).
3. From the command line interface, run the script, using the following command for your database software.
 - **DB2:** `db2 -tf createDatabase.sql`
 - **DB2 for z/OS:** `db2 -tf createDatabase_Cognos.sql`. The database script can be run using either the SPUFI or the DSNTEP2 utility.
 - **Oracle:** `sqlplus dbadmin/password @ database_name @createDatabase.sql` where *dbadmin* is an Oracle user with administrative authority

database_name is the Oracle ID (for example, **orcl**)

- **Microsoft SQL Server:** `sqlcmd -U dbadmin -P password -e -i createDatabase.sql` where *dbadmin* is a SQL Server user with administrative authority

4. For DB2 for z/OS only:

- a. On DB2 for z/OS, you must create the table spaces using the IBM Cognos BI scripts `tablespace_db2z0S.sql` and `NC_TABLESPACES.sql`. See the full instructions in the IBM Cognos BI information center:

Suggested Settings for Creating the Content Store in DB2 on z/OS

Create Tablespaces for a DB2 Content Store on z/OS

- b. The first time IBM Cognos BI starts, it creates the tables using the following scripts:

`COGNOS_location/configuration/schemas/content/db2z0S/dbInitTest_db2z0S.sql`

`COGNOS_location/configuration/schemas/content/db2z0S/dbInitScript_db2z0S.sql`

`COGNOS_location/configuration/schemas/content/db2z0S/dbInitLock_db2z0S.sql`

`COGNOS_location/configuration/schemas/content/db2z0S/dbInitMeta_db2z0S.sql`

`COGNOS_location/configuration/schemas/delivery/zosdb2/NC_CREATE_DB2.sql`

For network deployment (ND) environments, the initial server startup will first copy these files from the master IBM Cognos BI installation location to the server location. Make sure that you have replaced the environment-specific variables in these files before the IBM Cognos BI server starts; otherwise the table creation scripts will fail when the server starts. To determine your *COGNOS_location*, see *Locating your runtime IBM Cognos BI root directory*.

5. Start WebSphere Application Server.

Creating messaging engine tables manually

If you did not automatically create the service integration (SI) bus tables for the IBM Business Monitor messaging engine during stand-alone profile creation, or while using the deployment environment configuration wizard or configuration wizard, you must create the tables manually. You must also create the tables manually if you are using DB2 for z/OS for the messaging engine data store.

You can also create a common event infrastructure (CEI) messaging engine table. When the deployment environment is created, the database scripts for CEI are generated. You must run the scripts manually to complete the configuration if you would like to enable the CEI event store (not recommended for production environments).

Use the database design tool (DbDesignGenerator) to generate scripts for the SI bus tables in version 8.0.

You can also use `sibDDLGenerator` as an alternative. For example, the command to generate SIB DDL scripts for DB2 for z/OS is `sibDDLGenerator -system db2 -version 8.1 -platform zos`.

The documentation for the `sibDDLGenerator` shows the versions of DB2 that are supported. It does not list all the versions of DB2 that are supported by IBM Business Monitor; however, you can specify version 8.1 as shown in the previous paragraph and the resulting DDL should be compatible with all supported versions.

Because IBM Business Monitor can have a CEI messaging engine as well as the IBM Business Monitor messaging engine, each created with the same table space and table names, ensure that you either use two different databases or two different schema names.

Generating scripts for creating database objects in DB2 for z/OS

If you have an existing database design file, you can use it to generate database scripts for creating IBM Business Monitor database objects in a DB2 for z/OS database subsystem.

Install IBM Business Monitor.

Ensure that you have the appropriate file permissions to create the database design file and the database scripts in the intended locations.

To generate the database scripts for creating your database objects, you can run the database design tool in silent mode with the **-g** command-line parameter. In this mode, the tool requires input from a database design file that defines the configuration for your DB2 for z/OS database. The database design file must already exist before you generate the database scripts.

You can run the database design tool in interactive mode to generate a database design file. Follow the prompts in the tool to define a DB2 for z/OS database configuration for your stand-alone or network deployment topology.

While defining a DB2 for z/OS database configuration, you can specify how to group the SQL database scripts that you want to generate for the IBM Business Monitor components. The default setting is for the scripts to be generated in individual directories for each component. Before you run the database design tool, decide on a location for storing the files that the tool will generate.

It is important to use a directory path and structure that reflects how you want the database objects to be distributed across the DB2 for z/OS subsystem. For each database to be created, use a single output directory, and generate all the schema that is required to create the database, into that directory. As a reference aide, you can also base the name of the SQL directory on the name of the database that you plan to create.

For example, if you intend to create a single database called W1MYDB, you can generate the database scripts for all the database components in the single directory `WAS_HOME/profiles/default/dbscripts/DB2-zOS/W1MYDB`. If you require two databases, which are scoped at the cell level and the cluster level, you can structure the database schema as shown in the following example:

- To create a database called W8CELLDB, which contains database objects that are scoped at the cell level, generate the database scripts for the MONITOR database component in a directory such as `WAS_HOME/profiles/default/dbscripts/DB2-zOS/W8CELLDB`. You can later run the generated schema to create the database objects for the MONITOR database component in the W8CELLDB database. *
- To create a database called W8S1DB, which contains the database objects that are scoped at the cluster level, generate the database scripts for all the remaining IBM Business Monitor components in a directory such as `WAS_HOME/profiles/default/dbscripts/DB2-zOS/W8S1DB`. You can later run the generated schema to create the database objects for these components in the W8S1DB database.

1. If necessary, copy the database design file, which defines your DB2 for z/OS configuration, to the workstation where IBM Business Monitor is installed, to make the file available for use with the **DbDesignGenerator** command.

2. Change to the IBM Business Monitor directory where the **DbDesignGenerator** command is stored:

```
cd WAS_HOME/util/dbUtils
```

For example: `cd /WebSphere/V8T8DM/DeploymentManager/util/dbUtils`

3. Run the **DbDesignGenerator** command using the following syntax:

```
./DbDesignGenerator.sh -g db_design_file
```

where *db_design_file* is the fully qualified name of the database design file. For example:

```
./DbDesignGenerator.sh -g /WebSphere/V8T8DM/DeploymentManager/profiles/default/dbscripts/  
DB2-zOS/W8CELL.nd.dbDesign
```

4. Review the information that is displayed on the screen, checking that no error messages are displayed. For each database component, the database design tool writes information messages to the screen to indicate that the scripts were generated in the directory specified in the database design file. For example, for the MONITOR database component, you see information similar to the following example:

```
[info] The script(s) have been generated in  
/WebSphere/V8T8DM/DeploymentManager/profiles/default/dbscripts/DB2-zOS/W8CELLDB for MONITOR
```

After the last set of scripts is generated, you see information similar to the following example:

```
[info] thanks, quitting now ...
```

Tip: In the database design file, the directories for the SQL scripts are defined by the *ddl_outDir* variable in each component section. If you want to generate the SQL scripts to a set of different directories, a quick way to do this is to manually update the values of the *ddl_outDir* variables. Then save the database design file, and run the **DbDesignGenerator** command again, as described in step 3 on page 60.

The following files are created:

- The database scripts are created in one or more specified directories. Each of the directories also contains a `createDB2.sh` script, which you can later run together with the database scripts to create the DB2 for z/OS database objects.
- A log file named `dbDesignGenerator.log` is created in the directory from which you ran the **DbDesignGenerator** command.

Creating databases in the DB2 for z/OS subsystem

When you use the database design tool (**DbDesignGenerator**) to define your database configuration, you can generate the database scripts that are required for creating the databases for the IBM Business Monitor components.

You can use various tools to run these database scripts:

- When you run the database design tool to generate the database scripts, the **createDB2.sh** script is also generated. You can use **createDB2.sh** to run the database scripts.
- You can use tools such as the DB2 command line processor, SPUFI, or DSNTEP2 to run the database scripts.

Choosing which tool to use

You can choose one tool over another based on experience and familiarity, or personal preference. Your organization might also have implemented standards or conventions for the tools used to create DB2 for z/OS objects, particularly in a production environment.

Considerations for choosing the `createDB2.sh` script

- **createDB2.sh** can create all your database objects in one simple execution of the tool, so it is a good choice if this is your first server implementation.
- **createDB2.sh** runs the database scripts that the database design tool (**DbDesignGenerator**) generates.
- **createDB2.sh** runs the SQL for each component in the correct sequence.
- **createDB2.sh** creates database objects according to a naming convention that you define.
- **createDB2.sh** organizes the layout of database objects across DB2 for z/OS databases.
- **createDB2.sh** issues GRANT permissions to database, storage group, and buffer pool objects.
- **createDB2.sh** automatically completes customization of the service integration bus Data Definition Language (DDL).
- **createDB2.sh** runs in a UNIX System Services environment.

- **createDB2.sh** produces an audit trail of the objects that it creates.

Considerations for choosing other tools

- You might prefer to use the DB2 command line processor to run the SQL statements in the UNIX Systems Services environment. You must first run the **createDB2.sh** script in a mode that bypasses execution of the SQL statements and instead consolidates them into two `.sql` files. You can then run these files by using the command line processor.
- There is no restriction on the naming or organization conventions that apply to the database objects other than the standard database subsystem restrictions.
- Some tools can be run from a z/OS environment.
- The tools can produce an audit trail of the DB2 database commands that have been issued.

Setting up alias name definitions for connecting to the DB2 for z/OS server

Before you run the **createDB2.sh** script, you must configure the DB2 command line processor by defining a set of environment variables and a **db2** command alias. You must also define alias names that can be used to connect to the DB2 for z/OS server.

Ensure that a properties file, for example, `clp.properties`, exists for the DB2 command line processor. If required, you can create your own properties file by using the sample properties file that is available in the directory where the command line processor is installed. For more information, see your DB2 for z/OS documentation.

Complete the following configuration steps in the z/OS UNIX System Services environment from which the **createDB2.sh** script will be run:

1. Configure the DB2 command line processor for each user ID that will work with DB2 for z/OS from the command line. You can update the personal or shared user profiles as follows:
 - Modify the CLASSPATH environment variable to include the `clp.jar` file.
 - Use the CLPPROPERTIESFILE environment variable to define the fully qualified name of the properties file for the command line processor.
 - Define the **db2** command as an alias for the command that starts the command line processor.
 - Specify the `DB2JccConfiguration.properties` file that defines the JDBC properties to be applied to the command line processor.

You can use the following syntax to add the required entries to the `.profile` or `/etc/profile` file:

```
export CLPHOME=clp_install_dir
export CLASSPATH=$CLASSPATH:$CLPHOME/lib/clp.jar
export CLPPROPERTIESFILE=clp_properties_file_path
alias db2="java -Ddb2.jcc.propertiesFile=file_path/DB2JccConfiguration.properties com.ibm.db2.clp.db2"
```

For example:

```
export CLPHOME=/shared/db2910_base
export CLASSPATH=$CLASSPATH:$CLPHOME/lib/clp.jar
export CLPPROPERTIESFILE=/wasv8config/clp.properties
alias db2="java -Ddb2.jcc.propertiesFile=file_path/DB2JccConfiguration.properties com.ibm.db2.clp.db2"
```

2. In the properties file for the command line processor, define alias names that can be used to connect to the DB2 for z/OS server. An alias name definition includes the following entities:
 - A URL that specifies the domain name or IP address of the database server, the port on which the server listens, the DB2 location name defined during installation, and the property for the JDBC connection. The URL can take the form: `server:port/database property=value`. The port and property values are optional, and the DB2 location name must be specified in uppercase characters.

- A user ID and an associated password that can be used to connect to the DB2 server. This user ID should correspond to the user ID (with SYSADM authority) that the DB2 system administrator uses to run the **createDB2.sh** script.

You can add the required alias name entries to the properties file by using the following syntax:

```
DB2ALIASNAME=URL,user_ID,password
```

For example:

```
DSNXWBD=localhost:9446/DSNXWBD,SYSADM1,SYSPWRD1
```

Tip: When you define a *DB2ALIASNAME* value in the properties file, ensure that the correct connection details are specified to avoid connecting to the wrong database and inadvertently overwriting its contents.

3. Configure the DB2 DBACRVW subsystem parameter to enable user IDs with DBADM authority on a database to perform the following tasks for other user IDs: create views on tables in the database, create aliases for tables, and create materialized query tables. You can use the installation Command List (CLIST) to access the DSNTIPP ISPF panel and update the DBADM CREATE AUTH field to set DB2 ZPARM DBACRVW=YES.

Use the **createDB2.sh** script to either run the SQL to create the database objects for a specified database, or to consolidate the SQL statements into two .sql files that you can run later using other database tools.

Creating DB2 for z/OS database objects using the createDB2.sh script

After creating the database scripts for the IBM Business Monitor components, you can run the **createDB2.sh** script to create one or more databases in the DB2 for z/OS subsystem and populate each database with objects.

You can also use tools such as the DB2 command line processor, SPUFI, or DSNTPEP2 to create and populate databases.

- Decide on the DB2 for z/OS database design and configuration, including the number of databases required for the IBM Business Monitor components. For example, in a stand-alone server environment, you might decide to set up all the component databases in a single DB2 for z/OS database.
- Decide on a naming convention for the DB2 for z/OS objects, such as databases, storage groups, VSAM catalog names (VCATs), schema prefixes, buffer pools, and security IDs.
- Create the required buffer pools. For more information, see Sample DB2 commands and SQL.
- Run the database design tool (**DbDesignGenerator**) to generate the database scripts that can be used to create the database objects for the IBM Business Monitor components. Set up your database configuration so that the database design tool creates a single output directory for each database to be created, and generates all the relevant database scripts, including the **createDB2.sh** script, which are required to create the database, into that directory.
- Use FTP to transfer the database scripts, including the **createDB2.sh** script, to the z/OS system that contains the DB2 for z/OS installation. Transfer the **createDB2.sh** script as an ASCII text file, and transfer the database schema files in binary mode. Also ensure that you retain the directory structure when you transfer the files.
- Grant execute permissions to the **createDB2.sh** script.
- Create or augment the profile.
- Set up alias name definitions for connecting to the DB2 server.

The number of databases that you create for your IBM Business Monitor installation can depend on your topology, and how you want to distribute your database objects across the DB2 for z/OS subsystem. Provided that the database scripts are grouped appropriately in the output directories that were specified when you ran the database design tool, you can run the **createDB2.sh** script once for each instance of a database to be created. For example:

- To create a single database, you can run **createDB2.sh** once from a directory that contains all the database scripts that were generated for all the IBM Business Monitor components.
- To create multiple databases at the cell level and cluster levels, you can run **createDB2.sh** once from each directory that contains the database scripts required to create the database objects for the cell and clusters.

Important: It is anticipated that the DB2 for z/OS system administrator will run the **createDB2.sh** script with a user ID that has SYSADM authority, to create the databases and storage groups. On completion, the system administrator can then grant DBADM authority for the IBM Business Monitor databases to the WebSphere administrator.

Complete the following steps for each database that you want to create:

1. In the z/OS system that contains the DB2 installation, access the UNIX System Services command shell and then change to the directory to which you transferred the database scripts for the database objects to be created. For example:

```
cd /u/work/S4CELLDB
```

2. Run the **createDB2.sh** script by using the following syntax:

```
createDB2.sh -DBAlias alias_name -DBName database_name -DBSto storage_group_name -DBCreate  
-DBVCat volume_catalog -DBUser DB_user_ID -RunSQL
```

where:

-DBAlias

Specifies an alias name, which maps to the DB2 server URL, user ID, and password, and which is used to connect to DB2. If you do not specify this parameter when you run the **createDB2.sh** script, you are prompted for a value.

-DBName

Specifies the name of the database to be created.

-DBSto

Specifies the storage group name for the volumes that hold the data sets where tables and indexes are stored.

-DBCreate

Creates the database.

-DBVCat

Specifies the name of the DB2 Virtual Storage Access Method (VSAM) catalog that records information about the data sets.

-DBUser

Specifies the user ID of the WebSphere administrator that has database administration authority for the IBM Business Monitor database being created.

-RunSQL

Runs the SQL statements that create the database objects.

For example:

```
createDB2.sh -DBAlias DSNXWBD -DBName S4CELLDB -DBSto S4DBSTO -DBCreate -DBVCat DSNV10PP  
-DBUser S4ADMIN -RunSQL For information about all the parameters that are available for the  
createDB2.sh script and example usage, see createDB2.sh script.
```

3. Review the messages that are displayed in the console, checking that no error messages are displayed.

Tip: The first time that you run **createDB2.sh** to create the database, you see a few messages because the script first attempts to drop the database, which at that stage does not yet exist. These messages can be ignored, and subsequent invocations of **createDB2.sh** for the same database will not produce such messages.

When the script has finished running, you can also review the `z_output.txt` file, which provides an audit trail of the operations completed and status messages. This file is stored in the directory from which you ran the `createDB2.sh` script.

Each database is created and populated with the required database objects.

Creating DB2 for z/OS database objects using the DB2 command line processor

When you run the `createDB2.sh` script, you can choose to run the SQL immediately to create the database objects for the specified database, or you can bypass execution of the SQL scripts so that you can run them later. If you bypass execution of the SQL, the `createDB2.sh` script consolidates the SQL statements into two files (`z_schema.sql` and `z_schemaProc.sql`) that you can run later by using the DB2 command line processor.

You can also run these `.sql` files by using any other database tool of your choice, such as SPUIFI or DSNTEP2.

- Decide on the DB2 for z/OS database design and configuration, including the number of databases required for the IBM Business Monitor components. For example, in a stand-alone server environment, you might decide to set up all the component databases in a single DB2 for z/OS database.
- Decide on a naming convention for the DB2 for z/OS objects, such as databases, storage groups, VSAM catalog names (VCATs), schema prefixes, buffer pools, and security IDs.
- Create the required buffer pools. For more information, see Sample DB2 commands and SQL.
- Run the database design tool (**DbDesignGenerator**) to generate the database scripts that can be used to create the database objects for the IBM Business Monitor components. Set up your database configuration so that the database design tool creates a single output directory for each database to be created, and generates all the relevant database scripts, including the `createDB2.sh` script, which are required to create the database, into that directory.
- Use FTP to transfer the database scripts, including the `createDB2.sh` script, to the z/OS system that contains the DB2 for z/OS installation. Transfer the `createDB2.sh` script as an ASCII text file, and transfer the database schema files in binary mode. Also ensure that you retain the directory structure when you transfer the files.
- Grant execute permissions to the `createDB2.sh` script.
- Create or augment the profile.
- Set up alias name definitions for connecting to the DB2 server.

Provided that the database scripts are grouped appropriately in the output directories that were specified when you ran the database design tool, you can run the `createDB2.sh` script once for each instance of a database to be created.

Important: It is anticipated that the DB2 for z/OS system administrator will run the `createDB2.sh` script with a user ID that has SYSADM authority, to create the databases and storage groups. On completion, the system administrator can then grant DBADM authority for the IBM Business Monitor databases to the WebSphere administrator.

Complete the following steps for each database that you want to create:

1. In the z/OS system that contains the DB2 installation, access the UNIX System Services command shell and then change to the directory to which you transferred the database scripts for the database objects to be created. For example:

```
cd /u/work/S4CELLDB
```

2. Run the `createDB2.sh` script by using the following syntax:

```
createDB2.sh -DBAlias alias_name -DBName database_name -DBSto storage_group_name -DBCreate  
-DBVCat volume_catalog -DBUser DB_user_ID
```

where:

-DBAlias

Specifies an alias name, which maps to the DB2 server URL, user ID, and password, and which is used to connect to DB2. If you do not specify this parameter when you run the **createDB2.sh** script, you are prompted for a value.

-DBName

Specifies the name of the database to be created.

-DBSto

Specifies the storage group name for the volumes that hold the data sets where tables and indexes are stored.

-DBCcreate

Creates the database.

-DBVCat

Specifies the name of the DB2 Virtual Storage Access Method (VSAM) catalog that records information about the data sets.

-DBUser

Specifies the user ID of the WebSphere administrator that has database administration authority for the IBM Business Monitor database being created.

Tip: By omitting the **-RunSQL** parameter, you bypass the execution of the SQL statements that create the database objects, and instead consolidate the statements into two .sql files.

For example:

```
createDB2.sh -DBAlias DSNXWBD -DBName S4CELLDB -DBSto S4DBSTO -DBCcreate -DBVCat DSNV10PP -DBUser S4ADMIN
```

For information about all the parameters that are available for the **createDB2.sh** script and example usage, see createDB2.sh script.

The `z_schema.sql` and `z_schemaProc.sql` files, which hold the consolidated SQL statements, are generated in the directory from which you ran the **createDB2.sh** script. The `z_schemaProc.sql` file contains SQL statements for stored procedures, and is generated in addition to `z_schema.sql` because stored procedures require the “at” sign (@) as a statement termination character when running the command line processor.

3. Run the DB2 command line processor in batch mode to run the SQL in the `z_schema.sql` file:

```
db2 -f /createDB2.sh_path/z_schema.sql
```

For example:

```
db2 -f /u/work/S4CELLDB/z_schema.sql
```

The command line processor reads the data in the file, and processes the commands in the file consecutively.

4. Run the DB2 command line processor again to run the SQL in the `z_schemaProc.sql` file, and additionally use the **-td** parameter to define @ as the statement termination character:

```
db2 -td@ -f /createDB2.sh_path/z_schemaProc.sql
```

For example:

```
db2 -td@ -f /u/work/S4CELLDB/z_schemaProc.sql
```

Each database is created and populated with the required database objects.

Considerations for HADR setup and configuration

Review the following considerations while you plan to set up and configure DB2 for high availability disaster recovery (HADR).

- “Verify status of databases for takeover” on page 67
- “Configure data sources for HADR” on page 67

- “Set up programmatic transaction retry properties”
- “Specify user roles for HADR” on page 68
- “Start the messaging engine after the takeover” on page 68
- “Access additional information” on page 68

Verify status of databases for takeover

When a site failure occurs, HADR enables the standby database to take over as the primary database, with full DB2 functionality. Before the takeover occurs, verify the DB2 HADR status of both the primary database and the standby database to see if the takeover is allowed or if an error is returned. Sometimes, the takeover might cause an error or might not be allowed.

For more information, see the TAKEOVER HADR command topic. Review the command parameters and the usage notes to determine whether to perform the takeover.

Configure data sources for HADR

Configure the DB2 data sources for HADR in the IBM Business Manager admin console, as described in the Configuring client reroute for applications that use DB2 databases topic.

Keep in mind the following considerations when you configure the data sources for IBM Business Process Manager products:

- It is recommended to enable the automatic client reroute when setting up DB2 HADR.
- For messaging engine and cell level data sources, the *Alternate server names* and *Alternate port numbers* properties must be configured.
- The alternate port must be the external port for the DB2 server, not the HADR service port that is specified in `/etc/services`. For example, if the HADR service port `DB2_HADR_1`, specified in `/etc/services`, is 55001, and the DB2 server uses the external port 50000, you must specify port 50000 for the data source alternate port in the admin console.

Set up programmatic transaction retry properties

To support programmatic transaction retries, two new properties have been added to the `00static.xml` file, with the following values:

```
<transaction-reroute-retries>3</transaction-reroute-retries>
<transaction-reroute-retry-delay-in-millis>10000</transaction-reroute-retry-delay-in-millis>
```

Use the `100Custom.xml` configuration file to customize the changes in `00Static.xml` if values other than default are required. Complete the following steps:

1. Locate `100Custom.xml` configuration file:
 - For a network deployment environment, the file path is `<DMGR-profile-root>\config\cells\
<cell-name>\nodes\
<custom-node-name>\servers\
<server-name>\server_type\config\100Custom.xml`.
 - For a stand-alone server environment, the file path is: `<stand-alone-profile-root>\config\cells\
<cell-name>\nodes\
<stand-alone-node-name>\servers\
<server-name>\server_type\config\100Custom.xml`.

2. Edit the `100Custom.xml` file. Edit the following section to look like this example:

```
<server merge="mergeChildren">
  <transaction-reroute-retries merge="replace">10</transaction-reroute-retries>
  <transaction-reroute-retry-delay-in-millis
merge="replace">3000</transaction-reroute-retry-delay-in-millis>
</server>
```

3. Save your changes.

Provide all the client reroute properties for all your data sources.

Specify user roles for HADR

When setting up HADR, specify appropriate user roles per platform to determine who can perform different HADR tasks.

- For Windows, use the DB2 administrative user: `db2admin`
- For Linux, use the DB2 instance user, `db2inst1`, rather than the administrative user, `dasusr1`.

For example, if the DB2 instance user is specified, the `db2inst1` user backs up the primary database, copies the backup image to the standby server, and then restores or starts the standby server using this image. If the administrative user is specified, the `dasusr1` user is the owner of the copied image, which the `db2inst1` user who performs the backup and restore actions cannot access. Because the two users belong to different groups and have different access rights to files, the HADR setup might fail.

Start the messaging engine after the takeover

If the auto restart for the messaging engine is disabled, you must manually start the messaging engine after the database takeover occurs.

When two messaging engine servers exist in the same cluster, with messaging server 1 in an active state and messaging engine server 2 in a joined state, you might not have a running messaging engine server in your environment because of the following sequence of events:

1. The database that the messaging engines use has been taken over.
2. Messaging engine server 1 shut down to prevent data loss.
3. Messaging engine server 2 started all the messaging engines and is working as the active server while the messaging engine server 1 is still down.
4. Another takeover of the database occurred.
5. Messaging engine server 2 shut down to prevent data loss.
6. Both messaging engine servers 1 and 2 are down.

Access additional information

If more information is needed, use the following links.

- If an outage occurs in your DB2 HADR environment, see [Detecting and responding to system outages in a high availability solution](#).
- After the failover occurs, if the DB2 HADR status is not peer and if some data loss occurs, configure the DB2 HADR status to peer as described in the following topics:
 - [Performing an HADR failover operation](#)
 - [Reintegrating a database after a takeover operation](#)

Configuring Oracle Real Application Cluster (RAC) for use with IBM Business Monitor

Oracle Real Application Clusters (RAC) is an option of an Oracle database that brings together two or more computers to form a clustered database that behaves as a single system. In a RAC database, Oracle processes that are running in separate nodes access the same data from a shared disk storage.

When you create IBM Business Monitor profiles using Oracle, enter the host and port of one of the RAC servers and the service name of the RAC service for the database name.

Then, after the systems are running, complete the configuration steps to modify the WebSphere data sources that should connect to the Oracle RAC with the RAC service name.

Depending on the version of Oracle RAC you are using with IBM Business Monitor, you might have to complete some configuration steps.

- If you are using Oracle 11g R2 with the SCAN feature, IBM Business Monitor does not need additional manual configuration if you specify the service name during profile creation or topology configuration. `jdbc:oracle:thin:@//[SCAN_LISTENER_HOST]:SCAN_LISTENER_PORT]/SERVICE` is the format of the JDBC URL generated during configuration and will work for Oracle RAC without any manual updates.
- If you do not want to use the SCAN feature or are using an earlier version of Oracle that does not support the SCAN feature, you must follow the configuration steps in the procedure to configure IBM Business Monitor for use with Oracle RAC.

There are two scenarios to consider:

- If you are using a Standalone profile, you need to create the profile using SID as the value for the database name.
- If you are setting up a Network Deployment environment, the profiles and the clusters need to be configured using SID.

IBM Business Monitor always creates the JDBC URL in the following format:

```
jdbc:oracle:thin:@//[SCAN_LISTENER_HOST]:[SCAN_LISTENER_PORT]/SERVICE
```

You can edit that format for use with Oracle RAC:

```
jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=rac-node1)(PORT=1521))
(ADDRESS=(PROTOCOL=TCP)(HOST=rac-node2)(PORT=1521))
(FAILOVER=on)(LOAD_BALANCE=on)
(CONNECT_DATA=(SERVER=DEDICATED)
(SERVICE_NAME=service_name)))
```

Specify the RAC URL as the Oracle URL when defining the relevant Oracle JDBC data sources:

1. In the administrative console, select **Resources > JDBC > Data sources**.
2. Edit all of the data sources using Oracle with the JDBC URL to use one of the formats shown in “About this task”.

If you are using IBM Cognos BI, after the systems have been restarted and are functioning, the IBM Business Monitor cubes can be published. When the first cube is published, the **WBMONITOR_DB** data source is created in IBM Cognos BI using the Oracle RAC URL that is now being used by the WebSphere data source.

If the cubes were published before the change in the Oracle RAC URL, complete the following steps:

1. In IBM Cognos BI, use **IBM Cognos Administration** to remove the **WBMONITOR_DB** data source.
2. Republish the cubes to re-create the IBM Cognos BI connection using the Oracle RAC URL.

Configuring Oracle Data Guard for IBM Business Monitor

You can configure Oracle Data Guard to be used with IBM Business Monitor. Oracle Data Guard provides high availability, disaster recovery, and data protection and is used to create, manage, and monitor one or more standby databases so that production Oracle databases can survive disasters and data corruptions.

When IBM Business Monitor is configured to use Oracle Data Guard, you typically have one production database, which is your primary database, and several standby databases. Then Oracle Data Guard automatically maintains each standby database by transmitting redo data from the primary database and applying the redo data to the standby database. If your production database becomes unavailable because

of a planned or an unplanned outage, Oracle Data Guard enables you to switch any standby database to the production role, minimizing the downtime that is associated with the outage.

Oracle Data Guard automatically maintains each standby database by transmitting redo data from the primary database and then applying the redo to the standby database.

A Typical Data Guard Configuration

1. Set up the Oracle Data Guard environment.
2. Create a database service from the primary database:
3. Create a trigger from the primary database by running the following command:

```

Exec DBMS_SERVICE.CREATE_SERVICE('BPM', 'BPM');

CREATE OR REPLACE TRIGGER START_SERVICES AFTER STARTUP ON DATABASE
DECLARE
  ROLE VARCHAR(30);
BEGIN
  SELECT DATABASE_ROLE INTO ROLE FROM V$DATABASE;
  IF ROLE = 'PRIMARY' THEN
    DBMS_SERVICE.START_SERVICE('ORCL'); END IF;
END;
/
  
```

Note: When you start a database, your primary database always starts a BPM service. Therefore, your client always connects to the primary database.

4. Restart the primary database or start the following service by running the following command:
5. Install the IBM Business Monitor.
6. Create profiles or a deployment environment that is similar to that of an Oracle instance database. While creating the profile, select **Oracle database** and connect to the database service that you created in step 2.

If all your primary and the standby databases are installed on the same server, the databases share the same IP address and Oracle listening port. No further configuration is required.

However, if your primary and standby databases are installed on different servers, they will have different IP addresses and the same Oracle listening port. If your primary and standby databases are on separate servers, you must modify all data sources, after which you will have a JDBC URL that resembles the following URL:

To modify the JDBC URL:

1. Log in to the IBM Business Monitor administrative console.
2. Go to **Resources > JDBC > Data sources**.
3. Modify all data sources that connect to the Oracle database with the URLs that resemble the following URL:

```

jdbc:oracle:thin:@(DESCRIPTION=
  (ADDRESS_LIST=
    (ADDRESS=(PROTOCOL=TCP)(HOST=<host A>)(PORT=1521))
  )
  
```

```
(ADDRESS=(PROTOCOL=TCP)(HOST=<host B>)(PORT=1521))
(ADDRESS=(PROTOCOL=TCP)(HOST=<host C>)(PORT=1521))
  (LOAD_BALANCE=off)
  (FAILOVER=on)
)
  (CONNECT_DATA=(SERVICE_NAME=BPM))
)
```

Chapter 6. Creating and augmenting profiles

After you have installed IBM Business Monitor, create at least one profile to prepare your runtime environment. You can create and augment profiles either through the Profile Management Tool or through the **manageprofiles** command.

If you are using Solaris in 64-bit mode, the Profile Management Tool user interface is not available. You must use the **manageprofiles** command. If you are using z/OS, you cannot use either the command or the Profile Management Tool. See "Creating common configurations for IBM Business Monitor for z/OS" instead.

There are three types of profiles: a stand-alone server profile, a deployment manager profile (a management profile with a deployment manager server), and a custom profile (managed node). Each profile defines a separate runtime environment, with separate files (commands, configuration files, and log files).

Creating and augmenting profiles using the Profile Management Tool

The Profile Management Tool in the WebSphere Customization Toolbox lets you create or augment profiles to manage your runtime environment.

Restriction: If you are using Solaris in 64-bit mode, the Profile Management Tool user interface is not available. You must use the **manageprofiles** command. If you are using z/OS, see "Creating common configurations for IBM Business Monitor for z/OS."

Windows

Important: To install or run the Profile Management Tool on Windows 7, Windows Vista, or Windows Server 2008, you must elevate your Microsoft Windows user account privileges. Whether you are an administrative user or a non-administrative user, right-click the `pmt.bat` file and select **Run as administrator**. Alternatively, use the **runas** command at the command line. For example:

```
runas /user:ADMINNAME /env pmt.bat
```

Non-administrative users are prompted for the administrator password.

For a single-server environment, create a stand-alone profile.

For a network deployment environment, complete the following steps:

1. Create the deployment manager profile before creating the other profiles. If you created a deployment manager profile before installing IBM Business Monitor (for example, for WebSphere Application Server or Process Server) and you plan to use the same deployment manager profile to manage IBM Business Monitor nodes, augment the profile using the template that IBM Business Monitor provides.
2. Create a custom profile for each node that you plan to add to the server cluster. Alternatively, augment an existing custom profile for each node that you plan to add.

Note: If the database server contains multiple versions of DB2 installed, or multiple DB2 instances, the server's default DB2 version or instance is used for profile creation. To control which DB2 version or instance is used, use the "Installing databases manually" procedure so that the database administrator can ensure that the proper version or instance is used.

If you are using an Oracle database, JDBC support is provided by the Oracle JDBC drivers for JVM 1.6. The `ojdbc6.jar` JDBC driver file is the Oracle-supported JDBC driver for use with WebSphere Application

Server version 7. The `ojdbc6.jar` file can be used for both Oracle 10g and Oracle 11g. For information about minimum required settings for Oracle, see the related link.

By default, the Profile Management Tool points to the `ojdbc6.jar` file supplied in `app_server_root\jdbcdrivers\Oracle`. Alternatively, you can download another Oracle `ojdbc6.jar` JDBC driver file and point to it when you run the Profile Management Tool or the `manageprofiles` command.

If you are using an SQL Server database, the SQL Server JDBC drivers for JVM 1.6 provide JDBC support. IBM Business Monitor uses the Microsoft JDBC 2.0 driver `sqljdbc4.jar` file. By default, the Profile Management Tool points to the `sqljdbc4.jar` file supplied in `app_server_root\jdbcdrivers\SQLServer`. Alternatively, you can download another Microsoft `sqljdbc4.jar` JDBC driver file and point to it when you run the Profile Management Tool or the `manageprofiles` command. For information about minimum required settings for SQL Server, see the related link.

Creating stand-alone profiles

If you have not created the IBM Business Monitor profile during a single-server installation, you must create the profile. The profile will be created in the WebSphere Application Server profiles directory.

Before completing this task, you must perform the following tasks:

- Verified the hardware and software provided here:
- Installed IBM Business Monitor
- Logged in to the system as a user with appropriate permissions (read, write, and execute) on the profiles directory of WebSphere Application Server

Windows

Important: To install or run the Profile Management Tool on Windows 7, Windows Vista, or Windows Server 2008, you must elevate your Microsoft Windows user account privileges. Whether you are an administrative user or a non-administrative user, right-click the `pmt.bat` file and select **Run as administrator**. Alternatively, use the `runas` command at the command line. For example:

```
runas /user:ADMINNAME /env pmt.bat
```

Non-administrative users are prompted for the administrator password.

Complete the following steps to create a stand-alone application server profile using the Profile Management Tool:

1. Open the Profile Management Tool using one of the following methods:
 - From the IBM Business Monitor First Steps console, click **Profile Management Tool**.
 -  Click **Start > Programs > IBM > Business Monitor 8.0 > Profile Management Tool**.
 -  Run `pmt.bat`, which is in the following directory: `app_server_root\bin\ProfileManagement`
 -   Change to the `app_server_root/bin/ProfileManagement` directory and type `./pmt.sh` in a terminal window.
2. On the Welcome to the Profile Management Tool panel, review the information, and click **Launch Profile Management Tool**.
3. On the Profiles panel, click **Create** to create a new profile.
4. On the Environment Selection panel, expand IBM Business Monitor, click **Stand-alone monitor server**, and click **Next**.

Restriction: If you cannot see the IBM Business Monitor option, it might indicate that you are using Solaris in 64-bit mode. In that case, you cannot use the Profile Management Tool and must use the `manageprofiles` command.

5. On the Profile Creations Options panel, select the type of installation you want to perform and click **Next**.
 - **Typical profile creation** (default): Creates the IBM Business Monitor profile that uses default configuration settings. The Profile Management Tool assigns unique names to the profile, node, and cell. The tool also installs the administrative console, installs default applications, and assigns unique port values. You can choose to enable administrative security during the configuration. Depending on the operating system and your user permissions, the tool might create a system service to run IBM Business Monitor.
 - **Advanced profile creation**: Creates the IBM Business Monitor profile using default configuration settings, or you can select your own IBM Business Monitor components. You can assign your own port values. You can choose to deploy the administrative console, deploy sample applications, and create a web server definition. Depending on the operating system and your user permissions, you might choose to run IBM Business Monitor as a system service. You can determine the IBM Business Monitor model configuration. You can specify a database design file or assign your own values for the IBM Business Monitor database configuration. . You can choose the IBM Cognos BI configuration for multidimensional data analysis.
6. If you selected **Typical profile creation**, skip to Step 11: Administrative Security panel.
7. Advanced: On the Optional Application Deployment panel, select **Deploy the administrative console** and **Deploy the default application**. The default application is a WebSphere Application Server application. Click **Next**.
8. Advanced: On the Profile Name and Location panel, accept the default name and location, or specify a profile name and directory path to contain the files for the runtime environment, such as commands, configuration files, and log files. The default profile name is **WBMon01**. On Windows, a typical profile directory is C:\IBM\WebSphere\AppServer\profiles\WBMon01.
9. Advanced: If you want to use the profile you are creating as the default profile, select **Make this profile the default**. Click **Next**.
10. Advanced: Set a performance tuning level appropriate for the profile you are creating. This parameter is a WebSphere Application Server parameter. For more information, see Tuning the application server using pre-defined tuning templates in the WebSphere Application Server information center.
11. Advanced: On the Node and Host Names panel, enter new values or accept the default values, and click **Next**.
 - The node name is used for administration. If the node is federated, the node name must be unique within the cell.
 - The server name is a logical name for the IBM Business Monitor server.
 - The host name is the domain name system (DNS) name (short or long) or the IP address of this computer.
 - The cell name is a logical name for the group of nodes administered by this deployment manager.
12. On the Administrative Security panel, select one of the following options and click **Next**.
 - To enable security, select the **Enable administrative security** check box and enter the user name and password information.
 - To disable security, clear the **Enable administrative security** check box.

For information about whether to enable security, see Administrative security in the WebSphere Application Server information center.

If you selected **Typical profile creation**, skip to Step 21: Database Configuration panel.

13. Advanced: On the Security Certificate (Part 1) panel, choose whether to create a default personal certificate and root signing certificate, or import them from keystores. To create new certificates, click **Next** to proceed to the verification page. To import existing certificates from keystores, browse to the certificates and then click **Next** to proceed to the verification page.
14. Advanced: On the Security Certificate (Part 2) panel, modify the certificate information to create new certificates during profile creation. If you are importing existing certificates from keystores, use the

information to verify that the selected certificates contain the appropriate information. If the selected certificates do not, click **Back** to import different certificates. You should change the default keystore password to protect the security of the keystore files and SSL certificates. For more information about securing communications between a server and a client, see Securing communications in the WebSphere Application Server information center.

15. Advanced: On the Port Values Assignment panel, review the ports that will be assigned during profile creation. You might want to keep track of these port values. Accept the given values or specify alternate port numbers and click **Next**.
16.  Advanced: On Windows systems, the Windows Service Definition panel is displayed. The option to **Run the Application Server process as a Windows service** is enabled by default and is configured to use local system account information to log on. Accept the default Windows service settings or disable the option, and click **Next**. To change the Windows service log on information, select the **Log on as specified user account** option and enter the user name and password for the alternate account.

The Windows service **Startup type** is set to **Automatic** by default. You can optionally change the **Startup type** to **Manual** or **Disabled** using the list.

Because services are global settings on Windows operating systems, any profile could start the service and as a result, you could lose track of which profile issued, for example, a “startServer” command. To avoid potential service request conflicts between different profiles, disable the **Run the Application Server process as a Windows service** option.

17. Advanced: On the Web Server Definition panel, select one of the following options:
 - If you want to create a web server definition, enable the **Create a Web server definition** option. Accept the subsequent web server information that is provided or make modifications as needed.

Web server type

Options include IBM HTTP Server, Microsoft Internet Information Services, Sun Java™ System, Lotus® Domino® Web Server, and Apache Web Server.

Web server operating system

Options include Windows, AIX, Solaris, and z/OS.

Web server name

Enter a name for the web server. The default name is "webserv1".

Web server host name or IP address

Enter the host name or IP address of the web server. The local host name appears by default.

Web server port (Default 80)

Enter the web server port number or accept the default (80).

- If you do not want to create a web server definition, clear the **Create a web server definition** check box.

Web server definitions define an external web server to WebSphere Application Server, enabling you to manage web server plug-in configuration files for the web server and in some cases to manage the web server. If you have not installed a web server or want to do this step later, you can easily do this step from the administrative console.

18. Advanced: If you chose to create a web server definition on the previous panel, enter a path for the web server installation directory and for the web server plug-in installation directory on the web Server Definition (Part 2) panel.
19. Advanced: On the IBM Business Process Manager Monitor Models panel, select **Deploy IBM Business Monitor global process monitor model** to install and configure the global process monitor model application. This model enables you to monitor BPEL or BPMN processes running on IBM Business Process Manager without generating and deploying monitor models.
20. Optional: Advanced: Configure the databases using a design file.

- a. Select **Use a database design file for database configuration** if you would like to use a design file instead of specifying the database parameters in the following panels.
- b. Click **Browse**.
- c. Specify the fully qualified path name for the design file.
- d. Click **Next**.
- e. Select **Delay execution of database scripts (must select if using a remote database)** if you do not want to create and configure local databases automatically or create tables in existing databases during profile creation. Local databases are created if this check box is not selected. If you select this option, you or the database administrator must manually run the scripts that are stored in the location specified in the database script output directory field on this page. If you create the scripts for Oracle, you must replace @DB_PASSWORD@ with the password for the schema name before running them.

Note: If the database server contains multiple versions of DB2 installed, or multiple DB2 instances, the server's default DB2 version or instance is used for profile creation. To control which DB2 version or instance is used, use the "Installing databases manually" procedure so that the database administrator can ensure that the proper version or instance is used.

If you choose to specify a design file, the database configuration panels in the Profile Management Tool are skipped. Instead, the design file location is passed to the command line to complete the database configuration. For more information on using a design file for database configuration, see "Creating or configuring database scripts using the database design tool."

21. On the Database Configuration panel, verify your MONITOR database configuration information:
 - a. For **Database product**, select your database from the list.
 - b. Select **Delay execution of database scripts (must select if using a remote database)** if you do not want to create and configure local databases automatically or create tables in existing databases during profile creation. Local databases are created if this check box is not selected. If you select this option, you or the database administrator must manually run the scripts that are stored in the location specified in the database script output directory field on this page. If you create the scripts for Oracle, you must replace @DB_PASSWORD@ with the password for the schema name before running them.

Note: If the database server contains multiple versions of DB2 installed, or multiple DB2 instances, the server's default DB2 version or instance is used for profile creation. To control which DB2 version or instance is used, use the "Installing databases manually" procedure so that the database administrator can ensure that the proper version or instance is used.

- c. In the **Database name** field, enter the database name or accept the default (MONITOR).
 - d. In the **Schema name** field, enter the schema name or accept the default (MONITOR). If you are using DB2 on z/OS, the IBM Business Monitor database schema name must be different from the Process Server common database schema name to prevent collisions between database objects.
 - e. Click **Next**.
22. Complete the following steps on the Database Configuration (Part 2) panel. The options will vary depending on what database product you selected on the previous panel:
 - a. Type *user_name* for the **User name** to authenticate with the database. This value represents an existing user ID with read and write permissions to MONITOR tables.

Note: If you are using an Oracle database, this field is not editable.

- b. Type *password* for the **Password** for database authentication. This value represents the password for the specified database user ID.
 - c. Type *password* in the **Confirm password** field. This value must match the value for **Password**.
 - d. Browse to or enter a path for the JDBC driver classpath files. The JDBC drivers for DB2, Oracle, and SQL Server are in **monitor_root/jdbcdrivers**. The default JDBC driver classpath is set to use

the product-specific files within this directory based on the database type that you selected on the Database Configuration panel. Alternatively, click **Browse** to enter a path to the JDBC driver classpath files.

- DB2 database: The following directory is created by default:

`monitor_root/jdbcdrivers/DB2`

- Oracle database: The following directory is created by default:

`monitor_root/jdbcdrivers/Oracle`

The `ojdbc6.jar` JDBC driver file is the Oracle-supported JDBC driver for use with WebSphere Application Server version 7. The `ojdbc6.jar` file can be used for both Oracle 10g and Oracle 11g. For information about minimum required settings for Oracle, see the related link.

- SQL Server database: The following directory is created by default:

`monitor_root/jdbcdrivers/SQLServer`

The `sqljdbc4.jar` JDBC driver file is the Microsoft SQL Server 2.0 JDBC driver. For information about minimum required settings for SQL Server, see the related link.

- e. Select one of the following options for the JDBC driver type:

- For Oracle databases:

- **OCI**: The OCI driver requires a local Oracle client installation.
- **Thin**: The Thin driver uses Java to communicate with the database and does not require a client on the local system.

- For DB2 databases, profiles of IBM Business Monitor on operating systems other than z/OS are created with type 4 drivers, and profiles on z/OS are created with type 2 drivers. You can change the type after profile creation by editing the data source properties in the administrative console. A type 2 driver is a native-API driver and requires the installation of database software or a database client on the local system. A type 4 driver is a pure-Java implementation and typically provides the best performance. For the MONITOR database, no database software or clients are required on the local system.

- f. Type *host_name* for the **Database server host name or IP address**. The default value is **localhost** or the fully qualified local host name if defined, and you should use this value for a single-server installation. If your database is on a remote server, you must type the fully qualified host name or IP address.

Note: Except for a single-server installation, do *not* use the value `localhost` since the cluster members depend on the actual host name or IP address.

- g. Type *port_number* for the **Database TCP/IP service port or listener port**. This value represents the port where the TCP/IP service is assigned or the port on which the database is listening.

- h. Optional: If you are using a DB2 on z/OS database, type *subsystem_name* for the **Subsystem name**. This value is the location of the DB2 for z/OS database. No spaces are allowed in the name.

- i. If you are using Oracle or SQL Server and you chose to create the database automatically, enter the following information:

- *system_user_name* for the **Database administrator user name**. This value is the name of the database administrator for Oracle or SQL Server. This user must have access to create and drop databases and users.
- *password* for the **Password**. This value is the password for the system administrator that is specified in the previous field.
- *password* in the **Confirm password** field.

- j. Click **Next**. If the MONITOR database has not yet been created, you will see a warning message. Click **Yes** to continue. You can create the database at a later time.

23. On the IBM Cognos BI Configuration panel, configure IBM Cognos BI for multidimensional data analysis from your dashboards.
 - To deploy IBM Cognos BI, click **Create a new Cognos server configuration** and provide the name of a database to be used for the IBM Cognos BI content store. The default name is COGNOSCS. On Oracle, the database name is the Oracle service name. On Microsoft SQL Server, the database name must be different from the MONITOR database name.

Provide a database user name and password. If you use the same user name for the content store as for the MONITOR database, you must use the same password. Because the database user provided for accessing the content store database must have privilege to create tables in the database, it is recommended that you create a new database user for the content store database only.

You must also provide the IBM Cognos BI administrator user name and password.

Note: The user name and password for the IBM Cognos BI content store database are kept in the Cognos_JDBC_Alias, which allows all database credentials to be maintained in one place. Whenever you start the IBM Business Monitor IBM Cognos BI server, the current values are passed to the IBM Cognos BI configuration to allow IBM Cognos BI access to the content store. Because of this integration, you cannot change the content store user name and password using the IBM Cognos BI Configuration application.

- If you want to use an existing version of IBM Cognos BI, click **Use an existing Cognos server configuration** and provide the following information.
 - **External Dispatcher URI:** The external dispatcher URI of the IBM Cognos BI server. You can find this URI in the IBM Cognos BI configuration client in **Local Configuration > Environment > Dispatcher Settings**. Use the value provided for the **External dispatcher URI**, for example, `http://my_host:my_port/p2pd/servlet/dispatch/ext`.
 - **Cognos administrator user name:** The IBM Cognos BI administrator user name if administrative security is enabled on the IBM Cognos BI server.
 - **Cognos administrator password:** The IBM Cognos BI administrator password if administrative security is enabled on the IBM Cognos BI server. Also, enter this password in the **Confirm Cognos administrator password** text box.

The IBM Cognos BI server does not have to be available to set this value. The server is required when you install monitor models if you want to perform multidimensional analysis for those models. To view the IBM Cognos BI configuration client, from the Start menu, click **Programs > IBM Cognos > IBM Cognos Configuration**.

24. On the Profile Creation Summary panel, review the information. If you need to make any modifications, click **Back** and make changes as necessary.
25. Click **Create** to create the profile.
26. On the Profile Creation Complete panel, review the information about the completed profile creation.
27. Optional: Access First Steps.
 -  Select the **Launch the IBM Business Monitor first steps** option.
 -   Go to `profile_root/firststeps.wbm` and run the `firststeps.sh` command.
28. Click **Finish** to exit the Profile Management Tool.

During profile creation, you set port values for all required ports. If you decide to change the ports after installation, you must reconfigure all port values for IBM Business Monitor to work properly.

If you plan to use the server to develop, test, and debug monitor models, you can use the IBM Business Monitor debugger application by installing the `com.ibm.wbimonitor.debug.server.application.ear` and `com.ibm.wbimonitor.ice.machine.application.ear` files from `Application_Server_Root/installableApps.wbm/debugger`.

Note: The debugger is already installed if the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_create.log` file or the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_augment.log` file contains the `isDeveloperServer` parameter.

Augmenting stand-alone profiles

You can use the Profile Management Tool to augment stand-alone profiles for IBM Business Monitor. If you plan to use the server to develop, test, and debug monitor models, you must install the monitor model debugger.

Understand the concepts of profiles, including the differences between stand-alone, network deployment and custom profiles. Understand the differences between the Typical profile augmentation option and the Advanced profile augmentation option, including under which scenarios you should use one over the other. The Typical profile augmentation option augments a profile with default configuration settings. The Advanced profile augmentation option lets you specify your own configuration values for the profile you are augmenting.

- Review the full list of prerequisites for creating or augmenting a profile at Profile concepts in the WebSphere Application Server information center.
- When you use the Profile Management Tool with the Motif graphical user interface on the Solaris operating system, the default size of the Profile Management Tool might be too small to view all the messages and buttons.
- If you plan to use a database design file for the Business Monitor database information, complete the steps in Chapter 5, “Creating the databases,” on page 51.

Use this procedure if you are augmenting a Business Monitor profile for a stand-alone configuration. The steps describe both Advanced profile creation and Typical profile creation options.

If Business Monitor is augmented as part of your product profile, this task is optional.

1. Start the Profile Management Tool.

Use one of the following commands:

-   `install_root/bin/ProfileManagement/pmt.sh`
-  `install_root\bin\ProfileManagement\pmt.bat`

The Welcome page opens.

2. On the Welcome page, click **Launch Profile Management Tool** or select the Profile Management Tool tab.

The Profiles tab opens.

The Profiles tab contains a list of profiles on your machine currently. For this procedure, it is assumed you are augmenting an existing application server profile with Business Monitor in a stand-alone configuration.

3. Select the profile that you want to augment, and click **Augment**. The **Augment** button cannot be selected unless a profile can be augmented.

The Augment Selection page opens in a separate window.

4. On the Augment Selection page, if the profile can be augmented to Business Monitor, the **Stand-alone Monitor server** option is available. Select the option and click **Next**.

5. On the Profile Augmentation Option page, decide whether to augment the stand-alone profile using the **Typical profile augmentation** or **Advanced profile augmentation** option.

The Typical profile augmentation option augments a profile with default configuration settings. The Advanced profile augmentation option lets you specify your own configuration values for the profile you are augmenting.

6. If you selected the **Typical profile augmentation** option, complete the following steps.

- a. On the Administrative Security page, re-enter the administrative user ID and password for the profile you are augmenting, and click **Next**.
- b. On the Database Configuration page, update the database details and click **Next**.
- c. On the Database Configuration (Part 2) page, specify the login details for the database and click **Next**.
- d. On the Cognos Configuration page, specify the information for the new or existing Cognos server and click **Next**.
- e. On the Profile Augmentation Summary page, click **Augment** to augment the profile or **Back** to change the characteristics of the profile.

