</component>
```

**Note:** In Liberty, a user can add the following element to the server.xml configuration file, and the properties will be injected into the HelloComponent class.

```
<HelloService firstKey="firstValue" secondKey="secondValue" />
```

4. Package the XML file into the bundle.

For example, the XML file is at the location OSGI-INF/HelloService.xml, and you add a header to the bundle manifest MANIFEST.MF file so that DS can locate the file:

Service-Component: OSGI-INF/HelloService.xml

If multiple components are packaged in the same bundle, the corresponding XML files must be entered as a comma-separated list. For example:

Service-Component: OSGI-INF/HelloService.xml, OSGI-INF/GoodbyeService

5. The Java implementation of the HelloService component is as follows:

```
package com.example.bundle;

import com.example;
import org.osgi.service.component.ComponentContext;

/**
 * This class must be public and have a public default constructor for it to be
 * usable by DS. This class is not required to be exported from the bundle.
 */
public class HelloComponent implements HelloService {
    /**
     * Optional: DS method to activate this component. If this method exists, it
     * will be invoked when the component is activated. Best practice: this
     * should be a protected method, not public or private
     *
     * @param properties
     *       : Map containing service & config properties
     *       populated/provided by config admin
     */
    protected void activate(ComponentContext cContext,
        Map<String, Object> properties) {
        modified(properties);
    }

    /**
     * Optional: DS method to deactivate this component. If this method exists,
     * it will be invoked when the component is deactivated. Best practice: this
     * should be a protected method, not public or private
     *
     * @param reason
     *       int representation of reason the component is stopping
     */
    protected void deactivate(ComponentContext cContext, int reason) {
    }

    /**
     * Optional: DS method to modify the configuration properties. This may be
     * called by multiple threads: configuration admin updates may be processed
     * asynchronously. This is called by the activate method, and otherwise when
     * the configuration properties are modified while the component is
     * activated.
     *
     * @param properties
     */
    public synchronized void modified(Map<String, Object> properties) {
        // process configuration properties here
    }

    /**
     * Service method defined by com.example>HelloService interface
     */
    public void sayHello() {
        System.out.println("Hello");
    }
}
```

## Enabling a service to receive configuration data

8.5.5.0

To enable a service to receive configuration data, you associate the service with a persisted identity, and code the service to receive the data. You can also provide descriptions and default values for this data, and make the labels and descriptions available in several languages.

### About this task

To enable a service to receive configuration data, there are a number of steps involved. Only associating the service with a configuration Admin persisted identity and coding the service to receive configuration properties are mandatory, and might be considered sufficient for embedded scenarios. The remaining steps improve the configuration experience for users.

The steps involved in enabling a service to receive configuration data are described in the following subtopics:

### Procedure

1. Associate the service with a Configuration Admin PID (persisted identity).
2. Code the service to receive the configuration properties during activation and when the configuration is modified.
3. Provide descriptions and default values for configuration metadata.
4. Provide translated strings for configuration property labels and descriptions.

### Associating a service with a persisted identity: 8.5.5.0

You associate a set of configuration properties with its consuming component as described in the OSGi Configuration Admin specification by using the the persisted identity (PID).

### About this task

The OSGi Configuration Admin specification provides a number of association mechanisms, of which the following are most commonly used in Liberty:

#### Register an implementation of `org.osgi.service.cm.ManagedService` or `org.osgi.service.cm.ManagedServiceFactory` directly with the OSGi Configuration Admin service (CA)

This is most commonly used in low-level kernel bundles, where service management through OSGi Declarative Services (DS) or Blueprint is not available at bundle start time. The registration specifies the PID that identifies the configuration set to be received.

#### Define a service to DS

This is the most common way for services in feature bundles to receive their configuration. The service name is used as the PID to associate configuration data. DS receives the configuration set from CA and passes it on to the defined service.

### Example

A service might be declared by using the following entry in the project \*.bnd file:

```
Service-Component: com.ibm.ws.transaction; \  
  provide:='com.ibm.tx.config.ConfigurationProvider'; \  
  immediate:='true'; \  
  modified:='modified'; \  
  implementation:=com.ibm.ws.transaction.services.JTMConfigurationProvider
```

This generates the following XML code, which can also be coded by the developer instead of using the **bnd** Service-Component entry:

```
<component name="com.ibm.ws.transaction" xmlns="http://www.osgi.org/xmlns/scr/v1.1.0"
    immediate="true" modified="modified">
    <implementation class="com.ibm.ws.transaction.services.JTMConfigurationProvider" />
    <service>
        <provide interface="com.ibm.tx.config.ConfigurationProvider" />
    </service>
    <property name="service.vendor" value="IBM" />
</component>
```

The component name, `com.ibm.ws.transaction` in this example, is used as the PID for the association of configuration data. If this component does not provide any metadata to describe its configuration, you can specify configuration properties for the component by using that PID in the `server.xml` file, or an included file, by defining an entry of the following form:

```
<com.ibm.ws.transaction made.up.property.key="47">
```

### What to do next

Code the service to receive the configuration properties during activation and when the configuration is modified.

### Coding the service to receive configuration properties: **8.5.5.0**

Configuration properties are available through the `org.osgi.service.component.ComponentContext` object that is provided on the activation method.

### Before you begin

You must complete the task described in “Associating a service with a persisted identity” on page 1796.

### About this task

If properties are updated after activation has occurred, the method used for injection depends on the context that the service provides in its OSGi Declarative Services (DS) declaration.

Generally, it is best to declare a method that is to be used specifically for injection of updated properties by using the **modified** attribute on the service declaration. If a modified method is not available, DS deactivates and then reactivates the service with the new properties.

Deactivating and then activating a service can also cause dependent services to be recycled, and should be avoided unless specifically required. Using the **modified** attribute is the preferred way to receive configuration updates.

### Example

In the previous task, “Associating a service with a persisted identity” on page 1796, you defined a service to DS. The following are examples of activate and modified methods from the DS declaration described in that task.

```
private static Dictionary<String, Object> _props = null;

protected void activate(ComponentContext cc) {
    _props = cc.getProperties();
}

protected void modified(Map<?, ?> newProperties) {
```

```

    if (newProperties instanceof Dictionary) {
        _props = (Dictionary<String, Object>) newProperties;
    } else {
        _props = new Hashtable(newProperties);
    }
}

```

When you get values from the configuration properties, use the following mechanisms to allow some flexibility:

- Code the methods to expect at least the default properties that are included in the same bundle, but to make allowances for user overrides, so that migration of user configuration is not necessary.
- Ignore redundant or unrecognized properties.

The service must be able to operate on the default configuration alone. To provide a reasonable level of function, user overrides must not be mandatory.

### What to do next

Provide descriptions and default values for configuration metadata

## Advanced Configuration

8.5.5.0

Advanced configuration includes information about providing descriptions and the default values for configuration and OSGi Metatype Service Extensions.

The configuration properties for each service can be described in metadata that complies with the OSGi Metatype Service specification. The resulting XML file is packaged into the bundle in the OSGI-INF/metatype directory, in accordance with the specification. For more information, see Providing Descriptions and default values for configuration.

The Liberty runtime and developer tools recognize some extensions to the OSGi Metatype specification for more complex configurations and a better presentation in a user interface. For more information, see OSGi Metatype Service Extensions.

### Describing configuration by using the OSGi Metatype service

8.5.5.0

The configuration properties for each service can be described in metadata that complies with the OSGi Metatype Service specification. The metadata can include default values, translatable names and descriptions, and information to allow validation of input values. The resulting XML file is packaged into the bundle that contains your service, in the OSGI-INF/metatype directory, in accordance with the specification.

### About this task

Providing metadata to describe your configuration is optional, but it does provide the following benefits:

- default values can be separated from the implementation code into the metatype XML file where they are easy to locate;
- appropriate data types and other validation data can be specified for each attribute, allowing validation by the configuration parser and developer tools, and simplifying the code you write to process the attributes;
- your configuration will be included in the XML schema that describes the available configuration to the developer tools and other utilities;

- translatable names and descriptions can be provided for each attribute, and will be displayed in the developer tools.

## Procedure

1. Create an xml file in the OSGI-INF/metatype directory of your bundle and add a namespace declaration for the OSGi Metatype namespaces:

```
<metatype:MetaData xmlns:metatype="http://www.osgi.org/xmlns/metatype/v1.1.0">
</metatype:MetaData>
```

2. Add an object class definition (OCD) element to contain the set of attributes, with an identifier and, optionally, a name and description. Also provide a Designate element to map the OCD to the PID used in your code and the server.xml file.

```
<OCD name="b2c" description="bundle two config" id="b2c-id">
</OCD>
```

```
<Designate pid="testBundleTwo">
<Object ocdref="b2c-id" />
</Designate>
```

3. Add attribute definition (AD) elements for each configuration property, within the OCD. Each attribute needs an identifier which is also used in the server.xml file and in the code that receives the injected configuration. It can optionally have a name and description which can be used by the developer tools and other graphical tools. Specifying a data type allows the runtime environment to validate the input for that type and simplifies your processing code. Specifying a useful default value allows the user-supplied configuration to be minimal, and contains all your configuration defaults in a known location:

```
<AD name="boolProperty" description="a boolean property" id="boolProp"
type="Boolean" default="false" />
```

4. Then you have the following metatype.xml file.

```
<?xml version="1.0" encoding="UTF-8"?>
<metatype:MetaData xmlns:metatype="http://www.osgi.org/xmlns/metatype/v1.1.0" >
```

```
<OCD name="b2c" description="bundle two config" id="testBundleTwo-2-id">
<AD name="textProperty" description="a text property"
id="textProp" type="String" default="default string" />
<AD name="boolProperty" description="a boolean property"
id="boolProp" type="Boolean" default="false" />
<AD name="intProperty" description="an integer property"
id="intProp" type="Integer" default="14" />
</OCD>
```

```
<Designate pid="testBundleTwo-2">
<Object ocdref="testBundleTwo-2-id" />
</Designate>
```

```
</metatype:MetaData>
```

5. Code your service to receive the configuration properties. Without the metatype description, all your properties will be provided as String values and will be processed as follows:

```
String textProp = (String) properties.get("textProp");
Boolean boolProp = Boolean.parseBoolean((String) properties.get("boolProp"));
int intProp = Integer.parseInt((String) properties.get("intProp"));
```

```
String textProp = (String) properties.get("textProp");
Boolean boolProp = (Boolean) properties.get("boolProp");
int intProp = (Integer) properties.get("intProp");
```

And the runtime environment will already have validated that the input values are of the correct types.

## What to do next

Provide translated strings for configuration property labels and descriptions.

## Single versus multiple configuration instances

8.5.5.0

You can also configure multiple configuration instances by using the OSGi metatype services.

As described in the “Describing configuration by using the OSGi Metatype service” on page 1798, you can use OSGi metatype service to support a single set of configuration properties for a given service (as identified by a configuration PID). It is also common to support multiple instances of the same configuration type, for example in the way that the Liberty profile supports multiple entries for applications and data sources. This can be done by providing a metatype definition that tells the Liberty configuration parser, and the Configuration Admin service, that it is dealing with a factory configuration. Also, the class that receives the configuration needs to implement the `org.osgi.service.cm.ManagedServiceFactory` interface.

To support multiple instances of top-level configuration elements in the `server.xml` file as follows:

```
<server>
  <teenager name="joy" age="15" />
  <teenager name="angela" age="18" />
</server>
```

You must define the configuration in metadata by adding a **factoryPid** attribute to the Designate element.

**Note:** A **pid** attribute is still needed if you use a `ManagedServiceFactory` interface to receive the configuration; if you use a declarative service (DS) component, this is not required.

```
<?xml version="1.0" encoding="UTF-8"?>
<metatype:MetaData xmlns:metatype="http://www.osgi.org/xmlns/metatype/v1.1.0"
  xmlns:ibm="http://www.ibm.com/xmlns/appservers/osgi/metatype/v1.0.0">

  <OCD id="teenager-ocd" name="teenager" >
    <AD id="name" name="name" type="String" />
    <AD id="age" name="age" type="Integer" />
  </OCD>

  <Designate factoryPid="teenager" pid="teenager">
    <Object ocdref="teenager-ocd" />
  </Designate>

</metatype:MetaData>
```

The `ManagedServiceFactory` implementation is registered as a `ManagedServiceFactory` service type, with the factory pid as follows:

```
bundleContext.registerService(ManagedServiceFactory.class, new MgdSvcFactoryImpl(), new Hashtable());
defaults.put(org.osgi.framework.Constants.SERVICE_PID, "teenager");
```

The `ManagedServiceFactory` implementation receives a set of properties for each instance of the *teenager* configuration, each one uniquely identified by its own (internally generated) PID which is provided to the `updated()` method as follows:

```
public void updated(String pid, Dictionary<String, ?> properties)
  throws ConfigurationException {
  String name = (String) properties.get("name");
  Integer age = (Integer) properties.get("age");
}
```

If a particular configuration instance is deleted, for example because one of the *teenager* elements is deleted from the `server.xml` file, the `ManagedServiceFactory` implementation is notified through the `deleted()` method, and the pid of the deleted instance is provided. This allows the `ManagedServiceFactory` implementation to keep track of the instances that are valid at any given time.

### Providing default instances of factory configurations: **8.5.5.0**

You can create default instances of your factory configuration when using the OSGi metatype services. One of the design principles of Liberty is to keep user configuration as small and simple as possible. By providing default instances of your factory configurations, you don't have to add these configurations into the `server.xml` file.

#### Example

To provide a default configuration instance, you need to include it in an XML file within your OSGi bundle, and reference the file by using the `IBM-Default-Config` header in the bundle manifest file as follows:

```
IBM-Default-Config: OSGI-INF/wlp/defaultInstances.xml
```

The format of the XML file is the same as that of the `server.xml` file, but you must specify a unique identifier for each instance. For example, to provide a default instance of the *teenager* configuration that is used in the example on the “Single versus multiple configuration instances” on page 1800 topic, the `defaultInstances.xml` file must have the following settings:

```
<server>
  <teenager id="predefined-teen1" name="Susie" age="19" />
</server>
```

The default instance is not exposed to users through the configuration schema, and therefore it is not visible in the development tools; however, you can document the instance so that your users can override the individual attributes in their `server.xml` files as follows:

```
<teenager id="predefined-teen1" age="13" />
```

This line of code will override the **age** attribute of the default instance, but the **name** attribute remains valid.

## Extensions to the OSGi metatype service

**8.5.5.0**

The Liberty runtime environment and developer tools recognize some extensions to the OSGi metatype specification for more complex configurations and a better presentation in a user interface.

### Runtime metatype extensions

Add this namespace to your `metatype.xml` file to use the following extensions:

```
xmlns:ibm="http://www.ibm.com/xmlns/appservers/osgi/metatype/v1.0.0"
```

#### **ibm:alias**

The alias extension is used to define a user-friendly name for the configuration while reducing the risk of clashes in the names of configuration elements in the `server.xml` file.

The following example shows the `ibm:alias` extension:

```

<OCD id="com.ibm.ws.jdbc.dataSource.properties"
  name="%properties"
  description="%properties.desc"
  ibm:alias="properties">
  <AD id="username".../>
</OCD>

```

In this example `properties` is the user-friendly name for the configuration. The alias must be different from the id.

When the `ibm:alias` entry is used in the `server.xml` file, it must be prefixed with the product extension name. The product extension name for extensions that are installed in the default user location is `usr`. For product extensions defined to the Liberty installation by using an `extension-name.properties` file in the `wlp/etc/extension` directory, the product extension name is the name that is chosen for `extension-name`.

For the metatype shown in the previous example, if the feature is installed in the default `usr` location then the following are examples of valid `server.xml` entries:

```

<usr_properties username="JANE"/>
<com.ibm.ws.jdbc.dataSource.properties username="JANE"/>

```

### **ibm:type**

Standard attribute types are defined in the metatype specification. Several IBM extended types are available. For more information, see “Extended types” on page 1803.

### **ibm:reference**

The reference attribute specifies the OCD type that a PID references. It is used only with the `ibm:pid` type and supports nesting of elements in the `server.xml` file; see “Nesting configuration elements” on page 1806.

The following example shows the `ibm:reference` extension: `<AD id="fooRef" type="String" ibm:type="pid" ibm:reference="com.ibm.ws.foo".../>`

### **ibm:final**

The final attribute indicates that the value cannot be specified in the config. Instead, the default value from the metatype is always used. Use `name="internal"` to indicate that tools not display this property.

The following example shows the `ibm:final` extension: `<AD id="foo" name="internal" ibm:final="true" type="String" default=${someVariable}"/>`

### **ibm:variable**

The variable attribute is used to specify a variable to be used for the default value if one is not specified. The behavior is to choose, in order:

- The value that is specified in `server.xml`
- The value that is specified as a system property, for example in `bootstrap.properties`
- The default value from the metatype

The following example shows `ibm:variable`: `<AD id="traceString" ibm:variable="trace.string" default=*.all=enabled".../>`

### **ibm:unique**

The unique attribute indicates that a configuration value must be unique across all attribute definitions that use the same unique attribute group. The following unique attribute groups are supported:

-

`jndiName`: use this group on attributes that register a service by using the `osgi.jndi.service.name` property with the JNDI name. For more information, see “Developing with the JNDI default namespace in a Liberty feature” on page 1819

### default value syntax

You can use `${prop-name}` syntax in default expressions to construct strings out of other configuration properties.

The following example shows a default value syntax:

```
<AD id="httpEndpoint.target"
  name="internal" description="internal use only"
  ibm:final="true" required="false" type="String"
  default="(&virtualHost=${id}) (enabled=true)"/>
```

## Extended types

### Duration

The duration type is used to express a time. It is described in multiple units of time. For example, "1h30m" would be an hour and a half. "1d5h10s" would be 1 day, 5 hours, and 10 seconds. The units are globalized, so users enter the values by using abbreviations from their local language.

For English, the following list shows the available units:

- d - Days
- h - Hours
- m - Minutes
- s - Seconds
- ms - Milliseconds

By default, when using the type duration, the value that is specified by the user is evaluated in milliseconds. For example, "10s" would be a long value of 10000 in the dictionary. Furthermore, if a user specifies a value without any unit, this value will be evaluated in milliseconds. For example, a value of "10" would be evaluated as 10 milliseconds. However, you can also specify the duration type such that it evaluates into a different unit. For example, specifying a value of "10" with `ibm:type="duration(s)"` will be evaluated as 10 seconds, and stored as 10 in the dictionary.

The following list shows the possible types:

- duration(h)
- duration(m)
- duration(s)
- duration(ms)
- duration

There is no difference between specifying duration and duration(ms).

#### Note:

Best practice: Always include a unit in the value, and express the value with the unit that is easiest to read. For example, instead of specifying a value of "7200" with `ibm:type="duration(s)"`, specify the value as "2h".

The following examples show the duration type:

- `<AD id="timeout" type="String" ibm:type="duration(s)".../>`
- `<AD id="timeout" type="String" ibm:type="duration".../>`

### Location

The location type allows UI tools to provide a more helpful presentation of attributes that represent various file and directory locations. It does not affect processing by the runtime environment. The dictionary object is always a String.

The following examples show the possible types:

**location**

References a file. The reference can be an absolute, relative file, or it can be a url to a file.

**location(file)**

References a file by using an absolute or relative file path.

**location(dir)**

References a dir by using an absolute or relative file path.

**location(url)**

References a file at the end of a url.

The following example shows the location type:  
`<AD id="location" name="%appmgr.location.name" description="%appmgr.location.desc" type="String" required="true" ibm:type="location"/>`

**Password**

The password type is used for password fields. When used, the dictionary object is an instance of `com.ibm.wsspi.kernel.service.utils.SerializableProtectedString`. The value of the password field is not logged in the trace file. Developer tools displays the encoding options that can be used for a password field. Valid encoding options are xor and aes.

The following example shows the password type:  
`<AD id="password" type="String" ibm:type="password" .../>`

**Hashed password**

The passwordHash type is similar to the password type and is used for hashed password fields. When used, the dictionary object is an instance of `com.ibm.wsspi.kernel.service.utils.SerializableProtectedString`. The value of the hashed password field is not logged in the trace file. Developer tools displays the encoding options that can be used for a hashed password field. Valid encoding options are xor, aes, and hash.

Validate a new password against a hashed password by using the `PasswordUtil.encode(String, String, Map)` method, with the following parameters:

1. New password.
2. Hash algorithm, which is obtained by calling the `PasswordUtil.getCryptoAlgorithm` method. The hash algorithm must match the algorithm of the hashed password.
3. Properties object, where one of the properties uses `PasswordUtil.PROPERTY_HASH_ENCODED` for the key and the hashed password for the value.

If the return value of `PasswordUtil.encode` is the same as the hashed password, then the passwords match.

The following example shows the passwordHash type:  
`<AD id="hashedPassword" type="String" ibm:type="passwordHash" .../>`

**Pid**

The pid type is used to reference another object in the config. It is used with the `ibm:reference` attribute and supports nesting of elements in the `server.xml`; see “Nesting configuration elements” on page 1806.

The following example shows the pid type:  
`<AD id="fooRef" type="String" ibm:type="pid" ibm:reference="com.ibm.ws.foo" .../>`

## OnError

The onError type results in an instance of the onError enumeration in the dictionary. The possible values are WARN, FAIL, and IGNORE.

The following example shows the onError type:<AD id="errorBehavior" type="String" ibm:type="onError".../>

## User interface metatype extensions

Add this namespace to your metatype.xml file to use the following extensions:

```
xmlns:ibmui="http://www.ibm.com/xmlns/appservers/osgi/metatype/ui/v1.0.0"
```

### ibmui:localization

The localization extension is used to specify the metatype localization file. The metatype localization file is used to look up the translations for labels and descriptions of other UI extensions. In most cases, the value of the ibmui:localization extension matches the localization attribute on the <Metadata> element.

The following example shows the ibmui:localization extension:

```
<OCD id="com.ibm.ws.jdbc.dataSource.properties"
  name="%properties"
  description="%properties.desc"
  ibmui:localization="OSGI-INF/110n/metatype">
  <AD id="username".../>
</OCD>
```

### ibmui:extraProperties

The extraProperties extension is used to indicate that an arbitrary set of configuration attributes can be set on this configuration.

The following example shows the ibmui:extraproperties extension:

```
<OCD id="com.ibm.ws.jdbc.dataSource.properties"
  name="%properties"
  description="%properties.desc"
  ibmui:extraProperties="true">
  <AD id="username".../>
</OCD>
```

The label and description that is associated with extension is looked up in the metatype localization file (if one is specified by using the ibmui:localization extension). For the extension label, first extraProperties.<ocd id>.name and then extraProperties.name keys are checked. For the extension description, first extraProperties.<ocd id>.description and then extraProperties.description keys are checked.

### ibmui:group

The group extension is used to specify that the attribute belongs to a group. In the user interface, the attributes that are annotated with the same group are grouped.

The following examples show the ibmui:group extension:

- <AD id="username" ibmui:group="userInfo".../>
- <AD id="password" ibmui:group="userInfo".../>
- <AD id="port" ibmui:group="hostInfo".../>

The group label and description information are looked up in the metatype localization file (if one is specified by using the ibmui:localization extension). For the group label, first <group>.<ocd id>.name and then <group>.name keys are checked. For the group description, first <group>.<ocd id>.description and then <group>.description keys are checked.

## Nesting configuration elements:

You can use metatype extensions to define configuration that can be expressed as nested XML elements in the `server.xml` file.

### Examples

The following example shows how to support this user configuration in the `server.xml` file:

```
<family mother="jane" father="john">
  <child name="susie" age="8" />
  <child name="danny" age="5" />
</family>
```

The metatype XML uses `ibm:type="pid"` and `ibm:reference` as shown in following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<metatype:MetaData
  xmlns:metatype="http://www.osgi.org/xmlns/metatype/v1.1.0"
  xmlns:ibm="http://www.ibm.com/xmlns/appservers/osgi/metatype/v1.0.0">

  <OCD id="family" name="family">
    <AD id="mother" name="mother" type="String" default="Ma" />
    <AD id="father" name="father" type="String" default="Pa" />
    <AD id="child" name="child" ibm:type="pid" ibm:reference="child-pid"
      required="false" type="String" cardinality="6" />
  </OCD>

  <Designate pid="family">
    <Object ocdref="family" />
  </Designate>

  <OCD id="child" name="child" >
    <AD id="name" name="name" type="String" />
    <AD id="age" name="age" type="Integer" />
  </OCD>

  <Designate factoryPid="child-pid">
    <Object ocdref="child" />
  </Designate>

</metatype:MetaData>
```

The following example show how the code that receives the family properties uses the `ConfigurationAdmin` service to obtain the child property sets:

```
public void updated(Dictionary<String, ?> properties)
  throws ConfigurationException {

  Set<String> pids = new HashSet<String>();
  String mother = "null";
  String father = "null";

  try {
    if (properties != null) {
      mother = (String) properties.get("mother");
      father = (String) properties.get("father");
      String[] children = (String[]) properties.get("child");
      if (children == null || children.length == 0) {
        return;
      }

      // Get the configuration admin service
      ConfigurationAdmin configAdmin = null;
    }
  }
}
```

```

ServiceReference configurationAdminReference =
    bundleContext.getServiceReference(ConfigurationAdmin.class.getName());

if (configurationAdminReference != null) {
    configAdmin = (ConfigurationAdmin)
        bundleContext.getService(configurationAdminReference);
}

for (String childPid : children) {
    pids.add(childPid);
    Configuration config = configAdmin.getConfiguration(childPid);
    String name = (String) config.getProperties().get("name");
    Integer age = (Integer) config.getProperties().get("age");
}
}
}

catch (Exception e) {
    e.printStackTrace();
}
}

```

## Localizing the configuration metadata

### 8.5.5.0

The name and description attributes of each metadata entry can be localized, and the translated strings packaged into language-specific properties files.

### Example

The following example shows how the location of the localized files is specified in the header of the metatype file:

```

<metatype:MetaData xmlns:metatype="http://www.osgi.org/xmlns/metatype/v1.1.0"
    localization="OSGI-INF/I10n/metatype">

```

where OSGI-INF/I10n is the location of the translated properties files in the bundle, and metatype is the prefix of the default language properties file. For example, if the default values, usually in English, are in a file called metatype.properties, then each locale is added with its own suffix: metatype\_fr.properties, metatype\_es.properties and so on.

Unlike the metatype XML file, which must always be in the OSGI-INF/metatype directory, the translated files can be in any location that is within the bundle and specified by the **localization** attribute. It is better to not put the properties files in the OSGI-INF/metatype directory alongside the metatype XML file; the Metatype service attempts to parse anything in that location as an XML file, and although that does not cause a failure, it generates unwanted exceptions in the console. The Liberty convention is to put them in the OSGI-INF/I10n directory, but that is not mandatory.

In the metatype XML file, to show that a value is a localized string you use a percent sign at the start of the value. For example, you might use the following definition in the metatype XML file:

```

<AD name="%client.inactivity.timeout" description="%client.inactivity.timeout.desc"
    id="clientInactivityTimeout" required="false" type="Integer" default="60" />

```

and you might use the following definition in the properties file:

```

client.inactivity.timeout=Client inactivity timeout
client.inactivity.timeout.desc=The maximum duration, in seconds, between transactional requests
from a remote client. Any period of client inactivity that exceeds this timeout results in the
transaction being rolled back in this application server.

```

## Providing an application endpoint

You can make a Liberty feature available as web applications by including one or more web application bundles (WABs) in the feature. A WAB is an OSGi bundle with a Web-ContextPath manifest header.

### Procedure

To enable WABs in your feature's bundles, add the `com.ibm.wsspi.appserver.webBundle-1.0` feature to the Subsystem-Content: header in the `.mf` file of your feature:

```
Subsystem-Content:  
my.user.feature.bundle; version="[1,1.0.100)",  
com.ibm.wsspi.appserver.webBundle-1.0; type="osgi.subsystem.feature"
```

## Securing an application endpoint

0.5.5.0

You can secure your feature's application endpoint by performing the following steps:

### Procedure

1. In the `.mf` file of your feature, add the `com.ibm.wsspi.appserver.webBundleSecurity-1.0` feature to the Subsystem-Content: header. This addition causes any protected servlets (as specified in your feature bundle's `WEB-INF/web.xml` file) to be authenticated, and enables role base authorization. You can also assign users, groups, and special subjects to any roles that are defined in the `WEB-INF/web.xml` file.

```
Subsystem-Content:  
my.user.feature.bundle; version="[1,1.0.100)",  
com.ibm.wsspi.appserver.webBundleSecurity-1.0; type="osgi.subsystem.feature"
```

2. To map roles to users, groups, and special subjects, do the following steps:
  - a. Add the `IBM-Authorization-Roles` header to your OSGi bundle's `MANIFEST.MF` file. The header must specify a name which is the id of a role mapping you specify in the `server.xml` file.  
`IBM-Authorization-Roles: my.feature.role.map`
  - b. In the `server.xml` file, add an `authorization-roles` element to map the role names to users and groups. The `id` attribute of the `authorization-roles` element must have the same value as the `IBM-Authorization-Roles` header in the `MANIFEST.MF` file. Add a `<security-role>` subelement for each role that you want to assign user and groups to.

```
<authorization-roles id="my.feature.role.map">  
  <security-role name="employee">  
    <special-subject type="ALL_AUTHENTICATED_USERS"/>  
  </security-role>  
  <security-role name="manager">  
    <user name="bob"/>  
    <user name="mary"/>  
    <group name="managers"/>  
  </security-role>  
</authorization-roles>
```

## Liberty SPI utilities

Liberty provides service programming interfaces (SPI) to complete various tasks.

