Chapter 1. Developing with Evidence

Custom evidence solutions can be developed with Cúram Evidence. All of the evidence server-side infrastructure artifacts are available in the `curam.core.sl.infrastructure.impl` package. The evidence metadata entity contains metadata about each evidence type. This entity must be populated before evidence maintenance can proceed. Evidence maintenance functions are available in the administration application.

Introduction

Purpose

The purpose of this document is to provide assistance to developers intending to implement evidence solutions using Cúram's Evidence solution. It outlines common pieces of evidence maintenance functionality and describes how a developer can design / implement such functionality.

Prerequisites

The readers should be familiar with the evidence capturing aspect of case management as well as its use in determining eligibility and entitlement on a case. They should also have read "The Evidence Pattern" in the Designing Cúram Evidence Solutions guide.

Audience

This document is targeted at a technical audience, both developers and architects, intending to implement evidence solutions using Cúram's Evidence framework.

Server / Client Evidence Components

Server Side Artifacts

All of the Evidence server side infrastructure artifacts are shipped in the "curam.core.sl.infrastructure.impl" package. The key elements found here include the Evidence Controller / Evidence Controller Hook (see section 3.8) classes and the Evidence Interfaces. The Interfaces form part of the Interface Hierarchy. The Participant Evidence Interface and Evidence Interface both extend the parent Interface, Standard Evidence Interface. These Evidence Interfaces will be the artifacts of most interest to designers / developers as each evidence entity will need to implement this interface.

Standard Evidence Interface

The Standard Evidence Interface defines the following methods, which are common to both inheriting interfaces. The interface and its associated methods are shown with the appropriate Javadoc comments.

        throws ApplicationException, InformationalException;
}

```

Adopting an interface approach enforces a pattern upon entity design and development as each entity must implement the same interface. This approach allows the Cúram Enterprise Framework to provide as much common functionality as possible so that custom implementations can concentrate more on business aspects of evidence maintenance, such as validations. Each evidence entity must implement the Evidence Interface to have access to the Evidence Controller class. This class implements the common business logic across all evidence entities and the custom business logic specific to each evidence entity.

Accessing Non-modeled Functions

When the Evidence Interfaces are implemented by evidence entities, the methods defined by these interfaces will be implemented by those entities. These methods will of course be non-modeled so will only exist on the evidence entity impl classes. In order to access the non-modeled functions, it's necessary to cast from the impl class. Examples of this can be seen in the entity program listings later in section 3.2 of this document. This casting mechanism will not work though unless the factory class is extending the impl class as opposed to the base class. The only way that this can be achieved, if no non-stereotyped functions are being added to the class, is to add a non-stereotyped dummy function. If this is not done, it will result in a runtime error when the casting is executed.

Client Side Artifacts

The client side infrastructure artifacts are located inside the `.\webclient\components\core\Evidence Infrastructure` directory. This folder primarily contains uim and vim client pages. The vim files will typically be included inside solution specific uim pages to manage generic evidence details whereas the uim pages contain complete out-of-the-box evidence maintenance functionality.

The key benefit of the .im files is that they can be changed in line with any enhancements made to the evidence maintenance solution without any impact on specific implementations, i.e. the upgrade is seamless.

Examples of infrastructural .vim files are as follows:

- Evidence_createHeader.vim
- Evidence_modifyHeader.vim
- Evidence_viewHeader.vim
- Evidence_viewHeaderForModal.vim

These artifacts manage the infrastructural attributes of evidence maintenance and should be included in create, modify and view evidence pages. This will be highlighted later when a sample implementation of the Evidence solution is discussed. Some further examples of vim files include:

- Evidence_typeWorkspace.vim
- Evidence_workspaceInEditHighLevelView.vim
- Evidence_workspaceActiveHighLevelView.vim

These artifacts are used to populate evidence workspaces. An evidence workspace is a central location for managing evidence. The above vim files will be included by workspace.uim pages.

Some examples of infrastructural uim pages which provide entire evidence maintenance functions are:

- Evidence_applyChanges1.uim
- Evidence_addNewEvidence.uim
- Evidence_dashboard.uim

Evidence_applyChanges1 lists all work-in-progress evidence, i.e. all new and updated evidence or evidence that is pending removal. The display and action bean on this page live on the Evidence facade which is part of the centralized evidence maintenance functionality.

Evidence_addNewEvidence lists all possible evidence types, filtered by category, and launches an appropriate create page for each.

Evidence_dashboard lists all evidence types on the given case broken into categories. It highlights which types have In Edit evidence recorded and which have verifications or issues outstanding.

Note: It is important to note that in some cases .vim files found in the client infrastructure package are actually included in infrastructure pages. For instance, Evidence_dashboardView.vim is included inside the Evidence_dashboard page and Evidence_flowView.vim is included inside the Evidence_flow page.

Developing an Evidence Solution

Administration

Evidence Metadata

The Evidence Metadata entity contains metadata information relating to each evidence type. This entity must be populated before evidence maintenance can proceed. A number of evidence page names, including the view and modify page names, are included in the metadata. These page names are retrieved at runtime via evidence infrastructure resolve scripts and via implementations of the Evidence Type interface on the server. The records on the Evidence Metadata entity are effective dated to facilitate pages changing over time, due to legislation for example.

Product Evidence Link

The Product Evidence Link entity links evidence to a product. In some circumstances, evidence may be stored at the Integrated Case level but only some of this evidence may apply to a given product on the Integrated Case. To know which evidence should be attributed to a given product, a lookup of this entity is performed as part of the attribution processing and only evidence linked to the product is attributed.

Common Evidence Maintenance Operations

In this section, some common evidence maintenance operations are outlined. This is done using sequence diagrams, client screenshots and server code snippets from the a sample product implementation. This product is used for demonstration purposes only.

Create Evidence

The development, both client and server, of a create evidence operation is outlined here.

Create Evidence Sequence Diagram

Figure 1: Sequence Diagram for Creating Evidence

Client - Screen to Be Developed

The client page to be developed must include the evidence infrastructure page Evidence_createHeader.vim. This included.vim page facilitates the management of infrastructure attributes. For example, the Evidence Descriptor's receivedDate attribute is currently managed through this infrastructure page. If, at some point in the future, additional attributes which need to be managed through the create function were added to the Evidence Descriptor entity, then these attributes could be mapped through this infrastructure page. Hence, this requires just a once-off infrastructure change rather than many changes to custom artifacts.

Server - Methods to Be Implemented

The SEGEvidenceMaintenance.createAssetEvidence facade operation calls the evidence service layer implementation.

```
// -----  
/**  
 * Creates an Asset evidence record.  
 *  
 * @param dtls Details of the new evidence record to be created.  
 *  
 * @return The details of the created record.  
 */  
public ReturnEvidenceDetails createAssetEvidence(  
    AssetEvidenceDetails dtls)  
    throws ApplicationException, InformationalException {  
  
    // set the informational manager for the transaction  
    TransactionInfo.setInformationalManager();  
  
    // Asset evidence manipulation object  
    Asset evidenceObj = AssetFactory.newInstance();  
  
    // return object  
    ReturnEvidenceDetails createdEvidenceDetails =  
        new ReturnEvidenceDetails();  
  
    // create the Asset record and populate the return details  
    createdEvidenceDetails =  
        evidenceObj.createAssetEvidence(dtls);  
  
    createdEvidenceDetails.warnings =  
        EvidenceControllerFactory.newInstance().getWarnings();  
  
    return createdEvidenceDetails;  
}
```

These overloaded Asset.createAssetEvidence service layer operations call the Evidence Controller infrastructure function for inserting evidence.