The progress of the augmentation is displayed in the Profile Configuration Progress window. When the profile augmentation is complete, the Profile Augmentation Complete page is displayed with the message **The Profile Management tool augmented the profile successfully**.

Attention: If errors are detected during profile augmentation, other messages might appear in place of the success message, for example:

- **The Profile Management tool augmented the profile but errors occurred**, which indicates that profile augmentation completed but errors were generated.
- **The Profile Management tool cannot augment the profile**, which indicates that profile augmentation failed completely.

The Profile Augmentation Complete page identifies the log file to reference in order to troubleshoot the problems.

7. If you selected the **Advanced profile augmentation** option, complete the following steps.
 - a. On the Administrative Security page, re-enter the administrative user ID and password for the profile you are augmenting.
 - b. On the IBM Business Process Manager Monitor Model page, click **Next**.
 - c. If you want to use a design file that you have already created to configure the databases for the augmented profile, complete the following steps instead of using the Database Configuration pages.
 - 1) Select **Use a database design file** for database configuration.
 - 2) Click **Browse**.
 - 3) Specify the fully qualified path name for the design file.
 - 4) Click **Next**.
 - d. If you haven't used a database design file, on the Database Configuration page, perform the following actions:
 - 1) From the Select a database product list, select the database product to be used by the profile.
 - 2) Select the **Override the default output directory for database scripts** check box if you want to set the directory into which the sql scripts used to create the database tables are written. If you do not select the check box, the scripts are output to the default directory.
 - 3) Click **Next** to display the Database Configuration (Part 2) page.

The information on the Database Configuration (Part 2) page varies depending on the value specified from the Select a database product list on the Database Configuration page.
 - e. On the Database Configuration (Part 2) page, complete the database configuration. Depending on your database product, you must specify a user name and password to authenticate with the database, the JDBC driver information, and host, port, and schema.
 - f. On the Cognos Configuration page, specify the information for the new or existing Cognos server and click **Next**.
 - g. On the Profile Augmentation Summary page, click **Augment** to augment the profile or **Back** to change the characteristics of the profile.

The progress of the augmentation is displayed in the Profile Configuration Progress window. When the profile augmentation is complete, the Profile Augmentation Complete page is displayed with the message **The Profile Management tool augmented the profile successfully**.

Attention: If errors are detected during profile augmentation, other messages might appear in place of the success message, for example:

- **The Profile Management tool augmented the profile but errors occurred**, which indicates that profile augmentation completed but errors were generated.
- **The Profile Management tool cannot augment the profile**, which indicates that profile augmentation failed completely.

The Profile Augmentation Complete page identifies the log file to reference in order to troubleshoot the problems.

If you plan to use the server to develop, test, and debug monitor models, you can use the IBM Business Monitor debugger application by installing the `com.ibm.wbimonitor.debug.server.application.ear` and `com.ibm.wbimonitor.ice.machine.application.ear` files from `Application_Server_Root/installableApps.wbm/debugger`.

Note: The debugger is already installed if the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_create.log` file or the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_augment.log` file contains the `isDeveloperServer` parameter.

Creating deployment manager profiles

You must have a deployment manager profile to manage all federated servers in a cluster. If you are setting up a network deployment environment, create this profile first.

Before completing this task, you must complete the following tasks:

- Verified that all hardware and software prerequisites have been met
- Installed IBM Business Monitor
- Logged in to the system as a user with appropriate permissions (read, write, and execute) on the profiles directory of WebSphere Application Server
- Installed the database

Windows

Important: To install or run the Profile Management Tool on Windows 7, Windows Vista, or Windows Server 2008, you must elevate your Microsoft Windows user account privileges. Whether you are an administrative user or a non-administrative user, right-click the `pmt.bat` file and select **Run as administrator**. Alternatively, use the `runas` command at the command line. For example:

```
runas /user:ADMINNAME /env pmt.bat
```

Non-administrative users are prompted for the administrator password.

Complete the following steps to create a deployment manager profile using the Profile Management Tool:

1. Open the Profile Management Tool using one of the following methods:
 - From the IBM Business Monitor First Steps console, click **Profile Management Tool**.
 - Windows Click **Start > Programs > IBM > Business Monitor 8.0 > Profile Management Tool**.
 - Windows Run `pmt.bat`, which is in the following directory: `app_server_root\bin\ProfileManagement`
 - Linux Change to the `app_server_root/bin/ProfileManagement` directory and type `./pmt.sh` in a terminal window.

2. On the Welcome to the Profile Management Tool panel, review the information, and click **Launch Profile Management Tool**.
3. On the Profiles panel, click **Create** to create a new profile.
4. On the Environment Selection panel, expand IBM Business Monitor, click **Monitor server deployment manager**, and click **Next**.

Restriction: If you cannot see the IBM Business Monitor option, it might indicate that you are using Solaris in 64-bit mode. In that case, you cannot use the Profile Management Tool and must use the **manageprofiles** command.

5. On the Profile Creations Options panel, select the type of installation you want to perform and click **Next**.
 - **Typical profile creation** (default): Creates a deployment manager profile that uses default configuration settings. The Profile Management Tool assigns unique names to the profile, node, host, and cell. The tool also installs the administrative console and assigns unique port values. You can choose to enable administrative security during the configuration. Depending on the operating system and your user permissions, the tool might create a system service to run the deployment manager. You can specify your own values for the IBM Business Monitor database configuration.
 - **Advanced profile creation:** Creates a deployment manager using default configuration settings. You can specify the values for host and cell, assign your own port values, and choose whether to deploy the administrative console. Depending on the operating system and your user permissions, you might have the option to run the deployment manager as a system service. You can specify a database design file or assign your own values for the IBM Business Monitor database configuration.
6. If you selected **Typical profile creation**, skip to Step 10: Administrative Security panel.
7. Advanced: On the Optional Application Deployment panel, select **Deploy the administrative console**, and click **Next**.
8. Advanced: On the Profile Name and Location panel, accept the default name and location, or specify a profile name and directory path to contain the files for the runtime environment, such as commands, configuration files, and log files. The default profile name is **Dmgr01**. On Windows, a typical profile directory is C:\IBM\WebSphere\AppServer\profiles\Dmgr01.
9. Advanced: If you want to use the profile you are creating as the default profile, select **Make this profile the default**. Click **Next**.
10. Advanced: On the Node, Host, and Cell Names panel, enter new values or accept the default values, and click **Next**.
 - The node name is used for administration. If the node is federated, the node name must be unique within the cell.
 - The host name is the domain name system (DNS) name (short or long) or the IP address of this computer.
 - The cell name is a logical name for the group of nodes administered by this deployment manager.
11. On the Administrative Security panel, select one of the following options and click **Next**.
 - To enable security, select the **Enable administrative security** check box and enter the user name and password information.
 - To disable security, clear the **Enable administrative security** check box.

For information about whether to enable security, see Administrative security in the WebSphere Application Server information center.

If you selected **Typical profile creation**, skip to Step 16: Database Configuration panel.

12. Advanced: On the Security Certificate (Part 1) panel, choose whether to create a default personal certificate and root signing certificate, or import them from keystores. To create new certificates, click **Next** to proceed to the verification page. To import existing certificates from keystores, browse to the certificates and then click **Next** to proceed to the verification page.

13. Advanced: On the Security Certificate (Part 2) panel, modify the certificate information to create new certificates during profile creation. If you are importing existing certificates from keystores, use the information to verify that the selected certificates contain the appropriate information. If the selected certificates do not, click **Back** to import different certificates. You should change the default keystore password to protect the security of the keystore files and SSL certificates. For more information about securing communications between a server and a client, see Securing communications in the WebSphere Application Server information center.
14. Advanced: On the Port Values Assignment panel, review the ports that will be assigned during profile creation. You might want to keep track of these port values. Accept the given values or specify alternate port numbers and click **Next**.
15.  Advanced: On Windows systems, the Windows Service Definition panel is displayed. The option to **Run the Application Server process as a Windows service** is enabled by default and is configured to use local system account information to log on. Accept the default Windows service settings or disable the option, and click **Next**. To change the Windows service log on information, select the **Log on as specified user account** option and enter the user name and password for the alternate account.

The Windows service **Startup type** is set to **Automatic** by default. You can optionally change the **Startup type** to **Manual** or **Disabled** using the list.

Because services are global settings on Windows operating systems, any profile could start the service and as a result, you could lose track of which profile issued, for example, a "startServer" command. To avoid potential service request conflicts between different profiles, disable the **Run the Application Server process as a Windows service** option.

16. Optional: Advanced: Configure the databases using a design file.
 - a. Select **Use a database design file for database configuration** if you would like to use a design file instead of specifying the database parameters in the following panels.
 - b. Click **Browse**.
 - c. Specify the fully qualified path name for the design file.
 - d. Click **Next**.
 - e. Select **Delay execution of database scripts (must select if using a remote database)** if you do not want to create and configure local databases automatically or create tables in existing databases during profile creation. Local databases are created if this check box is not selected. If you select this option, you or the database administrator must manually run the scripts that are stored in the location specified in the database script output directory field on this page. If you create the scripts for Oracle, you must replace @DB_PASSWORD@ with the password for the schema name before running them.

Note: If the database server contains multiple versions of DB2 installed, or multiple DB2 instances, the server's default DB2 version or instance is used for profile creation. To control which DB2 version or instance is used, use the "Installing databases manually" procedure so that the database administrator can ensure that the proper version or instance is used.

If you choose to specify a design file, the database configuration panels in the Profile Management Tool are skipped. Instead, the design file location is passed to the command line to complete the database configuration. For more information on using a design file for database configuration, see "Creating or configuring database scripts using the database design tool."

17. On the Database Configuration panel, verify your MONITOR database configuration information:
 - a. Select your database product from the list.
 - b. Select **Delay execution of database scripts (must select if using a remote database)** if you do not want to create and configure a local database automatically or create tables in an existing one during profile creation or augmentation. A local database will be created if this check box is not selected. If you select this option, you or the database administrator must manually run the scripts that are stored in the location specified in the database script output directory field on this

page. If you create the scripts for Oracle, you must replace @DB_PASSWORD@ with the password for the schema name before running them.

Note: If the database server contains multiple versions of DB2 installed, or multiple DB2 instances, the server's default DB2 version or instance is used for profile creation. To control which DB2 version or instance is used, use the "Installing databases manually" procedure so that the database administrator can ensure that the proper version or instance is used.

- c. In the **Database name** field, enter the database name or accept the default (MONITOR).
 - d. In the **Schema name** field, enter the schema name or accept the default (MONITOR). If you are using DB2 on z/OS, the IBM Business Monitor database schema name must be different from the Process Server common database schema name to prevent collisions between database objects.
 - e. Click **Next**.
18. Complete the following steps for the MONITOR database on the Database Configuration (Part 2) panel. The options will vary depending on what database product you selected on the previous panel:
- a. Type *user_name* for the **User name** to authenticate with the database. This value represents an existing user ID with read and write permissions to MONITOR tables.

Note: If you are using an Oracle database, this field is not editable.

- b. Type *password* for the **Password** for database authentication. This value represents the password for the specified database user ID.
- c. Type *password* in the **Confirm password** field. This value must match the value for **Password**.
- d. Browse to or enter a path for the JDBC driver classpath files. The JDBC drivers for DB2, Oracle, and SQL Server are in **monitor_root/jdbcdrivers**. The default JDBC driver classpath is set to use the product-specific files within this directory based on the database type that you selected on the Database Configuration panel. Alternatively, click **Browse** to enter a path to the JDBC driver classpath files.
 - DB2 database: The following directory is created by default:
monitor_root/jdbcdrivers/DB2
 - Oracle database: The following directory is created by default:
monitor_root/jdbcdrivers/Oracle

The ojdbc6.jar JDBC driver file is the Oracle-supported JDBC driver for use with WebSphere Application Server version 7. The ojdbc6.jar file can be used for both Oracle 10g and Oracle 11g. For information about minimum required settings for Oracle, see the related link.

- SQL Server database: The following directory is created by default:
monitor_root/jdbcdrivers/SQLServer

The sqljdbc4.jar JDBC driver file is the Microsoft SQL Server 2.0 JDBC driver. For information about minimum required settings for SQL Server, see the related link.

- e. Select one of the following options for the JDBC driver type:
 - For Oracle databases:
 - **OCI:** The OCI driver requires a local Oracle client installation.
 - **Thin:** The Thin driver uses Java to communicate with the database and does not require a client on the local system.
 - For DB2 databases, profiles of IBM Business Monitor on operating systems other than z/OS are created with type 4 drivers, and profiles on z/OS are created with type 2 drivers. You can change the type after profile creation by editing the data source properties in the administrative console. A type 2 driver is a native-API driver and requires the installation of database software or a database client on the local system. A type 4 driver is a pure-Java

implementation and typically provides the best performance. For the MONITOR database, no database software or clients are required on the local system.

- f. Type *host_name* for the **Database server host name or IP address**. The default value is **localhost** or the fully qualified local host name if defined, and you should use this value for a single-server installation. If your database is on a remote server, you must type the fully qualified host name or IP address.

Note: Except for a single-server installation, do *not* use the value `localhost` since the cluster members depend on the actual host name or IP address.

- g. Type *port_number* for the **Database TCP/IP service port or listener port**. This value represents the port where the TCP/IP service is assigned or the port on which the database is listening.
- h. Optional: If you are using a DB2 on z/OS database, type *subsystem_name* for the **Subsystem name**. This value is the location of the DB2 for z/OS database. No spaces are allowed in the name.
- i. If you are using Oracle or SQL Server and you chose to create the database automatically, enter the following information:
 - *system_user_name* for the **Database administrator user name**. This value is the name of the database administrator for Oracle or SQL Server. This user must have access to create and drop databases and users.
 - *password* for the **Password**. This value is the password for the system administrator that is specified in the previous field.
 - *password* in the **Confirm password** field.
- j. Click **Next**. If the MONITOR database has not yet been created, you will see a warning message. Click **Yes** to continue. You can create the database at a later time.

19. On the Cognos Content Store Database panel, if you do not already have an existing IBM Cognos Business Intelligence installation that you plan to use, enter the information to create the IBM Cognos BI content store database for multidimensional data analysis from your dashboards.
 - a. Click **Create a new Cognos content store database**.
 - b. Provide the name of a database to be used for the IBM Cognos BI content store. The default name is COGNOSCS. On Oracle, the database name is the Oracle service name. On Microsoft SQL Server, the database name must be different from the MONITOR database name.
 - c. Provide a user name and password for the database, and confirm the password. If you use the same user name for the content store as for the MONITOR database, you must use the same password. Because this user requires full access rights, it is a good idea to create a new database user for the content store database only.

Note: The user name and password for the IBM Cognos BI content store database are kept in the `Cognos_JDBC_Alias`, which allows all database credentials to be maintained in one place. Whenever you start the IBM Business Monitor IBM Cognos BI server, the current values are passed to the IBM Cognos BI configuration to allow IBM Cognos BI access to the content store. Because of this integration, you cannot change the content store user name and password using the IBM Cognos BI Configuration application.

20. On the Profile Creation Summary panel, review the information. If you need to make any modifications, click **Back** and make changes as necessary.
21. Click **Create** to create the profile.
22. On the Profile Creation Complete panel, review the information about the completed profile creation.
23. Optional: Access First Steps.
 -  Select the **Launch the IBM Business Monitor first steps** option.
 -   Go to `profile_root/firststeps.wbm` and run the `firststeps.sh` command.
24. Click **Finish** to exit the Profile Management Tool.

During profile creation, you set port values for all required ports. If you decide to change the ports after installation, you must reconfigure all port values for IBM Business Monitor to work properly.

If you plan to use the server to develop, test, and debug monitor models, you can use the IBM Business Monitor debugger application by installing the `com.ibm.wbimonitor.debug.server.application.ear` and `com.ibm.wbimonitor.ice.machine.application.ear` files from `Application_Server_Root/installableApps.wbm/debugger`.

Note: The debugger is already installed if the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_create.log` file or the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_augment.log` file contains the `isDeveloperServer` parameter.

Augmenting deployment manager profiles

In a network deployment environment, you must have a deployment manager profile. Rather than create a new one, you can optionally augment an existing deployment manager profile to be the deployment manager profile for IBM Business Monitor.

Before completing this task, you must complete the following tasks:

- Verified that all hardware and software prerequisites have been met
- Installed IBM Business Monitor
- Logged in to the system as a user with appropriate permissions (read, write, and execute) on the profiles directory of WebSphere Application Server
- Installed the database

Windows

Important: To install or run the Profile Management Tool on Windows 7, Windows Vista, or Windows Server 2008, you must elevate your Microsoft Windows user account privileges. Whether you are an administrative user or a non-administrative user, right-click the `pmt.bat` file and select **Run as administrator**. Alternatively, use the `runas` command at the command line. For example:

```
runas /user:ADMINNAME /env pmt.bat
```

Non-administrative users are prompted for the administrator password.

You can augment an existing WebSphere Application Server, Process Server, or WebSphere Enterprise Service Bus profile with the IBM Business Monitor template. Similarly, if you installed WebSphere Application Server and augmented the profile for IBM Business Monitor, you can augment that profile with Process Server or WebSphere Enterprise Service Bus if you choose.

Complete the following steps to augment an existing deployment manager profile using the Profile Management Tool:

1. Open the Profile Management Tool using one of the following methods:
 - From the IBM Business Monitor First Steps console, click **Profile Management Tool**.
 -  Click **Start > Programs > IBM > Business Monitor 8.0 > Profile Management Tool**.
 -  Run `pmt.bat`, which is in the following directory: `app_server_root\bin\ProfileManagement`
 -   Change to the `app_server_root/bin/ProfileManagement` directory and type `./pmt.sh` in a terminal window.
2. On the Welcome to the Profile Management Tool panel, review the information, and click **Launch Profile Management Tool**.

3. On the Profiles panel, select a profile from the list and click **Augment** to augment an existing profile. (You can expand a profile to see the augmentations that have already been done.) You must select an existing deployment manager profile to augment to be the IBM Business Monitor deployment manager profile.

Restriction: If you cannot see the IBM Business Monitor option, it might indicate that you are using Solaris in 64-bit mode. In that case, you cannot use the Profile Management Tool and must use the **manageprofiles** command.

4. On the Augment Selection panel, click **Monitor server deployment manager** from the list, and click **Next**.
5. On the Profile Augmentation Options panel, click **Advanced profile augmentation**, and click **Next**. If you click **Typical**, some of the panels are not shown.
6. Optional: If the profile you are augmenting has security enabled, complete the following steps on the Administrative Security panel:
 - a. Type *user_name* for the **User name**.
 - b. Type *password* for the **Password**.
 - c. Type *password* in the **Confirm password** field.
 - d. Click **Next**.
7. Optional: Advanced: Configure the databases using a design file.
 - a. Select **Use a database design file for database configuration** if you would like to use a design file instead of specifying the database parameters in the following panels.
 - b. Click **Browse**.
 - c. Specify the fully qualified path name for the design file.
 - d. Click **Next**.
 - e. Select **Delay execution of database scripts (must select if using a remote database)** if you do not want to create and configure local databases automatically or create tables in existing databases during profile creation. Local databases are created if this check box is not selected. If you select this option, you or the database administrator must manually run the scripts that are stored in the location specified in the database script output directory field on this page. If you create the scripts for Oracle, you must replace @DB_PASSWORD@ with the password for the schema name before running them.

Note: If the database server contains multiple versions of DB2 installed, or multiple DB2 instances, the server's default DB2 version or instance is used for profile creation. To control which DB2 version or instance is used, use the "Installing databases manually" procedure so that the database administrator can ensure that the proper version or instance is used.

If you choose to specify a design file, the database configuration panels in the Profile Management Tool are skipped. Instead, the design file location is passed to the command line to complete the database configuration. For more information on using a design file for database configuration, see "Creating or configuring database scripts using the database design tool."

8. On the Database Configuration panel, verify your MONITOR database configuration information:
 - a. Select your database product from the list.
 - b. Select **Delay execution of database scripts (must select if using a remote database)** if you do not want to create and configure a local database automatically or create tables in an existing one during profile creation or augmentation. A local database will be created if this check box is not selected. If you select this option, you or the database administrator must manually run the scripts that are stored in the location specified in the database script output directory field on this page. If you create the scripts for Oracle, you must replace @DB_PASSWORD@ with the password for the schema name before running them.

Note: If the database server contains multiple versions of DB2 installed, or multiple DB2 instances, the server's default DB2 version or instance is used for profile creation. To control which DB2 version or instance is used, use the "Installing databases manually" procedure so that the database administrator can ensure that the proper version or instance is used.

- c. In the **Database name** field, enter the database name or accept the default (MONITOR).
 - d. In the **Schema name** field, enter the schema name or accept the default (MONITOR). If you are using DB2 on z/OS, the IBM Business Monitor database schema name must be different from the Process Server common database schema name to prevent collisions between database objects.
 - e. Click **Next**.
9. Complete the following steps for the MONITOR database on the Database Configuration (Part 2) panel. The options will vary depending on what database product you selected on the previous panel:
- a. Type *user_name* for the **User name** to authenticate with the database. This value represents an existing user ID with read and write permissions to MONITOR tables.

Note: If you are using an Oracle database, this field is not editable.

- b. Type *password* for the **Password** for database authentication. This value represents the password for the specified database user ID.
- c. Type *password* in the **Confirm password** field. This value must match the value for **Password**.
- d. Browse to or enter a path for the JDBC driver classpath files. The JDBC drivers for DB2, Oracle, and SQL Server are in **monitor_root/jdbcdrivers**. The default JDBC driver classpath is set to use the product-specific files within this directory based on the database type that you selected on the Database Configuration panel. Alternatively, click **Browse** to enter a path to the JDBC driver classpath files.

- DB2 database: The following directory is created by default:

`monitor_root/jdbcdrivers/DB2`

- Oracle database: The following directory is created by default:

`monitor_root/jdbcdrivers/Oracle`

The `ojdbc6.jar` JDBC driver file is the Oracle-supported JDBC driver for use with WebSphere Application Server version 7. The `ojdbc6.jar` file can be used for both Oracle 10g and Oracle 11g. For information about minimum required settings for Oracle, see the related link.

- SQL Server database: The following directory is created by default:

`monitor_root/jdbcdrivers/SQLServer`

The `sqljdbc4.jar` JDBC driver file is the Microsoft SQL Server 2.0 JDBC driver. For information about minimum required settings for SQL Server, see the related link.

- e. Select one of the following options for the JDBC driver type:
 - For Oracle databases:
 - **OCI:** The OCI driver requires a local Oracle client installation.
 - **Thin:** The Thin driver uses Java to communicate with the database and does not require a client on the local system.
 - For DB2 databases, profiles of IBM Business Monitor on operating systems other than z/OS are created with type 4 drivers, and profiles on z/OS are created with type 2 drivers. You can change the type after profile creation by editing the data source properties in the administrative console. A type 2 driver is a native-API driver and requires the installation of database software or a database client on the local system. A type 4 driver is a pure-Java implementation and typically provides the best performance. For the MONITOR database, no database software or clients are required on the local system.

- f. Type *host_name* for the **Database server host name or IP address**. The default value is **localhost** or the fully qualified local host name if defined, and you should use this value for a single-server installation. If your database is on a remote server, you must type the fully qualified host name or IP address.

Note: Except for a single-server installation, do *not* use the value `localhost` since the cluster members depend on the actual host name or IP address.

- g. Type *port_number* for the **Database TCP/IP service port or listener port**. This value represents the port where the TCP/IP service is assigned or the port on which the database is listening.
 - h. Optional: If you are using a DB2 on z/OS database, type *subsystem_name* for the **Subsystem name**. This value is the location of the DB2 for z/OS database. No spaces are allowed in the name.
 - i. If you are using Oracle or SQL Server and you chose to create the database automatically, enter the following information:
 - *system_user_name* for the **Database administrator user name**. This value is the name of the database administrator for Oracle or SQL Server. This user must have access to create and drop databases and users.
 - *password* for the **Password**. This value is the password for the system administrator that is specified in the previous field.
 - *password* in the **Confirm password** field.
 - j. Click **Next**. If the MONITOR database has not yet been created, you will see a warning message. Click **Yes** to continue. You can create the database at a later time.
10. On the Cognos Content Store Database panel, if you do not already have an existing IBM Cognos Business Intelligence installation that you plan to use, enter the information to create the IBM Cognos BI content store database for multidimensional data analysis from your dashboards.
 - a. Click **Create a new Cognos content store database**.
 - b. Provide the name of a database to be used for the IBM Cognos BI content store. The default name is COGNOSCS. On Oracle, the database name is the Oracle service name. On Microsoft SQL Server, the database name must be different from the MONITOR database name.
 - c. Provide a user name and password for the database, and confirm the password. If you use the same user name for the content store as for the MONITOR database, you must use the same password. Because this user requires full access rights, it is a good idea to create a new database user for the content store database only.

Note: The user name and password for the IBM Cognos BI content store database are kept in the `Cognos_JDBC_Alias`, which allows all database credentials to be maintained in one place. Whenever you start the IBM Business Monitor IBM Cognos BI server, the current values are passed to the IBM Cognos BI configuration to allow IBM Cognos BI access to the content store. Because of this integration, you cannot change the content store user name and password using the IBM Cognos BI Configuration application.

11. On the Profile Augmentation Summary panel, review the information. If you need to make any modifications, click **Back** and make changes as necessary.
12. Click **Augment** to augment the profile.
13. On the Profile Augmentation Complete panel, review the information about the completed profile augmentation.
14. Optional: Access First Steps.
 -  Select the **Launch the IBM Business Monitor first steps** option.
 -   Go to `profile_root/firststeps.wbm` and run the `firststeps.sh` command.
15. Click **Finish** to exit the Profile Management Tool.

During profile creation, you set port values for all required ports. If you decide to change the ports after installation, you must reconfigure all port values for IBM Business Monitor to work properly.

If you plan to use the server to develop, test, and debug monitor models, you can use the IBM Business Monitor debugger application by installing the `com.ibm.wbimonitor.debug.server.application.ear` and `com.ibm.wbimonitor.ice.machine.application.ear` files from `Application_Server_Root/installableApps.wbm/debugger`.

Note: The debugger is already installed if the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_create.log` file or the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_augment.log` file contains the `isDeveloperServer` parameter.

Creating custom profiles for nodes

For a network deployment, you must create a custom profile for each node you plan to add to the IBM Business Monitor server cluster. The profile will be created in the WebSphere Application Server profiles directory.

Before completing this task, you must have completed the following tasks:

- Verified that all hardware and software prerequisites have been met
- Installed IBM Business Monitor
- Logged in to the system as a user with appropriate permissions (read, write, and execute) on the profiles directory of WebSphere Application Server
- Ensured that the deployment manager is running.

Tip: If you are planning to enable security on these nodes, you should configure security before proceeding with the custom node creation. A link to detailed information for configuring security is provided below.

Windows

Important: To install or run the Profile Management Tool on Windows 7, Windows Vista, or Windows Server 2008, you must elevate your Microsoft Windows user account privileges. Whether you are an administrative user or a non-administrative user, right-click the `pmt.bat` file and select **Run as administrator**. Alternatively, use the **runas** command at the command line. For example:

```
runas /user:ADMINNAME /env pmt.bat
```

Non-administrative users are prompted for the administrator password.

Complete the following steps to create a custom profile for each cluster member using the Profile Management Tool:

1. Open the Profile Management Tool using one of the following methods:
 - From the IBM Business Monitor First Steps console, click **Profile Management Tool**.
 -  Click **Start > Programs > IBM > Business Monitor 8.0 > Profile Management Tool**.
 -  Run `pmt.bat`, which is in the following directory: `app_server_root\bin\ProfileManagement`
 -   Change to the `app_server_root/bin/ProfileManagement` directory and type `./pmt.sh` in a terminal window.
2. On the Welcome to the Profile Management Tool panel, review the information, and click **Launch Profile Management Tool**.
3. On the Profiles panel, click **Create** to create a new profile.

4. On the Environment Selection panel, expand IBM Business Monitor, click **Monitor server custom profile**, and click **Next**. Creating a custom profile will allow you the flexibility to create servers and clusters as you continue setting up your environment.

Restriction: If you cannot see the IBM Business Monitor option, it might indicate that you are using Solaris in 64-bit mode. In that case, you cannot use the Profile Management Tool and must use the **manageprofiles** command.

5. On the Profile Creations Options panel, select the type of installation you want to perform and click **Next**.
 - **Typical profile creation** (default): Creates a custom profile that uses default configuration settings. The Profile Management Tool assigns unique names to the profile, node, and host. The node will be federated to an existing deployment manager.
 - **Advanced profile creation:** Creates a custom profile using default configuration settings. You can specify the values for the location of the profile and names of the profile, node, and host. The node will be federated to an existing deployment manager.
6. If you selected **Typical profile creation**, skip to Step 10: Federation panel.
7. Advanced: On the Profile Name and Location panel, accept the default name and location, or specify a profile name and directory path to contain the files for the runtime environment, such as commands, configuration files, and log files. The default profile name is **Custom01**. On Windows, a typical profile directory is C:\IBM\WebSphere\AppServer\profiles\Custom01.
8. Optional: Advanced: If you want to use the profile you are creating as the default profile, select **Make this profile the default**. Click **Next**.
9. Advanced: On the Node and Host Names panel, enter new values or accept the default values, and click **Next**.
 - The node name is used for administration. If the node is federated, the node name must be unique within the cell.
 - The host name is the domain name system (DNS) name (short or long) or the IP address of this computer.
10. On the Federation panel, complete the following steps to identify the deployment manager profile that you plan to use:

Note: You can choose to federate the node later (using `add_node`) by selecting **Federate this node later**. If you select this option, all the fields are disabled. One advantage of federating later is that you might save yourself from creating a profile twice. If the node was federated during the profile creation and for some reason it failed (for example, the machine clock for the node is out of sync with that of the deployment manager), you need to create the profile again to ensure its validity. Federating the node at a later stage, therefore, provides a finer control on the federation procedure.

- a. Type *host_name* for the **Deployment manager host name or IP address**. This value is the fully qualified host name or IP address of the server where the deployment manager profile was created.
 - b. Type *port_number* for the **Deployment manager SOAP port number**. The default value is 8879.
 - c. Optional: If administrative security is enabled on the deployment manager, type *user_name* for the **User name**. The user name must be an existing WebSphere Application Server user for the deployment manager. This value is required for authentication with the deployment manager.
 - d. Optional: If administrative security is enabled on the deployment manager, type *password* for the **Password**. This password must be the password for the *user_name* you provided.
 - e. Click **Next**.
11. If you selected **Typical profile creation**, go to Step 15: Profile Creation Summary panel
 12. Advanced: On the Port Values Assignment panel, review the ports that will be assigned during profile creation. You might want to keep track of these port values. Accept the given values or specify alternate port numbers and click **Next**.

13. Advanced: On the Database Configuration panel, complete the following steps:
 - a. Select your database product from the drop-down list.
 - b. Type or browse to the directory where the JDBC classpath files are located in the **Location (directory) of JDBC driver classpath files**.
 - c. Click **Next**.
14. On the Profile Creation Summary panel, review the information. If you need to make any modifications, click **Back** and make changes as necessary.
15. Click **Create** to create the profile.
16. On the Profile Creation Complete panel, review the information about the completed profile creation.
17. Optional: Access First Steps.
 -  Select the **Launch the IBM Business Monitor first steps** option.
 -   Go to **profile_root/firststeps.wbm** and run the **firststeps.sh** command.
18. Click **Finish** to exit the Profile Management Tool.

During profile creation, you set port values for all required ports. If you decide to change the ports after installation, you must reconfigure all port values for IBM Business Monitor to work properly.

If you plan to use the server to develop, test, and debug monitor models, you can use the IBM Business Monitor debugger application by installing the `com.ibm.wbimonitor.debug.server.application.ear` and `com.ibm.wbimonitor.ice.machine.application.ear` files from `Application_Server_Root/installableApps.wbm/debugger`.

Note: The debugger is already installed if the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_create.log` file or the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_augment.log` file contains the `isDeveloperServer` parameter.

Augmenting custom profiles for nodes

For a network deployment, you need a custom profile for each node you plan to add to the IBM Business Monitor server cluster. Rather than create a new one, you can optionally augment an existing custom profile for each node.

Before completing this task, you must have completed the following tasks:

- Verified that all hardware and software prerequisites have been met
- Installed IBM Business Monitor
- Logged in to the system as a user with appropriate permissions (read, write, and execute) on the profiles directory of WebSphere Application Server
- Ensured that the deployment manager is running.

 Windows

Important: To install or run the Profile Management Tool on Windows 7, Windows Vista, or Windows Server 2008, you must elevate your Microsoft Windows user account privileges. Whether you are an administrative user or a non-administrative user, right-click the `pmt.bat` file and select **Run as administrator**. Alternatively, use the **runas** command at the command line. For example:

```
runas /user:ADMINNAME /env pmt.bat
```

Non-administrative users are prompted for the administrator password.

Complete the following steps to augment a profile for each cluster member using the Profile Management Tool:

1. Open the Profile Management Tool using one of the following methods:

- From the IBM Business Monitor First Steps console, click **Profile Management Tool**.
 -  Click **Start > Programs > IBM > Business Monitor 8.0 > Profile Management Tool**.
 -  Run `pmt.bat`, which is in the following directory: `app_server_root\bin\ProfileManagement`
 -   Change to the `app_server_root/bin/ProfileManagement` directory and type `./pmt.sh` in a terminal window.
2. On the Welcome to the Profile Management Tool panel, review the information, and click **Launch Profile Management Tool**.
 3. On the Profiles panel, select a profile from the list and click **Augment** to augment an existing profile. (You can expand a profile to see the augmentations that have already been done.) You must select an existing custom profile to augment to be the IBM Business Monitor custom profile. A custom profile will allow you the flexibility to create servers and clusters as you continue setting up your environment.

Restriction: If you cannot see the IBM Business Monitor option, it might indicate that you are using Solaris in 64-bit mode. In that case, you cannot use the Profile Management Tool and must use the `manageprofiles` command.

4. On the Augment Selection panel, click **Monitor server custom profile** from the list, and click **Next**.
5. On the Profile Augmentation Options panel, click **Advanced profile augmentation**, and click **Next**. If you click **Typical**, some of the panels are not shown.
6. If you see the Federation panel, complete the following steps to identify the deployment manager profile that you plan to use:

Note: If the profile was not previously federated, you will not see this panel.

- a. Type *host_name* for the **Deployment manager host name or IP address**. This value is the fully qualified host name or IP address of the server where the deployment manager profile was created.
 - b. Type *port_number* for the **Deployment manager SOAP port number**. The default value is 8879.
 - c. Optional: If administrative security is enabled on the deployment manager, type *user_name* for the **User name**. The user name must be an existing WebSphere Application Server user for the deployment manager. This value is required for authentication with the deployment manager.
 - d. Optional: If administrative security is enabled on the deployment manager, type *password* for the **Password**. This password must be the password for the *user_name* you provided.
 - e. Click **Next**.
7. On the Database Configuration panel, complete the following steps:
 - a. Select your database product from the list.
 - b. Type or browse to the directory where the JDBC classpath files are located in the **Location (directory) of JDBC driver classpath files**.
 - c. Click **Next**.
 8. Click **Augment** to augment the profile.
 9. On the Profile Augmentation Complete panel, review the information about the completed profile augmentation.
 10. Optional: Access First Steps.
 -  Select the **Launch the IBM Business Monitor first steps** option.
 -   Go to `profile_root/firststeps.wbm` and run the `firststeps.sh` command.
 11. Click **Finish** to exit the Profile Management Tool.

During profile creation, you set port values for all required ports. If you decide to change the ports after installation, you must reconfigure all port values for IBM Business Monitor to work properly.

If you plan to use the server to develop, test, and debug monitor models, you can use the IBM Business Monitor debugger application by installing the `com.ibm.wbimonitor.debug.server.application.ear` and `com.ibm.wbimonitor.ice.machine.application.ear` files from *Application_Server_Root/installableApps.wbm/debugger*.

Note: The debugger is already installed if the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_create.log` file or the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_augment.log` file contains the `isDeveloperServer` parameter.

Creating and augmenting profiles using the `manageprofiles` command

Instead of using the Profile Management Tool, you can use the `manageprofiles` command to create profiles from the command line. If you are running Solaris in 64-bit mode, you must use the `manageprofiles` command because the Profile Management Tool is not supported. If you are using z/OS, see "Creating common configurations for IBM Business Monitor for z/OS."

Important: The `manageprofiles` command does not support profile augmentation using the `profileTemplate` parameter for cells in a different package.

Carefully consider the available parameters before creating or augmenting your profile. It is not simple to modify a profile after creation or augmentation.

Before completing this task, you must perform the following tasks:

- Verified the hardware and software provided here:
- Installed IBM Business Monitor
- Logged in to the system as a user with appropriate permissions (read, write, and execute) on the profiles directory of WebSphere Application Server

If you are using an Oracle database, JDBC support is provided by the Oracle JDBC drivers for JVM 1.6. The `ojdbc6.jar` JDBC driver file is the Oracle-supported JDBC driver for use with WebSphere Application Server version 7. The `ojdbc6.jar` file can be used for both Oracle 10g and Oracle 11g. For information about minimum required settings for Oracle, see the related link.

By default, the Profile Management Tool points to the `ojdbc6.jar` file supplied in `app_server_root\jdbcdrivers\Oracle`. Alternatively, you can download another Oracle `ojdbc6.jar` JDBC driver file and point to it when you run the Profile Management Tool or the `manageprofiles` command.

If you are using an SQL Server database, the SQL Server JDBC drivers for JVM 1.6 provide JDBC support. IBM Business Monitor uses the Microsoft JDBC 2.0 driver `sqljdbc4.jar` file. By default, the Profile Management Tool points to the `sqljdbc4.jar` file supplied in `app_server_root\jdbcdrivers\SQLServer`. Alternatively, you can download another Microsoft `sqljdbc4.jar` JDBC driver file and point to it when you run the Profile Management Tool or the `manageprofiles` command. For information about minimum required settings for SQL Server, see the related link.

Windows

Important: To install or run the `manageprofiles` command on Windows 7, Windows Vista, or Windows Server 2008, you must elevate your Microsoft Windows user account privileges using the `runas` command. Remember to put double quotation marks around the `manageprofiles` command and all parameters. For example:

```
runas /env /user:MyAdminName "manageprofiles.bat -create -profileName WBMON01
-templatePath C:\Program Files\IBM\WebSphere\AppServer\profileTemplates\wbmonitor\default
-wmDBJDBCClasspath C:\Program Files\IBM\WebSphere\AppServer\jdbcdrivers\DB2"
```

Non-administrative users are prompted for the administrator password.

For a single-server environment, create a stand-alone profile.

For a network deployment environment, complete the following steps:

1. Create the deployment manager profile before creating the other profiles. If you created a deployment manager profile before installing IBM Business Monitor (for example, for WebSphere Application Server or Process Server) and you plan to use the same deployment manager profile to manage IBM Business Monitor nodes, augment the profile using the template that IBM Business Monitor provides.
2. Create a custom profile for each node that you plan to add to the server cluster. Alternatively, augment an existing custom profile for each node that you plan to add.

Note: If the database server contains multiple versions of DB2 installed, or multiple DB2 instances, the server's default DB2 version or instance is used for profile creation. To control which DB2 version or instance is used, use the "Installing databases manually" procedure so that the database administrator can ensure that the proper version or instance is used.

To create a profile manually, complete the following steps:

1. Open a command prompt, and navigate to the following directory:
app_server_root/bin
2. Run the **manageprofiles.bat** or **manageprofiles.sh** command using the required parameters. See the reference pages for details of the parameters for each type of profile.

If you plan to use the server to develop, test, and debug monitor models, you can use the IBM Business Monitor debugger application by installing the `com.ibm.wbimonitor.debug.server.application.ear` and `com.ibm.wbimonitor.ice.machine.application.ear` files from *Application_Server_Root/installableApps.wbm/debugger*.

Note: The debugger is already installed if the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_create.log` file or the `WAS_HOME/logs/manageprofiles/PROFILE_NAME_augment.log` file contains the *isDeveloperServer* parameter.

Chapter 7. Verifying the installation

After you have installed IBM Business Monitor and created a profile, you can optionally use the First Steps Console to verify that the product was installed correctly.

1. Access First Steps.

-   Open a command window. Go to `profile_root/firststeps.wbm` and run the `firststeps.sh` command.
-  From the Profile Creation Complete panel, select the **Launch the IBM Business Monitor first steps** option.
-  Go to **Start > All Programs > IBM > Business Monitor 7.5 > Profiles > *profile_name* > First Steps**.
-  Go to `profile_root\firststeps.wbm` and run the `firststeps.bat` command.

Important: To install or run First Steps on Windows 7, Windows Vista, or Windows Server 2008, you must elevate your Microsoft Windows user account privileges by right-clicking `firststeps.bat` and selecting **Run as administrator**. This is required for both administrative and nonadministrative users.

2. From the First Steps console, select the option to perform an installation verification test.

3. Review results.

If you enabled security for IBM Business Monitor, after the installation completes, you must set up users by supplying a user ID and password for the MonitorBusAuth authentication alias. See [Specifying credentials in an IBM Business Monitor secured environment](#) for more details.

In addition to the installation verification test, the First Steps console provides options to run the Profile Management Tool, open the WebSphere Application Server administrative console, and open Business Space.

  On a Linux or UNIX system, you might have to change the ownership from root user to a different user. You perform this task on IBM Business Monitor exactly as you would on WebSphere Application Server or Process Server. See the related links below for more information.

If you are creating a new IBM Business Monitor profile or augmenting an existing profile with IBM Business Monitor resulted in a result code of `INSTCONFPARTIALSUCCESS` or `INSTCONFFAILED`, consult the table in the related reference link.

Chapter 8. Determining port numbers

To determine the port number to use with web interfaces such as Business Space and the portlet-based dashboards, review the configuration in the WebSphere Application Server administrative console.

In a network deployment (ND) environment, you normally use a proxy server or an HTTP server for security reasons and for workload balancing. Instead of incoming HTTP requests going directly to a specific cluster member, they go to a proxy server that can spread the requests across the multiple cluster members that perform the work. In this case, you need the host name and port number of the proxy server or web server, which in turn forwards the request to a cluster member.

- To determine the port numbers for an application server, complete the following steps:
 1. In the WebSphere Application Server administrative console, select **Servers > Server Types > WebSphere application servers**.
 2. Select the name of your server or cluster member (such as **server1**).
 3. Under Communications, click **Ports**.

The port number to use with web interfaces such as Business Space and the portlet-based dashboards is listed as **WC_defaulthost_secure** in an environment with security and **WC_defaulthost** in an environment without security. This page also provides the port number for the bootstrap port, the SOAP connector port, and other ports that you might be asked to enter while working with IBM Business Monitor.

- To determine the port numbers for a proxy server, complete the following steps:
 1. In the WebSphere Application Server administrative console, select **Servers > Server Types > WebSphere proxy servers**.
 2. Select the name of your server (such as **proxy**).
 3. Under Communications, click **Ports**.

The port number to use with web interfaces such as Business Space and the portlet-based dashboards is listed as **PROXY_HTTPS_ADDRESS** in an environment with security and **PROXY_HTTP_ADDRESS** in an environment without security. This page also provides the port number for the bootstrap port, the SOAP connector port, and other ports that you might be asked to enter while working with IBM Business Monitor.

Web modules are deployed to a virtual host (by default named **defaulthost**). Virtual hosts are configured in the administrative console by clicking **Environment > Virtual hosts**. The virtual host that you choose for each web module must include the HTTP or HTTPS port that is used by the server (or cluster member) where the web modules are deployed. Additionally, each of the IBM Business Monitor web modules should use the same virtual host. There are web modules in most of the IBM Business Monitor, Business Space, and REST applications (EAR files).

Chapter 9. Configuring the environment

After you have installed IBM Business Monitor in a network deployment (ND) topology, you must complete additional configuration tasks to install required resources and fully prepare your environment for monitoring.

When you create a stand-alone profile for IBM Business Monitor, the required resources are created automatically as part of the profile creation process. You can use the administrative console to check status, or to redeploy a component that has been manually removed, but typically the configuration tasks in this section are required only for network deployment (ND).

Creating the deployment environment using a pattern

You can use the deployment environment configuration wizard to create the cluster or clusters and configure all the required components for the IBM Business Monitor network deployment (ND) topology.

Before creating clusters and configuring the IBM Business Monitor components, ensure that you have performed the following tasks:

- You have installed IBM Business Monitor.
- You have created the IBM Business Monitor deployment manager profile or augmented an existing deployment manager profile with IBM Business Monitor.
- You have created the MONITOR database.
- You have started the deployment manager.
- You have created and federated at least one IBM Business Monitor custom profile or augmented an existing custom profile with IBM Business Monitor.
- You have started the custom profile or profiles.

Before starting the configuration process, make sure that you are synchronizing node changes automatically (in the administrative console, click **System Administration** > **Console Preferences** and select **Synchronize changes with Nodes**). Otherwise, you must synchronize changes manually after each major step.

Two patterns are available for IBM Business Monitor: the Single Cluster pattern and the Remote Messaging, Remote Support, and Web (four-cluster) pattern.

One of the optional steps in the deployment environment configuration wizard includes importing a database design document. The database design document defines the database configuration for the selected deployment environment features and the information from the design document is reflected on the Database page of the wizard. IBM Business Monitor includes a response-driven database design tool (DbDesignGenerator) that prompts users for information on the databases that will be used by IBM Business Monitor (information such as the database platform and the database, schema, and user names). The output of the database design tool is a database design document that is used by the database design tool to create the database scripts.

To configure the deployment environment, complete the following steps:

1. In the administrative console, click **Servers** > **Deployment Environments**.
2. To launch the deployment environment configuration wizard, click **New** on the Deployment Environments page.
 - a. The **Create a deployment environment based on a pattern** option is selected.

- b. Enter a unique name for the deployment environment in the **Deployment environment name** field.
 - c. If you want to view all of the configuration steps in the wizard, select **Detailed: Show all steps**. If you choose **Fast path: Show only needed steps**, the wizard displays only those pages that do not have assigned default values. Choose **Fast path: Show only needed steps** only if you are agreeable to accepting the system-provided default values for the deployment environment configuration. This topic assumes that you have chosen **Detailed: Show all steps**.
 - d. Click **Next** to display the Deployment Environment Features page.
3. On the Deployment Environment Features page, select the feature for the deployment environment and click **Next** to either view a list of compatible features, or to view a list of deployment environment patterns. Features represent the runtime processing capabilities of your deployment environment. The list of available features on the Deployment Environment Features page is based on the deployment manager profile. If your deployment manager profile has been augmented to include other products as well as IBM Business Monitor (for example, IBM Business Process Manager) the Deployment Environment Features page lists these features as well. The default value for the deployment environment feature matches the runtime capabilities of your deployment manager.
 4. On the Select compatible deployment environment features page, select additional features as necessary and click **Next** to view the list of patterns associated with your feature selections. Only one deployment environment configuration can exist with the **WBM** feature. If a deployment environment configuration with the **WBM** feature already exists, you will not be able to continue, even if the deployment environment configuration has not been generated.
 5. On the Select the deployment environment pattern page, select the pattern and click **Next** to display the Select Nodes page.

The list of patterns that display on the Deployment Environment Patterns page is dynamic. This list is activated by, and dependent on, the following environment conditions and configuration decisions:

- The platform on which you have installed the software
- The selections that you have made on the Select the deployment environment feature page and the Select compatible deployment environment features page.

Typically you will have a choice between the Single Cluster pattern and the Remote Messaging, Remote Support, and Web (four-cluster) pattern. For descriptions of these patterns, see the "High availability (network deployment) topology" page in the planning section.

6. On the Select Nodes page, select the nodes that you want to include in this deployment environment, then click **Next** to display the Cluster members page.

Select one or more IBM Business Monitor nodes for the deployment environment. You can identify the IBM Business Monitor nodes by an entry for **WBM** in the version column of the list. If a node does not have an entry for **WBM** in the version column and you want to enable it for IBM Business Monitor, augment the node's profile with IBM Business Monitor and restart the deployment environment configuration wizard.

All selected nodes must be IBM Business Monitor nodes. If you selected additional features in step 3, select nodes that also support the additional features.

For high-availability and failover environments, select at least two nodes on at least two separate hosts. For additional scalability, select more than two nodes.

To include a node, select the check box next to the node name.

7. On the Clusters page, assign at least one cluster member on at least one node for each function of the deployment environment.

By default one cluster member is assigned on each node for each function. You change the number by replacing the number in each column. For network deployment, clusters can collaborate to provide specific functionality to the environment. Depending on your requirements, you assign specific functions to each cluster within the deployment environment, to provide performance, failover, and capacity.

A 0 (zero) value for a node means that the node does not contribute to the selected function, based on features that you have selected.

There must be at least one cluster member assigned for each function. For high-availability and failover environments, indicate at least two cluster members per function. For additional scalability, indicate more cluster members for a function.

You can specify the initial port using the **Specify the port number for the first cluster group (Optional)**: text box. Port numbers are reserved and assigned to each node for the cluster members using the port number that is specified. If you specify an initial port when you create the deployment environment, that same initial port specified would be assigned to the first cluster member and subsequent cluster groups would be assigned ports after increasing the port value by 20. For example, if the port number for the first cluster group is 2000, the port numbers of the cluster members would be 2000, 2001, 2002, and so on. The port number of the second cluster group would be 2020 and the port numbers for the members of the second cluster group would be 2020, 2021, 2022, and so on. The port number of the third cluster group would be 2040.

Note: If there is already a node on that physical system then there may be port conflicts and these would need to be resolved manually by changing the port values.

After assigning cluster members, you can click **Next** to display the Cluster naming pages for each cluster type of the deployment environment. The Cluster naming substeps that display will vary depending on the deployment environment pattern selected. If you do not want to customize cluster names or cluster member names, use the wizard navigation pane to go directly to the REST services page and continue to the next step.

- a. Optional: Customize the cluster names and cluster member names. Use the Cluster naming page to customize cluster names or cluster member names for the cluster type. You can also modify cluster short names and cluster member short names. There is one substep page for each cluster type in the pattern that you have selected. The information on each substep page is as follows:

Field	Description	Value
Cluster	A read-only field specifying the functional role of the cluster.	<p>The value varies depending on the cluster type, as follows:</p> <ul style="list-style-type: none"> • Application Deployment Target • Supporting Infrastructure • Messaging Infrastructure • Web Application Infrastructure <p>For information on the functional role provided by each cluster type, see "Topologies and deployment environment patterns."</p>

Field	Description	Value
Cluster name	The system-generated default value for the cluster name.	The default values are based on a naming convention of <i>Deployment Environment Name.Cluster type name</i> , where <i>Cluster type name</i> is one of the following values: <ul style="list-style-type: none"> • AppTarget - For clusters performing the role of application deployment target • Messaging - For clusters performing the role of messaging infrastructure • Support - For clusters performing the role of supporting infrastructure • Web - For clusters performing the role of supporting web applications
Cluster member name	The system-generated default value for the cluster member name. Servers that are a part of a cluster are called cluster members.	Accept the system-generated default value or specify a name of your choosing. The default value for the cluster member name is based on the following naming convention: <i>cluster name.node name.node number sequence</i> . The number of cluster member names that display in the table match the number of cluster members that you entered for the cluster type column and node row on the Clusters page.

8. On the System REST Service endpoints page, configure service endpoints for Representational State Transfer (REST) application programming interfaces (APIs).

If you want widgets to be available in Business Space, you must configure the REST service endpoints for those widgets. For the host name and port, if you want REST requests to go directly to the application server, enter the application server host name and port. If you want REST requests to go to a proxy server or HTTP server that sits in front of one or more application servers, enter the host name and port of the proxy server or HTTP server. In the second case, you must have already set up a proxy server or an HTTP server. Otherwise, skip this page and configure the endpoints later.

- a. Configure a full URL path for all REST services by selecting either **https://** or **http://** from the **Protocol** list.
- b. Enter the name of the proxy server or HTTP server in the **Host Name or Virtual Host in a Load-Balanced Environment** field.

Enter the host or virtual host name and port number that a client needs to communicate with the server or cluster. In a clustered environment, this is typically the load balancer host name and port. If you leave the host and port fields empty, the values default to the values of an individual cluster member host and its HTTP port. For a load-balanced environment, you must later change the default values to the virtual host name and port of your load balancer. Make sure to designate a fully qualified host name.
- c. In the **Port** field, enter the port that a client needs to communicate with the server or cluster.
- d. In the table of REST services, if you want to modify the description of the REST service endpoint, overwrite the entry in the Description field. The other fields are read-only.
- e. Click **Next** to go to the Import the database configuration page.

9. Optional: On the Import the database configuration page, click **Browse** to go to the database design document or enter the path to the database design document and then click **Next** to go to the Data sources page. If you import a design document, the information from the design document is reflected on the Database page of the wizard. The design document can be based on a database design that you created using the database design tool, or it can be the supplied design document based on the pattern and feature that you have selected.
10. On the Database page, configure the database parameters for data sources of the deployment environment, then click **Next** to go to the Security page.