### Resource location symbols

0.5.5.0

Liberty user configuration is made more portable through the use of variables that represent symbolic locations. Use of these variables helps to prevent the coding of absolute paths that would make the user configuration brittle and less portable. Feature code that receives configuration properties might have to deal with values that contain such variables.

The location service of Liberty can be used to resolve symbolic locations to physical resources. For example, the symbolic location `${wlp.install.dir}/myFile` can be mapped to the local file `myFile` in the installation directory of Liberty. Most methods return a `WsResource` object that wraps the physical resource, but you can also use the `resolveString` method to transform the symbolic location into a `String` that can be used to obtain a `File` object.

The name of the location service is `com.ibm.wsspi.kernel.service.location.WsLocationAdmin` and it is provided by the Liberty kernel, so you do not have to specify a feature in your `server.xml` file to make it available. **8.5.5.0** The Java API documentation for each Liberty SPI is available in a separate `.zip` file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

## Symbols

The `com.ibm.wsspi.kernel.service.location.WsLocationConstants` class defines symbols that refer to directory locations:

- `/`
- `server.config.dir`
- `server.output.dir`
- `server.workarea.dir`
- `shared.app.dir`
- `shared.config.dir`
- `shared.resource.dir`
- `wlp.install.dir`
- `wlp.server.name`
- `wlp.user.dir`
- `usr.extension.dir`

For the meaning of each symbol, see “Liberty:Directory locations and properties” on page 1434.

## Monitoring local files for changes

**8.5.5.0**

Liberty has highly dynamic behavior, responding to changes in configuration, applications and other resources. Much of this dynamic behavior is based on monitoring of the local file system for changes. The service that performs this monitoring is available to all Liberty features through the `FileMonitor` SPI. The file monitor service is provided by the Liberty kernel, so you do not have to specify a feature in your `server.xml` file to make it available.

### About this task

The `FileMonitor` SPI provides different properties to specify what resources are monitored and with what frequency. You have to implement the `FileMonitor` interface and register the implementation class into the service registry.

**8.5.5.0** The Java API documentation for each Liberty SPI is available in a separate `.zip` file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

### Example

```
...
import com.ibm.wsspi.kernel.filemonitor.FileMonitor;
...

public class MyFileMonitor implements FileMonitor {
```

```

...
private final BundleContext bundleContext;
...
public MyFileMonitor(BundleContext bundleContext) {
    this.bundleContext = BundleContext;
    ...
}

public ServiceRegistration<FileMonitor> monitorFiles(Collection<String> paths, long monitorInterval) {
    ...
    final Hashtable<String, Object> fileMonitorProps = new Hashtable<String, Object>();
    fileMonitorProps.put(FileMonitor.MONITOR_FILES, paths);
    fileMonitorProps.put(FileMonitor.MONITOR_INTERVAL, monitorInterval);
    ...
    return bundleContext.registerService(FileMonitor.class, this, fileMonitorProps);
}
...
}

```

## Configuring tracing and logging for features in the Liberty profile

**8.5.5.0**

You can use the tracing and logging mechanism of the Liberty profile for Liberty features. The logging service is part of the Liberty kernel so you do not have to specify a feature in your `server.xml` file to use it.

### About this task

Liberty provides the following SPIs for integrating tracing and logging in your customized feature code:

#### **com.ibm.websphere.ras**

The `com.ibm.websphere.ras` package provides classes to log messages and trace records, as well as some extension points. In general, feature code can use the `java.util.logging` package to log trace and messages, and to control the output through Liberty logging configuration, but the extended capability of the WebSphere package is sometimes useful and the trace guards are slightly more efficient when trace is disabled.

#### **com.ibm.websphere.ras.annotations**

The `com.ibm.websphere.ras.annotations` package provides annotations for use with classes in the other packages. For example, an `@Sensitive` annotation can be used to prevent the contents of the annotated variable from appearing in trace or message output.

#### **com.ibm.ws.ffdc**

The `com.ibm.ws.ffdc` package provides facilities to write first failure data capture (FFDC) records to assist in debugging unexpected exceptions.

#### **com.ibm.wsspi.logging**

The `com.ibm.wsspi.logging` package provides interception points of log and ffdc records.

**8.5.5.0**

The Java API documentation for each Liberty SPI is available in a separate `.zip` file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

### Procedure

The following steps show you how to configure an example Liberty feature, called `myfeature`, to use the tracing and logging mechanism of Liberty:

1. Specify the location of the message file for the feature `myfeature`, and the name of the group that is required by the `com.ibm.websphere.ras.TraceComponent` class.

```

import java.util.ResourceBundle;

public class myFeatureConstants {

```

```

public static final String TR_RESOURCE_BUNDLE =
    "com.mycompany.myFeature.internal.resources.FeatureMessages";

public static final String TR_GROUP = "myFeature";

public static final ResourceBundle messages = ResourceBundle.getBundle(TR_RESOURCE_BUNDLE);
}

```

2. In the implementation class of the feature service code, call the register() method of the com.ibm.websphere.ras.TraceComponent class to register the implementation class with the trace manager that is provided by Liberty. Then, you can configure the trace manger to track the DS methods of the feature.

```

...
import com.ibm.websphere.ras.Tr;
import com.ibm.websphere.ras.TraceComponent;

public class myFeatureServiceImpl {

    private static final TraceComponent tc = Tr.register(myFeatureServiceImpl.class);

    protected void activate(ComponentContext cc, Map<String, Object> newProps) {
        if (tc.isDebugEnabled()) {
            Tr.debug(tc, "myFeatureComponentImpl activated"); }
        ...
    }
}

```

3. Use the TraceOptions annotation to specify the trace group name and the message bundle name.

```

@TraceOptions(traceGroup = myFeatureConstants.TR_GROUP, messageBundle =
    myFeatureConstants.TR_RESOURCE_BUNDLE)
package com.mycompany.myFeature;

import com.ibm.websphere.ras.annotation.TraceOptions;
import com.mycompany.myfeature.internal.myFeatureConstants;
...

```

### Generating first failure data capture (FFDC) records: **8.5.5.0**

FFDC records include the exception stack and optional additional data that is recorded when an unexpected exception is caught by your code. Methods on the com.ibm.ws.ffdc.FFDCFilter class are used to generate these records, and there are a number of methods that might cause a variety of data to be captured.

#### Example

A typical use of the FFDCFilter class is as follows:

```

try{
    // ... do something
} catch (Exception e) {
    FFDCFilter.processException(e, getClass().getName(), unique-probe-id);
    if (TraceComponent.isAnyTracingEnabled() && tc.isDebugEnabled()) {
        Tr.debug(tc, "Exception when doing something; " + e);
    }
    return;
}

```

Where the source id (class name in this example) and the unique probe id (typically the source code line number) combine to provide the exact location in the source code that generates the resulting record. By default, the records are written to the \${server.output.dir}/logs/ffdc directory.

The file space used by the FFDC records in the case of a persistently occurring exception is limited by automatic filtering of duplicate records. For any matching source id, probe id, and exception name, at most 10 exceptions with unique messages are written per day.

Feature code can contribute data to FFDC records by registering a `com.ibm.ws.ffdc.DiagnosticModule` implementation with the FFDC class. Feature code can also intercept FFDC records by registering a `com.ibm.wsspi.logging.IncidentForwarder` implementation with the FFDC class.

## Adding web services global handlers

8.5.5.4

Components that need to register web services handlers to all the web services end points must implement the Handler interface and register that implementation in the service registry.

### Before you begin

The global handler service is provided either by **jaxws-2.2**, **jaxrs-1.1**,  **jaxrs-2.0**, or **jaxrs-2.0 client**, so you must specify the following feature or feature combinations in your `server.xml` file:

- **jaxws-2.2**
- **jaxrs-1.1**
-  **8.5.5.6** **jaxrs-2.0**
-  **8.5.5.6** **jaxrs-2.0 client**
- **jaxws-2.2** and **jaxrs-1.1**
-  **8.5.5.6** **jaxws-2.2** and **jaxrs-2.0**
-  **8.5.5.6** **jaxws-2.2** and **jaxrs-2.0 client**

### About this task

The Handler SPI provides different properties to specify the `ENGINE_TYPE`, the `FLOW_TYPE`, and the client side (`IS_CLIENT_SIDE`) or the server side (`IS_SERVER_SIDE`) where handlers take effect.

You must implement the Handler interface and register the implementation class into the service registry.

The Java API documentation for each Liberty SPI is available in a separate compressed file in one of the Javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

### Deploying the handler bundle:

You can deploy the handler bundle by using the WebSphere Application Server Developer Tools for Eclipse .

#### Procedure

1. Click **File > New > Other** and then expand **OSGi**.
2. Click **OSGi Bundle Project** and click **Next**. The New OSGi Bundle Project window opens.
3. Enter `MyHandler` as the Project name. In the Target runtime list, select **WebSphere Application Server Liberty**. If no runtime exists, click **New Runtime** to create a WebSphere(r) Application Server Liberty runtime.
4. Clear the **Add bundle to application** ratio.
5. Click **Next** twice and go to the OSGi Bundle page.

6. On the **OSGi Bundle** page, check **Generate an activator, a Java class that controls the life cycle of the bundle**. Leave the **Activator name** as `myhandler.Activator` and click **Finish**.
7. Click **Window > Preferences > Plug-in Development > Target Platform** and select **WebSphere Application Server Liberty with SPI**.

**Note:** Ensure that you have added WebSphere Application Server Liberty runtime in 3 on page 1812.

8. Click **Apply** and click **OK**.
9. Expand **MyHandler > BundleContent > META-INF** and open the `MANIFEST.MF` file by using the **Plug-in Manifest Editor**.
10. Create the `MyHandler` and `MyActivator` classes:

```

...
import com.ibm.wsspi.webservices.handler.Handler;
...

public class MyHandler implements Handler {
    ...
    public void handleFault(GlobalHandlerMessageContext arg0) {
        ...
    }
    public void handleMessage(GlobalHandlerMessageContext msgctxt) throws Exception {
        if (msgctxt.getFlowType().equalsIgnoreCase(HandlerConstants.FLOW_TYPE_OUT)) {
            ...
        }
        ...
    }
    ...
}

public class MyActivator implements BundleActivator {
    ...
    public void start(BundleContext context) throws Exception {

        final Hashtable<String, Object> handlerProps = new Hashtable<String, Object>();
        handlerProps.put(HandlerConstants.ENGINE_TYPE, HandlerConstants.ENGINE_TYPE_JAXWS);
        handlerProps.put(HandlerConstants.FLOW_TYPE, HandlerConstants.FLOW_TYPE_IN);
        handlerProps.put(HandlerConstants.IS_CLIENT_SIDE, true);
        handlerProps.put(HandlerConstants.IS_SERVER_SIDE, true);
        handlerProps.put(org.osgi.framework.Constants.SERVICE_RANKING, 3);
        MyHandler myHandler = new MyHandler();
        context.registerService(Handler.class, myHandler, handlerProps);
        ...
    }
    ...
}

```

11. Click **File > New > Other** and then expand **OSGi**.
12. Click **Liberty Feature Project** and then click **Next**. The **Liberty Feature Project** window opens.
13. Specify `MyHandlerFeature` as the **Project name**.
14. In the **Target runtime list**, select **WebSphere Application Server Liberty** and click **Next**. The **OSGi Bundles Selection Page** opens.
15. On **OSGi Bundles Selection Page**, select **MyHandler 1.0.0** as the **Contained Bundles** and click **Finish**.
16. Modify `Manifest:MyHandler` in `MyHandler` project. Click the `MANIFEST.MF` tab and add `com.ibm.wsspi.webservices.handler` to the `Import-package` element.
17. Right-click the `MyHandlerFeature` project, click **Install Feature** to install the feature to Liberty runtime.
18. Edit the `server.xml` file to enable the `MyHandlerFeature`:

```

<featureManager> .....
<feature>jsp-2.2</feature>
<feature>jaxws-2.2</feature> // you can also use one of the following feature or feature combinations: jaxrs-1.1, jaxrs-2.0,
jaxws-2.2 and jaxrs-1.1, jaxws-2.2 and jaxrs-2.0, jaxws-2.2 and jaxrsClient-2.0
<feature>usr:MyHandlerFeature</feature> .....
</featureManager>

```

## Adding custom scaling listeners

8.5.5.9

You can create a custom scaling listener bundle by using WebSphere Application Server Developer Tools for Eclipse. A custom scaling listener is notified of all pending scaling actions. The listener can then permit or deny the scaling action. It can also decide to handle the action, thus provide a full customization of the scaling behavior.

### Before you begin

Ensure your Liberty installation has the `scalingController-1.0` feature. For information about scaling controllers, see “Setting up auto scaling for Liberty collectives” on page 1503 and “Scaling Controller” on page 950.

### About this task

You must implement the listener interface and register the implementation class into the service registry. Your scaling listener can permit or deny and handle scaling actions.

The Java API documentation for each Liberty SPI is available in a separate compressed file in one of the API documentation subdirectories of the `${wlp.install.dir}/dev` directory.

### Procedure

1. Click **File** > **New** > **Other** and then expand **OSGi**.
2. Click **OSGi Bundle Project** and click **Next**. The New OSGi Bundle Project window opens.
3. Enter `ScalingSPISampleBundle` as the Project name. In the Target runtime list, select **WebSphere Application Server Liberty**. If no runtime exists, click **New Runtime** to create a WebSphere Application Server Liberty runtime.
4. Clear the **Add bundle to application** radio button.
5. Click **Next** twice and go to the OSGi Bundle page.
6. On the OSGi Bundle page, check **Generate an activator, a Java class that controls the life cycle of the bundle**. Leave the **Activator name** as `scalingspisamplebundle.Activator` and click **Finish**.
7. Click **File** > **New** > **Other** and then expand **OSGi**.
8. Click **Liberty Feature Project** and then click **Next**. The Liberty Feature Project window opens.
9. Specify `ScalingSPISampleFeature` as the Project name.
10. In the Target runtime list, select **WebSphere Application Server Liberty** and click **Next**. The OSGi Bundles Selection Page opens.
11. On OSGi Bundles Selection Page, select **ScalingSPISampleBundle 1.0.0** as the **Contained Bundles** and click **Finish**.
12. Click **Window** > **Preferences** > **Plug-in Development** > **Target Platform** and select **WebSphere Application Server Liberty with SPI**.
13. Click **Apply** and click **OK**.
14. Expand **ScalingSPISampleBundle** > **BundleContent** > **META-INF** and open the `MANIFEST.MF` file by using the **Plug-in Manifest Editor**.

15. Select the **Dependencies** tab and add the `com.ibm.wsspi.scaling.action.consumer` and `com.ibm.wsspi.scaling.action.controller` packages to the Imported Packages pane. You might need to press **Ctrl+S** to save the changes.
16. In the `ScalingSPISampleBundle` project, add an implementation class called `ScalingSPISamplePlugin`. This new class implements the `com.ibm.wsspi.scaling.action.consumer.ScalingActionPlugin` interface.

```
package scalingspisamplebundle;

import com.ibm.wsspi.scaling.action.consumer.ScalingActionPlugin;
import com.ibm.wsspi.scaling.action.controller.ScalingActionContext;
import com.ibm.wsspi.scaling.action.controller.ScalingActionContext.ActionType;
import com.ibm.wsspi.scaling.action.controller.ScalingActionContext.ActionDecision;;

/**
 * This a sample Liberty scaling SPI plugin that acts as a template for developing a custom
 * SPI plugin. In this plugin, no actual work is done and the return value to the Liberty Scaling
 * controller is always DEFAULT_ACTION.
 */
public class ScalingSPISamplePlugin implements ScalingActionPlugin {

    /** {@inheritDoc} */
    @Override
    public ActionDecision actionRequired(ScalingActionContext action) {

        ActionDecision returnType = ActionDecision.DEFAULT_ACTION;

        if (action.getActionType() == ActionType.START_SERVER) {
            returnType = startServer(action);
        }
        else if (action.getActionType() == ActionType.CREATE_SERVER) {
            returnType = createServer(action);
        }
        else if (action.getActionType() == ActionType.STOP_SERVER) {
            returnType = stopServer(action);
        }

        return returnType;
    }

    private ActionDecision startServer(ScalingActionContext action) {
        // perform some action to start a server

        return ActionDecision.DEFAULT_ACTION;
    }

    private ActionDecision createServer(ScalingActionContext action) {
        // perform some action to create a server

        return ActionDecision.DEFAULT_ACTION;
    }

    private ActionDecision stopServer(ScalingActionContext action) {
        // perform some action to stop a server

        return ActionDecision.DEFAULT_ACTION;
    }
}
```

17. In the `ScalingSPISampleBundle` project, open the `Activator` class and edit the `start(BundleContext)` method to add code that registers the new listener service.

```
public void start(BundleContext context) throws Exception {
    final Hashtable<String, Object> properties = new Hashtable<String, Object>();
    ScalingSPISamplePlugin scalingSPISamplePlugin = new ScalingSPISamplePlugin();
    context.registerService(ScalingActionPlugin.class, scalingSPISamplePlugin, properties);
}
```

If prompted to import a `HashMap`, select to import `java.util.HashMap`.

18. Right-click the **ScalingSPISampleFeature** project, and click **Install Feature** to install the feature to Liberty runtime.

The **Install Feature** menu option is in the Enterprise Explorer view of the Java EE perspective.

19. Edit the `server.xml` file to enable the `ScalingSPISampleFeature`.

```
...
<featureManager>
  ...
  <feature>scalingController-1.0</feature>
  <feature>usr:ScalingSPISampleFeature</feature>
</featureManager>
...
```

## Exposing REST endpoints within Liberty

8.5.5.4

You can use the REST Handler framework in the Liberty SPI to expose new REST endpoints.

### About this task

The REST Handler framework is for Liberty extenders to use when exposing new REST endpoints. You can expose REST endpoints in an OSGi component, or a set of components.

### Procedure

1. Create an OSGi component that registers itself as listening to a sub-root that appends to `/ibm/api` and implements the `com.ibm.wsspi.rest.handler.RESTHandler` interface; for example:

```
@Component(service = { RESTHandler.class },
            configurationPolicy = ConfigurationPolicy.IGNORE,
            immediate = true,
            property = { "service.vendor=IBM",
                        RESTHandler.PROPERTY_REST_HANDLER_ROOT + "/myTest/abc" })
public class RESTHANDLERTest1 implements RESTHandler {
  ...
}
```

2. Package the component into an OSGi bundle that is part of your extended user feature.

3. Ensure that your feature includes the OSGi subsystem content:

```
com.ibm.websphere.appserver.restHandler-1.0; type="osgi.subsystem.feature"
```

4. Configure SSL certificates in the `server.xml` file.

5. Configure a user or group to the administrator role in the `server.xml` file.

- Map to the administrator role for Liberty
- **z/OS** Map to the administrator role for Liberty on z/OS

6. Start your feature.

Starting the feature starts the REST Handler framework and registers your OSGi component. After the feature starts, you can make calls to `https://<host>:<https_port>/ibm/api/myTest/abc`.

## Including protected features

Your feature can include one or more other features by listing them in the `Subsystem-Content` header of the feature manifest file. Any feature in the same product extension as your own feature can be included; if the included feature is in a different product extension, or in Liberty, it must have public or protected visibility.

The included feature must be specified by its `Subsystem-SymbolicName`, and have a type of `"osgi.subsystem.feature"`; for example:

Subsystem-Content:

```
com.ibm.wsspi.appserver.webBundle-1.0; type="osgi.subsystem.feature",
com.ibm.websphere.appserver.json-1.0; type="osgi.subsystem.feature"
```

For information on Liberty public features, see “Liberty features” on page 826. The following section describes Liberty protected features.

## Liberty protected features

### Application Manager

This feature provides advanced capability for implementing new application containers.

Subsystem-SymbolicName: com.ibm.websphere.appserver.appmanager-1.0.

Provided API and SPI:

- dev/api/ibm/com.ibm.websphere.appserver.api.basics\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.application\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.artifact\_1.0.9.jar

### Classloader service

This feature provides advanced capability for implementing new application containers.

Subsystem-SymbolicName: com.ibm.websphere.appserver.classloading-1.0.

Provided API and SPI:

- dev/spi/ibm/com.ibm.websphere.appserver.spi.classloading\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.artifact\_1.0.9.jar

### Container services

This feature provides advanced capability for implementing new application containers.

Subsystem-SymbolicName: com.ibm.websphere.appserver.containerServices-1.0,

Provided API and SPI:

- dev/spi/ibm/com.ibm.websphere.appserver.spi.containerServices\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.anno\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.artifact\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.javaeedd\_1.0.9.jar

### Transaction manager 1.1

This feature provides a JTA 1.1 compliant transaction manager.

Subsystem-SymbolicName: com.ibm.websphere.appserver.transaction-1.1.

Provided API and SPI:

- dev/api/spec/com.ibm.ws.javaee.transaction.1.1\_1.0.9.jar
- dev/api/ibm/com.ibm.websphere.appserver.api.transaction\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.containerServices\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.anno\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.artifact\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.javaeedd\_1.0.9.jar

### Transaction manager 1.2

This feature provides a JTA 1.2 compliant transaction manager.

Subsystem-SymbolicName: com.ibm.websphere.appserver.transaction-1.2.

Provided API and SPI:

- dev/api/spec/com.ibm.ws.javaee.transaction.1.2\_1.0.9.jar
- dev/api/ibm/com.ibm.websphere.appserver.api.transaction\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.containerServices\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.anno\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.artifact\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.javaeedd\_1.0.9.jar

## Web Bundle

This feature supports the use of web application bundles (WABs) in features. Include this feature if your feature provides an application endpoint, as described in “Providing an application endpoint” on page 1808.

Subsystem-SymbolicName: com.ibm.wsspi.appserver.webBundle-1.0.

Provided API and SPI:

- dev/api/spec/com.ibm.ws.javaee.servlet.3.0\_1.0.9.jar
- dev/api/ibm/com.ibm.websphere.appserver.api.servlet\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.servlet\_1.0.9.jar

## Web Bundle Security

This feature supports the application of security to web bundles; see “Securing an application endpoint” on page 1808.

Subsystem-SymbolicName: com.ibm.wsspi.appserver.webBundleSecurity-1.0.

Provided API and SPI:

- dev/api/spec/com.ibm.ws.javaee.servlet.3.0\_1.0.9.jar
- dev/api/ibm/com.ibm.websphere.appserver.api.servlet\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.servlet\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.containerServices\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.anno\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.artifact\_1.0.9.jar
- dev/spi/ibm/com.ibm.websphere.appserver.spi.javaeedd\_1.0.9.jar

## Locating OSGi applications

You can use classes in the org.apache.aries.blueprint package to extend the OSGi application programming model; this third-party SPI is provided through the blueprint-1.0 server feature. You must access OSGi application bundles in to apply your extensions. In Liberty, OSGi applications run as Subsystems. To locate an OSGi application you can create a ServiceTracker in a user feature.

## About this task

This topic describes how the developer of a user feature can locate running OSGi applications. This task is often required for user features that provide programming model extensions to OSGi applications. For example, a new user feature might provide such extensions by implementing a new bundle extender, often referred to as a *container*, or, more simply, by tracking and invoking services published from within certain OSGi applications.

Such user features must use the BundleContext of a particular running OSGi application to create new BundleTracker and ServiceTracker instances. This BundleContext can be obtained from the org.osgi.service.subsystem.Subsystem that is associated with the OSGi application. The following procedure describes how to obtain that SubSystem service.

## Procedure

To locate an OSGi application by creating a ServiceTracker in a user feature, complete the following steps:

1. Construct an org.osgi.framework.Filter that is targeted to the Subsystem that you want to locate.
2. Create an org.osgi.util.tracker.ServiceTracker that uses the Filter from step 1 to obtain the org.osgi.service.subsystem.Subsystem service that is associated with the OSGi application that you want to locate. This Subsystem service instance provides everything you require to work with the OSGi application.

## Example

The following example shows how to locate an application with symbolic name `my.app` by using a `ServiceTracker` in a user feature:

```
import org.osgi.framework.BundleContext;
import org.osgi.service.subsystem.Subsystem;
import org.osgi.util.tracker.ServiceTracker;
import org.osgi.util.tracker.ServiceTrackerCustomizer;
```

In the following code extract, the variable `ctx` is the `BundleContext` of one of the bundles of the user feature:

```
String SERVICE_FILTER = "(&(objectClass=org.osgi.service.subsystem.Subsystem)
                        (subsystem.type=osgi.subsystem.application)(subsystem.symbolicName=my.app))"

    org.osgi.framework.Filter filter = ctx.createFilter(SERVICE_FILTER);
```

The last 'null' parameter can be replaced with an instance of a class that implements `ServiceTrackerCustomizer<Subsystem, Subsystem>`:

```
org.osgi.util.tracker.ServiceTracker<Subsystem, Subsystem> str = new ServiceTracker<Subsystem, Subsystem>(ctx, filter, null);
```

The `SERVICE_FILTER` can be constructed to make use of such constants as:

```
org.osgi.framework.Constants.OBJECTCLASS;
org.osgi.service.subsystem.SubsystemConstants.SUBSYSTEM_SYMBOLICNAME_PROPERTY;
org.osgi.service.subsystem.SubsystemConstants.SUBSYSTEM_TYPE_APPLICATION;
org.osgi.service.subsystem.SubsystemConstants.SUBSYSTEM_TYPE_PROPERTY;
```

## Developing with the JNDI default namespace in a Liberty feature

### 8.5.5.0

You can make an object available in the default Java Naming and Directory Interface (JNDI) namespace. To do that, you must register it in the OSGi service registry with the `osgi.jndi.service.name` service property. The value of `osgi.jndi.service.name` is the required JNDI name. Similarly, to find an object in the default JNDI namespace, you can search the OSGi service registry with the `osgi.jndi.service.name` service property. The value of `osgi.jndi.service.name` is the JNDI name.

### About this task

Compared with explicitly calling `Context.bind` or `Context.lookup`, using the service registry has the following benefits:

- Your feature works properly when `jndi-1.0` is enabled, but your feature does not need an explicit dependency on JNDI.
- You do not need to explicitly unbind objects from JNDI when your feature is removed because the OSGi framework automatically unregisters services when bundles are stopped.
- You can easily implement lazy initialization using declarative services or `ServiceFactory` rather than using `Reference` and `ObjectFactory`.

For more information about JNDI, see [Naming](#).

### Procedure

1. Register a service using the `osgi.jndi.service.name` property with the JNDI name. For more information about registering services, see “[Registering OSGi services](#)” on page 1790.
2. Update your `metatype.xml` to allow a JNDI name to be specified in server configuration. To allow users to specify a JNDI name for your service, you should use the `jndiName` id for consistency with other features in the Liberty run time, for example:

```
<AD id="jndiName" name="JNDI name" description="JNDI name for a widget." type="String" ibm:unique="jndiName"/>
```

You can use an internal attribute to automatically set the `osgi.jndi.service.name` service property with the value of the `jndiName` attribute, for example:

```
<AD id="osgi.jndi.service.name" name="internal" description="internal" type="String" default="{jndiName}"/>
```

For more information about OSGi Metatype, see “Advanced Configuration” on page 1798.

3. **8.5.5.1** Implement the `ResourceFactory` interface if you need Java EE resource reference information. If your service needs Java EE resource reference information, such as `res-auth`, you can register a `ResourceFactory` in the OSGi service registry with the `jndiName` and `creates.objectClass` properties. The `ResourceFactory` service is re-registered automatically with the `osgi.jndi.service.name` property. For example:

```
import com.ibm.wsspi.resource.ResourceFactory;
public class WidgetResourceFactory implements ResourceFactory { ... }

Properties properties = new Properties();
properties.put(ResourceFactory.JNDI_NAME, "widget/abc");
properties.put(ResourceFactory.CREATE_OBJECT_CLASS, Widget.class.getName());
bundleContext.registerService(ResourceFactory.class, new WidgetResourceFactory(), properties);
```

Alternatively, the service could be registered automatically using declarative services and metatype. In that case, you can specify the `creates.objectClass` property as a declarative services property. You do not need to specify the `jndiName` property because it is set automatically from the user configuration with the `<AD id="jndiName">` element in the `metatype.xml` file in step 2 on page 1819, and you do not need an `<AD id="osgi.jndi.service.name">` element in the `metatype.xml` file because the `ResourceFactory` service will be re-registered automatically.