```
// -----  
/**  
 * Creates an Asset record.  
 *  
 * @param dtls Contains Asset evidence record creation details.  
 *  
 * @return the new evidence ID and warnings.  
 */  
public ReturnEvidenceDetails createAssetEvidence(  
    AssetEvidenceDetails dtls)  
    throws ApplicationException, InformationalException {  
  
    return createAssetEvidence(dtls, null, null, false);  
}
```

```

// -----
/**
 * Creates a Asset record.
 *
 * @param dtls Contains Asset evidence record creation details.
 *
 * @param sourceEvidenceDescriptorDtls If this function is called
 * during evidence sharing, this parameter will be non-null and
 * it represents the header of the evidence record being shared
 * (i.e. the source evidence record)
 *
 * @param targetCase If this function is called during evidence
 * sharing, this parameter will be non-null and it represents the
 * case the evidence is being shared with.
 *
 * @param sharingInd A flag to determine if the function is
 * called in evidence sharing mode. If false, the function is
 * being called as part of a regular create.
 *
 * @return the new evidence ID and warnings.
 */
public ReturnEvidenceDetails createAssetEvidence(
    AssetEvidenceDetails dtls,
    EvidenceDescriptorDtls sourceEvidenceDescriptorDtls,
    CaseHeaderDtls targetCase, boolean sharingInd)
    throws ApplicationException, InformationalException {

    // validate the mandatory fields
    validateMandatoryDetails(dtls);

    EvidenceControllerInterface evidenceControllerObj =
        (EvidenceControllerInterface)
            EvidenceControllerFactory.newInstance();
    EvidenceDescriptorInsertDtls evidenceDescriptorInsertDtls =
        new EvidenceDescriptorInsertDtls();

    ReturnEvidenceDetails createdEvidence =
        new ReturnEvidenceDetails();

    if (sharingInd) {

        EvidenceDescriptorDtls sharedDescriptorDtls =
            evidenceControllerObj.shareEvidence(
                sourceEvidenceDescriptorDtls,
                targetCase);

        // Return the evidence ID and warnings
        createdEvidence.evidenceKey.evidenceID =
            sharedDescriptorDtls.relatedID;
        createdEvidence.evidenceKey.evType =
            sharedDescriptorDtls.evidenceType;

    } else {

        // As there is no participant associated with this evidence
        // we must retrieve the case participant to set the evidence
        // descriptor participant.
        CaseHeaderKey caseHeaderKey = new CaseHeaderKey();
        caseHeaderKey.caseID = dtls.caseIDKey.caseID;
        evidenceDescriptorInsertDtls.participantID =
            CaseHeaderFactory.newInstance().readCaseParticipantDetails(
                caseHeaderKey).concernRoleID;
    }
}

```

```

// Evidence descriptor details
evidenceDescriptorInsertDtls.caseID = dtls.caseIDKey.caseID;
evidenceDescriptorInsertDtls.evidenceType =
    CASEEVIDENCE.ASSET;
evidenceDescriptorInsertDtls.receivedDate =
    dtls.descriptor.receivedDate;

// Upon creation, the change reason should be Initial
evidenceDescriptorInsertDtls.changeReason =
    EVIDENCECHANGEREASON.INITIAL;

// Evidence Interface details
EIEvidenceInsertDtls eiEvidenceInsertDtls =
    new EIEvidenceInsertDtls();
eiEvidenceInsertDtls.descriptor.assign(
    evidenceDescriptorInsertDtls);
eiEvidenceInsertDtls.evidenceObject = dtls.dtls;

// Insert the evidence
EIEvidenceKey eiEvidenceKey =
    evidenceControllerObj.insertEvidence(eiEvidenceInsertDtls);

// Return the evidence ID and warnings
createdEvidence.evidenceKey.evidenceID =
    eiEvidenceKey.evidenceID;
createdEvidence.evidenceKey.evType =
    eiEvidenceKey.evidenceType;
createdEvidence.warnings =
    evidenceControllerObj.getWarnings();
}

return createdEvidence;
}

```

Modify Evidence

The development, both client and server, of a modify evidence operation is outlined here.

Modify Evidence Sequence Diagram

Figure 2: Sequence Diagram for Modifying Evidence

Client - Screen to Be Developed

The client page to be developed must include the evidence infrastructure page Evidence_modifyHeader1.vim. This included.vim page facilitates the viewing / modification of some infrastructure attributes. For example, received date can be viewed or modified via this.vim. Also, change reason and effective date of change can be set on the edited record. If, at some point in the future, additional attributes which need to be managed through the modify function were added to the Evidence Descriptor entity, then these attributes could be mapped through this infrastructure page. Hence, this requires just a once-off infrastructure change rather than many changes to custom artifacts.

The inclusion of Evidence_modifyHeader1.vim facilitates the following three types of evidence modification:

- Editing Evidence In Place

This refers to the modification of incorrect data on a piece of evidence which has not yet been activated. In this scenario, if the effective date is modified an error will be thrown informing the user that the date can only be modified when updating an active record.

- Evidence Correction

An evidence correction occurs when a piece of data on an active evidence record is modified resulting in the current active record being superseded. In this scenario, the effective date field must not be modified as this will result in a new record in the succession being created - see evidence succession.

- Evidence Succession

If the user modifies the effective date when updating a piece of active evidence, they are specifying a new record in the succession set, i.e. the new record will have the same successionID as the active record. Therefore, the active record will essentially be copied and made effective from the effective date specified by the user and the update applied to this record.

Note: Activation of newly created records in a succession will cause reattribution of records in that succession set.

Server - Methods to Be Implemented

The SEGEvidenceMaintenance.modifyAssetEvidence facade operation calls the evidence service layer implementation.

```
// -----  
/**  
 * Modifies an Asset evidence record.  
 *  
 * @param details The modified evidence details.  
 *  
 * @return The details of the modified evidence record.  
 */  
public ReturnEvidenceDetails modifyAssetEvidence(  
    AssetEvidenceDetails dtls)  
    throws ApplicationException, InformationalException {  
  
    // set the informational manager for the transaction  
    TransactionInfo.setInformationalManager();  
  
    // Asset evidence manipulation object  
    Asset evidenceObj = AssetFactory.newInstance();  
  
    // return object  
    ReturnEvidenceDetails modifiedEvidenceDetails =  
        new ReturnEvidenceDetails();  
  
    // modify the Asset record and populate the return details  
    modifiedEvidenceDetails =  
        evidenceObj.modifyAssetEvidence(dtls);  
  
    modifiedEvidenceDetails.warnings =  
        EvidenceControllerFactory.newInstance().getWarnings();  
  
    return modifiedEvidenceDetails;  
}
```

The Asset.modifyAssetEvidence service layer operation calls the Evidence Controller infrastructure function for modifying evidence.

```
// -----  
/**  
 * Modifies an Asset record.  
 *  
 * @param dtls Contains Asset evidence record modification  
 *             details.  
 *  
 * @return The modified evidence ID and warnings.  
 */
```

```

public ReturnEvidenceDetails modifyAssetEvidence
    (AssetEvidenceDetails details)
    throws ApplicationException, InformationalException {

    // validate the mandatory fields
    validateMandatoryDetails(details);

    // EvidenceController business object
    EvidenceControllerInterface evidenceControllerObj =
        (EvidenceControllerInterface)
            EvidenceControllerFactory.newInstance();

    EIEvidenceKey eiEvidenceKey = new EIEvidenceKey();

    //
    // Call the EvidenceController to modify the evidence
    //

    eiEvidenceKey.evidenceID = details.dtls.evidenceID;
    eiEvidenceKey.evidenceType = CASEEVIDENCE.ASSET;

    // Create the evidence interface modification struct and assign
    // the details
    EIEvidenceModifyDtls eiEvidenceModifyDtls =
        new EIEvidenceModifyDtls();
    eiEvidenceModifyDtls.descriptor.receivedDate =
        details.descriptor.receivedDate;
    eiEvidenceModifyDtls.descriptor.versionNo =
        details.descriptor.versionNo;
    eiEvidenceModifyDtls.descriptor.effectiveFrom =
        details.descriptor.effectiveFrom;
    eiEvidenceModifyDtls.descriptor.changeReceivedDate =
        details.descriptor.changeReceivedDate;
    eiEvidenceModifyDtls.descriptor.changeReason =
        details.descriptor.changeReason;
    eiEvidenceModifyDtls.evidenceObject = details.dtls;

    evidenceControllerObj.modifyEvidence(
        eiEvidenceKey, eiEvidenceModifyDtls);

    //
    // Return details from the modify operation
    //

    ReturnEvidenceDetails returnEvidenceDetails =
        new ReturnEvidenceDetails();
    returnEvidenceDetails.evidenceKey.evidenceID =
        eiEvidenceKey.evidenceID;
    returnEvidenceDetails.evidenceKey.evType =
        eiEvidenceKey.evidenceType;
    returnEvidenceDetails.warnings =
        evidenceControllerObj.getWarnings();

    return returnEvidenceDetails;
}

```

Read Evidence

The development, both client and server, of a read evidence operation is outlined here.

View Evidence Sequence Diagram

Figure 3: Sequence Diagram for Viewing Evidence

Client - Screen to Be Developed

The client page includes the evidence infrastructure page Evidence_viewHeaderForModal.vim. This included.vim facilitates the viewing of some infrastructure attributes.

Server - Methods to Be Implemented

The SEGEvidenceMaintenance.readAssetEvidence façade operation calls the evidence service layer implementation.