On this page, define the database information for the components that are included in this deployment environment. Where possible, the wizard supplies default information for the parameters, but change those values to match the values that you defined when you planned the environment. If you change providers, you can click the **Edit Provider** button to edit the provider that you selected.

Note: If you imported a database design document, the information on the Database page reflects the data source configuration as it exists in the database design document that you imported. If you make changes to the data source configuration after importing a database design document, your changes might be incompatible with the DDL generated by the database design tool and the original values.

Whether or not this step displays for a fast path deployment environment configuration is conditional. This step displays for a fast path deployment environment configuration if more than one database has been defined.

This step always displays if you are using a DB2 for z/OS or an Oracle database provider.

The IBM Business Monitor feature provides the following entries:

Component	Data source
Business Monitor messaging engine data source	Data source for the IBM Business Monitor messaging engine.
Cognos Content Store	<p>Data source for the IBM Cognos Business Intelligence content store. (Displayed only if IBM Cognos BI has been installed and not yet configured.)</p> <p>The Content Store data source is created in the IBM Cognos BI configuration and not as a WebSphere data source. Leave the Create tables option checked; otherwise this data source is marked as a deferred configuration. IBM Cognos BI creates the tables on first startup.</p> <p>A WebSphere authentication alias (Cognos_JDBC_Alias) is created based on the user name and password provided for this data source. This authentication alias is not used directly by IBM Cognos BI but it enables all database user names and passwords to be maintained using the same process. On server startup, IBM Business Monitor sends the current user name and password values to the IBM Cognos BI configuration.</p> <p>For DB2 on z/OS, you must install the COGNOSCS database manually.</p>
Business Space	<p>Data source for the Business Space component. If you select the Create tables option, the schema name used by Business Space must already exist in the database.</p> <p>Important: For Oracle only, you must run <code>app_server_root/dbscripts/BusinessSpace/Oracle/createSchema_BusinessSpace.sql</code> to create the schema user and grant the required rights.</p>

If you selected other product features for this topology, other feature-specific entries might also appear here.

The default schema names that are displayed on this page might conflict with your site naming convention or might conflict with existing schemas. As such, it is likely that you will need to change the schema name.

Note: For DB2 for z/OS databases, the schema name that is configured on the panel will be used for the DB2 z/OS SQLID value. If the DB2 z/OS SQLID value needs to be different in your environment, then after the deployment environment wizard is finished, you can manually update the data sources that have been created and change the currentSQLID Custom Property to the correct value.

You can edit all key parameters, such as the database name, whether or not to create tables, the data source runtime user name, and the user name and password for the data source to connect to the database.

Note: For DB2 for z/OS databases, the database name is the database subsystem name. For other versions of DB2, the database name is the MONITOR database name. For Oracle databases, the database name is the Oracle System ID.

You can select which database to use for the given component.

The **Create tables** option is not available if you are using a DB2 for z/OS or an Oracle database provider.

For Oracle, the **Schema** field is disabled and empty, and the **User name** is not pre-filled with the common database user name. You must enter a user name and password for each data source.

Note: No validation takes place to ensure that user names are unique, so be aware that you might create a duplicate user name, resulting in table conflicts.

- On the Security page, enter the user IDs and passwords that are needed to configure the IBM Business Monitor components. The IBM Business Monitor feature provides the following entries:

Component	ID and Password
Authentication alias for the CEI event service JMS resources	Specify the user ID and password to use to secure the default common event infrastructure (CEI) service integration bus.
Cognos Administration access authentication	Specify a user ID and password with administrative rights to the IBM Cognos BI service. (Displayed only if IBM Cognos BI has been installed and not yet configured.)

If you selected other product features for this topology, other feature-specific entries might also appear here.

- Optional: If the Business Process Choreographer page is displayed, set parameters for the Business Process Choreographer configuration and then click **Next** to display the Web application context roots page. On this page you specify the values for:
 - Security roles
 - Authentication aliases
- Optional: If the Web application context roots page is displayed, set the context root for component-based web applications in your deployment environment or accept the system-provided default values for the context roots. Then click **Next** to display the Summary page.

The table contains the following control information.

Web Application

The name of the web application.

Some of the components that are part of the deployment environment you are creating contain web applications. The **Web application** column can include the following components:

- Business Process Choreographer Explorer
- Business Space
- Business Process Rules Manager

Context Root

The current value of the context root for the component.

By default, the default context root for the web application applies. You can change the context roots by typing over the value in the **Context Root** field.

Note: The Business Space context root is read only and cannot be edited.

14. Verify that the information on the Summary page is correct and click **Finish and Generate Environment** to save and complete the configuration of the deployment environment. To exit without completing the configuration, click **Finish**.

Clicking **Finish** saves the deployment environment configuration - but does not generate it.

Click **Cancel** cancels the deployment configuration and does not save the configuration.

15. If you clicked **Finish and Generate Environment** to generate a deployment environment, stop and restart all clusters, nodes, and the deployment manager.

If you selected not to generate the environment at the end of the deployment environment configuration wizard (by clicking **Finish** rather than **Finish and Generate Environment**), you can view the deployment environment configuration at **Server > Deployment Environments > name of deployment environment**. From there, you can click **Generate** to generate the environment. When the configuration completes, you can examine the configuration files to view the changes.

Either save the changes to the master configuration or discard them. If you click a deployment environment in the list, and there are still configuration steps to perform, you will see a list of deferred configuration steps. After generating a deployment environment, stop and restart all clusters, nodes, and the deployment manager.

Important: The cluster that will be running the IBM Cognos BI service requires that each cluster member be started individually. You must wait for the IBM Cognos BI service to initialize fully before starting the next cluster member.

Importing deployment environment definitions based on design documents

You can import an existing deployment environment definition based on a design document from another deployment manager to use as a base for configuring a new deployment environment.

- You must have a copy of an exported deployment environment design document from another deployment manager.
- You must be able to access the deployment environment design document (an XML file) from the deployment manager into which you are importing the deployment environment design.
- The deployment manager that imports the deployment environment definition must support at least all of the functions that are defined in the deployment environment design document. For example, you can import a deployment environment design that was created on a WebSphere Enterprise Service Bus deployment manager into a Process Server deployment manager but not vice versa.

Note: When security and role-based authorization are enabled, you must log in to the administrative console as an administrator to perform this task.

Important: You cannot import multiple deployment environment design documents from a compressed file at the same time. You must extract the design documents from the compressed file and then import the XML files one at a time.

Before starting the configuration process, make sure that you are synchronizing node changes automatically (in the administrative console, click **System Administration > Console Preferences** and select **Synchronize changes with Nodes**). Otherwise, you must synchronize changes manually after each major step.

Importing an existing deployment environment design to create a new one can minimize the amount of time you spend configuring a deployment environment. If an existing environment is similar to the one you want to create, export it and then import it into the deployment manager that you are configuring.

1. In the administrative console, click **Servers > Deployment Environments**.
2. Click **Import** in the Deployment Environments page to launch the Deployment Environment Configuration wizard.
The wizard starts with **Create a deployment environment based on an imported design** selected.
3. Click **Browse** and select the deployment environment design document (XML file) to import or type the full path to it.
4. Click **Next** to load the configuration and launch the Import deployment environment wizard.
The wizard displays the Select Nodes page, unless all the node names match currently federated nodes. If all nodes match, the wizard displays the Database page.

Important: Clicking configure in any panel in the wizard configures the deployment environment with the current values.

5. Optional: From the list of possible nodes on the Select Nodes page, select the nodes to include in the deployment environment and click **Next**.

To include a node, select the check box next to the node name.

Important: **Next** is not available if the nodes selected do not meet the constraints imposed by the imported deployment environment design. For example, if there is a requirement for the deployment environment to contain a node named "Mandatory_Node" and 3 other nodes with any name, you will be unable to continue until you select "Mandatory_Node" and 3 other nodes.

6. On the Clusters page, assign at least one cluster member on at least one node for each function of the deployment environment.

By default one cluster member is assigned on each node for each function. You change the number by replacing the number in each column. For network deployment, clusters can collaborate to provide specific functionality to the environment. Depending on your requirements, you assign specific functions to each cluster within the deployment environment, to provide performance, failover, and capacity.

A 0 (zero) value for a node means that the node does not contribute to the selected function, based on features that you have selected.

There must be at least one cluster member assigned for each function. For high-availability and failover environments, indicate at least two cluster members per function. For additional scalability, indicate more cluster members for a function.

You can specify the initial port using the **Specify the port number for the first cluster group (Optional):** text box. Port numbers are reserved and assigned to each node for the cluster members using the port number that is specified. If you specify an initial port when you create the deployment environment, that same initial port specified would be assigned to the first cluster member and subsequent cluster groups would be assigned ports after increasing the port value by 20. For example, if the port number for the first cluster group is 2000, the port numbers of the cluster members would be 2000, 2001, 2002, and so on. The port number of the second cluster group would be 2020 and the port numbers for the members of the second cluster group would be 2020, 2021, 2022, and so on. The port number of the third cluster group would be 2040.

Note: If there is already a node on that physical system then there may be port conflicts and these would need to be resolved manually by changing the port values.

After assigning cluster members, you can click **Next** to display the Cluster naming pages for each cluster type of the deployment environment. The Cluster naming substeps that display will vary depending on the deployment environment pattern selected. If you do not want to customize cluster names or cluster member names, use the wizard navigation pane to go directly to the REST services page and continue to the next step.

- a. Optional: Customize the cluster names and cluster member names. Use the Cluster naming page to customize cluster names or cluster member names for the cluster type. You can also modify cluster short names and cluster member short names. There is one substep page for each cluster type in the pattern that you have selected. The information on each substep page is as follows:

Field	Description	Value
Cluster	A read-only field specifying the functional role of the cluster.	The value varies depending on the cluster type, as follows: <ul style="list-style-type: none"> • Application Deployment Target • Supporting Infrastructure • Messaging Infrastructure • Web Application Infrastructure For information on the functional role provided by each cluster type, see "Topologies and deployment environment patterns."
Cluster name	The system-generated default value for the cluster name.	The default values are based on a naming convention of <i>Deployment Environment Name.Cluster type name</i> , where <i>Cluster type name</i> is one of the following values: <ul style="list-style-type: none"> • AppTarget - For clusters performing the role of application deployment target • Messaging - For clusters performing the role of messaging infrastructure • Support - For clusters performing the role of supporting infrastructure • Web - For clusters performing the role of supporting web applications
Cluster member name	The system-generated default value for the cluster member name. Servers that are a part of a cluster are called cluster members.	Accept the system-generated default value or specify a name of your choosing. The default value for the cluster member name is based on the following naming convention: <i>cluster name.node name.node number sequence</i> . The number of cluster member names that display in the table match the number of cluster members that you entered for the cluster type column and node row on the Clusters page.

7. On the System REST Service endpoints page, configure service endpoints for Representational State Transfer (REST) application programming interfaces (APIs).

If you want widgets to be available in Business Space, you must configure the REST service endpoints for those widgets. For the host name and port, if you want REST requests to go directly to the application server, enter the application server host name and port. If you want REST requests to go to a proxy server or HTTP server that sits in front of one or more application servers, enter the host name and port of the proxy server or HTTP server. In the second case, you must have already set up a proxy server or an HTTP server. Otherwise, skip this page and configure the endpoints later.

- a. Configure a full URL path for all REST services by selecting either **https://** or **http://** from the **Protocol** list.
 - b. Enter the name of the proxy server or HTTP server in the **Host Name or Virtual Host in a Load-Balanced Environment** field.
Enter the host or virtual host name and port number that a client needs to communicate with the server or cluster. In a clustered environment, this is typically the load balancer host name and port. If you leave the host and port fields empty, the values default to the values of an individual cluster member host and its HTTP port. For a load-balanced environment, you must later change the default values to the virtual host name and port of your load balancer. Make sure to designate a fully qualified host name.
 - c. In the **Port** field, enter the port that a client needs to communicate with the server or cluster.
 - d. In the table of REST services, if you want to modify the description of the REST service endpoint, overwrite the entry in the Description field. The other fields are read-only.
 - e. Click **Next** to go to the Import the database configuration page.
8. Optional: On the Import the database configuration page, click **Browse** to go to the database design document or enter the path to the database design document and then click **Next** to go to the Data sources page. If you import a design document, the information from the design document is reflected on the Database page of the wizard. The design document can be based on a database design that you created using the database design tool, or it can be the supplied design document based on the pattern and feature that you have selected.
 9. On the Database page, configure the database parameters for data sources of the deployment environment, then click **Next** to go to the Security page.

On this page, define the database information for the components that are included in this deployment environment. Where possible, the wizard supplies default information for the parameters, but change those values to match the values that you defined when you planned the environment. If you change providers, you can click the **Edit Provider** button to edit the provider that you selected.

Note: If you imported a database design document, the information on the Database page reflects the data source configuration as it exists in the database design document that you imported. If you make changes to the data source configuration after importing a database design document, your changes might be incompatible with the DDL generated by the database design tool and the original values.

Whether or not this step displays for a fast path deployment environment configuration is conditional. This step displays for a fast path deployment environment configuration if more than one database has been defined.

This step always displays if you are using a DB2 for z/OS or an Oracle database provider.

The IBM Business Monitor feature provides the following entries:

Component	Data source
Business Monitor messaging engine data source	Data source for the IBM Business Monitor messaging engine.

Component	Data source
Cognos Content Store	<p>Data source for the IBM Cognos Business Intelligence content store. (Displayed only if IBM Cognos BI has been installed and not yet configured.)</p> <p>The Content Store data source is created in the IBM Cognos BI configuration and not as a WebSphere data source. Leave the Create tables option checked; otherwise this data source is marked as a deferred configuration. IBM Cognos BI creates the tables on first startup.</p> <p>A WebSphere authentication alias (Cognos_JDBC_Alias) is created based on the user name and password provided for this data source. This authentication alias is not used directly by IBM Cognos BI but it enables all database user names and passwords to be maintained using the same process. On server startup, IBM Business Monitor sends the current user name and password values to the IBM Cognos BI configuration.</p> <p>For DB2 on z/OS, you must install the COGNOSCS database manually.</p>
Business Space	<p>Data source for the Business Space component. If you select the Create tables option, the schema name used by Business Space must already exist in the database.</p> <p>Important: For Oracle only, you must run <code>app_server_root/dbscripts/BusinessSpace/Oracle/createSchema_BusinessSpace.sql</code> to create the schema user and grant the required rights.</p>

If you selected other product features for this topology, other feature-specific entries might also appear here.

The default schema names that are displayed on this page might conflict with your site naming convention or might conflict with existing schemas. As such, it is likely that you will need to change the schema name.

Note: For DB2 for z/OS databases, the schema name that is configured on the panel will be used for the DB2 z/OS SQLID value. If the DB2 z/OS SQLID value needs to be different in your environment, then after the deployment environment wizard is finished, you can manually update the data sources that have been created and change the currentSQLID Custom Property to the correct value.

You can edit all key parameters, such as the database name, whether or not to create tables, the data source runtime user name, and the user name and password for the data source to connect to the database.

Note: For DB2 for z/OS databases, the database name is the database subsystem name. For other versions of DB2, the database name is the MONITOR database name. For Oracle databases, the database name is the Oracle System ID.

You can select which database to use for the given component.

The **Create tables** option is not available if you are using a DB2 for z/OS or an Oracle database provider.

For Oracle, the **Schema** field is disabled and empty, and the **User name** is not pre-filled with the common database user name. You must enter a user name and password for each data source.

Note: No validation takes place to ensure that user names are unique, so be aware that you might create a duplicate user name, resulting in table conflicts.

10. On the Security page, enter the user IDs and passwords that are needed to configure the IBM Business Monitor components. The IBM Business Monitor feature provides the following entries:

Component	ID and Password
Authentication alias for the CEI event service JMS resources	Specify the user ID and password to use to secure the default common event infrastructure (CEI) service integration bus.
Cognos Administration access authentication	Specify a user ID and password with administrative rights to the IBM Cognos BI service. (Displayed only if IBM Cognos BI has been installed and not yet configured.)

If you selected other product features for this topology, other feature-specific entries might also appear here.

11. Optional: If the Business Process Choreographer page is displayed, set parameters for the Business Process Choreographer configuration and then click **Next** to display the Web application context roots page. On this page you specify the values for:
 - Security roles
 - Authentication aliases
12. Optional: If the Web application context roots page is displayed, set the context root for component-based web applications in your deployment environment or accept the system-provided default values for the context roots. Then click **Next** to display the Summary page.

The table contains the following control information.

Web Application

The name of the web application.

Some of the components that are part of the deployment environment you are creating contain web applications. The **Web application** column can include the following components:

- Business Process Choreographer Explorer
- Business Space
- Business Process Rules Manager

Context Root

The current value of the context root for the component.

By default, the default context root for the web application applies. You can change the context roots by typing over the value in the **Context Root** field.

Note: The Business Space context root is read only and cannot be edited.

13. Verify that the information on the Summary page is correct and click **Finish and Generate Environment** to save and complete the configuration of the deployment environment. To exit without completing the configuration, click **Finish**.
Clicking **Finish** saves the deployment environment configuration - but does not generate it.
Click **Cancel** cancels the deployment configuration and does not save the configuration.
14. If you clicked **Finish and Generate Environment** to generate a deployment environment, stop and restart all clusters, nodes, and the deployment manager.

If you selected not to generate the environment at the end of the deployment environment configuration wizard (by clicking **Finish** rather than **Finish and Generate Environment**), you can view the deployment environment configuration at **Server > Deployment Environments > name of deployment environment**. From there, you can click **Generate** to generate the environment. When the configuration completes, you can examine the configuration files to view the changes.

Either save the changes to the master configuration or discard them. If you click a deployment environment in the list, and there are still configuration steps to perform, you will see a list of deferred configuration steps. After generating a deployment environment, stop and restart all clusters, nodes, and the deployment manager.

Important: The cluster that will be running the IBM Cognos BI service requires that each cluster member be started individually. You must wait for the IBM Cognos BI service to initialize fully before starting the next cluster member.

Adding an IBM Business Monitor deployment environment to an IBM Business Process Manager server deployment environment

To add an IBM Business Monitor deployment environment on top of an existing IBM Business Process Manager deployment environment using the deployment environment configuration wizard, there are some additional steps to perform.

You must either install and register the IBM BPM widgets into the IBM Business Monitor Business Space (the easiest and therefore preferred method) or install and register the IBM Business Monitor widgets into the IBM BPM Business Space.

Create the IBM Business Monitor deployment environment following the steps in the "Creating the deployment environment using a pattern" parent topic.

Next, either install the IBM BPM widgets into the IBM Business Monitor Business Space or install the IBM Business Monitor widgets into the IBM BPM Business Space. The first is the easiest and therefore the preferred method.

Installing IBM Business Process Manager widgets into IBM Business Monitor Business Space

To install IBM Business Process Manager widgets into IBM Business Monitor Business Space, install the widgets and then register the Representational State Transfer (REST) service endpoints to the widgets.

After you have generated the deployment environment, complete the following steps:

1. Install the IBM BPM Business Space widgets into the IBM Business Monitor deployment environment. The Business Space widgets are located under the IBM BPM root directory (such as IBM/BPM) /BusinessSpace/registryData/product_name/widgets. To install IBM BPM-only widgets, specify *BPM_install_root*/BusinessSpace/registryData/BPM/widgets as the value for the **-widgets** parameter. For example:

```
AdminTask.installBusinessSpaceWidgets('[-clusterName cluster_name -widgets
install_root/BusinessSpace/registryData/BPM/widgets/]
```

2. Register the REST service endpoints to the widgets. The REST services are only available on the IBM BPM clusters and they must be registered in the IBM Business Monitor cluster so that the widgets can be used from the IBM Business Monitor Business Space.

You can register the REST service endpoints either in the administrative console or from the command line. Follow the instructions in the "Configuring Business Space and registering REST endpoints on the administrative console" or "Registering Business Space widget REST service endpoints using the command line" related tasks.

- For the **-clusterName** parameter, specify the IBM BPM cluster name where the REST services are installed.
- For the **-businessSpaceClusterName** parameter, specify the cluster where IBM Business Monitor Business Space is installed.

The following examples use Jython.

- For a single-cluster environment:

```
AdminTask.registerRESTServiceEndpoint('[-clusterName <WPS cluster name> -type
"{com.ibm.bpm}BFM" -businessSpaceClusterName <Monitor cluster name>']')
```

- For a four-cluster environment, where IBM Business Monitor Business Space is installed on the web cluster of the deployment environment:

```
AdminTask.registerRESTServiceEndpoint('[-clusterName WPSCluster.AppTarget -type
"{com.ibm.bpm}BFM" -businessSpaceClusterName MonCluster.WebTarget]')
```

Installing IBM Business Monitor widgets into BPM Business Space

To install IBM Business Monitor widgets into IBM Business Process Manager Business Space, install the widgets, register the Representational State Transfer (REST) service endpoints to the widgets, and complete the IBM Cognos Business Intelligence widgets endpoint configuration.

After you have generated the deployment environment, complete the following steps:

1. Install the IBM Business Monitor Business Space widgets into the IBM BPM deployment environment.

```
AdminTask.installBusinessSpaceWidgets('[-clusterName cluster_name -widgets
install_root/BusinessSpace/registryData/WBM/widgets/']')
```

2. Register the REST service endpoints to the widgets. The REST services are only available on the IBM BPM clusters and they must be registered in the IBM Business Monitor cluster so that the widgets can be used from the IBM Business Monitor Business Space.

You can register the REST service endpoints either in the administrative console or from the command line. Follow the instructions in the "Configuring Business Space and registering REST endpoints on the administrative console" or "Registering Business Space widget REST service endpoints using the command line" related tasks.

- For the **-clusterName** parameter, specify the IBM BPM cluster name where the REST services are installed.
- For the **-businessSpaceClusterName** parameter, specify the cluster where IBM Business Monitor Business Space is installed.

The following examples use Jython.

- For a single-cluster environment:

```
AdminTask.registerRESTServiceEndpoint('[-clusterName <WPS cluster name> -type
"{com.ibm.bpm}BFM" -businessSpaceClusterName <Monitor cluster name>']')
```

- For a four-cluster environment, where IBM Business Monitor Business Space is installed on the web cluster of the deployment environment:

```
AdminTask.registerRESTServiceEndpoint('[-clusterName WPSCluster.AppTarget -type
"{com.ibm.bpm}BFM" -businessSpaceClusterName MonCluster.WebTarget']')
```

3. Complete the IBM Cognos BI widgets service endpoint configuration by following the instructions in "Configuring IBM Business Monitor and Business Space to use an existing IBM Cognos BI service."

Creating the deployment environment using custom topology

Instead of using one of the provided deployment environment patterns, you can set up your own clusters and configure the IBM Business Monitor components in a network deployment (ND) topology.

Before creating clusters and configuring the IBM Business Monitor components, ensure that you have performed the following tasks:

- You have installed IBM Business Monitor.
- You have created the IBM Business Monitor deployment manager profile or augmented an existing deployment manager profile with IBM Business Monitor.
- You have created the MONITOR database.
- You have started the deployment manager.
- You have created and federated at least one IBM Business Monitor custom profile or augmented an existing custom profile with IBM Business Monitor.
- You have started the custom profile or profiles.

The following instructions describe how to create clusters, configure the common event infrastructure (CEI) event service, and install and configure the required components using the configuration wizard or the wsadmin commands.

Creating IBM Business Monitor clusters

In a network deployment (ND) environment, IBM Business Monitor components must be deployed to clusters.

Before creating clusters and configuring the IBM Business Monitor components, ensure that you have performed the following tasks:

- You have installed IBM Business Monitor.
- You have created the IBM Business Monitor deployment manager profile or augmented an existing deployment manager profile with IBM Business Monitor.
- You have created the MONITOR database.
- You have started the deployment manager.
- You have created and federated at least one IBM Business Monitor custom profile or augmented an existing custom profile with IBM Business Monitor.
- You have started the custom profile or profiles.

Use an existing custom profile to create the first cluster member. You can add as many additional cluster members as you want in each cluster that you create (see "Adding cluster members"). To create the IBM Business Monitor cluster, complete the following steps from the administrative console:

1. In the navigation panel, click **Servers > Clusters > WebSphere application server clusters**.
2. Click **New** to start the Create a new cluster wizard.
3. Specify a name for the cluster.
4. Select **Prefer local** to enable host-scoped routing optimization. This setting improves performance by looking up EJBs in a cluster member on the same node whenever possible.
5. Click **Next** to proceed to the Create first cluster member step.
6. Specify the name of the first cluster member.
7. Specify a node for the first cluster member. This node must be an IBM Business Monitor node.
8. Select the option to **Create the member using an application server template**.
9. Select an application server template containing the text *defaultWBM* in the name, and click **Next**.

Important: If there is no template with *defaultWBM* in the name, make sure that you have selected a node that has been augmented with IBM Business Monitor.

If the first cluster member is not created using an application server template with *defaultWBM* in the name, your IBM Business Monitor environment will not function properly, and you will have to delete all the existing cluster members and re-create the first cluster member.

10. Click **Next** to proceed to the Create additional cluster members step.
11. Optional: To add additional cluster members, complete the following steps for each cluster member:
 - a. Specify a unique name for the additional member. The name must be unique within the node.
 - b. Specify a node for the additional cluster member. This node must be an IBM Business Monitor node.
 - c. Click **Add member**.
12. Click **Next** to proceed to the summary panel.
13. Review the information and click **Finish**.
14. Click **Save** to save changes to the master configuration.

After initially creating a cluster, you can add additional cluster members at any time.

To start a cluster the first time after the IBM Cognos Business Intelligence service is installed, start each server individually. Do not use the ripplestart option, because this option does not give IBM Cognos BI enough time to initialize.

The administrative console might report issues when you first start the IBM Cognos Business Intelligence server. The initialization of each server instance in the IBM Cognos Business Intelligence content store database and disk area during the first startup takes much longer than a normal IBM Cognos Business Intelligence startup.

Adding cluster members

You can add as many cluster members as you want to an existing cluster.

Important: If the first cluster member is not created using an application server template with defaultWBM in the name, your IBM Business Monitor environment will not function properly, and you will have to delete all the existing cluster members and re-create the first cluster member.

To create additional cluster members, complete the following steps:

1. In the navigation panel, click **Servers > Clusters > WebSphere application server clusters > *cluster_name* > Cluster members**.
2. Click **New** to start the Create new cluster members wizard.
3. For each new cluster member, complete the following steps:
 - a. Specify a unique name for the additional member. The name must be unique within the node.
 - b. Specify a node for the additional cluster member. This node must be an IBM Business Monitor node.
 - c. Click **Add member**.
4. Click **Next** to proceed to the summary panel.
5. Review the information and click **Finish**.
6. Click **Save** to save changes to the master configuration.

Note: During the IBM Business Monitor installation, the Cognos service is also installed on the node and will be configured on the new server when a member is added to a cluster.

Federating additional nodes

After you have created a high availability environment in a network deployment cell, you can federate additional nodes into the cell at a later time if needed.

Important: IBM Business Monitor does not support portal-based dashboards in the same cell as IBM Business Monitor server v8.0.

To federate existing nodes into the deployment manager, complete the following steps for each node:

1. Start the deployment manager.
2. From the profile directory corresponding to the node you want to federate, run the **addNode** command, specifying the host name of the deployment manager and optionally, the SOAP connector port number of the deployment manager.

```
profile_root\bin\addNode.bat dmgr_host_name [dmgr_soap_port]
```

```
profile_root/bin/addNode.sh dmgr_host_name [dmgr_soap_port]
```

To run the command with tracing enabled, use the **-trace** option; for example: **addNode host_name -trace**

For additional details on how to run the **addNode** command, see the related information in the WebSphere Application Server information center.

Configuring CEI event services

Before configuring the IBM Business Monitor components using the administrative console, you must have a Common Event Infrastructure (CEI) event service in your network deployment cell that IBM Business Monitor can use to send events. The same CEI event service can also be used to receive events.

If you created a stand-alone profile for IBM Business Monitor or used the deployment environment configuration wizard, a CEI event service has already been created for you. If you are adding IBM Business Monitor on Process Server topology, you can use the CEI event service that is deployed by Process Server for IBM Business Monitor. Otherwise, follow the instructions on this page to create a new CEI event service.

Use the **wbmDeployCEIEventService** command to install a CEI event service on a server or cluster and create the resources it requires (the service integration bus and messaging engine). You can also configure security and enable the default CEI event service data store if required. (The event service data store is not recommended for production environments.) In the core topology for high availability, the CEI event service is installed on the support cluster.

To install and configure a new CEI event service, complete the following steps:

1. Open a command prompt, and change directories to the **bin** directory of the deployment manager profile (by default, DMGR01) where WebSphere Application Server is installed, or to the **bin** directory of the stand-alone profile in a single-server environment.
2. Launch **wsadmin** by running the following command:
 - **wsadmin.sh**
 - **wsadmin.bat**
3. Run the **wbmDeployCEIEventService** command interactively by entering the following command:

```
(jacl) $AdminTask wbmDeployCEIEventService {-interactive}
(jython) AdminTask.wbmDeployCEIEventService('-interactive')
```

Alternatively, you can run the command by providing all the parameters. For an example, see "Configuring IBM Business Monitor components using wsadmin commands" in the related links.

4. Save the results using the following command:

```
(jacl) $AdminConfig save
(jython) AdminConfig.save()
```
5. To synchronize the nodes, in the administrative console, click **System administration > Nodes**, select all of the nodes, and click **Full Resynchronize**.
6. Restart the deployment manager to see the CEI links show up in the administrative console.

The CEI event service is enabled.

For a full list of parameters and an example, see IBM Business Monitor CEI event service

If you did not perform the data store step while running **wbmDeployCEIEventService**, you can optionally create the data store for the CEI event service later.

Configuring the environment using the configuration wizard

You can configure the required IBM Business Monitor environment using the configuration wizard in the administrative console.

You must have completed the following tasks:

- Created and federated at least one IBM Business Monitor custom profile or augmented an existing custom profile with IBM Business Monitor (see "Creating and augmenting profiles").
- Created at least one cluster using the **defaultWBM** application server template (see "Creating IBM Business Monitor clusters").
- Configured a local Common Event Infrastructure (CEI) event service that IBM Business Monitor can use to send and receive events (see "Configuring CEI event services").

Before starting the configuration process, make sure that you are synchronizing node changes automatically (in the administrative console, click **System Administration > Console Preferences** and select **Synchronize changes with Nodes**). Otherwise, you must synchronize changes manually after each major step.

You can configure the required and optional components using the IBM Business Monitor configuration section of the administrative console. For instructions to manually configure all of the IBM Business Monitor components, use the related information links to access the task information.

1. In the navigation panel, click **Servers > IBM Business Monitor configuration**. A list of required and optional components is displayed. Review the status of each component. If you have an ND environment and have not configured a deployment environment, none of the components will be installed or configured, and you must complete the remaining steps to install and configure the components.
2. Configure the outbound CEI event service by completing the following steps. The outbound CEI event service is used to send events from IBM Business Monitor, including alerts. You must configure an event emitter factory to point to the outbound CEI event service.

Important: Before configuring the event emitter factory, you must have a local CEI service that IBM Business Monitor can use to send events. If you need to create a local CEI service, see “Configuring CEI event services” on page 116 for instructions.

- a. In the list of components, click **Outbound CEI event service**. The status for the outbound CEI event service and event emitter factory is displayed. If you have an existing `MonitorEmitterFactory`, the name of the CEI event service that the emitter factory is configured to use is listed in the status box. If you have not already configured the emitter factory, you will see the message “Local CEI event service exists, but event emitter factory does not exist.” In that case, you must create and configure the emitter factory.
 - b. Under **Configure an event emitter factory**, select the server or cluster for the event emitter factory. All available servers and clusters are listed. You can select only servers that have a CEI event service configured. (The available servers and clusters are shown with asterisks (*)). If you have more than one server with the same name, be sure to choose the server on the correct node.
 - c. To launch the configuration wizard, click **Configure the Event Emitter Factory**. An outbound event emitter factory named `MonitorEmitterFactory` is created for the cell. The status box for the outbound CEI event service is updated to indicate the CEI event service that the `MonitorEmitterFactory` is configured to use.
 - d. Return to the configuration page by clicking **IBM Business Monitor configuration** in the breadcrumb listing.
3. Create the service integration bus and configure the messaging engine by completing the following steps. IBM Business Monitor requires its own bus and messaging engine before it can monitor events.

If you do not have an existing bus, one is created for you when you configure the messaging engine. The bus is named **MONITOR.<cell_name>.Bus** and the name cannot be changed.

- a. In the list of components, click **Messaging engine**. The status for the service integration bus and the messaging engine is displayed.
- b. To launch the configuration wizard, click **Configure the Messaging Engine**.
- c. On the **Select a bus member** panel, choose one of the following options to select the location where the messaging engine will be created, and click **Next**:
 - **Cluster:** Choose this option to create the messaging engine on an existing cluster. You must select the cluster name from the list.
 - **Server:** Choose this option to create the messaging engine on a server. You must select the server from the list. If you have more than one server with the same name, be sure to choose the server on the correct node.

- d. On the **Select the type of message store** panel, choose one of the following options, and click **Next**:
 - **Data store**: A data store is a message store that contains a set of tables that are accessible to all members of the cluster that hosts the messaging engine.
 - **File store**: A file store is a message store that uses files in a file system through the operating system. This option is not available if you chose **Cluster** on the **Select a bus member** panel.
 - e. If you are using a data store, choose one of the following options on the **Provide the message store properties** panel:
 - **Create a default data source with generated JNDI name**: By default, the data store uses Derby. This option is not available if you selected **Cluster** on the **Select a bus member** panel.
 - **Use an existing data source**: If you select this option, complete the following fields:
 - **Data source JNDI name**: Select the JNDI name that corresponds to the database that you are planning to use. For example, `jdbc/wbm/MonitorMEDatabase`.
 - **Schema name**: Enter the schema name. For example, `MONME00`.
 - **Authentication alias**: Select the authentication alias that you are planning to use. You must select the authentication alias if you want the tables to be created. For example, `Monitor_JDBC_Alias`.
 - **Create tables**: Select this option to create the tables in the database. If you do not select this option, the database administrator must create the tables.
 - f. On the **Confirm** panel, review the information and click **Finish** to complete the configuration. The bus and messaging engine status boxes are updated with the new configuration information.

Note: You might have to wait a few moments for the messaging engine to start successfully.
 - g. Return to the configuration page by clicking **IBM Business Monitor configuration** in the breadcrumb listing.
4. Verify that the bus and messaging engine have the correct user ID for your environment:
 - a. In the navigation panel, click **Security > Bus Security**.
 - b. Click the bus for the IBM Business Monitor server. The Buses configuration properties page is displayed.
 - c. Under Additional Properties, click **Security**. Another properties page is displayed.
 - d. Under Authorization Policy, click **Users and groups in the bus connector role**.
 - e. Verify that your user ID exists. If it does not exist, complete these steps to add it:
 - 1) Click **New**.
 - 2) Select **Users**, and enter a filter that will find your user ID. Click **Next**.
 - 3) Select your ID from the list and click **Next**.
 - 4) Review the changes and click **Finish**.
 - f. Return to the configuration page by clicking **IBM Business Monitor configuration** in the breadcrumb listing.
 5. Install the IBM Business Monitor action services application by completing the following steps. The action services application invokes actions, such as sending dashboard alerts or email notifications, when it receives defined situation events emitted by and other applications. Situation events typically indicate business situations that need attention, such as a printer running out of paper or a metric exceeding a certain value.
 - a. In the list of components, click **Action services**. The status for the application is displayed. If the application is properly installed, the location of the installed application is listed in the status box.
 - b. Under **Deploy action services**, select the server or cluster for the action services application from the list. All available servers and clusters are listed. You must select a server where IBM Business Monitor has been installed. If you have more than one server with the same name, be sure to choose the server on the correct node.

- c. To install the application, click **Deploy Action Services**. The application is installed and the Monitor action services group profile is created. The application status box is updated with the location of the installed application, named IBM_WBM_ACTIONSERVICES. If this application has been installed to a cluster, the application will appear unavailable until all nodes in the cluster have been synchronized.
 - d. Return to the configuration page by clicking **IBM Business Monitor configuration** in the breadcrumb listing.
6. Install the Monitor scheduled services application by completing the following steps. You must install this application to schedule recurring services, such as the data movement service and the key performance indicator (KPI) history for monitor models.
 - a. In the list of components, click **Monitor scheduled services**. The status for the application is displayed. If the application is properly installed, the location of the installed application is listed in the status box.
 - b. Under **Deploy Monitor Scheduled Services**, select the server or cluster for the Monitor scheduled services application from the list. All available servers and clusters are listed. You must select a server where IBM Business Monitor has been installed. If you have more than one server with the same name, be sure to choose the server on the correct node.
 - c. To install the application, click **Deploy Monitor Scheduled Services**. The application status box is updated with the location of the installed application, named IBM_WBM_DATA_SERVICES. If this application has been installed to a cluster, the application will appear unavailable until all nodes in the cluster have been synchronized.
 - d. Return to the configuration page by clicking **IBM Business Monitor configuration** in the breadcrumb listing.

You can view the scheduled services for each installed monitor model by clicking **Applications > Monitor services > Monitor scheduled services**

7. Optional: If you plan to use the IBM Cognos Business Intelligence service to conduct multidimensional analysis on your dashboards, in the list of optional components, click **Cognos**. The status for the service is displayed. If the service is properly installed, the location of the installed service is listed in the status box. (If you installed IBM Cognos BI with IBM Business Monitor and created a stand-alone profile, the IBM Cognos BI service is already deployed.)
 - a. To deploy a new IBM Cognos BI service, select the server or cluster for the IBM Cognos BI service from the list. All available servers and clusters are listed. (The available servers and clusters are shown with asterisks (*)). If you have more than one server with the same name, be sure to choose the server on the correct node.

Provide a database name to be used for the content store. On DB2 and Microsoft SQL Server, the database name must be different from the MONITOR database name. Provide a database user name and password. If you use the same user name for the content store as for the MONITOR database, you must use the same password. Because the database user provided for accessing the content store database must have privilege to create tables in the database, it is recommended that you create a new database user for the content store database only.

Note: The user name and password for the IBM Cognos BI content store database are kept in the Cognos_JDBC_Alias, which allows all database credentials to be maintained in one place. Whenever you start the IBM Business Monitor IBM Cognos BI server, the current values are passed to the IBM Cognos BI configuration to allow IBM Cognos BI access to the content store. Because of this integration, you cannot change the content store user name and password using the IBM Cognos BI Configuration application. If administrative security is enabled, you must also provide the IBM Cognos BI administrator user name and password.

Click **Create a New Cognos Service**. The status box is updated with the location of the installed service. If this service has been installed to a cluster, the service will appear unavailable until all nodes in the cluster have been synchronized and restarted. If the deployment takes more time

than is provided by the administrative console response timeout, you might see a timeout message. Wait a few more minutes before attempting to restart the servers.

- b. If you already have an existing version of IBM Cognos BI installed, under **Use an existing Cognos service**, provide the external dispatcher URI of the IBM Cognos BI server. You can find this URI in the IBM Cognos BI configuration client in **Local Configuration > Environment > Dispatcher Settings** (for example, `http://my_host:my_port/p2pd/servlet/dispatch/ext`). If administrative security is enabled on the IBM Cognos BI server, you must also provide the IBM Cognos BI administrator user name and password.
Click **Use an Existing Cognos Service**. The status box is updated with the location of the installed service.
 - c. Return to the configuration page by clicking **IBM Business Monitor configuration** in the breadcrumb listing.
8. Optional: If you plan to use the IBM Business Monitor dashboards on mobile devices, you must install the application by completing the following steps. If you do not plan to use the dashboards on mobile devices, you are not required to complete these steps.
- a. In the list of optional components, click **Dashboards for mobile devices**. The status for the application is displayed. If the application is properly installed, the location of the installed application is listed in the status box.
 - b. Under **Deploy Dashboards for mobile devices**, select the server or cluster for the dashboards on mobile devices application from the list. All available servers and clusters are listed. You must select a server where IBM Business Monitor has been installed. If you have more than one server with the same name, be sure to choose the server on the correct node.
 - c. To install the application, click **Deploy the Dashboards for Mobile Devices**. The application status box is updated with the location of the installed application, named `IBM_WBM_MOBILE_DASHBOARD`. If this application has been installed to a cluster, the application will appear unavailable until all nodes in the cluster have been synchronized.
 - d. Return to the configuration page by clicking **IBM Business Monitor configuration** in the breadcrumb listing.
9. Optional: If you plan to use the Java Messaging Service (JMS) and Representational State Transfer (REST) event emitter services, you must install the API service applications by completing the following steps. Rather than coding or generating Common Base Events directly, you can then use these event emitter services. You provide the event XML, and the event emitter services receive the event XML and wrap it in a Common Base Event so that IBM Business Monitor can process it.
- a. In the list of optional components, click **Inbound event emitter services (JMS and REST)**. The status for the applications is displayed. If the application are properly installed, the locations of the installed applications are listed in the status box.
 - b. Under **Deploy event emitter services**, select the server or cluster for the applications from the list. All available servers and clusters are listed. You must select a server where IBM Business Monitor has been installed. If you have more than one server with the same name, be sure to choose the server on the correct node.
 - c. To install the applications, click **Deploy Event Emitter Services**. The application status box is updated with the locations of the installed applications. If the applications have been installed to a cluster, the applications will appear unavailable until all nodes in the cluster have been synchronized.
 - d. Return to the configuration page by clicking **IBM Business Monitor configuration** in the breadcrumb listing.
10. Optional: To configure the Representational State Transfer (REST) Services Gateway for widgets for Business Space, complete the following steps.

Note: Because the REST Services Gateway is a shared component, you cannot configure it using the configuration wizard. If you create clusters using the deployment environment configuration wizard,

or create a stand-alone profile, the REST Services Gateway is configured for you. The REST Services Gateway must be deployed and registered with Business Space before your team can use the widgets in Business Space.

- a. In the administrative console, click **Servers > Server Types > WebSphere application servers** or **Servers > Clusters > WebSphere application server clusters**.
- b. Click the name of your server or cluster.
- c. On the Configuration page, under **Business Integration**, click **Rest Services**.

11. Optional: To configure Business Space, complete the following steps.

Note: Because Business Space is a shared component, you cannot configure it using the configuration wizard. If you create clusters using the deployment environment configuration wizard, or create a stand-alone profile, Business Space is configured for you.

- a. In the administrative console, click **Servers > Server Types > WebSphere application servers** or **Servers > Clusters > WebSphere application server clusters**.
- b. Click the name of your server or cluster.
- c. On the Configuration page, under **Business Integration**, click **Business Space Configuration**.

12. After you have finished configuring components, synchronize the nodes. In the administrative console, click **System administration > Nodes**, select all of the nodes, and click **Full Resynchronize**. Then stop and restart all of the clusters and servers.

To verify that all applications are correctly installed and configured, log out of the administrative console. Then, log in to the administrative console and navigate to **Servers > IBM Business Monitor configuration**. Verify that all items are complete and marked with a green check icon.

If you did not choose to create the messaging engine tables, or did not have permission to create them, the tables must be created manually by a database administrator. See "Creating messaging engine tables manually" in the related links.

If you want to receive events from a CEI event source that is running on a remote server, you must also perform cross-cell configuration. See "Configuring how to receive events" for instructions.

Configuring the environment using wsadmin commands

Rather than using the configuration wizard, you can configure the IBM Business Monitor environment using the WebSphere command-line administration tool (wsadmin).

The following wsadmin commands are required to configure IBM Business Monitor.

Table 7. Required wsadmin commands

Command	Purpose
wbmDeployCEIEventService	Creates and configures the CEI event service that IBM Business Monitor requires to receive and send events.
wbmConfigureEventEmitterFactory	Configures the event emitter factory that IBM Business Monitor requires to generate and send events. This command must be run after the wbmDeployCEIEventService command.
wbmDeployMessagingEngine	Installs and configures the messaging engine and service integration bus required for IBM Business Monitor.
wbmDeployActionServices	Installs the IBM Business Monitor action services application. This application invokes actions, such as sending dashboard alerts or email notifications, when it receives defined situation events. This command must be run after the wbmConfigureEventEmitterFactory command.

Table 7. Required wsadmin commands (continued)

Command	Purpose
wbmDeployScheduledServices	Installs the Monitor scheduled services application that schedules recurring services, such as the data movement service and the key performance indicator (KPI) history for monitor models.

The following wsadmin commands are optional.

Table 8. Optional wsadmin commands

Command	Purpose
wbmDeployCognosService wbmSetCognosDispatcher	Installs a new IBM Cognos Business Intelligence service for multidimensional analysis, or connects to an existing IBM Cognos BI service.
wbmSetCognosDatabaseUser wbmSetCognosAdminUser	Changes the passwords for the IBM Cognos BI content store database and the IBM Cognos BI administrator.
wbmRemoveCognosService	Removes the IBM Cognos BI service that was installed with IBM Business Monitor.
wbmDeployDashboardsForMobileDevices	Installs and configures the application that is required for running the dashboards on mobile devices.
wbmDeployEventEmitterServices	Installs and configures the REST event emitter service and the JMS event emitter service applications. The JMS event emitter can asynchronously publish XML events to a Java Messaging Service (JMS) queue without the Common Base Event wrapper, so that XML events can be put on the JMS queue even when IBM Business Monitor services are unavailable. The REST event emitter can synchronously publish events without the Common Base Event wrapper. You define the XSD that describes the structure of the business information, and the REST API generates and sends the event in the correct format for IBM Business Monitor.
wbmDeployBPMEmitterService	Installs and configures the IBM Business Process Manager event emitter service application for use by IBM BPM.
wbmConfigureQueueBypassDatasource	Creates the data source needed to enable queue bypass communication when IBM Business Monitor is installed in a different cell from the CEI server.

To run the wsadmin tool, complete the following steps:

1. Open a command prompt, and change directories to the **bin** directory of the deployment manager profile (by default, DMGR01) where WebSphere Application Server is installed, or to the **bin** directory of the stand-alone profile in a single-server environment.
2. Launch **wsadmin** by running one of the following commands:
 - **wsadmin.sh -lang jacl -user <user_name> -password <password>**
 - **wsadmin.sh -lang jython -user <user_name> -password <password>**
 - **wsadmin.bat -lang jacl -user <user_name> -password <password>**
 - **wsadmin.bat -lang jython -user <user_name> -password <password>**
3. Run the commands you need. The following example uses Jacl to run the **wbmConfigureEventEmitterFactory** command and then save the changes:

```
$AdminTask wbmConfigureEventEmitterFactory {-cluster firstCluster}  
$AdminConfig save
```

The following example uses Jython:

```
AdminTask.wbmConfigureEventEmitterFactory('[-cluster firstCluster]')  
AdminConfig.save()
```

4. After running the commands, save the changes before exiting wsadmin. To save the changes, use the following syntax:
(jacl) \$AdminConfig save
(jython) AdminConfig.save()
5. In a network deployment environment, synchronize the nodes. In the administrative console, click **System administration > Nodes**, select all of the nodes, and click **Full Resynchronize**. Then stop and restart all of the clusters and servers.

Interactive mode

When you use an administrative command in interactive mode, you go through a series of steps to collect your input interactively. This process provides a text-based wizard and a similar user experience to the wizard in the administrative console. If you use the **-interactive** parameter, you are prompted to enter each value in turn.

The following examples show how to use this parameter.

```
(jacl) $AdminTask wbmConfigureEventEmitterFactory {-interactive}  
(jython) AdminTask.wbmConfigureEventEmitterFactory('-interactive')
```

You can use the **help** command to obtain help for any administrative command.

```
(jacl) $AdminTask help wbmConfigureEventEmitterFactory  
(jython) print AdminTask.help ('wbmConfigureEventEmitterFactory')
```

For the details and parameters of the commands, see Configuration commands (wsadmin).

Configuring the environment manually

You should always use the IBM Business Monitor configuration wizard or deployment environment configuration wizard to configure the IBM Business Monitor environment. This manual information is included to help in advanced or troubleshooting scenarios.

Configuring the event emitter factory for IBM Business Monitor for z/OS

IBM Business Monitor uses an outbound CEI event service to create and send events. The event service in turn uses an event emitter factory that requires configuration. The preferred way to install the event emitter factory is to use the IBM Business Monitor configuration wizard, the deployment environment configuration wizard, or the wsadmin task. It is also possible to configure the event emitter factory manually.

Complete the following steps from the deployment manager administrative console:

1. In the navigation panel, click **Service integration > Common Event Infrastructure > Event emitter factories > Default Common Event Infrastructure**.
2. Under Additional Properties, click **Event Service Transmission**.
3. Select your event service from the **Event service** list, and click **OK**.
4. Click **Save** to save all changes to the master configuration.
5. In the navigation panel, click **Service integration > Common Event Infrastructure > Event emitter factories**.
6. Select **cell** for the **Scope**.
7. Click **New**.

8. Type *factory_name* for the **Name**. Where *factory_name* can be any name you choose. For example, MonitorEmitterFactory.
9. Type **com/ibm/monitor/MonitorEmitterFactory** for the **JNDI Name**.
10. Under **Event transmission**:
 - a. Select the check box **Support event service transmission**.
 - b. From the list in the **JNDI name for event service transmission** field, select **Use entry from below**.
 - c. In the entry field below the **JNDI name for event service transmission** field, enter one of the following options:
 - Cluster: **cell/clusters/*cluster_name*/com/ibm/events/configuration/bus-transmission/Default**
Where:
cluster_name represents the cluster where the CEI is deployed.
 - Server: **cell/nodes/*node_name*/servers/*server_name*/com/ibm/events/configuration/bus-transmission/Default**
Where:
node_name represents the node where the CEI is deployed
server_name represents the server where the CEI is deployed.
11. Clear the **Compatibility mode with previous event service transmission protocol** check box.
12. Click **OK**, and click **Save** to save changes to the master configuration.

Installing the IBM Business Monitor action services application

The IBM Business Monitor action services application invokes actions, such as sending dashboard alerts or email notifications, when it receives defined situation events emitted by IBM Business Monitor and other applications. Situation events typically indicate business situations that need attention, such as a printer running out of paper or a metric exceeding a certain value.

Before installing monactionmgr.ear, you must enable CEI and the Startup Beans Service on the server where you are installing the action services application.

Complete the following steps to install the action services application using the administrative console:

1. In the navigation panel, click **Applications > Application types > WebSphere enterprise applications**.
2. Click **Install**.
3. Choose one of the following options for the **Path to the new application**:
 - **Local file system**: Choose this option if the file is on the local system.
 - **Remote file system**: Choose this option if you are accessing the administrative console using a web browser on a different system.
4. Click **Browse**, and browse to select the monactionmgr.ear file, and click **Next**. The EAR files are located in the following directory after installation:

monitor_root/installableApps.wbm

 Where:
 monitor_root represents the directory where IBM Business Monitor is installed
5. On the Select installation options panel, click **Next**.
6. On the Map modules to servers panel, click *server_name* or *cluster_name* where you want to install the application.
7. Select the check boxes on the rows associated with each module, and click **Apply**.
8. Click **Next**.
9. Review the summary information and click **Finish**.

Creating the Monitor action services group profile

After you have installed the Monitor action services application, you must create an event group profile to receive events.

Before beginning this task, you must have completed the following tasks:

- Installed the Monitor action services application
- Configured common event infrastructure (CEI) event services for IBM Business Monitor
- Started the deployment manager

Using the administrative console, complete the following steps to create the event group profile:

1. In the navigation panel, click **Service integration > Common Event Infrastructure > Event service**.
2. Under Additional Properties, click **Event services**.
3. Click **Default Common Event Infrastructure event server**.
4. Under Additional Properties, click **Event groups**.
5. Click **New**.
6. Type **Action Services Group Profile** for the Event group name.
7. Type **CommonBaseEvent[extendedDataElements/@name = 'BusinessSituationName']** for the **Event selector string**.
8. Click **Apply**.
9. Under Additional Properties, click **Distribution queues**.
10. Click **New**.
11. Select **jms/ActionManager/queue** from the **Queue JNDI name** drop-down list.
12. Select **jms/ActionManager/QueueConnFactory** from the **Queue connection factory JNDI name**.
13. Click **Apply**.
14. Click **Save** to save changes to master configuration.

Installing Monitor scheduled services

The Monitor scheduled services application supports multiple services, some of which optimize performance or are used for base processing. You can configure it on the WebSphere Application Server administrative console. You must install this application to schedule recurring services, such as the data movement service and the key performance indicator (KPI) history for monitor models.

Complete the following steps to install the Monitor scheduled services application:

1. In the navigation panel, click **Applications > Application types > WebSphere enterprise applications**.
2. Click **Install**.
3. Choose one of the following options for the **Path to the new application**:
 - **Local file system**: Choose this option if the file is on the local system.
 - **Remote file system**: Choose this option if you are accessing the administrative console using a web browser on a different system.
4. Click **Browse**, and browse to select the **MonitorDataServices.ear** file, and click **Next**. The EAR files are located in the following directory after installation:

monitor_root/installableApps.wbm

Where:

monitor_root represents the directory where IBM Business Monitor is installed

5. On the Select installation options panel, click **Next**.
6. On the Map modules to servers panel, click **server_name** or **cluster_name** where you want to install the application.