4. Locate an object using the `osgi.jndi.service.name` property with the JNDI name. For example:  
`bundleContext.getServiceReference(DataSource.class, "(osgi.jndi.service.name=jdbc/myds)");`

**8.5.5.0** Alternatively, you can locate a `ResourceFactory` using the `jndiName` and `creates.objectClass` properties.

5. Update your `metatype.xml` to allow a resource to be specified in `server.xml` using the id of the resource. This allows the resource to be accessed regardless of whether or not the resource has a `jndiName`. For example,

```
<AD id="dataSourceRef" type="String" ibm:type="pid" ibm:reference="com.ibm.ws.jdbc.dataSource" cardinality="1" name="%d
```

If you are using declarative services, you can use an internal attribute to set a `.target` service property with a filter. For example, if your declarative services component has a reference named `dataSource`, you can use the following attribute definition to ensure that the `dataSource` that is referenced by the `dataSourceRef` configuration attribute is used.

```
<AD id="dataSource.target" type="String" default="(service.pid={dataSourceRef})" ibm:final="true" name="internal" desc
```

## Developing a custom TAI as a Liberty feature

### 8.5.5.0

You can develop a custom TAI as a Liberty feature by implementing the `com.ibm.wsspi.security.tai.TrustAssociationInterceptor` interface provided in the Liberty server and creating a product extension.

### About this task

For a general view of custom TAI, see “Developing a custom TAI for Liberty” on page 1998.

For more information about product extensions, see “Liberty profile: Product extension” on page 967.

**Avoid trouble:** If you have multiple TAIs, you can configure all of them by using either the user feature or the shared library. Do not mix the two TAI configurations.

## Procedure

1. Implement the custom TAI. For more information, see “Developing a custom TAI for Liberty” on page 1998.
2. Convert the implementation class into an OSGi service. You can do the conversion in one of the following ways:
  - Convert your custom TAI class into a Declarative Service (DS) component. For more information, see “Declaring your services to OSGi Declarative Services” on page 1794.
  - Write a new custom TAI class that is a DS component and delegate it to your custom TAI class.
  - Register the custom TAI class directly in the Service Registry (SR) by using the OSGi core APIs. For more information, see “Working with the OSGi service registry” on page 1789.
3. Package the custom TAI as an OSGi bundle and export the custom TAI service. For information on creating an OSGi bundle, see *Creating an OSGi service bundle*.
4. Create a feature manifest to include the OSGi bundle. For more information about feature manifest file, see “Liberty feature manifest files” on page 1773.
5. After the feature is installed into the user product extension location, configure the `server.xml` file with the feature name. For example:

```
<featureManager>
  ...
  <feature>usr:customTaiSample-1.0</feature>
</featureManager>
```

## Dynamic content management

You typically install bundles into the runtime environment by listing them in the `Subsystem-Content` header of the feature manifest file. However, you can also dynamically add and remove OSGi bundles by installing a user-written bundle as part of the `Subsystem-Content` of a user-written feature. The user-written bundle obtains the OSGi bundle context to install and control additional bundles.

## Installing, starting, stopping, and uninstalling bundles in Liberty

**Note:** In the following sections, the user-written feature is called `UserFeatureA` and the user-written bundle is called `FeatureBundleA`.

### Installing bundles

You can write `FeatureBundleA` to obtain the OSGi bundle context, `org.osgi.framework.BundleContext`, by using one of the following methods:

- Implement the `BundleActivator` interface, `org.osgi.framework.BundleActivator`. The `BundleContext` parameter of the `start` method is passed in by the OSGi framework, which is available to the user-written bundle when that bundle is activated. For more information on the `BundleActivator` interface, see “Developing an OSGi bundle with simple activation” on page 1788.
- Implement an available specification, such as OSGi Declarative Services or Blueprint, that provides access to the bundle context through another method or interface. For more information, see “Composing advanced features by using OSGi Declarative Services” on page 1793 and *Blueprint bundles*.

After `FeatureBundleA` obtains the bundle context, additional bundles can be installed by using either the `installBundle(String location)` or `installBundle(String location, InputStream stream)` methods.

Bundles that are dynamically installed resume state on a default restart. They do not persist across a clean start and require reinstallation. See *Bundle caching* for more details.

## Starting bundles

If you want an installed bundle to be started, it is the responsibility of the installing bundle, `FeatureBundleA`, to call the `start` method for the bundle.

## Stopping and uninstalling bundles

If the user-written feature, `UserFeatureA`, is removed from the server configuration, then `FeatureBundleA` is stopped and also uninstalled. Uninstallation of `FeatureBundleA` triggers uninstallation of all the bundles that were installed by `FeatureBundleA`, if they are not already uninstalled. The `org.osgi.framework.Bundle.uninstall()` method is called for each bundle, which stops and uninstalls it. This uninstallation process also applies if `FeatureBundleA` is uninstalled by any other means.

If `UserFeatureA` is removed from the server configuration when the server is stopped, the bundles that were installed by `UserFeatureA` are removed on the next server start. If the start levels of the bundles are unmodified from their defaults, the bundles are removed before they are restarted. If the start levels of the bundles were modified, they might not be removed until after they have restarted.

Other lifecycle management tasks are done by `FeatureBundleA` according to the OSGi core specification, by using the `org.osgi.framework.Bundle` and `org.osgi.framework.BundleContext` interfaces.

## Bundle caching, package visibility, and programming model support in Liberty

### Bundle caching

When the server is shut down, all the currently installed bundles are stopped and OSGi metadata is persisted to a bundle cache. On a default start, these installed bundles are returned to their previous state. On a clean start, any bundles that were installed by `FeatureBundleA` have their persistent data deleted. As a result, on a clean start these bundles are not resumed.

`FeatureBundleA` itself is resumed because it is reinstalled by the feature manager, provided `UserFeatureA` is still in the server configuration. If you want to reinstall any bundles after a clean start, it is the responsibility of `FeatureBundleA` to do the reinstallation. You are not notified about a clean start, but you can check whether a bundle is installed by using the OSGi `BundleContext` `getBundle(String location)` method.

### Package visibility

Bundles that are dynamically installed, and are not listed in the `Subsystem-Content` header of the feature manifest file, have the following visibility:

- Dynamically installed bundles can import any API and SPI packages provided by the currently configured set of features.
- Packages that are exported by other bundles within the same product extension that are not declared as API or SPI, are not visible to dynamically installed bundles.
- Packages that are exported from dynamically installed bundles cannot be declared as API or SPI.
- There are no restrictions on importing packages that are exported from dynamically installed bundles.

### Programming model support

Dynamically installed bundles can use implementations of OSGi enterprise specifications provided that the appropriate runtime features are configured to enable them.

---

## Packaging and installing Liberty features

8.5.5.0

You can package and install Liberty features to WebSphere Application Server Liberty.

## About this task

A Liberty feature may be packaged as a subsystem archive, as defined by the OSGi Enterprise specification (5.0). A subsystem archive is a compressed file with an `.esa` extension that includes the feature manifest and the resource files that constitute the feature. The WebSphere Application Server developer tools will import and export Liberty features by using the subsystem archive format, and features can be installed to a Liberty runtime environment by using the **featureManager** command if they are in the `.esa` format.

## Procedure

- You can manually install a Liberty features onto Liberty.
  - To install the feature to the Liberty kernel, the feature manifest file must be in the `${wlp.install.dir}/lib/features` directory and related bundles in the `${wlp.install.dir}/lib` directory;
  - To install the feature into the user configuration, the feature manifest file must be in the `${wlp.user.dir}/extension/lib/features` directory, and related bundles must be in the `${wlp.user.dir}/extension/lib` directory;
  - To install the feature into a product extension, the feature manifest file and related bundles must be in the product extension directory. The product extension is registered in the `${wlp.user.dir}/etc/extension/lib/features` directory using a `<extension-name>.properties` file. For more information, see “Liberty profile: Product extension” on page 967.
- You can also use the **featureManager** command that is provided in the `${wlp.install.dir}/bin` directory to install a Liberty feature if it is packaged as an `.esa` file.
  - To install a feature as a user feature, use the following command:  

```
featureManager install my_feature.esa --to=usr
```
  - To install a feature to a product extension location, use the following command:  

```
featureManager install my_feature.esa --to=my_extension
```

For more information about the **featureManager** command, see “Liberty:featureManager command” on page 1405.

## Provide product information for your feature extension

**8.5.5.0**

You can provide Version Product information for your Feature Extension

You can provide Version Product information for your Feature Extensions by providing the installation with a uniquely named product information properties file in the `lib/versions` directory of the extension. The file extension must be `.properties`.

You can add Version Product information manually or by using the **featureManager** script's installation option under the following conditions:

- The subsystem manifest file in the feature archive contains a `subsystem-content` entry that points to the product information properties file that is being installed.
- The product information properties file can be installed only if the feature that is being installed defines the **IBM-Feature-Version**.
- The product information properties file in the feature archive (`.esa`) has the following path  
`wlp/lib/versions/filename.properties`.

The following properties can be specified in the product information properties file:

```
com.ibm.websphere.productId=yourProductID
com.ibm.websphere.productOwner=TheProductOwner
com.ibm.websphere.productVersion=yourProductVersion
```

```
com.ibm.websphere.productName=yourProductName
com.ibm.websphere.productInstallType=yourProductInstallType
com.ibm.websphere.productEdition=yourProductEdition
com.ibm.websphere.productQualifier=yourProductQualifier
```

If you want to override a particular feature extension information, include the following property in your product information properties file:

```
com.ibm.websphere.productReplaces=theProductIdToReplace
```

If your product is eligible for Getting Started Subcapacity Pricing (GSSP), set the following property to true in your product information properties file:

```
com.ibm.websphere.gssp=true
```

The following is an example of how to define subsystem entry content for installing the feature extension by using the featureManager script, subsystem.mf:

```
Subsystem-ManifestVersion:1
...
Subsystem-Content: userProdExt; version="[1,1.0.100]",
user.ext.version.info; type="file"; location:="lib/versions/user.ext.version.info.properties"
IBM-Feature-Version: 2
```

The following is an example that shows the output of the *productInfo* script using the *version* option that shows the product name and version entries that are specified in the product information properties file:

```
com.ibm.websphere.productId=XYZ Product ID
com.ibm.websphere.productOwner=XYZ Inc
com.ibm.websphere.productVersion=1.0.0
com.ibm.websphere.productName=XYZ User Product
com.ibm.websphere.productInstallType=Archive
com.ibm.websphere.productEdition=Enterprise Edition
```

```
Command:
productInfo version
```

```
Output:
Product name: Websphere Application Server
Product version: 8.5.5.0
```

```
Product name: XYZ User Product
Product version: 1.0.0
```

---

## Embedding Liberty in your applications

**8.5.5.0**

You can use the System Programming Interfaces (SPIs) that are provided by Liberty to configure, control, and monitor a Liberty server in your applications.

### About this task

Liberty provides the following SPIs to start or stop a Liberty server:

- `com.ibm.wsspi.kernel.embeddable.Server`
- `com.ibm.wsspi.kernel.embeddable.ServerBuilder`

Use a Future object to store the result of a start or stop operation. The return codes that are used by embedded operations are the same as the return codes used by the **server** command. For more information about return codes, JVM options used by the server script, and the process environment used by the server script, see “Liberty:server command options” on page 1569.

Additionally, you can receive asynchronous notifications when the server is starting, has started, or has stopped by creating your own class that implements the `com.ibm.wsspi.kernel.embeddable.ServerEventListener` interface.

**Note:** To create an instance of an embedded server within your application, you must carry out the following steps:

- Include the `ws-server.jar` file on the class path. The `ws-server.jar` file is in the `${wlp.install.dir}/bin/tools` directory of the Liberty installation.
- Specify the name of the target server. The target server must exist.
- Optional: Configure the `ws-javaagent.jar` file with the `-javaagent` JVM option. The `ws-javaagent.jar` file is in the `${wlp.install.dir}/bin/tools` directory of the Liberty installation. You are advised to configure the `ws-javaagent.jar` file, but it is not mandatory unless you use capabilities of the server that require it, such as monitoring or trace. If you contact IBM support, you might need to provide trace, and if so, you must start the server with the `ws-javaagent.jar` file, even if you do not normally use it.

**Note:** In an embedded environment:

- Environment variables are not checked, and the `jvm.options` and `server.env` files are not read.
- Management of the JVM and environment is assumed to be managed by the caller.

## Procedure

1. Import the SPIs into your caller class and define the arguments that are required to operate the Liberty server.

```
import com.ibm.wsspi.kernel.embeddable.Server;
import com.ibm.wsspi.kernel.embeddable.ServerBuilder;

public class MyEmbeddedServer {
    String serverName="defaultServer";
    File userDir = new File("usr");
    File outputDir = new File("usr/servers/");
    ...
}
```

Where

- The **serverName** is required, and must match the name of a previously created server.
  - The **userDir** is optional and used to set the path of the user directory. By default, the user directory is `${wlp.user.dir}`.
  - The **outputDir** is optional and used to set the path of the output directory. By default, the output directory is `${wlp.user.dir}/servers`.
2. Initialize the server by using the `ServerBuilder` class.

```
ServerBuilder sb = new ServerBuilder();
Server libertyServer = sb.setName(serverName)
                        .setUserDir(userDir)
                        .setOutputDir(outputDir)
                        .build();
```
  3. Call the `Server.start()` method to start the server. Call `get()` on the future to block until the start operation completes. Use one of the following to determine whether the server started successfully:
    - Check the returned result code.
    - Use the `successful()` method.
    - If the server is started, the `server.isRunning()` method returns true.

```
Future<Result> startReturnCode = libertyServer.start();
Result result = startReturnCode.get(); // block until operation complete, if necessary
System.out.println("Start returned: success=" + result.successful() + ", rc=" + result.getReturnCode() + ", ex=" + result.getException());
```

4. Call the `Server.stop()` method to stop the server. Call `get()` on the future to block until the stop operation completes. Use one of the following to determine whether the server stopped successfully:
  - Check the returned result code.
  - Use the `successful()` method.
  - If the server is stopped, the `server.isRunning()` method returns false.

```
Future<Result> stopReturnCode = libertyServer.stop();
Result result = stopReturnCode.get(); // block until operation complete, if necessary
System.out.println("Stop returned: success=" + result.successful() + ", rc=" + result.getReturnCode() + ", ex=" + result.getException());
```

5. Implement the `ServerEventListener` interface. If you implement the `ServerEventListener` interface, you can receive notifications when the server is started or stopped.

```
// update the class declaration to indicate that it implements ServerEventListener
public class MyEmbeddedServer implements ServerEventListener {
    ...
    MyEmbeddedServer() throws ServerException {
        // set the listener via the server builder
        ServerBuilder sb = new ServerBuilder();
        Server libertyServer = sb.setName(serverName)
                                .setServerEventListener(this)
                                .build();
    }

    ...
    @Override
    public void serverEvent(ServerEvent event) {
        // provide an implementation of the serverEvent method
        System.out.println("serverEvent: " + event);
    }
}
```

---

## Creating Liberty servers from custom configurations

### 8.5.5.0

You can create a server from a custom configuration for any environment that you require.

### About this task

The Liberty server script `create` command offers a `--template` option. You can use this option to support server creation from a custom configuration located within a `templates/servers/<template-name>` sub-directory of your product extension. Custom server templates must contain at least a `server.xml` file, and can contain any configuration files, for example: `bootstrap.properties` or `jvm.options`.

### Procedure

You can use the `--template` option in the following way: `server create --template=<extension-name>:<template-name>`

---

## Disabling z/OS operator console command handling in the Liberty server

z/OS

### 8.5.5.2

You can listen for and handle z/OS operator console commands directly from your application or product extension feature. However, doing so conflicts with the built-in Liberty for z/OS operator console command handler. If you want to listen for commands directly, you need to disable the built-in Liberty for z/OS operator console command listener.

## About this task

Liberty provides the following property to disable the handling of z/OS operator console commands by the Liberty server:

```
websphere.os.extension=zosNoConsoleExtensions-1.0
```

## Procedure

1. Stop the Liberty server.
2. Set `websphere.os.extension=zosNoConsoleExtensions-1.0` in your `${server.config.dir}/bootstrap.properties` file.
3. Start the Liberty server.

When you start the Liberty server with this new setting, it no longer listens for z/OS console commands. This change allows your application to handle z/OS console commands itself. For more information on implementing z/OS console command listeners and handlers within an application, see *MVS Programming Authorized Assembler Services Guide: Communicating with a program (EXTRACT, QEDIT)*, or the equivalent for your level of z/OS.

---

## Chapter 8. Securing Liberty and its applications

This information applies to all types of applications that are deployed on Liberty.

### About this task

Security in Liberty supports all the Servlet 3.0 security features and secured Java JMX connections. The following Liberty features are applicable to security in Liberty:

- `appSecurity-2.0` enables security for **8.5.5.0** for web applications when the `servlet-3.0` feature is present and for EJB components when the `ejbLite-3.1` feature is present.
- `ssl-1.0` enables SSL connections using HTTPS.
- **z/OS** `zosSecurity-1.0` includes the support for SAF Registry and Authorization on the z/OS platform.
- `restConnector-1.0` enables remote access by JMX client through a REST-based connector.
- `oauth-2.0` enables authorization to resources by using the OAuth 2.0 protocol.
- **8.5.5.0** `ldapRegistry-3.0` provides support for the LDAP user registry.

To learn about how security works in Liberty, see “Liberty: Security” on page 971.

**Best practice:** **8.5.5.0** There are several security configuration examples on the `WASdev.net` website for reference when configuring security for your applications on Liberty. If you see any differences in the configuration created by the developer tools and the examples, modify the configuration to fit the configuration in the examples for that feature.

### Procedure

- Use `quickStartSecurity` for minimal security configuration
- Secure communications in Liberty
- Access a secured JMX connector in Liberty
- Authenticate users in Liberty
- Authorize access to resources in Liberty
- Secure a database access application
- Develop extensions to the Liberty security infrastructure

---

## Getting started with security in Liberty

You can use the `<quickStartSecurity>` element to quickly enable a simple (one user) security setup for Liberty.

### About this task

You can set up a secured Liberty server and web application by following some basic configuration steps. Configuration actions within Liberty are dynamic, which means the configuration updates take effect without having to restart the server.

### Procedure

1. Create and start your server.
  - **Windows** On Windows systems:

```
server.bat create MyNewServer
server.bat start MyNewServer
```

- **AIX** **Linux** **UNIX** **HP-UX** **Solaris** **IBM i** **z/OS** On all systems other than Windows systems:

```
server create MyNewServer
server start MyNewServer
```

2. **8.5.5.0** Include the appSecurity-2.0 and servlet-3.0 features in the server.xml file. The server.xml file is in the server directory of *myNewServer*, for example, wlp\usr\servers\myNewServer\server.xml.

```
<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>servlet-3.0</feature>
</featureManager>
```

3. Define the user name and password that is to be granted the Administrator role for server management activities.

```
<quickStartSecurity userName="Bob" userPassword="bobpwd" />
```

**Note:** Choose a user name and password that are meaningful to you. Never use the name and password in the example for your applications.

4. Configure the deployment descriptor with relevant security constraints to protect web resource. For example, use <auth-constraint> and <role-name> elements to define a role that can access web resource.

The following example web.xml file shows that access to all the URIs in the application is protected by the testing role.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE web-app PUBLIC "-//Sun Microsystems, Inc.//DTD Web Application 2.3//EN"
    "http://java.sun.com/dtd/web-app_2_3.dtd">
```

```
<web-app id="myWebApp">

  <!-- SERVLET DEFINITIONS -->
  <servlet id="Default">
    <servlet-name>myWebApp</servlet-name>
    <servlet-class>com.web.app.MyWebAppServlet</servlet-class>
    <load-on-startup/>
  </servlet>

  <!-- SERVLET MAPPINGS -->
  <servlet-mapping id="ServletMapping_Default">
    <servlet-name>myWebApp</servlet-name>
    <url-pattern>/*</url-pattern>
  </servlet-mapping>

  <!-- SECURITY ROLES -->
  <security-role>
    <role-name>testing</role-name>
  </security-role>

  <!-- SECURITY CONSTRAINTS -->
  <security-constraint>
    <web-resource-collection>
      <url-pattern>/*</url-pattern>
    </web-resource-collection>
    <auth-constraint>
      <role-name>testing</role-name>
    </auth-constraint>
  </security-constraint>

  <!-- AUTHENTICATION METHOD: Basic authentication -->
```

```

<login-config>
  <auth-method>BASIC</auth-method>
</login-config>

</web-app>

```

5. Configure your application in the `server.xml` file.

In the following example, the user Bob is mapped to the testing role of the application:

```

<application type="war" id="myWebApp" name="myWebApp"
  location="${server.config.dir}/apps/myWebApp.war">
  <application-bnd>
    <security-role name="testing">
      <user name="Bob" />
    </security-role>
  </application-bnd>
</application>

```

6. Access your application and log in with the user name Bob. The default URL for the myWebApp application is `http://localhost:9080/myWebApp`

## Results

You have now secured your application.

## Liberty:Quick overview of security

To understand the basic workflow of security in Liberty, some common security terms are detailed along with an example.

### Security key terms

#### Authentication

Authentication confirms the identity of a user. The most common form of authentication is user name and password, such as through basic authentication or form login for web applications. When a user is authenticated, the source of a request is represented as a Subject object at run time.

#### Authorization

Authorization determines whether a user has access to a given role within the system. The Java EE model uses subjects, roles, and role mappings to determine if access is allowed.

**Role** A role is defined within the Java EE application. Some roles, such as the Administrator role, are predefined by the system. Other roles are defined by the application developer. In Java EE, subjects are usually granted or denied access to a role based on the roles they perform within the application.

#### Subject

A subject is both a general term and a Java object: `javax.security.auth.Subject`. Generally, the term subject means active entities within the system, such as users on the system, and even the system process itself.

### Security workflow example

The following example demonstrates how the security is applied when a user requests access to a resource. For example, a user Bob wants to access a servlet myWebApp. See the code samples in “Getting started with security in Liberty” on page 1829.

To access the servlet myWebApp, the following conditions must be true:

1. Bob must be able to log in to the system because the servlet is protected.
2. Bob must be in the testing role because the servlet is restricted by using an `auth-constraint` element in the deployment descriptor.

If Bob cannot log in to the system, or Bob is not in the testing role, then the access to the servlet myWebApp is denied.

Another user Alice can log in to the system because Alice is a valid user. But Alice is not in the testing role. An HTTP 403 error (Access Denied/Forbidden) displays when Alice logs in.

## Setting up BasicRegistry and role mapping on Liberty

You can configure Liberty to authenticate and authorize users by using a basic user registry.

### Before you begin

**8.5.5.0** The Liberty features appSecurity-2.0 and servlet-3.0 must be enabled in the server.xml file.

For more information about security configuration in Liberty, see “Getting started with security in Liberty” on page 1829.

### About this task

You can set up a basic user registry and configure more role mapping in the server.xml file for a Liberty server by going through the following steps.

### Procedure

1. Configure the basic registry as follows. Use a user name and password that are meaningful to you. Never use the name and password from this example in your applications.

```
<basicRegistry id="basic" realm="WebRealm">
  <user name="Bob" password="bobpwd" />
</basicRegistry>
```

2. Optional: Grant the user or group the Administrator role if the user, or group of users, is used to perform remote system management activities. This step is done automatically when using the quickStartSecurity element or may be accomplished by adding the administrator-role element to the server.xml file as shown.

```
<administrator-role>
  <user>Bob</user>
  <group>myAdmins</group>
</administrator-role>
```

3. Encode the password within the configuration. You can get the encoded value by using the securityUtility encode task.
4. Optional: Add additional users. Make sure that each user name is unique.

```
<basicRegistry id="basic" realm="WebRealm">
  <user name="Bob" password="bobpwd" />
  <user name="user1" password="user1pwd" />
  <user name="user2" password="user2pwd" />
</basicRegistry>
```

5. Create groups for users. Make sure that each group name must be unique.

```
<basicRegistry id="basic" realm="WebRealm">
  <user name="Bob" password="bobpwd" />
  <user name="user1" password="user1pwd" />
  <user name="user2" password="user2pwd" />

  <group name="myAdmins">
    <member name="Bob" />
    <member name="user1" />
  </group>

  <group name="users">
```

```

        <member name="user1" />
        <member name="user2" />
    </group>
</basicRegistry>

```

6. Assign some users and groups to the testing role of an application.

```

<application type="war" id="myWebApp" name="myWebApp"
    location="{server.config.dir}/apps/myWebApp.war">
    <application-bnd>
        <security-role name="testing">
            <user name="Bob" />
            <user name="user1" />
            <group name="users" />
        </security-role>
    </application-bnd>
</application>

```

## What to do next

Configure security-related elements in the deployment descriptor of your application. See “Getting started with security in Liberty” on page 1829 for a sample `web.xml` file.

---

## Securing communications in Liberty

You can configure the Liberty server to provide secure communications between a client and the server.

### About this task

Communications are secured with Secure Sockets Layer (SSL) protocol. The SSL protocol provides transport layer security including authenticity, data signing, and data encryption to ensure a secure connection between a client and server that uses WebSphere® Application Server. The foundation technology for SSL is public key cryptography, which guarantees that when an entity encrypts data using its public key, only entities with the corresponding private key can decrypt that data. The Liberty Server uses Java Secure Sockets Extension (JSSE) as the SSL implementation for secure connections. JSSE handles the handshake negotiation and protection capabilities that are provided by SSL to ensure that secure connectivity exists across most protocols. JSSE relies on X.509 certificate-based asymmetric key pairs for secure connection protection and some data encryption. Key pairs effectively encrypt session-based secret keys that encrypt larger blocks of data. The SSL implementation manages the X.509 certificates.

To configure secure communications, you can either specify a minimal SSL configuration or a detailed SSL configuration in the `server.xml` file. The minimal configuration only requires the SSL feature and a keystore entry to be specified. **8.5.5.0** There are several security configuration examples on the `WASdev.net` website for reference when configuring security for your applications on Liberty.

**8.5.0.1** The SSL configuration that is designated as the default SSL configuration is used to create the process's default `SSLContext` using the `SSLContext.setDefault()` method. The default SSL configuration can be the minimal SSL configuration, or the configuration that is identified by the `sslRef` attribute on the `sslDefault` element if multiple SSL configurations are defined. Because the default `SSLContext` is set on the process, the `javax.net.ssl.keyStore` and `javax.net.ssl.trustStore` properties will not be recognized.

### Procedure

- Enable SSL communications between a client and a Liberty server
- Optional: Create a keystore from the command prompt
- Optional: Encode passwords from the command prompt
- Optional: Configure client certificate authentication between your application and the Liberty server

## Enabling SSL communication in Liberty

To enable SSL communication in Liberty, there is a minimal set of SSL configuration options. It assumes most of the SSL options require some keystore configuration information.

### About this task

SSL client authentication occurs during the connection handshake by using SSL certificates. The SSL handshake is a series of messages that are exchanged over the SSL protocol to negotiate for connection-specific protection. During the handshake, the secure server requests that the client send back a certificate or certificate chain for the authentication. To enable SSL in Liberty, you add the `ssl-1.0` Liberty feature to the configuration root document file, `server.xml`, along with code of the keystore information for authentication.

By default, the path and file name for the configuration root document file is `path_to_liberty/wlp/usr/servers/server_name/server.xml`. `path_to_liberty` is the location that you installed Liberty on your operating system, and `server_name` is the name of your server. However, you can change the path. See “Customizing the Liberty environment” on page 1565.

### Procedure

1. Enable the `ssl-1.0` Liberty feature in the `server.xml` file.

```
<featureManager>
  <feature>ssl-1.0</feature>
</featureManager>
```

**Note:** If application security is required and security information is redirected to a secure port, you must add the `appSecurity-2.0` Liberty feature to the `server.xml` file.

2. Add the keystore service object entry to the `server.xml` file. The `keyStore` element is called `defaultKeyStore` and contains the keystore password. The password can be entered in clear text or encoded. The `securityUtility encode` option can be used to encode the password.

```
<keyStore id="defaultKeyStore" password="yourPassword" />
```

This configuration is the minimum that is needed to create an SSL configuration. In this configuration, the server creates the keystore and certificate if it does not exist during SSL initialization. The password that is provided must be at least 6 characters long. The keystore is assumed to be a JKS keystore that is called `key.jks` in the server `home/resources/security` directory. If the file does not exist the server creates it for you. If the server creates the keystore file, it also creates the certificate inside of it. The certificate is a self-signed certificate with a validity period of 365 days, the CN value of the certificate's subjectDN is the host name of the machine where the server is running, and has a signature algorithm of `SHA256withRSA`.

**Note:** When the use of a collective controller is not practical, perhaps there is only one or two Liberty servers, a self-signed certificate can be used to restrict the number of clients that can connect to the Liberty member server. It is suggested that an IHS server is used in front of the Liberty servers, where an appropriate CA signed certificate can be used, along with CN whitelisting to control which clients can connect to HIS. A trusted channel between IHS and the Liberty member server can be maintained by using the self signed certificate.

An example of a SAF keyring in the minimal configuration:

```
<keyStore id="defaultKeyStore" location="safkeyring:///WASKeyring"
  type="JCERACFKS" password="password" fileBased="false"
  readOnly="true" />
```

RACF keyring needs to be set up before you configure them for use by the Liberty server. The server does not create certificates and add them to RACF.

The single keystore entry for a minimal SSL configuration can be extended to include the location and type as well.