```

// -----
/**
 * Reads an Asset evidence record.
 *
 * @param key Identifies the evidence record to read.
 *
 * @return The details of the evidence record.
 */
public ReadAssetEvidenceDetails readAssetEvidence(
    EvidenceCaseKey key)
    throws ApplicationException, InformationalException {

    // Asset evidence manipulation object
    Asset evidenceObj = AssetFactory.newInstance();

    // return object
    ReadAssetEvidenceDetails readEvidenceDetails =
        new ReadAssetEvidenceDetails();

    // read the Asset record and populate the return details
    readEvidenceDetails = evidenceObj.readAssetEvidence(key);
  
```

```

return readEvidenceDetails;
}

```

This service layer operation calls the Evidence Controller infrastructure function for reading evidence.

```

// -----
/**
 * Reads an Asset record.
 *
 * @param key contains ID of record to read.
 *
 * @return Asset evidence details read.
 */
public ReadAssetEvidenceDetails readAssetEvidence(
    EvidenceCaseKey key)
    throws ApplicationException, InformationalException {

    // EvidenceController business object
    EvidenceControllerInterface evidenceControllerObj =
        (EvidenceControllerInterface)
            EvidenceControllerFactory.newInstance();

    EIEvidenceKey eiEvidenceKey = new EIEvidenceKey();
    eiEvidenceKey.evidenceID = key.evidenceKey.evidenceID;
    eiEvidenceKey.evidenceType = CASEEVIDENCE.ASSET;

    // Retrieve the evidence details
    EIEvidenceReadDtls eiEvidenceReadDtls =
        evidenceControllerObj.readEvidence(eiEvidenceKey);

    // Retrieve the evidence descriptor details
    EvidenceDescriptor evidenceDescriptorObj =
        EvidenceDescriptorFactory.newInstance();

    EvidenceDescriptorKey evidenceDescriptorKey =
        new EvidenceDescriptorKey();
    evidenceDescriptorKey.evidenceDescriptorID =
        eiEvidenceReadDtls.descriptor.evidenceDescriptorID;

    EvidenceDescriptorDtls evidenceDescriptorDtls =
        evidenceDescriptorObj.read(evidenceDescriptorKey);

    //
    // Return the evidence
    //

    ReadAssetEvidenceDetails readEvidenceDetails =
        new ReadAssetEvidenceDetails();
    readEvidenceDetails.descriptor
        .assign(evidenceDescriptorDtls);

    readEvidenceDetails.descriptor.approvalRequestStatus =
        eiEvidenceReadDtls.descriptor.approvalRequestStatus;
    readEvidenceDetails.descriptor.updatedBy =
        eiEvidenceReadDtls.descriptor.updatedBy;
    readEvidenceDetails.descriptor.updatedDateTime =
        eiEvidenceReadDtls.descriptor.updatedDateTime;

    // assign the evidence to the return object
    readEvidenceDetails.dtls.assign(
        (AssetDtls)(eiEvidenceReadDtls.evidenceObject));
}

```

```

return readEvidenceDetails;
}

```

List Evidence

The development, both client and server, of a list evidence operation is outlined here. The list operation is used to populate an evidence workspace page.

List Evidence Sequence Diagram

Figure 4: Sequence Diagram for Listing Evidence

Server - Methods to Be Developed

Much of the data displayed on the workspace page is retrieved via the Evidence Descriptor entity. The description and period are retrieved via Evidence Interface methods which must be implemented for each evidence type.

- *Asset.getDetailsForListDisplay* entity operation

The description, or summary details, is retrieved via the `getDetailsForListDisplay` Evidence Interface method which is implemented by the evidence entities. The implementation of the `getDetailsForListDisplay` method for the Asset is shown below. This interface function is also used to retrieve summary data when applying, approving, rejecting evidence as well as in evidence sharing, verifications and issues screens.

```

// -----
/**
 * Gets evidence details for the list display
 *
 * @param key Evidence key containing the evidenceID and
 * evidenceType
 *
 * @return Evidence details to be displayed on the list page
 */
public EIFieldsForListDisplayDtls getDetailsForListDisplay(
    IEvidenceKey key)
    throws ApplicationException, InformationalException {

    // Return object

```

```

EIFieldsForListDisplayDtls eiFieldsForListDisplayDtls =
    new EIFieldsForListDisplayDtls();

// Asset entity key
final AssetKey assetKey = new AssetKey();
assetKey.evidenceID = key.evidenceID;

// Read the Asset entity to get display details
final AssetDtls assetDtls =
    AssetFactory.newInstance().read(assetKey);

// Set the start / end dates
eiFieldsForListDisplayDtls.startDate = assetDtls.startDate;
eiFieldsForListDisplayDtls.endDate = assetDtls.endDate;

LocalisableString summary = new LocalisableString(
    BIZOBJDESCRIPTIONS.BIZ_OBJ_DESC_ASSET);

summary.arg(
    CodeTable.getOneItem(SAMPLEASSETTYPE.TABLENAME,
        assetDtls.assetType));

// Format the amount for display
TabDetailFormatter formatterObj =
    TabDetailFormatterFactory.newInstance();
AmountDetail amount = new AmountDetail();
amount.amount = assetDtls.value;
summary.arg(formatterObj.formatCurrencyAmount(amount).amount);

eiFieldsForListDisplayDtls.summary =
    summary.toClientFormattedText();

return eiFieldsForListDisplayDtls;
}

```

(deprecated) Evidence Dashboard and EvidenceFlow

The **Evidence Dashboard** and **EvidenceFlow** are user interface constructs introduced to assist user navigation to all evidence on a case. No custom code is required in order to configure these for a custom case as these are infrastructural.

From these pages, a user can select a particular evidence type which should open the respective evidence workspace for that type of evidence. In the case of the Dashboard, this will open in a new tab, whereas the EvidenceFlow will redirect the bottom portion of the page.

The existence of 'In Edit' evidence records, outstanding verifications and outstanding issues are all highlighted graphically.

The list of evidence types on the case may be split into categories on these pages, by defining the category on the AdminICEvidenceLink table for Integrated Cases, or on the ProductEvidenceLink table for Product Deliveries.

Validations

The infrastructure facilitates the validation of work-in-progress changes. The validate page can be used either at a case level or on an individual evidence type.

The purpose of the case level validate page is to provide a means to test validations in advance of applying the changes. For some products, the full evidence set may be quite sizeable resulting in the apply changes listing containing a considerable number of evidence changes of varying evidence types. In that scenario, the individual evidence type validate page may make it easier to associate a validation message with the correct evidence record. The validate page allows a user to pre-test the evidence changes. The user can see which validations will fail and fix them before applying the changes.

More On Validations

Two of the Evidence Interface functions which form part of the infrastructure support for evidence validation are `selectForValidations` and `validate`.

The `selectForValidations` function will typically be used to select all evidences which are related to or are dependant on the piece of evidence being validated. An example of this would be the modification of an amount on a parent evidence record. As part of the validation of the parent evidence, a check might need to be performed to ensure the sum of the child evidence records does not exceed the modified parent amount.

When a user applies changes to evidence records, the Evidence Controller calls out to the `selectForValidations` interface function on the entities for each evidence record. The logic within this method retrieves all related 'Active' and 'In Edit' evidences within the hierarchy for validation. For instance, if we are validating a child evidence record within a parent-child-grandchild relationship structure, both parent evidence and grandchild evidence are retrieved for the validation processing.

Once processing returns to the Evidence Controller, a filter is applied to the list of evidence. This filters the input list and leaves only 'Active' records, or 'In Edit' records as appropriate depending on whether the function must validate against work-in-progress or active only evidence. This filtered list is then passed to the `validate` function where custom validation is applied.

The program listing below shows a `selectForValidations` implementation used in the Asset demo.