7. Select the check boxes on the rows associated with each module, and click **Apply**.
8. Click **Next**.
9. Review the summary information and click **Finish**.

In a network deployment environment, after installing the Monitor scheduled services application, you must create a scheduler resource on the same cluster. Follow the instructions in "Creating and configuring a scheduler resource."

Creating and configuring a scheduler resource:

A scheduler resource is a component that drives the scheduler processing by delegating work to the local work manager, which is created at the cell scope during the installation. In a stand-alone server environment, a scheduler resource is created for you during the IBM Business Monitor installation. In a network deployment environment, you must create a scheduler resource on the same server or cluster as the MonitorDataServices.ear file. This topic provides the steps for creating a scheduler resource using the administrative console.

You must first have installed the Monitor scheduled services, following the instructions in the link below.

After installing the scheduled services, use the steps below to create a scheduler resource for a server or cluster.

1. On the administrative console navigation panel, click **Resources > Schedulers**.
2. In the **Scope** field, select a server or cluster scope. It must be the same server or cluster as the MonitorDataServices.ear file.
3. Click **New**.
4. In the **Name** field, enter the name to be displayed for the resource, such as DataServicesScheduler.
5. In the **JNDI Name** field, enter sched/wbm/DataServicesScheduler.
6. Enter a brief description of this scheduler resource.
7. Optional: Optional. Enter a category to use to classify or group the resource.
8. In the **Data source JNDI name** field, select jdbc/wbm/MonitorDatabase.
9. Optional: For the data source alias, choose **Monitor_JDBC_Alias**.
10. In the **Table prefix** field, enter the string prefix to assign to the scheduler tables, including the database schema. This prefix differentiates one scheduler from another which enables them to share the same database. In a typical Monitor environment, the prefix should match the prefix that was used in the Monitor installation DDL, `<MONITOR_SCHEMA_NAME>.MONSCHED_`, for example `MONITOR.MONSCHED_</MONITOR_SCHEMA_NAME>`.
11. In the **Poll interval** field, indicate the number of seconds that you want the scheduler to poll the database to look for new work. For IBM Business Monitor, a value of 30 to 60 seconds is recommended.
12. In the **Work manager JNDI name** field, select the work manager, `wm/wbm/DataServicesWorkManager`.
13. To enable administrative security allowing access only to administrators, click **Use administration roles**.
14. Click **OK** to save this scheduler resource.

Installing dashboards for mobile devices

You can use IBM Business Monitor dashboards on mobile devices. You must install the application using the WebSphere Application Server administrative console.

Complete the following steps to install the dashboards on mobile devices application:

1. In the navigation panel, click **Applications > Application types > WebSphere enterprise applications**.

2. Click **Install**.
3. Choose one of the following options for the **Path to the new application**:
 - **Local file system**: Choose this option if the file is on the local system.
 - **Remote file system**: Choose this option if you are accessing the administrative console using a web browser on a different system.
4. Click **Browse**, and browse to select the MobileDashboard.ear file, and click **Next**. The EAR files are located in the following directory after installation:
monitor_root/installableApps.wbm
Where:
monitor_root represents the directory where IBM Business Monitor is installed
5. On the Select installation options panel, click **Next**.
6. On the Map modules to servers panel, click *server_name* or *cluster_name* where you want to install the application.
7. Select the check boxes on the rows associated with each module, and click **Apply**.
8. Click **Next**.
9. Review the summary information and click **Finish**.

After you have installed the application and installed some monitor models, you can access the dashboard for mobile devices using the following web address:

`http://host_name:port_number/mobile`

Where:

host_name represents the fully qualified host name or IP address of the server where the application is installed

port_number represents the default port for IBM Business Monitor applications

For the dashboards to work properly on mobile devices, you must configure Business Space. To configure Business Space, you must complete tasks such as enabling the widgets and configuring REST services.

Installing event emitter services

You can manually install the event emitter services that you use with IBM Business Monitor. Before manually installing event emitter services, you must first create resources for the event emitter services.

Creating resources for manually installed event emitter services:

When you manually install event emitter services, you must first create resources. If you do not use the configuration wizard to install the emitter services, or if you deploy more than one instance of the emitter services for performance reasons, you must manually create all required resources for the event emitter services. See the related links. You use the administrative console to create the required resources.

Before you begin this task, you must create the IBM Business Monitor service integration bus (SIB). For instructions, see the related reference.

This topic provides instructions for creating the following required resources:

- JMS destination queue
- JMS error destination queue
- Error queue connection factory
- Queue connection factory
- JMS queue
- JMS error queue

- Activation specification
- Event emitter factory for the REST event emitter service
- Event emitter factory for the JMS event emitter service

Note: If you are creating these resources for a JMS emitter for the first time on a server (if the event services were not previously deployed manually on the server or by the configuration wizard), you can choose to use all the default names to simplify installation of the emitter services. In the following steps, the default names are indicated. You can reuse already-defined event emitter factories or create new event emitter factories. Create separate event emitter factories for REST and for JMS.

Use the administrative console to create the resources, and create the resources in the order given.

- To create the JMS destination queue, complete the following steps:
 - Select **Service integration > Buses**, and click **MONITOR.cell_name.Bus**.
 - Select **Destination resources > Destinations**, and then click **New**.
 - When the **create new destination queue creation** wizard launches, ensure that **Queue** is selected, and click **Next**.
 - Name the resource `MonitorEventEmitterQueue2`. The default is **MonitorEventEmitterQueue**.
 - For the description, provide a general description of the queue (for example: Queue for the Business Monitor server JMS event emitter queue. Click **Next**.
 - Select the **Node** where the Bus member resides, click **Next**, and then click **Finish**.
- To create the JMS error destination queue, repeat Step 1. Name the resource `MonitorEventEmitterErrorQueue2`. The default is **MonitorEventEmitterErrorQueue**. For the description, type Bus for the Business Monitor server JMS event emitter error queue.
- Specify the error queue as the exception destination queue.
 - Select **Service integration > Buses**, and click **MONITOR.cell_name.Bus**.
 - Select **Destination resources > Destinations**, and select the destination queue that you created in Step 1.
 - In the **Exception destination** section, select the **Specify** button, and specify the name of the error queue that you created in Step 2
 - Click **OK**, and then click **Save**.
- To create the error queue connection factory, complete the following steps:
 - Select **Resources > JMS > Queue connection factories**.
 - Select the appropriate scope for the new error queue connection factory, and click **New**.
 - Click **OK** to accept the default messaging provider.
 - On the **Configuration** tab, type the **Name**, **Description**, and **JNDI name** for the new error queue connection factory, and select the **Bus name**. Click **OK**, and then click **Save**. See the following list items:
 - **Name:** `MonitorEmitterErrorQConnFactory2`
The default name is **MonitorEmitterErrorQConnFactory**.
 - **Description:** ErrorQConnFactory for the Business Monitor server JMS event emitter queue
 - **JNDI name:** `jms/MonitorEventEmitter/ErrorQConnFactory2`
The default JNDI name is **jms/MonitorEventEmitter/ErrorQConnFactory**.
 - **Bus name:** `MONITOR.cell_name.Bus`
 - Specify the Security Settings for a secure environment, and then click **Apply**. The authentication alias for XA recovery is **MonitorBusAuth**. The Container-managed authentication alias is **MonitorBusAuth**.
- To create the queue connection factory, repeat Step 4. Use the following information:
 - **Name:** `MonitorEmitterQConnFactory2`

The default name is **MonitorEmitterQueueConnFactory**.

- **Description:** QConnFactory for the Business Monitor server JMS event emitter queue
- **JNDI name:** `.jms/MonitorEventEmitter/QueueConnFactory2`

The default JNDI name is **`.jms/MonitorEventEmitter/QueueConnFactory`**

- **Bus name:** `MONITOR.cell_name.Bus`

- To create the JMS queue, complete the following steps:
 - Select **Resources > JMS > Queues**.
 - Select the appropriate scope for the new queue, and click **New**.
 - Click **OK** to accept the default messaging provider.
 - On the **Configuration** tab, type the **Name** and **JNDI name** for the new queue, and select the **Bus name** and the **Queue name**. Click **Apply**. See the following list items:
 - **Name:** `MonitorEventEmitterQueue2`
The default name is **MonitorEventEmitterQueue**
 - **JNDI name:** `.jms/MonitorEventEmitter/Queue2`
The default JNDI name is **`.jms/MonitorEventEmitter/Queue`**.
 - **Bus name:** `MONITOR.cell_name.Bus`
 - **Queue name:** Select the JMS destination queue that you created in Step 1 on page 129
- To create the JMS error queue, repeat Step 6. Use the following information:
 - **Name:** `MonitorEventEmitterErrorQueue2`
The default name is **MonitorEventEmitterErrorQueue**
 - **JNDI name:** `.jms/MonitorEventEmitter/ErrorQueue2`
The default JNDI name is **`.jms/MonitorEventEmitter/ErrorQueue`**
 - **Bus name:** `MONITOR.cell_name.Bus`
 - **Queue name:** Select the JMS error destination queue that you created in Step 2 on page 129
- To create the activation specification, complete the following steps:
 - Select **Resources > JMS > Activation specifications**.
 - Select the appropriate scope for the new activation specification, and click **New**.
 - Click **OK** to accept the default messaging provider.
 - On the **Configuration** tab, type the **Name**, **JNDI name**, and select the **Bus name**, **Destination type**, and **Destination JNDI** for the new activation specification. See the following list items:
 - **Name:** `MonitorEventEmitterActivationSpec2`
The default name is **MonitorEventEmitterActivationSpec**
 - **JNDI name:** `.jms/MonitorEventEmitter/ActivationSpec2`
The default JNDI name is **`.jms/MonitorEventEmitter/ActivationSpec`**.
 - **Bus name:** `MONITOR.cell_name.Bus`
 - **Destination type:** Queue
 - **Destination JNDI:** Select the JMS destination that you created in Step 1 on page 129
 - Set the **Authentication Alias** to `MonitorBusAuth`. Click **OK**, and then click **Save**.
- To create the event emitter factory for the REST event emitter service, follow these steps:
 - Select **Service integration > Common Event Infrastructure > Event emitter factories**
 - Select the appropriate scope for the new event emitter factory, and click **New**.
 - On the **Configuration** tab, type the **Name** and **JNDI name** for the new event emitter factory. Click **Apply**. See the following list items:
 - **Name:** `EmitterFactoryForREST2`
The default name is **EmitterFactoryForREST**.

- **JNDI name:** com/ibm/monitor/EmitterFactoryForREST2

The default JNDI name is **com/ibm/monitor/EmitterFactoryForREST**.

- d. Under Event transmission, select **Support event service transmission**, select **Use entry from below**, and then type com/ibm/events/configuration/bus-transmission/Default.
10. To create the event emitter factory for the JMS event emitter service, repeat Step 9 on page 130. Click **OK**, and then click **Save**. See the following list items:
 - **Name:** EmitterFactory2
The default name is **EmitterFactory**.
 - **JNDI name:** com/ibm/monitor/EmitterFactory2
The default JNDI name is **com/ibm/monitor/EmitterFactory**.
11. Restart your server so that the changes take effect. If you are creating resources in a network deployment (ND) environment, restart the cluster where the resources were created.

Manually installing event emitter services:

You can manually install the event emitter services that you use with IBM Business Monitor. When you manually install event emitter services, you can use existing resources or you can create resources for the event emitter services.

If you choose to create resources for the event emitter services, you must create the resources before you manually install event emitter services. See the related link for instructions about creating resources.

Note: For increased performance in a network deployment (ND) environment, deploy the IBM_WBM_EMITTER_SERVICES application on the server where the common event infrastructure (CEI) event service is installed. If you have set up clusters, deploy the emitter services in the support cluster along with the CEI event service.

Complete the following steps to manually install event emitter services:

1. In the IBM Business Monitor administrative console, select **Applications > Application Types > WebSphere enterprise applications**.

Note: If you created resources as described in Creating resources for manually installed emitter services, remember to restart your server before you deploy the application. If you created resources in an ND environment, restart the cluster where the resources were created.

2. Click **Install**.
3. Choose one of the following options for the **Path to the new application**:
 - **Local file system:** Choose this option if the file is on the local system.
 - **Remote file system:** Choose this option if you are accessing the administrative console using a web browser on a different system.
4. Click **Browse**, browse to select the EmitterServices.ear file, and click **Next**. The EAR files are located in the following directory after installation:

monitor_root/installableApps.wbm

Where:

monitor_root represents the directory where IBM Business Monitor is installed

5. On the Select installation options panel, select **Detailed**, and then click **Next**. On the next panel, click **Continue**.
6. If the emitter services application was already deployed by an administrator or the configuration wizard, create a unique name for your application. For example: *IBM_WBM_EMITTER_SERVICES2*.
 - a. On the Map modules to servers panel, click the *server_name* or *cluster_name* where you want to install the application.
7. Select the check boxes on the rows associated with each module, and click **Apply**.

8. Click **Next**.
9. Optional: If you want to use resources that you created and do not want to accept the defaults, you must make changes on the Bind listeners for message-driven beans panel.
 - a. For the **Activation Specification Target Resource JNDI name**, specify the JNDI name that you created in Step 8 of Creating resources for manually installed emitter services. The default is *jms/MonitorEventEmitter/ActivationSpec*.
 - b. For the **Destination JNDI name**, specify the JNDI name of the JMS Queue (not the Destination queue) that you created in Step 6 of Creating resources for manually installed emitter services. The default is *jms/MonitorEventEmitter/Queue*.
 - c. Set the **ActivationSpec authentication alias** to **MonitorBusAuth**.
10. Optional: On the Map resource references to resources panel, you can specify resources that you created, or you can accept the defaults. Then click **Next**.
 - a. For the **Target Resource JNDI name for the EventEmitterMDB**, specify the JNDI name that you created in step 9 of Creating resources for manually installed emitter services, or you can use the default. The default is *com/ibm/monitor/EmitterFactory*.
 - b. For the **Target Resource JNDI name for the EventEmitterREST**, specify the JNDI name that you created in step 9 of Creating resources for manually installed emitter services, or you can use the default. The default is *com/ibm/monitor/EmitterFactoryForREST*.

Note: After you click **Next**, you might see the following information:

ADMA8019E: The resources that are assigned to the application are beyond the deployment target scope. Resources are within the deployment target scope if they are defined at the cell, node, server, or application level when the deployment target is a server, or at the cell, cluster, or application level when the deployment target is a cluster. Assign resources that are within the deployment target scope of the application or confirm that these resources assignments are correct as specified.

This information is not an error. Click **Continue**.

11. Optional: If the emitter services application was already deployed during product installation or deployed manually by an administrator, give the associated context root of this application a unique name.
 - a. On the Map context roots for web modules panel, name the associated context root */rest/bpm/events2*. The default is */rest/bpm/events*.
12. Use this step to map users or groups to the eventemitters role. Or you can map all authenticated users by selecting the eventEmitters role and clicking **Map special subjects** and then **All Authenticated in Application's realm**.
 - a. On the Map security roles to users or groups panel, select **eventEmitters role**, click **Map special subjects**, and then click **All Authenticated in Application's realm for a secure environment**. If security is not enabled, select **Everyone**.
13. Review the summary information and click **Finish**.
14. Select **Applications > Enterprise Applications > IBM_WBM_EMITTER_REST_SERVICES**, and click **Start**.

Using the configuration wizard to install event emitter services:

You can use the configuration wizard to install the event emitter services for IBM Business Monitor. See the related link.

Chapter 10. Configuring IBM Business Monitor components

After you have installed IBM Business Monitor, you can configure additional components.

Configuring IBM Cognos BI

To set up the IBM Cognos Business Intelligence service to conduct multidimensional analysis on your dashboards, you can configure a new IBM Cognos BI service after you install IBM Business Monitor, or you can configure an existing IBM Cognos BI service to use with IBM Business Monitor.

Configuring a new IBM Cognos BI service

When you install IBM Business Monitor, you can optionally install a new IBM Cognos Business Intelligence service. You can configure the new IBM Cognos BI service in the following ways: create a deployment environment, run the configuration wizard from the administrative console, use the **wbmDeployCognosService** command, or create an IBM Business Monitor stand-alone profile in the Profile Management Tool. You must also create an IBM Cognos BI database and user name for the content store.

IBM Business Monitor copies database drivers and application files to the IBM Cognos BI installation directories during the creation or augmentation of a IBM Business Monitor deployment manager or stand-alone profile. IBM Business Monitor also creates the IBM Cognos BI enterprise application (EAR file) to have it available for deployment of the IBM Cognos BI service.

Cluster requirements

For cluster members, at least 1 GB of extra disk space is required for IBM Cognos BI because a runtime instance must be created on each cluster member.

It is important to start only one of the cluster members at a time and wait for IBM Cognos BI to initialize fully before starting the next cluster member. IBM Cognos BI requires extra time when it is started for the first time, because the runtime instance must be created and the content store database must be initialized.

Starting another cluster member before the content store is fully initialized can cause corruption to the database. If this corruption occurs, it will be noted in the `cogserver.log` file for the IBM Cognos BI runtime instance. To recover, drop the content store database, re-create the database, and then restart a single cluster member. The DDL script to create the database is located in the `/dbscripts/Cognos` directory on the deployment manager.

Database requirements

The IBM Cognos BI service requires a separate database for its content store repository (called, by default, the COGNOSCS database). You can create this database while configuring a stand-alone or deployment manager profile, use the database design tool (dbDesignGenerator), or manually create the database using the scripts provided by IBM Business Monitor.

The IBM Cognos BI service creates tables in the IBM Cognos BI content store database the first time it is started. Because the database user provided for accessing the content store database must have privilege to create tables in the database, it is recommended that you create a new database user for the content store database only.

Systems where the IBM Cognos BI server is running must have the database client installed. The WebSphere environment must have access to the client and the client must be configured to connect to

the MONITOR database. See the "Database considerations" page and the information for your specific database.

Security requirements

When IBM Cognos BI is first deployed, the preconfigured group named Everyone belongs to several built-in groups and roles in the IBM Cognos BI namespace, including the **System Administrators** role. You must remove the Everyone group from all built-in groups and roles, and replace it with groups, roles, or users authorized to restrict access to IBM Cognos BI software and administration.

See "Configuring IBM Cognos BI security" for more configuration settings.

When IBM Cognos BI and Business Space are not running on the same cluster member, you must add the IBM Cognos BI host name and port number to the list of trusted servers in IBM Cognos BI. Otherwise, you will not be able to view the pages in Business Space. See step 3 on page 138 in "Configuring IBM Business Monitor and Business Space to use an existing IBM Cognos BI service."

IBM Cognos BI system compatibility

When you create or augment an IBM Business Monitor deployment manager profile, the configuration files are copied and an enterprise archive (EAR) file is generated for IBM Cognos BI. The IBM Cognos BI EAR file is specific for the platform architecture (operating system and bit mode). When IBM Business Monitor deploys the IBM Cognos BI service, it uses the EAR file that was generated on the deployment manager for all nodes in the cell that are running IBM Cognos BI. To successfully run the EAR file, all nodes must be of the same type. If you have nodes that are of a different type from the deployment manager, you must generate an EAR file on one of the nodes. See "Generating an EAR file for IBM Cognos BI on a custom IBM Business Monitor node."

Bit modes

All IBM Cognos BI servers are configured to run in the same bit mode as the deployment manager. For example, if the deployment manager is running on a 32-bit platform, all IBM Cognos BI servers are configured in 32-bit mode.

If you want to change the bit mode, complete the following steps for each IBM Cognos BI server:

1. In the administrative console, click **Servers > Server types > WebSphere application servers > server name**. The Configuration panel is displayed.
2. Under Server Infrastructure, expand **Java and Process Management** and click **Process Definition**.
3. Under Additional Properties, click **Environment Entries**. Click **PATH** for each server and update the path settings for the environment variables to point to the correct directory. For 32-bit systems, point to the bin directory. For 64-bit systems, point to the bin64 directory.
4. Synchronize the node and restart the server.

libfreebl3.so library for Red Hat Enterprise Linux 6.0

Add **LD_PRELOAD=/lib64/libfreebl3.so** to the Java Virtual Machine (JVM) environment entry for the application server that is hosting IBM Cognos BI. Complete the following steps:

1. In the administrative console, click **Servers > Server types > WebSphere application servers > server name**. The Configuration panel is displayed.
2. Under Server Infrastructure, expand **Java and Process Management** and click **Process Definition**.
3. Under Additional Properties, click **Environment Entries**.
4. Add the **LD_PRELOAD=/lib64/libfreebl3.so** path to the JVM environment variable using a **:** as a delimiter.

Locating your runtime IBM Cognos BI root directory

Because IBM Cognos BI configuration settings and binaries are for a single runtime instance, IBM Business Monitor might have to create a new copy for each runtime instance during deployment of the service. IBM Business Monitor checks on startup for updates to the base installation of IBM Cognos BI and applies those to the copy made for each runtime instance. Therefore, if service is required for IBM Cognos BI, only the base installation must be updated.

The copy for each runtime instance is placed under the profile running the IBM Cognos BI service. All configuration, runtime binaries, and log files are kept in unique directories for each runtime instance. The following table shows the location of the IBM Cognos BI root directory for the IBM Cognos BI runtime instance:

Table 9. Location of the IBM Cognos BI root directory

Server type	Directory
First stand-alone server	<code>app_server_root/cognos</code>
Second stand-alone server	<code>profile_root/profile_name/cognos/server_name</code>
Cluster member server	<code>profile_root/profile_name/cognos/server_name</code>

Updating the IBM Cognos BI configuration

IBM Business Monitor saves updates to the IBM Cognos BI configuration each time the AdminTask **wbmDeployCognosService** command is run. For example, if the security setting changes from Federated to Stand-alone LDAP, or the Content Manager database settings change, run the **wbmDeployCognosService** command to reconfigure IBM Cognos BI, based on the parameters you pass to the command as well as the current WebSphere settings for the database and user registry.

The changes to the runtime instance of the IBM Cognos BI configuration are made during the server startup based on the changes from **wbmDeployCognosService**. IBM Business Monitor checks for changes to the IBM Cognos BI configuration each time the server is started.

Run the **wbmDeployCognosService** command for the following types of changes to WebSphere:

- User registry changes
- Database changes to either IBM Business Monitor or IBM Cognos BI
- Hostname, IP address, and HTTP port address changes

Important: Updates made to the IBM Cognos BI configuration using **wbmDeployCognosService** will be ignored if the IBM Cognos BI Configuration application program has been used to make manual changes to the configuration. Once you have used the IBM Cognos BI Configuration application program, you must continue to use it to make changes.

Run the **wbmSetCognosDatabaseUser** command for the following types of changes (or edit the Cognos_JDBC_Alias WebSphere authorization alias directly):

- IBM Cognos BI Content Store database user name or password

Run the **wbmSetCognosAdminUser** command for the following types of changes (or edit the Cognos_Admin_Alias WebSphere authorization alias directly)

- IBM Cognos BI administrative user name or password

Manually updating the IBM Cognos BI configuration

When the IBM Business Monitor preconfigured configuration settings for IBM Cognos BI are not sufficient for complex configurations, you must manually configure IBM Cognos BI using the IBM

Cognos BI Configuration application. Use the IBM Cognos BI Configuration application to set the host and port addresses of systems running Business Space to the valid domains or host settings of the IBM Cognos BI firewall settings.

For each unique configuration, there is a unique start script

-  cogconfig.bat
-   cogconfig.sh

The script is located in one of the following directories:

- *cognos_installation_root/bin* for 32-bit servers
- *cognos_installation_root/bin64* for 64-bit servers

Use the Table 9 on page 135 table to find the *cognos_installation_root* directory.

For each unique configuration, there is a unique start script cogconfig.bat or cogconfig.sh located in the *cognos_installation_root/bin* for 32-bit servers or the *cognos_installation_root/bin64* for 64-bit servers. Use the Table 9 on page 135 table to find the *cognos_installation_root* directory.

If there is a problem starting the script because Java is not found, run a command similar to the following to set the environment to locate the version of Java used with your WebSphere server:

-  SET JAVA_HOME=C:\WAS70\java
-   export JAVA_HOME=/opt/IBM/WebSphere/AppServer/java

Important: Do not run the IBM Cognos BI Configuration application until after the IBM Cognos BI server has been started at least once. The first startup copies the configuration (and the binaries unless the first stand-alone server is starting), and also creates the encryption keys and encrypts the passwords within the configuration.

Tip: After the IBM Cognos BI configuration has been saved using the IBM Cognos BI Configuration application, IBM Business Monitor no longer checks for changes to the IBM Cognos BI configuration. However, IBM Business Monitor continues to update the user names and passwords such that you only need to make changes to these in one place (for example, using the WebSphere administrative console to change the authorization alias). IBM Business Monitor updates the IBM Cognos BI configuration during server startup with the name and password from the **Cognos_JDBC_Alias** WebSphere security alias. If you are using the WebSphere stand-alone LDAP repository, changes to the LDAP access are updated in the IBM Cognos BI configuration.

If you need to use the IBM Cognos Administration client, it is located at http://host_name:port_number/p2pd/servlet/dispatch/ext.

Manually setting the IBM Cognos BI address that IBM Business Monitor uses

Use the **wbmSetCognosDispatcher** command to set the address of a remote or an existing IBM Cognos BI service, or to modify the address of a locally installed IBM Cognos BI service. To allow single sign-on for interactions between IBM Cognos BI and IBM Business Monitor, the IBM Cognos BI address should end with /ext (the full IBM Cognos BI external dispatcher address).

After changing the address, restart all IBM Business Monitor servers.

Generating an EAR file for IBM Cognos BI on a custom IBM Business Monitor node

When you create or augment an IBM Business Monitor deployment manager profile, the enterprise archive (EAR) file that is generated for IBM Cognos Business Intelligence is specific for the operating

system and bit mode. To successfully run the EAR file, all nodes must be of the same type. If you have nodes that are of a different type from the deployment manager, you must generate an EAR file on one of the nodes.

To generate an EAR file on a custom IBM Business Monitor node, complete the following steps:

1. Copy the following files from IBM Business Monitor directories to IBM Cognos BI installation directories.

Important: You must rename some of the files (as shown in the table) to replace existing files.

Copy from (location and file name)	Copy to (location and file name)
app_server_root/scripts.wbm/cognos/application.xml	app_server_root/cognos/war/p2pd/application.xml.template
app_server_root/scripts.wbm/cognos/web.xml	app_server_root/cognos/webapps/p2pd/WEB-INF/web.xml.withCM
app_server_root/scripts.wbm/cognos/ibm-web-ext.xmi	app_server_root/cognos/webapps/p2pd/WEB-INF/ibm-web-ext.xmi
app_server_root/installableApps.wbm/monAuthProvider.jar	app_server_root/cognos/webapps/p2pd/WEB-INF/lib/monAuthProvider.jar

2. Open a command prompt in app_server_root/cognos/war/p2pd.
3. Run the following command:

 **build.bat ear**

  **build.sh ear**

This command creates a WebSphere EAR file called p2pd.ear in the IBM Cognos BI root directory. Building the EAR file might take several minutes.

4. Copy the new p2pd.ear file to the deployment manager, replacing the existing file in app_server_root/cognos.
5. Deploy the IBM Cognos BI service.

Configuring IBM Business Monitor and Business Space to use an existing IBM Cognos BI service

If you already have IBM Cognos Business Intelligence installed, you can use your existing IBM Cognos BI service with IBM Business Monitor. You can connect to your existing IBM Cognos BI service in the following ways: run the IBM Business Monitor configuration wizard from the administrative console, use the **wbmSetCognosDispatcher** command, or create a stand-alone profile in the Profile Management Tool. You must then perform some configuration tasks.

After you have connected IBM Business Monitor to your IBM Cognos BI server, you must perform additional steps to set up Business Space and to handle your data services.

Important: The remote IBM Cognos BI must be running on a WebSphere Application Server, and when administrative security is enabled, the user repository must be the same on the IBM Business Monitor server and the IBM Cognos BI server.

Make sure that the database client is running and has access to the IBM Business Monitor database on the remote IBM Cognos BI server. Also be sure the IBM Business Monitor database has been cataloged with the remote IBM Cognos BI server with the same name as the catalog entry on the IBM Business Monitor server.

If you created a deployment environment from the administrative console, a new IBM Cognos BI was installed for you. To remove it, use the **wbmRemoveCognosService** command. (If you ran the

wbmSetCognosDispatcher command before creating a deployment environment, the IBM Cognos BI service was not deployed and therefore does not require removal.)

To set up Business Space to work with your existing IBM Cognos BI, complete the following steps:

1. Configure single sign-on between the WebSphere Application Server running Business Space and the WebSphere Application Server running IBM Cognos BI. See Enabling single sign-on.
2. Configure IBM Cognos BI for single sign-on. See Configuring an existing IBM Cognos BI service for single sign-on.
3. Add the IBM Cognos BI host name and port number to the list of trusted servers in IBM Cognos BI. Otherwise, you will not be able to view the pages in Business Space.
 - a. Open the IBM Cognos BI Configuration client. To open the client, run the `cogconfig.bat` or `cogconfig.sh` file located in `cognos_installation_root/bin` for 32-bit servers or `cognos_installation_root/bin64` for 64-bit servers.
 - b. Select **Local Configuration > Security > IBM Cognos Application Firewall**.
 - c. Click the pencil icon next to **Valid domains or hosts** and add the IBM Cognos BI host and port number configured in the endpoint from Business Space. For example, add `1c2d266009.example.com:9080`. If you have multiple hosts, click **Add** to add more entries.
 - d. Click **OK**. Click **Save**.
 - e. Restart the server that is running IBM Cognos BI.
4. Because Business Space end points for IBM Cognos BI are configured when the IBM Cognos BI remote URL is configured, verify that the custom properties of the **Mashups Endpoints** resource environment provider are correct:
 - a. From the WebSphere administrative console, click **Resources > Resource Environment > Resource Environment Providers > Mashups Endpoints > Custom properties**.
 - b. Verify the following custom properties for the **Mashups Endpoints** resource environment provider:

```
{com.ibm.cognos}cognosServiceRootId.url  
{com.ibm.cognos}cognosDispatcherRootId.url  
{com.ibm.cognos}cognosWebContentRootId.url
```
5. If the properties you checked in step 4 are not correct, complete the following steps:
 - a. Update the following service endpoint file.
`install_root/BusinessSpace/registryData/WBM/endpoints/cognosEndpoints.xml`In each of the three `<tns:url>` sections, add the IBM Cognos BI server host name and port at the beginning of the line.
For example, if your host name is `1c2d266009.example.com` and your port number is `9080`, the completed file would look like:

```
<tns:Endpoint>  
<tns:id>{com.ibm.cognos}cognosServiceRootId</tns:id>  
<tns:type>{com.ibm.cognos}cognosServiceRootId</tns:type>  
<tns:version>1.0.0.0</tns:version>  
<tns:url>http://1c2d266009.example.com:9080/p2pd/servlet/dispatch/ext/</tns:url>  
<tns:description>Location of backing services for Cognos widgets</tns:description>  
</tns:Endpoint>  
  
<tns:Endpoint>  
<tns:id>{com.ibm.cognos}cognosDispatcherRootId</tns:id>  
<tns:type>{com.ibm.cognos}cognosDispatcherRootId</tns:type>  
<tns:version>1.0.0.0</tns:version>  
<tns:url>http://1c2d266009.example.com:9080/p2pd/servlet/dispatch/ext/</tns:url>  
<tns:description>Location of Cognos Dispatcher</tns:description>  
</tns:Endpoint>  
  
<tns:Endpoint>  
<tns:id>{com.ibm.cognos}cognosWebContentRootId</tns:id>  
<tns:type>{com.ibm.cognos}cognosWebContentRootId</tns:type>
```

```

<tns:version>1.0.0.0</tns:version>
<tns:url>http://1c2d266009.example.com:9080/p2pd/servlet/</tns:url>
<tns:description>Location of Cognos web content</tns:description>
</tns:Endpoint>
</tns:BusinessSpaceRegistry>

```

For more information about modifying the endpoints files, see Enabling widgets for cross-cell environments.

- b. Run the **updateBusinessSpaceWidgets** command for the `cognosEndpoints.xml` file. Follow the instructions in Enabling widgets for cross-cell environments.

Configuring IBM Cognos BI with WebSphere Portal

If you are using IBM Cognos Business Intelligence with WebSphere Portal, you must update the **ProxyServlet_Servlet** section of the `web.xml` file.

For complete information about configuring Business Space to work with WebSphere Portal, see "Configuring widgets to work with WebSphere Portal."

1. Export the WebSphere Portal enterprise archive (EAR) file, `wps.ear`, according to your network configuration. If you have a cluster environment, the WebSphere Portal EAR file must be exported from the WebSphere Application Server Network Deployment machine.
 - a. At a command line, change to the `application_server_profile_root/bin` directory.
 - b. Run the following command to export the `wps.ear` file to a temporary directory (make sure that all commands are entered on one line):
 -  **wsadmin.bat** -user `admin_user_id` -password `admin_password` -c "\$AdminApp export wps directory/wps.ear"
 -   **./wsadmin.sh** -user `admin_user_id` -password `admin_password` -c '\$AdminApp export wps directory/wps.ear'

where `admin_user_id` is the administrator's user ID, `admin_password` is the administrator's password, and `directory` is the temporary directory.
2. Create the `/wps_expanded` subdirectory. Use the **EARExpander** scripting tool to expand the contents of the exported EAR file (make sure that all commands are entered on one line).
 -  **EARExpander.bat** -ear `directory\wps.ear` -operationDir `directory\wps_expanded` -operation `expand`
 -   **./EARExpander.sh** -ear `directory/wps.ear` -operationDir `directory/wps_expanded` -operation `expand`
3. Make a backup copy of `directory/wps_expanded/wps.war/WEB-INF/web.xml`.
4. Update `directory/wps_expanded/wps.war/WEB-INF/web.xml`.
 - a. Open `web.xml`.
 - b. Find the following section:

```

<servlet id="ProxyServlet_Servlet">
  <servlet-name>ProxyServlet</servlet-name>
  <servlet-class>com.ibm.wps.proxy.servlet.ProxyServlet</servlet-class>
</servlet>

```
 - c. Replace the section with the following text:

```

<servlet id="ProxyServlet_Servlet">
  <servlet-name>ProxyServlet</servlet-name>
  <servlet-class>com.ibm.wps.proxy.servlet.ProxyServlet</servlet-class>
  <init-param>
    <param-name>useCtxPathForCookies</param-name>
    <param-value>true</param-value>
  </init-param>
</servlet>

```
5. Delete the original `wps.ear` file from the directory where you initially exported it.

6. Use the **EARExpander** command to collapse the EAR file directory back into an EAR file.
 -  **EARExpander.bat -ear *directory*\wps.ear -operationDir *directory*\wps_expanded -operation collapse**
 -   **./EARExpander.sh -ear *directory*/wps.ear -operationDir *directory*/wps_expanded -operation collapse**
7. Use the **wsadmin** command to update the WebSphere Portal EAR file.

Note: If you have a managed cell (with or without a cluster), perform this step on the deployment manager machine.

-  **wsadmin.bat -user *admin_user_id* -password *admin_password* -c "\$AdminApp install *directory*/wps.ear {-update -appname wps -nodeployejb}"**
-   **./wsadmin.sh -user *admin_user_id* -password *admin_password* -c '\$AdminApp install *directory*/wps.ear {-update -appname wps -nodeployejb}'**

where *admin_user_id* is the administrator's user ID, *admin_password* is the administrator's password, and *directory* is the temporary directory.

8. Restart WebSphere Portal server. In a cluster configuration, restart the cluster.
9. Add the IBM Cognos BI host name and port number to the list of trusted servers in IBM Cognos BI. Otherwise, you will not be able to view the pages in Business Space.
 - a. Open the IBM Cognos BI Configuration client. To open the client, run the `cogconfig.bat` or `cogconfig.sh` file located in `cognos_installation_root/bin` for 32-bit servers or `cognos_installation_root/bin64` for 64-bit servers.
 - b. Select **Local Configuration > Security > IBM Cognos Application Firewall**.
 - c. Click the pencil icon next to **Valid domains or hosts** and add the IBM Cognos BI host and port number configured in the endpoint from Business Space. For example, add `1c2d266009.example.com:9080`. If you have multiple hosts, click **Add** to add more entries.
 - d. Click **OK**. Click **Save**.
 - e. Restart the server that is running IBM Cognos BI.

Configuring the reporting data source in IBM Cognos BI

When you publish cube packages for your first monitor model, a reporting data source named `WBMONITOR_DB` is automatically created in IBM Cognos BI. The `WBMONITOR_DB` data source is used to connect to the `MONITOR` database for dimensional reporting.

The `WBMONITOR_DB` data source is configured based on the values copied from the WebSphere Application Server JDBC data source named `Monitor_database`.

If you cannot publish cube packages because of database connectivity issues, or if you change the user name or password for the IBM Business Monitor database, you must reconfigure the `WBMONITOR_DB` data source connection using the IBM Cognos Administration client. Alternatively, you can delete the `WBMONITOR_DB` data source in the IBM Cognos Administration client and republish a cube package from the IBM Business Monitor administrative console, using the `Manage Cognos Cubes` page, to automatically regenerate the `WBMONITOR_DB` data source based on the latest configuration values in the WebSphere Application Server JDBC data source named `Monitor_database`.

1. Start the IBM Cognos Administration client at `http://host_name:port_number/p2pd/servlet/dispatch/ext`.
2. Go to **IBM Cognos Administration > Configuration > Data Source Connections > WBMONITOR_DB**. From there, you can configure and test the connection, and edit the user name and password.

Tip: When you are testing the `WBMONITOR_DB` connection, you should see two **Succeeded** messages.

- The first message is of the type "IBM DB2 / Compatible" (or "Oracle / Compatible" or "SQL Server / Compatible"). This message is for the connection that uses the native database client. This connection is required to publish cube packages.
- The second message is of the type " / Dynamic." This message is for the Type 4 JDBC connection. This connection is required to run IBM Cognos BI reports.

If either of these connection types show **Failed**, edit the configuration or sign-on information and retest. You can safely ignore failures for other connection types.

Configuring IBM Business Monitor widgets for WebSphere Portal

IBM Business Monitor no longer provides portlet-based dashboards. However, your IBM Business Monitor widgets can still be displayed in WebSphere Portal.

To display widgets in WebSphere Portal, complete the following high-level steps:

1. Configure Business Space.
2. Configure widgets to work with WebSphere Portal.
3. Configure IBM Cognos Business Intelligence to work with WebSphere Portal.

Configuring how to receive events

You can configure how events flow from applications to the Common Event Infrastructure (CEI) as well as how they flow from CEI to IBM Business Monitor.

Asynchronous event considerations

The flow from an emitting application to the common event infrastructure (CEI) can be synchronous or asynchronous. With synchronous event transmission, an application waits for successful event delivery before proceeding with the rest of its transaction. With asynchronous event transmission, an application places events on a queue and proceeds with processing.

When you use asynchronous event transmission, you can minimize the impact on the emitting application, which might be important when monitoring mission-critical applications. However, with asynchronous event transmission, events can be received by a monitor model in a different order than they occurred in the emitting application.

For models where event order is important, incorrect event sequence order can result in model processing exceptions and incorrectly calculated data. If you need the order of events to be guaranteed, make sure that the application that is emitting events to IBM Business Monitor uses synchronous event emission, or define an event sequence path in the monitor model to provide information about the event processing order.

One way to tell whether the events are being emitted asynchronously is to check the administrative console under **Service integration > Common Event Infrastructure > Event emitter factories**. Select the emitter factory, which might be named something like **Default Common Event Infrastructure emitter**. The panel that is displayed has an Event transmission area with settings that control how events are emitted. JMS transmission is asynchronous and event service transmission is synchronous.

If you decide to use asynchronous event emission and it is important that the events be processed in the order in which they were produced, define an event sequence path in the monitor model. For more information about how to define event sequence paths, see the related links.

Configuring authorization for asynchronous event delivery

If you are planning to receive events that are emitted from an application that uses an event emitter factory with asynchronous delivery, and you did not use the deployment environment configuration

wizard or the **wbmDeployCEIEventService** AdminTask to set up your environment, you must configure the IBM Business Monitor server to communicate with the common event infrastructure (CEI) server.

If you used the deployment environment configuration wizard or the **wbmDeployCEIEventService** AdminTask to set up your environment, this configuration is done for you. You must perform this task to configure the authorization information for JMS only if you are configuring your own CEI server or using a non-default event emitter factory rather than the Default Common Event Infrastructure emitter.

Before you begin this task, you must log in to the WebSphere Application Server administrative console. If you are using a remote CEI server and using the queue-based method to receive events, ensure that you have configured the service integration bus links before beginning this task. See the related task about "Configuring queue-based event management in a multiple-cell environment."

As an alternative to using the administrative console, you can run the wsadmin task **setEventServiceJmsAuthAlias** to perform the steps that are provided in this topic.

Using the WebSphere Application Server administrative console, complete the following steps:

1. Specify the authorization aliases for the queue connection factory.
 - a. In the navigation panel, click **Resources > JMS > Queue connection factories**.
 - b. Click **CommonEventInfrastructure_QueueCF** in the list of queue connection factories.
 - c. In the Security Settings section, select an alias from the **Authentication alias for XA recovery** list. The alias must have a user that has a bus connector role for the CEI bus. (In **Service Integration > Buses**, click the **Security** column for the bus that is described as **CommonEventInfrastructure Bus**.)
 - d. Select an alias from the **Container-managed authentication alias** list. Typically you can select the same alias as in the previous substep.
 - e. Click **OK** and save your changes to the master configuration.
2. Specify an authorization alias for the activation specification.
 - a. In the navigation panel, click **Resources > JMS > Activation specifications**.
 - b. Click **CommonEventInfrastructure_ActivationSpec** in the list of activation specifications.
 - c. In the Security Settings section, select an alias from the **Authentication alias** list.
 - d. Click **OK** and save your changes to the master configuration.
3. Specify the authorization aliases for the topic connection factories.
 - a. In the navigation panel, click **Resources > JMS > Topic connection factories**.
 - b. Click **CommonEventInfrastructure_AllEventsTopicCF** in the list of topic connection factories.
 - c. In the Security Settings section, select an alias from the **Authentication alias for XA recovery** list. The alias must have a user that has a bus connector role for the CEI bus. (In **Service Integration > Buses**, click the **Security** column for the bus that is described as **CommonEventInfrastructure Bus**.)
 - d. Select an alias from the **Container-managed authentication alias** list. Typically you can select the same alias as in the previous substep.
 - e. Click **OK** and save your changes to the master configuration.

Receiving events from CEI

In IBM Business Monitor, you can choose to receive events from the inbound Common Event Infrastructure (CEI) server using two different transport types: JMS (queue-based) and table-based (also known as queue bypass).

Queue-based event delivery uses Java Messaging Service (JMS) to deliver events from CEI to the monitor model. Table-based event delivery (formerly known as queue bypass) uses a database table to deliver events from CEI to the monitor model.

With table-based event delivery, the work can be distributed among multiple cluster members. Additionally, the event flow skips the JMS queue of the monitoring model and directs all events into the event database table of the model. For most environments, this method improves performance by avoiding a persistence step that is required by the JMS queue. Other benefits of the table-based methods are that you no longer have to configure the service integration bus and link when receiving events from a remote cell, and you can rebuild earlier models to use this method.

Receiving events using table-based event delivery

You can configure your common event infrastructure (CEI) event service to send the events to the event database table for the monitor model. You do not need to configure the service integration bus link and its associated resources. Bypassing the JMS queue improves performance by eliminating an additional persistence step that is required for the queue.

When you use table-based event delivery in IBM Business Monitor 8.0.1, the work can be distributed among multiple cluster members. For most environments, this method improves performance and simplifies the system configuration.

- **Pre-6.2 models:** Table-based event delivery is not supported. To use this method for monitor models from a version earlier than 6.2, you must first upgrade the monitor model using the Business Monitor development toolkit. Change the version number, generate a new EAR file, and deploy a new version of the monitor model. If you choose not to upgrade the model, you must use queue-based event delivery.
- **Version 6.2 and 7 models:** These models can use the table-based method (formerly known as queue bypass). If you want to exploit the scalability enhancements of version 8.0.1, you must upgrade the monitor model using a version 8.0.1 Business Monitor development toolkit.
- **Version 7.5 models:** These models can take advantage of the scalability enhancements if you use table-based event delivery.

Restriction: If you are using SQL Server as the database, you cannot use the table-based event delivery method unless the emitting application is running on WebSphere Application Server 7.0 (or Process Server 7.0) or later. You must use the queue-based method.

You can enable the table-based method in a single-cell or multiple-cell environment. Choose the following task depending on your environment to complete the configuration for this method.

Configuring table-based event delivery in a single-cell environment:

If you have a single-server (stand-alone) environment or you have IBM Business Monitor version 7.0 or later (or version 7.0.0.3 for z/OS) or later installed on every node in the cell, then there are no further steps required to receive events. If the common event infrastructure (CEI) event service is deployed to a node in the cell without IBM Business Monitor or Process Server, then you must install the IBM Business Monitor JAR files for routing events on that CEI node.

Process Server version 7.0 and later on distributed platforms (and Process Server version 7.0.0.3 and later on z/OS platforms) provides the files needed to support remote event emission. If you are using an earlier version of Process Server, complete the following steps to configure table-based event delivery in a single-cell environment.

1. In the **app_server_root/scripts.wbm/crossCell** directory of the local IBM Business Monitor server installation, locate the appropriate file depending on your operating system and the version of WebSphere Application Server that the CEI event service is running on.
 - `monitorCommunicationWithWAS80BasedCells.tar`, `monitorCommunicationWithWAS70BasedCells.tar`, `monitorCommunicationWithWAS61BasedCells.tar`, or `monitorCommunicationWithWAS60BasedCells.tar`.
 - `monitorCommunicationWithWAS80BasedCells.zip`, `monitorCommunicationWithWAS70BasedCells.zip`, `monitorCommunicationWithWAS61BasedCells.zip`, or `monitorCommunicationWithWAS60BasedCells.zip`.

2. Copy the appropriate file to the **app_server_root/plugins** directory on every WebSphere Application Server installation in the remote node that hosts a CEI target and does not have IBM Business Monitor or Process Server version 7.0 (or version 7.0.0.3 for z/OS) or later installed, and extract the contents.
3. On each WebSphere Application Server installation where you extracted the contents of the file:
 - a. Shut down all Java virtual machines (JVMs) that are using **app_server_root/java/bin/java**, including node agents, servers, deployment managers, and wsadmin prompts.
 - b. Run **profile_root/bin/osgiCfgInit** for every profile on the WebSphere Application Server installation.
 - c. Restart all node agents and servers.

Configuring table-based event delivery in a multiple-cell environment:

If your IBM Business Monitor is installed in a different cell from the CEI event service, you must complete additional configuration steps to enable the communication between the cells.

For secure environments, before performing this task, ensure that the following tasks have been completed:

- If security is enabled in either the remote or local cell, it must be enabled in both.
- If security is enabled, you must enable server-to-server trust (SSL) between the remote CEI server and the local IBM Business Monitor server (see Configuring server-to-server SSL in multiple-cell environments).
- LTPA keys must be shared across cells and the cells must have the same ID (see Sharing LTPA keys).
- The **Use identity assertion** setting must be enabled in the local cell and the remote cell (see Enabling identity assertion).

In a multiple-cell environment, if IBM Business Monitor is not installed on the remote cell that is emitting events, you must configure the deployment manager and CEI servers in the remote cell so that they can emit events to the tables. Process Server version 7.0 and later on distributed platforms (and Process Server version 7.0.0.3 and later on z/OS platforms) provides the files needed to support remote event emission. Previous versions of Process Server do not provide these files automatically. Consequently, the instructions are slightly different depending on whether the remote cell that is emitting events is a distributed cell that has Process Server version 7.0 (version 7.0.0.3 for z/OS) or later installed.

To configure table-based event delivery across multiple cells, complete the following steps:

- If Process Server version 7.0 (version 7.0.0.3 for z/OS) or later is **not** installed in the remote cell (the cell without IBM Business Monitor):
 1. In the **app_server_root/scripts.wbm/crossCell** directory of the local IBM Business Monitor server installation, locate the appropriate file depending on your operating system and the version of WebSphere Application Server that the CEI event service is running on.
 - `monitorCommunicationWithWAS70BasedCells.tar` or `monitorCommunicationWithWAS61BasedCells.tar`.
 - `monitorCommunicationWithWAS70BasedCells.zip` or `monitorCommunicationWithWAS61BasedCells.zip`.
 2. Copy the appropriate file to the **app_server_root/plugins** directory of the remote deployment manager and extract the contents.
 3. Copy the same file to the **app_server_root/plugins** directory on every WebSphere Application Server installation in the remote cell that hosts a CEI target and does not have IBM Business Monitor or Process Server version 7.0 (or version 7.0.0.3 for z/OS) or later, and extract the contents.
 4. On each WebSphere Application Server installation where you extracted the contents of the file:
 - a. Shut down all Java virtual machines (JVMs) that are using **app_server_root/java/bin/java**, including node agents, servers, deployment managers, and wsadmin prompts.

- b. Run `profile_root/bin/osgiCfgInit` for every profile on the WebSphere Application Server installation.
 - c. Restart all node agents and servers.
5. On the remote deployment manager or stand-alone server, run the `wbmConfigureQueueBypassDatasource` wsadmin command. See Table-based CEI across multiple cells for an example and list of parameters for this command. After you run the command and save the configuration changes, restart the remote deployment manager or stand-alone server.
- If Process Server version 7.0 (or version 7.0.0.3 for z/OS) or later is installed in the remote cell:
 1. On the remote deployment manager or stand-alone server, run the `wbmConfigureQueueBypassDatasource` wsadmin command. See Table-based CEI across multiple cells for an example and list of parameters for this command.
 2. After you run the command and save the configuration changes, restart the remote deployment manager or stand-alone server.
1. When you deploy a monitor model with a remote CEI, you need to select the **Remote** CEI location option, as described in the step entitled "Select Monitor model CEI options" in the topic Deploying monitor models.
2. **If you are running a CEI server on z/OS:** After you complete the table-based CEI configuration, when you deploy a monitor model, the following error is recorded in the CEI logs on z/OS:
- ```
CEI61Configur E
com.ibm.wbimonitor.observationmgr.spi.impl.CEI61RemoteConfigurationSessionImpl
reloadCEIConfig(String[] eventServerAppNames) CWMRT7314E: Error while trying to reload the CEI configuration.
```

To complete the CEI configuration, complete the following steps:

- a. Restart the CEI server or cluster (for the emitting CEI on z/OS).
  - b. On the IBM Business Monitor deployment manager, run the `confirmCEIServerReboot(String modelID)` method of the Lifecycle Services MBean to indicate that CEI has been restarted. To run the command from a wsadmin prompt, complete the following steps:
    - 1) Establish a connection to the Lifecycle Services MBean:
 

```
wsadmin> set ls [$AdminControl completeObjectName type=LifecycleServices,*]
```
    - 2) Confirm that CEI has been restarted:
 

```
wsadmin> $AdminControl invoke $ls confirmCEIServerReboot { "<model ID>"}
```
3. Before you can receive events from IBM Business Process Manager, you must configure IBM Business Process Manager to enable event emission to IBM Business Monitor.
- a. See one of the following topics for a description of how events flow from IBM Business Process Manager to IBM Business Monitor:
    - Event flow if you are using IBM Business Process Manager V8.0.1.x
    - Event flow if you are using IBM Business Process Manager V8.5.0.x
  - b. See one of the following topics for the steps to enable event emission:
    - Configuring event flow to a remote server if you are using IBM Business Process Manager V8.0.1.x
    - Configuring event flow to a remote server if you are using IBM Business Process Manager V8.5.0.x

## Receiving events using queue-based event delivery

To receive events using the Java Messaging Service (JMS) queues, you do not need to perform any additional steps unless you want to enable communication between the IBM Business Monitor server and a remote CEI server. You must use the queue-based method for event management if you are using a monitor model that was created using IBM Business Monitor 6.1 in an IBM Business Monitor 8.0 environment without upgrading your monitor model.

You can use queue-based event management in a single-cell or multiple-cell environment. If your CEI server is in a remote cell to the cell where IBM Business Monitor is installed, then you must complete additional configuration steps to enable the communication across the two cells.

#### **Configuring queue-based event delivery in a single-cell environment:**

If your IBM Business Monitor is installed in the same cell as the CEI event service, and you are using the queue-based method to receive events, there are no further steps to take. The required JAR files were copied to the correct folders and the service integration bus was created when IBM Business Monitor was installed.