```
<keyStore id="defaultKeyStore" location="myKeyStore.p12" password="yourPassword" type="PKCS12"/>
```

The **location** parameter can be an absolute path to the keystore file. If it is an absolute path, then the keystore file is assumed to have been already created. Keystore of other types can also be specified in the minimal SSL configuration if the keystore file is already created. When the minimal SSL configuration is used, the SSL configuration defaults are used to create the SSL context for an SSL handshake. The configuration protocol is `SSL_TLS` by default. The HIGH ciphers, 128 bit, and higher cipher suites can be used.

## Liberty:SSL configuration attributes

SSL configurations contain attributes that you use to control the behavior of the server SSL transport layer on Liberty. This topic iterates all the settings available for an SSL configuration.

### SSL Feature

To enable SSL on a server, the SSL feature must be included in the `server.xml` file:

```
<featureManager>
  <feature>ssl-1.0</feature>
</featureManager>
```

### SSL Default

You can have multiple SSL configurations configured. If more than one SSL configuration is configured, then the default SSL configuration must be specified in the `server.xml` file that uses the `sslDefault` service configuration.

*Table 127. Attribute of the `sslDefault` element.* This table describes the attribute of the `sslDefault` element.

Attribute	Description	Default Value
<b>sslRef</b>	The <code>sslRef</code> attribute specifies the name of the SSL configuration to be used as the default.	The default SSL Configuration name is <code>defaultSSLConfig</code> .

In the `server.xml` file, the entry is as follows:

```
<sslDefault sslRef="mySSLSettings" />
```

### SSL Configuration

You use the SSL configuration attributes to customize the SSL environment to suit your needs. These attributes can be set on the `ssl` service configuration element in the `server.xml` file.

*Table 128. Attributes of the `SSL` element.* This table describes the attributes of the `ssl` element.

Attribute	Description	Default Value
<b>id</b>	The <code>id</code> attribute assigns a unique name to the SSL configuration object.	No default value; a unique name must be specified.
<b>keyStoreRef</b>	The <code>keyStoreRef</code> attribute names the keystore service object that defines the SSL configurations keystore. The keystore holds the key that is required to make an SSL connection.	No default value; a keystore reference must be specified.
<b>trustStoreRef</b>	The <code>trustStoreRef</code> attribute names the keystore service object that defines the SSL configurations truststore. The truststore holds certificates that are required for signing verification.	<code>trustStoreRef</code> is an optional attribute. If the reference is missing, the keystore that is specified by <code>keyStoreRef</code> is used.

Table 128. Attributes of the SSL element (continued). This table describes the attributes of the ssl element.

Attribute	Description	Default Value
<b>clientAuthentication</b>	The <b>clientAuthentication</b> attribute determines whether SSL client authentication is required.	Default value is <b>false</b> .
<b>clientAuthenticationSupported</b>	The <b>clientAuthenticationSupported</b> attribute determines whether SSL client authentication is supported. The client does not have to supply a client certificate. If the <b>clientAuthentication</b> attribute is set to true, the value of the <b>clientAuthenticationSupported</b> attribute is overwritten.	Default value is <b>false</b> .
<b>sslProtocol</b>	The <b>sslProtocol</b> attribute defines the SSL handshake protocol. The protocol can be SDK-dependent, so if you modify the protocol make sure that the value is supported by the SDK you are running under.	Default value is <b>SSL_TLS</b> .
<b>securityLevel</b>	The <b>securityLevel</b> attribute determines the cipher suite group to be used by the SSL handshake. The attribute has one of the following values: <ul style="list-style-type: none"> <li>• <b>HIGH</b> (128-bit ciphers and higher)</li> <li>• <b>MEDIUM</b> (40-bit ciphers)</li> <li>• <b>WEAK</b> (for all ciphers without encryption)</li> <li>• <b>CUSTOM</b> (if the cipher suite group is customized).</li> </ul> When you set the <b>enabledCiphers</b> attribute with a specific list of ciphers, the system ignores this attribute.	Default value is <b>HIGH</b> .
<b>enabledCiphers</b>	The <b>enabledCiphers</b> attribute is used to specify a unique list of cipher suites. Separate each cipher suite in the list with a space. If the <b>enabledCiphers</b> attribute is set, then the <b>securityLevel</b> attribute is ignored.	No default value.
<b>serverKeyAlias</b>	The <b>serverKeyAlias</b> attribute names the key in the keystore to be used as the SSL configurations key. This attribute is only required if the keystore has more than one key entry in it. If the keystore has more than one key entry and this attribute does not specify a key, then the JSSE picks a key.	No default value.
<b>clientKeyAlias</b>	The <b>clientKeyAlias</b> attribute names the key in the keystore to be used as the key for SSL configuration when <b>clientAuthentication</b> is enabled. The attribute is only required if the keystore contains more than 1 key entry.	No default value.

Note:

- The key manager is used by the SSL handshake to determine what certificate alias to use. The key manager is not configured in the `server.xml` file. It is retrieved from the security property `ssl.KeyManagerFactory.algorithm` of the SDK.
- The trust manager is used by the SSL handshake to make trust decisions. The trust manager is not configured in the `server.xml` file. It is retrieved from the security property `ssl.TrustManagerFactory.algorithm` of the SDK.

Here is an example of how the `ssl` element is configured in the `server.xml` file:

```
<!-- Simple ssl configuration service object. This assumes there is a keystore object named -->
<!-- defaultKeyStore and a truststore object named defaultTrustStore in the server.xml file. -->
  <ssl id="myDefaultSSLConfig"
      keyStoreRef="defaultKeyStore"
      trustStoreRef="defaultTrustStore" />
```

```
<!-- A ssl configuration service object that enabled clientAuthentication -->
<!-- and specifies the TLS protocol be used. -->
  <ssl id="myDefaultSSLConfig"
      keyStoreRef="defaultKeyStore"
      trustStoreRef="defaultTrustStore"
      clientAuthentication="true"
      sslProtocol="TLS" />
```

```
<!-- An SSL configuration service object that names the serverKeyAlias -->
<!-- to be used by the handshake. This assumes there is a certificate -->
<!-- called "default" in the keystore defined by keyStoreRef. -->
  <ssl id="myDefaultSSLConfig"
      keyStoreRef="defaultKeyStore"
      serverKeyAlias="default" />
```

## Keystore Configuration

The keystore configuration consists of the attributes that are required to load a keystore. These attributes can be set on the keystore service configuration in the `server.xml` file.

*Table 129. Attributes of the keystore element.* This table explains the attributes of the keystore element.

Attribute	Description	Default Value
<b>id</b>	The <b>id</b> attribute defines a unique identifier of the keystore object.	No default value, a unique name must be specified.
<b>location</b>	The <b>location</b> attribute specifies the keystore file name. The value can include the absolute path to the file. If the absolute path is not provided, then the code looks for the file in the <code>\${server.config.dir}/resources/security</code> directory.	In the SSL minimal configuration, the location of the file is assumed to be <code>\${server.config.dir}/resources/security/key.jks</code> .
<b>type</b>	The <b>type</b> attribute specifies the type of the keystore. Check that the keystore type that you specify is supported by the SDK you are running on.	Default value is <b>jks</b> .

Table 129. Attributes of the keystore element (continued). This table explains the attributes of the keystore element.

Attribute	Description	Default Value
<b>password</b>	The <b>password</b> attribute specifies the password that is used to load the keystore file. The password can be stored either in clear text or encoded. For information about how to encode the password, see the securityUtility encode option.	Must be provided.
<b>provider</b>	The <b>provider</b> attribute specifies the provider to be used to load the keystore. Some keystore types required a provider other than the SDK default.	By default no provider is specified.
<b>fileBased</b>	The <b>fileBased</b> attribute specifies whether the keystore is file-based.	Default value is <b>true</b> .
<b>pollingRate</b>	The rate at which the server checks for updates to a keystore file.	<b>500ms</b> .
<b>updateTrigger</b>	The method that is used to trigger the server to reload a keystore file. Specify <b>polled</b> to enable the server for checking the keystore file for changes, <b>mbean</b> to enable the server to wait for an mbean to reload the keystore file, or <b>disabled</b> to disable file monitoring.	<b>disabled</b> .

Keystore files can be reloaded by the server if the **updateTrigger** attribute is set to **polled** or **mbean**. If **polled** is enabled, then the server monitors the keystore file for changes based on the rate set in the **pollingRate** attribute. If the **updateTrigger** attribute is set to **mbean** then the server will reload the keystore file when it receives notification from the `WebSphere:service=com.ibm.ws.kernel.filemonitor.FileNotificationMBean` MBean. File monitoring is disabled by default.

Here is an example of how the keystore element is configured in the `server.xml` file:

```
<!-- A keystore object called defaultKeyStore provides a location, -->
<!-- type, and password. The MyKeyStoreFile.jks file is assumed -->
<!-- to be located in ${server.config.dir}/resources/security -->
<!-- This keystore is configured to be monitored every 5 seconds -->
<!-- for updates -->
  <keyStore id="defaultKeyStore"
    location="MyKeyStoreFile.jks"
    type="JKS" password="myPassword"
    pollingRate="5s"
    updateTrigger="polled" />

<!-- A keystore object called defaultKeyStore provides a location, -->
<!-- type, and password. The MyKeyStoreFile.jks file is assumed -->
<!-- to be located in ${server.config.dir}/resources/security -->
<!-- This keystore is configured to be reloaded when the server -->
<!-- recieves an mbean notification to do so -->
  <keyStore id="defaultKeyStore"
    location="MyKeyStoreFile.jks"
    type="JKS" password="myPassword"
    updateTrigger="mbean" />
```

## Full SSL Configuration Example

Here is an example of a full SSL configuration in the `server.xml` file. This example has the following SSL configurations:

- `defaultSSLSettings`
- `mySSLSettings`

By default, the SSL configuration is set to `defaultSSLConfig`.

```
<featureManager>
  <feature>ssl-1.0</feature>
</featureManager>

<!-- default SSL configuration is defaultSSLSettings -->
<sslDefault sslRef="defaultSSLSettings" />
<ssl id="defaultSSLSettings"
  keyStoreRef="defaultKeyStore"
  trustStoreRef="defaultTrustStore"
  clientAuthenticationSupported="true" />
<keyStore id="defaultKeyStore"
  location="key.jks"
  type="JKS" password="defaultPWD" />
<keyStore id="defaultTrustStore"
  location="trust.jks"
  type="JKS" password="defaultPWD" />

<ssl id="mySSLSettings"
  keyStoreRef="myKeyStore"
  trustStoreRef="myTrustStore"
  clientAuthentication="true" />
<keyStore id="LDAPKeyStore"
  location="{server.config.dir}/myKey.p12"
  type="PKCS12"
  password="{xor}CDo9Hgw=" />
<keyStore id="LDAPTrustStore"
  location="{server.config.dir}/myTrust.p12"
  type="PKCS12"
  password="{xor}CDo9Hgw=" />
```

## Liberty:Keystores

Liberty can create only a keystore type of Java Keystore (JKS). Support for other types of keystore in Liberty can depend on what is supported by the underlying Java Runtime Environment (JRE). The following are the different keystore types in Liberty.

For more information on configuration attributes of the keystore element, see “Liberty:SSL configuration attributes” on page 1835.

## JKS and JCEKS

Java Keystore (JKS) and Java Cryptography Extensions Keystore (JCEKS) are common between the IBM JRE and the Oracle JRE, and can be configured the same using either JRE. JKS is the default keystore type in Liberty, and the only type of keystore Liberty can create. If no keystore type is specified in the configuration, JKS is used.

An example of JKS keystore configuration is as follows:

```
<keyStore id="sampleJKSKeyStore"
  location="MyKeyStoreFile.jks"
  type="JKS" password="myPassword" />
```

An example of JCEKS keystore configuration is as follows:

```
<keyStore id="sampleJCEKSKeyStore"
  location="MyKeyStoreFile.jceks"
  type="JCEKS" password="myPassword" />
```

8.5.5.9

## PKCS11 keystore

A hardware cryptographic keystore can be configured so that the Liberty server can be used to provide cryptographic token support.

The user must provide a hardware device-specific configuration file. The configuration file is a text file that contains entries in the format of `attribute = value`. The file must contain at least the name and library attribute. For example:

```
name = HWDevice
library = /opt/foo/lib/libpkcs11.so
```

The name attribute is a name that is being given to this instance of the device. The library attribute contains a path to the library provided by the hardware device to access the device. The configuration file can also contain configuration data specific to the hardware device.

To configure a PKCS11 keystore in Liberty the keystore element must contain the following fields:

- `id` - Uniquely identify the keystore element in the configuration.
- `location` - The path to the hardware device-specific configuration file.
- `type` - PKCS11 must be specified as the keystore type.
- `fileBased` - Must be false to identify this keystore as a device.
- `password` - Password that is needed to access keys in the device.
- `provider` - The provider that is needed. For the IBM JRE, the value must be `IBMPKCS11Impl` and for Oracle JRE it must be `SunPKCS11`.

Here is an example configuration:

```
<keyStore id="hwKeyStore"
  location="${server.config.dir}/HWCrypto.cfg"
  type="PKCS11"
  fileBased="false"
  password="{xor}Lz4sLCgwLTs="
  provider="IBMPKCS11Impl"/>
```

## PKCS12 keystore

Public Key Cryptography Standards #12 (PKCS12) keystore can be used, but not created by Liberty, when you use the IBM JRE. An example of PKCS12 keystore configuration is as follows:

```
<keyStore id="samplePKCS12KeyStore"
  location="MyKeyStoreFile.p12"
  type="PKCS12" password="myPassword" />
```

## CMS keystore

CMS keystore can be configured, but not created by Liberty, when you use the IBM JRE. However, some special configuration is required. The CMS provider is not available by default on the IBM JRE, therefore it must be added to the provider list in the `java.security` file of the IBM JRE. In the following example, the `com.ibm.security.cmskeystore.CMSProvider` class is added to the end of the list. Ensure that the provider number is correct in the provider list. Liberty does not use the CMS keystore stash file to gain access to the keystore.

```

security.provider.1=com.ibm.jsse2.IBMJSSEProvider2
security.provider.2=com.ibm.crypto.provider.IBMJCE
security.provider.3=com.ibm.security.jgss.IBMJGSSProvider
security.provider.4=com.ibm.security.cert.IBMCertPath
security.provider.5=com.ibm.security.sasl.IBMSASL
security.provider.6=com.ibm.xml.crypto.IBMXMLCryptoProvider
security.provider.7=com.ibm.xml.enc.IBMXMLEncProvider
security.provider.8=org.apache.harmony.security.provider.PolicyProvider
security.provider.9=com.ibm.security.jgss.mech.spnego.IBMSPNego
security.provider.10=com.ibm.security.cmskeystore.CMSProvider

```

To use the CMS keystore, the configuration in the `server.xml` file is as follows:

```

<keyStore id="sampleCMSKeyStore"
password="myPassword"
location="MyKeyStoreFile.kdb"
provider="IBMCMSProvider"
type="CMSKS"/>

```

z/OS

## RACF keyring types

RACF keyrings can be used, but not created by Liberty, as keystores on z/OS. The two keyring types that are available are JCERACFKS and JCEHYBRIDRACFKS.

### JCERACFKS keystore

JCERACFKS is a RACF keyring type. You must set up RACF before Liberty can use it. Supply a URL to the keyring in the `location` attribute, and set the `fileBased` attribute to `false`.

An example of using the JCERACFKS keystore is as follows:

```

<keyStore id="sampleKeyring" location="safkeyring:///Keyring"
type="JCERACFKS" password="password" fileBased="false"
readOnly="true" />

```

### JCEHYBRIDRACFKS keystore

JCEHYBRIDRACFKS is a special keyring that checks whether a hardware keystore type is configured. If the JCEHYBRIDRACFKS keystore is not configured, the RACF keyring is used. It is supported on IBM Java 7 SR3 and later. You must edit the `java.security` file and add the `com.ibm.crypto.ibmjcehybrid.provider.IBMJCEHYBRID` class to the top of the provider list. Ensure that the provider numbers are adjusted for the new entry.

An example of using the JCEHYBRIDRACFKS keystore is as follows:

```

<keyStore id="sampleHybridKeyring" location="safkeyringhybrid:///HybridKeyring"
type="JCEHYBRIDRACFKS" password="{xor}Lz4sLCgwLTs=" fileBased="false"
readOnly="true" />

```

## Enabling the IBM JCE Hybrid Provider for Liberty

The IBM JCE Hybrid Provider `IBMJCEHYBRID`, is for use by an application that is designed to use cryptographic hardware and processors when they are available, but continues without those cryptographic features when they are not available. Using the `IBMJCEHYBRID` provider enables an application to take advantage of JCE providers without having to include complex error handling for when cryptographic features are not available.

### Before you begin

Ensure that the `IBMJDK` running on z/OS is at Java 7 SR3 or later.

## | About this task

| The IBMJCEHYBRID provider does not do any cryptographic operations, but routes requests to JCE providers registered with the Java Security Framework. The IBMJCEHYBRID provider must be the first JCE provider in the active JVM provider list, which is initialized from the `java.security` provider list. The IBMJCEHYBRID provider routes requests to, and provides failover for, JCE providers according to the security provider registrations done at JVM initialization. This function enables an application to take advantage of cryptographic features when they are available and to use a provider that does not depend on these features when they are not available.

## | Procedure

1. Add the provider to the `java.security` file with the hardware cryptographic provider.

```
security.provider.1=com.ibm.jsse2.IBMJSSEProvider2
security.provider.2=com.ibm.crypto.ibmjcehybrid.provider.IBMJCEHYBRID
security.provider.3=com.ibm.crypto.hwcca.provider.IBMJCECCA
security.provider.4=com.ibm.crypto.provider.IBMJCE
security.provider.5=com.ibm.security.jgss.IBMJGSSProvider
security.provider.6=com.ibm.security.cert.IBMCertPath
security.provider.7=com.ibm.security.sasl.IBMSASL
```
2. Configure the keyring in `file server.xml` to set the location to use `safkeyringhybrid`, and the type to `JCEHYBRIDRACFKS`. The following example shows the definition of a minimal SSL configuration keystore.

```
<keyStore id="defaultKeyStore" location="safkeyringhybrid:///mykeyring" type="JCEHYBRIDRACFKS"
password="{<u>xor</u>Lz4sLCgwTs=" fileBased="false" readOnly="true"/>
```

## | SSL defaults in Liberty

8.5.5.7

Specifies the default SSL certificate, keystore, and configuration in Liberty.

### Default Certificate and keystore

As a convenience tool to help developers get up and running, users can use the **createSSLCertificate** parameter in the **securityUtility** command to create self-signed certificates. Users can either call the tool directly from the command line or let the server call it to create the default certificate and keystore on server startup.

The server creates the default keystore and certificate if a user has a keystore element that is called `defaultKeyStore` in the `server.xml` file. For example:

```
<keyStore id="defaultKeyStore" password="yourPassword" />
```

If a keystore configuration for the `defaultKeyStore` is in place and the keystore does not exist when the server starts, the server calls the **createSSLCertificate** parameter to create the keystore with a password that is specified in the configuration.

Default keystore details:

- Location: The keystore file is called `key.jks` and is in the `server` or `clients` `resources/security` directory.
- Keystore type: The keystore type is `JKS`.
- Password: Password that is provided in the configuration.

Default certificate that is created by Liberty details:

- Type: The certificate is a self-signed certificate.
- Size: The default certificate size is 2048.
- Signature algorithm: The signature algorithm for the certificate is `SHA256WITHRSA`.

- Validity: The certificate is valid for 365 days.
- SubjectDN: The certificate gets created with CN=<hostname>,OU=<client or server name>,O=ibm,C=US as the SubjectDN.

The **createSSLCertificate** parameter can be called on the command line if users would like to customize the certificate.

**Note:** When the use of a collective controller is not practical, perhaps there is only one or two Liberty servers, a self-signed certificate can be used to restrict the number of clients that can connect to the Liberty member server. It is suggested that an IHS server is used in front of the Liberty servers, where an appropriate CA signed certificate can be used, along with CN whitelisting to control which clients can connect to HIS. A trusted channel between IHS and the Liberty Member server can be maintained by using the self signed certificate.

## Default SSL configuration

The minimal configuration that is needed for SSL is a single keystore element called `defaultKeyStore`. When the `defaultKeyStore` exists in the configuration the run time builds an SSL configuration that is called `defaultSSLConfig` around it.

`defaultSSLConfig` details:

- Protocol: When the IBM JRE is used, the protocol is set to `SSL_TLS` by default. If the Oracle JRE is used SSL is used as the protocol.
- Ciphers: The cipher list is built by getting a list of supported ciphers from the underlying JRE. By default the list is reduced to all the ciphers that are 128 bit and higher or 3DES. RC4 is removed because they are not considered safe to have enabled. ECDHE ciphers are removed because they can cause errors if you are going to a server that does not support them. The cipher list can be customized to include them.
- Client authentication: By default `clientAuthentication` and `clientAuthenticationSupported` are disabled.
- Keystore: In the default configuration `defaultKeyStore` is used as both the key and truststore.

An `ssl` element that is called `defaultSSLConfig` can be entered in the `server.xml` file for customization of the SSL configuration properties. A customized `ssl` element that is called `defaultSSLConfig` is still treated like the default SSL configuration as long as a different SSL configuration has not been identified as the default. For more information on attributes that can be used to customize an SSL configuration, see `SSL configuration attributes`.

To designate a different `ssl` element in the configuration as the default SSL configuration, users can identify that with the `sslDefault` element.

```
<sslDefault sslRef="customSSLConfiguration" />
```

The attributes from the Liberty default SSL configuration are used to create an `SSLContext`. That `SSLContext` is set on the process as the default `SSLContext` by using the Java API `SSLContext.setDefault()`. If an application makes a call to an API like `URLConnection()` with an `https` URL and does not provide any SSL information, then the application picks up the default `SSLContext` of the process and in this case is the `SSLContext` that is created with the Liberty default SSL configuration.

If there is no default SSL configuration in Liberty, then the JSSE's default `SSLContext` is used. The JSSE's default `SSLContext` uses the `cacerts` file for the keystore and truststore. There is no default SSL configuration in Liberty if there is no SSL feature that is defined or if the SSL configuration that exists is not identified as the default. The default configuration is either the called `defaultSSLConfig`, which can be implicit if a `defaultKeyStore` is defined or an alternative SSL configuration can be designated by using the `sslDefault` element.

The `javax` system properties, `javax.net.ssl.keystore`, is used to set up the keystore and truststore information for the default SSL context and must not be used. If the properties are set on the process, then the call to `SSLContext.setDefault()` wipes them out.

## Creating SSL certificates for your Liberty using the Utilities menu

Using the Liberty Utilities menu in the developer tools, you can create an SSL certificate.

### Procedure

1. In the Servers view, right-click your Liberty server, and select **Utilities > Create SSL Certificate**.
2. On the Create SSL Certificate page, you can create a default secure socket layer (SSL) certificate to use with your server.
  - a. In the **Keystore password** field, type a password for your SSL certificate.
  - b. Click the **Specify validity period (days)** field, and specify the number of days you want the certificate to be valid for. Minimum length of time is 365 days.
  - c. Click the **Specify subject (DN):** field, and provide a value for your SSL subject.
3. Click **Finish**.

## Creating SSL certificates from the command line

You can use the `securityUtility` command to create a default SSL certificate for use by the Liberty configuration.

### Procedure

1. Open a command line, then change directory to the `wlp/bin` directory.
2. Create an SSL certificate.

Run the following command. If you do not specify a server name or a password, the command does not run. See “Liberty:securityUtility command.”

```
securityUtility createSSLCertificate --server=server_name --password=your_password
```

### Results

You have created a default keystore `key.jks` for the specified server. The keystore file is located under the `/resources/security` directory of the specified server. If a default keystore already exists, the command does not execute successfully.

### What to do next

You can configure your server to use the keystore and enable the SSL in the server configuration by adding the following lines to the server configuration file:

```
<featureManager>  
  <feature>ssl-1.0</feature>  
</featureManager>  
  
<keyStore id="defaultKeyStore" password="keystore_password" />
```

See “Enabling SSL communication in Liberty” on page 1834.

### Liberty:securityUtility command

The `securityUtility` command supports plain text encryption and SSL certificate creation for Liberty.

### Syntax

The command syntax is as follows:

```
securityUtility task [options]
```

Where the **options** are different based on the value of **task**.

## Parameters

The following tasks are available for the `securityUtility` command:

### encode

Encodes the provided *text* by using Base64. If no options are specified, the command enters interactive mode. Otherwise, the provided *text* is encoded. If the *text* includes spaces it must be put in quotation marks.

#### 8.5.5.0

The options are:

#### **--encoding=encoding\_type**

Specifies how to encode the password. Supported encodings are `xor`, `aes`, and `hash`. If this option is not provided, the default is `xor`.

**Note:** The hash encoding option is used for encoding passwords for the basic user registry only.

#### **--key=encryption\_key**

Specifies the key to be used when encoding using AES encryption. This string is hashed to produce an encryption key that is used to encrypt and decrypt the password. The key can be provided to the server by defining the variable `wlp.password.encryption.key` whose value is the key. If this option is not provided, a default key is used.

#### **--notrim**

Specify whether space characters are removed from the beginning and end of the specified text. If this option is specified, the provided text is encoded as it is. If this option is not specified, space characters from the beginning and end of the specified text is removed.

*text* The text that is to be encoded.

See also “Liberty: The limits to protection through password encryption” on page 1009.

### createSSLCertificate

Creates a default keystore including an SSL certificate for use in a server or client configuration.

#### 8.5.5.6

#### **Keystore details:**

location: In the server's or client's directory under `resource/security/key.jks`.

type: JKS

password: Password provided with the `--password` option. The password is needed to open the keystore file and retrieve the key from the keystore file.

#### 8.5.5.6

#### **Certificate details:**

type: Self-signed certificate

size: 2048 by default, alternate size can be specified with the `--keySize` option.

signature algorithm: SHA256withRSA, can be customized with the `--sigAlg` option.

validity: 365 days by default, can be customized with the `--validity` option.

SubjectDN: CN=<hostname>,OU=<client or server name>,O=ibm,C=us by default, can be customized with the `--subject` option.

The options are:

**8.5.5.6 --server=name**

Specifies the name of the Liberty server for which the keystore and certificate is created. This option cannot be used if the `--client` option is specified.

**8.5.5.6 --client=name**

Specifies the name of the Liberty client for which the keystore and certificate is created. This option cannot be used if the `--server` option is specified.

**8.5.5.6 --keySize=size**

Specifies the certificate key bit size. The default value is 2048.

**--password=password**

Specifies the password to be used in the keystore, which must be at least 6 characters in length. This option is required.

**--passwordEncoding=password\_encoding\_type**

Specifies how to encode the keystore password. Supported encoding value is `xor` or `aes`. If this option is not provided, a default value of `xor` is used.

**--passwordkey=password\_encryption\_key**

Specifies the key to use to encode the keystore password by using AES encryption. This string is hashed to produce an encryption key that is used to encrypt and decrypt the password. The key can be provided to the server by defining the variable `wlp.password.encryption.key` whose value is the key. If this option is not provided, a default key is used.

**--validity=days**

Specifies the number of days that the certificate is valid, which must be equal to or greater than 365. If this option is not provided, a default value of 365 is used.

**8.5.5.6 --subject=DN**

Specifies the Distinguished Name (DN) for the certificate subject and issuer. If this option is not provided, a default value of `CN=<hostname>,OU=<server or client name>,O=ibm,C=us` is used. The CN value is retrieved by using a java method to get the machine's local host name. If the host name cannot be resolved, the IP address is returned.

**8.5.5.7 --sigAlg**

Specifies the signature algorithm that is used to sign the self-signed certificate. The signature algorithm that is supported depends on what is supported by the underlying JRE. Stronger signature algorithms might require the JRE to have the unrestricted policy file in place.

The command accepts `SHA256withRSA` (default), `SHA1withRSA`, `SHA384withRSA`, `SHA512withRSA`, `SHA1withECDSA`, `SHA256withECDSA`, `SHA384withECDSA`, and `SHA512withECDSA`. The signature algorithms that end with `RSA` creates certificates with `RSA` keys and those that end with `ECDSA` creates certificates with `Elliptical Curve (EC)` keys.

**Note:** If you are using certificates that are created with `EC` keys, then your server needs a customized ciphers list in the `ssl` configuration to include `EC` ciphers.

**help** Prints help information for a specified task.

## Usage

The following examples demonstrate correct syntax:

```
securityUtility encode
```

### 8.5.5.0

```
--encoding=aes GiveMeLiberty securityUtility createSSLCertificate --server=myserver  
--password=myspassword --validity=365 --subject=CN=mycompany,O=myOrg,C=myCountry  
securityUtility help createSSLCertificate
```

#### CAUTION:

Different operating system might treat some characters differently. For the Windows environment, if you have ! in your input string, it needs to be escaped by the ^ character. For example,

```
D:\Liberty\images\855\Liberty855\wlp\bin>securityUtility encode "a^!"
```

## Configuring your web application and server for client certificate authentication

You can configure your web application on Liberty using SSL client authentication.

### Before you begin

This topic assumes that you have already created the SSL certificates, for example as described in “Creating SSL certificates from the command line” on page 1844.

### About this task

Client certificate authentication occurs if the server-side requests that the client-side send a certificate. A WebSphere server can be configured for client certificate authentication on the SSL configuration. To do this, you add the `ssl-1.0` Liberty feature to the `server.xml` file, along with code that tells the server the keystore information for authentication.

For details of which aspects of SSL are supported, see “Liberty features” on page 826.

### Procedure

1. Ensure that the deployment descriptor for your web application specifies client certificate authentication as the authentication method to use.

Check that the deployment descriptor includes the following element:

```
<auth-method>CLIENT-CERT</auth-method>
```

**Note:** You can use a tool such as Rational Application Developer to create the deployment descriptor.

2. Optional: Generate an SSL certificate using the command line. See “Liberty:securityUtility command” on page 1844.
3. Configure your server to enable SSL client authentication by adding the following lines to the `server.xml` file:

```
<featureManager>  
  <feature>ssl-1.0</feature>  
</featureManager>  
  
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore"  
  trustStoreRef="defaultTrustStore" clientAuthenticationSupported="true" />  
<keyStore id="defaultKeyStore" location="key.jks" type="JKS" password="defaultPWD" />  
<keyStore id="defaultTrustStore" location="trust.jks" type="JKS" password="defaultPWD" />
```

- If you specify `clientAuthentication="true"`, the server requests that a client sends a certificate. However, if the client does not have a certificate, or the certificate is not trusted by the server, the handshake does not succeed.
- If you specify `clientAuthenticationSupported="true"`, the server requests that a client sends a certificate. However, if the client does not have a certificate, or the certificate is not trusted by the server, the handshake might still succeed.

- If you do not specify either `clientAuthentication` or `clientAuthenticationSupported`, or you specify `clientAuthentication="false"` or `clientAuthenticationSupported="false"`, the server does not request that a client send a certificate during the handshake.
4. Add a client certificate to your browser. See the documentation of your browser for adding client certificates.
  5. Make sure the server trusts any client certificates that are used.
  6. Make sure any client certificates used for client authentication are mapped to a user identity in your registry.
    - For the basic registry, the user identity is the common name (CN) from the distinguished name (DN) of the certificate.
    - For a Lightweight Directory Access Protocol (LDAP) registry, the DN from the client certificate must be in the LDAP registry.
  7. To use basic authentication, user ID and password only, if client certificate authentication does not succeed, add the following line to your `server.xml` file.
 