```
// -----  
/**  
 * Selects all the records for validations  
 *  
 * @param evKey Contains an evidenceID / evidenceType pairing  
 *  
 * @return List of evidenceID / evidenceType pairings  
 */  
public EIEvidenceKeyList selectForValidation(  
    EIEvidenceKey evKey)  
    throws ApplicationException, InformationalException {  
  
    // Return object  
    EIEvidenceKey eiEvidenceKey = new EIEvidenceKey();  
  
    // Casting to impl due to calling non-modeled interface  
    curam.seg.evidence.entity.intf.AssetOwnership  
        assetOwnershipObj =  
        (curam.seg.evidence.entity.impl.AssetOwnership)  
        AssetOwnershipFactory.newInstance();  
  
    eiEvidenceKey.evidenceID = evKey.evidenceID;  
    eiEvidenceKey.evidenceType =  
        CASEEVIDENCE.ASSET;  
  
    EIEvidenceKeyList eiEvidenceKeyList =  
        assetOwnershipObj.readAllByParentID(eiEvidenceKey);  
  
    eiEvidenceKeyList.dtls.add(0, evKey);  
  
    return eiEvidenceKeyList;  
}
```

The code here, on the Asset parent entity, makes a call to the `readAllByParentID` interface method implementation on the child entity, Asset Ownership. The implementation of the `readAllByParentID` function on the Asset Ownership is shown in the program listing below.

```
// -----  
/**  
 * Read all Asset Ownership records  
 *  
 * @param key Contains the evidenceID and evidenceType
```

```

*
* @return A list of evidenceID and evidenceType pairs
*/
public EIEvidenceKeyList readAllByParentID(EIEvidenceKey key)
    throws ApplicationException, InformationalException {

    // Return object
    EIEvidenceKeyList eiEvidenceKeyList = new EIEvidenceKeyList();

    // Create the link entity object
    EvidenceRelationship evidenceRelationshipObj =
        EvidenceRelationshipFactory.newInstance();

    // parent entity key
    ParentKey parentKey = new ParentKey();
    parentKey.parentID = key.evidenceID;
    parentKey.parentType = key.evidenceType;

    // Reads all relationship details for the specified parent
    ChildKeyList childKeyList =
        evidenceRelationshipObj.searchByParent(parentKey);

    // Iterate through the link details list
    for (int i = 0; i < childKeyList.dtls.size(); i++) {

        if (childKeyList.dtls.item(i).childType.equals(
            CASEEVIDENCE.ASSETOWNERSHIP)) {

            EIEvidenceKey listEvidenceKey = new EIEvidenceKey();

            listEvidenceKey.evidenceID =
                childKeyList.dtls.item(i).childID;
            listEvidenceKey.evidenceType =
                childKeyList.dtls.item(i).childType;

            eiEvidenceKeyList.dtls.addRef(listEvidenceKey);
        }
    }

    return eiEvidenceKeyList;
}

```

The function above retrieves all child evidence keys for the specified parent. The childID and childType pairings are returned to the calling mechanism.

Evidence Attribution

Evidence attribution refers to the assignment of a period of time to a given piece of evidence during which that piece of evidence will be used for entitlement calculations. The attribution period may range from a basic one to one mapping from the business start and end dates through to a more sophisticated algorithm considering any number of factors. This custom logic calculates the attribution period and the evidence controller takes care of synchronizing these with the specified effective dates – see example(s) below. It should also be noted that the attribution from and to dates can be null in which case the piece of evidence is assumed effective from the case start date to the expected end date.

One of the Evidence Interface functions is `calcAttributionDatesForCase` and the implementation of this function on an entity class is where the attribution from and to dates are determined for evidence on that entity.

Re-attribution

When evidence is modified as part of a succession and subsequently activated, re-attribution of the evidence records in the succession set occurs. A basic example of how this works is shown below:

Business Start Date: 3rd May 2006 (=attribution from date)

Business End Date: 30th July 2006 (=attribution to date)

A succession record is created effective from 5th June 2006. On activation of this record, the evidence is re-attributed and the following attribution records created:

3rd May 2006 to 4th June 2006

5th June 2006 to 30th July 2006

Re-attribution also occurs if evidence in a succession set is removed. For example, if the following three attribution records exist for records in the same succession set

3rd May 2006 to 4th June 2006

5th June 2006 to 30th July 2006

31st July 2006 to 29th Sept 2006

and the evidence record associated with the middle one is removed, applying changes will cause the following re-attribution

3rd May 2006 to 30th July 2006

31st July 2006 to 29th Sept 2006

The attribution record from 5th June 2006 to 30th July 2006 remains on the database but won't be picked up by eligibility processing as the associated evidence is removed, i.e. has a status of 'Canceled'.

Evidence Relationship

By default, the Evidence infrastructure facilitates the linking of parent-child evidence via the EvidenceRelationship link entity. The structure of the EvidenceRelationship link entity is as follows:

<i>Table 1: Evidence Relationship Link Entity</i>
Evidence Relationship
evidenceRelationshipID
parentID
parentType
childID
childType

This supports the relationship between any parent-child evidence and does away with the necessity for customers to model their own link entities for managing such relationships. When evidence is being inserted, the generic EvidenceController.insertEvidence function makes a call to the business process EvidenceRelationship.createLink. If a parent type has been specified, i.e. passed in from the client as part of the insert, then a record will be written to the EvidenceRelationship entity linking the child evidence to its parent. Also, a call is made to the business process EvidenceRelationship.cloneLinks directly after the call to the interface operation insertEvidenceOnModify. From cloneLinks, two further calls are made to cloneLinksForParent and cloneLinksForChild.

If customers are using their own link entities to manage relationships, they will need to override the Evidence Relationship business processes for creating and cloning links. The evidence type is available in the input keys of both these functions which means that responsibility can be delegated to the appropriate custom relationship processing based on the evidence type in the key.

Registering Evidence Implementations

The evidence maintenance pattern requires the set of evidence entities to be registered before they can be used. This is so that the controller can access these evidence entities at runtime.

The Core Cúram Framework does not know in advance which evidence entities will be used for the given evidence maintenance facility associated with a particular product implementation. The evidence types and their implementation must be paired at runtime.

Evidence Registrar Module

Google Guice dependency injection should be used in order to register the different evidence types and their implementations. This can be done by writing a new module class, or adding to a pre existing one. Once this is added to the ModuleCalssName table, then at runtime it will be loaded and the evidence types registered.

Google Guice dependency injection example:

```
/*
 * Copyright 2011 Cúram Software Ltd.
 * All rights reserved.
 *
 * This software is the confidential and proprietary information
 * of Cúram Software, Ltd. ("Confidential Information"). You
 * shall not disclose such Confidential Information and shall use
 * it only in accordance with the terms of the license agreement
 * you entered into with Cúram Software.
 */

package curam.seg.evidence.service.impl;

import curam.codetable.CASEEVIDENCE;
import com.google.inject.AbstractModule;
import curam.core.impl.FactoryMethodHelper;
import java.lang.reflect.Method;
import com.google.inject.multibindings.MapBinder;
import curam.core.impl.RegistrarImpl;
import curam.core.impl.Registrar.RegistrarType;

/**
 * A module class which provides registration for all of the
 * evidence hook implementations.
 */
public class SEGRegistrarModule extends AbstractModule {

    @Override
    public void configure() {

        // Register all hook implementations which implement the
        // interface EvidenceInterface.
        MapBinder<String, Method> evidenceInterfaceMapBinder =
            MapBinder.newMapBinder(binder(), String.class,
                Method.class, new RegistrarImpl(RegistrarType.EVIDENCE));