#### **Configuring queue-based event delivery in a multiple-cell environment:**

If your IBM Business Monitor is installed in a different cell from the CEI server, you must complete additional configuration steps to enable the communication between the cells. To receive events from the JMS queue in this cross-cell environment, you must configure IBM Business Monitor server to receive common event infrastructure (CEI) events from a remote CEI server.

Before performing this task, verify that the following items have been completed:

- The remote CEI service has been deployed and configured.
- The service integration bus for the local IBM Business Monitor server has been created.

For secure environments, you must also ensure that the following tasks have been completed:

- If security is enabled in either the remote or local cell, it must be enabled in both.
- If security is enabled, you must enable server-to-server trust (SSL) between the remote CEI server and the local IBM Business Monitor server (see *Configuring server-to-server SSL in multiple-cell environments*).
- LTPA keys must be shared across cells and the cells must have the same ID (see *Sharing LTPA keys*).
- The **Use identity assertion** setting must be enabled in the local cell and the remote cell (see *Enabling identity assertion*).

To configure the queue-based method of event management, you must install the cross-cell files, create the remote service integration bus, and create the link between the local and remote buses. Process Server version 7.0 and later on distributed platforms (and Process Server version 7.0.0.3 and later on z/OS platforms) provides the files needed to support remote event emission.

**Important:** If you are monitoring events in IBM Business Process Manager in a multiple-cell environment, the configuration is a two-step process:

1. Complete the steps in this procedure.
2. Configure IBM Business Process Manager to enable event emission to IBM Business Monitor, as described in step 3 on page 147 of “What to do next.”

To configure queue-based event management across multiple cells, complete the following steps:

**Important:** If Process Server version 7.0 (or version 7.0.0.3 for z/OS) or later is installed in the remote cell, you can skip steps 1-3 and go directly to step 4.

1. In the `app_server_root/scripts/wbm/crossCell` directory of the local IBM Business Monitor server installation, locate the appropriate file depending on your operating system and the version of WebSphere Application Server that the CEI server is running on.
  - monitorCommunicationWithWAS70BasedCells.tar, monitorCommunicationWithWAS61BasedCells.tar, or monitorCommunicationWithWAS60BasedCells.tar.
  - monitorCommunicationWithWAS70BasedCells.zip, monitorCommunicationWithWAS61BasedCells.zip, or monitorCommunicationWithWAS60BasedCells.zip.

2. Copy the appropriate file to the **app\_server\_root/plugins** directory of the remote CEI server (either the stand-alone server or the remote deployment manager) and extract the contents.
3. From the **app\_server\_root/bin** directory on the remote CEI server, run the appropriate command to configure the application server or process server to recognize the .jar file: **osgiCfgInit.bat** or **osgiCfgInit.sh**.
4. From the **app\_server\_root/scripts.wbm/crossCell** directory of the local IBM Business Monitor server installation, choose one of the methods below to run the service integration bus cross-cell configuration utility. For more information about this utility, see the related links.
  - To run the command interactively, enter:
 

```
configRemoteMonitorBus.sh
configRemoteMonitorBus.bat
```
  - To run the command using a properties file, review the **configRemoteMonitorBus.props** file and change any necessary properties. The **configRemoteMonitorBus.props** file is an example properties file that is located in the **app\_server\_root/scripts.wbm/crossCell** directory, but you can create your own properties file for your configuration:
 

```
configRemoteMonitorBus.sh -props properties_file_name
configRemoteMonitorBus.bat -props properties_file_name
```

Where:

*properties\_file\_name* is the fully qualified name of the properties file that contains the required values for the configuration. The path to the properties file must be fully specified for the script to find the properties file. The cross-cell configuration utility creates a service integration bus in the remote cell. The name of the bus is **MONITOR.<remote\_cell\_name>.bus**, where *<remote\_cell\_name>* is the name of the remote cell.

5. When the script completes, restart both the local IBM Business Monitor and the remote Process Server or IBM Business Process Manager server.
6. Verify that the remote service integration bus exists and that the link between the local and remote buses was created successfully, by following the steps in the topic "Verifying the remote IBM Business Monitor bus and service integration link."
1. When you deploy a monitor model with a remote CEI, you need to select the **Remote** CEI location option, as described in the step entitled "Select Monitor model CEI options" in the topic Deploying monitor models.
2. **If you have a secured environment:** You can deploy a monitor model in a secured environment with a remote CEI and queue-based event management. After deploying a monitor model, you need to complete the installation by following the instructions in the topic "Completing the installation of a monitor model in a secured queue-based environment."
3. Before you can receive events from IBM Business Process Manager, you must configure IBM Business Process Manager to enable event emission to IBM Business Monitor.
  - a. See one of the following topics for a description of how events flow from IBM Business Process Manager to IBM Business Monitor:
    - Event flow if you are using IBM Business Process Manager V8.0.1.x
    - Event flow if you are using IBM Business Process Manager V8.5.0.x
  - b. See one of the following topics for the steps to enable event emission:
    - Configuring event flow to a remote server if you are using IBM Business Process Manager V8.0.1.x
    - Configuring event flow to a remote server if you are using IBM Business Process Manager V8.5.0.x

*Verifying the remote IBM Business Monitor bus and service integration link:*

After you have configured the IBM Business Monitor server to use the common event infrastructure (CEI) server on a remote WebSphere Application Server or Process Server, you must verify that you successfully created the remote bus and service integration link.

To verify that the remote bus and the service integration bus link exist and are active, complete the following steps:

1. From the administrative console on the remote WebSphere Application Server or Process Server, click **Service Integration > Buses**.
2. Click the **MONITOR.<cell\_name>.bus** bus that you are verifying, where *<cell\_name>* is the name of the cell where the remote CEI server is installed.
3. Under Topology, click **Messaging Engines**. One messaging engine is defined. The **Status** field displays a green arrow if the messaging engine is active.
4. Click the messaging engine, and then click **Additional Properties > Service integration bus links**. If you are connecting the remote cell to a single monitor installation and a monitor installation to a single remote cell, one link is defined. You can, however, have more than one link. The **Status** field displays a green arrow if the link is active.
5. Optional: To verify using the System.out log, look for a message similar to the message provided here. The messaging engine name is different for each machine:  
CWSIP03821: Messaging engine FADB84EB685E209F responded to subscription request,  
Publish Subscribe topology now consistent.

**Note:** You can perform the same procedure on the IBM Business Monitor server to validate that the IBM Business Monitor server side of the service integration bus link is active.

---

## Configuring dashboards

Install and configure the Business Space component so that dashboards work properly in the IBM Business Monitor runtime environment.

You must install the product software. When you install your product, Business Space files are included with the installation for the profiles that you configured.

The Business Space component is supported with the following database products:

- DB2 Universal
- DB2 for IBM i
- DB2 for z/OS
- Microsoft SQL Server
- Oracle 11g

To find out which databases are supported with your product, check the supported databases for the product.

If you install IBM Business Process Manager, WebSphere Enterprise Service Bus, or IBM Business Monitor and create a stand-alone server profile with the typical option, the Business Space component is installed and configured automatically with a DB2 Express database. If you are using a stand-alone server profile, you can use the Profile Management Tool with the advanced option to configure Business Space to work with your runtime environment.

For all products, if you are setting up deployment manager and custom profiles, the simplest way to configure the Business Space component is with the Deployment Environment Configuration wizard.

If you have a stand-alone server environment or you are using the Deployment Environment wizard to configure your runtime environment, Representational State Transfer (REST) service endpoints are configured and enabled automatically. For other environments, use the REST services administrative console page to configure the REST services. If you want IBM Business Monitor widgets to be available, you must configure the REST service endpoints for those widgets. You must register the REST endpoints so that IBM Business Monitor associates widgets with the endpoints and the widgets appear in the palette for use.

If you are using deployment manager and custom profiles, you can use the administrative console to configure the Business Space component.

After your original setup work on the Profile Management Tool or the administrative console, you must also configure the Business Space database.

No matter what tool you used to configure the Business Space component, you must make sure that the configuration works with the security for your IBM Business Monitor environment.

After you have installed and configured the Business Space component, users of your runtime environment can open it from the following URL: `http://host:port/BusinessSpace`, where *host* is the name of the host where your server is running and *port* is the port number for your server.

## Configuring dashboards using the Profile Management Tool

You can configure the Business Space component as part of your IBM Business Monitor profile by using the Profile Management Tool.

You can start the Profile Management Tool after product installation. In addition, you can use the Profile Management Tool capabilities from the command line by using the **manageprofiles** command-line utility parameter **-configureBSpace** after product installation. In both situations, Business Space is installed with the same database product as the database product you designate for the IBM Business Monitor database. If you selected a database that is not supported with Business Space, the Profile Management Tool configures Business Space with the IBM DB2 Express database.

If you use the **manageprofiles** command-line utility, follow the **manageprofiles** documentation for your business process management product. Review the following considerations for using **manageprofiles**:

- If you use Oracle or SQL Server on a stand-alone server, you must create the database manually instead of using the **-dbCreateNew** parameter.
- If you have a remote database in a clustered environment, you must create the database manually, copy over the generated scripts to the remote machine with the database, and run the scripts from that location.

For deployment manager and custom profiles, you can use the administrative console or the Deployment Environment Configuration wizard. If you use the Profile Management Tool to create a deployment manager and custom profiles (managed nodes) with the **Deployment environment** profile creation option, Business Space is configured automatically with your deployment environment, but you must manually run scripts to configure the database tables.

For more advanced configuration options on a stand-alone server profile, you must use pages on the administrative console to configure Business Space. For example, if you want to designate a data source that is different than the database you selected for your profile (the IBM Business Monitor database), you must use the administrative console to configure the Business Space component.

- For a stand-alone server, start the Profile Management Tool, select the **Stand-alone server profile** option and complete the following steps.
  1. Complete the Profile Creation Options page. The Business Space component is configured with your product data source.

2. When you designate the host name for your profile, use a fully qualified host name.
  3. On the Database Design page, you have the option of using a database design file that you have created using the database design tool that contains all database configuration for your product, including the Business Space database configuration. For more information about database design files, see *Creating a Business Space database design properties file*.
  4. Complete the profile creation using the Profile Management Tool. The Business Space component is installed. It is configured for the same database product that you designated for the IBM Business Monitor database (or with DB2 Express if the database product is not supported).
  5. If the database is remote, you must configure the database tables after running the Profile Management Tool.
- For a deployment environment, start the Profile Management Tool, select the **Deployment manager profile** or **Custom profile** option and complete the following steps.
    1. On the Profile Creation Options page, select the **Deployment environment** option to configure each profile with customized configuration values and use it in a deployment environment based on a supplied pattern.
    2. Follow the Profile Management Tool steps to create a deployment manager profile and custom profiles (managed nodes).
    3. After all the custom nodes are federated, run scripts to configure the database tables manually.

**Important:** If your product database is an Oracle database, the Business Space component is configured with the Profile Management Tool or the `manageprofiles` command-line utility to use the same database, with the default schema `IBMBUSSP`, and the default password that you enter during profile creation. If you want to use a different password for the `IBMBUSSP` user name, you must use the administrative console to update JDBC Resources:

1. Find the data source `jdbc/mashupsDS`.
2. Modify the value of the authentication alias to make it match the password of the Business Space schema name.
3. Save your changes and restart the server.

Before using dashboards, set up security that you need to use with the Business Space component and the widgets that your team is using.

**Tip:** The Business Space component uses a proxy component to connect to your REST services. In some cases, if REST services are not responsive, you must update the connection timeout settings to your REST services, depending on the performance of the REST service servers. For more information, see *Changing the timeout settings for the Business Space Ajax proxy*.

## Configuring dashboards as part of the Deployment Environment Configuration wizard

Configuration of the Business Space component and of Representational State Transfer (REST) services for IBM Business Monitor widgets are automatically included in the Deployment Environment Configuration wizard. You can decide which REST services to configure.

Before you begin this task, you must complete the following tasks:

- Install your product.
- Create a profile, making sure to designate a fully qualified host name for the profile.
- Enable security, if you want to set up a secured environment for dashboards.

If you are setting up deployment manager and custom profiles, this method is the simplest way to configure the Business Space component for use with dashboards.

1. On the administrative console, click **Servers > Deployment Environments > New**. A series of pages in the wizard guides you through the process of creating your deployment environment.

2. Either define the new deployment environment or import a file that contains deployment environment definitions. You can create a deployment environment based on one of the IBM-supplied patterns or you can create a custom deployment environment.
3. On the Deployment Environment Patterns page, select one of the deployment environment patterns.
4. On the Select Nodes page, designate the nodes to participate in your deployment environment.
5. On the Clusters page, specify the number of cluster members from each node to assign to specific deployment environment functions.
6. On the Database page, configure the data source for Business Space, one of the components listed in the table. You can edit the description, test the connection, and set the database product you want to use for the Provider. If you want the Business Space database tables to be automatically created and configured, select the **Create tables** check box. If you do not select the check box, you must manually configure the Business Space database. The database product list contains all databases supported by each component.

**Tip:** If you select the **Create tables** check box, make sure that the database has been created before creating the deployment environment.

7. On the Security page, configure the authentication aliases WebSphere uses when accessing secure components. The authentication alias user name and password can be changed on this page. These aliases are used to access secure components but do not provide access to data sources.
8. On the REST Services page, configure the services for the widgets you want available in your IBM Business Monitor runtime environment.
  - Type the port number and the host or virtual host that a client needs to communicate with the server or cluster. In a clustered environment, this is typically the load-balancing server host name and port.
  - If you leave the host and port fields empty, the values default to values of an individual cluster member host and its HTTP port. For a load-balanced environment, you must later change the default values to the virtual host name and port of the load-balancing server. Make sure to designate a fully qualified host name.
  - Set the description for the widgets if needed.
9. On the next page, click **Finish** or **Finish and Generate Environment**.
10. Optional: If you did not select the **Create tables** check box on the Database page, run the scripts to configure the database tables for Business Space before starting the deployment environment or the clusters. For more information, see *Configuring the Business Space database*.

**Tip:** The Business Space component uses a proxy component to connect to your REST services. In some cases, if REST services are not responsive, you must update the connection timeout settings to your REST services, depending on the performance of the REST service servers. For more information, see *Changing the timeout settings for the Business Space Ajax proxy*.

## Configuring dashboards for network deployment environments

If you have a distributed or network deployment environment, configure the Business Space component for IBM Business Monitor using the administrative console or commands.

If you are using deployment manager and custom profiles, you must configure Representational State Transfer (REST) endpoints, configure the Business Space component, register the REST endpoints, and configure database tables.

## Configuring REST services

If you have a stand-alone server environment or you are using the Deployment Environment wizard to configure your runtime environment, Representational State Transfer (REST) services are configured and enabled automatically. For other environments, use the administrative console to configure the REST services.

If you want widgets to be available in dashboards, you must configure the REST services for those widgets. Later you must register the REST endpoints so that dashboards associate widgets with the endpoints and the widgets appear in the palette for use.

You can configure all REST services for a specific server or cluster. Or, you can select individual services to configure. You can manage individual service configuration by viewing all services for a service provider or by viewing all services for your environment.

REST services are typically exposed on the REST Gateway. Some REST services are implemented by their dedicated system application. The REST Services Gateway application enables common system REST services. The REST Services Gateway application is created when REST services are configured.

Make sure that the REST Services Gateway application is deployed for the particular scope that you are using. You configure REST services for the REST Services Gateway and other service providers by using the REST service providers configuration administrative console page. In order for some widgets to be enabled, you must do this on the scope where the widgets are running. The REST Services Gateway application is deployed to a specific scope when you add it on the REST service providers configuration administrative console page. To add a REST Services Gateway for a given scope, navigate to **Servers > Server types > *my\_server* > Business Integration > REST services** or **Servers > Clusters > *my\_cluster* > Business Integration > REST services**. Then configure the REST services gateway provider for the given server or cluster.

For clustered environments, all administration and configuration tasks for REST services are completed on the REST Services Gateway Dmgr application on the deployment manager. The REST Services Gateway Dmgr application is used with the following widgets:

- Module Browser
- Module Assembly
- Module Properties
- Proxy Gateway
- Module Health
- System Health

### Configuring all REST services on the administrative console:

Configure all Representational State Transfer (REST) services for your environment by using the REST service administrative console page.

Before you complete this task, you must have installed IBM Business Monitor.

The deployment of the REST services is performed automatically in a stand-alone server profile. For other types of configurations, the administrative console page allows you to configure REST services for all of your IBM Business Monitor widgets that are used in dashboards. On the REST Services page, you can view all services for your environment and enable or disable each service individually.

You also must register the REST endpoints with the Business Space component so that widgets are associated with the endpoints, and the widgets appear in dashboards for use. To ensure that the REST endpoints are registered, see [Configuring Business Space and registering REST endpoints on the administrative console](#).

If you want to configure multiple instances of the same REST service endpoint, you must manually edit the endpoints file and the widgets metadata file.

The REST Services Gateway application enables common system REST services. The REST Services Gateway application is created when REST services are configured.

1. Click **Services > REST services > REST services**.

The REST Services page opens, displaying all REST services in your environment.

2. For the **Scope section**, designate all to view all REST services in your environment, or select a server or cluster where you have REST services enabled. If REST services that you expected to see for the selected scope are missing, enable the REST Services Gateway or the related REST service providers on the server or cluster. See "Configuring REST services for a server, cluster or component."
3. In the table that lists the REST services for the provider, in each row, select the **Enabled** check box if you want to enable the individual REST service, or clear the **Enabled** check box if you want to disable the individual REST service.
4. For each individual service that you want to enable, type a meaningful description in the **Description** column.
5. Click **OK** to commit the changes to the services.
  - Configure dashboards for your network deployment environment.
  - Configure the database tables (if you are using a remote database or a network deployment environment).
  - Register REST service endpoints.
  - For multiple instances of service endpoints, for example if you have partitioning of work on two clusters, and you want to have widgets showing data from each cluster, you must enable the additional widgets manually for each additional cluster.
  - Set up security for dashboards.

*Configuring REST services in a service provider:*

Configure Representational State Transfer (REST) services in a service provider by using the REST service providers configuration administrative console page.

Before you complete this task, you must have installed IBM Business Monitor.

The deployment of the REST services is performed automatically in a stand-alone server profile. For other types of configurations, the administrative console allows you to configure REST services for all of your product's widgets. On the REST service providers configuration administrative console page, you can view all services for a selected service provider and enable or disable each service individually. The page allows you to manage individual service configuration by working with all services for a service provider.

You also must register the REST endpoints with the Business Space component so that widgets are associated with the endpoints, and the widgets appear in dashboards for use. To ensure that the REST endpoints are registered, see Configuring dashboards and registering REST endpoints on the administrative console.

If you want to configure multiple instances of the same REST service endpoint, you must manually edit the endpoints file and the widgets metadata file.

The REST Services Gateway application enables common system REST services. The REST Services Gateway application is created when REST services are configured.

The following REST service providers are available and are configured on the scope shown:

- **REST Services Gateway:** To add a REST Services Gateway for a given scope, navigate to **Servers > Server types > my\_server > Business Integration > REST services** or **Servers > Clusters > my\_cluster > Business Integration > REST services**. Configure the REST services gateway provider for the given server or cluster.
  - **REST Services Gateway Dmgr:** The REST Services Gateway provider on the deployment manager is configured automatically when creating a deployment manager profile for IBM Business Process Manager or WebSphere Enterprise Service Bus. This provider hosts administrative REST services used by the Module Browser, Module Administration, Health Monitor and Proxy Gateway widgets.
1. Click **Services > REST services > REST service providers** .  
The REST service providers page opens, displaying all REST service providers.
  2. Click a provider link to configure the services for the group of REST services managed by that provider.  
The REST service providers configuration page opens, displaying all REST services in the provider.
  3. Select a **Protocol** from the list for all REST services that you want to configure so they are available in IBM Business Monitor dashboards. Configure a full URL path by selecting either **https://** or **http://** and then completing the **Host Name or Virtual Host in a Load-Balanced Environment** and **Port** fields. Use a fully qualified host name.  
If you want REST requests to go directly to the application server, type the application server host name and port. If you want REST requests to go to a proxy server or HTTP server that sits in front of one or more application servers, type the host name and port of the proxy server or HTTP server that you have already set up. In an environment with a load balancer or proxy server between the browser and the REST services, make sure that what you designate for the protocol, host, and port matches the browser URL for accessing dashboards
  4. In the table that lists the REST services for the provider, in each row, select the **Enabled** check box if you want to enable the individual REST service, or clear the **Enabled** check box if you want to disable the individual REST service.
  5. For each individual service that you want to enable, type a meaningful description in the **Description** column.
  6. Click **OK** to commit the changes to the services.
- Configure dashboards for your network deployment environment.
  - Configure the database tables (if you are using a remote database or a network deployment environment).
  - Register REST service endpoints.
  - For multiple instances of service endpoints, for example if you have partitioning of work on two clusters, and you want to have widgets showing data from each cluster, you must enable the additional widgets manually for each additional cluster.
  - Set up security for dashboards.

*Configuring REST services for a server, cluster, or component:*

Configure Representational State Transfer (REST) services for a server, cluster or a component by using the REST Services administrative console page.

Before you complete this task, you must have installed IBM Business Monitor.

The deployment of the REST services is performed automatically in a stand-alone server profile. For other types of configurations, the REST Services administrative console page allows you to configure services for a server, a cluster, or a component.

This task configures the REST service provider application for a particular server or cluster. You must configure the provider application before REST services are available on a server or cluster. For more on REST service providers, see *Configuring REST services in a service provider*.

You also must register the REST endpoints with the Business Space component so that widgets are associated with the endpoints, and the widgets appear in dashboards for use. To ensure that the REST endpoints are registered, see *Configuring dashboards and registering REST endpoints* on the administrative console.

If you want to configure multiple instances of the same REST service endpoint, you must manually edit the endpoints file and the widgets metadata file.

The REST Services Gateway application enables common system REST services. The REST Services Gateway application is created when REST services are configured.

1. Click one of the following.

- For REST services on a server, click: **Servers > Server Types > WebSphere application servers > *name\_of\_server* > Business Integration > REST Services**
- For REST services on a cluster, click: **Servers > Clusters > WebSphere application server clusters > *name\_of\_cluster* > Business Integration > REST Services**

The REST Services page appears, displaying all default REST services that you can configure for widgets for use with your product or component. If a REST service has already been configured, you see a message displayed.

2. Select a **Protocol** from the list for all REST services that you want to configure so they are available in IBM Business Monitor dashboards. Configure a full URL path by selecting either **https://** or **http://** and then completing the **Host Name or Virtual Host in a Load-Balanced Environment** and **Port** fields. Use a fully qualified host name.

If you want REST requests to go directly to the application server, type the application server host name and port. If you want REST requests to go to a proxy server or HTTP server that sits in front of one or more application servers, type the host name and port of the proxy server or HTTP server that you have already set up. In an environment with a load balancer or proxy server between the browser and the REST services, make sure that what you designate for the protocol, host, and port matches the browser URL for accessing dashboards. This same restriction applies for all environments that use Flex-enabled widgets.

3. In the table of REST services, in each row, select the **Enabled** check box if you want to enable the individual REST service, or clear the **Enabled** check box if you want to disable the individual REST service.

4. In the table of REST services, type a meaningful description for each of the REST services in the **Description** field.

5. Click **OK** to commit the changes to the services.

To modify the REST service configuration at a later time, you can come back to the REST Services page or you can use other administrative console pages to manage the configuration of REST service endpoints. The REST service providers page allows you to select service provider that you want to configure. The REST services page accessed from **Services > REST services** allows you to configure all REST services in your environment.

- Configure dashboards for your network deployment environment.
- Configure the database tables (if you are using a remote database or a network deployment environment).
- Register REST service endpoints.
- For multiple instances of service endpoints, for example if you have partitioning of work on two clusters, and you want to have widgets showing data from each cluster, you must enable the additional widgets manually for each additional cluster.
- Set up security for dashboards.

## Configuring REST services using the command line:

All widgets required for your product are installed with the Business Space component. The Representational State Transfer (REST) services for widgets must be configured, enabled, and registered with Business Space before your team can use dashboards. If you do not use the REST Services administrative console page, use the **updateRESTGatewayService** command.

Before you complete this task, you must have installed IBM Business Monitor.

The deployment of the REST services is performed automatically in a stand-alone server profile. For other types of configurations, the REST Services administrative console page or the **updateRESTGatewayService** command allows you to configure services for REST application programming interfaces (APIs) for all of your product's widgets.

You also must register the REST endpoints with the Business Space component so that widgets are associated with the endpoints, and the widgets appear in dashboards for use.

If you want to configure multiple instances of the same REST service endpoint, you must manually edit the endpoints file and the widgets metadata file.

1. Open a command window.

The **wsadmin** command can be found in the *profile\_root/bin* directory for a stand-alone server environment, or in the *deployment\_manager\_profile\_root/bin* directory for a network deployment environment.

2. At the command prompt, type the **wsadmin** command to start the **wsadmin** environment.
3. Use the **updateRESTGatewayService** command to configure REST services specifying the cluster or the server and node. The **-enable** parameter is optional, and if not specified, defaults to true.
4. Run the save command.

The following example uses Jython to run the **updateRESTGatewayService** command and then save the changes. It configures the REST services on a cluster.

```
AdminTask.updateRESTGatewayService(['-clusterName
 cluster_name'])
AdminConfig.save()
```

The following example uses Jacl:

```
$AdminTask updateRESTGatewayService {-clusterName
 cluster_name}
$AdminConfig save
```

- Configure dashboards for your network deployment environment.
- Configure the database tables (if you are using a remote database or a network deployment environment).
- Register REST service endpoints.
- For multiple instances of service endpoints, for example if you have partitioning of work on two clusters, and you want to have widgets showing data from each cluster, you must enable the additional widgets manually for each additional cluster.
- Set up security for dashboards.

## Configuring dashboards and registering REST endpoints on the administrative console

You can install and configure the Business Space component using the administrative console.

Before you begin this task, you must complete the following tasks:

- Install the product software and created a profile. When you install your product, Business Space files are included with the installation for the profiles that you set up. Your profile is not configured for dashboards until you explicitly configure the Business Space component on the profile.
- Enable security, if you want to set up a secured environment for dashboards.
- Configure Representational State Transfer (REST) services. If you have a stand-alone server environment or you are using the Deployment Environment wizard to configure your runtime environment, the REST service endpoints are configured and enabled automatically. For other environments, use the REST services administrative console page to configure the REST services. If you want widgets to be available in dashboards, you must configure the REST services for those widgets. On the Business Space Configuration administrative console page, you register the REST endpoints so that Business Space associates widgets with the endpoints and the widgets appear in the palette for use.
- If you want to configure the Business Space component on a server or cluster using a different data source than the product data source: Create the data source in the server or cluster scope with the correct JNDI name of jdbc/mashupDS before configuring the Business Space component using the administrative console.
- For Oracle, to use a different schema for the Business Space database tables than the one used by the product database, complete the following steps to create a data source manually before you open the Business Space Configuration page:
  1. Create the schema using the database product software.
  2. Use the administrative console to configure the JDBC provider.
  3. Use the administrative console to create a data source with the JNDI name of jdbc/mashupDS at the server or cluster scope, depending on your environment.
  4. Use the administrative console to create an authentication alias. Set the user name to the schema you created and set the authentication according to your Oracle setup.
  5. Set the authentication alias on the data source.

If you are using deployment environments or other advanced profile configuration, you must use the administrative console to configure the Business Space component to work with dashboards in your runtime environment.

1. Ensure that the administrative console is running.
2. In the navigation pane click **Servers > Server Types > WebSphere application servers** or **Servers > Clusters > WebSphere application server clusters**.
3. Select the name of your server or cluster target.
4. On the Configuration page, under **Business Integration**, click **Business Space Configuration**. The Business Space Configuration page opens. If Business Space has already been configured, you can view this page, but you cannot edit the fields.
5. Select the **Install Business Space service** check box.
6. In the **Database schema name** box, type the name of the database schema that you want to use for the Business Space database.

**Note:** In Oracle, the schema is the same as the user name set on the authentication alias on the data source.

7. If no data source is designated in the **Existing Business Space data source** field, go to **Create Business Space data source using** and select a data source that connects to the database you want to use with Business Space.

Designating a data source under **Create Business Space data source using**: creates a data source for Business Space with a JNDI name of jdbc/mashupDS that is modeled on the data source you selected.

The Business Space data source is created on the server or cluster on which you are configuring Business Space, even if the product data source is on a different server or cluster.

**Tip:** If you do not see an existing data source that you want to use, you must cancel the Business Space Configuration page, set up the database and the data source that you want to use, and then restart the Business Space Configuration page to complete the configuration. For more information, see the Before you begin section.

8. Click **OK**.
9. To register the proper deployment target (cluster or server) for the system REST endpoints for each of the widgets you are using in Business Space, click **REST service endpoint registration**.  
The target that you select for a REST service endpoint type can set the scope of the data displayed in some widgets. Or, you might want to select a particular cluster or server for better performance or availability.  
If you do not specify the target, the REST endpoint of this type is not registered with Business Space, and any widgets that need the REST service endpoint of this type will not be visible in Business Space.
10. Save the configuration.
11. Run the scripts to configure the Business Space database tables before starting the deployment environment or the clusters. The scripts were generated when you completed the configuration. For more information, see Configuring the Business Space database.

**Note:** If you are using Oracle, the password of the authentication alias of the Business Space data source is set to same as the Business Space schema name. The default value of the schema is IBMBUSSP. When you configure the Business Space component, you can specify a different schema on the administrative console or in the command line. In that case, the default password is the same as the schema you specify. If you want to use a different password for the Business Space user name, you must use the administrative console to updated JDBC Resources: Find the data source jdbc/mashupsDS. Modify the value of the authentication alias to make it match the password of the Business Space schema name. Save your changes and restart the server.

**Tip:** The Business Space component uses a proxy component to connect to your REST services. In some cases, if REST services are not responsive, you must update the connection timeout settings to your REST services, depending on the performance of the REST service servers. For more information, see Changing the timeout settings for the Business Space Ajax proxy.

## Configuring dashboards using the command line

You can set up and configure the Business Space component using the **wsadmin** command. You can use the **wsadmin** command to perform the same configuration of Business Space that you can perform in the administrative console.

Before you begin this task, you must complete the following tasks:

- Install the product software and create a profile. When you install your product, Business Space files are included with the installation for the profiles that you set up. Your profile is not configured for Business Space until you explicitly configure Business Space on the profile.
- If you want to set up a secured environment for Business Space, enable security.
- If you plan to use a database design file for the Business Space database information, complete the steps in Creating a Business Space database design properties file.
- Configure Representational State Transfer (REST) services. If you have a stand-alone server environment or you are using the Deployment Environment wizard to configure your runtime environment, the REST service endpoints are configured and enabled automatically. For other environments, use the REST services administrative console page to configure the REST services. If you want widgets to be available in Business Space, you must configure the REST service endpoints for those widgets. You must register the REST endpoints so that Business Space associates widgets with the endpoints and the widgets appear in the palette for use.

- If you want to configure Business Space on a server or cluster using a different data source than the product data source, create the data source in the server or cluster scope with the correct JNDI name of `jdbc/mashupDS` before configuring Business Space (before running the **configureBusinessSpace** command).
- For Oracle, to use a different schema for the Business Space tables than the one used by the product database, complete the following steps to create a data source manually before you run the commands to install and configure Business Space in the procedure below:
  - Use the administrative console to configure the JDBC provider.
  - Use the administrative console to create a data source with the JNDI name of `jdbc/mashupDS` at the server or cluster scope, depending on your environment.

You can use the command line to configure Business Space if you want to write scripts instead of using the administrative console to configure Business Space.

If you are not sure whether Business Space is already configured, you can run the **getBusinessSpaceDeployStatus** command to check whether Business Space is configured on a server, cluster, or cell. For more information about that command, see "getBusinessSpaceDeployStatus command."

To configure Business Space, complete the following steps.

1. Open a command window.

The `wsadmin` command can be found in the `profile_root/bin` directory for a stand-alone server environment, or in the `deployment_manager_profile_root/bin` directory for a network deployment environment.

2. At the command prompt, type the **wsadmin** command to start the **wsadmin** environment.
3. Use the **installBusinessSpace** command to install the Business Space enterprise archive (EAR) files in your runtime environment.
4. Use the **configureBusinessSpace** command to configure the data source for Business Space and copy the scripts that configure the database tables to `profile_root/dbscripts/BusinessSpace/node_name_server_name/database_type/database_name` for a stand-alone server or `profile_root/dbscripts/BusinessSpace/cluster_name/database_type/database_name` for a cluster.

If you did not specify the **createTables** parameter as `true` when running the **configureBusinessSpace** command, you must run the scripts that configure the database tables. For more information about the scripts, see Configuring the Business Space database.

If you are using a database design file for database configuration, you can use the **-bspacedbDesign** parameter to designate that file when you run the **configureBusinessSpace** command.

If you are using Windows Authentication with Microsoft SQL Server, make sure to specify the **-dbWinAuth** parameter as `true`.

5. After each command, run `AdminConfig.save()` (Jython) or `$AdminConfig save` (Jacl).
6. Run the scripts to configure the database tables for Business Space before starting the deployment environment or the clusters. For more information, see Configuring the Business Space database.

Configuring Business Space sets up a browser-based graphical user interface for the business users of your application that is running with the profile you set up. In Business Space, you and your application users can customize content from products in the WebSphere business process management portfolio.

The following example uses Jython to run the **installBusinessSpace** and **configureBusinessSpace** commands to install the EAR files and configure the data source for Business Space on a cluster. The example designates the schema and the product database to use with Business Space when multiple products are installed. In a situation where both IBM Business Process Manager and IBM Business Monitor are installed, this example creates a Business Space data source using the properties of the IBM Business Process Manager data source.

```
AdminTask.installBusinessSpace('[-clusterName myCluster -save true]')
```

```
AdminTask.configureBusinessSpace('[-clusterName myCluster -schemaName mySchema -productTypeForDatasource WPS -save true]')
```

The following example uses Jacl:

```
$AdminTask installBusinessSpace {-clusterName myCluster -save true}
```

```
$AdminTask configureBusinessSpace {-clusterName myCluster -schemaName mySchema -productTypeForDatasource WPS -save true}
```

**Tip:** If you are using Oracle, the password of the authentication alias of the Business Space data source is set to the same name as the schema name of Business Space. The default value of the schema is IBMUSP. When you configure Business Space, you can specify a different schema on the administrative console or in the command line. In that case, the default password is the same as the schema you specify. If you want to use a different password for the Business Space user name, you must use the administrative console to update JDBC Resources: Find the data source jdbc/mashupsDS. Modify the value of the authentication alias to make it match the password of the Business Space schema name. Save your changes and restart the server.

After configuring Business Space, you must complete the following steps to enable Business Space for your runtime environment.

- Register the endpoints with the **registerRESTserviceEndpoint** command.
- Set up security that you need to use with Business Space and the widgets your team is using. For more information, see "Setting up security for Business Space."

**Tip:** The Business Space component uses a proxy component to connect to your REST services. In some cases, if REST services are not responsive, you must update the connection timeout settings to your REST services, depending on the performance of the REST service servers. For more information, see Changing the timeout settings for the Business Space Ajax proxy.

## Creating a Business Space database design properties file

If your Business Space database type is other than the default, create a database design properties file to simplify the database creation process.

Design file templates for each database type are provided in the *install\_root/BusinessSpace/config.bspace/MetadataFiles* directory; for example, the design file template for DB2 is called *BSpace\_DB2-distributed.properties*.

1. Create a new file by making a copy of the template file for your database type.
2. Change the values of the property settings in the database design properties file, according to your configuration. Comments are provided in the file to help you choose the correct property values.

Supply the full path of your database design properties file in one of the following locations, depending on your product environment and configuration preference:

- If you are using the profile management tool to configure Business Space with a profile, designate the database design file by selecting the **Use a database design file** option.
- If you are using the **manageprofiles** command-line utility to configure Business Space with a profile, designate the database design file with the **-bspacedbDesign** parameter.
- If you are using the **configureBusinessSpace** command to configure Business Space, designate the database design file with the **-bspacedbDesign** parameter.

## Configuring the Business Space database

You can manually install database tables for Business Space on a remote database server with scripts that are generated by the installation program. If you are using a deployment environment, or if your database is remote, you must install these tables after configuring Business Space.

Before you complete this task, you must complete the following tasks:

- Install the product.
- Create profiles and configure servers or clusters for Business Space.
- For Oracle: create the database.
- For Microsoft SQL Server: set SQL Server instance authentication. The SQL Server JDBC driver supports mixed authentication mode only. Therefore, when the SQL Server instance is created, the authentication must be set to **SQL Server and Windows**.
- For all databases, make sure that the database is installed using a UTF-8 Universal character set if you want to use Business Space in your environment.
- Make sure that your application server with Business Space is stopped.

If you are using DB2 for z/OS and the required resources have not already been set up as part of the core product installation, complete the following additional items before you begin this task:

- Create a TEMP database and a TEMP table space to contain the declared temporary tables for processing scrollable cursors.
- Create a dedicated STOGROUP to contain the Business Space data.

For DB2 for z/OS, if you want to use a different storage group (for example, if you do not want Business Space database tables to be added to the same database and storage group as the common database), you must edit and run the `createTablespace_BusinessSpace.sql` script after you configure Business Space and before you configure the Business Space database tables.

- Edit the `createTablespace_BusinessSpace.sql` file, available in the following location:  
*profile\_root/dbscripts/BusinessSpace/node\_name\_server\_name/database\_type/database\_name* for a stand-alone server, or *profile\_root/dbscripts/BusinessSpace/cluster\_name/database\_type/database\_name* for a cluster, where *database\_type* is **DB2zOS**.
- Change the **VCAT** value from **@VCAT@** to the name or alias of the catalog of the integrated catalog facility for the storage group to use.

If you are using DB2 V9.x, and you would like performance improvements, edit the `createTablespace_BusinessSpace.sql` file. The `createTablespace_BusinessSpace.sql` file is available in *profile\_root/dbscripts/BusinessSpace/node\_name\_server\_name/database\_type/database\_name* for a stand-alone server, or *profile\_root/dbscripts/BusinessSpace/cluster\_name/database\_type/database\_name* for a cluster.

- Change **IMMEDIATE SIZE 8000 PAGESIZE 32K** to **IMMEDIATE SIZE 8000 AUTOMATIC PAGESIZE 32K**.
- Add the line **PREFETCHSIZE AUTOMATIC** after **EXTENTSIZE 16** under both **CREATE SYSTEM TEMPORARY TABLESPACE @TSDIR@TMPTP** and **CREATE REGULAR TABLESPACE @TSDIR@REGTP**.

The `configBusinessSpaceDB` script sets up tables for Business Space with a specific database. (If you want to create tables on an existing database other than the specific one, use the `createdBTables` script with your product instead of the `configBusinessSpaceDB` script.)

**Important:** Business Space tables must be created in a table space with a page size of 32K. If the default table space does not have a page size of 32K, the tables are not created.

To configure the database tables for Business Space, complete the following steps:

1. Make sure that you are using a user ID with sufficient authority to create tables.

2. Locate the script in the profile you most recently configured, and save it to a location on the same system with the database.

- For all databases except DB2 for z/OS, locate the `configBusinessSpaceDB.bat` or `configBusinessSpaceDB.sh` script.
- For DB2 for z/OS, if you do not run the `createDB.sh` script, you must run the Business Space files individually. Locate `createTablespace_BusinessSpace.sql` and `createTable_BusinessSpace.sql`.

By default, the scripts are located in the following directory: `profile_root/dbscripts/BusinessSpace/node_name_server_name/database_type/database_name` for a stand-alone server, or `profile_root/dbscripts/BusinessSpace/cluster_name/database_type/database_name` for a cluster. The updated scripts (with the information that you entered during profile creation) are located in the profile for the server or cluster that you most recently configured. If you used the Deployment Environment Configuration wizard, the scripts are located in the deployment manager profile. When you configure a remote database, copy the scripts from the system where your product is installed to a place on the remote system.

3. Edit the script from step 2, and change the page size to 32K.

4. Open a command prompt and run one of the following commands, based on your operating system.

Copy the folder with the batch files and scripts to the same location as your database and run the command there. Your user ID must have access to the command-line interpreter for the database type and have permission to run commands.

-   `configBusinessSpaceDB.sh`
-  `configBusinessSpaceDB.bat`

For DB2 and SQL Server, use the optional `-createDB` parameter if you want to create a different database instead of using the existing database.

**Tip:** When using SQL Server, you see the following warning statements in the `systemout.log` file after running the database script: **... Warning! The maximum key length is 900 bytes ...** If you are using the federated repositories as a user registry, you can ignore the warnings. If you are using the stand-alone LDAP registry, ensure that the number of characters in all the user distinguished name (DN) entries in your organization do not exceed the 131 character limit. If the number of characters in any of the user DN entries exceeds 131 characters, you must change the user account registry to the federated repositories option.

For DB2 for z/OS, run the following files in order:

- `createTablespace_BusinessSpace.sql`
- `createTable_BusinessSpace.sql`

5.    For DB2 and DB2 for z/OS, bind the command-line interface to the Business Space database using the following commands:

```
db2 connect to database_name
db2 bind DB2_installation_directory\bnd\@db2cli.lst blocking all grant public
db2 connect reset
```

where:

*database\_name* is the name of the Business Space database

*DB2\_installation\_directory* is the directory where DB2 is installed

6. If you are creating the Business Space database again, after it had been previously deleted, you must import the Business Space templates and spaces before you can use the Business Space environment. Complete the steps at Updating Business Space templates and spaces after installing or updating widgets.

- Update the endpoints for widgets that you want to be available in Business Space.
- Set up security for Business Space and the widgets that your team is using.

## Registering widget REST service endpoints using the command line

If you configure the Business Space component using the administrative console, you must register Representational State Transfer (REST) endpoints so that your team can use IBM Business Monitor widgets in dashboards. If you do not register your endpoints on the administrative console using the Business Space Configuration and the System REST service endpoint registration pages, you can use the **registerRESTServiceEndpoint** command.

Before you complete this task, you must complete the following tasks:

- Install your product.
- Configure the REST services for the widgets that you are using in dashboards by using the REST Services administrative console page or the **updateRESTGatewayService** command. If you have a stand-alone server environment or you are using the Deployment Environment wizard to configure your runtime environment, the REST services are configured and enabled automatically.
- Configure the Business Space component by using either the Business Space Configuration administrative console page or the **installBusinessSpace** and **configureBusinessSpace** commands.
- Configure the database tables (if you are using a remote database or a network deployment environment).

REST services are registered automatically if you have a stand-alone server environment and you configured the Business Space component with the administrative console or the Profile Management Tool, or if you used the Deployment Environment wizard to configure your runtime environment. Otherwise, you must configure the REST services and then register them.

You can use the System REST service endpoint registration administrative console page or the **registerRESTServiceEndpoint** command to register endpoints for REST services for all of your product's widgets in dashboards. Then the Business Space component automatically associates widgets with these endpoints, and the widgets appear in the palette for use.

You can use the **registerRESTServiceEndpoint** command to register a set of endpoints for a given provider, a deployment target, or all unique endpoints in a cell. This command registers the endpoints of the REST services that are in the same cell as Business Space.

1. Open a command window.

The `wsadmin` command can be found in the `profile_root/bin` directory for a stand-alone server environment, or in the `deployment_manager_profile_root/bin` directory for a network deployment environment.

2. At the command prompt, type the `wsadmin` command to start the `wsadmin` environment.
3. Use the **registerRESTServiceEndpoint** command to register the Business Space endpoints for REST services for all your product's widgets.
4. After each command, run the save command.

The following example uses Jython to run the **registerRESTServiceEndpoint** command and then save the changes. It registers all configured and enabled REST services on the cluster with Business Space.

```
AdminTask.registerRESTServiceEndpoint('[-clusterName
name_of_rest_services_cluster -businessSpaceClusterName
name_of_business_space_cluster]')
AdminConfig.save()
```

where `name_of_rest_services_cluster` is the cluster name where REST services are configured and `name_of_business_space_cluster` is the cluster name where Business Space is deployed.

The following example uses Jacl:

```
$AdminTask registerRESTServiceEndpoint
{-clusterName name_of_rest_services_cluster
-businessSpaceClusterName name_of_business_space_cluster}
$AdminConfig save
```

where *name\_of\_rest\_services\_cluster* is the cluster name where REST services are configured and *name\_of\_business\_space\_cluster* is the cluster name where Business Space is deployed.

The **appName**, **webModuleName**, **type**, **name**, **version**, **nodeName**, **serverName**, or **clusterName** parameters are optional.

If you do not specify **type**, **appName**, and **webModuleName** parameters, all unique REST service endpoints configured on the deployment target are registered.

If you do not specify any of those parameters, all unique REST service endpoints configured on any deployment target are registered.

**Tip:** The Business Space component uses a proxy component to connect to your REST services. In some cases, if REST services are not responsive, you must update the connection timeout settings to your REST services, depending on the performance of the REST service servers. For more information, see [Changing the timeout settings for the Business Space Ajax proxy](#).

## Removing the virtual host from the primary cluster member

In some network deployment topologies, administrators might remove the virtual host from the primary member of a cluster to ensure that all traffic goes through a web server. Configuring the Business Space component on a cluster restores the virtual host, and you might decide to remove the virtual host so that your environment works the same way that it was set up originally.

Business Space requires one cluster member to perform load operations for the initial startup of the server. If the primary cluster member does not have a virtual host, the Business Space configuration adds a virtual host to perform the initial load operations.

After you have configured Business Space on a cluster, check the WebSphere Application Server *default\_host* list to see whether it contains a virtual host for the primary cluster member.

To remove access to the virtual host, complete one of the following actions.

- Disable the virtual host for the primary cluster member after the initial startup of the cluster.
- Delete the virtual host for the primary cluster member using the administrative console (click **Environment** > **Virtual Hosts** > *default\_host* > **Host Aliases**) or commands (see [Working with virtual host properties files](#) in the WebSphere Application Server documentation).

## Configuring a proxy server or load-balancing server to use with dashboards

If you are using an environment with a proxy server or a load-balancing server, you must set up your environment so that dashboards work properly.

In a Network Deployment, or clustered, environment, you might set up a proxy server or an HTTP server for routing, security reasons, and for workload balancing. Instead of incoming HTTP requests going directly to an application server, they go to a proxy server that can spread the requests across multiple application servers that perform the work.

You can use other routing servers in place of or in front of the proxy server, for example IBM HTTP Server.

**Important:** The proxy server (or an alternate routing server) is required for workload balancing HTTP requests across two or more cluster members. The proxy server allows clients to access the applications within this topology.

In an environment with a load-balancing server or a proxy server between the browser and the dashboards and REST services, make sure that what you designate for the REST services protocol, host, and port matches the browser URL for accessing dashboards. On the REST service providers page on the administrative console, verify that for all providers, such as the Business Flow Manager and the Human Task Manager, have the correct protocol, host, and port. For more information about modifying the REST services, see *Configuring REST services in a service provider*.

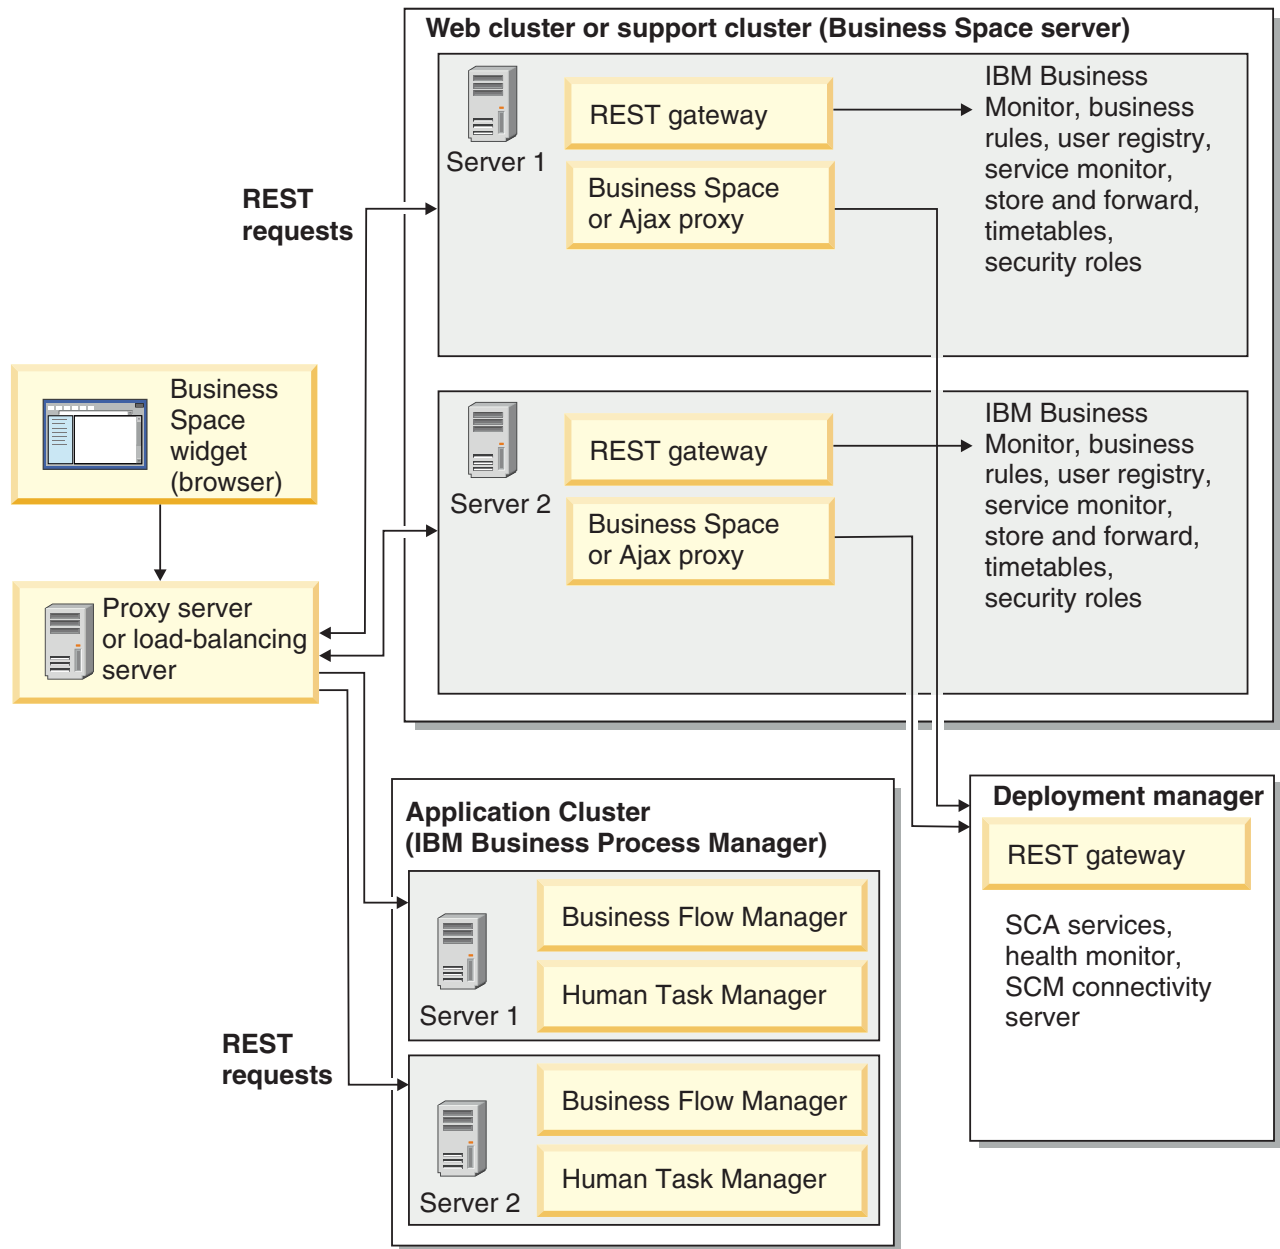

Figure 1. Typical topology

If you use IBM HTTP Server, you must complete additional mapping steps to verify that modules are mapped to the web server and that the host aliases are configured.

If you use a WebSphere Application Server proxy server, you must make sure that all the modules are enabled for the proxy server.

If you use a reverse proxy setup for an HTTP server, you must map the URLs for Business Space and widgets.

### Configuring IBM HTTP Server for dashboards:

If you use IBM HTTP Server, you must complete additional mapping steps so that dashboards work in your IBM Business Monitor environment.

Before you configure IBM HTTP Server to work with dashboards, complete the following steps:

- Install IBM HTTP Server
- Make sure that Secure Sockets Layer (SSL) is enabled for IBM HTTP Server.
- Make sure that the web server definition for IBM HTTP Server has been added to the application server.

During the installation of the IBM HTTP Server plug-in, a `configureWeb_server` script is produced by the installation process on the web server machine. The `configureWeb_server` script is intended to map web application modules to the web server. Therefore, run this script after the generation of the deployment environment.

1. Make sure that modules are mapped to the web server. For each of the applications required by dashboards, verify that the web server is one of the selected targets.