```
<webAppSecurity allowFailOverToBasicAuth="true" />
```

**Note:** If you specify `allowFailOverToBasicAuth="false"` or do not specify `allowFailOverToBasicAuth`, and the client certificate authentication does not succeed, the request generates a 403 Authentication error message, and the client is not prompted for basic authentication.

## Setting up Liberty to run in SP800-131a

8.5.5.0

You can set up Liberty to meet the SP800-131a requirement that is originated by the National Institute of Standards and Technology (NIST).

### About this task

SP800-131a requires longer key lengths and stronger cryptography. The specification also provides a configuration that enables users to move to a strict enforcement of SP800-131a. The configuration also enables users to run with a mixture of settings from both FIPS140-2 and SP800-131a. SP800-131a can be run in two modes, transition and strict. The transition mode is offered to give user a setting to move their environment to SP800-131a strict mode. In transition mode, it is optional to use the SP800-131a required certificates and to set the protocol to SP800-131a

Strict enforcement of SP800-131a requirements on Liberty includes the following:

- The use of the TLSv1.2 protocol for the Secure Sockets Layer (SSL) context.
- Certificates must have a minimum length of 2048. Elliptical Curve (EC) certificate require a minimum size of 244-bit curves.
- Certificates must be signed with a signature algorithm of SHA256, SHA384, or SHA512. Valid signatureAlgorithms include:
  - SHA256withRSA
  - SHA384withRSA
  - SHA512withRSA
  - SHA256withECDSA
  - SHA384withECDSA
  - SHA512withECDSA

**Note:** If SHA384withECDSA or SHA512withECDSA is used, the unrestricted policy file needs to be in place for the IBM JDK.

- SP800-131a approved Cipher suites.

**Note:** To configure a Liberty server to run in SP800-131a mode, users must be running with a level of the IBM JDK that supports SP800-131a. The minimal levels of the IBM JDK include Java 6 sr 10, Java 6.0.1 sr 2, or Java 7.

For more information about the SP800-131a standard, see the National Institute of Standards and Technology.

You can configure Liberty to run in SP800-131a strict mode or transition mode as following:

## Procedure

- Configure Liberty to run in SP800-131a strict mode.
  1. Make sure that you are running on a level of the IBM JDK that supports SP800-131a.
  2. Make sure that certificates of your server meet the criteria for SP800-131a.
    - Certificates have a minimum length of 2048 and Elliptical Curve (EC) certificates have a minimum size of 244-bit curve.
    - Certificates are signed with at least SHA256 or signed with one of the signature algorithms listed previously.
  3. Configure your SSL Configuration to use the TLSv1.2 protocol. See “Enabling SSL communication in Liberty” on page 1834 and “Liberty:SSL configuration attributes” on page 1835 for more details.
  4. When using collectives, if the `sslProtocol` is updated, two configuration changes must be made:
    - `${wlp.install.dir}/etc/server.env` must specify the `-Dhttps.protocols` property in order for the `${wlp.install.dir}/bin/collective` utility to successfully communicate with the controller.  
For example:

```
JVM_ARGS=-Dhttps.protocols=TLSv1.2
```
    - Each internal collective replication `ssl id` must be updated with the desired protocol.  
For Example:

```
<ssl id="controllerConnectionConfig" sslProtocol="TLSv1.2"/>
<ssl id="memberConnectionConfig" sslProtocol="TLSv1.2"/>
```
  5. Optional: If Elliptical Curve (EC) ciphers are required, list them in the **enabledCiphers** attribute. EC ciphers are not included when cipher lists are generated using the **securityLevel** attribute of the SSL Configuration. For the full list of ciphers, see the Java Technology Security information.
  6. The Java Secure Socket Extension (JSSE) is enabled to run in SP800-131a strict mode by setting the system property `com.ibm.jsse2.sp800-131` to *strict*. For example, `-Dcom.ibm.jsse2.sp800-131=strict`. See “Customizing the Liberty environment” on page 1565 for how to set system properties in the `jvm.options` file.
- Configure Liberty to run in SP800-131a transition mode.
  1. Make sure that you are running a level of the IBM JDK that support SP800-131a.
  2. Optional: If Elliptical Curve (EC) ciphers are required, list them in the **enabledCiphers** attribute. EC ciphers are not included when cipher lists are generated using the **securityLevel** attribute of the SSL Configuration. For the full list of ciphers, see the Java Technology Security information.
  3. The JSSE is enabled to run in SP800-131a transition mode by setting the system property `com.ibm.jsse2.sp800-131` to *transition*. For example, `-Dcom.ibm.jsse2.sp800-131=transition`. See “Customizing the Liberty environment” on page 1565 for how to set system properties in the `jvm.options` file.

**Note:** If you change your protocol to use TLSv1.2, make sure that your browser supports TLSv1.2.

## Configuring an httpEndpoint to use an SSL configuration other than the default

By default, an httpEndpoint element uses the server default SSL configuration, defaultSSLConfig. You can configure an httpEndpoint to use an SSL configuration other than the default SSL configuration.

### About this task

You can configure an httpEndpoint to use an SSL configuration in multiple ways. The following examples show different ways to configure an httpEndpoint to use an SSL configuration other than the default SSL configuration.

### Procedure

- Set the SSL options directly on the httpEndpoint. The following example shows how to set the SSL options on the httpEndpoint, and assumes that you have an SSL configuration that is named wasListenerSSLConfig already defined that is not in this example:

```
<httpEndpoint id="defaultHttpEndpoint"
  host="${listener.host}"
  httpPort="${http.port}"
  httpsPort="${https.port}">
  <sslOptions sslRef="wasListenerSSLConfig" />
</httpEndpoint>
```

- Reference an sslOption element in the httpEndpoint. The following example shows how to reference an sslOption element, and assumes that you have an SSL configuration that is named wasListenerSSLConfig already defined that is not in this example:

```
<sslOptions id="mySSLOptions" sslRef="wasListenerSSLConfig" />
```

```
<httpEndpoint id="defaultHttpEndpoint"
  host="${listener.host}"
  httpPort="${http.port}"
  httpsPort="${https.port}"
  sslOptionsRef="mySSLOptions"
/>
```

- Change the default sslOptions element to point to an SSL configuration other than the default SSL configuration. This option does not alter the httpEndpoint. The following example shows how to change the default sslOptions element, and assumes that you have an SSL configuration that is named wasListenerSSLConfig already defined that is not in this example:

```
<sslOptions id="defaultSSLOptions" sslRef="wasListenerSSLConfig" />
```

---

## Authenticating users in Liberty

The Liberty server uses a user registry to authenticate a user and retrieve information about users and groups to perform security-related operations, including authentication and authorization.

### About this task

To learn about how authentication works in Liberty, see “Liberty:Authentication” on page 976.

The authentication tasks that you can configure might vary depending on your requirements. Unless you have used the quickStartSecurity element that can configure only one user, you have to configure the user registry at the least. You do not have to configure the values for JAAS, authentication Cache and SSO tasks unless you want to change the default values. Configure TAI configuration only when you have an implementation of TAI interface to handle authentication.

You can complete one or more of the following authentication tasks:

## Procedure

- Configure authentication cache in Liberty
- Configure a custom JAAS login module for Liberty
- Configure SSO on Liberty
- Configure a user registry for Liberty
- Configure RunAS authentication in Liberty
- Configure TAI for Liberty

## Configuring a user registry for Liberty

You can store user and group information for authentication in several types of registries. For example you can use a basic user registry, an LDAP registry, or a Custom User Registry. **8.5.5.0** Optionally, you can configure two or more LDAP registries so that the operations are executed on all the configured registries. For example, when you perform an operation of searching a user, the search is performed on all the configured LDAP registries. **z/OS** For z/OS systems, you can use a SAF registry.

## Procedure

- Configure a basic user registry for Liberty
- Configure an LDAP user registry for Liberty
- **z/OS** Configure the SAF registry for Liberty on z/OS(r)

## Configuring a basic user registry for Liberty

You can configure a basic user registry in Liberty for authentication.

## About this task

You can use a basic user registry by defining the users and groups information for authentication on the Liberty server. To do this, you add the appSecurity-2.0 Liberty feature to the server.xml file, along with user information in the basicRegistry element.

## Procedure

1. Add the appSecurity-2.0 Liberty feature to the server.xml file.
2. Optional: To use SSL, add the ssl-1.0 Liberty feature in the server.xml file. See “Enabling SSL communication in Liberty” on page 1834.
3. Configure the basic registry for the server as follows:

```
<basicRegistry id="basic" realm="customRealm">
  <user name="mlee" password="p@ssw0rd" />
  <user name="rkumar" password="pa$$w0rd" />
  <user name="gjones" password="{xor}Lz4sLCgwLTs=" />
  <group name="students">
    <member name="mlee" />
    <member name="rkumar" />
  </group>
</basicRegistry>
```

### Notes:

- You must use unique names for your users and groups.
- You should remove all trailing and leading spaces from the user and group names.
- If user ID or password contains characters other than US-ASCII, make sure that the file is saved by using UTF-8 character encoding.
- **Distributed operating systems** If you use the WebSphere Application Server Developer Tools for Eclipse, the password is encoded for you automatically.

- If you edit the `server.xml` file directly, you can use the **securityUtility encode** command to encode the password for each user. The `securityUtility` command-line tool is available in the `$INSTALL_ROOT/bin` directory. When you run the **securityUtility encode** command, you either supply the password to encode as an input from the command line or, if no arguments are specified, the tool prompts you for the password. The tool then outputs the encoded value. Copy the value output by the tool, and use that value for the password. For example, to encode the password `GiveMeLiberty`, run the following command:  
**securityUtility encode GiveMeLiberty**
- **8.5.5.0** There are several security configuration examples on the `WASdev.net` website for reference when configuring security for your applications on Liberty.

## Configuring LDAP user registries in Liberty

You can configure one or more Lightweight Directory Access Protocol (LDAP) servers in Liberty for authentication.

### Before you begin

Ensure that your LDAP server is up and running, and that the host name and port number of the LDAP server are already in your known list.

### About this task

You can use an existing LDAP server for application authentication in Liberty. **8.5.5.0** To do this, you add the `appSecurity-2.0` feature to the `server.xml` file and specify, in the `server.xml` file, the `ldapRegistry-3.0` feature, and the configuration information for connecting to the LDAP server.

**Avoid trouble:** **8.5.5.0** There are several security configuration examples on the `WASdev.net` website for reference when configuring security for your applications on Liberty. For more information, see the link in the related reference for config snippets.

### Procedure

1. **8.5.5.0** Add the `appSecurity-2.0` and `ldapRegistry-3.0` Liberty features to the `server.xml` file.
2. Optional: To communicate with an SSL-enabled LDAP server, add the `ssl-1.0` Liberty feature in the `server.xml` file.
3. Optional: Copy the truststore to the server configuration directory. For example, you can use the `${server.config.dir}` variable.

For SSL communication with an LDAP server to succeed, the Signer certificate for the LDAP server must be added to the truststore that is referenced by the **sslAlias** attribute of the `<ldapRegistry>` element. In the following examples, the Signer certificate must be added to the `LdapSSLTrustStore.jks`.

4. Configure the LDAP entry for the server.

If you do not want SSL for the LDAP server, remove all SSL and keystore-related lines from the following examples.

You configure the LDAP server in the `server.xml` file or by using the WebSphere Application Server Developer Tools for Eclipse. **8.5.5.0** There are several security configuration examples on the `WASdev.net` website for reference when configuring security for your applications on Liberty.

- For IBM Directory Server:

```
<ldapRegistry id="ldap" realm="SampleLdapIDSRealm"
  host="ldapserver.mycity.mycompany.com" port="389" ignoreCase="true"
  baseDN="o=mycompany,c=us"
  ldapType="IBM Tivoli Directory Server"
  sslEnabled="true"
```

```

    sslRef="LDAPSSLSettings">
    <idsFilters
    userFilter="( &uid=%v)(objectclass=ePerson)"
    groupFilter="( &cn=%v)(|(objectclass=groupOfNames)
    (objectclass=groupOfUniqueNames)(objectclass=groupOfURLs)))"
    userIdMap="*:uid"
    groupIdMap="*:cn"
    groupMemberIdMap="mycompany-allGroups:member;mycompany-allGroups:uniqueMember;
    groupOfNames:member;groupOfUniqueNames:uniqueMember">
    </idsFilters>
</ldapRegistry>

<ssl id="LDAPSSLSettings" keyStoreRef="LDAPKeyStore" trustStoreRef="LDAPTrustStore" />

<keyStore id="LDAPKeyStore" location="\${server.config.dir}/LdapSSLKeyStore.jks"
    type="JKS" password="{xor}CDo9Hgw=" />
<keyStore id="LDAPTrustStore" location="\${server.config.dir}/LdapSSLTrustStore.jks"
    type="JKS" password="{xor}CDo9Hgw=" />

```

- For Microsoft Active Directory Server:

```

<ldapRegistry id="ldap" realm="SampleLdapADRealm"
    host="ldapserverserver.mycity.mycompany.com" port="389" ignoreCase="true"
    baseDN="cn=users,dc=adtest,dc=mycity,dc=mycompany,dc=com"
    bindDN="cn=testuser,cn=users,dc=adtest,dc=mycity,dc=mycompany,dc=com"
    bindPassword="testuserpwd"
    ldapType="Microsoft Active Directory"
    sslEnabled="true"
    sslRef="LDAPSSLSettings">
    <activatedFilters
    userFilter="( &sAMAccountName=%v)(objectcategory=user)"
    groupFilter="( &cn=%v)(objectcategory=group)"
    userIdMap="user:sAMAccountName"
    groupIdMap="*:cn"
    groupMemberIdMap="memberOf:member" >
    </activatedFilters>
</ldapRegistry>

<ssl id="LDAPSSLSettings" keyStoreRef="LDAPKeyStore" trustStoreRef="LDAPTrustStore" />

<keyStore id="LDAPKeyStore" location="\${server.config.dir}/LdapSSLKeyStore.jks"
    type="JKS" password="{xor}CDo9Hgw=" />
<keyStore id="LDAPTrustStore" location="\${server.config.dir}/LdapSSLTrustStore.jks"
    type="JKS" password="{xor}CDo9Hgw=" />

```

If you use the WebSphere Application Server Developer Tools for Eclipse, the `bindPassword` password is encoded for you automatically. If you edit the `server.xml` file directly, you can use the **securityUtility encode** command to encode the `bindPassword` password for you. The `securityUtility` command-line tool is available in the `$INSTALL_ROOT/bin` directory. When you run the **securityUtility encode** command, you either supply the password to encode as an input from the command line or, if no arguments are specified, the tool prompts you for the password. The tool then outputs the encoded value. Copy the value output by the tool, and use that value for the `bindPassword` password.

5. **8.5.0.1** **8.5.5.0** Optional: Configure certificate filter mode for the LDAP server.

```

<ldapRegistry id="LDAP" realm="SampleLdapIDSRealm"
    host="myldap.ibm.com" port="389" ignoreCase="true"
    baseDN="o=ibm,c=us"
    ldapType="IBM Tivoli Directory Server" searchTimeout="8m"
    certificateMapMode="CERTIFICATE_FILTER"
    certificateFilter="uid=${SubjectCN}">
    <idsFilters
    userFilter="( &uid=%v)(objectclass=ePerson)"
    groupFilter="( &cn=%v)(|(objectclass=groupOfNames)
    (objectclass=groupOfUniqueNames)(objectclass=groupOfURLs)))"
    userIdMap="*:uid"
    groupIdMap="*:cn"

```

```

        groupMemberIdMap="ibm-allGroups:member;ibm-allGroups:uniqueMember;
        groupOfNames:member;groupOfUniqueNames:uniqueMember">
    </idsFilters>
</ldapRegistry>

```

For more information about certificate map mode in Liberty, see “Liberty:LDAP certificate map mode” on page 1856.

6. **8.5.5.3** Optional: You can define mapping between LDAP attributes and the user registry <externalId> attribute.

You can define mapping between LDAP attributes and the user registry <externalId> attribute. After the mapping is configured, when you use the user registry <externalId> attribute for any operation, the value will be equivalent to the value of the LDAP attribute that is mapped. The following example code shows the mapping that is defined for the user registry <externalId> attribute with the LDAP <distinguishedName> attribute for the entity type <PersonAccount>. The <autoGenerate> attribute is optional, and the value is false by default.

```

<ldapRegistry id="LDAP" realm="SampleLdapIDSRealm"
  host="myldap.ibm.com" port="389" ignoreCase="true"
  baseDN="o=ibm,c=us"
  ldapType="IBM Tivoli Directory Server" searchTimeout="8m">
  <attributeConfiguration>
    <externalIdAttribute name="distinguishedName" entityType="PersonAccount" autoGenerate="false"></externalIdAttribute>
  </attributeConfiguration>
</ldapRegistry>

```

7. Optional: Configure failover for multiple LDAP servers.

```

<ldapRegistry id="LDAP" realm="SampleLdapIDSRealm"
  host="ldapserver1.mycity.mycompany.com" port="389" ignoreCase="true"
  baseDN="o=ibm,c=us" ldapType="IBM Tivoli Directory Server" idsFilters="ibm_dir_server">
  <failoverServers name="failoverLdapServersGroup1">
    <server host="ldapserver2.mycity.mycompany.com" port="389" />
    <server host="ldapserver3.mycity.mycompany.com" port="389" />
  </failoverServers>
  <failoverServers name="failoverLdapServersGroup2">
    <server host="ldapserver4.mycity.mycompany.com" port="389" />
  </failoverServers>
</ldapRegistry>

```

```

<idsLdapFilterProperties id="ibm_dir_server"
  userFilter="(&uid=%v)(objectclass=ePerson)"
  groupFilter="(&cn=%v)(|(objectclass=groupOfNames)
    (objectclass=groupOfUniqueNames)(objectclass=groupOfURLs))"
  userIdMap="*:uid" groupIdMap="*:cn"
  groupMemberIdMap="ibm-allGroups:member;ibm-allGroups:uniqueMember;
  groupOfNames:member;groupOfUniqueNames:uniqueMember">
</idsLdapFilterProperties>

```

For more information about the ldapRegistry and failoverServers elements, see .

8. **8.5.5.0** Optional: Configure multiple LDAP registries. If multiple LDAP registries are configured in the server.xml file, they are federated automatically. Ensure that the users are unique across all federated repositories, otherwise the user registry operations are not successful.

**Note:** **8.5.5.0** When you use multiple federated LDAP repositories, each repository must define a unique baseDN.

```

<ldapRegistry host="ldapserver1.mycity1.mycompany.com" baseDN="o=mycompany,c=us"
  port="123" ldapType="IBM Tivoli Directory Server">
</ldapRegistry>

<ldapRegistry host="ldapserver2.mycity2.mycompany.com"
  baseDN="cn=users,dc=secfv2,dc=mycity2,dc=mycompany,dc=com"
  port="456"

```

```

    ldapType="Microsoft Active Directory"
    bindDN="cn=testuser,cn=users,dc=secfv2,dc=mycity2,dc=mycompany,dc=com"
    bindPassword="{xor}KzosKyos0i0vKDs=">
</ldapRegistry>

```

**Note:**

- Specifying the federatedRepository element is not mandatory to federate multiple LDAP registries because they are federated automatically. If the federatedRepository element is specified to configure the participatingBaseEntry and primaryRealm elements, then the user registry operations are performed only on the repositories that are defined in the primaryRealm element. You can define the input and output property mappings for different user registry APIs under the primaryRealm element.
- The **name** attribute of the participatingBaseEntry element must be the same as the value of **baseDN** attribute that is specified in the ldapRegistry element. In the example follows, the **baseDN** and **name** attributes are configured for the LDAP registry on the host *ldapsrv1.mycity1.mycompany.com*. The value of **baseDN** attribute must be the same as that of sub tree in your LDAP server and the value of **name** attribute must be the name of that sub tree in the federated user registry. It is optional to specify the **name** attribute. By default, the **name** attribute uses the same value as the **baseDN** attribute. If the **name** attribute is specified in the ldapRegistry element, then the **name** attribute in the participatingBaseEntry element must use the same value as the **name** attribute in the ldapRegistry element.

```

<ldapRegistry host="ldapsrv1.mycity1.mycompany.com" baseDN="o=mycompany,ou=myou,c=us"
    port="123" ldapType="IBM Tivoli Directory Server" name="o=mybaseentry">
</ldapRegistry>

```

```

<ldapRegistry host="ldapsrv2.mycity2.mycompany.com"
    baseDN="cn=users,dc=secfv2,dc=mycity2,dc=mycompany,dc=com"
    port="456"
    ldapType="Microsoft Active Directory"
    bindDN="cn=testuser,cn=users,dc=secfv2,dc=mycity2,dc=mycompany,dc=com"
    bindPassword="{xor}KzosKyos0i0vKDs=">
</ldapRegistry>

```

```

<federatedRepository>
  <primaryRealm name="RealmName" delimiter="@" allowOpIfRepoDown="true">
    <participatingBaseEntry name="o=mybaseentry"/>
    <participatingBaseEntry name="cn=users,dc=secfv2,dc=mycity2,dc=mycompany,dc=com"/>
    <uniqueUserIdMapping inputProperty="uniqueName" outputProperty="uniqueName"/>
    <userSecurityNameMapping inputProperty="principalName" outputProperty="principalName"/>
    <userDisplayNameMapping inputProperty="principalName" outputProperty="principalName"/>
    <uniqueGroupIdMapping inputProperty="uniqueName" outputProperty="uniqueName"/>
    <groupSecurityNameMapping inputProperty="cn" outputProperty="cn"/>
    <groupDisplayNameMapping inputProperty="cn" outputProperty="cn"/>
  </primaryRealm>
</federatedRepository>

```

For more information about the federated ldapRegistry elements, see .

9. **8.5.5.0** Optional: You can configure other optional attributes for the LDAP registry, such as **contextPool** or **ldapCache**, as given in the following example:

```

<ldapRegistry id="IBMDirectoryServerLDAP" realm="SampleLdapIDSRealm"
    host="host.domain.com" port="389" ignoreCase="true"
    baseDN="o=domain,c=us"
    bindDN="cn=testuser,o=domain,c=us"
    bindPassword="mypassword"
    ldapType="IBM Tivoli Directory Server"
    searchTimeout="8m">
  <contextPool enabled="true" initialSize="1" maxSize="0" timeout="0s" waitTime="3000ms" preferredSize="3"/>
</ldapCache>

```

```

    <attributesCache size="4000" timeout="1200s" enabled="true" sizeLimit="2000"/>
    <searchResultsCache size="2000" timeout="600s" enabled="true" resultsSizeLimit="1000"/>
  </ldapCache>
</ldapRegistry>

```

**Note:**

- Federated user registry uses the context pooling mechanism to improve the performance of concurrent access to an LDAP server. Context pooling works at a higher level than the connection pooling. Each context entry in the context pool corresponds to a socket connection to the LDAP server. The bind credentials that are used by this pool are specified when you configure the LDAP registry.
- Federated repository uses the cache mechanism for performance enhancement. It caches information about the LDAP users and groups based on the user operations performed. For example, if you perform a search operation on the LDAP users and groups, the result of the operation is cached. You can enable the `ldapCache` element in the `server.xml` file as shown in the previous example.

**Troubleshooting tip:** **8.5.5.2** To troubleshoot any LDAP authentication issues, use the following trace specifications in the `bootstrap.properties` file:

```
com.ibm.ws.security.wim.*=all:com.ibm.websphere.security.wim.*=all
```

**Liberty:LDAP certificate map mode:** **8.5.0.1**

The certificate map mode is used to specify whether to map X.509 certificates into an LDAP directory by **EXACT\_DN** or **CERTIFICATE\_FILTER** in Liberty.

The **EXACT\_DN** means that the Distinguished Name (DN) in the certificate must exactly match the user entry in the LDAP server, including case and spaces. To use the specified certificate filter for the mapping, you can use the **CERTIFICATE\_FILTER**.

**Certificate filter**

Specifies the filter certificate mapping property for the LDAP filter. The filter is used to map attributes in the client certificate to entries in the LDAP registry.

If more than one LDAP entry matches the filter specification at run time, authentication fails because the result is an ambiguous match. The syntax this filter is:

```
LDAP attribute=${Client certificate attribute}
```

.

An example of a simple certificate filter is: `uid=${SubjectCN}`.

You can also specify multiple properties and values as part of a certificate filter. The LDAP attribute of the filter specification depends on the schema that your LDAP server is configured to use. The client certificate attribute is one of the public attributes in your client certificate. The client certificate attribute must begin with a dollar sign, \$, and opening brace, {, and end with a closing brace, }. The attributes are case-sensitive.

The following LDAP attributes are supported:

- uid
- initials
- sAMAccountName
- displayName
- distinguishedName
- displayName
- description

The following client certificate attributes are supported:

- `${SubjectCN}`
- `${SubjectDN}`
- `${IssuerCN}`
- `${IssuerDN}`
- `${SerialNumber}`

An example of an LDAP configuration with certificate filter mode enabled:

```
<ldapRegistry id="LDAP" realm="SampleLdapIDSRealm"
  host="myldap.ibm.com" port="389" ignoreCase="true"
  baseDN="o=ibm,c=us"
  certificateMapMode="CERTIFICATE_FILTER"
  certificateFilter="uid=${SubjectCN}"
  userFilter="(&(uid=%v)(objectclass=person))"
  groupFilter="(&(cn=%v)(|(objectclass=groupOfNames)
    (objectclass=groupOfUniqueNames)(objectclass=groupOfURLs)))"
  userIdMap="*:uid"
  groupIdMap="*:cn"
  groupMemberIdMap="ibm-allGroups:member;ibm-allGroups:uniqueMember;
    groupOfNames:member;groupOfUniqueNames:uniqueMember"
  ldapType="IBM Tivoli Directory Server" searchTimeout="8m" />
```

## Activating and configuring the SAF registry on z/OS

z/OS

The System Authorization Facility (SAF) registry holds information required to perform security-related functions such as authenticating users and retrieving information about users, groups, or groups associated with users. You activate and configure the SAF registry through the configuration file `server.xml`. In addition, you can configure your Liberty server to use SAF authorization.

### About this task

By adding the appropriate features to the `server.xml` file, you can accomplish the following tasks:

- Activate the SAF user registry
- Configure the SAF user registry to use authorized services
- Enable applications to use the SAF user registry
- Configure the SAF user registry

By default, the SAF registry uses unauthorized UNIX System Services (USS) to perform authentication. For better performance, you can enable the authorized SAF services by configuring the SAFCREDS resources. For more information, see “Enabling z/OS authorized services in Liberty for z/OS” on page 1942.

For information on how to configure your Liberty server to use SAF authorization, see “Configuring authorization for applications in Liberty” on page 1939

### Procedure

1. Activate the SAF user registry. Add the `zosSecurity-1.0` feature to the `server.xml` file:  
`<feature>zosSecurity-1.0</feature>`

**Note:** By default, the SAF user registry uses unauthorized USS services such as `__passwd` to perform authentication.

2. For better performance, configure the SAF user registry to use authorized services such as `initACEE` to perform authentication by configuring the SAFCREDS resources. For more information, see “Enabling z/OS authorized services in Liberty for z/OS” on page 1942.

3. Enable application security by adding the feature `appSecurity-2.0`, along with either the `servlet-3.0` feature for web application, or the `ejbLite-3.1` feature for EJB applications.