        evidenceInterfaceMapBinder
            .addBinding(CASEEVIDENCE.ASSET)
            .toInstance(FactoryMethodHelper.getNewInstanceMethod(
                curam.seg.evidence.entity.fact.AssetFactory.class));
    }
}
```

Legacy Evidence Registrar

The legacy mechanism for registration of evidence entities is still supported. i.e. using the Application Properties to specify the factories to populate a hashmap of the hook classes. The factory code will not change in order to maintain backward compatibility but all out of the box, legacy implementations have been deprecated.

Customizing Evidence Maintenance

As the Evidence Controller functionality is generic to all evidence solutions, the only way to facilitate an organization's unique requirements is by the provision of hooks where custom logic can be located to extend the core solution. Callouts to these hooks, or extension points, are made within the Evidence Controller maintenance functions.

The Cúram infrastructure handles the maintenance of evidence, such as adding, modifying, removing, and applying changes. The infrastructure is independent of the evidence type, that is, by default all evidence types are treated the same.

Customers might experience a need to customize the processing available for immediate use to meet project-specific needs. To facilitate this, the EvidenceControllerHook interface provides a set of extension points that allow custom code to be run at points in the evidence maintenance process.

In addition to adding custom code to these extension points, customers can specify 'case type' specific logic. This allows multiple implementations of the EvidenceControllerHook to be provided. Each implementation can be mapped to a 'case type' to give case type-specific customization. For example, the postRemoveEvidence for evidence on a Product Delivery case might be different than the postRemoveEvidence that is run on an Integrated Case.

Evidence Controller Hook

Evidence Controller Hook is the evidence infrastructure class which contains the extension points for the evidence maintenance pattern. An example of a hook in this class is postRemoveEvidence. A call is made to this function inside the Evidence Controller removeEvidence operation. Customers must override the hook with their custom version if they want to perform post remove evidence processing.

Providing a custom implementation of the EvidenceControllerHook

To inject a custom implementation at the provided extension points, the abstract base class curam.core.sl.infrastructure.impl.EvidenceControllerHook can be extended and the wanted methods can be overridden.

For most methods of the base abstract class, the implementation does nothing, but some default implementations are provided such as for the PreRemoveEvidence method. The Javadocs of the class can be referenced to understand what the default implementation does. The super().methodName() notation can be used to start the default implementation from an overridden method to retain the base functionality, if required.

To create a new custom EvidenceController hook, the following steps are taken:

- A new process class is modeled in, for example, CustomHook. This process must have a 'Generalization' relationship with EvidenceControllerHook class (extends EvidenceControllerHook)
- An implementation of the newly created process is created, in which any wanted methods are overridden:

```
public class CustomHook extends curam.sample.sl.base.CustomHook {  
  
    @Override  
    public void postInsertEvidence(CaseKey caseKey,  
        EIEvidence eiEvidenceKey){  
  
    }  
}
```

- A new Module class is created, where the wanted product type is bound to the custom hook implementation. This class must extend AbstractModule and a configuration for this module class must be added to MODULECLASSNAME.dmx:

```
public class TestRegistrarModule extends AbstractModule{  
  
    @Override  
    protected void configure() {  
        MapBinder<String, Method> evidenceControllerMapBinder =
```

```

MapBinder.newMapBinder(binder(), String.class, Method.class,
    new RegistrarImpl(RegistrarType.EVIDENCE_CONTROLLER_HOOK));

    evidenceControllerMapBinder
        .addBinding(PRODUCTTYPE.CUSTOMPRODUCTTYPE)
        .toInstance(FactoryMethodHelper.getNewInstanceMethod(
            CustomHookFactory.class));
    }
}

```

This adds a binding of CustomHook implementation to PRODUCTTYPE.CUSTOMPRODUCTTYPE product type string. Product type is used as a key during the EvidenceControllerHook implementation look-up. The infrastructure compares this key to the value returned by the implementation of CaseTypeEvidence.getCaseTypeCode() that is specific to the evidence type that is being processed. CaseTypeEvidence has many implementations, and they return different case type codes. Refer to the Javadoc to determine the run type of any particular implementation. The key that is used in the binding Module must match the value that is returned by getCaseTypeCode(), otherwise the custom hook is not picked up. For example, evidence on a Product Delivery case uses a "productType" code that is defined in the PRODUCTDELIVERY database table. Commonly used case type codes are listed in [Table 2 on page 25](#).

<i>Table 2: Commonly used case types</i>	
Case Name	Case Type Code database location
Default	CASHEADER.caseTypeCode
Integrated Case	CASHEADER.integratedCaseType
Product Delivery	PRODUCTDELIVERY.productType
Screening Case	SCREENINGCONFIGURATION.name
Assessment Delivery	ASSESSMENTCONFIGURATION.assessmentType
Investigation Delivery	INVESTIGATIONDELIVERY.investigationType

The Evidence Controller Hook Manager class manages the static initialization of the Evidence Controller Hook mapping and the retrieval of the subclass of the Evidence Controller Hook. If no subclass is found, the version of the Evidence Controller Hook class that is available for immediate use is returned.

Evidence Controller Hook Registrar & Manager

Following on from the Evidence Registrar and the underlying Dependency Injection pattern, a similar approach has been taken for the registration of the Evidence Controller Hook class. An Evidence Controller Hook Registrar interface is shipped as part of the evidence infrastructure.

As before, at runtime, the Evidence Controller invokes the Registrar's register method which performs the dependency injection of the associated custom Evidence Controller Hook. This is the class which will have extended the out-of-the-box Evidence Controller Hook and overridden the methods being customized. This "injector" class is located through runtime configuration where the injector class itself is referred to as the "Evidence Controller Hook Registrar".

The dependency injection involves two steps. First, a custom Evidence Controller Hook Registrar, which implements the Evidence Controller Hook Registrar interface, must be located and the Registrar then invoked to register the customized hook class. For example, the product type and custom Evidence Controller Hook class pairing will be entered into a hashmap and then the class looked up via the product type when it's required. In order to locate the Evidence Controller Hook Registrar, its class name must be configured using the environment variable "curam.case.evidencecontrollerhook.registrars". Note: additional entries need to be added to this environment variable in a comma delimited format.

The implementation of the Registrar's register method must reference the customized Evidence Controller Hook class. Doing this in code, rather than as configuration, provides a compile time check that

the referenced class exists. The existence of the Registrar, though, is only ascertained from the provided configuration, and may result in a runtime failure if the application is mis-configured.

The Evidence Controller Hook Manager class manages the static initialization of the Evidence Controller Hook mapping as well as the retrieval of the subclass of the Evidence Controller Hook. If no subclass is found, the out-of-the-box version of the Evidence Controller Hook class is returned.

Customization of Multiple Participant Evidence

This section describes the customization options for multiple participant evidence.

Multiple participant evidence is a feature that allows users to insert multiple records, modify multiple records or discard multiple records in a single action. This can save time and effort when caseworkers are managing multiple clients on a case, such as adding the same address for all family members in a single operation.

The following sections describe the customization options and extension points available to developers for multiple participant evidence.

Multiple Participant Evidence Extension Points

The following section describes the multiple participant evidence extension points.

A number of extension points have been provided to allow for customization. The following hook points have been provided.

- Pre create multiple participant evidence.
- Post create multiple participant evidence.
- Pre modify multiple participant evidence.
- Post modify multiple participant evidence.
- Pre discard multiple participant evidence.
- Post discard multiple participant evidence

Example Implementation

To enact custom functionality, do the following;

1. Create a new class in your custom package that implements the `curam.core.sl.infrastructure.impl.MultiEvidenceHook`.
2. Implement each method of the interface.

It is worth noting, the arguments supplied to the customization hook points are clones of the original. Modification of the values will not be reflected in the default flow.

```
class CustomMultiEvidenceHookImpl implements
curam.core.sl.infrastructure.impl.MultiEvidenceHook
{
    /**
     * Include your custom processing in this function
     * and it will
     * be invoked before the multiple create operation.
     */
    public void preCreateMultiEvidence( final
List<CaseParticipantRoleKey> participantList)throws ApplicationException,
InformationalException
    {
        for (final CaseParticipantRoleKey item : participantList) {
            // Custom participant processing for pre create
            // multiple participant evidence
            ...
        }
    }
}
```

```
    }  
    // Implement all other interface methods, even if they do nothing.  
    ...  
}
```

Example Configuration

Once you have create a MultiEvidenceHook implementation you must configure it for use.

1. In your custom package create a new class that extends `com.google.guice.AbstractModule`.
2. Bind the custom implementation to interface using Guice binding.