- a. Log in to the administrative console as an administrative user.
- b. Click **Applications > Application Types > WebSphere enterprise applications**.
- c. From the Enterprise Applications panel, click the name of the application.

Check the following applications. You might have some or all applications in this list, based on which products you are using with Business Space.

- For all products, select the following applications:
  - **BSpaceEAR\_nodename\_servername**
  - **BSpaceForms\_nodename\_servername**
  - **BSpaceHelp\_nodename\_servername**
  - **BusinessSpaceHelpEAR\_nodename\_servername**
  - **REST Services Gateway**
  - **mm.was\_nodename\_servername**
  - **PageBuilder2\_nodename\_servername**
- For IBM Business Monitor, select the following applications:
  - **HumanTaskManagementWidgets\_nodename\_servername**
  - **WBMDashboardWeb\_nodename\_servername**

- d. For each application, on the Configuration tab, under Modules, click **Manage Modules**.
- e. On the Manage Modules page for your application, make sure that the web server is one of the selected targets for each of your modules.
  - In the table, check the Server column for each module to make sure that the web server is one of the selected targets for each of your modules. For example, for the `mm.was_nodename_servername` application, look for the web server to be displayed in the Server column: **WebSphere:cell=qaxs41Cell02,node=qaxs41Node03,server=httpserver**  
**WebSphere:cell=qaxs41Cell02,cluster=Golden.WebApp.**
  - If you need to add the web server, select the check box next to the name of the module. Then, in the Clusters and servers list, use the Ctrl key to select multiple targets. For example, to have a web server serve your application, press the Ctrl key and then select the application server cluster and the web server together. Click **Apply**, **OK** and **Save** to save any changes.

2. Verify that the host name alias `default_host` contains the correct information for every cluster member, web server, or proxy server.

- a. Log in to the administrative console as an administrative user.

- b. Click **Servers > Server Types > WebSphere application servers**.
  - c. For every cluster member, click the name of the application server to view the port number for the **WC\_defaulthost** port name.
    - Under Communications, expand **Ports**.
    - For the port name **WC\_defaulthost**, remember its port number.
  - d. From the left navigation area of the administrative console, click **Environment > Virtual hosts**.
  - e. Click the **default\_host** name.
  - f. Under Additional Properties, click **Host Aliases**.
  - g. If the host name and port number for the cluster members is not displayed on the list, click **New** to add the missing entry to the list. The wildcard character \* (asterisk) is supported for the host name.
  - h. If you add a new entry, click **Save** and **Synchronize**.
3. When using an HTTP server front end to work with dashboards, you must set **Accept content for all requests** to **true** for the web server plug-in in the WebSphere Application Server administrative console under **Web servers > webserver1 > Plug-in properties > Request and response**.

### Configuring a WebSphere Application Server proxy server for dashboards:

If you use a WebSphere Application Server proxy server, make sure that all the modules are enabled for the proxy server so that dashboards work in your IBM Business Monitor environment.

Before you configure WebSphere Application Server proxy server to work with dashboards, complete the following steps:

1. Make sure that you have applied the latest version of WebSphere Application Server.
  2. Create a proxy server (click **Servers > Server Types > WebSphere proxy servers**). For more information, see Setting up the proxy server in the WebSphere Application Server information center.
  3. Make sure that the HTTP protocol is selected.
1. Optional: Make sure that modules are mapped to the WebSphere Application Server proxy server. For each of the applications that dashboards require, verify that the modules are enabled for the proxy server.
    - a. Log on to the administrative console as an administrative user.
    - b. Select **Applications > Application Types > WebSphere enterprise applications**.
    - c. From the Enterprise Applications panel, select the name of the application.  
Check the following applications. You might have some or all applications in this list, based on which products you are using with Business Space.
      - For all products, select the following applications:
        - **BSpaceEAR\_nodename\_servername**
        - **BSpaceForms\_nodename\_servername**
        - **BSpaceHelp\_nodename\_servername**
        - **BusinessSpaceHelpEAR\_nodename\_servername**
        - **REST Services Gateway**
        - **mm.was\_nodename\_servername**
        - **PageBuilder2\_nodename\_servername**
      - For IBM Business Monitor, select the following applications:
        - **HumanTaskManagementWidgets\_nodename\_servername**
        - **WBMDashboardWeb\_nodename\_servername**
    - d. For each application, if you click the name of the application, then **Virtual hosts**, verify that it uses the value **default\_host**.

- e. For each application, on the **Configuration** tab, under **Modules**, click **Manage Modules**, then on the Manage Modules page for the application, click each module, and select **Web Module Proxy Configuration** and verify that **Enable Proxy** is selected.
2. Verify that the host name alias `default_host` contains the correct information for every cluster member, web server, or proxy server.
  - a. Log on to the administrative console as an administrative user.
  - b. Select **Servers > Server Types > WebSphere application servers**.
  - c. For every cluster member, select the name of the application server to view the port number for the `WC_defaulthost` port name.
    - Under Communications, expand **Ports**.
    - Note the port number for the `WC_defaulthost` port.
  - d. From the left navigation area of the administrative console, select **Environment > Virtual hosts**.
  - e. Click `default_host`.
  - f. Under Additional Properties, click **Host Aliases**.
  - g. If the host name and port number for the cluster members is not displayed in the list, click **New** to add the missing entry to the list. You can use the wildcard character \* (asterisk) for the host name.
  - h. If you add a new entry, click **Save** and then click **Synchronize**.
3. To use HTTP protocol, configure the WebSphere Application Server proxy server.
  - a. Log on to the administrative console as an administrative user.
  - b. Select **Servers > Server Types > WebSphere proxy servers**, and then select the proxy server that you previously created.
  - c. Expand **HTTP Proxy Server Settings** and click **Proxy settings**.
  - d. Click **Custom Properties** and add a new property with a name of `cache.query.string` for a name and a value of `true`.
  - e. Click **Save**, and then restart the proxy server.

### Mapping dashboard URLs for a reverse proxy server:

If you have a reverse proxy setup for your HTTP server, when you are configuring the HTTP server to work with IBM Business Monitor dashboards, you must map the URLs so that dashboards work properly.

1. Edit your HTTP server configuration file.
2. Map all of the URLs for dashboards and the widgets that your business users work with in dashboards.

URLs for general Business Space framework (all products):

- `/BusinessSpace/*`
- `/mum/*`
- `/BusinessSpaceHelp/*`
- `/BSpaceWebformsProxy/*`
- `/themes/*`
- `/pageBuilder2/*`

Additional URLs for IBM Business Monitor widgets:

- `/BusinessDashboard/*`
- `/monitorServerComponent/*`
- `/mobile/*`
- `/rest/*`
- `/p2pd/*`

**Note:** The /p2pd/\* URLs apply to IBM Cognos Business Intelligence.

3. If you want to expose a public URL for dashboards that is different from the URL of the IBM Business Monitor server, you must configure the proxy to include the **X-Forwarded-Host** and **X-Forwarded-Protocol** headers in HTTP requests. For example, to expose a service as **https://example.com:8080**, you must include the following HTTP request headers:

```
X-Forwarded-Host: example.com:8080
X-Forwarded-Protocol: https
```

**Important:** The **X-Forwarded-Host** and **X-Forwarded-Protocol** headers are only used if you have applied the fix for APAR JR45956 in your environment. See JR45956: PORTAL NOT WORKING WITH PROXY SERVER CONFIGURED.

## Enabling widgets for cross-cell environments

You must manually edit endpoints files if dashboards are running on a different cell than where the Representational State Transfer (REST) services are running, or if widgets are on different cells than IBM Business Monitor.

Before you complete this task, you must have completed the following tasks:

- Installed IBM Business Monitor.
- Created profiles, and configured the Business Space component on a deployment target (server or cluster).
- Configured the database tables (if you are using a remote database or deployment environment).

All widgets required for your product are installed with IBM Business Monitor, but you must configure and register the endpoints needed by the widgets before your team can use them in dashboards. You can configure and register the endpoints by using administrative console pages. However, if your product and REST services are installed on a different cell than the Business Space component, you must edit REST service endpoints files so that they access the REST services and your widgets work properly in IBM Business Monitor.

Edit one or more of the service endpoint files and widget endpoint files, based on the widgets that you are using with IBM Business Monitor. Service endpoint files typically contain `Endpoint` or `Endpoints` in the XML file name, and widget endpoint files typically contain `Widget` or `Widgets` in the XML file name. The following list includes IBM business process management examples of service endpoint files and widget endpoint files:

- IBM Business Monitor: `monitorEndpoints.xml` and `monitorWidget.xml`
- IBM Business Monitor with IBM Cognos Business Intelligence: `cognosEndpoints.xml` and `cognosWidget.xml`
- `wsumEndpoint.xml` and `wsumWidget.xml` (for user membership)

If you are an administrator, you can register endpoints and enable widgets by performing the following steps.

1. Copy the remote widget compressed file found at `install_root\BusinessSpace\registryData\product_name\product_name_widget_set_name_crosscell.zip` to the cell where Business Space is configured during product installation. Widgets can be found in the directory and can be copied to a temporary folder.
2. Extract the `crosscell.zip` to a temporary directory.
3. Locate the service endpoint files and widget endpoints files.  
In the directory where you extracted the file, look in the `endpoints` directory to view all the widget endpoint files and service endpoint files. The file names typically end with `Endpoints.xml` or `Endpoint.xml`.
4. Configure the endpoints as needed by editing the service endpoint files and the widget endpoint files.
  - a. Edit the service endpoint files to point to the service.

Each endpoint in the service endpoint file is designated by a `<tns:Endpoint>` block. Identify the block that you want to change. Look for comments that identify where you make the edits, for example:

```
<!-- When your REST service is remote from your Business Space server, update the following
url value with the fully qualified URL to the service.
For example https://host.domain.com:9443/rest/bpm/monitor/ -->
<tns:url>/rest/bpm/monitor/</tns:url>
```

**Tip:** If you do not intend to activate some endpoints, you can remove them from the file to prevent confusion.

The location identified by an endpoint is specified in `<tns:url>`. This value is a path in a web module, specified as a full or relative HTTP URL. By default, the URL is relative. Change it to a full URL path, for example, `https://virtualhost.com:virtualport/rest/bpm/htm` or `http://host1:9445/WBPublishingDRAFT/`, where the protocol, host, and port identify how the product web module can be accessed.

To locate the port number for the server, perform the following steps:

- Log in to the administrative console.
- Click **Servers > Server Types > WebSphere application servers**.
- Click the server for which you want to find the port number, and then expand the Ports section.

All applications use the same port as shown in either the `wc_defaulthost` (unsecured host) parameter or the `wc_defaulthost_secure` (secure host) parameter.

**Tip:** If you are using an HTTP server to access your web modules for load balancing, use the host name and port settings of the HTTP server.

- b. Edit the widget endpoint files to point to the Business Space location where the widgets are deployed.

Each endpoint in the service endpoint file is designated by a `<tns:id>` block. Identify the block that you want to change. Look for comments that identify where you make the edits, for example:

```
<!-- When using widgets in a remote configuration, update the following
url value with the fully qualified URL of the widget web module.
For example https://host.domain.com:9443/BusinessDashboard/ -->
<tns:url>/BusinessDashboard/</tns:url>
```

The location identified by an endpoint is specified in `<tns:url>`. Change it to a full URL path that points to the Business Space location where the widgets are deployed, for example, `https://host.domain.com:port/BusinessDashboard/`

5. In the cell where the Business Space server is configured, run the `updateBusinessSpaceWidgets` command to update the endpoint URLs after you have modified the endpoints XML files.
  - a. For your profile, open a command window. The `wsadmin` command can be found at the `profiles\profile_name\bin` directory. For a clustered environment, run the command from the `deployment_manager_profile_root\bin` directory. For a stand-alone server environment, run the command from the `profile_root\bin` directory.
  - b. At the command prompt, type the `wsadmin` command to start the `wsadmin` environment.
  - c. Run the `updateBusinessSpaceWidgets` command. For a clustered environment, specify the `-clusterName` parameter. For a stand-alone server environment, specify the `-serverName` and `-nodeName` parameters. Specify the `-endpoints` parameter with the full path for the directory where you extracted the widget endpoint files. Specify the `-catalogs` parameter to point to the directory where you extracted the widget catalog file.
6. Restart the server.

The following example endpoint file is for IBM Business Monitor widgets.

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- START NON-TRANSLATABLE -->
```

```

<tns:BusinessSpaceRegistry
 xmlns:tns="http://com.ibm.bspace/BusinessSpaceRegistry"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://com.ibm.bspace/BusinessSpaceRegistry
 BusinessSpaceRegistry.xsd ">

 <tns:Endpoint>
 <tns:id>{com.ibm.wbimonitor}monitorServiceRootId</tns:id>
 <tns:type>{com.ibm.wbimonitor}monitorServiceRootId</tns:type>
 <tns:version>1.0.0.0</tns:version>
 <tns:url>/rest/</tns:url>
 <tns:description>Location of backing services for Monitor widgets
 </tns:description>
 </tns:Endpoint>

</tns:BusinessSpaceRegistry>
<!-- END NON-TRANSLATABLE -->

```

- After running the **installBusinessSpaceWidgets** command or the **updateBusinessSpaceWidgets** command, you must perform manual steps to update dashboards templates and spaces. For more information, see Updating templates and spaces after installing or updating widgets.
- For multiple instances of service endpoints, for example for partitioning of work on two clusters, and you want to have widgets showing data from each cluster, you must enable the additional widgets manually for each additional cluster. You must edit both the widget endpoints files and the widget catalog files. For more information, see Enabling widgets to work with multiple endpoints.
- If you have enabled security for your environment, you must make sure that it is set up properly to work with dashboards.

## Enabling widgets to work with multiple endpoints

If you have one dashboard instance configured and you have a need to create another instance of the service endpoints in your environment, you must configure IBM Business Monitor so that the widgets can display data from the multiple service endpoints. You must edit two files: the endpoints file, which registers endpoints with the Business Space component, and the widget catalog file, which contains definitions of widgets.

Before you complete this task, you must have completed the following tasks:

- Installed the product.
- Created a server or cluster and configured it for Business Space .
- Configured the database tables (if you are using a remote database or deployment environment).
- Configured the additional Representational State Transfer (REST) services for your additional widgets.

In a deployment environment, you can have partitioning of work. For example, you can have two clusters, one that processes accounting data and one that processes insurance data. However, a service endpoint serves only one cluster. To access both partitions of work from dashboard, you must register two separate widgets, one for each partition of work, so you can access them both from dashboard. For example, you could have an Account Human Task List widget and an Insurance Task List widget in the catalog (both with the same actual human task list code).

You must manually edit the endpoints file and the widget catalog file.

Widget service endpoint files are bundled with each product and are added during the installation of the product. You must edit one or more service endpoint files, based on the products you have installed, and the widgets you are using with IBM Business Monitor. The following list includes IBM business process management examples of widget service endpoint files:

- IBM Business Monitor: `monitorEndpoints.xml`

- IBM Business Monitor with IBM Cognos Business Intelligence: `cognosEndpoints.xml`
- WebSphere Enterprise Service Bus: `webbWidgetEndpoints.xml` (for Mediation Policy Administration, Service Browser, and Proxy Gateway widgets), `bpmAdministrationEndpoints.xml` (for Administration widgets)
- IBM Business Process Manager: `wpsEndpoints.xml`, `bpmAdministrationEndpoints.xml` (for Administration widgets), `webbWidgetEndpoints.xml` (for Mediation Policy Administration, Service Browser, and Proxy Gateway widgets), `HumanTaskManagementEndpoints.xml` (for business processes and human tasks), `bspaceWFSEndpoints.xml` (for using Lotus Webform Server with Human Task Management widgets)
- All products: `wsumEndpoint.xml` (for user membership)

Widget catalog files contain the definition of widgets for your product. You must edit one or more of the following widget files, based on the products you have installed, and the widgets you are using with Business Space. The following list includes IBM business process management examples of widget catalog files:

- IBM Business Monitor: `catalog_WBMonitor.xml`
- WebSphere Enterprise Service Bus: `catalogProxyGateway.xml` and `catalog_ServiceAdmin.xml`
- IBM Business Process Manager: `catalog_BPMAdministration.xml`, `catalog_BusinessRules.xml`, `catalog_ServiceAdmin.xml`, and `catalog_HumanTaskManagement.xml`

Both the service endpoint files and the widget catalog files are located at `install_root\BusinessSpace\registryData\product_name\`. The endpoints files are located in the endpoints subdirectory, and the catalog files are located in the catalogs subdirectory.

The `install_root\BusinessSpace\registryData\product_name\` directory contains service endpoint and widget catalog template files for your product. You can copy the files that you need to use as a template and add your changes.

1. In order to have multiple instances of a widget, you must install the applications that provide widgets with a unique application name and context root for each widget instance.
  - a. Deploy the widget application on the Business Space deployment target (the same server or cluster on which the **BSpaceEAR\_server\_node** application is running) for each widget instance. The following list includes IBM business process management examples of widget Enterprise Archive (EAR) files:
    - `BPMAdministrationWidgets_nodename_servername` (for WebSphere Enterprise Service Bus and IBM Business Process Manager)
    - `HumanTaskManagementWidgets_nodename_servername` (for IBM Business Process Manager and IBM Business Monitor)
    - `WBMDashboardWeb_nodename_servername` (for IBM Business Monitor)
    - `webbWidgets_nodename_servername` (for WebSphere Enterprise Service Bus)
  - b. When deploying, update the application name and the web module context root names to a unique name. Take note of the context root names that you use.
2. Edit the new REST service endpoints for the additional application deployment targets (the server or cluster where the REST services application is deployed). Create a service endpoints file to add service endpoints.
  - a. Locate the endpoint files in the `install_root\BusinessSpace\registryData\product_name\endpoints` directory. Copy the endpoints template file, and remove all the endpoints that you do not intend to change.
  - b. Edit the endpoints file and add an additional service endpoint starting with `<tns:Endpoint>`, with a unique ID (`<tns:id>`) and the URL for the new endpoint (`<tns:url>`), but with the same version, and optionally all the locales as the original endpoint. The type (`<tns:type>`) must have the same value as the ID (`<tns:id>`). You can change the name and description, for example, **My team's insurance task list**.

c. When adding endpoints, pay attention to the following information:

- **<tns:id>**: The ID can be any string but must be unique for all registered endpoints. Ensure that this ID is unique when you are adding additional endpoints.
- **<tns:type>**: The type must have the same value as **<tns:id>**.
- **<tns:url>**: For the service endpoint, if the URL is relative, then it is assumed that the REST service endpoint is co-located with the Business Space server. If the URL is relative, make sure the URL is same as the context root you deployed, but with beginning and end directory indications, for example, **<tns:url>/REST\_Endpoint\_for\_server2/</tns:url>**. If your endpoint is on a remote system, update this field with an absolute URL, but with an end directory indication.
- **<tns:description>**: Type a meaningful description that further details the nature of the data set that this endpoint is working on. It could either be based on the cluster that is working on the data set or the nature of the data set, for example, **insurance claim human tasks** or **accounting data human tasks**.

d. Save your changes.

Example service endpoint, located in `monitorEndpoints.xml`:

```
<tns:Endpoint>
 <tns:id>{com.ibm.wbimonitor}monitorServiceRootId</tns:id>
 <tns:type>{com.ibm.wbimonitor}monitorServiceRootId</tns:type>
 <tns:version>1.0.0.0</tns:version>
 <tns:url>/rest/bpm/monitor/</tns:url>
 <tns:description>Location of backing services for Monitor widgets
</tns:description>
</tns:Endpoint>
```

3. In the service endpoints file, add a widget endpoint for each widget instance.

a. Edit the endpoints file that you created in step 2. Add an additional widget endpoint starting with **<tns:Endpoint>** and with a unique ID (**<tns:id>**). The type (**<tns:type>**) must have the same value as the ID (**<tns:id>**). The URL for the new endpoint (**<tns:url>**) should be the same as the context root you deployed in step 1., but with beginning and end directory indications, for example, **<tns:url>/BspaceWidgetsWPS2/</tns:url>**. The widget endpoint you add should contain the same version and can optionally contain all the locales as the original endpoint. You can change the name and description.

b. When adding endpoints, pay attention to the following information:

- **<tns:id>**: The ID can be any string but must be unique for all registered endpoints. Ensure that this ID is unique when you are adding additional endpoints.
- **<tns:type>**: The type must have the same value as **<tns:id>**.
- **<tns:url>**: For the widget endpoint, make sure the URL is same as the context root you deployed, but with beginning and end directory indications, for example, **<tns:url>/BspaceWidgetsWPS2/</tns:url>**.
- **<tns:description>**: Type a meaningful description that further details the nature of the data set that this endpoint is working on. It could either be based on the cluster that is working on the data set or the nature of the data set, for example, **insurance claim human tasks** or **accounting data human tasks**.

c. Save your changes.

Example widget endpoint, located in `monitorEndpoints.xml`:

```
<tns:Endpoint>
<tns:id>{com.ibm.wbimonitor}monitorWidgetRootId2</tns:id>
 <tns:type>{com.ibm.wbimonitor}monitorWidgetRootId2</tns:type>
 <tns:version>1.0.0.0</tns:version>
 <tns:url>/BusinessDashboards/</tns:url>
 <tns:description>Location for Monitor widgets</tns:description>
</tns:Endpoint>
```

4. Create a widget catalog file to add new widget definitions.

- a. Locate the widget catalog file in the `install_root\BusinessSpace\registryData\product_name\catalogs` directory. Copy the catalog template file. For the new file name, use the following standard: `catalog_widget.xml` (with no spaces in the file name), where `widget` is the same as the `id` value of the `<catalog>` element in the file. Remove all the `<category>` elements that you do not intend to change. For the category that you are working with, remove all the `<entry>` elements that you do not intend to change.
- b. Add an `<entry>` with a unique ID, for example, `id="{com.ibm.bspace.widget}widget_id` and a unique name, for example, `unique-name="{com.ibm.bspace.widget}widget_name`. You can keep all the other definitions.
- c. Change the title and description to make the new widget available as a distinct widget in Business Space that outlines the nature of the new endpoint. For example, you could name your widget **My team's insurance task list** in the `<title>`. The title should help the business users choose the right widget. The description should help the business users understand the nature of the data and the functionality of the widget that they are selecting.
- d. Edit the new widget catalog XML file to reference the new widget endpoint: Change the definition to match the `<tns:id>` of the widget endpoint you added in step 3.a.

For example, change it to: ...

```
<definition>endpoint://{com.ibm.wbimonitor}monitorWidgetRootId2/com/ibm/wbimonitor/
common/iWidgets/instances_iWidget.xml</definition>
```

...

- e. In the `<metadata>` of the catalog file, make sure the `endpoint://` matches the type and the ID in the endpoint file (`<tns:type>` and `<tns:id>`).
- f. In the `<metadata>` of the catalog file, make sure the `"refVersion"` : matches the version in the endpoint file (`<tns:version>`).
- g. Save your changes.

You can use the widget definition in the example code snippet below as a basis to make your changes::

```
<entry id="{com.ibm.wbimonitor}instances"
unique-name="{com.ibm.wbimonitor}instances">
 <title>
 <!-- END NON-TRANSLATABLE -->
 <nls-string xml:lang="en">Instances</nls-string>
 <!-- START NON-TRANSLATABLE -->
 </title>
 <description>
 <!-- END NON-TRANSLATABLE -->
 <nls-string xml:lang="en">Instances</nls-string>
 <!-- START NON-TRANSLATABLE -->
 </description>
 <shortDescription>
 <!-- END NON-TRANSLATABLE -->
 <nls-string xml:lang="en">This widget displays a dashboard with
the available monitoring context in either individual instances or user-
defined groups of context instances.</nls-string>
 <!-- START NON-TRANSLATABLE -->
 </shortDescription>
 <definition>endpoint://{com.ibm.wbimonitor}monitorWidgetRootId
/com/ibm/wbimonitor/common/iWidgets/instances_iWidget.xml</definition>
 <content>endpoint://{com.ibm.wbimonitor}monitorWidgetRootId/img/
thumb_instances.gif</content>
 <preview>endpoint://{com.ibm.wbimonitor}monitorWidgetRootId/img/
prev_instances.gif</preview>
 <previewThumbnail>endpoint://{com.ibm.wbimonitor}monitorWidgetRootId/
img/prev_instances.gif</previewThumbnail>
 <help>endpoint://{com.ibm.bspace}bspaceWidgetHelpRootId/topic/
com.ibm.bspace.help.widg.mon.doc/topics/help_instance_what.is.html</help>
 <icon>endpoint://{com.ibm.wbimonitor}monitorWidgetRootId/img/
```

```

icon_instances.gif</icon>
 <metadata name="com.ibm.mashups.builder.autoWiringEnabled">true
</metadata>
 <metadata name="com.ibm.bspace.version">7.0.0.0</metadata>
 <metadata name="com.ibm.bspace.owner">International Business
Machines Corp.</metadata>
 <metadata name="com.ibm.bspace.serviceEndpointRefs">
[{"name":"serviceUrlRoot", "required":"true",
"refId":"endpoint://{com.ibm.wbimonitor}monitorServiceRootId",
"refVersion":"1.0.0.0"}]</metadata>
 </entry>

```

5. Place the new service endpoint file and the new widget catalog file in a compressed file, and run the **updateBusinessSpaceWidgets** command, using the **-widgets** parameter to specify the compressed file location.
  - After running the **updateBusinessSpaceWidgets** command, you must perform manual steps to update dashboards templates and spaces. For more information, see Updating templates and spaces after installing or updating widgets.
  - If dashboards are running on a different cell than where the REST services are running, you must manually edit the endpoints files.
  - If you have enabled security for your environment, you must make sure that it is set up properly to work with dashboards.

## Setting up specific widgets to work in dashboards

Some of the widgets that come with your product require additional configuration steps before you can use them in dashboards.

Your business process management product includes several widgets, and some require additional configuration to communicate with your solution from dashboards.

### Installing the default dashboard space on z/OS

In most operating systems, the default dashboard space is installed automatically. However, for z/OS systems that are using the local OS user registry and SAF authorization, you must complete additional steps to install the default space.

The Business Space component uses the primary administrative user name for setting the administrator for the welcome space. However, on z/OS there is no concept of primary administrator when using the local OS user registry and SAF authorization. This means that you must provide a valid ID in the registry to install the default space.

- Complete the following steps for a stand-alone server:
  1. Modify the **MashupAdminFor00BSpace** property in the configuration file `profile_root/BusinessSpace/node_name/server_name/mm.runtime.prof/config/ConfigService.properties` with a valid user ID.
  2. Run the command **updatePropertyConfig** in the wsadmin environment of the profile:
    - Jython example:

```

AdminTask.updatePropertyConfig({'-serverName server_name -nodeName node_name -propertyFileName
"profile_root/BusinessSpace/node_name/server_name/mm.runtime.prof/config/
ConfigService.properties"
-prefix "Mashups_"})

```
    - Jacl example:

```

$AdminTask updatePropertyConfig {-serverName server_name -nodeName node_name -propertyFileName
"profile_root/BusinessSpace/node_name/server_name/mm.runtime.prof/config/
ConfigService.properties"
-prefix "Mashups_"}

```
  3. Save your changes to the master configuration using one of the following commands:
    - Jython example:

```
AdminConfig.save()
```

– Jacl example:

```
$AdminConfig save
```

.

4. In the profile where the server is located, open the `profile_root/BusinessSpace/node_name/server_name/mm.runtime.prof/public/oobLoadedStatus.properties` file and update the **importSpaces.txt** property:

```
importSpaces.txt=true
```

5. Restart the server.

- Complete the following steps for a cluster:

1. Modify the **MashupAdminForOBSpace** property in the configuration file `deployment_manager_profile_root/BusinessSpace/cluster_name/mm.runtime.prof/config/ConfigService.properties` with a valid user ID.
2. Run the command **updatePropertyConfig** in the wsadmin environment of the deployment manager profile:

– Jython example:

```
AdminTask.updatePropertyConfig({'-clusterName cluster_name -propertyFileName
"profile_root/BusinessSpace/cluster_name/mm.runtime.prof/config/ConfigService.properties"
-prefix "Mashups_"'})
```

– Jacl example:

```
$AdminTask updatePropertyConfig {-clusterName cluster_name -propertyFileName
"profile_root/BusinessSpace/cluster_name/mm.runtime.prof/config/ConfigService.properties"
-prefix "Mashups_"}
```

3. Save your changes to the master configuration using one of the following commands:

– Jython example:

```
AdminConfig.save()
```

– Jacl example:

```
$AdminConfig save
```

.

4. Get the name of the cell, node, and server for the custom profile:
  - a. In the deployment manager profile, open the `deployment_manager_profile_root/BusinessSpace/cluster_name/mm.runtime.prof/config/ConfigService.properties` file.
  - b. Look for the name of the cell, node, and server in the **com.ibm.mashups.directory.templates** or **com.ibm.mashups.directory.spaces** properties.
  - c. Use the name of the cell, node, and server to locate the custom profile.
5. In the custom profile, open the `custom_profile_root/BusinessSpace/cluster_name/mm.runtime.prof/public/oobLoadedStatus.properties` file and update the **importSpaces.txt** property:

```
importSpaces.txt=true
```
6. Resynchronize the custom profile:
  - a. Open the administrative console and click **System administration > Nodes**.
  - b. Click **Full Resynchronize**.
7. Restart the cluster.

## Setting up security for dashboards

If you are using dashboards with your environment, you must consider security options for the Business Space component. If you want to turn on security, set up application security and designate a user repository. To define administrators, assign a Business Space superuser role.

For best results, enable security before you configure the Business Space component. If you enable security later, use the administrative console Global security administration page, to enable both administrative security and application security. On the same administrative console page, you also can designate a user account repository, including changing from the default federated repositories option to another user repository. To designate which users can perform administrator actions in dashboards, assign the Business Space superuser role. Other security configuration might be needed for your specific environment.

**Restriction:** The Business Space component does not support fine-grained access control in Java 2 security.

**Important:** By default, the Ajax proxy configuration used with widgets does not restrict access to any IP addresses. For convenience, the Ajax proxy is configured by default to be open, which is not secure for production scenarios. To configure the Ajax proxy so that it displays only content from selected sites or blocks content from selected sites, follow the steps at Blocking IP addresses using the Business Space Ajax proxy.

**Tip:** If you want Process Portal to run inside an HTML frame, complete the steps in Enabling Process Portal to run in an HTML frame.

## Enabling security for dashboards

If you expect to use a secured environment, enable security before you configure dashboards. However, if needed, you can enable security manually later. To turn on security for dashboards you must enable both application security and administrative security for the Business Space component.

Before you complete this task, you must have completed the following tasks:

- Check that your user ID is registered in the user registry for your product.

The Business Space component is preconfigured to ensure authentication and authorization of access. Users are prompted to authenticate when accessing dashboard URLs. Unauthenticated users are redirected to a login page.

The Business Space component is configured to be accessed by HTTPS by default. If you prefer HTTP because dashboard is already behind a firewall, you can switch to HTTP by running the `configBSpaceTransport.py` script. The `configBSpaceTransport.py` script has parameters to switch to either HTTP or HTTPS if you want to change from a previous setting. See Designating HTTP or HTTPS settings for dashboards.

To enable authenticated access to dashboards, you must have a user registry configured and application security enabled. Authorization to spaces and page content is handled internally as part of managing spaces.

1. For complete instructions on security, see the security documentation for your product.
2. For the Business Space application, on the Global security administrative console page, select both **Enable administrative security** and **Enable application security**.
3. If you want to enable or remove security after you have configured the Business Space component with your IBM Business Monitor profile, you must modify the `noSecurityAdminInternalUserOnly` property in the `ConfigServices.properties` file.

The `noSecurityAdminInternalUserOnly` property specifies the administrator ID for dashboards when security is disabled. By default, Business Space configuration sets the property to `BPMAAdministrator` if security is disabled. When security is enabled, by default this property is set to the application server admin ID. If you want to enable or remove security after you have configured the Business Space component, use the application server admin ID.

- a. Modify the `ConfigServices.properties` file `noSecurityAdminInternalUserOnly` property to set it to the application server admin ID. The `ConfigServices.properties` file is located at `profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\`

ConfigService.properties for a stand-alone server or *deployment\_manager\_profile\_root\BusinessSpace\cluster\_name\mm.runtime.prof\config\ConfigService.properties* for a cluster.

- b. Run the **updatePropertyConfig** command using the wsadmin scripting client.

**Important:** For Windows, the value for the **propertyFileName** parameter must be the full path to the file, and all backslashes must be double, for example: **AdminTask.updatePropertyConfig([-serverName *server\_name* -nodeName *node\_name* -propertyFileName "*profile\_root\BusinessSpace\node\_name\server\_name\mm.runtime.prof\config\ConfigService.properties*" -prefix "Mashups\_"])**.

- For a stand-alone server:

The following example uses Jython:

```
AdminTask.updatePropertyConfig(['-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name
\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"]')
AdminConfig.save()
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name
\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"}
$AdminConfig save
```

- For a cluster:

The following example uses Jython:

```
AdminTask.updatePropertyConfig(['-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"]')
AdminConfig.save()
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"}
$AdminConfig save
```

- c. Restart the server.

- d. Log in to dashboards and reassign the owners of the default spaces to the new administrator ID.

- After the administrative security and application security are turned on, you receive a prompt for a user ID and password when you log in to dashboards. You must use a valid user ID and password from the selected user registry in order to log on. After you turn on administrative security, whenever you return to the administrative console, you must log in with the user ID that has administrative authority.
- If you want to change the user account repository from the default for your product profile, follow the steps in *Selecting the user account repository for dashboards*.
- If you have a cross-cell environment where dashboards are remote from where IBM Business Monitor is running, and the nodes are not in the same cell, set up single-sign-on (SSO) and Secure Sockets Layer (SSL) certificates. Follow the instructions in *Setting up SSO and SSL for dashboards*.
- To designate who can perform administrator actions in the dashboard environment, see *Assigning the superuser role*.

## Selecting the user repository for dashboards

The federated repositories option is the default user account repository option for profiles. You can change the type of user account repository if needed for your environment.

Before you complete this task, you must have completed the following tasks:

- Enable application security and administrative security. See *Enabling security for dashboards*.
- Check that your user ID is registered in the user registry for your product.

To enable authenticated access to dashboards, you must have a user registry configured and application security enabled. For information about application security, see [Enabling security for dashboards](#).

Considerations for using a user account registry with dashboards:

- Based on the type of LDAP configuration that you are using, your settings can impact your ability to access Business Space correctly. Make sure that the user filters, the group filters, and mapping settings are configured properly. For more information, see [Configuring Lightweight Directory Access Protocol search filters in the WebSphere Application Server documentation](#).
  - Based on the type of federated repository configuration that you are using, your settings can affect your ability to access Business Space correctly. Make sure that the realms are configured properly. For more information, see [Managing the realm in a federated repository configuration in the WebSphere Application Server documentation](#).
  - The LDAP security is set up by default to use the login property `uid` (user ID) for searching in Business Space. If your LDAP security is changed to use another unique LDAP field, such as `mail` (email address) for the login property, then you must modify the `userIdKey` property in the `ConfigServices.properties` file in order for searching to work in Business Space. Follow step 3 below.
  - If you are using a Microsoft SQL Server database and the **Standalone LDAP** registry, make sure that the user distinguished name (user DN) does not exceed 450 characters. If any of the user DN entries exceed 450 characters, you must designate the **Federated repositories** option for the user account repository.
  - If you are using **Federated repositories**, you have additional capabilities in your widgets and framework, such as enhanced search capabilities. When searching for users to share spaces and pages, the search scope includes email, a full user name, and user ID.
1. On the Global security administrative console page, under **User account repository**, designate either **Federated repositories**, **Local Operating System**, **Standalone LDAP registry**, or **Standalone custom registry**.
  2. Restart the server.
  3. If you want to change the default user repository from the default **Federated repositories**, modify the **MashupAdminForOOBSpace** property in the `ConfigServices.properties` to designate the correct user ID (the UID property for your user repository) as the valid administrator ID.
    - a. Copy the modified file into an empty folder on your system. The `ConfigServices.properties` file is located at `profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties` for a stand-alone server or `deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\ConfigService.properties` for a cluster.
    - b. Run the `updatePropertyConfig` command using the `wsadmin` scripting client.

**Important:** For Windows, the value for the `propertyFileName` parameter must be the full path to the file, and all backslashes must be double, for example: `AdminTask.updatePropertyConfig('[-serverName server_name -nodeName node_name -propertyFileName "profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"]')`.

- For a stand-alone server:

The following example uses Jython:

```
AdminTask.updatePropertyConfig('[-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name
\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"]')
AdminConfig.save()
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name
\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"}
$AdminConfig save
```

- For a cluster:

The following example uses Jython:

```
AdminTask.updatePropertyConfig('[-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"]')
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"}
```

- c. Log into dashboards and reassign the owners of the default spaces to the new administrator ID.
4. If you are using an LDAP repository with a unique LDAP field, such as mail (email address) for the login property instead of uid (user ID), modify the **userIdKey** property in the `ConfigServices.properties` file in order for searching to work in Business Space.
  - a. Locate the `ConfigServices.properties` file at `profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties` for a stand-alone server or `deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\ConfigService.properties` for a cluster.
  - b. Change the **userIdKey** attribute from `uid` to match the login property for your LDAP user repository, for example, `mail`.
  - c. Copy the modified file into an empty folder on your system.
  - d. Run the **updatePropertyConfig** command using the `wsadmin` scripting client.

**Important:** For Windows, the value for the **propertyFileName** parameter must be the full path to the file, and all backslashes must be double, for example: **AdminTask.updatePropertyConfig('[-serverName *server\_name* -nodeName *node\_name* -propertyFileName "*profile\_root*\\BusinessSpace\\*node\_name*\\*server\_name*\\mm.runtime.prof\\config\\ConfigService.properties" -prefix "Mashups\_"]')**.

- For a stand-alone server:

The following example uses Jython:

```
AdminTask.updatePropertyConfig('[-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name
\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"]')
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name
\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"}
```

- For a cluster:

The following example uses Jython:

```
AdminTask.updatePropertyConfig('[-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"]')
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"}
```

5. If you want to restrict logging in to dashboards to a subset of users and groups, you can change the mapping of the Business Space Java EE security role.

- a. Update the user/group mapping for two enterprise applications: **BSpaceEAR\_node\_server** and **mm.was\_node\_server** (for a stand-alone server environment) or **BSpaceEAR\_cluster** and **mm.was\_cluster** (for a network deployment environment).
- b. Click **Applications > Application Types > WebSphere enterprise applications** and select the two applications.
- c. In the right panel, under Detail Properties, select **Security role to user/group mapping**.
- d. Remap the **businessspaceusers** and **Allauthenticated** roles from the two applications by first removing the special subject.
- e. Click **Map Special Subjects** and select **None**.
- f. Click **Map Users** or **Map Groups** and assign each role to your selected users or groups.

Changing the Java EE security role mapping does not affect the user/group search function in Business Space.

6. Restart the server.
7. Log in to dashboards and reassign the owners of the default spaces to the new administrator ID.
  - To set authorization to pages and spaces in dashboards, you can manage authorization when creating the pages and spaces.
  - To designate who can perform administrator actions in dashboards, see Assigning the superuser role.

**Note:**

If you find the following errors in the SystemOut.log file, you might have extra attributes in your user registry that cannot be processed:

```
00000046 SystemErr R Caused by: com.ibm.websphere.wim.exception.WIMSystemException: CWWIM1013E
 The value of the property secretary is not valid for entity uid=xxx,c=us,ou=yyy,o=ibm.com.
00000046 SystemErr R at com.ibm.ws.wim.adapter.ldap.LdapAdapter.setPropertyValue
(LdapAdapter.java:3338)
```

Set the following attributes in the ConfigServices.properties file to bypass those attributes:

```
com.ibm.mashups.user.userProfile = LIMITED
com.ibm.mashups.user.groupProfile = LIMITED
```

The ConfigServices.properties file is located at *profile\_root*\BusinessSpace\*node\_name*\*server\_name*\mm.runtime.prof\config\ConfigService.properties for a stand-alone server or *deployment\_manager\_profile\_root*\BusinessSpace\*cluster\_name*\mm.runtime.prof\config\ConfigService.properties for a cluster. After modifying the ConfigServices.properties file, run the **updatePropertyConfig** command using the wsadmin scripting client by following the instructions in step 4.d.

**Note:**

If you have Java EE security enabled in a cluster, consider tightening the entry in the server policy applied to the Business Space help location.

The Business Space help location policy is:

```
grant codeBase "file:${was.install.root}/profiles/profile_name/temp/node_name/" {
permission java.security.AllPermission;
};
```

Tighten the policy by changing it to:

```
grant codeBase "file:${was.install.root}/profiles/profile_name/temp/node_name/server_name/
BSpaceHelpEAR_node_name_server_name/BSpaceHelp.war/" {
```

```
permission java.security.AllPermission;
```

```
};
```

## Setting up SSO and SSL for dashboards

For remote environments where dashboards and your product server are in different cells, set up single-sign-on (SSO) and Secure Sockets Layer (SSL) configuration manually.

Before you complete this task, you must have completed the following tasks:

- Enable application security and administrative security. See [Enabling security for dashboards](#).
- Check that your user ID is registered in the user registry for your product.

**Tip:** If you have separate cells configured, make sure that SSO considerations are taken into account (including that LTPA keys are in sync, shared user names/realm names are in sync, and certificates are imported as appropriate). In some cases, with IBM Business Process Manager, there might be multiple repositories in the realm, which might result in a realm-mismatch error. See [Managing the realm in a federated repository configuration in the WebSphere Application Server documentation](#).

1. If dashboards are remote from where your product is running, and if the node where dashboards are running and the node where your product is running are not in the same cell, you must complete manual steps to make sure that SSO is enabled. For example, if you are using more than one product, the servers are on different nodes, and you want them all to be able to work with the Business Space server, you must manually configure SSO. To enable SSO, complete the following steps:
  - a. On the administrative console for each server, open the Global security page by clicking **Security > Global security**. Expand **Web and SIP security** and click **single sign-on (SSO)** to make sure that the **Enabled** check box is selected.
  - b. Make sure that all the nodes use the same **User account repository** information.
  - c. Follow the steps in [Import and export keys in the WebSphere Application Server information center](#).
2. If you are using HTTPS in the endpoints file, the endpoint location is on a different node than dashboards, and the SSL certificate is a self-signed SSL certificate, you must import it.

Make sure that the signers are configured in the appropriate truststores for the dashboard server and the IBM Business Monitor server. See [Secure communications using Secure Sockets Layer \(SSL\) in the WebSphere Application Server information center](#).

For more information about SSO and SSL, see the [WebSphere Application Server information center](#).

## Designating HTTP or HTTPS settings for dashboards

The Business Space component is configured to be accessed by HTTPS by default. You can change the protocol from the default or back to the default by running a script.

When only HTTPS connections are allowed, any HTTP requests are redirected to HTTPS.

This task describes how to change the protocol by running the `configBSpaceTransport.py` script.

1. Locate the `install_root\BusinessSpace\scripts\configBSpaceTransport.py` script.
2. If you have a stand-alone server, run one of the following commands on the server:
  - To allow only HTTPS connections to dashboards, enter the following command:

```
wsadmin -lang jython -user user_name -password password
-f configBSpaceTransport.py -httpsonly
```

- To allow HTTP connections to dashboards, enter the following command:

```
wsadmin -lang jython -user user_name -password password
-f configBSpaceTransport.py -allowhttp
```

**Tip:** By default, the command applies to the current server and node. If you want to specify a different location, use the optional **-serverName** and **-nodeName** parameters.

3. If you have a network deployment environment, then depending on the locations of the **BSpaceEAR** and dashboards applications, you must run the `configBSpaceTransport.py` script one or two times.

a. Run one of the following commands on the deployment manager profile to update the cluster where the **BSpaceEAR** application is deployed.

- To allow only HTTPS connections to dashboards, enter the following command:

```
wsadmin -lang jython -user user_name -password password
 -f configBSpaceTransport.py -httpsonly
 -clusterName bspace_cluster
```

- To allow HTTP connections to dashboards, enter the following command:

```
wsadmin -lang jython -user user_name -password password
 -f configBSpaceTransport.py -allowhttp
 -clusterName bspace_cluster
```

Where `bspace_cluster` is the cluster where the Business Space application is deployed.

b. If the dashboards applications are not deployed to the same cluster as the **BSpaceEAR** application, you must run one of the following commands on the deployment manager profile to update the cluster where the dashboards applications are deployed.

- To allow only HTTPS connections to dashboards, enter the following command:

```
wsadmin -lang jython -user user_name -password password
 -f configBSpaceTransport.py -httpsonly
 -clusterName application_cluster
 -bspaceClusterName bspace_cluster
```

- To allow HTTP connections to dashboards, enter the following command:

```
wsadmin -lang jython -user user_name -password password
 -f configBSpaceTransport.py -allowhttp
 -clusterName application_cluster
 -bspaceClusterName bspace_cluster
```

Where `application_cluster` is the cluster where the dashboards applications are deployed and `bspace_cluster` is the cluster where the **BSpaceEAR** application is deployed.

The required connection protocol for dashboards is selected.

## Setting up security for system REST services

To set up security for the data in the widgets based on users and groups, you must modify the users that are mapped to the REST services gateway application.

Before you complete this task, you must have completed the following tasks:

- Enable application security and administrative security. See [Enabling security for dashboards](#).
- Check that your user ID is registered in the user registry for your product.

How you map users to a REST service provider application affects all the services for the provider.

To see the affected services, select **Services > REST services > REST service providers**, and select the matching provider application in the list of providers.

1. On the administrative console, select one of the following options:

- For a server environment, select **Applications > Application types > WebSphere enterprise applications > REST Services Gateway**
- In addition, for a network deployment environment, select **Applications > Application types > WebSphere enterprise applications > REST Services Gateway Dmgr**

2. In the right panel, under Detail Properties, select **Security role to user/group mapping**.

3. To control access to the data in all the REST services widgets, add users and groups to the **RestServicesUser** role.

## Configuring Tivoli Access Manager WebSEAL to work with dashboards

If you have Tivoli® Access Manager WebSEAL and you want to use it with IBM Business Monitor dashboards, you must complete several additional configuration steps.

Before you complete this task, you must have completed the following tasks:

- Enable application security and administrative security. See *Enabling security for dashboards*.
- Check that your user ID is registered in the user registry for your product.
- Make sure that Tivoli Access Manager and IBM Business Monitor have the same users in the user registries.

If you want to use Tivoli Access Manager WebSEAL with IBM Business Monitor dashboards, you must configure WebSEAL to work with Tivoli Access Manager, configure WebSEAL to work with your product application server, and configure host junctions for your environment.

1. Configure WebSEAL to work with Tivoli Access Manager.
  - a. Ensure that WebSEAL is installed and configured properly.
  - b. To create a trusted user account in Tivoli Access Manager, which can be used for configuring TAI, issue the following commands:

```
pdadmin -a sec_master -p domino123
```

```
pdadmin sec_master> user create -gsouser -no-password-policy taiuser
"cn=taiuser,ou=websphere,o=ibm,c=us" taiuser taiuser ptaiuser
```

```
pdadmin sec_master> user modify taiuser password-valid yes
```

```
pdadmin sec_master> user modify taiuser account-valid yes
```

- c. Create the junction between WebSEAL and your product application server using the `-c iv_creds` option for TAI++ and `-c iv_user` for TAI. Enter either of the following commands as one line, using the variables that are appropriate for your environment:

For TAI++

```
server task webseald-server create -t tcp -b supply -c iv_creds
-h host_name -p websphere_app_port_number /junction_name
```

**Tip:** The `junction_name` must begin with `/`.

- d. In the WebSEAL configuration file `webseal_install_directory/etc/webseald-default.conf`, set the following parameter:

```
basicauth-dummy-passwd=webseal_userid_passwd
```

For example, if you set the `taiuser/ptaiuser` in Tivoli Access Manager, set the following parameter: `basicauth-dummy-passwd = ptaiuser`

If you are using a form-based authentication, set the following parameters:

```
forms-auth=both
```

```
ba-auth=none
```

2. If needed, configure WebSEAL to work with your product application server by enabling the TAI++ interceptor on the server.
  - a. In the administrative console, select **Global security > Authentication mechanisms and expiration**.
  - b. Expand **Web and SIP security**, and then select **Trust Association**. Select the check box and click **Apply**.
  - c. To get **TAMTrustAssociationInterceptorPlus** to appear under **Interceptors**, add `com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus` and restart the server.
  - d. Select **Interceptors > TAMTrustAssociationInterceptorPlus > custom properties**, and add the following properties:

Name	Value
com.ibm.websphere.security.webseal.configURL	\${WAS_INSTALL_ROOT}/java/jre/PdPerm.properties
com.ibm.websphere.security.webseal.id	iv-creds
com.ibm.websphere.security.webseal.loginId	tauser (if the user tauser/ptaiuser was created in the Tivoli Access Manager)

- e. Restart the cell.
  - f. To access the client, go to `https://webseal_server_name:webseal_port/junction_name/web_uri_for_client`.
3. Configure the host junctions for your environment, so that the IBM Business Monitor widgets appear. Complete one of the following steps, depending on whether you are using virtual host junctions or transparent host junctions. Standard junctions are not supported.
- If you are using virtual host junctions, create a virtual host junction. A virtual host junction eliminates the need to create separate junctions.
    - a. Make sure that a virtual host has been configured. Virtual host junctions match a host and port number and forward addresses to the target host. No URL filtering occurs, and all requests that match are forwarded to the target host.
    - b. Make sure that the following applications are available to the same virtual host. You may have some or all of the applications, based on which products you are using with Business Space.
      - BusinessSpaceHelpEAR\_nodename\_servername
      - BSpaceEAR\_nodename\_servername
      - BSpaceForms\_nodename\_servername
      - HumanTaskManagementWidgets\_nodename\_servername
      - PageBuilder2\_nodename\_servername
      - REST Services Gateway
      - mm.was\_nodename\_servername
      - WBMDashboardWeb\_nodename\_servername

**Note:** This list of applications covers only the applications required by Business Space. You might need to add other applications to the list for non-Business Space scenarios using Tivoli Access Manager WebSEAL.

- c. Run the following command using pdadmin: **server task webseal server virtualhost create -t transport -h target\_host [-p port] [-v virtual\_host\_name] virtual\_host\_label**
- Use the following information:
- *webseal server* is the name of the WebSEAL server where you will create the virtual host entry.
  - *transport* is the type of transport. Valid entries are tcp, ssl, tcpproxy, and sslproxy.
  - *target\_host* is the host of the required application.
  - *virtual\_host\_name* is used to match HTTP requests to a virtual host junction. If no value is entered, it is made up of the target host and port by default. For example, if you set the *virtual\_host\_name* to `myvirthost.ibm.com:80`, WebSEAL matches the URLs containing `myvirthost.ibm.com:80` and routes it to the host provided in the pdadmin command.
  - *virtual\_host\_label* is the label used to identify the entry in WebSEAL. It must be unique.

For dashboards to run as expected, both `ssl` and `tcp` entries must be created for the type of transport. When you need both Secure Sockets Layer (SSL) and Transmission Control Protocol (TCP) to be supported in the same virtual host junction, you must use the `-g vhost_label` option, where *vhost\_label* is the original virtual host label to share configuration. This option finds a previously created virtual host junction (one created earlier, where the *virtual\_host\_label* matches the label provided in the `-g` option), and shares that configuration. The second entry still requires its own *virtual\_host\_label*, but it can share the target host, port, and other values. If

you do not provide this `-g` option, a second virtual host cannot be created because WebSEAL sees the target host and port as being identical to a previously created junction (which is not allowed).

- If you are using transparent host junctions, create a series of transparent path junctions for the widgets for each product.
  - a. Review each context root you have defined. See Mapping dashboard URLs for a reverse proxy server).
  - b. For each context root defined, run the following command using `padmin`: **`server task webseal server create -t transport type (ssl) or (tcp) -x -h hostname path.`**

For example, type: **`server task webseald-default create -t tcp -x -h monServer.ibm.com /BusinessSpace.`**

- c. Update the following two properties in `ConfigService.properties` of the Business Space server:
 

```
reverseProxyHost = WebSEAL host
reverseProxyPort = WebSEAL port, for example: 80
```
- d. Run the **`updatePropertyConfig`** command using the `wsadmin` scripting client.

- For a stand-alone server:

The following example uses Jython:

```
AdminTask.updatePropertyConfig(['-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name\
mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"]])
AdminConfig.save()
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name\
mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"}
$AdminConfig save
```

- For a cluster:

The following example uses Jython:

```
AdminTask.updatePropertyConfig(['-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\
ConfigService.properties" -prefix "Mashups_"]])
AdminConfig.save()
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\
ConfigService.properties" -prefix "Mashups_"}
$AdminConfig save
```

4. Complete additional configuration steps to resolve issues with browser cookies and virtual hosts.
  - a. To resolve renaming of the Business Space cookie, add the following content to the WebSEAL configuration file:
 