```
<feature>zosSecurity-1.0</feature>  
<feature>appSecurity-2.0</feature>  
<feature>servlet-3.0</feature>
```

**8.5.5.0** `<feature>ejbLite-3.1</feature>`

4. Configure the SAF registry by adding a **safRegistry** element in the `server.xml` file:  
`<safRegistry id="saf" realm="myrealm" />`

The **safRegistry** element has the following attributes:

- ID** The ID that uniquely identifies this registry instance. The ID can be anything you want, but must be unique with respect to other configured registries such as the basic registry and the LDAP registry. You can use the ID to refer to this registry instance in other elements of the `server.xml` file.
- realm** The realm associated with the SAF registry. If you do not specify a realm, the default is the plex name (ECVTSPLEX). If the server is authorized to use the SAFCREDS resources, then the default realm is read from the SAF product by extracting the APPLDATA field in the SAFDFLT profile under the REALM class. If that field is empty, then the default realm is used.

#### Mixed-case passwords: **z/OS**

Knowing when a password is interpreted as case sensitive or not can directly affect how you use a local operating system registry. WebSphere Application Server exploits the mixed case password option for the Resource Access Control Facility (RACF), so you can use case sensitive passwords.

Since z/OS Version 1.7, RACF supports the option of a mixed case password. You select this option for RACF by using the **SETROPTS PASSWORD(MIXEDCASE)** command. To use case sensitive passwords in WebSphere Application Server for a local operating system registry, you must comply with all of the following requirements:

- Use z/OS Version 1.7 or later

**Note:** To use Liberty capabilities of z/OS, you must use Version 1.11 or later.

- Use the local operating system registry
- Turn on the RACF mixed case option with the **SETROPTS PASSWORD(MIXEDCASE)** command

**Important:** All three of these requirements must be met; otherwise the WebSphere Application Server password will not be sensitive to case.

If you use a Lightweight Directory Access Protocol (LDAP) configuration, you can use mixed case passwords.

For more information on the mixed case password feature in z/OS Version 1.7, see z/OS V1R7.0 Security Server RACF Security Administrator's Guide. This guide is available under *Security Server and Integrated Security Services*. Within the guide, see section 5.2.1.

There is an SDBM alternative setup for LDAP. For more information, see the topic SDBM authorization in the *Tivoli Directory Server for z/OS* section of the z/OS V1R11 information center.

## Configuring SCIM for user and group member management

**8.5.5.8**

You can configure the scim-1.0 feature in the server.xml file to enable user and group member management. System for Cross-domain Identity Management (SCIM) defines REST APIs to create, retrieve, update, and delete (CRUD) users and groups. Calls are made through a systems management REST WAB. The local calls will be HTTP over localhost through Web API only; no java APIs for local calls.

## Procedure

Adding the scim-1.0 feature in the server.xml file enables SCIM functions. But to complete the configuration, you must also perform the following configuration steps:

- **SSL Configuration:** The REST services are protected and can be accessed only on the HTTPS port. For more information about how to complete the SSL configuration, see “Enabling SSL communication in Liberty” on page 1834.
- **Configuration of Federation Registry:** The SCIM functions is only supported by the Federation Registry. To quickly set up a federation registry by using LDAP, see “Configuring LDAP user registries in Liberty” on page 1852.
- **Configuration of an administrator role:** The REST services are only accessible by an administrator, so a user needs to be configured with an administrator role. For more information about mapping the administrator role to Liberty, see “Mapping the administrator role for Liberty” on page 1644.

**Note:** For configuration of the administrator role for SCIM, you cannot use the Quick Start Registry.

- **Configuration of HTTPS port (optional):** The HTTP end point must be configured. For more information about the httpEndpoint feature element configuration, see the httpEndpoint section in “Admin Center” on page 855.

After the configuration steps are completed, the scim-1.0 feature is now ready to be used. A sample configuration in the server.xml file is shown in the following example:

```
<server description="server1">
  <!-- Enable features -->
  <featureManager>
    <feature>appSecurity-2.0</feature>
    <feature>servlet-3.0</feature>
  <feature>ldapRegistry-3.0</feature>
  <feature>scim-1.0</feature>
  <feature>ssl-1.0</feature>
  </featureManager>

  <httpEndpoint id="defaultHttpEndpoint" httpPort="9080" httpsPort="9090">
    <tcpOptions soReuseAddr="true" />
  </httpEndpoint>

  <ldapRegistry id="LDAP1" realm="SampleLdapIDSRealm" host="9.127.1.90" port="1389" ignoreCase="true"
    baseDN="o=ibm,c=us" ldapType="IBM Tivoli Directory Server" searchTimeout="8m" recursiveSearch="true"
    bindDN="cn=xxxx" bindPassword="xxxxxx">
    <ldapEntityType name="PersonAccount">
      <rdnProperty name="uid" objectClass="inetOrgPerson"/>
      <objectClass>inetOrgPerson</objectClass>
    </ldapEntityType>
    <ldapEntityType name="Group">
      <objectClass>groupofnames</objectClass>
    </ldapEntityType>
  </objectClass>ibm-nestedGroup</objectClass>
  <rdnProperty name="cn" objectClass="groupofnames"/>
  </ldapEntityType>
  <attributeConfiguration>
    <attribute name="title" propertyName="honorificPrefix" syntax="String" entityType="PersonAccount">
      </attribute>
  </attribute name="initials" propertyName="middleName" syntax="String" entityType="PersonAccount">
    </attribute>
  </attribute name="st" propertyName="honorificSuffix" syntax="String" entityType="PersonAccount">
```

```

        </attribute>
<attribute name="l" propertyName="homeStateOrProvinceName" syntax="String" entityType="PersonAccount">
    </attribute>
<attribute name="street" propertyName="homeStreet" syntax="String" entityType="PersonAccount">
    </attribute>
<attribute name="postalAddress" propertyName="homeCity" syntax="String" entityType="PersonAccount">
    </attribute>
<attribute name="postalCode" propertyName="homePostalCode" syntax="String" entityType="PersonAccount">
    </attribute>
    <attribute name="postOfficeBox" propertyName="homeCountryName" syntax="String" entityType="PersonAccount">
    </attribute>
    <attribute name="departmentNumber" propertyName="photoURLThumbnail" syntax="String" entityType="PersonAccount">
    </attribute>
<attribute name="description" propertyName="photoURL" syntax="String" entityType="PersonAccount">
    </attribute>
</attributeConfiguration>
<groupProperties>
    <memberAttribute name="member" dummyMember="uid=dummy" objectClass="groupOfNames" scope="direct"/>
<memberAttribute name="ibm-memberGroup" objectClass="ibm-nestedGroup" scope="direct"/>
</groupProperties>
</ldapRegistry>

<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore" />
<keyStore id="defaultKeyStore" password="Liberty"/>

<administrator-role>
    <user>wasadmin</user>
</administrator-role>

<federatedRepository>
    <primaryRealm name="WIMRegistry">
        <participatingBaseEntry name="o=ibm,c=us"/>
    </primaryRealm>
</federatedRepository>
</server>

```

## SCIM operations in Liberty: 8.5.5.8

The System for Cross-domain Identity Management (SCIM) 1.1 specifications are supported in Liberty.

### Retrieving resources

WebSphere Application Server Liberty supports SCIM 1.1 specifications. For more information about the specification, see <http://www.simplecloud.info/>.

To retrieve a known resource, you must send a GET request to the configured HTTP endpoint. For example, `/Users/{id}` or `/Groups/{id}`.

The following example shows the operations against an LDAP registry.

```

<ldapRegistry id="LDAP1" realm="SampleLdapIDSRealm" host="9.127.1.90" port="1389" ignoreCase="true"
    baseDN="o=ibm,c=us" ldapType="IBM Tivoli Directory Server" searchTimeout="8m" recursiveSearch="true"
    bindDN="xxxxxx" bindPassword="xxxxxx">
    <ldapEntityType name="PersonAccount">
        <rdnProperty name="uid" objectClass="inetOrgPerson"/>
        <objectClass>inetOrgPerson</objectClass>
    </ldapEntityType>
    <ldapEntityType name="Group">
        <objectClass>groupofnames</objectClass>
    </ldapEntityType>
</objectClass>ibm-nestedGroup</objectClass>
    <rdnProperty name="cn" objectClass="groupofnames"/>
</ldapEntityType>

```

```

    <attributeConfiguration>
      <attribute name="title" propertyName="honorificPrefix" syntax="String" entityType="PersonAccount">
        </attribute>
    <attribute name="initials" propertyName="middleName" syntax="String" entityType="PersonAccount">
      </attribute>
    <attribute name="st" propertyName="honorificSuffix" syntax="String" entityType="PersonAccount">
      </attribute>
    <attribute name="l" propertyName="homeStateOrProvinceName" syntax="String" entityType="PersonAccount">
      </attribute>
    <attribute name="street" propertyName="homeStreet" syntax="String" entityType="PersonAccount">
      </attribute>
    <attribute name="postalAddress" propertyName="homeCity" syntax="String" entityType="PersonAccount">
      </attribute>
    <attribute name="postalCode" propertyName="homePostalCode" syntax="String" entityType="PersonAccount">
      </attribute>
    <attribute name="postOfficeBox" propertyName="homeCountryName" syntax="String" entityType="PersonAccount">
      </attribute>
    <attribute name="departmentNumber" propertyName="photoURLThumbnail" syntax="String" entityType="PersonAccount">
      </attribute>
    <attribute name="description" propertyName="photoURL" syntax="String" entityType="PersonAccount">
      </attribute>
    </attributeConfiguration>
  <groupProperties>
    <memberAttribute name="member" dummyMember="uid=dummy" objectClass="groupOfNames" scope="direct"/>
  <memberAttribute name="ibm-memberGroup" objectClass="ibm-nestedGroup" scope="direct"/>
  </groupProperties>
</ldapRegistry>

```

To retrieve a resource from the LDAP, you must send a GET request as `https://localhost:9090/ibm/api/scim/Users/uid=jsmith,o=ibm,c=us`.

## Querying resources

To query resources, you must send a GET request to the configured HTTP endpoint and specify the filter for searching. You can also specify the attributes parameter to return a subset of values from the returned resources and specify the paging and sorting parameters to organize the returned resources. The following examples show some of the filter options:

- Specify the parameter to retrieve subset of the values: For example: `https://localhost:9090/ibm/api/scim/Users?filter=givenname sw` "Jo" retrieves all users whose name starts with "Jo".
- Specify the attributes parameter to retrieve subset of the values: For example: `https://localhost:9090/ibm/api/scim/Users?filter=givenname sw "Jo" &attributes=username,emails&filter=name.familyname eq "Smith"` retrieves the email addresses of the user name that starts with "Jo" and whose family name is "Smith".
- Specify the paging and sorting parameters to retrieve organized resources. For example, `https://localhost:9090/ibm/api/scim/Users?filter=givenname sw "Jo"&attributes=username&sortBy=username&startIndex=3&count=5` retrieves the third page of the sorted result with each page containing five user names that start with "Jo" and whose family name is "Smith".

### Notes:

- The underlying federated repositories determine whether the values that are specified in the filters are case-sensitive. In case of LDAP, the values are not case-sensitive by default, unless the attribute is mapped to a case-sensitive LDAP attribute.
- User name cannot be used in the search filter.
- When federating basic, SAF or custom registries that do not support the SCIM attributes, the filter pattern is always searched against the user name and only the user name attribute is returned.

## Creating resources

To create new resources, you must send a POST request to the resource endpoint, that is, Users or Groups. The POST content must contain the user json object and the HTTP header content-type must be set to application/json.

**Note:** The application/xml content type is not supported.

To create a user, the following request must be posted to `https://localhost:9090/ibm/api/scim/Users`  
Content-Type

Content-Type: application/json

Content-Length: ...

```
{
  "schemas":["urn:scim:schemas:core:1.0"],
  "userName":"bjensen",
  "externalId": "uid=bjensen,o=ibm,c=us",
  "name":{"
    "familyName":"Jensen",
    "givenName":"Barbara"
  }
}
```

The request must contain all the attributes that are required to successfully create a User or Group in the user registry. For example, in a back-end Tivoli Directory Server LDAP, the minimum set of LDAP attributes needed to create a user would be uid, sn, and cn; so any request for creation of user must contain userName, givenName, and familyName. The create operation fails if there are any schema violation from the user registry.

The externalId attribute acts like an identifier and must be specified. The attribute format depends on the specification of back-end user registry. In the previous example, the back-end is an LDAP server with a baseEntry as o=ibm,c=us and the RDN property for the user is set as UID, so the externalId becomes uid=bjensen,o=ibm,c=us.

Based on the create request, the created user object is returned.

```
{
  "schemas":["urn:scim:schemas:core:1.0"],
  "id":"uid=bjensen,o=ibm,c=us",
  "userName":"bjensen",
  "externalId":"uid=bjensen,o=ibm,c=us",
  "name":{"
    "formatted":"Barbara Jensen",
    "familyName":"Jensen",
    "givenName":"Barbara"
  }},
  "meta":{"
    "lastModified":"2015-09-15T14:30:11",
    "location":"https://localhost:9090/ibm/api/scim/Users/uid=bjensen",
    "created":"2015-09-15T14:30:11"
  }
}
```

When more than one LDAPs are configured and a create operation needs to be invoked, a default parent for the entity must be defined. The defined parent specifies the base entry under which the new entity would be created. The following example shows the configuration of a default parent for PersonAccount.

```
<federatedRepository>
  <primaryRealm name="WIMRegistry">
    <participatingBaseEntry name="o=ibm,c=us"/>
    <participatingBaseEntry name="o=ldap"/>
  </primaryRealm>
</supportedEntityType>
```

```

        <defaultParent>o=ldap</defaultParent>
        <name>PersonAccount</name>
    </supportedEntityType>
</federatedRepository>

```

## Modifying resources

To modify resources, one needs to send a PUT request to the resource endpoint, that is, /Users or /Groups. A PUT request performs a complete update of the resource. Any attributes that is not specified in the input are deleted.

**Note:** Partial updates with PATCH are not supported.

To modify the previously created resource, the following request must be posted to `https://localhost:9090/ibm/api/scim/Users/uid=bjensen,o=ibm,c=us`.

```

Content-Type: application/json
Content-Length: ...

```

```

{
  "schemas":["urn:scim:schemas:core:1.0"],
  "userName":"bjensen",
  "externalId":"uid=bjensen,o=ibm,c=us",
  "name":{
    "familyName":"Jensen",
    "givenName":"Barb"
  }
}

```

This request modifies the given name of the object from *Barbara* to *Barb*. The ID specified in the URL must match the `externalId` specified in the user object.

To modify a Group `cn=employeeGroup,o=ibm,c=us` and change the Group membership, the member attribute needs to be specified.

```

Content-Type: application/json
Content-Length: ...

```

```

{
  "id":"cn=employeeGroup,o=ibm,c=us",
  "schemas":["urn:scim:schemas:core:1.0"],
  "displayName":"employeeGroup",
  "externalId":"cn=employeeGroup,o=ibm,c=us",
  "members":[{"value":"uid=bjensen,o=ibm,c=us", "type":"User"}, {"value":"cn=consultants,o=ibm,c=us", "type":"Gr"}
}

```

To modify a Group `cn=employeeGroup,o=ibm,c=us` and remove all the members from a group an empty member attribute needs to be specified.

```

Content-Type: application/json
Content-Length: ...

```

```

{
  "id":"cn=employeeGroup,o=ibm,c=us",
  "schemas":["urn:scim:schemas:core:1.0"],
  "displayName":"employeeGroup",
  "externalId":"cn=employeeGroup,o=ibm,c=us",
  "members":[]
}

```

## Deleting resources

To delete resources, you need to send a DELETE request to the resource endpoint, that is, /Users or /Groups. For example, to delete the user uid=bjensen,o=ibm,c=us that is created in the previous example, send a request to `https://localhost:9090/ibm/api/scim/Users/uid=bjensen,o=ibm,c=us`

**Note:** SCIM runs only on Java 7 or later.

## Configuring additional properties for users and groups

8.5.5.8

You can configure additional properties for users and groups of federated repositories. To enable schema or property extensions, ensure that the property can be read from and written to the underlying repositories.

### Procedure

1. You can specify the following additional property information in the `server.xml` file to enable schema or property extension.
  - Extended Property Name – The name of the extended property. Ensure that the name specified is unique and does not match with an existing property name.
  - Data type – The data type of the extended property. The possible values are Integer, Long, String, Boolean, Date, Double, BigInteger, BigDecimal.
  - Entity type – The entity to which the property applies. The possible values are PersonAccount or Group.

Single or multi-valued - You can set the value of the property to be either single or multi-valued. A default value can also be set for the property. When an entity is created and no value is specified for the property, the default value is used. For a multi-valued property, you can add an extended property named `assetId` for storing assets assigned to a user. If each user can be assigned more than one assets then the `assetId` needs to be multi-valued. You must ensure that the attribute to which the `assetId` is mapped is also a multi-valued attribute in the back-end LDAP .

The following sample shows the configuration in `server.xml`:

```
<federatedRepository>
  <primaryRealm name="WIMRegistry">
    <participatingBaseEntry name="o=ibm,c=us"/>
  </primaryRealm>
  <extendedProperty dataType="String" name="extendedProperty" entityType="PersonAccount"> </extendedProperty>
</federatedRepository>
```

2. To use the extended property in the code, you must use the generic getter/setter methods as shown in the following example:

```
PersonAccount person = new PersonAccount();
...
person.set("extendedProperty", "xyz");
...
String value = (String)person.get("extendedProperty");
```

3. To ensure that property can be read from and written to the LDAP, you have the following two options:
  - Pass-through: If the name of the extended property is same as the name of the LDAP attribute, then the property is passed through and read from and written to the attribute.
  - Property Mapping: If the name of the extended property is different from the name of the LDAP attribute, then the property needs to be mapped by using attribute mapping.

The following sample configuration shows the mapping of the extended property to an attribute named `extendedAttribute`.

```
<attributeConfiguration>
  <attribute name="extendedAttribute" propertyName="extendedProperty" syntax="String" entityType="PersonAccount"><
</attributeConfiguration>
```

## Liberty:Dynamic changes to security

Some specific information on how dynamic configuration changes impact security on Liberty is introduced in this topic.

### Dynamically changing the user registry

Changing the user registry can impact both the server configuration and clients using the server. Before you change the user registry dynamically (without restarting the server), consider the following:

- If you change the user registry type or realm name, all web clients must clear their single sign-on tokens.
- If you change the user registry type or realm name, any values of **accessId** that are specified in the authorization bindings must be updated. The **accessId** takes the form of `user:realmName/uniqueId` or `group:realmName/uniqueId`. The **realmName** in the **accessId** must match the **realmName** for the configuration user registry.

### Developing a custom user repository for Liberty

8.5.5.8

You can develop a custom user repository class by implementing the `com.ibm.ws.security.wim.RepositoryFactory` and `com.ibm.ws.security.wim.Repository` interfaces that are provided in the Liberty server.

#### About this task

The repository interfaces enable support to virtually any type of account repository.

#### Procedure

1. Implement the repository factory (`com.ibm.ws.security.wim.RepositoryFactory`) interface. The `RepositoryFactory` interface gets the configuration parameters and creates an instance of the repository. For example,

```
public Repository getRepository(Map<String, Object> properties) throws WIMException {
    return new CustomRepository(properties);
}
```
2. Implement the repository (`com.ibm.ws.security.wim.Repository`) interface. This class has the actual repository operations.

```
public class CustomRepository extends RepositoryConfiguration implements Repository {

    public CustomRepository(Map<String, Object> properties) {
        System.out.println("Constructor with " + properties);
    }
}
```
3. Convert the implementation class into an OSGi service. For more information, see “Declaring your services to OSGi Declarative Services” on page 1794.
4. Package the custom user repository as an OSGi bundle and export the user repository service. For more information about creating an OSGi bundle, see *Creating an OSGi service bundle*.
5. Create a feature manifest to include the OSGi bundle. For more information, see “Liberty profile: Product extension” on page 967.
6. After the feature is installed into the user product extension location, configure the `server.xml` file with the feature name. For example:

```
<featureManager>
...
<feature>usr:customRepositorySample-1.0</feature>
</featureManager>
```

For a downloadable custom user registry sample, see [https://developer.ibm.com/wasdev/downloads/#asset/samples-Custom\\_User\\_Registry](https://developer.ibm.com/wasdev/downloads/#asset/samples-Custom_User_Registry).

## Example

Refer to the following samples of repository factory and repository interfaces.

### Repository factory interface

```
package com.myorg;

import java.util.Map;

import org.osgi.service.component.ComponentContext;

import com.ibm.websphere.security.wim.exception.WIMException;
import com.ibm.ws.security.wim.Repository;
import com.ibm.ws.security.wim.RepositoryFactory;

public class CustomRepositoryFactory implements RepositoryFactory {

    @Override
    public Repository getRepository(Map<String, Object> properties) throws WIMException {
        System.out.println("getRepository " + properties);
        return new CustomRepository(properties);
    }

    public void activate(ComponentContext cc, Map<String, Object> properties) {
        System.out.println("In activate");
    }

    public void deactivate(ComponentContext cc) {
        System.out.println("In deactivate");
    }
}
```

### Repository interface

```
package com.myorg;

import java.util.Map;

import com.ibm.websphere.security.wim.exception.WIMException;
import com.ibm.websphere.security.wim.model.Root;
import com.ibm.ws.security.wim.Repository;
import com.ibm.ws.security.wim.RepositoryConfiguration;

public class CustomRepository extends RepositoryConfiguration implements Repository {

    public CustomRepository(Map<String, Object> properties) {
        System.out.println("Constructor with " + properties);
    }

    @Override
    public Root create(Root arg0) throws WIMException {
        throw new WIMException("Method not supported");
    }

    @Override
    public Root delete(Root arg0) throws WIMException {
        throw new WIMException("Method not supported");
    }

    @Override
    public Root get(Root arg0) throws WIMException {
        throw new WIMException("Method not supported");
    }
}
```

```

    }

    @Override
    public String getRealm() {
        return "customRepository";
    }

    @Override
    public Root login(Root arg0) throws WIMException {
        throw new WIMException("Method not supported");
    }

    @Override
    public Root search(Root arg0) throws WIMException {
        throw new WIMException("Method not supported");
    }

    @Override
    public Root update(Root arg0) throws WIMException {
        throw new WIMException("Method not supported");
    }
}

```

## Configuring the authentication cache in Liberty

You can modify how authenticated users are cached in Liberty.

### About this task

Because the creation of a subject might impact performance, Liberty provides an authentication cache to store a subject after an authentication of a user is successful. The cache is initialized with a certain number of entries, determined by the **initialSize** attribute, and has a maximum number of entries, determined by the **maxSize** attribute. If the maximum size is reached, then the earliest entries that were used are removed from the cache. If a user has been inactive for longer than period that is specified by the **timeout** attribute, then the entry for that user is removed from the cache. By default, the cache size is initialized to 50 entries and a maximum of 25000 entries, with a timeout of 600 seconds.

You do not have to configure the values for the `authCache` element unless you want to change the default values of the authentication cache.

For more information about authentication case, see “Authentication cache” on page 978.

#### Note:

- Any change that is made to the user registry configuration in the `server.xml` file clears the authentication cache. However, if changes are made to an external user registry, such as LDAP, the authentication cache is unaffected.
- You must consider the following effects of the timeout value on your configuration:
  - Larger authentication cache timeout values can increase security risks. For example, you might revoke a user in the user registry or repository, but the revoked user can log in by using the credential that is cached in the authentication cache until the cache is refreshed.
  - Smaller authentication cache timeout values can affect performance. When this value is smaller, the Liberty server accesses the user registry or repository more frequently.
  - Larger numbers of entries in the authentication cache, which is caused by an increased number of users, increases the memory usage of the authentication cache. Thus, the application server might slow down and affect performance.

## Procedure

1. Enable the appSecurity-2.0 Liberty feature by adding the following code to the server.xml file.

```
<featureManager>
  <feature>appSecurity-2.0</feature>
</featureManager>
```

2. Optional: To change the default options for the authentication cache, add the **<authCache>** element to the server.xml file. In the following example, the initial size of the authentication cache is changed to 100 entries with a maximum of 50000 entries, and the timeout is changed to 15 minutes.

```
<authCache initialSize="100" maxSize="50000" timeout="15m"/>
```

3. Optional: To disable the authentication cache, set the attribute **cacheEnabled** to false in the **<authentication>** element as follows:

```
<authentication id="Basic" cacheEnabled="false" />
```

For more information about the **<authCache>** and **<authentication>** elements, see .

## Configuring a JAAS custom login module for Liberty

You can configure a custom Java Authentication and Authorization Service (JAAS) login module before or after you have configured the Liberty server login module.

### Before you begin

**8.5.5.9** We support the server.xml file, client.xml file and the JAAS configuration file for JAAS configuration. However, it is suggested to configure the JAAS custom login module in the server.xml file or client.xml file. For further details about configuring the JAAS configuration file, see “Configuring an application JAAS custom login context entry and login module using a JAAS configuration file for Liberty” on page 1869.

Make sure you have a JAR file containing the JAAS custom login module, which implements the javax.security.auth.spi.LoginModule interface as described in “Developing JAAS custom login modules for a system login configuration” on page 2002. In this topic, JAAS custom login module uses hashtable, callbacks or shared state variables provided by the Liberty server to pass authentication data to the system login module.

### About this task

You can use a custom login module to either make additional authentication decisions or add information to the subject to make finer-grained authorization decisions inside your application. See “JAAS configuration” on page 978 and “JAAS login modules” on page 979 for a more detailed overview.

You can also use the developer tools to configure a custom JAAS login module.

**Distributed operating systems**

See “Configuring JAAS on Liberty by using developer tools” on page 1870. **8.5.5.0** There are several security configuration examples on the WASdev.net website for reference when configuring security for your applications on Liberty. See “Configuring JAAS on Liberty by using developer tools” on page 1870.

To configure a JAAS custom login module, complete the following steps:

## Procedure

1. Enable the appSecurity-2.0 Liberty feature in the server.xml file.

```
<featureManager>
  <feature>appSecurity-2.0</feature>
</featureManager>
```

2. Create a class `com.sample.CustomLoginModule` that implements the `LoginModule` interface and package it into the `CustomLoginModule.jar` file.

3. Create a `<library>` element that uses a `<fileset>` element indicating where the `CustomLoginModule.jar` file is. In this example, the library `id` is `customLoginLib`.

```
<library id="customLoginLib">
  <fileset dir="{server.config.dir}" includes="CustomLoginModule.jar"/>
</library>
```

4. Create a `<jaasLoginModule>` element. In this example, the `id` is `custom`.

a. Configure the custom login module to require a successful authentication by setting the `controlFlag` attribute to `REQUIRED`.

b. Set the `libraryRef` attribute to `customLoginLib`, the `id` of the `<library>` element configured in the previous step. This login module also has two options: `UserRegistry` is `ldap` and `mapToUser` is `user1`.

```
<jaasLoginModule id="myCustom"
  className="com.sample.CustomLoginModule"
  controlFlag="REQUIRED" libraryRef="customLoginLib">
  <options myOption1="value1" myOption2="value2"/>
</jaasLoginModule>
```

5. Create a `<jaasLoginContextEntry>` element with an `id` and a unique `name` of the system-defined JAAS configuration: `system.WEB_INBOUND`. You can also set this JAAS configuration to `system.DEFAULT`, `WSLogin`, or your own JAAS configuration. On the `loginModuleRef` attribute, add `custom`, the `id` of the `jaasLoginModule` element created in the previous step. Putting this `id` first in the list means that it is the first JAAS login module to be called. You must also list the other default login modules: `hashtable`, `userNameAndPassword`, `certificate`, and `token`.