```
public class HookModule extends AbstractModule {  
    @Override public void configure()  
    {  
        // Bind custom multi evidence hook  
  
        bind(MultiEvidenceHook.class).to(CustomMultiEvidenceHookImpl .class);  
    }  
}
```

Multiple Participant Evidence Customization

The following section describes how to configure custom filters.

Customization of the Multiple Participant Evidence feature provides the ability to configure custom filters. The multiple participant evidence maintenance filters provide control over the list of options presented to the user during multiple participant operations, namely;

1. The list of participants that are presented to the user during create operations.
2. The list of evidence that is presented to the user during modify operations.
3. The list of evidence presented to the user during a discard operations.

There are two types of filter, Global filter and Evidence type filters.

1. Global filters allow a general filter to be applied to all evidence, removing the need to apply for every evidence type, and also ensuring the filter is applied to newly created evidence types that support Multiple Participant Evidence.
2. Evidence type filters allow specific filters to be applied at the evidence type level giving a more fine grained control over how filters are applied.

Global Filters Configuration

The following sections describe how to implement a global filter.

Global filters are applied to all evidence types. These filters can be used to provide general rules that are applied across all evidence types. This removes the need to replicate filtering rules across multiple types and removes the need to create new filters for each newly created evidence type.

Default Global Filters

When displaying a multiple participant create, update or discard page the list of items that is presented to the user is constructed from the case participants or case evidence. For more information on how these lists are constructed, refer to the Javadoc information of the `curam.evidence.impl.DynamicEvidenceMultiEvidenceOperations` class.

After the unfiltered list is constructed a global filter is applied for each operation type. For more information on how each default global filter works, refer to the Javadoc information of the `curam.core.sl.infrastructure.impl.MultiEvidenceFiltersImpl`.

Replacing Global Filters

If the default global filter is not suitable for your business scenario, it can be replaced with a custom version by configuring a new global filter.

The following sections present examples of how to implement a global filter;

- Global Filter for Multiple Create,
- Global Filter for Multiple Modify,
- Global Filter for Multiple Discard.

Global Filter for Multiple Create

The following example shows how a global create filter can be applied to all evidence types that use multiple participant evidence maintenance. The class must extend the `AbstractMultiEvidenceFiltersImpl` and implement the `evaluateParticipantForMultiCreate` operation.

The filter in this example has the following criteria.

1. Participant exists on the case for the given received date.
2. Participant is of type PRIMARY or MEMBER.
3. Participant is active.

```
public class CustomMultiEvidenceFiltersImpl extends
AbstractMultiEvidenceFiltersImpl
{
    /**
     * Removes the given participant from the list presented during
multiple participant create
     * operation.
     * The participant will be removed if they are not active, current
and have a participant
     * type of PRIMARY OR MEMBER.
     *
     * @param participant
     *     a case participant who is currently included in the
multiple create list.
     * @return
     *     true if the participant should be excluded from the list.
     */
    protected boolean excludeParticipantFromMultiCreate(final
MultiParticipantDtls participant)
    {
        return participant.recordStatus.equals(RECORDSTATUS.NORMAL) &&
            (participant.typeCode.equals(CASEPARTICIPANTROLETYPE.PRIMARY)
||
            participant.typeCode.equals(CASEPARTICIPANTROLETYPE.MEMBER))
&& new
                DateRange(participant.startDate,
participant.endDate).contains(getCurrentReceivedDate());
    }
}
```

Global Filter for Multiple Modify

The following example shows how a global modify filter can be applied to all evidence types that use multiple participant evidence maintenance. The class must extend the `AbstractMultiEvidenceFiltersImpl` and implement the `evaluateParticipantForMultiModify` operation.

The filter in this example has the following criteria.

1. For the participant whose evidence the modify operation was initiated from, filter out all other evidence records belonging to this participant.
2. Filter evidence that does not exist on the case for the given received date.

```

/**
 * Custom class to redefine the global filter for the multiple
 participant maintenance
 * evidence lists.
 */
public class CustomMultiEvidenceFiltersImpl extends
AbstractMultiEvidenceFiltersImpl
{
/**
 * Return true if you want to filter this item from the list of
 evidence that can be
 * modified.
 *
 * @param evidence
 *   an evidence record that is currently included in the
 multiple participant update list.
 *
 * @return true if the evidence should be excluded from the
 multiple participant update
 * list.
 */
protected boolean excludeEvidenceFromMultiModify(final
MultiEvidenceDtls evidence) {
// Do not exclude by default
boolean shouldExclude = false;
try {
shouldExclude = evidence.participantID !=
getCurrentEvidenceDescriptorDtls().participantID
&& !new DateRange(evidence.startDate,
evidence.endDate).contains(
getCurrentDynamicEvidenceObject().getReceivedDate());
} catch (AppException e) {
// Do not exclude
} catch (InformationalException e){
// Do not exclude
}
return shouldExclude;
}
}

```

Global Filter for Multiple Discard

The following example shows how a global discard filter can be applied to all evidence types that use multiple participant evidence maintenance. The class must extend the `AbstractMultiEvidenceFiltersImpl` and implement the `evaluateParticipantForMultiDiscard` operation.

The filter in this example has the following criteria.

1. For the participant whose evidence the discard operation was initiated from, filter out all other evidence records belonging to this participant.

```

/**
 * Custom class to redefine the global filter for the multiple
 participant maintenance
 * evidence lists.
 */

```

```

        public class CustomMultiEvidenceFiltersImpl extends
AbstractMultiEvidenceFiltersImpl implements MultiEvidenceFilters {

    /**
     * Return true if you want to filter this given item from the
list of evidence that can be
     * discarded.
     *
     * @param evidence
     *      an evidence record that is currently included in the
multiple participant update list.
     *
     * @return true if the evidence should be excluded from the
multiple participant update
     * list.
     */
    protected boolean excludeEvidenceFromMultiDiscard(final
MultiEvidenceDtls evidence) {
        boolean shouldFilter = false;
        try {
            shouldFilter = evidence.participantID !=
getCurrentEvidenceDescriptorDtls().participantID;
        } catch (AppException e) {
            // Do not filter
        } catch (InformationalException e){
            // Do not filter
        }
        return shouldFilter;
    }
}
}

```

Global Filters Configuration

The following example shows how to configure your custom filter for use. In this example, the CustomMultiEvidenceFiltersImpl class is bound to the default MultiEvidenceFiltersImpl class which will result in the custom class overriding the default class.

1. In your custom package create a new class that extends com.google.guice.AbstractModule.
2. Bind the custom implementation to interface using Guice binding.

```

    /**
     * Configure Filters for Multiple Participant Evidence
Maintenance.
     */
    public class FilterModule extends AbstractModule {
        @Override
        public void configure() {
            // Bind custom evidence filter

            bind(MultiEvidenceFiltersImpl.class).to(CustomMultiEvidenceFiltersImpl.class)
;
        }
    }
}

```

Evidence Type Filters

The following sections describe how to implement an evidence filter.

Evidence type filters provide the mechanism to customize specific evidence types for multiple participant update operations. A custom filter can be configured to be applied to 1 or more evidence types..

Note: An evidence type filter will **replace** the global filter. The type specific filter will receive the full set of records that can be legitimately displayed for the operation. E.g. all case participants including canceled ones or all evidence of the same type, regardless of whether it is canceled or end dated. While this gives the developer full control over how records will be filtered, it is likely they will need to re-apply some of the global rules..

Evidence type filters are configured by mapping the evidence type code of an evidence to a custom filter..

Multiple Participant Evidence Filter Implementation

A multiple participant evidence filter can be implemented by extending `curam.core.sl.infrastructure.impl.AbstractMultiEvidenceFiltersImpl` abstract class. Filter customization is done in two steps.

1. Implement a custom filter by extending the `AbstractMultiEvidenceFiltersImpl`.
2. Add a binding for the custom filter implementation using Guice binder.

Implementing New Multiple Participant Evidence Specific Filter

The following example demonstrates how to create an evidence type specific filter. The example excludes email addresses, from the multiple update list of an email address modify or discard operation, if they are not of the same type as the email address record selected for update..

1. Create a custom class that extends `AbstractMultiEvidenceFiltersImpl` and implements the `exclude` methods for modify and discard operations.