```
[preserve-cookie-names]
name = com.ibm.bspace.UserName
name = com.ibm.wbimonitor.UserName
```
  - b. Optional: If you are using non-default virtual hosts with a context root, you might encounter issues with dashboard pages. You might need to stop the junction from rewriting the JavaScript on the pages. Run the following command:

```
server task default-webseald create -f -h hostname -p portnumber -t tcp -b supply -c
iv-user,iv-creds,iv-groups -x -s /context_root
```

## Assigning the superuser role

You can assign users to be superusers (or dashboard administrators). A superuser can view, edit, and delete all spaces and pages, can manage and create templates, and can change ownership of a space by changing the owner ID.

Before you complete this task, you must have completed the following tasks:

- Enable application security and administrative security. See [Enabling security for dashboards](#).
- Check that your user ID is registered in the user registry for your product.

Assign the superuser role by using the following application server security role: **Admin**. Using this method gives you flexibility in assigning the role to any number of your organization's existing groups and users. It doesn't require the creation of an administrators group in the user registry for the sole purpose of acting as the focal point for the superuser.

If you already have a Business Space superuser assigned from an earlier version than V7.5, you can modify the superuser by user group instead. See [Assigning the superuser by user group](#).

- If you are setting up administrators with the superuser role for the first time, complete the following steps.
  1. Log in to the administrative console for your product.
  2. Click **Applications > Application Types > WebSphere enterprise applications** and select one of the following applications:
    - **mm.was\_node\_server** (for a stand-alone server environment)
    - **mm.was\_cluster** (for a network deployment environment)
  3. Click **Security role to user/group mappings**.
  4. Select the row for the **Admin** role, and click the **Map Users** button or the **Map Groups** button to map either users or groups to the Admin role.
  5. Click **Save**.
  6. Restart the server.
- If you previously assigned superusers based on user groups, and you want to switch to this simpler way to manage superusers by role, complete the following steps.
  1. Open the configuration file.
    - For a stand-alone server: `profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties`
    - For a cluster: `deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\ConfigService.properties`
  2. Change the following property values in the configuration file as shown:  
**com.ibm.mashups.adminGroupName = {com.ibm.mashups.J2EERole.Admin}**  
**com.ibm.mashups.widget.attributes.configure.groups=**
  3. Run the **updatePropertyConfig** command in the **wsadmin** environment of the profile.

**Important:** For Windows, the value for the **propertyFileName** parameter must be the full path to the file, and all backslashes must be double, for example: **AdminTask.updatePropertyConfig('[-serverName server\_name -nodeName node\_name -propertyFileName "profile\_root\BusinessSpace\node\_name\server\_name\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups\_"]')**.

- For a stand-alone server:

The following example uses Jython:

```
AdminTask.updatePropertyConfig('[-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name
\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"]')
AdminConfig.save()
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name
\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"}
$AdminConfig save
```

- For a cluster:

The following example uses Jython:

```
AdminTask.updatePropertyConfig('[-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"]')
AdminConfig.save()
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"}
$AdminConfig save
```

4. Restart the server.
5. Use the previous procedure to assign users to the Business Space superuser roles.

## Assigning the superuser by user group

You can assign users to be superusers (or dashboard administrators) based on user groups.

Before you complete this task, you must have completed the following tasks:

- Enable application security and administrative security. See Enabling security for dashboards.
- Check that your user ID is registered in the user registry for your product.

**Tip:** If you previously used user groups to assign the Business Space superuser role, you can switch to the simpler way to assign Business Space superusers by role. See Assigning the superuser role.

A superuser can view, edit, and delete all spaces and pages, can manage and create templates, and can change ownership of a space by changing the owner ID.

If administrative security is enabled when you configure IBM Business Monitor, consider the following information about groups and superusers:

- Users belonging to the special user group, **administrators**, have a superuser role by default. As a result, the superuser role assignment is handled by user group membership.
- In a single-server environment, the IBM Business Monitor server creates the **administrators** user group in the default user registry. The administrator ID provided during configuration is automatically added as member of this group.
- In a network deployment environment, the **administrators** user group is not created automatically. Use the `createSuperUser.py` script to create the user group and add members to that group in the default user registry.
- If another user registry (for example, LDAP) is used instead of the default user registry, or if the default user registry is used but you do not want to use the **administrators** user group, you must identify the user group that you are using for the dashboard superusers. Make sure that the value that you provide can be understood by the user registry. For example, for LDAP, you might provide a name like `cn=administrators,dc=company,dc=com`. For more information about identifying this user group, see the instructions for changing the administrators group in the What to do next section.
- For widgets in WebSphere Portal, the default group **wpsadmins** is also used for the superuser role. Members of this group are granted the superuser role.

**Note:** Security must be enabled if you want to use widgets in WebSphere Portal.

If administrative security is not enabled when you configure IBM Business Monitor, only the special user ID **BPMAdministrator** has the superuser role.

If you have a network deployment environment, you must run the `createSuperUser.py` script to assign the superuser role: to create the user group and add members. Before you run the script, complete the following steps:

- Make sure the default **administrators** group name is not changed on the administrative console.
  - Use the default file-based user repository for the user registry.
  - Start the server or the deployment manager for your IBM Business Monitor environment for the profile where dashboards are installed.
1. Locate the script `install_root\BusinessSpace\scripts\createSuperUser.py` for assigning the superuser role to a user.
  2. Open a command prompt, and change directories to the following directory: `profile_root\bin`, where `profile_root` represents the directory for the profile where IBM Business Monitor is installed.
  3. Type the following command: `wsadmin -lang jython -f install_root\BusinessSpace\scripts\createSuperUser.py user_short_name password` where `user_short_name` is the unique identifier for a user in Virtual Member Manager (VMM), and `password` is the VMM password for that user. If that user exists in VMM, the user is added to the administrator group.

**Note:** When the path contains a space, for example, if `install_root` is My install dir, you must enclose the path names in quotation marks. For example, type the following command: `wsadmin -lang jython -f "My install dir\BusinessSpace\scripts\createSuperUser.py" user_short_name_in_VMM.`

To open the Business Space component, use the following URL: `http://host:port/BusinessSpace`, where `host` is the name of the host where your server is running and `port` is the port number for your server.

You can change the default special user group named **administrators**. Perform the following steps to check the current group name or change it to other name.

Inspect the value for the metric **com.ibm.mashups.adminGroupName** in the configuration file:

- `profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties` on a stand-alone server, or
- `deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\ConfigService.properties` on a cluster.

**Important:** For Windows, when you run the **updatePropertyConfig** command, the value for the **propertyFileName** parameter must be the full path to the file, and all backslashes must be double, for example: `AdminTask.updatePropertyConfig([-serverName server_name -nodeName node_name -propertyFileName "profile_root\\BusinessSpace\\node_name\\server_name\\mm.runtime.prof\\config\\ConfigService.properties" -prefix "Mashups_"])`.

If you want to change an administrative group, perform the following steps on a stand-alone server:

1. Make sure that the group exists in the user repository.
2. Modify the metric **com.ibm.mashups.adminGroupName** in the configuration file `profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties`.
3. Run the command `updatePropertyConfig` in the `wsadmin` environment of the profile: `$AdminTask updatePropertyConfig {-serverName server_name -nodeName node_name -propertyFileName "profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"}` and run `$AdminConfig save`.
4. Restart the server.

If you want to change an administrative group, perform the following steps on a cluster:

1. Make sure that the group exists in the user repository.
2. Modify the metric **com.ibm.mashups.adminGroupName** in the configuration file `deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\ConfigService.properties`.
3. Run the command `updatePropertyConfig` in the wsadmin environment of the deployment environment profile: `$AdminTask updatePropertyConfig {-clusterName cluster_name -propertyFileName "deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"}` and run `$AdminConfig save`.
4. Restart the deployment manager.

If you want to change the superuser when security is not enabled, perform the following steps on a stand-alone server:

1. Modify the metric **noSecurityAdminInternalUserOnly** in the configuration file `profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties`.
2. Run the command `updatePropertyConfig` in the wsadmin environment of the profile: `$AdminTask updatePropertyConfig {-serverName server_name -nodeName node_name -propertyFileName "profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"}` and run `$AdminConfig save`.
3. Restart the server.

If you want to change the superuser when security is not enabled, perform the following steps on a cluster:

1. Modify the metric **noSecurityAdminInternalUserOnly** in the configuration file `deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\ConfigService.properties`.
2. Run the command `updatePropertyConfig` in the wsadmin environment of the deployment environment profile: `$AdminTask updatePropertyConfig {-clusterName cluster_name -propertyFileName "deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"}` and run `$AdminConfig save`.
3. Restart the deployment manager.

## Preventing users from creating spaces

You can customize IBM Business Monitor so that only users logging in with a superuser role can create spaces.

By default, all users can create spaces. However, you can lock down dashboards so that only people who log in using a superuser ID can create or import spaces.

**Important:** The lock-down procedure described in this topic applies only to dashboard spaces. It does not restrict other access to dashboards.

These superusers (or dashboard administrators) can create a space and transfer ownership to other users. The users who are assigned ownership of spaces can then administer the spaces as if they had created them. For example, they can set who can view and edit the space and its properties and they can add pages. Other than the superuser role, you cannot define groups or individual users who are allowed to create spaces.

To limit creating spaces to superusers only, complete the following steps.

1. Change the **com.ibm.mashups.lockeddown** setting to true in the configuration file:
  - For a stand-alone server: `profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties`

- For a cluster: `deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\ConfigService.properties`

The default value of false means that all users can create spaces. When the value is true, only superusers can create spaces.

2. Run the **updatePropertyConfig** command in the **wsadmin** environment of the profile:

- For a stand-alone server:

The following example uses Jython:

```
AdminTask.updatePropertyConfig(['-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name
\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"]')
AdminConfig.save()
```

**Important:** For Windows, the value for the **propertyFileName** parameter must be the full path to the file, and all backslashes must be double, for example: **AdminTask.updatePropertyConfig(['-serverName server\_name -nodeName node\_name -propertyFileName "profile\_root\BusinessSpace\node\_name\server\_name\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups\_"]')**.

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name
\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"}
$AdminConfig save
```

- For a cluster:

The following example uses Jython:

```
AdminTask.updatePropertyConfig(['-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"]')
AdminConfig.save()
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"}
$AdminConfig save
```

The next time that users log into a dashboard space, they will not be able to create a space unless they log in using a superuser ID.

## Enabling searches for user registries without wildcards

If your user registry is set up to not use wildcards, you must complete additional configuration steps so that searches work properly in dashboards and for widgets that search the user registry.

Before you complete this task, you must have completed the following tasks:

- Enable application security and administrative security. See Enabling security for dashboards.
- Check that your user ID is registered in the user registry for your product.

By default, when a dashboard user searches for users or groups by typing one or more characters, the dashboard automatically adds wildcard characters. For example, if the user registry is an LDAP server and the user types `smit`, the dashboard converts this into a `*smit*` query so that the return includes names like `Smith`, `Smithers`, and `Psmith`. However, if you do not want the automatic wildcards because, for example, your user registry does not permit them, you can disable this functionality.

To turn off the automatic wildcard searches for your environment, complete the following steps.

- For a stand-alone server, complete the following steps:

1. Update the `profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties` configuration file with `com.ibm.mashups.user.stripWildcards=true`.
2. Run the `updatePropertyConfig` command in the wsadmin environment of the profile:

The following example uses Jython:

```
AdminTask.updatePropertyConfig(['-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"]])
AdminConfig.save()
```

**Important:** For Windows, the value for the `propertyFileName` parameter must be the full path to the file, and all backslashes must be double, for example: `AdminTask.updatePropertyConfig(['-serverName server_name -nodeName node_name -propertyFileName "profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\config\ConfigService.properties" -prefix "Mashups_"]])`.

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-serverName server_name -nodeName node_name
-propertyFileName "profile_root\BusinessSpace\node_name\server_name\mm.runtime.prof\
config\ConfigService.properties" -prefix "Mashups_"}
$AdminConfig save
```

3. Restart the server.
- For a cluster, complete the following steps:
    1. Update the `deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\ConfigService.properties` configuration file with `com.ibm.mashups.user.stripWildcards=true`.
    2. From the deployment manager, run the `updatePropertyConfig` command in the wsadmin environment of the profile:

The following example uses Jython:

```
AdminTask.updatePropertyConfig(['-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\
ConfigService.properties" -prefix "Mashups_"]])
AdminConfig.save()
```

The following example uses Jacl:

```
$AdminTask updatePropertyConfig {-clusterName cluster_name -propertyFileName
"deployment_manager_profile_root\BusinessSpace\cluster_name\mm.runtime.prof\config\
ConfigService.properties" -prefix "Mashups_"}
$AdminConfig save
```

3. Restart the deployment manager.

## Commands (wsadmin scripting) for configuring the Business Space component for dashboards

Look up a scripting object or command class to find details about its command syntax.

The `wsadmin` tool is located under `<WAS_INSTALL_DIR>/bin` and `<WAS_PROFILE_DIR>/bin`. Use one of the following commands to launch it:

- For Jython:

```
Windows wsadmin -lang jython
```

```
Linux UNIX ./wsadmin.sh -lang jython
```

- For Jacl:

```
Windows wsadmin
```

Linux **UNIX** `./wsadmin.sh`

For most of the Business Space commands, it is recommended that you run the `wsadmin` tool in disconnected mode (that is, with the server stopped). To do this, use the `-conntype NONE` parameter:

- For Jython:

Windows `wsadmin -lang jython -conntype NONE`

Linux **UNIX** `./wsadmin.sh -lang jython -conntype NONE`

- For Jacl:

Windows `wsadmin -conntype NONE`

Linux **UNIX** `./wsadmin.sh -conntype NONE`

To open the information center table of contents to the location of this reference information, click the **Show in Table of Contents** button on your information center border.

## configureBusinessSpace command

Use the `configureBusinessSpace` command to configure the Business Space database.

This command configures the Business Space data source and generates the scripts that create and configure database tables.

After using the command, save your changes to the master configuration using one of the following commands:

- For Jython:  
`AdminConfig.save()`
- For Jacl:  
`$AdminConfig save`

If the application server is not running, supply the `-conntype NONE` option when running this command.

## Required parameters

**-serverName** *server\_name*

A parameter that specifies the server name for the configuration. For configuring Business Space on a server, you must specify both a **serverName** and a **nodeName**.

**-nodeName** *node\_name*

A parameter that specifies the node name for the configuration. For configuring Business Space on a server, you must specify both a **serverName** and a **nodeName**.

**-clusterName** *cluster\_name*

A parameter that specifies the cluster name for the configuration. For configuring Business Space on a cluster, you must specify a **clusterName**.

## Optional parameters

**-createTables** *true|false*

Specifies if you want to create the Business Space database tables. If the value is set to **true**, for DB2, Oracle, or SQL Server, the database is configured with Business Space tables. Setting this parameter to **true** requires that the Business Space database has been created before running this command. The default value is **false**.

**-dbName** *database\_name*

Specifies the database that you are using for Business Space. If your application server and DB2 are on same z/OS image, you must specify the **-dbName** parameter.

**-dbWinAuth true|false**

Specifies if you are using Windows Authentication with Microsoft SQL Server. If you want to use Windows Authentication in your SQL Server environment, you must specify this parameter as **true**. The default is **false**.

**-schemaName *schema\_name***

An optional parameter that specifies the database schema for the Business Space database configuration. The default value is IBMBUSSP.

**-tablespaceDir *table\_space\_path***

An optional parameter that specifies a directory path or file name prefix for the files used as the physical locations of table spaces. The default value is BSP. Valid for DB2, Oracle and SQL Server (otherwise ignored). For SQL Server, this parameter applies to the primary data file and log files.

**-tablespaceNamePrefix *table\_space\_prefix***

An optional parameter that specifies a prefix string added to the beginning of table space names to make them unique. The default value is BSP. If a table space name prefix is longer than four characters, it is truncated to four characters. Valid for DB2, DB2 z/OS V8, DB2 z/OS V9, and Oracle (otherwise ignored).

**-dbLocationName *database\_location\_name***

An optional parameter that specifies the database location name on z/OS. The default value is BSP or the product database name. Valid on DB2 z/OS V8 and V9 (otherwise ignored).

**-storageGroup *storage\_group***

An optional parameter that specifies the storage group on z/OS for Business Space. If you are using z/OS, you must update the database scripts that are generated before running them. For more information about the scripts, see *Configuring Business Space database tables*.

**-bspacedbDesign *database\_design\_file\_name***

An optional parameter that specifies a database design file that you are using to define all database configuration information, including the schema, and the table space directory. If you designate a database design file using the **-bspacedbDesign** parameter, you do not need to designate the **-schemaName**, **-tablespaceDir**, or **-storageGroup** parameters, unless you want to override what is in the database design file for particular database configuration information.

**Note:** The JNDI name of jdbc/mashupDS is always used for a Business Space data source, so the JNDI name in the database design file is not used. If a data source with a JNDI name of jdbc/mashupDS exists, this command stops without configuring the profile unless you also specify the **-replaceDatasource true** parameter.

**-productTypeForDatasource *product\_database***

An optional parameter that specifies properties to use to create the data source to use with Business Space. Designating a **productTypeForDatasource** creates a data source for Business Space with a JNDI name of jdbc/mashupDS that is modeled on the data source of an installed product, such as IBM Process Server, WebSphere Enterprise Service Bus, IBM Business Monitor, and WebSphere Business Compass. Valid values are WPS (to designate IBM Business Process Manager or WebSphere Enterprise Service Bus), WPBS (to designate WebSphere Business Compass), and WBM (to designate IBM Business Monitor). If the **bspacedbDesign** parameter is also specified, the **productTypeForDatasource** overrides the database type and JDBC provider, and the JNDI name in the database design file is not used.

**Note:** If a data source with a JNDI name of jdbc/mashupDS exists, this command stops without configuring the profile unless you also specify the **-replaceDatasource true** parameter.

**-replaceDatasource true|false**

An optional parameter that specifies whether the **configureBusinessSpace** command runs if the profile has already been configured. The default value is **false**. When a profile is configured for Business Space, a data source with a JNDI name of jdbc/mashupDS is created. If the data source exists and you run the **configureBusinessSpace** command without specifying **-replaceDatasource**

**true**, the command does not change the configuration. If you specify **true**, the command deletes the data source and its JDBC provider, creates new ones, and creates new DDL scripts.

**-save true|false**

A parameter that indicates saving your configuration changes. The default value is **false**.

## Examples

The following example uses the **configureBusinessSpace** command to configure a Business Space data source on a server.

- Jython example:

```
AdminTask.configureBusinessSpace('[-nodeName myNode -serverName
myServer]')
```

- Jacl example:

```
$AdminTask configureBusinessSpace {-nodeName myNode -serverName
myServer}
```

The following example uses the **configureBusinessSpace** to configure a Business Space data source on a cluster and save the changes.

- Jython example:

```
AdminTask.configureBusinessSpace('[-clusterName myCluster -save
true]')
```

- Jacl example:

```
$AdminTask configureBusinessSpace {-clusterName myCluster -save
true}
```

The following example uses the **configureBusinessSpace** to configure a Business Space data source on a cluster, with a schema name and a product data source designated for IBM Process Server.

- Jython example:

```
AdminTask.configureBusinessSpace('[-clusterName myCluster
-schemaName myCluster -productTypeForDatasource WPS -save true]')
```

- Jacl example:

```
$AdminTask configureBusinessSpace {-clusterName myCluster
-schemaName myCluster -productTypeForDatasource WPS -save true}
```

The following example uses the **configureBusinessSpace** to configure a Business Space data source on a cluster using database information that is in the database design file.

- Jython example:

```
AdminTask.configureBusinessSpace('[-clusterName myCluster
-bspacedbDesign "C:/Bspace_dbDesign.properties" -save true]')
```

- Jacl example:

```
$AdminTask configureBusinessSpace {-clusterName myCluster
-bspacedbDesign "C:/Bspace_dbDesign.properties" -save true}
```

## getBusinessSpaceDeployStatus command

Use the **getBusinessSpaceDeployStatus** command to check whether the Business Space component is configured on a particular deployment target.

This command checks whether the Business Space component is configured on a server, node, or cluster that you specify. If you don't set any parameters, it checks if the Business Space component is configured in the cell.

After using the command, save your changes to the master configuration using one of the following commands:

- For Jython:  
`AdminConfig.save()`
- For Jacl:  
`$AdminConfig save`

If the application server is not running, supply the `-conntype NONE` option when running this command.

## Required parameters

- serverName** *server\_name*  
A parameter that specifies the server name to check for Business Space.
- nodeName** *node\_name*  
A parameter that specifies the node name to check for Business Space.
- clusterName** *cluster\_name*  
A parameter that specifies the cluster name to check for Business Space.

## Examples

The following example uses the **getBusinessSpaceDeployStatus** command to check whether Business Space is configured on a server.

**Tip:** If you are using jython, you can add the **print** statement before the command if you want to see formatted output.

- Jython example:  
`AdminTask.getBusinessSpaceDeployStatus(['-nodeName myNode -serverName myServer'])`
- Jacl example:  
`$AdminTask getBusinessSpaceDeployStatus {-nodeName myNode -serverName myServer}`

The following example uses the **getBusinessSpaceDeployStatus** command to check whether Business Space is configured on a cluster.

- Jython example:  
`AdminTask.getBusinessSpaceDeployStatus(['-clusterName myCluster'])`
- Jacl example:  
`$AdminTask getBusinessSpaceDeployStatus {-clusterName myCluster}`

The following example uses the **getBusinessSpaceDeployStatus** command to return a list of all deployment targets (server and clusters) configured for Business Space in a cell.

If you run the command from the profile root bin directory, the command returns a list of all deployment targets (server and clusters) configured for Business Space in a cell.

If you run the command from the installation root bin directory, the command returns a list of all deployment targets (server and clusters) configured for Business Space in the same installation root directory.

- Jython example:  
`AdminTask.getBusinessSpaceDeployStatus()`
- Jacl example:  
`$AdminTask getBusinessSpaceDeployStatus`

## installBusinessSpace command

Use the **installBusinessSpace** command to set up the Business Space component on your IBM Business Monitor environment.

The **installBusinessSpace** command can be used to install the Business Space enterprise archive (EAR) files in your runtime environment. It can also be used to update the configuration without installing Business Space.

After using the command, save your changes to the master configuration using one of the following commands:

- For Jython:  
`AdminConfig.save()`
- For Jacl:  
`$AdminConfig save`

If the application server is not running, supply the `-conntype NONE` option when running this command.

### Required parameters

Either `serverName` and `nodeName`, or `clusterName` are required.

#### **-serverName** *server\_name*

A parameter that specifies the server name for the configuration. For configuring Business Space on a server, you must specify both the **serverName** and the **nodeName** parameters.

#### **-nodeName** *node\_name*

A parameter that specifies the node name for the configuration. For configuring Business Space on a server, you must specify both the **serverName** and the **nodeName** parameters.

#### **-clusterName** *cluster\_name*

A parameter that specifies the cluster name for the configuration. For configuring Business Space on a cluster, you must specify the **clusterName** parameter.

### Optional parameters

#### **-noWidgets** *true|false*

An optional parameter that if set to **true** prevents the product widgets from being installed on the deployment target. Then, if you want to install widgets, you must use the **installBusinessSpaceWidgets** command after the Business Space configuration has completed successfully. The default value is **false**.

#### **-save** *true|false*

An optional parameter that indicates saving your configuration changes. The default value is **false**.

#### **-configUpdateOnly** *true|false*

An optional parameter that if set to **true** only updates the configuration, without installing the Business Space enterprise archive (EAR) files on the deployment target. The default value is **false**.

#### **-configEnv** *environment*

An optional parameter that updates the profile settings to set the Business Space environment. You might use this parameter in the following situations:

- If you have augmented your IBM Business Process Manager Standard profile to include IBM Business Monitor, IBM Operational Decision Management, or IBM Case Manager, and you find that when you log onto Process Portal, you do not see the globe icon that allows users to switch to Business Space spaces that include widgets from these products. In this situation, you must run the **installBusinessSpace** command with **-configEnv bpm\_adv** and **-configUpdateOnly true** to enable the globe icon. See “Examples: Enabling the globe icon in Process Portal” on page 198 later in this topic for an example.

- If, after creating a profile for a product that includes Business Space (such as WebSphere Business Monitor, IBM Case Manager, or IBM Operational Decision Management) in an environment that includes an IBM Business Process Manager product, the Process Portal is available instead of Business Space. In this situation, manually switch back to the Business Space environment by completing the following steps:
  1. Update the Business Space profile setting by running the **installBusinessSpace** wsadmin command with the **-configEnv business\_space -configUpdateOnly true -save true** parameters. For example, if your Business Space is configured on a cluster named myCluster, use one of the following commands:
    - Using Jacl:
 

```
$AdminTask installBusinessSpace {-clusterName myCluster -configUpdateOnly true -configEnv bspace2 -save true}
```
    - Using Jython
 

```
AdminTask.installBusinessSpace(['-clusterName', 'myCluster', '-configUpdateOnly', 'true', '-configEnv', 'bspace2', '-save', 'true'])
```

If your Business Space is configured on a server, you must use the **-ServerName** and **-nodeName** parameters instead of the **-clusterName** parameter.
  2. Edit the `install_root\profiles\application_server_name\BusinessSpace\node_name\server_name\mm.runtime.prof\public\oobLoadedStatus.properties` file and add the following three lines to it:
 

```
importTemplates.txt=true
importSpaces.txt=true
importThemes.txt=true
```
  3. Start or restart the server.
  4. Clear the browser cache and then log into Business Space.

## Examples: Installing Business Space

The following example uses the **installBusinessSpace** command to install Business Space EAR files on a server.

- Jython example:
 

```
AdminTask.installBusinessSpace(['-nodeName myNode -serverName myServer -save true'])
```
- Jacl example:
 

```
$AdminTask installBusinessSpace {-nodeName myNode -serverName myServer -save true}
```

The following example uses the **installBusinessSpace** to install Business Space EAR files on a cluster.

- Jython example:
 

```
AdminTask.installBusinessSpace(['-clusterName myCluster -save true'])
```
- Jacl example:
 

```
$AdminTask installBusinessSpace {-clusterName myCluster -save true}
```

## Examples: Enabling the globe icon in Process Portal

The following cluster example uses the **installBusinessSpace** to enable the globe icon in Process Portal, that allows users to switch to spaces that include IBM Business Monitor widgets. This example does not install the Business Space EAR files. This example only applies if you have augmented your IBM Business Process Manager Standard profile to include IBM Business Monitor.

Jacl example:

```
wsadmin>$AdminTask installBusinessSpace {-clusterName myCluster -configUpdateOnly true -configEnv bpm_adv -save true}
```

Jython example:

```
AdminTask.installBusinessSpace(['-clusterName', 'myCluster', '-configUpdateOnly', 'true',
'-configEnv', 'bpm_adv', '-save', 'true'])
```

## installBusinessSpaceWidgets command

Use the **installBusinessSpaceWidgets** command to install, deploy and register widgets for use with the Business Space component.

The **installBusinessSpaceWidgets** command installs, deploys, and registers designated widgets contained in a compressed file or an enterprise archive (EAR) file. If widgets are already deployed, the **installBusinessSpaceWidgets** command refreshes the binary and registration information.

The structure of the widget compressed file contains the following items:

- [ear\widgets\_*name*.ear] one or more EAR files.
- [catalog\catalog\_*name*.xml]
- [endpoints\\*.xml] widget endpoints
- [templates\\*.zip] Templates must be in a compressed file and follow IBM Lotus Mashups template format.
- [help\eclipse\plugins\\*]

All folders are not required. Empty folders are valid.

After using the command, save your changes to the master configuration using one of the following commands:

- For Jython:  
AdminConfig.save()
- For Jacl:  
\$AdminConfig save

If the application server is not running, supply the **-conntype NONE** option when running this command.

## Required parameters

### **-serverName** *server\_name*

A parameter that specifies the server name for the configuration. For configuring Business Space on a server, you must specify both a **serverName** and a **nodeName**.

### **-nodeName** *node\_name*

A parameter that specifies the node name for the configuration. Either a **serverName**, **nodeName**, or **clusterName** is required. For configuring Business Space widgets on a server, you must specify both a **serverName** and a **nodeName**.

### **-clusterName** *cluster\_name*

A parameter that specifies the cluster name for the configuration. For configuring Business Space widgets on a cluster, you must specify a **clusterName**.

### **-widgets** *widgets\_path*

A parameter that specifies one of the following:

- The full path for the directory that contains the compressed files or the EAR files that contain the widgets. If you specify a directory, all widgets will be installed for all compressed files and EAR files in that directory.
- The full path to an individual compressed file that contains the widgets.
- The full path to an individual EAR file that contains the widgets.

### **-save** **true|false**

A parameter that indicates saving your configuration. The default value is **true**.

## Optional parameters

### **-save true|false**

A parameter that indicates saving your configuration. The default value is **true**.

## Examples

The following example uses the **installBusinessSpaceWidgets** to install, deploy, and register widgets on a server.

- Jython example:

```
AdminTask.installBusinessSpaceWidgets(['-nodeName node_name
-serverName server_name -widgets
install_root/BusinessSpace/registryData/product_name/widgets/MyWidget.zip'])
```

- Jacl example:

```
$AdminTask installBusinessSpaceWidgets {-nodeName node_name
-serverName server_name -widgets
install_root/BusinessSpace/registryData/product_name/widgets/MyWidget.zip}
```

The following example uses the **installBusinessSpaceWidgets** to install, deploy, and register widgets on a cluster.

- Jython example:

```
AdminTask.installBusinessSpaceWidgets(['-clusterName cluster_name
-widgets X:/WPS/Temp'])
```

- Jacl example:

```
$AdminTask installBusinessSpaceWidgets {-clusterName cluster_name
-widgets X:/WPS/Temp}
```

Manual steps are required for updating Business Space templates and spaces after running the **installBusinessSpaceWidgets** or **updateBusinessSpaceWidgets** command. For more information, see [Updating templates and spaces after installing or updating widgets](#).

## registerRESTServiceEndpoint command

Use the **registerRESTServiceEndpoint** command to register configured and enabled Representational State Transfer (REST) endpoints so that your team can use IBM Business Monitor widgets.

This command registers the REST service endpoints so that Business Space is properly connected to widgets for your product. This command registers the endpoints of the REST services that are in the same cell as Business Space.

After using the command, save your changes to the master configuration using one of the following commands:

- For Jython:  
`AdminConfig.save()`
- For Jacl:  
`$AdminConfig save`

If the application server is not running, supply the `-conntype NONE` option when running this command.

## Required parameters

### **-clusterName *name\_of\_rest\_services\_cluster***

A parameter that specifies the cluster name for the REST service. When registering REST services endpoints for a cluster, you must specify a **clusterName**.

**-nodeName** *name\_of\_rest\_services\_node*

A parameter that specifies the node name for the REST service. When registering REST services endpoints for a server, you must specify both a **serverName** and a **nodeName**.

**-serverName** *name\_of\_rest\_services\_server*

A parameter that specifies the server name for the REST service. When registering REST services endpoints for a server, you must specify both a **serverName** and a **nodeName**.

**-businessSpaceClusterName** *name\_of\_business\_space\_cluster*

The Business Space cluster name. If Business Space is configured on a cluster, you must specify a **businessSpaceClusterName**.

**-businessSpaceNodeName** *name\_of\_business\_space\_node*

The Business Space node name. If Business Space is configured on a server, you must specify both a **businessSpaceServerName** and a **businessSpaceNodeName**.

**-businessSpaceServerName** *name\_of\_business\_space\_server*

The Business Space server name. If Business Space is configured on a server, you must specify both a **businessSpaceServerName** and a **businessSpaceNodeName**.

## Optional parameters

**-appName** *name\_of\_provider\_application*

The application name of the REST service provider.

**-name** *name\_of\_rest\_service*

The name of the REST service.

**-type** *name\_of\_service\_type*

The type of the service. This parameter is optional. If this parameter is not specified, all unique REST service endpoints configured for a specified REST service provider on a specified deployment target are registered. If you want to specify a specific service endpoint, use the **<tns:type>** value that is in the endpoints file for a widget. The service endpoints files are located at *install\_root\BusinessSpace\registryData\product\_name\endpoints* directory. For example, *bpmAdministrationEndpoints.xml* contains all service endpoint types that are used by Administration widgets. The value of the **<tns:type>** element is **{com.ibm.bpm}SCA**:

```
<tns:Endpoint>
 <tns:id>{com.ibm.bpm}SCA</tns:id>
 <tns:type>{com.ibm.bpm}SCA</tns:type>
 <tns:version>6.2.0.0</tns:version>
 <tns:url>/rest/sca/v1</tns:url>
 <tns:description>Location backend SCA REST Services
 for Module Administration widgets and Service Monitoring widget
</tns:description>
</tns:Endpoint>
```

For Jacl, make sure to use double quotation marks around the value, for example: ... **-type** **"{com.ibm.bpm}SCA"** ...

**-version** *name\_of\_version*

The version of the REST service provider.

**-webModuleName** *name\_of\_web\_module*

The web module name of the REST service provider.

## Examples

The following example uses the **registerRESTServiceEndpoint** command. It registers all configured and enabled REST services on the cluster with Business Space.

- Jython example:

```
AdminTask.registerRESTServiceEndpoint('[-clusterName
name_of_rest_services_cluster -businessSpaceClusterName
name_of_business_space_cluster]')
```

- Jacl example:

```
$AdminTask registerRESTServiceEndpoint {-clusterName
name_of_rest_services_cluster -businessSpaceClusterName
name_of_business_space_cluster}
```

## uninstallBusinessSpaceWidgets command

Use the **uninstallBusinessSpaceWidgets** command to remove widgets and widget definitions from the profile, including removing individual widget assets (application, catalog, endpoints, spaces, templates, help).

The **uninstallBusinessSpaceWidgets** command removes widget files in a designated compressed file or an enterprise archive (EAR) file. The structure of the widget compressed file contains the following items:

- [ear\widgets\_*name*.ear] one or more EAR files.
- [catalog\catalog\_*name*.xml]
- [endpoints\\*.xml] widget endpoints
- [templates\\*.zip] Templates must be in a compressed file and follow IBM Lotus Mashups template format.
- [help\eclipse\plugins\\*]

All folders are not required. Empty folders are valid.

**Note:** If you customized REST endpoint information without using the **updateBusinessSpaceWidgets** command, those endpoint changes are lost after running the **uninstallBusinessSpaceWidgets** command.

After using the command, save your changes to the master configuration using one of the following commands:

- For Jython:  
AdminConfig.save()
- For Jacl:  
\$AdminConfig save

If the application server is not running, supply the **-conntype NONE** option when running this command.

## Required parameters

**-serverName** *server\_name*

A parameter that specifies the server name for the configuration. For configuring Business Space on a server, you must specify both a **serverName** and a **nodeName**.

**-nodeName** *node\_name*

A parameter that specifies the node name for the configuration. For configuring Business Space on a server, you must specify both a **serverName** and a **nodeName**.

**-clusterName** *cluster\_name*

A parameter that specifies the cluster name for the configuration. For configuring Business Space on a cluster, you must specify a **clusterName**.

**-widgets** *widgets\_path*

A parameter that specifies one of the following:

- the full path for the directory that contains the compressed files or the widget EAR files that contain the widgets. If you specify a directory, all widgets will be installed for all compressed files and EAR files in that directory.
- the full path to an individual compressed file that contains the widgets.

- the full path to an individual EAR file that contains the widgets.

## Optional parameters

### **-save true|false**

A parameter that indicates saving your configuration changes. The default value is **true**.

## Example

The following example uses the **uninstallBusinessSpaceWidgets** command to remove widgets from a cluster.

**Note:** The examples are for illustrative purposes only. They include variable values and are not meant to be reused as snippets of code.

- Jython example:

```
AdminTask.uninstallBusinessSpaceWidgets('[-clusterName
 cluster_name -widgets X:/WPS/Temp]')
```

- Jacl example:

```
$AdminTask uninstallBusinessSpaceWidgets {-clusterName
 cluster_name -widgets X:/WPS/Temp}
```

## updateBusinessSpaceWidgets command

Use the **updateBusinessSpaceWidgets** command to update previously configured widgets and their endpoints, catalogs, templates, and help plugins.

The **updateBusinessSpaceWidgets** command updates widget binary files, catalog files, endpoint files, templates, and help plug-ins for widgets that have been previously installed and configured for Business Space.

The **updateBusinessSpaceWidgets** command updates widget files in a designated compressed file or an enterprise archive (EAR) file. The structure of the widget compressed file contains the following items:

- [ear\widgets\_name.ear] one or more EAR files.
- [catalog\catalog\_name.xml]
- [endpoints\\*.xml] widget endpoints
- [templates\\*.zip] Templates must be in a compressed file and follow IBM Lotus Mashups template format.
- [help\eclipse\plugins\\*]

All folders are not required. Empty folders are valid.

After using the command, save your changes to the master configuration using one of the following commands:

- For Jython:

```
AdminConfig.save()
```

- For Jacl:

```
$AdminConfig save
```

If the application server is not running, supply the **-conntype NONE** option when running this command.

## Required parameters

### **-serverName server\_name**

A parameter that specifies the server name for the configuration. For configuring Business Space widgets on a server, you must specify both a **serverName** and a **nodeName**.

**-nodeName** *node\_name*

A parameter that specifies the node name for the configuration. Either a `serverName`, `nodeName`, or `clusterName` is required. For configuring Business Space widgets on a server, you must specify both a `serverName` and a `nodeName`.

**-clusterName** *cluster\_name*

A parameter that specifies the cluster name for the configuration. For configuring Business Space on a cluster, you must specify a `clusterName`.

## Optional parameters

**-widgets** *widget\_path*

A parameter that specifies the full path for the directory where widget enterprise archive (EAR) files or widget compressed files are located or the full path to a specific EAR file or widget compressed file.

**-endpoints** *endpoint\_path*

A parameter that specifies the full path for the directory where the widget endpoint files are located or the full path to a specific endpoint file.

**-catalogs** *catalog\_path*

A parameter that specifies the full path for the directory that contains the widget catalog files or the full path to a specific catalog file.

**-templates** *template\_path*

A parameter that specifies the full path for the directory that contains the widget template files or the full path to a specific template file.

**-helpplugins** *help\_path*

A parameter that specifies the full path for the directory that contains the widget online help plugin files or the full path to a specific widget online help plugin file.

**-noWidgets true|false**

Specifies that you do not want to update the widget EAR files that are contained within the widgets compressed file.

**-noEndpoints true|false**

Specifies that you do not want to update the specified endpoint files that are contained in the widgets compressed file.

**-noCatalogs true|false**

Specifies that you do not want to update the catalog definition files that are contained in the widgets compressed file.

**-noTemplates true|false**

Specifies that you do not want to update the templates that are contained in the widgets compressed file.

**-noHelp true|false**

Specifies that you do not want to update the help files that are contained in the widgets compressed file.

**-save true|false**

A parameter that indicates saving your configuration. The default value is `true`.

## Examples

The following example uses the `updateBusinessSpaceWidgets` to update widgets on a cluster.

Jython example:

```
AdminTask.updateBusinessSpaceWidgets(['-clusterName cluster_name
-widgets widget_path'])
```

Jacl example:

```
$AdminTask updateBusinessSpaceWidgets {-clusterName cluster_name
 -widgets widget_path}
```

The following example uses the **updateBusinessSpaceWidgets** to update widgets on a server.

Jython example:

```
AdminTask.updateBusinessSpaceWidgets(['-nodeName node_name
 -serverName server_name -widgets widget_path'])
```

Jacl example:

```
$AdminTask updateBusinessSpaceWidgets {-nodeName node_name
 -serverName server_name -widgets widget_path}
```

Manual steps are required for updating templates and spaces after running the **installBusinessSpaceWidgets** or **updateBusinessSpaceWidgets** command. For more information, see [Updating templates and spaces after installing or updating widgets](#).

## updateRESTGatewayService command

Use the **updateRESTGatewayService** command to update a Representational State Transfer (REST) gateway service so that REST services are configured and enabled.

This command updates the REST Gateway service so that REST services are configured and enabled. The deployment of the REST services is performed automatically in a stand-alone server profile. For other types of configurations, the REST Services administrative console page or the **updateRESTGatewayService** allows you to configure REST services for all of your product's widgets in Business Space.

After using the command, save your changes to the master configuration using one of the following commands:

- For Jython:  
AdminConfig.save()
- For Jacl:  
\$AdminConfig save

If the application server is not running, supply the **-conntype NONE** option when running this command.

## Required parameters

**-clusterName** *cluster\_name*

A parameter that specifies the cluster name for the REST service. For configuring REST services on a cluster, you must specify a **clusterName**.

**-nodeName** *node\_name*

A parameter that specifies the node name for the REST service. For configuring REST services on a server, you must specify both a **serverName** and a **nodeName**.

**-serverName** *server\_name*

A parameter that specifies the server name for the REST service. For configuring REST services on a server, you must specify both a **serverName** and a **nodeName**.

**-enable true | false**

Indicates if the REST service is enabled. Valid values include **true** or **false**.

## Optional parameters

**-type** *name\_of\_service\_type*

The type of the REST service.

**-version** *name\_of\_version*  
The version of the REST service.

## Examples

The following example uses the **updateRESTGatewayService** command to update the REST Gateway service so that REST services are configured and enabled.

- Jython example:

```
AdminTask.updateRESTGatewayService(['-nodeName node1 -serverName
server1 -type "{com.ibm.bpm}TimeTable" -version 6.2.0.0 -enable
true'])
```

- Jacl example:

```
$AdminTask updateRESTGatewayService {-nodeName node1 -serverName
server1 -type "{com.ibm.bpm}TimeTable" -version 6.2.0.0 -enable true}
```

## Updating templates and spaces after installing or updating widgets

Manual steps are required for updating templates and spaces after running the **installBusinessSpaceWidgets** or **updateBusinessSpaceWidgets** commands in a clustered environment.

You must complete the following additional steps if you have previously used the **installBusinessSpaceWidgets** command or the **updateBusinessSpaceWidgets** command.

1. If IBM Business Monitor is configured in a cluster, perform the following steps:
  - a. Identify the custom profile for oobLoadedStatus properties file:
    - 1) In deployment manager profile, open the *deployment\_manager\_profile\_root*\BusinessSpace\*cluster\_name*\mm.runtime.prof\config\ConfigService.properties file.
    - 2) Look for the name of cell, node and server in the **com.ibm.mashups.directory.templates** or **com.ibm.mashups.directory.spaces** properties.  
For example, in **com.ibm.mashups.directory.templates = config/cells/Cell01/nodes/Node01/servers/Server1/mm/templates**, you can locate the custom profile by the **Cell01** cell name and the **Node01** node name.
    - 3) Use the name of cell, node and server to locate the custom profile.
  - b. In the custom profile, open the *custom\_profile\_root*\BusinessSpace\*cluster\_name*\mm.runtime.prof\public\oobLoadedStatus.properties file and update the **importTemplates.txt** or **importSpaces.txt** properties:

```
importTemplates.txt=true
importSpaces.txt=true
```

If you have created the Business Space database after it was deleted, or if you need to reload the theme for any other reason, also update the following property:

```
importThemes.txt=true
```
  - c. Resynchronize the custom profile.
    - 1) Open the administrative console and click **System administration > Nodes**.
    - 2) Click **Full Resynchronize**.
  - d. Restart the cluster.
2. If IBM Business Monitor is configured in a managed server, perform the following steps:
  - a. In the custom profile where the managed server is located, open the *custom\_profile\_root*\BusinessSpace\*node\_name*\*server\_name*\mm.runtime.prof\public\oobLoadedStatus.properties file and update the **importTemplates.txt** or **importSpaces.txt** properties:

```
importTemplates.txt=true
importSpaces.txt=true
```

If you have created the Business Space database after it was deleted, or if you need to reload the theme for any other reason, also update the following property:

```
importThemes.txt=true
```

- b. Resynchronize the custom profile.
  - 1) Open the administrative console and click **System administration > Nodes**.
  - 2) Click **Full Resynchronize**.
- c. Restart the server.

## Configuring the Business Space Ajax proxy

You might want to modify the Business Space Ajax proxy for special considerations in dashboards, such as changing timeout settings or blocking IP addresses for secure production environments.

The Ajax proxy file, `proxy-config.xml`, is located in the following location if you are using the environment that is shipped with IBM Business Monitor:

```
profile_root/BusinessSpace/node_name/server_name/mm.runtime.prof/config/proxy-config.xml.
```

For issues with the Ajax proxy, see IBM Mashups tech notes at <http://www-01.ibm.com/support/search.wss?tc=SSWP9P>.

**Important:** The Ajax proxy is configured to be closed by default but provides a default policy that allows access to all Business Space endpoints for dashboards. Follow the steps in Adding proxy policies to the Business Space Ajax proxy to allow access for additional URLs, and follow the steps in Blocking IP addresses using the Business Space Ajax proxy to restrict access to specific IP addresses.

1. Modify the `proxy-config.xml` file as needed.

For example, if you are changing the timeout settings for the Business Space Ajax proxy, you modify the `proxy:value` for `socket-timeout`.

2. Run the `updateBlobConfig` command using the `wsadmin` scripting client, designating the `-serverName` and `-nodeName` parameters for a stand-alone server or `-clusterName` for a cluster, `-propertyFileName` with the value of the path for the `proxy-config.xml` file, and `-prefix` with the value `Mashups_`.

The following example uses Jython:

```
AdminTask.updateBlobConfig(['-serverName server_name -nodeName node_name
-propertyFileName "profile_root/BusinessSpace/node_name/server_name/mm.runtime.prof/config/
proxy-config.xml" -prefix "Mashups_"]])
AdminConfig.save()
```

The following example uses Jacl:

```
$AdminTask updateBlobConfig {-serverName server_name -nodeName node_name
-propertyFileName "profile_root/BusinessSpace/node_name/server_name/mm.runtime.prof/config/
proxy-config.xml" -prefix "Mashups_"}
$AdminConfig save
```

## Adding proxy policies to the Business Space Ajax proxy

Add additional proxy policies to the `proxy-config.xml` file so that dashboards work properly in a distributed environment.

The Business Space Ajax proxy contains predefined policies to some IBM URLs, but is not open to all URLs. If you use resources from remote sites in Business Space, add new policies in the `proxy-config.xml` file following the formatting of one of the predefined policies, such as the `<proxy:policy url="http://www-03.ibm.com/*" acf="none" basic-auth-support="true">`, to allow content from the remote sites to work properly in the Web Feed widget and the Google Gadgets widget.

If you had a previous version of Business Space, and you want the Ajax proxy to continue to be open to all URLs as it was in the previous version, change `<proxy:policy url="endpoint:/*" acf="none" basic-auth-support="true">` to `<proxy:policy url="*" acf="none" basic-auth-support="true">`.

1. Open the proxy-config.xml file. For information about where to find the Ajax proxy file, see Configuring the Business Space Ajax proxy.
2. To restrict the Ajax proxy so that it allows access to only specific endpoints, make sure that the proxy-config.xml file contains `<proxy:policy url="endpoint://*" acf="none" basic-auth-support="true">` instead of `<proxy:policy url="*" acf="none" basic-auth-support="true">`.
3. Add policies for remote content.

The following predefined policies allow access to web feeds from specific remote sites so that they work properly in the Web Feed widget.

```
<proxy:policy url="http://www.ibm.com/*" acf="none" basic-auth-support="true">
<proxy:actions>
<proxy:method>GET</proxy:method>
</proxy:actions>
</proxy:policy>
```

```
<proxy:policy url="http://www-03.ibm.com/*" acf="none" basic-auth-support="true">
<proxy:actions>
<proxy:method>GET</proxy:method>
</proxy:actions>
</proxy:policy>
```

```
<proxy:policy url="http://www.redbooks.ibm.com/*" acf="none" basic-auth-support="true">
<proxy:actions>
<proxy:method>GET</proxy:method>
</proxy:actions>
</proxy:policy>
```

To allow access to additional web feeds, Google Gadgets, or other remote content, add a policy like the following example:

```
<proxy:policy url="http://your_URL" acf="none" basic-auth-support="true">
<proxy:actions>
<proxy:method>GET</proxy:method>
</proxy:actions>
</proxy:policy>
```

4. Complete the Ajax proxy configuration to fit your environment. See Configuring the Business Space Ajax proxy.

## Changing the timeout settings for the Business Space Ajax proxy

dashboards use a proxy component to connect to your Representational State Transfer (REST) services. If REST services are not responsive, update the connection timeout settings to your REST services, depending on the performance of the REST service servers.

If the REST service connections are timing out, update the following settings.

If you are using the Business Space environment that is shipped with your business process management product, the socket-timeout value is set to 30 seconds by default. Change it to an appropriate value for your situation.

If you are using Business Space with WebSphere Portal, the socket-timeout value is set to 10 seconds by default. Change it to an appropriate value for your situation (30 seconds, if you are using IBM Business Process Manager administration widgets).

1. Open the proxy-config.xml file. For information about where to find the Ajax proxy file, see Configuring the Business Space Ajax proxy.
2. Change the `proxy:value` for `socket-timeout`. The time is specified in milliseconds.

```
<proxy:meta-data>
<proxy:name>socket-timeout</proxy:name>
<proxy:value>30000</proxy:value>
</proxy:meta-data>
```

3. Complete the Ajax proxy configuration to suit your environment. For information, see *Configuring the Business Space Ajax proxy*.

## Blocking IP addresses using the Business Space Ajax proxy

The Ajax proxy forwards requests from widgets to your product and target servers, if the servers are remote from the IBM Business Monitor server. The Ajax proxy is configured to be closed by default but provides a default policy that allows access to all endpoints. You can configure the Ajax proxy to restrict access to specific IP addresses.

**Important:** The Ajax proxy is configured to be closed by default but provides a default policy that allows access to all Business Space endpoints. Follow the steps in *Adding proxy policies to the Business Space Ajax proxy* to allow access for additional URLs, and follow the steps below to restrict access to specific IP addresses.

If you want to restrict access to specific IP addresses, you can edit the Ajax proxy to filter IP addresses to allow or deny access. You define blacklist or whitelist rules in the `proxy-config.xml` file.

1. Open the `proxy-config.xml` file. For information about where to find the Ajax proxy file, see *Configuring the Business Space Ajax proxy*.
2. Add filter rules that allow or deny access.

To define a blacklist rule for a particular IP address or set of addresses, use a **proxy:deny** element. To define a whitelist rule for a particular IP address or set of addresses, use a **proxy:allow** element. The filter rules are applied in order, with the last applicable filter rule taking precedence over previous filter rules.

Add the `<proxy:ipfilter>` information under the proxy rules of the `proxy-config.xml` file (after proxy policies and before `</proxy-rules>`).