```
<jaasLoginContextEntry id="system.WEB_INBOUND" name="system.WEB_INBOUND"
  loginModuleRef="myCustom, hashtable, userNameAndPassword, certificate, token" />
```

**Note:** The option name cannot start with a period (`.`), `config.`, or `service` and must be unique. Also, the property name `id` or `ID` is not allowed.

For more information about the `<jaasLoginContextEntry>`, `<jaasLoginModule>`, `<options>`, and `<library>` elements, see .

## Configuring an application JAAS custom login context entry and login module using a JAAS configuration file for Liberty

8.5.5.9

JAAS configuration information can be configured in a JAAS configuration file.

### About this task

We support the `server.xml` file, `client.xml` file and the JAAS configuration file for JAAS configuration. However, it is suggested to configure the JAAS custom login module in the `server.xml` file or `client.xml` file. For further details about configuring the JAAS custom login module, see “Configuring a JAAS custom login module for Liberty” on page 1868.

The Liberty server reads the JAAS configuration file for an application JAAS custom login context entry and login module. The changes that are made to the JAAS configuration file are used by the local application and take effect after the application server is restarted. The JAAS configuration in the `server.xml` file takes precedence over what is defined in the JAAS configuration file. A configuration entry in the JAAS configuration file is overridden by an entry of the same alias name in the `server.xml` file.

To configure a JAAS custom login module, complete the following steps:

## Procedure

1. Enable the appSecurity-2.0 Liberty feature in the server.xml file.  

```
<featureManager>
  <feature>appSecurity-2.0</feature>
  ...
</featureManager>
```
2. Create a JAAS custom login module class.  
For example, com.sample.CustomLoginModule that implements the LoginModule interface and package it into the CustomLoginModule.jar file.
3. Create the default jaas directory.

### For the server

```
${server.config.dir}/resources/security/jaas
```

### For the client

```
${client.config.dir}/resources/security/jaas
```

**Note:** All JAAS custom login modules that are specified in the JAAS configuration file must place in the default jaas directory.

4. Place the CustomLoginModule.jar file in the default jaas directory.
5. Create a JAAS configuration file.  
For example, create a myJaas.conf file and place it in the \${server.config.dir}/resources/security/jaas directory that has the following content:

```
myCustomLoginContext {
  com.sample.CustomLoginModule required myOption1="value1" myOption2="value2"
};
```

6. Configure the JAAS configuration file using the jvm.options file. For example,  
-Djava.security.auth.login.config=\${server.config.dir}/resources/security/jaas/myJaas.conf

**Note:** We only support the application custom JAAS login module in the JAAS configuration file. Do not put the default system JAAS configuration information in the JAAS configuration file.

**Note:** The JAAS configuration file is not dynamically updated if you made any changes. We strongly recommend configuring the JAAS configuration information in the server.xml file or client.xml file.

## Configuring JAAS on Liberty by using developer tools

### Distributed operating systems

You can configure a JAAS configuration (system.WEB\_INBOUND) with a custom login module for Liberty by editing the configuration. You do not have to configure JAAS unless you want to customize it.

### Before you begin

For a description of the underlying process of configuring a server, and detailed information about specific aspects of server configuration, see “Administering Liberty manually” on page 1564.

**Avoid trouble:** The developer tools creates the reference to a JAAS login module using the loginModuleRef element. You must change it and use the **loginModuleRef** attribute of jaasLoginContextEntry element. There are several security configuration examples on the WASdev.net website for reference when configuring security for your applications on Liberty.

## Procedure

1. Select **JAAS Login Context Entry** and click **Add**, then enter the login module names.

2. Select **JAAS Login Module: myCustom** and configure your custom login module by entering the **ID** and the **Class name**, then click the arrow next to the **Add** button and select **Global Element** to enter the shared library information.
3. Enter the **ID** for the shared library in the pop-up panel and click **OK**.
4. Configure **Name** and **Description** fields for the shared library, then click the arrow next to the **Add** button and select **Child Element** to add a **Fileset** reference as a child element.
5. Configure the **Fileset**. Click **Browse** in the **Base Directory** field and select the directory where the JAR file is located. Then, click **Browse** in the **Includes pattern** field to select your JAR file that contains your custom login module implementation.
6. Optional: If your custom login module needs any options, you can right-click **JAAS Login Module**, select **Add** and then select **login module options**.
7. Save the configuration. You can find the following configuration saved in the `server.xml` file.

```
<jaasLoginContextEntry name="system.WEB_INBOUND" id="system.WEB_INBOUND">
  <loginModuleRef>myCustom, hashtable, userNameAndPassword, certificate, token</loginModuleRef>
</jaasLoginContextEntry>

<jaasLoginModule className="com.sample.CustomLoginModule"
  id="myCustom" libraryRef="customLoginLib">
</jaasLoginModule>

<library id="customLoginLib" name="customLoginLib"
  description="Custom login module shared library">
  <fileset dir="{server.config.dir}" includes="CustomLoginModule.jar"/>
</library>
```

8. **Required:** To make the configuration work, you must change the `jaasLoginContextEntry` element to include the `loginModuleRef` attribute. You must remove the `loginModuleRef` element and add it as an attribute of the `jaasLoginContextEntry` element.

Here is an example of configuration using the `loginModuleRef` attribute.

```
<jaasLoginContextEntry name="system.WEB_INBOUND" id="system.WEB_INBOUND"
  loginModuleRef="myCustom, hashtable, userNameAndPassword, certificate, token" />

<jaasLoginModule className="com.sample.CustomLoginModule"
  id="myCustom" libraryRef="customLoginLib">
</jaasLoginModule>

<library id="customLoginLib" name="customLoginLib"
  description="Custom login module shared library">
  <fileset dir="{server.config.dir}" includes="CustomLoginModule.jar"/>
</library>
```

## Configuring a Java Authentication SPI for Containers (JASPIC) User Feature

8.5.5.6

You can develop a JASPIC provider to authenticate inbound web requests by using the `com.ibm.wsspi.security.jaspi.ProviderService` interface that is provided in the Liberty server.

### About this task

The Java Authentication SPI for Containers specification, JSR 196, defines an interface for authentication providers. In the Liberty server, you must package your JASPIC provider as a user feature. Your feature must implement the `com.ibm.wsspi.security.jaspi.ProviderService` interface.

## Procedure

1. Create an OSGi component that provides a service that implements the `com.ibm.wsspi.security.jaspi.ProviderService` interface.

The `ProviderService` interface defines method, `getAuthProvider`, which the Liberty runtime invokes to retrieve an instance of your JASPIC provider class that implements the `javax.security.auth.message.config.AuthConfigProvider` interface.

The following example uses OSGi declarative services annotations:

```
@package com.mycompany.jaspi;

import java.util.Map;
import javax.security.auth.message.config.AuthConfigFactory;
import javax.security.auth.message.config.AuthConfigProvider;
import org.osgi.service.component.ComponentContext;
import com.mycompany.jaspi.SampleAuthProvider;
import com.ibm.wsspi.security.jaspi.ProviderService;

@Component(service = { ProviderService.class },
           configurationPolicy = ConfigurationPolicy.IGNORE,
           immediate = true,
           property = { "myProviderProperty1=value1",
                       "myProviderProperty2=value2"})
public class SampleJaspiProviderService implements ProviderService {

    Map<String, String> configProps = null;

    // This method called by the Liberty runtime
    // to get an instance of AuthConfigProvider
    @Override
    public AuthConfigProvider getAuthProvider(Map<String, String>
   AuthConfigFactory factory)
    {
        return new SampleAuthProvider(configProps, factory);
    }

    protected void activate(ComponentContext cc) {
        // Read provider config properties here if needed,
        // then pass them to the AuthConfigProvider factory.
        // This example reads the properties from the OSGi
        // component definition.
        configProps = (Map<String, String>) cc.getProperties();
    }

    protected void deactivate(ComponentContext cc) {}
}
```

2. Package the component into an OSGi bundle that is part of your user feature, along with your JASPIC authentication provider.
3. Ensure that your feature includes the OSGi subsystem content: `com.ibm.websphere.appserver.jaspic-1.1; type="osgi.subsystem.feature"`.
4. After the feature is installed into the user product extension location, configure the `server.xml` file with the feature name. For example:

```
<featureManager>
...
<feature>usr:myJaspiProvider</feature>
</featureManager>
```

## Configuring LTPA in Liberty

You can configure a Liberty server to use a specific Lightweight Third Party Authentication (LTPA) keys file, user-defined password, and expiration time.

## About this task

The LTPA is configured by default when security is enabled for a Liberty server for the first time. The default location of the automatically generated LTPA keys file is `${server.output.dir}/resources/security/ltpa.keys`. The LTPA keys are encrypted with a randomly generated key and a default password of WebAS is initially used to protect the keys. The password is required when importing the LTPA keys into another server. To protect the security of the LTPA keys, you must change the password. When the LTPA keys are exchanged between servers, this password must match across the servers for Single Sign On (SSO) to work.

The default expiration timeout is 120 minutes. The expiration value refers to how long the LTPA tokens are valid before they expire.

**8.5.0.1** To enable dynamic reloading of the LTPA keys when copying an LTPA keys file from another server, you can specify a file monitor interval before copying the LTPA keys file. The monitor interval value refers to how often the LTPA keys file is monitored for updates.

For more information about LTPA, see LTPA concept in Liberty.

## Procedure

1. Configure the `<ltpa>` element in the `server.xml` file as follows, replacing the sample values in the example with your values:

```
<ltpa keysFileName="yourLTPAKeysFileName.keys" keysPassword="keysPassword" expiration="120" />
```

2. **8.5.0.1** Optional: Set the **monitorInterval** attribute to check the `ltpa.keys` file for key changes to be dynamically reloaded. Specify a positive integer followed by a unit of time, which can be hours (h), minutes (m), or seconds (s). In the following example, the LTPA keys file is checked for changes to be dynamically reloaded every 5 seconds:

```
<ltpa keysFileName="yourLTPAKeysFileName.keys" keysPassword="keysPassword"
      expiration="120" monitorInterval="5s" />
```

3. Encode the password within the configuration. You can get the encoded value by using the `securityUtility encode` command.
4. **8.5.0.1** Optional: Copy an existing LTPA keys file to the location specified in the **keysFileName** attribute. The default value is `${server.output.dir}/resources/security/ltpa.keys`. **8.5.0.1**  
For more information on `<ltpa>` element, see .

## OpenID

8.5.5.4

OpenID is an open standard where users can authenticate themselves to multiple entities without the need to manage multiple accounts or sets of credentials. WebSphere Application Server Liberty supports OpenID 2.0 and plays a role as a Relying Party in web single-sign-on.

### OpenID Provider (OP)

An OpenID Authentication server that can assert whether a user controls a unique identifier.

### Relying Party (RP)

An entity that requires proof that a user controls a unique identifier.

### OpenID Identifier:

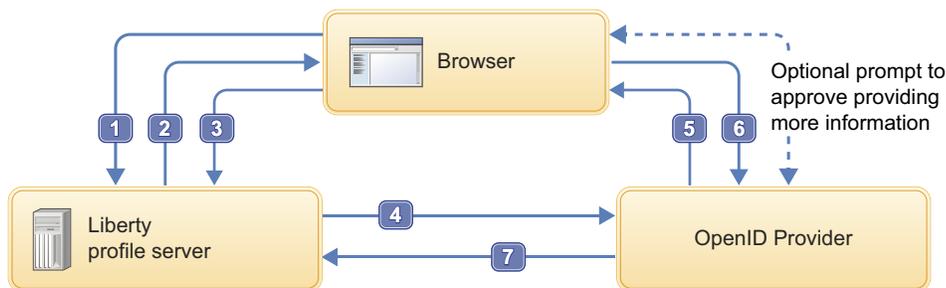

An http or https URL that belongs to an OpenID provider or a user.

Accessing various entities such as websites often requires a unique account that is associated with each entity. OpenID enables a single set of credentials that are handled by an OpenID Provider to grant access to any number of entities that support OpenID.

When required to sign in to an entity, such as a website that supports OpenID and acts as a Relying Party, users perform authentication by interacting directly with an OP rather than providing their credentials to the RP itself. An OP verifies the identity of the user and sends an authentication confirmation back to the RP. When this confirmation is received from the OP, the RP accepts the user as authenticated.

A typical OpenID authentication flow is described as follows:

1. A user attempts to access a protected resource, such as a web page.
2. The Liberty server, acting as a RP, presents a form login page for the protected resource.
3. The user enters an OpenID identifier.
4. The RP takes the identifier and redirects the user to the appropriate OP.
5. The OP prompts the user for credentials.
6. The user enters credentials for the account that is associated with the OP.
7. The OP authenticates the user and optionally prompts the user to approve or deny providing user information to the RP, and subsequently redirects the user back to the RP with the authentication result.
8. If the OP authentication is successful, the RP attempts to authorize the user.
9. If the user authorization is successful, the RP establishes an authenticated session with the user.

OpenID helps minimize the chances of user credentials or sensitive information being mishandled. With OpenID, a user's credentials are only exchanged with the OpenID Provider, meaning no website other than the OP ever sees the user's credentials. This standard helps mitigate the possibility of an unscrupulous or insecure website compromising the identity of a user. The user also controls how much personal information is shared with the websites visited. For example, users can choose to allow the name and email address that are associated with their OpenID account to be shared with one website while electing not to provide their email address, or any information at all, to another website.

The OpenID standard specifications that are supported include:

OpenID Authentication 2.0.

OpenID Attribute Exchange 1.0.

**Note:** The OpenID 2.0 Claimed Identifier should be used to identify a user per spec, Identifying the end user. However, the Claimed Identifier is not user friendly and many Relying Parties choose one of the OpenID attributes to represent the user. The most popular attribute used to represent the user is a user's email address.

It is known that some OpenID attributes, including email, might not be validated by the OpenID provider. If you do not trust that a provider will provide you a verified email address, then you must not use the provider's email as the authenticated user name in the WebSphere Application Server.

## OpenID Connect

8.5.5.4

OpenID Connect is a simple identity protocol and open standard that is built on top of the OAuth 2.0 protocol that enables client applications to rely on authentication that is performed by an OpenID Connect Provider to verify the identity of a user.

OpenID Connect uses OAuth 2.0 for authentication and authorization and then builds identities that uniquely identify users. Client applications can also obtain basic profile information about a user in an interoperable and REST-like manner from OpenID Connect Providers.

The WebSphere Application Server Liberty supports OpenID Connect 1.0 and plays a role as a Client, or Relying Party, and as a Provider in web single sign-on. The following OpenID Connect specification is supported:

8.5.5.4

OpenID Connect Core 1.0

For those using a Liberty server as a Web-based Relying Party, the 

8.5.5.4

 OpenID Connect Basic Client Implementer's Guide 1.0 is a subset of the OpenID Connect Core specification that is easier to read and provides details for Web-based Relying Parties that use the Authorization Code Flow.

### Access Token

A credential that is used to access protected resources. An access token is a string that represents an authorization that is issued to the client.

### Authorization Endpoint

A resource on an OpenID Provider that accepts an authorization request from a client to perform authentication and authorization of a user. The authorization endpoint returns an authorization grant, or code, to the client in the Authorization Code Flow. In the Implicit Flow, the authorization endpoint returns an ID token and access token to the client.

### Authorization Grant

A credential that represents a user's authorization to access resources, and is used by a client to obtain an access token.

**Claim** Information asserted about an entity. Examples of a claim include phone number, first name, last name, and others.

### ID Token

JSON Web Token (JWT) that contains claims about the authenticated user.

### Introspection Endpoint

A resource on an OpenID Provider that enables a client that is holding an access token to retrieve information that was used to create the access token, such as the user name, granted scopes, client ID, or other information.

### OpenID Connect Provider (OP)

An OAuth 2.0 authorization server that is capable of providing claims to a client, or Relying Party (RP).

### Refresh Token

Issued to the client by the OP and is used to obtain a new access token when the current access token expires, or to obtain more access tokens.

**Relying Party (RP)**

Either a Liberty server configured as an OpenID Connect Client, or a client application that requires claims from an OpenID Provider (OP).

**Scope** Privilege or permission that is allowed to access resources of a third party.

**Token Endpoint**

A resource on an OP that accepts an authorization grant, or code, from a client in exchange for an access token, ID token, and refresh token.

**The Liberty server as an OpenID Connect Client**

You can configure the WebSphere Application Server Liberty to function as an OpenID Connect Client. This setup enables the Liberty server to rely on another Liberty server that is acting as an OP for user authentication and authorization.

A Liberty server that is configured to act as an OpenID Connect Client supports the Authorization Code Flow of the OpenID Connect 1.0 standard.

In the Authorization Code Flow, all token exchanges are handled by using the token endpoint of the OpenID Connect Provider. First, the client submits an authorization request to the authorization endpoint of the OP. Upon successful authentication and authorization with the OP, the client receives an authorization grant, or code, from the OP. This authorization code can then be sent in a request to the token endpoint of the OP. The client receives an ID token, an access token, and a refresh token in the response from the token endpoint. The client then validates the ID token and retrieves the subject identifier of the user. This profile flow is intended for clients that can securely maintain a client secret between themselves and the OP. This flow also allows clients to obtain a refresh token.

For configuring a Liberty server as an OpenID Connect Client, see “Configuring an OpenID Connect Client in Liberty” on page 1924

**The Liberty server as an OpenID Connect Provider**

You can configure the WebSphere Application Server Liberty to function as an OpenID Connect Provider. This setup enables the Liberty server to act as an authorization server that can be used by OpenID Connect Clients.

A Liberty server that is configured to act as an OpenID Connect Provider supports the Authorization Code Flow and Implicit Flow of the OpenID Connect 1.0 standard. Each flow determines how the ID token, access token, and refresh token are returned to the client.

The Authorization Code Flow handles all token exchanges by using the token endpoint of the OpenID Connect Provider. An OpenID Connect Provider accepts an authorization request from a client at the OP's authorization endpoint. If authentication is necessary, the OpenID Connect Provider performs the appropriate authentication. The OpenID Connect Provider also obtains any required consent or authorization from the user, for example by prompting the user in a browser for permission to grant access to certain scopes. If successful, or if no authentication was required, the OpenID Provider sends back an authorization grant, or code, to the client. The OpenID Connect Provider then accepts a request that is submitted to its token endpoint by the client that includes the authorization code. The request that includes the authorization code is validated by the OpenID Provider. Upon successful validation, the OpenID Connect Provider returns a response to the client that includes an ID token and an access token.

In the Implicit Flow, unlike the Authorization Code Flow, all tokens are returned from the authorization endpoint; the token endpoint of the OP is not used. First, a client prepares and sends an authentication request to the authorization endpoint of the OP. The OpenID Connect Provider then performs any necessary authentication and also obtains any required consent or authorization from the user. For example, the OpenID Connect Provider prompts the user in a browser for permission to grant access to

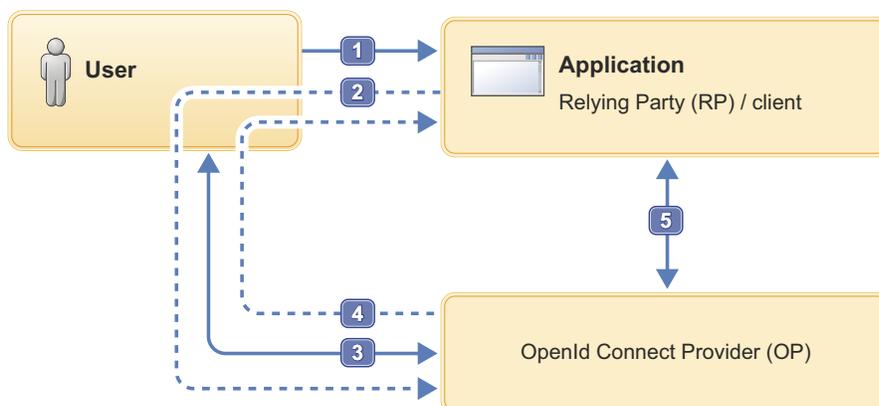

certain scopes. Upon successful authentication and authorization, the OpenID Connect Provider sends back an ID token and an access token to the client. The client then validates the ID token and retrieves the subject identifier of the user. This profile flow is intended for clients that cannot securely maintain a client secret between themselves and the OP, such as native applications.

For configuring a Liberty server as an OpenID Connect Provider, see “Configuring an OpenID Connect Provider in Liberty” on page 1899

## Authorization Code Flow

A typical OpenID Connect Authorization Code Flow is described as follows:

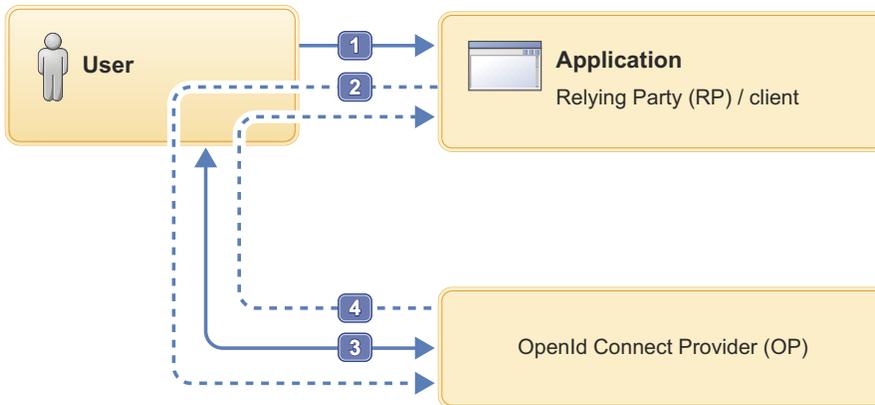

1. A user accesses an application on the RP.
2. The RP prepares an authentication request and redirects the user to the OP.
3. The OP authenticates the user, for example by prompting the user for credentials. The user authorizes the RP to access the information that is required by the application. The OP generates a one-time use authorization code for the RP.
4. The OP redirects the user back to the RP with the authorization code.
5. The RP calls the token endpoint of the OP to exchange the authorization code for an access token, ID token, and a refresh token.
6. The RP uses the ID token to authorize the user.

## Implicit Flow

The Implicit Flow is only supported by Liberty servers that are acting as an OpenID Connect Provider. A typical OpenID Connect Implicit Flow is described as follows:

1. A user accesses an application on the RP.
2. The RP prepares an authentication request and redirects the user to the OP.
3. The OP authenticates the user, for example by prompting the user for credentials. The user authorizes the RP to access the information that is required by the application.
4. The OP redirects the user back to the RP with an ID token and an access token.
5. The RP uses the ID token to authorize the user.

## Configuring an OpenID Relying Party in Liberty

8.5.5.4

You can configure a Liberty server to function as an OpenID Relying Party to take advantage of web single-sign-on.

### Before you begin

You must have at least one OpenID Provider (OP) that is trusted with authenticating users. Several third-party OpenID Providers are available.

### About this task

You can have users authenticated with an OpenID Provider by enabling the `openid-2.0` feature in Liberty, and in addition to other optional configuration information.

### Procedure

1. Add the `openid-2.0` Liberty feature to the `server.xml` file. Add the following element declaration inside the `featureManager` element in your `server.xml` file:

```
<feature>openid-2.0</feature>
```

2.  Update the `server.xml` file with the OpenID Relying Party configuration options that are specified by an `<openId>` element.

You can either predefine an OpenID provider URL in your `server.xml` file by using the **providerIdentifier** attribute of the `<openId>` element, or you can package your application with `FormLogin` which gives users an option to submit an OpenID provider URL to use for authentication.

If the **providerIdentifier** attribute is added to the `server.xml` file, the Liberty server will automatically redirect users to the OpenID provider specified by that attribute. If the **providerIdentifier** attribute is not defined in the `server.xml` file, the Liberty server will first send a login form to ask the user to select or confirm an OpenID provider prior to redirecting the user to the OpenID provider.

The following is a sample OpenID configuration that defines an OpenID provider:

```
<openId id="myOpenId" providerIdentifier="https://openid.acme.com/op" userInfoRef="email">
  <userInfo id="email" alias="email" uriType="http://axschema.org/contact/email" count="1" required="true" />
</openId>
```

Adding the `openid-2.0` feature automatically enforces a certain minimum configuration. Consequently, there is no `<openId>` element that is required to be explicitly specified in the `server.xml` file. Without an `<openId>` element that is specified, the following configuration is implicit:

```
<openId id="myOpenId" userInfoRef="email">
  <userInfo id="email" alias="email" uriType="http://axschema.org/contact/email" count="1" required="true" />
</openId>
```

By default, the user's email address that is returned from the OpenID Provider is used for identity assertion and subject creation.

3. Configure the server's truststore to include the signer certificates of the OpenID Providers that are supported. For information about keystores, see [Enabling SSL communication for Liberty](#).
  - a. Extract the signer certificate from the OpenID Provider. Most major web browsers provide support for extracting or exporting certificates from websites through the browser interface.
  - b. Import the OpenID Provider certificate to the server's truststore. For one method of importing certificates into a truststore, see the `-import` flag capabilities of the **keytool** utility that is found in your Java installation directory.
  - c. Use the `sslRef` attribute of the `<openId>` element to point to your SSL configuration. If no `sslRef` attribute is specified, the default SSL configuration described in the keystore page mentioned previously will be used. Your SSL configuration should include the appropriate references to the truststore containing the imported OpenID Provider certificates.

4. Optional: Configure the Authentication Filter.

If the `providerIdentifier` attribute is configured inside the `openId` element in the `server.xml` file, you can configure `authFilterRef` to limit the requests that should be intercepted by the OpenID provider defined by the `providerIdentifier` attribute.

For more information on configuring the authentication filter, see  [8.5.5.5](#) “Authentication Filters” on page 1937.

## Configuring SPNEGO authentication in Liberty

8.5.5.5

You can use single sign-on for HTTP requests by using the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) web authentication for WebSphere Application Server Liberty. SPNEGO single sign-on enables HTTP users to log in to a Microsoft® domain controller only once at their desktop and to achieve single sign-on (SSO) with the Liberty server.

### Before you begin

Configure the following software and ensure that it is available:

1. A Microsoft Windows® Server running an Active Directory Domain Controller and associated Kerberos Key Distribution Center (KDC). For this topic, an example host for such a domain controller is `myAdMachine.example.com`. The domain controller name is `mydomain.example.com` and the Kerberos realm name is `MYDOMAIN.EXAMPLE.COM`, which is the domain controller name in all uppercase letters.
2. A Microsoft Windows® domain member (client) that supports the SPNEGO authentication mechanism as defined in IETF RFC 2478. Examples of an appropriate client might be a modern browser or a Microsoft .NET client. Most modern browsers support SPNEGO authentication. For this topic, an example host for the client is `myClientMachine.example.com`.
3. A server platform with a Liberty server that has a protected resource within an application. Users in the Active Directory must be able to access Liberty server protected resources by using a native Liberty server authentication mechanism. For this topic, an example Liberty server host is `myLibertyMachine.example.com`.

**Note:** The software configuration must have a running domain controller, at least one client machine in that domain and a server platform with a Liberty server that has a protected resource within an application, for a total of three required machines. Using SPNEGO directly from the domain controller is not supported.

**Note:** Ensure the clocks for the client, Microsoft Active Directory server, and Liberty server are synchronized to within 5 minutes of each other, by default. The allowable difference in synchronization is configurable.

**Note:** Only IBM JDKs are supported currently. Non-IBM JDKs are not supported.

## About this task

The objective of this task is to allow users to successfully access Liberty server resources without having to authenticate again, and thus achieve Microsoft Windows® desktop single sign-on capability.

This task demonstrates how to configure a Liberty server to support single sign-on for HTTP requests by using SPNEGO web authentication.

## Procedure

1. On the Microsoft domain controller (myAdMachine.example.com), create a Kerberos service principal name (SPN) and keytab file for the Liberty server. :
  - a. Create a user account for the Liberty server. This is the account that is used to map to the Kerberos service principal name (SPN). For Active Directory machines, this can typically be done by going to **Start > Administrative Tools > Active Directory Users and Computers**, right-clicking on **Users** in the panel, and selecting **New > User**. This topic assumes that the user myLibertyMachine\_http was created with password security.
  - b. Run the Microsoft **setspn** command to map the user account to a Kerberos SPN. This user account represents the Liberty server as being a Kerberos service with the KDC. The following is an example **setspn** command:

```
C:\> setspn -a HTTP/myLibertyMachine.example.com myLibertyMachine_http
```

```
Registering ServicePrincipalNames for CN=myLibertyMachine_http,CN=Users,DC=MYDOMAIN,DC=EXAMPLE,DC=COM
HTTP/myLibertyMachine.example.com
Updated object
```

**Note:** If your Microsoft **setspn** command version supports the **-S** option, then you must use the **-S** option instead of **-A**.

- c. Create the Kerberos keytab file by using the Microsoft **ktpass** tool. The default name for this file is krb5.keytab.

The following is an example **ktpass** command:

```
C:\> ktpass -out krb5.keytab -princ HTTP/myLibertyMachine.example.com@MYDOMAIN.EXAMPLE.COM -mapUser myLibertyMachine
```

```
Targeting domain controller: myAdMachine.MYDOMAIN.EXAMPLE.COM
Using legacy password setting method
Successfully mapped HTTP/myLibertyMachine.example.com to myLibertyMachine_http.
Key created.
Output keytab to krb5.keytab:
Keytab version: 0x502
keysize 93 HTTP/myLibertyMachine.example.com@MYDOMAIN.EXAMPLE.COM ptype 1 (KRB5_NT_PRINCIPAL) vno 3 etype 0x17 (
```

Make sure that there is not a duplicated SPN in the Microsoft forest by using one of the following commands:

- If your Microsoft **setspn** command version supports the **-X** option to search for a duplicated SPN, then use **setspn -X**:

```
C:\>setspn -X HTTP/myLibertyMachine.example.com
```

```
Processing entry 0
found 0 group of duplicate SPNs.
```

- You can also use the Microsoft **ldif** command. The following example shows that one entry was returned, meaning there is not a duplicated SPN.