```
public class MyCustomEmailAddressMultiEvidenceFiltersImpl extends
AbstractMultiEvidenceFiltersImpl {

    @Override protected boolean
excludeEvidenceFromMultiModify(final MultiEvidenceDtls evidence){
        return excludeEmailAddressEvidence(evidence);
    }

    @Override protected boolean
excludeEvidenceFromMultiDiscard(final MultiEvidenceDtls evidence){
        return excludeEmailAddressEvidence(evidence);
    }

    /**
     * Exclude evidence from email address multiple evidence update.
     */
    protected boolean excludeEmailAddressEvidence(final
MultiEvidenceDtls evidence) {
        boolean shouldExclude = false;
        // Include by default.

        final EvidenceDescriptorKey evidenceDescriptorKey = new
EvidenceDescriptorKey();
        evidenceDescriptorKey.evidenceDescriptorID =
evidence.evidenceDescriptorID;
        try {
            // Re-apply the global filter rules because we have
disabled them by
            // adding this type specific filter.
            boolean evidenceShouldBeConsidered =
evidence.participantID != getCurrentEvidenceDescriptorDtls().participantID
            && !new DateRange(evidence.startDate,
evidence.endDate).contains(getCurrentDynamicEvidenceObject().getReceivedDa
te());

            if (evidenceShouldBeConsidered) {
```

```

        boolean shouldExclude =
        ((String)readDynamicEvidenceObject(evidenceDescriptorKey).getAttributeValue(
        PDCEmailAddress.emailAddressTypeAttr)).equals(
        (String)
        getCurrentDynamicEvidenceObject().getAttributeValue(PDCEmailAddress.emailA
        ddressTypeAttr));
    }
    catch (AppException e) {
        // Default to include
    }catch (InformationalException e){
        // Default to include
    }
    return shouldExclude;
}
}
}

```

2. Create a Guice Module to bind the implementation. If you are not familiar with the use of Guice Modules with Curam you can read more [here](#). Use the evidence type code to bind the implementation using the standard Guice map binder strategy. In this case the evidence type code needed for the binding is PDC0000260, which maps to the 'Email Addresses' evidence type. The evidence type code value can be looked up on the EvidenceType code table.

```

public class EvidenceFilterModule extends AbstractModule {
    @Override public void configure() {
        final MapBinder<String, MultiEvidenceFilters>
        pdcMultiEvidenceFiltersMapBinder =
        MapBinder.newMapBinder(binder(), String.class,
        MultiEvidenceFilters.class);

        pdcMultiEvidenceFiltersMapBinder.addBinding("PDC0000260").to(
        MyCustomEmailAddressMultiEvidenceFiltersImpl.class);
    }
}

```

Evidence End Dating Feature Implementation

Caseworkers create an evidence record by recording the evidence in the first page of the evidence wizard. If an administrator has enabled the end dating feature for the evidence type and if the end dating criteria are met, a second page is displayed in the evidence wizard where caseworkers can end date previous evidence records. Administrators need to be aware of some implementation details and behavior in relation to the end dating of evidence records through the evidence wizard.

The following information supplements the configuration information that is described in the *Enabling the End Dating of Previous Evidence When Creating Evidence* topic, and also the procedural information that is described in the *Applying End Dating in the Creation of New Evidence Records* topic. For more information, see the related links.

Navigating to the end dating evidence option in the evidence wizard

In the evidence wizard, to navigate from the first page where an evidence record is created to the second page where evidence records can be end dated, caseworkers must click **Save and Next**. Note the following points:

- If the create evidence transaction fails, the transaction is rolled back, no record is committed to the database, and the appropriate validation error is displayed to the caseworker on the same evidence record creation page. The caseworker is not redirected to the next wizard page.
- If the create evidence transaction is successful, the evidence is created and committed to the database, and the caseworker is directed to the second page of the wizard. Therefore, as the create and end date

processes are separated as end-to-end transactions, the caseworker cannot navigate back to the previous evidence record creation page.

Completing the evidence wizard

In the evidence wizard, when the caseworker clicks **Finish** in the evidence end dating page, the end date evidence transaction is triggered. Note the following points:

1. If the end date evidence transaction fails, the transaction is rolled back, no record is committed to the database and the appropriate validation errors are displayed to the caseworker in the same evidence end dating page. For dynamic evidence records, the end dating validation errors are aggregated, so that all validation errors are displayed to the caseworker. To enable aggregated validation error messages for non-dynamic evidence records, in the customized non-dynamic evidence validation classes, replace the `InformationalManager.failOperation()` method call with the `MultiFailOperation.failOperationWithMPO()` method call. If you do not replace the method, when the first validation error occurs, the application might display the validation error message in the user interface instead of in the aggregated validation error messages.

Note: The end date of all selected evidence records is aggregated in one single transaction. Therefore, if the end dating of one evidence record fails, the whole transaction is rolled back and no evidence records are end dated.

2. If the end date evidence transaction is successful, all selected evidence records are end dated and the data is committed to the database.

Customizing the default implementation

You can customize the default implementation in the `curam.core.sl.infrastructure.impl.ListAutoEndDateEvidenceImpl.listEvidenceForAutoEndDating()` method. The method lists the evidences to be end dated that are displayed in the evidence record end dating page of the evidence wizard. To customize the method, create a custom implementation class that extends the `curam.core.sl.infrastructure.impl.ListAutoEndDateEvidenceImpl` default implementation class.

The custom class must never directly implement the interface class because compilation exceptions might occur during an upgrade if you add new methods to the interface. To ensure that the application executes the new custom class rather than the default implementation, you must use the standard Guice dependency injection mechanism to implement a new module class that extends the `com.google.inject.AbstractModule` module. You must insert the fully qualified module class name into the `MODULECLASSNAME` database table.

Enabling hook points

You can enable the hook points through the standard Guice dependency injection mechanism. Hook points are provided to the evidence end dating feature through the following interface methods:

- The `curam.core.sl.infrastructure.impl.AutoEndDateEvidenceHook.preAutoEndDateEvidence(curam.core.facade.infrastructure.struct.AutoEndDateEvidenceDetails)` interface method is invoked before the end dating of evidence records.
- The `curam.core.sl.infrastructure.impl.AutoEndDateEvidenceHook.postAutoEndDateEvidence(curam.core.facade.infrastructure.struct.AutoEndDateEvidenceDetails)` interface method is invoked after the end dating of all evidence records.

The hook points are invoked only through the end dating process that is triggered when a caseworker clicks **Finish** in the evidence wizard evidence end dating page.

Participant Evidence Integration

Overview

Evidence is the term used for data in the calculation of eligibility and entitlement. Participant data is also regarded as evidence, a concern's date of birth for example, but in the past it wasn't always treated as classic evidence. It is obviously correct for a concern's date of birth to be maintained within the Participant Manager rather than being stored on a separate evidence entity, i.e. one that is interfaced to the Evidence API, but it must also be propagated across all cases belonging to the concern and any changes in such evidence must trigger reassessment.

- A modification applied to Participant data will automatically apply to all cases using this data
- Modifying such data will trigger reassessment of all cases using this data

The following Core Participant entities have been integrated with Evidence:

- Address
- AlternateID
- AlternateName
- BankAccount
- Citizenship
- ConcernRole
- ConcernRoleRelationship
- Education
- Employer
- Employment
- EmploymentWorkHour
- Foreign Residency
- Person
- ProspectEmployer
- ProspectPerson

Integration of Participant Data as Evidence

Participant Evidence Integration is available out of the box but, like evidence, it requires a certain amount of configuration. If the configuration is not carried out, then all newly integrated Participant evidence will not integrate with the Evidence API. It will, however, continue to function as it always has. Once configured, the Participant evidence will be linked to one or more cases via an Evidence Descriptor. As in the case of classic evidence, the Evidence Descriptor can be associated with either an Integrated Case or a Product Delivery.

The required configuration links the Participant evidence types to the Integrated Case(s) or Product(s) that will use them. Such data is stored on the AdminICEvidenceLink and ProductEvidenceLink respectively. Participant data that will be stored at the Integrated Case level needs to be configured on the AdminICEvidenceLink entity whereas Participant evidence that will be used by a Product needs to be configured on the ProductEvidenceLink entity.

Administration

AdminICEvidenceLink

Every integrated case type that wants to integrate the available 15 entities as evidence will need to insert an entry into the AdminICEvidenceLink table. This table must link evidenceMetadataID (from

EvidenceMetadata table) and adminIntegratedCaseID (from AdminIntegratedCase table) for each participant entity required as evidence and for each integrated case type.

ProductEvidenceLink

Every product delivery case type that wants to integrate the available 15 entities as evidence will need to insert an entry into the ProductEvidenceLink table. This table must link evidenceMetadataID (from EvidenceMetadata table) and productID (from Product table) for each participant entity required as evidence and for each product type.

Integrating new Participant entities as Evidence

Integrating new, or existing, Participant entities with Evidence requires a number of steps. As mentioned above, meta-data needs to be configured for Integrated Case types and Product types. As well as this, other infrastructural support needs to be implemented by a developer in order for the integration to work.

Implementing the ParticipantEvidenceInterface

A Participant entity being integrated into the Evidence solution must implement the ParticipantEvidenceInterface. This means that the entity will need to implement the following functions:

- calcAttributionDatesForCase
- getDetailsForListDisplay
- getEndDate
- getStartDate
- insertEvidence
- insertEvidenceOnModify
- modifyEvidence
- readAllByParentID
- readEvidence
- selectForValidation
- validate
- checkForReassessment
- createSnapshot
- getChangedAttributeList
- readAllByConcernRoleID
- removeEvidence

Register entity in a Registrar Module

Participant entities being integrated to Evidence need to be registered via a Registrar Module as outlined in [“Evidence Registrar Module”](#) on page 23. The out of the box participant evidence types has been configured in CoreRegistrarModule. This binds the evidence type to it's entity. These map bindings are loaded at runtime and are used by the Evidence Controller when looking up the appropriate evidence entity for a given type, i.e. the entity that has implemented the ParticipantEvidenceInterface.

Applying Participant Evidence to all Cases

A new hook class ApplyChangesForEvidence has been added.

The new ApplyChangesForEvidence class represents a hook which can be overridden by custom code. The ApplyChangesForEvidence.isApplyChangesAutomatedForEvidence method is called from Evidence Controller to decide whether reassessment needs to be triggered when evidence is applied. The default implementation defaults to false and therefore the user will have to manually apply the changes on the associated cases. If the solutions wish to customize, the implementers should use ProductHookRegistrar.registerApplyChangesHooks method to add details of the hooks to use for applying

changes. The static map attribute, `applyChangesHookMap` present in `ProductHookManager` class is used to store pairs of product type and the name of the class that implements the hook for that product type. The method `ProductHookManager.getApplyChangesHook` gets the implementation subclass of the `ApplyChangesForEvidence` class for the specified product type. The method `EvidenceController.applyParticipantEvidence` has been updated to obtain product delivery and product details for the case and then call `ProductHookManager.getApplyChangesHook` to obtain correct instance of the `ApplyChangesForEvidence` class for the given product.

Modifications required to existing business processes

In all places where there are existing calls to insert, modify, and less frequently, remove methods, the code needs to be updated to invoke the `EvidenceController` as well as the insert, modify and remove methods as appropriate. An example of how an insert works with Evidence is shown:

Before