```
<proxy:ipfilter>
<proxy:deny>9.6.0.0/255.255.0.0</proxy:deny>
<proxy:allow>9.6.1.0/255.255.255.0</proxy:allow>
<proxy:deny>9.6.1.4</proxy:deny>
</proxy:ipfilter>
```

In this example, the IP filter performs the following filters:

- blocks all 9.6.\*.\* IP addresses
- allows 9.6.1.\* but blocks the specific IP address 9.6.1.4

So, in this case, the proxy would not allow access to IP address 9.6.2.5 or 9.6.120.7 and would respond with the following message: `BMWPX0018E: The specified target hosts IP-address is prohibited by rule.`

The proxy would allow access to 9.6.1.5 or 9.6.1.120 but would deny access to 9.6.1.4.

As you add new filter rules, you can combine them in several ways, but the proxy always handles them in order. The last matching rule will always take effect, regardless of any allow and deny rules that come before it.

3. Complete the Ajax proxy configuration to suit your environment. For information, see *Configuring the Business Space Ajax proxy*.

## Postmigration tasks for Business Space

After migrating your product to V8.0.1, you must perform some additional tasks for the Business Space component before you start your servers or clusters and use dashboards.

### Migrating dashboards

If you are migrating from an earlier version of your product and you have the Business Space component configured, you must complete the following steps after migration before you can use dashboards.

Before you start this task, you must have migrated your product server or cluster and verified that the migration was successful.

You also must have migrated the Business Space database. Follow the instructions for migrating databases and data.

1. If you had custom widgets in a previous release, complete manual steps to make the widgets operational in IBM Business Monitor V8.0.1. For more information, see *Migrating custom widgets*.

**Tip:** The V7.0 data migration assists in migrating the widget catalog and endpoint of your custom widgets, so you do not need to manually migrate them again.

2. If you had an environment in the previous release with the Business Space component running on a different cell than the Representational State Transfer (REST) services, or with widgets on different cells than Business Space, you must update the endpoints files. For more information, see *Enabling widgets for cross-cell environments*.
3. If you had exported spaces or templates from your previous Business Space environment, import them into IBM Business Monitor V8.0.1 so that they are available to use.

**Tip:** If you migrated from version 6.x, for templates, first import them as spaces in the Space Manager, then convert the imported spaces to templates by clicking **Actions > Save as Template**.

After you complete these migration procedures, you can use IBM Business Monitor V8.0.1 and dashboards.

**Tip:** If you have used IBM Business Monitor V6.2, you must clear your browser cache before using IBM Business Monitor V8.0.1. This will help you avoid inadvertent, continued use of code and images from IBM Business Monitor V6.2.

## Configuring widgets to work with WebSphere Portal

If your team uses IBM WebSphere Portal, you can configure IBM Business Monitor widgets to work in the WebSphere Portal environment.

Before you configure widgets to work with WebSphere Portal, you must complete the following tasks:

- Install WebSphere Portal V7.0.0.2 Cumulative Fix Pack 12 or later. You can also install WebSphere Portal V8.0 with the WebSphere Portal V7.0.0.2 theme.
- Make sure that you have installed the WebSphere Portal V7.0.0.2 theme. See *Theme enablement in the WebSphere Portal documentation*.
- Make sure to apply the full profile to the pages that contain your widgets or to the entire theme. See the following topics in the WebSphere Portal documentation: *Setting a profile override on a page* and *Changing the theme default profile*.
- Install and configure IBM Business Monitor.
- Configure the Business Space component, and configure Representational State Transfer (REST) services, so widgets can access the services during run time. For more information, see *Configuring REST services*.
- Configure SSL and SSO. For more information, see *Configuring SSO and SSL for widgets on WebSphere Portal*.
- Complete specific configuration steps for your widgets, if required.

When you set up IBM Business Monitor widgets to work in WebSphere Portal, consider the following issues:

- Do not install your server product on a WebSphere Portal profile.

**Restriction:** Not all product widgets support running in WebSphere Portal. See your product's supported environments.

1. Create endpoint references on the WebSphere Portal application server. Product-specific endpoint reference entries must be created so that Business Space works properly in the WebSphere Portal

environment. Endpoints must be defined on the WebSphere Portal server, but they are created remotely using the **updateEndpointBindingsOnPortal** command run on your product server.

- a. Start the WebSphere Portal server and your product server.
- b. Copy the service endpoint files from the Business Space component and your product to a temporary directory on your product machine, for example, `c:/tmp/endpoints/`.

The service endpoint files are located on your product server in the following locations:

- `profile_root/BusinessSpace/node_name/server_name/mm.runtime.prof/endpoints/`
- `install_root/BusinessSpace/registryData/product_name/endpoints`

Some endpoints files might exist in both locations. Copy only the service endpoint files for which you need to create entries. You don't need to copy a file that was previously processed using the **updateEndpointBindingsOnPortal** command. The following list includes IBM business process management examples of service endpoint files and widget endpoint files:

- IBM Business Monitor: `monitorEndpoints.xml` and `monitorWidget.xml`
  - IBM Business Monitor with IBM Cognos Business Intelligence: `cognosEndpoints.xml` and `cognosWidget.xml`
  - `wsumEndpoint.xml` and `wsumWidget.xml` (for user membership)
- c. In a distributed environment, edit the service endpoint files to point to the correct URLs. Because endpoints are registered in the application server that hosts the WebSphere Portal server, it is required that all the endpoints point to the remote server with the Business Space component. The endpoints must include the fully qualified name or IP of the remote host, for example:

```
<tns:Endpoint>
 <tns:id>{com.ibm.bspace}bspaceCommonWidgetRootId</tns:id>
 <tns:type>{com.ibm.bspace}bspaceCommonWidgetRootId</tns:type>
 <tns:version>1.0.0.0</tns:version>
 <tns:url>http://Business_Space_Host:port/BusinessSpace/</tns:url>
 <tns:description>Location of Business Space Common Widgets</tns:description>
</tns:Endpoint>
```

Configure the endpoints as needed by editing the service endpoint files. Each endpoint in the file is designated by a **<tns:Endpoint>** block. Identify the block that you want to change. Look for comments that identify where you make the edits, for example:

```
<!-- When your REST service is remote from your Business Space server, update the following url
value with the fully qualified URL to the service.
For example https://host.domain.com:9443/rest/bpm/monitor/ -->
<tns:url>/rest/bpm/monitor/</tns:url>
```

**Tip:** If you do not intend to activate some endpoints, you can remove them from the file to prevent confusion.

The location identified by an endpoint is specified in **<tns:url>**. This value is a path in a web module, specified as a full or relative HTTP URL. By default, the URL is relative. Change it to a full URL path, for example, **https://virtualhost.com:virtualport/rest/bpm/htm** or **http://host1:9445/WBPublishingDRAFT/**, where the protocol, host, and port identify how the product web module can be accessed.

To locate the port number for the server, perform the following steps:

- Log in to the administrative console.
- Click **Servers > Server Types > WebSphere application servers**.
- Click the server for which you want to find the port number, and then expand the Ports section.

All applications use the same port as shown in either the **wc\_defaulthost** (unsecured host) parameter or the **wc\_defaulthost\_secure** (secure host) parameter.

**Important:** If you are using an HTTP server to access your web modules for load balancing, use the host name and port settings of the HTTP server.

- d. Open a wsadmin session on your product server. Run wsadmin.bat or wsadmin.sh in the *profile\_root/bin/* directory. The wsadmin session connects to the local product application server Java virtual machine.
- e. In the wsadmin session, run the **updateEndpointBindingsOnPortal** command. (In a network deployment environment, run it from the deployment manager.)

- Jython example:

```
AdminTask.updateEndpointBindingsOnPortal(['-nodeName Portal_node_name -serverName
WebSphere_Portal -endpointBindingDirectoryName directory_containing_endpoints_files -host
Portal_server_IP_or_host -port Portal_SOAP_port -user Portal_admin_ID -password
Portal_admin_password'])
```

- Jacl example:

```
$AdminTask updateEndpointBindingsOnPortal {-nodeName Portal_node_name -serverName
WebSphere_Portal -endpointBindingDirectoryName directory_containing_endpoints_files -host
Portal_server_IP_or_host -port Portal_SOAP_port -user Portal_admin_ID -password
Portal_admin_password}
```

For *Portal\_SOAP\_port* specify the SOAP port name for the remote WebSphere Portal server; the default is 10025. In a clustered environment, specify the SOAP port name of the Deployment Manager; the default is 8879.

- f. Restart the WebSphere Portal server.
  - g. From the WebSphere Portal administrative console, verify the endpoints by navigating to the resource environment provider named **WP Mashup Endpoints**. Click **Resources > Resource Environment > Resource Environment Providers > provider\_name > Custom Properties**.
2. Configure the Ajax proxy on the WebSphere Portal server. To allow remote URLs to access your product server from the WebSphere Portal server, you must configure the Ajax proxy.
- a. Update your existing proxy-config.xml file with the proxy policy example code snippet shown in Required entries for the proxy-config.xml file to configure widgets to work with WebSphere Portal.
  - b. Run the **checkin-wp-proxy-config** script.

In a clustered environment, run the script on the primary node.

```
ConfigEngine.[bat|sh] checkin-wp-proxy-config -DProxyConfigFileName=dir_path/
temporary_proxy_file.name -DWasPassword=application_server_password
-DWasUserid=application_server_user_ID -DPortalAdminId=WebSphere_Portal_administrator_ID
-DPortalAdminPwd=WebSphere_Portal_administrator_password where dir_path/
temporary_proxy_file.name is the complete path of your modified wp.proxy.config.xml file.
```

For more information about the proxy configuration, see the WebSphere Portal documentation at [http://www-10.lotus.com/ldd/portalwiki.nsf/dx/Global\\_proxy\\_configuration\\_wp7](http://www-10.lotus.com/ldd/portalwiki.nsf/dx/Global_proxy_configuration_wp7).

- c. From the administrative console, restart the application named **AJAX Proxy Configuration**.
3. Register the IBM Business Monitor widgets on WebSphere Portal.
- IBM Business Monitor widgets are registered as iWidgets with WebSphere Portal by a bulk import using the WebSphere Portal-specific widget catalog file with your product. The catalog XML file is available at the root of the product web archive (WAR) file. Each product has a different context root. There are two types of widgets: common widgets and product-specific widgets.

The context root for the common widgets is */BusinessSpace*, and the catalog file is

*catalog\_commonWidgets\_portal.xml*. For example, specify the URL to the catalog XML file for the common widgets as [http://localhost:9080/BusinessSpace/catalog\\_commonWidgets\\_portal.xml](http://localhost:9080/BusinessSpace/catalog_commonWidgets_portal.xml).

The following URLs are examples for business process management products:

- IBM Business Monitor: [http://Business\\_Space\\_hosting\\_Monitor:port/BusinessDashboard/catalog.xml](http://Business_Space_hosting_Monitor:port/BusinessDashboard/catalog.xml)
- IBM Business Monitor with IBM Cognos Business Intelligence: [http://Business\\_Space\\_hosting\\_Monitor:port/CognosWidgets/catalog.xml](http://Business_Space_hosting_Monitor:port/CognosWidgets/catalog.xml)

- a. Run the following command from `wp_profile\ConfigEngine` to register iWidgets using your product catalog XML file :

```
ConfigEngine.[bat|sh] register-iwidget-definition -DIWidgetCatalog=URL_to_catalog_XML_file
-DWasPassword=password -DWasUserid=ID -DPortalAdminId=ID
-DPortalAdminPwd=password
-DRegistrationAspects=catalogTitlesOverule,considerWidgetParam,considerUniqueName
```

Example for IBM Business Monitor:

```
ConfigEngine.bat register-iwidget-definition -DIWidgetCatalog=http://localhost:9080/
BusinessDashboard/catalog.xml -DWasPassword=admin -DWasUserid=admin
-DPortalAdminId=admin -DPortalAdminPwd=admin
-DRegistrationAspects=catalogTitlesOverule,considerWidgetParam,considerUniqueName
```

- b. To verify that the command ran correctly, look for Return Value:0. For more information about optional commands, see the WebSphere Portal documentation at [http://www-10.lotus.com/ldd/portalwiki.nsf/dx/Task\\_registeriwidgetdefinition\\_wp7](http://www-10.lotus.com/ldd/portalwiki.nsf/dx/Task_registeriwidgetdefinition_wp7).

After you have completed the setup for widgets to work with WebSphere Portal, complete the following tasks:

- If you are using IBM Business Monitor with IBM Cognos Business Intelligence, you must update the `web.xml` file **ProxyServlet\_Servlet** section.
- To find and add specific IBM Business Monitor iWidgets to a WebSphere Portal page and begin working in the WebSphere Portal environment, log in to the WebSphere Portal server and click **Actions > Edit Page**. The widgets are only visible under the **ALL** category. To find your widgets, select the **ALL** category and the name of the widget you want to add. Then, click the **Search** button.
- To enable the event exchange between iWidgets and native portlets on the same page in WebSphere Portal, and to enable the preservation of navigational states of widgets after switching pages, configure the pages that contain your IBM Business Monitor widgets to use client-side aggregation. For more information, see the WebSphere Portal documentation.
- When wiring your widgets, to ensure that all possible events of your widgets are shown, select **Consider semantic types or payload type for matching of sources and targets** as the matching mode. To change the matching mode, open the wiring editor and click **Settings**, then select **Consider semantic types or payload type for matching of sources and targets** and click **Done**.
- Make sure that the IBM Business Monitor widgets are wired to work together.
- To see the titles of your widgets, you must set the theme to **Portal 7.0.0.2 - Standard**. The default in WebSphere Portal is that portlet titles are not displayed in View mode, which means that some of the widgets menus might not be displayed. To set the theme to **Portal 7.0.0.2 - Standard**, from the WebSphere Portal administrative console, click **Administration > Manage Pages**, for your page click **Edit page layout > AppearancePortal 7.0.0.2 - Standard**. Then you will see the portlet titles in View mode.

## Configuring SSO and SSL for widgets on WebSphere Portal

If you want your product widgets to work in WebSphere Portal, you must set up single sign-on (SSO) between WebSphere Portal and IBM Business Monitor, and you must set up the Secure Sockets Layer (SSL) certificates so that they are exchanged between the WebSphere Portal and IBM Business Monitor.

You must configure SSO between the servers for WebSphere Portal and your product that includes Business Space widgets. In addition, establish SSL between WebSphere Portal and your product that includes Business Space widgets. This requires that the SSL signer certificates are exchanged between the servers.

For the servers for both WebSphere Portal and your product, you must use the same user name and password to log on to the administrative console.

**Tip:** If you have separate cells configured, make sure that SSO considerations are taken into account (including that LTPA keys are in sync, shared user names/realm names are in sync, and certificates are

imported as appropriate). In some cases, with IBM Business Process Manager, there might be multiple repositories in the realm, which might result in a realm-mismatch error. See *Managing the realm in a federated repository configuration* in the WebSphere Application Server documentation.

1. Set up SSO between WebSphere Portal and your product that includes Business Space widgets.
  - a. Log on to the administrative console of the deployment manager for your product that includes Business Space widgets.
  - b. Follow the steps in *Import and export keys* in the WebSphere Application Server information center.
2. Set up the SSL certificates so that they are exchanged between the servers of WebSphere Portal server and your product that includes Business Space widgets.

Make sure that the signers are configured in the appropriate truststores for the WebSphere Portal server and your product server. See *Secure communications using Secure Sockets Layer (SSL)* in the WebSphere Application Server information center.

### **updateEndpointBindingsOnPortal** command

Use the **updateEndpointBindingsOnPortal** command to create endpoint references on the WebSphere Portal application server so that your team can use the widgets on WebSphere Portal.

This command creates references to the Representational State Transfer (REST) endpoints on the WebSphere Portal application server. Business Space and product-specific endpoint reference entries must be created so that Business Space works properly in the WebSphere Portal environment. Business Space widgets are registered as iWidgets with WebSphere Portal by a bulk import using the WebSphere Portal-specific widget catalog file with your product. The catalog XML file is available at the root of the product web archive (WAR) file. Each product has a different context root. This command works only for the resource environment provider named **WP Mashup Endpoints**.

Before you run this command, you must install WebSphere Portal V7.0.0.1 or later, configure Business Space and REST services for your product, and configure SSL and SSO. For more information, see *Configuring widgets on WebSphere Portal*.

After using the command, save your changes to the master configuration using one of the following commands:

- For Jython:  
`AdminConfig.save()`
- For Jacl:  
`$AdminConfig save`

### **Required parameters**

**-serverName** *WebSphere\_Portal\_server\_name*

A parameter that specifies the name of the target server for the WebSphere Portal configuration. For configuring Business Space on a server, you must specify both a **serverName** and a **nodeName**.

**-nodeName** *WebSphere\_Portal\_node\_name*

A parameter that specifies the name of the target node for the WebSphere Portal configuration. For configuring Business Space on a server, you must specify both a **serverName** and a **nodeName**.

**-clusterName** *WebSphere\_Portal\_cluster\_name*

A parameter that specifies the name of the target cluster for the WebSphere Portal configuration. For configuring Business Space on a cluster, you must specify only a **clusterName**. Do not specify a **serverName** or a **nodeName**.

**-host** *server\_IP\_or\_host*

A parameter that specifies the IP or host name for the remote WebSphere Portal server. In a clustered environment, this parameter specifies the IP or host name of the Deployment Manager.

**-port** *SOAP\_port*

A parameter that specifies the SOAP port name for the remote WebSphere Portal server; the default is 10025. In a clustered environment, this parameter specifies the SOAP port name of the Deployment Manager; the default is 8879.

**-user** *admin\_ID*

A parameter that specifies the administrator ID for the remote WebSphere Portal server. In a clustered environment, this parameter specifies an ID with administrative rights on the Deployment Manager.

**-password** *admin\_password*

A parameter that specifies the administrator password for the remote WebSphere Portal server or the Deployment Manager.

**-endpointBindingDirectoryName** *directory\_containing\_endpoints\_files*

A parameter that specifies the directory that contains the endpoints files. Make sure that no other files exist in this directory.

## Examples

The following example creates endpoint references on the WebSphere Portal application server for a stand-alone environment.

- Jython example:

```
AdminTask.updateEndpointBindingsOnPortal(['-nodeName Portal_node_name -serverName
WebSphere_Portal -endpointBindingDirectoryName directory_containing_endpoints_files -host
Portal_server_IP_or_host -port Portal_SOAP_port_default_10025 -user Portal_admin_ID -password
Portal_admin_password'])
```

- Jacl example:

```
$AdminTask updateEndpointBindingsOnPortal {-nodeName Portal_node_name -serverName
WebSphere_Portal -endpointBindingDirectoryName directory_containing_endpoints_files -host
Portal_server_IP_or_host -port Portal_SOAP_port_default_10025 -user Portal_admin_ID -password
Portal_admin_password}
```

The following example creates endpoint references on the WebSphere Portal application server for a clustered environment.

- Jython example:

```
AdminTask.updateEndpointBindingsOnPortal(['-nodeName Portal_node_name -serverName
WebSphere_Portal -endpointBindingDirectoryName directory_containing_endpoints_files -host
DMGR_IP_or_host -port DMGR_SOAP_port_default_8879 -user DMGR_admin_ID -password
DMGR_admin_password'])
```

- Jacl example:

```
$AdminTask updateEndpointBindingsOnPortal {-clusterName Portal_cluster_name
-endpointBindingDirectoryName directory_containing_endpoints_files_on_local_system -host
DMGR_IP_or_host -port DMGR_SOAP_port_default_8879 -user DMGR_admin_ID -password
DMGR_admin_password}
```

## Required entries for the proxy-config.xml file to configure widgets to work with WebSphere Portal

Use the examples of required entries for the proxy-config.xml file to configure the Ajax proxy on the WebSphere Portal server. To allow remote URLs to your product server from the WebSphere Portal server, you must configure the Ajax proxy.

The following XML snippet shows the proxy policy required for business process management products. This must be set for all remote URLs that you intend to open with the WebSphere Portal proxy, for example, the Business Space server and your business process management server. Replace `<REMOTE_BPM_URL>` with the remote URL that needs to be opened with the WebSphere Portal proxy.

**Tip:** The socket-timeout value is set to 10 seconds by default. Business Space uses a proxy component to connect to your Representational State Transfer (REST) services. If REST services are not responsive, change the socket-timeout value to an appropriate value for your situation, for example 30 seconds. See [Changing the timeout settings for the Business Space Ajax proxy](#).

If you have multiple remote servers or URLs that need to be allowed with the proxy for the WebSphere Portal server, customize the proxy configuration by using dynamic policy entries. The proxy policy will differ from one deployment to the other. Refer to [WebSphere Portal documentation](#) for different ways to configure the WebSphere Portal server proxy.

The proxy-config.xml is located at `WebSphere_Portal_install_root\base\wp.proxy.config\installableApps\wp.proxy.config.ear\wp.proxy.config.war\WEB-INF`.

**Important:** The updated proxy-config.xml must be reviewed and approved by your WebSphere Portal administrators before being checked into WebSphere Portal.

The following example is for use with WebSphere Portal V7.0.0.2 Cumulative Fix Pack 12 or later:

```
<!-- BPM/Business Space proxy policy -->

<proxy:policy url="<REMOTE_BPM_URL>" acf="none">
 <proxy:actions>
 <proxy:method>GET</proxy:method>
 <proxy:method>HEAD</proxy:method>
 <proxy:method>POST</proxy:method>
 <proxy:method>DELETE</proxy:method>
 <proxy:method>PUT</proxy:method>

 </proxy:actions>
 <proxy:cookies>
 <proxy:cookie>LtpaToken</proxy:cookie>
 <proxy:cookie>LtpaToken2</proxy:cookie>
 <proxy:cookie>JSESSIONID</proxy:cookie>
 <proxy:cookie>CRN</proxy:cookie>
 <proxy:cookie>caf</proxy:cookie>
 <proxy:cookie>cam_passport</proxy:cookie>
 <proxy:cookie>cc_session</proxy:cookie>
 <proxy:cookie>userCapabilities</proxy:cookie>
 <proxy:cookie>usersessionid</proxy:cookie>
 </proxy:cookies>
 <proxy:headers>
 <proxy:header>User-Agent</proxy:header>
 <proxy:header>Accept*</proxy:header>
 <proxy:header>Content*</proxy:header>
 <proxy:header>Authorization*</proxy:header>
 <proxy:header>X-Method-Override</proxy:header>
 <proxy:header>Set-Cookie</proxy:header>
 <proxy:header>If-Modified-Since</proxy:header>
 <proxy:header>If-None-Match</proxy:header>
 <proxy:header>X-Server</proxy:header>
 <proxy:header>X-Update-Nonce</proxy:header>
 <proxy:header>X-Requested-With</proxy:header>
 <proxy:header>com.ibm.lotus.openajax.virtualhost</proxy:header>
 <proxy:header>com.ibm.lotus.openajax.virtualport</proxy:header>
 <proxy:header>Slug</proxy:header>
 <proxy:header>SOAPAction</proxy:header>
 </proxy:headers>
</proxy:policy>

<proxy:meta-data>
 <proxy:name>forward-http-errors</proxy:name>
 <proxy:value>true</proxy:value>
</proxy:meta-data>
```

```

<proxy:meta-data>
<proxy:name>socket-timeout</proxy:name>
<proxy:value>30000</proxy:value>
</proxy:meta-data>

```

The following example is for use with WebSphere Portal V8.0 with the WebSphere Portal V7.0.0.2 theme:

```

<!-- BPM/Business Space proxy policy -->
<!-- Please make sure the tags shown below match the tags in the existing proxy policy xml being edited
on your deployment. Also, edit the entry <policy url> below and change REMOTE_BPM_URL to the allowed BPM URL -->

<policy url="<REMOTE_BPM_URL>" acf="none">
<actions>
<method>GET</method>
<method>HEAD</method>
<method>POST</method>
<method>DELETE</method>
<method>PUT</method>

</actions>
<cookies>
<cookie>LtpaToken</cookie>
<cookie>LtpaToken2</cookie>
<cookie>JSESSIONID</cookie>
<cookie>CRN</cookie>
<cookie>caf</cookie>
<cookie>cam_passport</cookie>
<cookie>cc_session</cookie>
<cookie>userCapabilities</cookie>
<cookie>usersessionid</cookie>
</cookies>
<headers>
<header>User-Agent</header>
<header>Accept*</header>
<header>Content*</header>
<header>Authorization*</header>
<header>X-Method-Override</header>
<header>Set-Cookie</header>
<header>If-Modified-Since</header>
<header>If-None-Match</header>
<header>X-Server</header>
<header>X-Update-Nonce</header>
<header>X-Requested-With</header>
<header>com.ibm.lotus.openajax.virtualhost</header>
<header>com.ibm.lotus.openajax.virtualport</header>
<header>Slug</header>
<header>SOAPAction</header>
</headers>
</policy>

<meta-data>
<name>forward-http-errors</name>
<value>true</value>
</meta-data>
<meta-data>
<name>socket-timeout</name>
<value>30000</value>
</meta-data>

```

---

## Configuring the global process monitor model

The global process monitor model enables you to monitor any BPEL process and Human Tasks without monitor model generation or deployment steps. Processes are detected dynamically and tracked based on the events they emit. The collected data can be viewed in Business Space using the Instances, KPIs, and reporting widgets.

For information about using the global process monitor model, see Global Process Monitor on the Business Process Management Samples and Tutorials website, or the developerWorks article provided in the Related information link.

## Installing the global process monitor model manually

If you chose not to install the global process monitor model when you created the IBM Business Monitor profile, you can install it later by following the steps below. The GlobalProcessMonitorV751.ear file is already stored on your hard disk drive even if you did not install the global process monitor model during profile creation. Use the administrative console to install this file.

To install the GlobalProcessMonitorV751.ear file, complete the following steps:

1. From the administrative console, click **Applications > Monitor Models**. This table lists all currently installed monitor models.
2. Click **Install**.
3. Select **Local file system** and click **Browse**.
4. Navigate to the folder that contains the .ear file: **app\_server\_root/installableApps.wbm/monitorModels**, select GlobalProcessMonitorV751.ear, and click **Open**.
5. Make sure that "Prompt me only when additional information is required" is selected.
6. Click **Next** and accept all defaults until you reach the Summary page.
7. On the Summary page, verify that all of the information is correct, and click **Finish**.
8. Optional. To review, click **Review changes** before saving or discarding.
9. Click **Save** to save to the master configuration and save the model.

If the processes you are planning to monitor will run on the same server, no further configuration is required. Otherwise the monitor model must be configured to receive events from the remote (IBM Business Process Manager) CEI as described in "Configuring how to receive events," as well as from the local (IBM Business Monitor server) CEI because the global process monitor model sends events to itself.

## Enabling events for the global process monitor model

To enable the global process monitor to track processes and human tasks, you must enable BPEL events generation using Integration Designer. The events you enable determine how much information IBM Business Monitor will have about the running processes and human tasks. Event generation for IBM Business Process Manager is enabled by default.

The following suggestions provide some general recommendations about the BPEL events to enable:

- For each process that you want to monitor, enable all events at the process level. Typically, there will be only a few events that a process issues during execution (start, end, failures, deletion).
- For each activity that is of interest to you (typically staff activities and invocations), also enable all events.
- For each staff activity that should be monitored, go to the Details tab of its Properties view and find the link to the corresponding human task (if it does not exist, click the Open button to create it). Follow the link to the human task, go to the Event Monitor tab of its Properties view, and then enable the required audit events.
- If you monitor both a process and a subprocess that it calls, enable all events for the invoke activity that links the two.
- Disable events for short-running, automated steps.
- Enable all events for stand-alone human tasks that you want to monitor.
- Consider enabling all events for loops, as that will give you a history of loop iterations with time stamps.
- Enable variable change events for the process variables that you want to monitor, and not for other process variables.

For more information on enabling event generation, refer to the Integration Designer 8.0 documentation. A link is provided below.

## Configuring your dashboards for the global process monitor model

The global process monitor receives events about processes and human tasks running in IBM Business Process Manager. It detects deployed process and task definitions based on the events that they emit as they run, and tracks the running processes and tasks. You can set up your own dashboard for this monitor model, using the Instances, KPIs, and reporting widgets, or you can use one of the provided business spaces as a starting point.

Two Business Space configurations are provided in the following locations:

- `app_server_root/installableApps.wbm/monitorModels/BusinessSpace/GlobalProcessMonitor_BusinessSpace.zip`
- `app_server_root/installableApps.wbm/monitorModels/BusinessSpace/GlobalProcessMonitor_BusinessSpace_Advanced.zip`

Both have the same overall structure, but the advanced version shows additional technical detail, such as millisecond precision and time zone information for time stamps; process and task instance identifiers, process instance migration histories, and audit event counts. Use the Import function in Business Space to upload the configuration that you prefer. You can use it as-is, or as a starting point to configure your personalized dashboard views.

For initial orientation, it might help to understand the monitoring context structure of this model:

```
Process Definition
 Process Execution
 Process Execution Step
 Related Task Execution
 Process Execution Variable
 Step Definition
 Step Execution
 Related Task Execution

Task Definition
 Task Execution
```

There are additional monitoring context definitions for data that could not be held in a metric and therefore required child monitoring contexts. These should be considered as data containers that are part of their parent monitoring context. They are not shown in the previous structure, which only highlights the main monitoring context structure of this monitor model.

A Process Definition monitoring context corresponds to a deployed process template in IBM Business Process Manager. It monitors that template and provides summary information for the number of times it was started, is still running, and has completed; the minimum, maximum, and average duration of runs; and so forth. Navigating down to a Process Execution monitoring context, you find information about a particular process run (start time, current state, completion time, and so forth). The children of a Process Execution context are the monitoring contexts for its individual steps (activities, human tasks, and so forth) and process variables.

Alternatively, you can navigate from a Process Definition monitoring context down to its Step Definition monitoring contexts to see all known steps of this process template. (Only steps that ran at least once and sent events to IBM Business Monitor can be detected.) Navigating down again, you arrive at the Step Execution level, where the same information is found as at the Process Execution Step level, except that it is grouped differently. Here you will find all executions of a given step definition instead of all steps that make up one process run.

When you configure dashboards, either your own custom dashboards or the supplied dashboards, you can choose which metrics to display in your widgets. Any metrics with **Aux** as a prefix in the metric name are for internal processing only, and you should not add these metrics to your dashboard.

---

## Chapter 11. Installing the showcase model

The single-server version of IBM Business Monitor comes with a mortgage lending sample model that illustrates some of the functionality of IBM Business Monitor. If you created a stand-alone profile, you can install the Better Lender showcase model using the First Steps console.

To install the Better Lender showcase model from the First Steps console, you must make sure that IBM Cognos Business Intelligence is installed and started.

**Important:** If you need to use something other than the default table spaces defined within the database scripts that IBM Business Monitor provides, you must manually install the Better Lender showcase monitor model. You cannot use Installation Verification Test to install the showcase model. You then export the DDL that supports the monitor model, have your database administrator modify the table space name, and run the DDL manually.

If you created a stand-alone profile, you can use one of the following two methods.

- (Not for z/OS:) Install the showcase model using First Steps.
  1. Access First Steps from your stand-alone profile using one of the following options:
    - From the Profile Creation Complete panel, select the **Launch the IBM Business Monitor first steps** option.
    - Go to **Start > All Programs > IBM > Business Monitor 8.0 > Profiles > *profile\_name* > First Steps**.
    - Go to **profile\_root\firststeps.wbm** and run the **firststeps.bat** command.

**Important:** To install or run First Steps on Windows 7, Windows Vista, or Windows Server 2008, you must elevate your Microsoft Windows user account privileges by right-clicking **firststeps.bat** and selecting **Run as administrator**. This is required for both administrative and nonadministrative users.

- Open a command window. Go to **profile\_root/firststeps.wbm** and run the **firststeps.sh** command.
  - 2. From the First Steps console, select **Showcase model**.

**Note:** If you have security enabled, you are prompted for the WebSphere Application Server user ID and password.

- Install the showcase model using the administrative console and then import the dashboards for the showcase model:
  1. To install the showcase model, click **Applications > Monitor models**. Click **Install** and navigate to the `MortgageLendingBAMApplication.ear` file, which is located in one of the following directories:
    - `app_server_root/installableApps.wbm/samples/mortgageLending/`
    - `app_server_root\installableApps.wbm\samples\mortgageLending\`Use the default settings for the installation.
  2. To import the dashboards for the showcase model, complete the following steps:
    - a. Open a browser and enter the URL for Monitor dashboards that was provided by your administrator. For example, type `http://host_name:9080/BusinessSpace`.
    - b. Enter your user name and password to log in.
    - c. From the Welcome page, click **Manage Spaces**.
    - d. Click **Import Space**.

- e. Click **Browse** and navigate to the showcase\_dashboard.zip file, which is located in one of the following directories:
  - app\_server\_root/installableApps.wbm/showcase/dashboards/7.5
  - app\_server\_root\installableApps.wbm\showcase\dashboards\7.5

After the installation is complete, start the server and then open Business Monitor dashboards to view the Better Lender space. (The First Steps console provides options for both starting the server and launching Business Monitor dashboards.)

---

## Chapter 12. Updating IBM Business Monitor

You can install updates to IBM Business Monitor when they are available.

For upgrading from the previous version, see [Upgrading from IBM Business Monitor V8.0 to IBM Business Monitor V8.0.1](#).

Visit the IBM Support website to check for available fix packs and interim fixes.

---

### Updating IBM Cognos BI

If you update IBM Cognos Business Intelligence or your Java Database Connectivity (JDBC) drivers, you must also regenerate the IBM Cognos BI enterprise archive (EAR) file. The deployed IBM Cognos BI service application must be updated with the new EAR file.

All nodes running the IBM Cognos BI service application must be running the same version and service level of IBM Cognos BI.

**Important:** Update only the base IBM Cognos BI directories (the directories under the WebSphere root). The copied runtime instances (directories under the profile) will be updated by IBM Business Monitor the next time that the IBM Cognos BI server starts.

To update IBM Cognos BI and the EAR file, complete the following steps:

1. To update IBM Cognos BI:
  - a. Obtain the IBM Cognos BI service compressed file (tar.gz) for the platform type of your node.
  - b. Unpack the file into a working directory.
  - c. Locate and run the **issetup** command. When prompted for the installation location, enter `app_server_root/cognos`.

**Tip:**   If you cannot run the graphical user interface of the update, or if you know that you do not have the MOTIF package installed, you must copy the silent installer from your existing IBM Cognos BI installation. Complete the following steps:

- 1) Locate the following file in your existing IBM Cognos BI installation:  
`app_server_root/cognos/uninstall/issetupnx`
- 2) Copy the file to the working directory of the new installer, placing it in the same directory as **issetup**.
- 3) Update the file `response.ats` with the following values:  
`I Agree=y`  
`APPDIR=app_server_root/cognos`  
`C8BISRVR_APP=1`  
`C8BISRVR_APPLICATION_TIER=1`  
`C8BISRVR_GATEWAY=1`  
`C8BISRVR_CONTENT_MANAGER=1`  
`C8BISRVR_CONTENT_DATABASE=1`
- 4) Open a command prompt in the working directory and run:  
`./issetupnx -s`

2. To update the EAR file after updating IBM Cognos BI, complete the following steps:
  - a. If you have updated your JDBC drivers, you must apply the new version to IBM Cognos Business Intelligence as well as to IBM Business Monitor. Before regenerating the EAR file, apply the new version to IBM Cognos BI in the following directories:

```
app_server_root/cognos/webapps/p2pd/WEB-INF/lib
app_server_root/cognos/v5dataserver/lib
```

- b. On your deployment manager or stand-alone server, open a command prompt in `app_server_root/cognos/war/p2pd`.
- c. Run the following command:

```
Windows build.bat ear
```

```
Linux UNIX build.sh ear
```

This command creates a WebSphere EAR file called `p2pd.ear` in the IBM Cognos BI root directory. Building the EAR file might take several minutes.

- d. On your deployment manager or stand-alone server, open the WebSphere administrative console and click **Applications > Application type > WebSphere enterprise applications**.
- e. Select the **IBM Cognos** check box and click **Update**.
- f. Under **Specify the path to the replacement ear file**, browse to the EAR file you created in Step c.
- g. Complete the steps in the Update wizard to update the application. After you click **Finish**, the update might take several minutes.
- h. Save your changes. Saving the new configuration might take several minutes.
- i. Restart the application servers that were updated with the new IBM Cognos BI EAR file.

---

## Installing fix packs and interim fixes interactively

You can install updates to software packages using IBM Installation Manager interactively.

You cannot use this procedure to install updates on the underlying IBM DB2 Express or IBM Cognos BI. You must update these products following their normal update processes.

For upgrading from the previous version, see [Upgrading from IBM Business Monitor V8.0 to IBM Business Monitor V8.0.1](#).

Visit the [IBM Support website](#) to check for available fix packs and interim fixes.

Before you install a fix pack or interim fix, perform the following tasks:

1. Read the fix pack and interim fix documentation thoroughly. The documentation lists dependencies, such as WebSphere Application Server fix pack levels or other IBM product fixes that you must install before you apply the fix pack or interim fix.
2. To ensure that your implementation is performing the same way that it did before you applied the fix pack or interim fix, prepare a regression test plan.
3. Back up your database and profile.
4. Before you deploy the fix pack or interim fix to a production environment, install the fix pack or interim fix in a development or quality-assurance environment.
5. You must perform the installation using the same user account that you used to install the product packages.

Each installed package has the location embedded for its default IBM update repository. For Installation Manager to search the IBM update repository locations for the installed packages, the preference **Search service repositories during installation and updates** on the Repositories preference page must be selected. This preference is selected by default.

During the update process, Installation Manager might prompt you for the location of the repository for the base version of the package. If you installed the product from DVDs or other media, they must be available when you use the update feature.

For more information about Installation Manager, see the information center link in related information.

**Important:** Any existing profiles are preserved and do not need to be re-created.

To find and install product package updates:

1. Stop all software for the product that you are updating. Close programs and stop servers that have profiles for this product.
2. Start Installation Manager. From the Start page of the Installation Manager, click **Update**.  
 You can also click **Start > Programs > IBM > package group name > Update**. For example, click **Start > Programs > IBM > IBM Business Monitor > Update**.
3. If IBM Installation Manager is not detected on your system or if an older version is already installed, then you must continue with the installation of the latest release. Follow the on-screen instructions in the wizard to complete the installation of IBM Installation Manager.
4. If you do not have Internet access, download the interim fix or fix pack locally, extract it to its own directory, and add the new directory to Installation Manager.
  - a. Start Installation Manager.
  - b. From the Start page, click **File > Preferences > Repositories**.
  - c. From the Repositories page, click **Add Repository**.
  - d. In the Add Repository window, browse to the directory where the extracted files for the interim fix or fix pack are located.
  - e. Select the repository.config file and click **Open**.
  - f. From the Repositories page, click **OK**.
5. In the Update Packages wizard, select the package group containing the product package you want to update or select the **Update all** check box, and then click **Next**. Installation Manager searches for updates in its repositories and the predefined update sites for the software you are updating. A progress indicator shows the search is taking place.
6. If updates for a package are found, then they are displayed in the **Updates** list on the Update Packages page below their corresponding package. Only the latest recommended updates are displayed by default. Click **Show all** to display all updates found for the available packages.
  - a. To learn more about an update, click the update and review its description under **Details**.
  - b. If additional information about the update is available, a **More info** link is included at the end of the description text. Click the link to display the information in a browser. Review this information before installing the update.
7. Select the updates that you want to install or click **Select Recommended** to restore the default selections, and click **Next**. Updates that have a dependency relationship are automatically selected and cleared together.
8. On the Licenses page, read the license agreements for the selected updates. On the left side of the Licenses page, the list of licenses for the updates you selected is displayed; click each item to display the license agreement text. If you agree to the terms of all the license agreements, click **I accept the terms of the license agreements**. Then click **Next**. If you do not accept the terms of the license agreements, you cannot install the fix pack or interim fix.
9. On the Summary page, review your choices before installing the updates.
  - a. If you want to change the choices you made on previous pages, click **Back**, and make your changes.
  - b. When you are satisfied, click **Update** to download and install the updates. A progress indicator shows the percentage of the installation completed.
10. Optional: When the update process completes, a message that confirms the success of the process is displayed near the top of the page. Click **View log file** to open the log file for the current session in a new window. You must close the Installation Log window to continue.
11. Click **Finish** to close the wizard.

## 12. Close Installation Manager.

---

### Installing fix packs silently

You can install fix packs to IBM Business Monitor silently.

Visit the IBM Support website to check for available fix packs and interim fixes.

Before you install a fix pack, perform the following tasks:

1. Read the fix pack documentation thoroughly. The documentation lists dependencies, such as WebSphere Application Server fix pack levels or other IBM product fixes that you must install before you apply the fix pack.
2. To ensure that your implementation is performing the same way that it did before you applied the fix pack, prepare a regression test plan.
3. Back up your database and profile.
4. Before you deploy the fix pack to a production environment, install the fix pack in a development or quality-assurance environment.
5. You must perform the installation using the same user account that you used to install the product packages.

You cannot use this procedure to install updates on the underlying IBM DB2 Express or IBM Cognos BI. You must update these products following their normal update processes.

To add a fix pack to IBM Business Monitor silently, complete the following steps:

1. Read the license terms before updating. Adding **-acceptLicense** to the command line means that you accept all license terms. If you do not accept the license, you cannot perform the installation.
2. Run the following command:

**Important:** If you are running Windows 7, Windows Vista, or Windows Server 2008, start your command prompt by right-clicking and selecting **Run as administrator**.

Windows

```
extract_directory\IM\tools\imcl install list_of_product_IDs -acceptLicense -installationDirectory location -repositories repository -showVerboseProgress -log logName.log
```

UNIX

Linux

```
extract_directory/IM/tools/imcl install list_of_product_IDs -acceptLicense -installationDirectory location -repositories repository -showVerboseProgress -log logName.log
```

where:

- *list\_of\_product\_IDs* is a list of the IDs for the products you want to update, separated by spaces.

Table 10. Product IDs

Product	Product ID
IBM Business Monitor	com.ibm.websphere.MON.V80
IBM Business Monitor for z/OS	com.ibm.websphere.ZOS.MON.V80
WebSphere Application Server Network Deployment	com.ibm.websphere.ND.v80
WebSphere Application Base	com.ibm.websphere.BASE.v80

- *extract\_directory* is the path to where you extracted the fix pack files.
- *location* is the path to the directory where you want to update the products.

- *repository* is the path to the repository where you have extracted the fix pack files. For more than one repository, separate the repository locations with commas.
- *logName* is the name of the log file to record messages and results.

Installation Manager updates the list of products and writes a log file to the directory that you specified.

The following example updates IBM Business Monitor on Windows.

```
imcl install com.ibm.websphere.MON.V80 com.ibm.websphere.ND.v80 -acceptLicense
-installationDirectory C:\IBM\MON80 -repositories
D:\temp\MonServer\repository\fixpack1 -showVerboseProgress -log silentinstall.log
```

---

## Installing interim fixes silently

You can install an interim fix for IBM Business Monitor using the command-line mode of the Installation Manager.

Visit the IBM Support website to check for available fix packs and interim fixes.

Before you install an interim fix, perform the following tasks:

1. Read the interim fix documentation thoroughly. The documentation lists dependencies, such as WebSphere Application Server fix pack levels or other IBM product fixes that you must install before you apply the interim fix.
2. To ensure that your implementation is performing the same way that it did before you applied the interim fix, prepare a regression test plan.
3. Back up your database and profile.
4. Before you deploy the interim fix to a production environment, install the interim fix in a development or quality-assurance environment.
5. You must perform the installation using the same user account that you used to install the product packages.

This procedure uses a local directory to store the interim fix. For information about using an online repository that hosts the interim fix files and other configuration information, refer to the IBM Installation Manager information center.

To install an interim fix silently, complete the following steps:

1. Download the interim fix to the local system.
2. Create a new directory and extract the interim fix in the new directory.
3. Open a command prompt, and change directories to the `/eclipse/tools` directory under Installation Manager.

**Important:** If you are running Windows 7, Windows Vista, or Windows Server 2008, start your command prompt by right-clicking and selecting **Run as administrator**.

4. Make the appropriate replacements and run the following command:

```
imcl install fixID -repositories repositoryLocation -installationDirectory installationDirectory
-log logLocation
```

- a. Replace *fixID* with the ID of the interim fix. The ID can be found in the `repository.xml` file in the directory where you extracted the interim fix, in the `fix id` element. For example:

```
<fix id="8.0.0.0-WS-BPMADVWESB-IFJR39658" version="0.0.0.20111115_1047" offeringId="EnhancedFix"
offeringVersion="0.0.0.EnhancedFix">
```
- b. Replace *repositoryLocation* with the directory where you extracted the interim fix.
- c. Replace *installationDirectory* with the location where you installed IBM Business Monitor.
- d. Replace *logLocation* with the location and file name to log the installation information.

For example:

```
C:\Program Files\IBM\Installation Manager\eclipse\tools>imcl install 8.0.0.0-WS-BPMADWESB-IFJR39658
-repositories C:\interimFix\8.0.0.0-WS-BPMADWESB-IFJR39658/
-installationDirectory C:\IBM\BPM80 -log logfix.txt
```

The installation log (specified by the **-log** parameter) contains no error messages if the interim fix installation is successful. The command line shows a message that the fix was installed. For example:

Installed 8.0.0.0-WS-BPMADWESB-IFJR39658\_0.0.0.20110525\_1047 to the C:\IBM\BPM80 directory.

---

## Rolling back fix packs

Using the Roll back packages wizard, you can remove a fix pack from the IBM Business Monitor installation and revert to a previous version.

During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your system when you install a package. If the files are not available on your workstation, you must include the location of the repository from which you installed the previous version of the product in your Installation Manager preferences (**File > Preferences > Repository**). If you installed the product from DVDs or other media, they must be available when you use the rollback function.

Use the rollback function if you have applied a fix pack to a product package, and decide later that you want to remove the update and revert to the earlier version of the product. When you use the rollback function, the Installation Manager uninstalls the updated resources, and reinstalls the resources from the previous version.

When you roll back to an earlier version of a package, it is restored with same features that were associated with that version. Use the Modify Packages wizard to add and remove features.

For more information about Installation Manager, including how to perform a rollback from the command line, refer to the Installation Manager information center.

1. Stop all software for the product that you are rolling back. Close programs and stop servers that have profiles for this product.
2. Start the Installation Manager.
3. From the Start page of the Installation Manager, click **Roll back** to start the Roll back packages wizard.
4. On the Roll Back Packages page, from the Package Group Name list, select the package group that contains the packages that you want to roll back and click **Next**.
5. Select the version of the package that you want to roll back to and click **Next**.
6. Read the summary information and click **Roll Back** to roll back the package.
7. Optional: When the rollback process completes, a message that confirms the success of the process is displayed near the top of the page. Click **View log file** to open the log file for the current session in a new window.
8. Click **Finish** to close the wizard.
9. Close Installation Manager.

The fix pack you selected to roll back is removed.

---

## Uninstalling interim fixes interactively

You can uninstall one or more interim fixes for IBM Business Monitor using Installation Manager.

You must perform the uninstallation using the same user account that you used to install the product packages.

**Important:** An interim fix cannot be uninstalled when another interim fix has a dependency on it, unless the dependent interim fix is also selected to be uninstalled. If you try to remove an interim fix that has a dependency on it from another interim fix, you will receive an error message.

To uninstall an interim fix interactively, complete the following steps:

1. Stop all software for the product that you are updating. Close programs and stop servers that have profiles for this product.
2. Start the Installation Manager. On the Start page, click **Uninstall**.
3. On the Uninstall Packages page, select the interim fix or fixes to uninstall and click **Next**.
4. Review your selection on the Summary page and then click **Uninstall**. After the uninstallation finishes, the Complete page opens.
5. Click **Finish** to exit the wizard.

The uninstallation of the interim fix or fixes is complete.

**Important:** Do not delete the Eclipse configuration directory after uninstalling the interim fix or fixes. Deleting this information will interfere with the operation of Installation Manager. By default, this is the configuration directory in the `install_root`.

---

## Uninstalling interim fixes silently

You can uninstall an interim fix for IBM Business Monitor using the command-line mode of the Installation Manager.

You must perform the uninstallation using the same user account that you used to install the product packages.

**Important:** An interim fix cannot be uninstalled when another interim fix has a dependency on it, unless the dependent interim fix is also selected to be uninstalled. If you try to remove an interim fix that has a dependency on it from another interim fix, you will receive an error message.

To uninstall an interim fix silently, complete the following steps:

1. Stop all software for the product that you are updating. Close programs and stop servers that have profiles for this product.
2. Open a command prompt, and change directories to the `/eclipse/tools` directory under Installation Manager.

**Important:** If you are running Windows 7, Windows Vista, or Windows Server 2008, start your command prompt by right-clicking and selecting **Run as administrator**.

3. Make the appropriate replacements and run the following command:

```
imcl uninstall fixID -installationDirectory installationDirectory -log logLocation
```

- a. Replace *fixID* with the ID of the interim fix. The ID can be found in the `repository.xml` file in the directory where you extracted the interim fix, in the `fix id` element. For example:

```
<fix id="8.0.0.0-WS-BPMADVWESB-IFJR39658" version="0.0.0.20111115_1047" offeringId="EnhancedFix" offeringVersion="0.0.0.EnhancedFix">
```

- b. Replace *installationDirectory* with the location where you installed IBM Business Monitor.
- c. Replace *logLocation* with the location and file name to log the information.

For example:

```
C:\Program Files\IBM\Installation Manager\eclipse\tools>imcl uninstall 8.0.0.0-WS-BPMADVWESB-IFJR39658 -installationDirectory C:\IBM\BPM80 -log logfix.txt
```

The log (specified by the **-log** parameter) contains no error messages if uninstalling is successful. The command line shows a message that the fix was uninstalled.

---

## Chapter 13. Uninstalling IBM Business Monitor

You can remove IBM Business Monitor interactively or silently.

---

### Uninstalling IBM Business Monitor interactively

The Uninstall option in the Installation Manager enables you to uninstall packages from a single installation location. You can also uninstall all the installed packages from every installation location.

To uninstall the packages, you must log in to the system using the same user account that you used to install the product packages. A package cannot be uninstalled when another package has a dependency on it, unless the dependent package is also selected to be uninstalled.

1. Close the programs that you installed using Installation Manager.
2. Stop all running servers.
3. Display the Uninstall Packages page of the Installation Manager.
  - Start the Installation Manager. On the Start page, click **Uninstall**.
4. On the Uninstall Packages page, select IBM Business Monitor and associated packages that you want to uninstall.

**Tip:**  If you started Installation Manager from the Start menu (**Start > ... > Uninstall**) in the previous step, your IBM Business Monitor edition is pre-selected for uninstallation on the Uninstall Packages page.

If you no longer need to use DB2 Express, or intend to reinstall IBM Business Monitor, select the **IBM DB2 Express** option to uninstall DB2 Express. **CAUTION:**

**Only select the option to uninstall DB2 Express if you are sure that no other product is using DB2 Express. Selecting this option will delete all the DB2 Express databases and database assets even if other products, including products on a remote system, might use DB2 Express on this system.**

5. Click **Next**.
6. On the Summary page, review the list of packages that will be uninstalled, and then click **Uninstall**. After the uninstallation finishes, the Complete page opens.
7. Click **Finish** to exit the wizard.

When IBM Business Monitor is uninstalled, all profiles that are augmented to IBM Business Monitor are removed, including any WebSphere Application Server profiles that are augmented to IBM Business Monitor. For stand-alone monitor server profiles, the IBM Cognos BI service is removed.

Sample monitor models are not uninstalled to ensure that customizations of the models are preserved. To uninstall these models, see Removing monitor models and data.

If you plan to reinstall IBM Business Monitor, check for database issues that might affect the reinstallation procedure. Complete any action required before reinstalling the product:

- If databases were created in the previous install, ensure that the databases were dropped. See Reinstallation cannot create new profile when using the Typical installation and configuration option.
- If you uninstalled DB2 Express, ensure that the BPMINST directory was deleted.
- If you uninstalled DB2 Express, delete the remaining DB2 Express entries in the `/etc/service` file. This is necessary because the new installation requires that port 50000 be available. Update the following file to remove any references to DB2 Express and port 50000.

 `/etc/services`

 `C:\Windows\System32\drivers\etc\services`

For example, remove the following lines:

```
db2c_bpminst 50000/tcp
```

or

```
db2c_db2inst1 50000/tcp
```

---

## Uninstalling IBM Business Monitor silently

You can use the command-line mode of the Installation Manager to uninstall IBM Business Monitor.

Close all programs that you installed using the Installation Manager.

To uninstall, you must log in to the system using the same user account that you used to install.

To silently uninstall IBM Business Monitor, complete the following steps:

1. Open a command prompt, and change directories to the `/eclipse/tools` directory under Installation Manager.

**Important:** If you are running Windows 7, Windows Vista, or Windows Server 2008, start your command prompt by right-clicking and selecting **Run as administrator**.

2. Make the appropriate replacements and run the following command:

```
imcl uninstall list_of_product_IDs -installationDirectory installationDirectory -log logLocation -properties optionalProperties
```

- a. Replace *list\_of\_product\_IDs* with a list of the IDs for the products you want to uninstall, separated by spaces.

**Important:** The DB2 Express installation might be used by multiple products, including products on a remote system. If you uninstall DB2 Express, all DB2 Express databases and database assets are deleted.

Table 11. Product IDs

Product	Product ID
IBM Business Monitor	com.ibm.websphere.MON.V80
WebSphere Application Server Network Deployment	com.ibm.websphere.ND.v80
Installation Manager	com.ibm.cic.agent
DB2 for Linux 32-bit	com.ibm.ws.DB2EXP97.linuxia32
DB2 for Linux 64-bit	com.ibm.ws.DB2EXP97.linuxia64
DB2 for Windows 32-bit	com.ibm.ws.DB2EXP97.winia32
DB2 for Windows 64-bit	com.ibm.ws.DB2EXP97.winia64
IBM Cognos Business Intelligence for Windows x86 (32-bit)	com.ibm.ws.cognos.v1011.winia32
IBM Cognos BI for Windows x64 (64-bit)	com.ibm.ws.cognos.v1011.winia64
IBM Cognos BI for AIX PPC 32-bit	com.ibm.ws.cognos.v1011.aix32

- b. Replace *installationDirectory* with the location where you installed the product.
- c. Replace *logLocation* with the location and file name to log the information.

Installation Manager uninstalls the list of products and writes a log file to the directory that you specified.

The following example uninstalls IBM Business Monitor, WebSphere Application Server ND, and DB2 Express from Windows.

```
C:\Program Files\IBM\Installation Manager\eclipse\tools>imcl uninstall com.ibm.websphere.MON.V80
com.ibm.websphere.ND.v80 com.ibm.ws.cognos.v1011.winia32 com.ibm.ws.DB2EXP97.winia32
-installationDirectory C:\IBM\MON80 -log uninstalllog.txt
```

## Removing the showcase model

IBM Business Monitor comes with a mortgage lending showcase model that illustrates some of the functionality of IBM Business Monitor. You can install this model using First Steps.

To remove the showcase model:

1. Delete the Better Lender dashboard using the Space Manager.
2. Use the WebSphere Application Server administrative console to remove the alert templates.
3. If you have security enabled, remove the user role in the WebSphere Application Server administrative console.
4. Purge the model using the WebSphere Application Server administrative console.