```
// insert new citizenship entry
citizenshipObj.insert(citizenshipDtls);
```

After

```
//
// Call the EvidenceController object and insert evidence
// Evidence descriptor details
EvidenceDescriptorInsertDtls evidenceDescriptorInsertDtls =
    new EvidenceDescriptorInsertDtls();
evidenceDescriptorInsertDtls.participantID =
    details.concernRoleID;
evidenceDescriptorInsertDtls.evidenceType =
    CASEEVIDENCE.CITIZENSHIP;
evidenceDescriptorInsertDtls.receivedDate =
    Date.getCurrentDate();

// Evidence Interface details
EIEvidenceInsertDtls eiEvidenceInsertDtls =
    new EIEvidenceInsertDtls();
eiEvidenceInsertDtls.descriptor.assign(
    evidenceDescriptorInsertDtls);
eiEvidenceInsertDtls.descriptor.participantID =
    citizenshipDtls.concernRoleID;
eiEvidenceInsertDtls.evidenceObject =
    citizenshipDtls;

// EvidenceController business object
curam.core.sl.infrastructure.impl.EvidenceControllerInterface
    evidenceControllerObj =
    (curam.core.sl.infrastructure.impl.EvidenceControllerInterface)
    curam.core.sl.infrastructure.fact.EvidenceControllerFactory
    .newInstance();

// Insert the evidence
EIEvidenceKey eiEvidenceKey =
    evidenceControllerObj.insertEvidence(eiEvidenceInsertDtls);
```

Sequence Diagrams for Participant evidence

The development, both client and server, of creating and modifying evidence operations are outlined here:

Create Participant Evidence Sequence Diagram

Specific Processing For Participant Data when Creating Evidence

Figure 6: Evidence Sequence Diagram

Modify Participant Evidence Sequence Diagram

Figure 7: Modify participant

Implementing Conditional Verifications

Conditional Verification

Conditional Verifications is a feature, wherein, the flexibility is provided to determine if verification is applicable for evidence through programmatic support as opposed to manually means. The programmatic

support is encompassed through rule-class implementations and verification for a piece of evidence is determined based on a set of conditions. The Verification Engine will check the conditions specified, at the time of adding or modifying evidence but will create an outstanding verification only when a condition that has been defined is met and not every time a verifiable data item is added or modified. The conditions can range from conditions against the value of the verifiable data item to more complex conditions where the values of a set of dependent evidences determine whether or not verification is required.

Rule Artifacts supplied by Verification framework

To facilitate integration between Verification framework and the rule implementations supplied by other components, the framework supplies core Rule Artifacts. These artifacts contain abstract rule classes that other components rule implementations must adhere to. This section identifies and details such low level Rule Artifacts which will be supplied as part of Verification framework.

Rule Sets

The rule set '*VerificationRuleSet*' is available as part of Verification framework. This rule set holds all the framework's artifacts such as the rule classes and the data container classes.

Rule Classes

The following rule classes are available as part of VerificationRuleSet. The purpose of these rule classes are explained in the corresponding sections.

- VerificationDeterminator
- VerificationDeterminatorResult
- VerificationDeterminatorParams

Verification Determinator

The business logic that determines whether conditional verification is required for particular evidence type goes in this rule class. Components creating rule implementations must adhere to the specification by directly/indirectly extending this class. The following attributes are available in this rule class.

S.No	Rule attribute name	Type	Purpose
1	<i>determine</i>	<u>"Verification Determinator Result" on page 40</u>	The implementation will contain the business logic that determines the output of conditional verification. A value of 'TRUE' indicates to the evidence framework that verifications are not applicable for the evidence, whereas 'FALSE' denotes that verifications need to be explicitly added.
2	<i>verificationDeterminatorParams</i>	<u>"Verification Determinator Params" on page 40</u>	This attribute is populated by the Conditional verifications framework and contains the values for all the input parameters for a particular instance.

Verification Determinator Result

This rule class is a data container whose purpose is to store the results of business logic in the “Verification Determinator” on page 39. Currently this class has two attributes,

result - a boolean that states whether verification is required or not for a given evidence

reason - a codetable value from VerificationSkippedReason, which contains the values of reason for which the conditional verification is not applicable

It is the responsibility of the rule implementations to create/populate these attribute so that the verification framework, after examining the state of the attribute, can take appropriate business decisions.

Verification Determinator Params

While determining whether conditional verification is required or not, the framework will supply various input parameters to the rule implementation classes for various calculation purposes such as the evidence that is getting currently edited, the associated case identifier for the evidence etc. Please refer the following table for complete details of the input parameters.

S.No	Property Name	Data Type	Description
1	<i>verifiableDataItemName</i>	String	Represents the name of the 'Verifiable Data Item' such as 'Person Income', 'Date Of Birth' etc. The value comes from the code table 'VerifiableItemName'
2	<i>evidenceDescriptorID</i>	Number	The unique identifier of the evidence record in question
3	<i>caseID</i>	Number	The unique identifier of the case with which the evidence is associated

New Propagator

Verifications are applicable to active evidences as well as to evidences which are in 'in-edit' state. A new propagator – **ActiveInEditEvidenceRowRuleObjectPropagator** is provided for this very purpose, which will propagate both these evidence type. It is recommended to use this new propagator to propagate the evidences to the rule data objects that are used in the conditional verification implementation classes.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to actual people or business enterprises is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Privacy Policy considerations

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

Depending upon the configurations deployed, this Software Offering may use session cookies or other similar technologies that collect each user's name, user name, password, and/or other personally identifiable information for purposes of session management, authentication, enhanced user usability, single sign-on configuration and/or other usage tracking and/or functional purposes. These cookies or other similar technologies cannot be disabled.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see IBM's Privacy Policy at <http://www.ibm.com/privacy> and IBM's Online Privacy Statement at <http://www.ibm.com/privacy/details> the section entitled "Cookies, Web Beacons and Other Technologies" and the "IBM Software Products and Software-as-a-Service Privacy Statement" at <http://www.ibm.com/software/info/product-privacy>.

Trademarks

IBM, the IBM logo, and [ibm.com](http://www.ibm.com) are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at "Copyright and trademark information" at <http://www.ibm.com/legal/copytrade.shtml>.

Adobe, the Adobe logo, PostScript, and the PostScript logo are either registered trademarks or trademarks of Adobe Systems Incorporated in the United States, and/or other countries.

Java™ and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Other names may be trademarks of their respective owners. Other company, product, and service names may be trademarks or service marks of others.