```
C:\>ldifde -f check_SPN.txt -t 3268 -d "" -l servicePrincipalName -r "(servicePrincipalName=HTTP/myLibertyMachine.example.com)" -p subtree
```

```
Connecting to "myAdMachine.MYDOMAIN.EXAMPLE.COM"  
Logging in as current user using SSPI  
Exporting directory to file check_SPN.txt  
Searching for entries...  
Writing out entries.  
1 entries exported
```

For information on creating SPNs and keytab files on different KDC systems, see [Creating a Kerberos service principal name and keytab file](#).

2. On the Liberty server machine (myLibertyMachine.example.com), enable the Kerberos keytab and configuration files and SPNEGO web authentication.
  - a. Copy the Kerberos keytab file from the domain controller to the Liberty server machine. The default name of this file is krb5.keytab and the default location varies depending on the platform but is the same directory as the Kerberos configuration file. For default locations for various platforms, see the next step.
  - b. Create a Kerberos configuration file.

The Kerberos configuration file contains client configuration information, including the locations of KDCs for the realms of interest, defaults for the current Kerberos realm, and mappings of host names onto Kerberos realms. For Liberty servers, you must create this file manually.

The default location and name of this file varies depending on the operating system:

- **Windows** Windows - The default location is c:\winnt\krb5.ini. If the krb5.ini file is not in the c:\winnt directory, it might be in c:\windows
- **Linux** Linux - The default location is /etc/krb5.conf.
- **AIX** **z/OS** **HP-UX** **Solaris** AIX, z/OS, HP-UX, and Solaris - The default location is /etc/krb5/krb5.conf.

The following is a sample Kerberos configuration file for the AIX, z/OS, HP-UX, or Solaris platforms (based on the default keytab location):

```
[libdefaults]  
    default_realm = MYDOMAIN.EXAMPLE.COM  
    default_keytab_name = FILE:/etc/krb5/krb5.keytab  
    default_tkt_enctypes = rc4-hmac  
    default_tgs_enctypes = rc4-hmac  
    forwardable = true  
    renewable = true  
    noaddresses = true  
    clockskew = 300  
    udp_preference_limit = 1  
[realms]  
    MYDOMAIN.EXAMPLE.COM = {  
        kdc = myAdMachine.example.com:88  
        default_domain = example.com  
    }  
[domain_realm]  
    .example.com = MYDOMAIN.EXAMPLE.COM
```

**Note:** Realm names are usually specified in uppercase letters. If using Microsoft Active Directory, realm names are required to be uppercase.

**Note:** Not all of the KDC solutions available support all encryption types. Before choosing an encryption type, ensure that the KDC supports the encryption type that you want to use by consulting your Kerberos Administrator's and User's Guide.

Ensure that you have a common encryption type for the Kerberos configuration file, Kerberos keytab file, Kerberos SPN, and Kerberos client. For example, if the Kerberos client uses the

RC4-HMAC encryption type, the target server must also support the RC4-HMAC encryption type and the Kerberos configuration file must list RC4-HMAC first in the **default\_tgt\_encytypes** and **default\_tkt\_encytypes** parameters.

For additional information and requirements on the content of this file, see *Creating a Kerberos configuration file*.

c. Verify the Kerberos configuration and keytab files.

- You can use the JDK command **klist** to list the SPN in the keytab file.

```
klist -k -t /etc/krb5.keytab
```

- You can use the JDK command **kinit** to validate the SPN in the keytab file and the Kerberos configuration file.

```
kinit -k -t /etc/krb5.keytab HTTP/myLibertyMachine.example.com
```

After the **kinit** command you can use the **klist** command to list the Kerberos ticket. If you get the Kerberos ticket, then the Kerberos keytab and configuration are valid.

d. Configure and enable SPNEGO web authentication on the Liberty server.

You can enable SPNEGO web authentication by enabling the `spnego-1.0` feature of the Liberty profile.

1) Add the `spnego-1.0` feature to the `server.xml` file.

```
<featureManager>
  <feature>spnego-1.0</feature>
  <feature>appSecurity-2.0</feature>
  ...
</featureManager>
```

Adding the `spnego-1.0` feature automatically enforces a certain minimum configuration. You do not need to specify a `<spnego>` element in the `server.xml` file. Without specifying a `<spnego>` element, the following configuration is implicit.

```
<spnego
  canonicalHostName="true"
  disableFailOverToAppAuthType="true"
  trimKerberosRealmNameFromPrincipal="true"
  includeClientGSSCredentialInSubject="true" />
```

**Note:** The runtime forms the default SPN in the following format:

```
"HTTP/" + java.net.InetAddress.getLocalHost().getCanonicalHostName();
```

If the default SPN does not match what you have in the `krb5.keytab` file, then you need to specify the `servicePrincipalNames`, for example:

```
<spnego id="mySpnego" servicePrincipalNames="HTTP/myLibertyMachine.example.com"/>
```

**Note:** When the `spnego-1.0` feature is enabled and the `<spnego>` element is either omitted or not configured with an `authFilterRef` attribute, all requests to access protected resources use SPNEGO authentication.

For more information on configuring the authentication filter, see  **8.5.5.5** “Authentication Filters” on page 1937.

**Note:** When values for the `krb5Config` or `krb5Keytab` attributes are not given, each respective file is expected to exist at its default location. The default locations for the Kerberos configuration and keytab files on various platforms are given earlier in this topic.

2) Optional: Specify any additional configuration options as necessary. Liberty supports many common SPNEGO scenarios and configurations. For example, you can filter HTTP requests to require SPNEGO authentication for only certain requests, web applications, hosts, or user agents. Also, you can move the Kerberos configuration and keytab files away from their respective default locations. The following is a sample configuration that changes the default `<spnego>` settings:

```

<server>
  <featureManager>
    <feature>spnego-1.0</feature>
    <feature>appSecurity-2.0</feature>
    ...
  </featureManager>
  ...
  <authFilter id="myAuthFilter">
    <host id="myHost" name="example.com" matchType="contains" />
    <webApp id="myWebApp" name="protectedApp" matchType="equals" />
  </authFilter>

  <spnego id="mySpnego"
    includeClientGSSCredentialInSubject="false"
    krb5Config="${server.config.dir}/resources/security/kerberos/krb5.conf"
    krb5Keytab="${server.config.dir}/resources/security/kerberos/krb5.keytab"
    servicePrincipalNames="HTTP/myLibertyMachine.example.com"
    authFilterRef="myAuthFilter" />
  </spnego>
  ...
</server>

```

With this configuration, SPNEGO authentication is used for any requests that are received containing the host name `example.com` for resources within the web application `protectedApp`. In addition, the client's GSS credentials are not added to the user subject upon successful authentication. Finally, the Kerberos configuration and keytab files to be used by the server are given specific locations within the server configuration directory instead of their respective default locations.

For more configuration options, see  [8.5.5.5](#) The Simple and Protected GSS-API Negotiation Mechanism (SPNEGO).

For information on mapping Kerberos principal names to WebSphere user registry IDs, see Mapping of a client Kerberos principal name to the WebSphere user registry ID.

In the rare event that you wish to use Kerberos principal names for authorization, see  [8.5.5.5](#) "Using Kerberos principal name for authorization with SPNEGO authentication" on page 1886. These steps should be followed only when necessary and by users who specifically choose not to use the default mapping or JAAS custom login module mapping.

3. Configure the client application on the client application machine (`myClientMachine.example.com`).

The following steps must be done only on the client machine. Starting a browser on the Active Directory machine or Liberty server machine and performing these steps does not work.

The following steps are for users who are accessing SPNEGO-protected resources from a browser. You must have a browser installed that supports SPNEGO authentication.

Microsoft Internet Explorer:

- a. At the desktop, log in to the Windows Active Directory domain.
- b. In the Internet Explorer window, click **Tools > Internet Options**. In the window that is displayed, click the **Security** tab.
- c. Select the **Local intranet** icon and click **Sites**.
- d. If using Internet Explorer version 9 or older, go to the next step. If using Internet Explorer 10 or later, click **Advanced** in the Local intranet window.
- e. In the Local intranet window, complete the **Add this website to the zone** field with the web address of the host name so that single sign-on (SSO) can be enabled for the list of websites that are shown in the websites field. Your site information technology staff provides this information. Close the second Local intranet window and click **OK** to complete this step and close the Local intranet window.
- f. On the Internet Options window, click the **Advanced** tab and scroll to Security settings. Ensure that the **Enable Integrated Windows® Authentication** box is selected.
- g. Click **OK**. Restart your Microsoft Internet Explorer to activate this configuration.

Mozilla Firefox:

- a. At the desktop, log in to the Windows Active Directory domain.
- b. In the address field in Firefox, type `about:config`.
- c. In the Filter/Search box, type `network.n`.
- d. Double-click **network.negotiate-auth.trusted-uris**. This preference lists the sites that are permitted to engage in SPNEGO Authentication with the browser. Enter a comma-delimited list of trusted domains or URLs.

**Note:** You must set the value for `network.negotiate-auth.trusted-uris`.

- e. If the deployed SPNEGO solution is using the advanced Kerberos feature of Credential Delegation, double-click **network.negotiate-auth.delegation-uris**. This preference lists the sites for which the browser can delegate user authorization to the server. Enter a comma-delimited list of trusted domains or URLs.
- f. Click **OK**. The configuration reflects the updates.
- g. Restart your Firefox browser to activate this configuration.

**Note:** The user must be logged in to the domain controller for SPNEGO to work. Using the previous example machines, a user must log in to the domain controller at `MYDOMAIN.EXAMPLE.COM\username` in order for SPNEGO authentication through the browser to work.

**Note:** If you are prompted multiple times for a user ID and password, make sure that you enabled SPNEGO support on your client browser by following the previous instructions. You must also make sure that the `disableFailOverToAppAuthType` attribute in the `<spnego>` configuration is set to `false`.

## Results

Your Internet browser is now properly configured for SPNEGO authentication. You can use applications with secured resources that are deployed on Liberty servers without being prompted for a user ID and password.

To verify that SPNEGO is working, you can log in to the domain controller and then access a protected resource on the Liberty server, and because you are logged in to the domain controller, you are not prompted for credentials. However, if you do not log in to the domain controller and attempt to access a protected resource, you are prompted for credentials.

## Configuring Kerberos constrained delegation for out-bound SPNEGO tokens in Liberty

You can configure a Liberty server to support Kerberos constrained delegation for out-bound SPNEGO tokens.

### Before you begin

Make sure that you have configured SPNEGO web authentication.

Only IBM JDK 1.8 and later are supported.

### About this task

The Kerberos v5 extension called S4U (Services for Users) also known as constrained delegation comprises two parts:

**S4U2self**

Allows a Liberty server to obtain a service ticket to itself on behalf of a user. This can be used with any form of authentication that is supported by Liberty. S4U2self is the Kerberos Protocol Transition extension.

### S4U2proxy

Allows a Liberty server to obtain service tickets to trusted services on behalf of a user. These service tickets are obtained by using the user's service ticket to the Liberty service. The services are constrained by the Kerberos Key Distribution Center (KDC) administrator. S4U2proxy is the Kerberos Constrained Delegation extension.

The constrained delegation feature provides the following APIs to create the out-bound SPNEGO token for back end services that support SPNEGO authentication, such as .NET servers and other Liberty servers.

- S4U2self API:  
`com.ibm.websphere.security.s4u2proxy.SpnegoHelper.buildS4U2proxyAuthorizationUsingS4U2self()`
- S4U2proxy API:  
`com.ibm.websphere.security.s4u2proxy.SpnegoHelper.buildS4U2proxyAuthorization()`

The following steps use the same example system setup that is used in Configuring SPNEGO authentication in Liberty and illustrated in Single sign-on for HTTP requests using SPNEGO web authentication.

### Procedure

1. On the Microsoft domain controller `myAdMachine.example.com`, update the service principal name (SPN) that you use to validate the incoming SPNEGO token. For example, update the `HTTP/myLibertyMachine.example.com` SPN as follows:
  - a. To use S4U2self, perform the following steps:
    - 1) Open the user account that is mapped to the delegate SPN.
    - 2) Open the Attribute Editor tab.
    - 3) Modify the `userAccountControl` property as follows:
      - Trusted for auth delegation `0x1000000`, or the `TRUSTED_TO_AUTHENTICATE_FOR_DELEGATION` enum) must be true.
    - 4) Set the trusted service:
      - Open the Delegation tab in the user account.
      - Select the **Trust this user for delegation to specified services only** radio button.
      - Select the **Use any authentication protocol** radio button.
      - Click on **Add** to add the trusted service.
      - Click **Users or Computers**.
      - Enter the SPN to be used for the trusted service.
      - Click **Check Names** and verify that the appropriate object name was found.
      - Click **OK**.
      - Select the **SPN specified** and click **OK**.
  - b. To use S4U2proxy, perform the following steps:
    - 1) Open the user account that is mapped to the delegate SPN.
    - 2) Open the Attribute Editor tab.
    - 3) Modify the `userAccountControl` property as follows:
      - Trusted for auth delegation (`0x1000000`, or the `TRUSTED_TO_AUTHENTICATE_FOR_DELEGATION` enum) must be true.
    - 4) Set the trusted service:
      - Open the Delegation tab in the user account.

- Select the **Trust this user for delegation to specified services only** radio button.
  - Click on **Add** to add the trusted service.
  - Click **Users or Computers**.
  - Enter the SPN to be used for the trusted service.
  - Click **Check Names** and verify that the appropriate object name was found.
  - Click **OK**.
  - Select the **SPN specified** and click **OK**.
2. On the Liberty server machine (myLibertyMachine.example.com), enable the constrained delegation feature by adding constrainedDelegation-1.0 to the featureManager and configure the JAAS Kerberos login module in the server.xml file.

```
<featureManager>
  <feature>spnego-1.0</feature>
  <feature>constrainedDelegation-1.0</feature>
  ...
</featureManager>
<jaasLoginContextEntry id="com.ibm.security.jgss.krb5.accept" name="com.ibm.security.jgss.krb5.accept" loginModuleRef="U
  <jaasLoginModule id="useKeytab" className="com.ibm.security.auth.module.Krb5LoginModule" controlFlag="REQUIRED" libra
    <options
      credsType="both"
      debug="true"
      useDefaultCcache="false"
      tryFirstPass="true"
      forwardable ="true"
      principal="HTTP/myLibertyMachine.example.com"
      useKeytab="${server.config.dir}/resources/security/kerberos/krb5.keytab">
    </options>
  </jaasLoginModule>
```

```
<library id="jaasSharedLib" apiTypeVisibility="spec, ibm-api, api">
  <fileset dir="${server.config.dir}/lib/global/" includes="*" />
</library>
```

When the constrainedDelegation-1.0 feature is enabled, the following configuration is implicit:

```
<constrainedDelegation id="defaultConstrainedDelegation" s4U2selfEnabled="false" />
```

To use S4U2self, the following configuration is needed in the server.xml file:

```
<constrainedDelegation s4U2selfEnabled = "true" id="defaultConstrainedDelegation"/>
```

**Note:** When you use the S4U2proxy API, the jaasLoginContextEntry id and name com.ibm.security.jgss.krb5.accept can not change.

**Note:** By default, S4U2proxy is enabled and S4U2self is disabled. The S4U2self extension can be enabled or disabled by modifying the s4U2selfEnabled attribute in the server.xml file.

## Results

Your application is now ready to call the API provided by the constrained delegation feature.

## Using Kerberos principal name for authorization with SPNEGO authentication

8.5.5.5

You can use the fully qualified Kerberos principal name for authorization instead of using simple mapping or creating your own custom JAAS custom login module.

## About this task

The following steps should be rarely followed, and only by users who specifically choose not to use simple mapping, which is the default configuration, or choose not to add a JAAS custom login module to map the fully qualified Kerberos principal name to a user in the Liberty server user registry. This task allows you to use the fully qualified Kerberos principal name for authorization.

## Procedure

1. Configure the SPNEGO authentication to not trim the Kerberos realm name from the fully qualified Kerberos principal name by setting the `trimKerberosRealmNameFromPrincipal` attribute to `false`.
2. Configure the Liberty server to use either stand-alone LDAP or federated repositories.  
For more information on how to configure LDAP, see [Configuring LDAP user registries with Liberty](#).
  - a. Make sure that the Active Directory user exists in the LDAP user registry and that this user has a `userPrincipalName` attribute that is associated with it.
  - b. Update the LDAP filter in the `server.xml` file to search for the `userPrincipalName`, as shown in the following example:

```
<activatedLdapFilterProperties id="myactivatedfilters"
  userFilter="(&(userPrincipalName=%v))"
  groupFilter="(&(cn=%v))"
  userIdMap="*:userPrincipalName"
  groupIdMap="*:cn"
  groupMemberIdMap="ibm-allGroups:member">
</activatedLdapFilterProperties>
```

3. Configure the application bindings for the corresponding application to use the fully qualified Kerberos principal name as the user name along with a properly configured `access-id`. For example:

```
<application type="war" id="myApp" name="myApp" location="{server.config.dir}/apps/myApp.war">
  <application-bnd>
    <security-role name="Employee">
      <user name="kevin@MYDOMAIN.EXAMPLE.COM" access-id="CN=kevin,CN=Users,DC=MYDOMAIN,DC=EXAMPLE,DC=COM"/>
      ...
    </security-role>
    ...
  </application-bnd>
</application>
```

## Customizing SSO configuration using LTPA cookies in Liberty

With single sign-on (SSO) configuration support, web users can authenticate once when accessing Liberty resources such as HTML, JavaServer Pages (JSP) files, and servlets, or accessing resources in multiple Liberty servers that share the same Lightweight Third Party Authentication (LTPA) keys.

### Example

When a user passes authentication on one of Liberty servers, authentication information generated by the server is transported to the web browser in a cookie. The cookie is used to propagate the authentication information to other Liberty servers.

The LTPA is configured and ready for immediate use. The default cookie name used to store the SSO token is called `ltpaToken2`. If you want to use a different name for the cookie, you can customize the cookie name using the `ssoCookieName` attribute of the `<webAppSecurity>` element. If you customize the cookie name, make sure that all the servers that participate in SSO use the same cookie name.

For more information about SSO, see [SSO concept in Liberty](#).

The following example code sets the user to be logged out after the HTTP session expires and the name of the SSO cookie as `myCookieName`:

```
<webAppSecurity logoutOnHttpSessionExpire="true" ssoCookieName="myCookieName" />
```

**Note:** For SSO to work across Liberty servers, full profile servers, or both, set the following resources:

- The servers must use the same LTPA keys and share the same user registry.
- If the servers are not in the same domain, use the **ssoDomainNames** attribute of the <webAppSecurity> element to list the domains. The following example code sets the domain name to domain.com:  

```
<webAppSecurity ssoDomainNames="domain.com" />
```
- If the servers are in the same domain, set the **ssoUseDomainFromURL** attribute of the <webAppSecurity> element to true, or specify the domain name in the **ssoDomainNames** attribute. The following example code sets **ssoUseDomainFromURL** to true so that the domain name is taken from the request URL:  

```
<webAppSecurity ssoUseDomainFromURL="true" />
```

For details of all the available SSO settings, see the <webAppSecurity> element in .

## Configuring RunAs authentication in Liberty

You can delegate authentication to another identity by configuring the RunAs specification for Liberty.

### About this task

By mapping a specified user identity and optional password to a RunAs role, you can delegate the authentication process to a user that has the RunAs role.

**8.5.5.0** You must enable the appSecurity-2.0 and servlet-3.0 Liberty features and have a user registry for your application to configure the RunAs role.

For more information about RunAs authentication, see “RunAs() authentication” on page 984.

To configure RunAs authentication, complete the following steps:

### Procedure

1. **8.5.5.0** Enable the appSecurity-2.0 and servlet-3.0 Liberty features in the server.xml file.
2. Configure a user registry for your application.
3. Specify the <run-as> element in the deployment descriptor of your application.

The following example of web.xml file specifies subsequent calls be delegated to the user that is mapped to the role of Employee:

```
<servlet id="Servlet_1">
  <servlet-name>RunAsServlet</servlet-name>
  <display-name>RunAsServlet</display-name>
  <description>RunAsServlet</description>
  <servlet-class>web.RunAsServlet</servlet-class>
  <run-as>
    <role-name>Employee</role-name>
  </run-as>
</servlet>
```

4. **Distributed operating systems** Map the role that you specified in the previous step to a user. You can do this either in the ibm-application-bnd.xml/xml or in the server.xml file. In the <run-as> element, you must specify a user name. If you are using the ibm-application-bnd.xml file, the password is also required; if you are using the server.xml file, the password is optional. If the password is required, encode the password using the **securityUtility encode** command in the /bin directory. For more information about the **securityUtility** command, see “Liberty:securityUtility command” on page 1844.

The following example uses the <run-as> element within the <application-bnd> element of the server.xml file, where the Employee role has been mapped to the RunAs user of user5:

```
<application-bnd>
  <security-role name="Employee">
    <user name="user1" />
    <user name="user5" />
    <run-as userid="user5" password="{xor}Lz4sLCgwLTs=" />
  </security-role>
</application-bnd>
```

**Note:**

- Because the password is optional in the server.xml file, you can also use the following code for a user without a password:

```
<application-bnd>
  <security-role name="Employee">
    <user name="user1" />
    <user name="user5" />
    <run-as userid="user5" />
  </security-role>
</application-bnd>
```

- If you specify the <application-bnd> element in the server.xml file, your application must not be in the dropins folder. If you leave your application in the dropins folder, then you must disable application monitoring by setting the following in your server.xml file:

```
<applicationMonitor dropinsEnabled="false" />
```

The RunAs user name needs to be unique, and does not exist in external accounts. For example, if you authenticate a user to a SAML identity provider or OpenID Connect provider, make sure the RunAs user name is not in those external accounts.

For more information about the run-as element, see .

5. **z/OS** Configure RunAs authentication via SAF resource profiles, which is specific for z/OS users.

- a. **z/OS** Enable RunAs delegation via SAF.

```
<safAuthorization enableDelegation="true" />
```

- b. **z/OS** Assign the RunAs user identity to the app resource and role. This is done by setting the RunAs user identity into the APPLDATA field of the corresponding SAF resource profile. By default, the corresponding SAF resource profile for a given application and role is named {profilePrefix}.{appName}.{roleName} in the EJBROLE SAF class.

This is the same resource profile used by Liberty SAF Authorization for authorizing users to the application and role. The name of the profile is governed by the safRoleMapper configuration. For more information about mapping application and role names to SAF profile names, see Controlling how roles are mapped to SAF Profiles. Here are some example RACF commands for assigning user5 as the RunAs user for the application myapp and the role of Employee:

```
RDEFINE EJBROLE BBGZDFLT.myapp.Employee UACC(READ)
RALTER EJBROLE BBGZDFLT.myapp.Employee APPLDATA('user5')
SETROPTS GENERIC(EJBROLE) REFRESH
SETROPTS RACLIST(EJBROLE) REFRESH
```

## Configuring TAI in Liberty

You can configure Liberty to integrate with a third-party security service by using Trust Association Interceptors (TAI). The TAI can be called before or after single sign-on (SSO).

### Before you begin

Make sure that you have already installed a third-party security server as a reverse proxy server. The third-party security server can act as a front-end authentication server when the Liberty server applies its own authorization policy onto the resulting credentials, which are passed by the proxy server. You must also have a JAR file that contains the custom TAI class, which implements the com.ibm.wsspi.security.tai.TrustAssociationInterceptor interface.

**Note:** There is no support for monitoring changes of this JAR file.

## About this task

A TAI is used to validate HTTP requests between a third-party security server and a Liberty server. The TAI inspects the HTTP requests from the third-party security server to see whether they contain any security attributes. If the process of validating a request by the TAI is successful, the Liberty server authorizes the request by checking whether the client user has the required permission to access the resources.

For more information of custom TAI and SSO configuration with LTPA, see “Developing a custom TAI for Liberty” on page 1998 and “Customizing SSO configuration using LTPA cookies in Liberty” on page 1887.

You can also use the developer tools to configure a TAI service. **Distributed operating systems** For more information about the tools support, see “Configuring TAI on Liberty by using developer tools” on page 1891.

## Procedure

1. Enable the appSecurity-2.0 Liberty feature in the server.xml file.

```
<featureManager>
  <feature>appSecurity-2.0</feature>
</featureManager>
```
2. Deploy your applications to the Liberty server and enable all Liberty features, such as, jsp-2.2 and jdbc-4.0.
3. Place the TAI implementation library simpleTAI.jar in your server directory.
4. Update the server.xml file with the TAI configuration options and location of the TAI implementation library.

In the following server.xml file, the custom TAI is enabled, but does not do any authentication for unprotected URIs and does not allow to fallback to application authentication method if the TAI authentication fails. As shown in the example, the following configuration elements are available for TAI support:

- trustAssociation
- interceptors
- properties

```
<trustAssociation id="myTrustAssociation" invokeForUnprotectedURI="false"
  failOverToAppAuthType="false">
  <interceptors id="simpleTAI" enabled="true"
    className="com.sample.SimpleTAI"
    invokeBeforeSSO="true" invokeAfterSSO="false" libraryRef="simpleTAI">
    <properties prop1="value1" prop2="value2"/>
  </interceptors>
</trustAssociation>

<library id="simpleTAI">
  <fileset dir="${server.config.dir}" includes="simpleTAI.jar"/>
</library>
...
```

**Note:** The property name cannot start with a period (.), **config.**, or **service**. Also, the property name **id** or **ID** is not allowed.

**Note:** By default, the invokeBeforeSSO property is set to true. By using this setting TAI is invoked even when the SSO token is present and valid. However, if the expected behavior is to invoke TAI

only when the SSO token is invalid or not present, then this property can be disabled by setting it to false, and enabling the `invokeAfterSSO` property. By using this setting TAI is invoked only when the SSO token is not present or is invalid. In some cases, this setup might improve the performance of your system.

For more information about the `<trustAssociation>`, `<interceptors>` and `<properties>` elements, see also .

## Configuring TAI on Liberty by using developer tools

### Distributed operating systems

You can configure a TAI service for Liberty using developer tools.

### Before you begin

For a description of the underlying process of configuring a server, and detailed information about specific aspects of server configuration, see “Administering Liberty manually” on page 1564.

**Avoid trouble:** There are several security configuration examples on the `WASdev.net` website for reference when configuring security for your applications on Liberty.

### Procedure

1. Select the parent **Trust Association Interceptor** and enter an **ID** name.
2. Select the child **Trust Association Interceptor** and configure the **Class name** which is the fully qualified name of your TAI implementation class, then click the arrow next to the **Add** button and select **Global Element** to enter the shared library information.
3. Enter the **ID** for the shared library in the popup window and click **OK**.
4. Configure the **Name** and **Description** fields for the shared library, then click the arrow next to the **Add** button and select **Child Element** to add a fileset reference as a child element.
5. Configure the **Fileset**. Click **Browse** in the **Base directory** field and select the directory where the JAR file is located. Then, click **Browse** in the **Includes pattern** field to select your JAR file that contains your TAI implementation.
6. Configure **Interceptor properties** details by clicking **Add** to add properties for the interceptor.
7. Save the configuration. You can find the following configuration saved in the `server.xml` file.

```
<trustAssociation id="myTrustAssociation" invokeForUnprotectedURI="false"
    failOverToAppAuthType="false">
  <interceptors id="simpleTAI" enabled="true"
    className="com.ibm.websphere.security.sample.SimpleTAI"
    invokeBeforeSSO="true" invokeAfterSSO="false" libraryRef="simpleTAI">
    <properties hostName="machine1" application="test1"/>
  </interceptors>
</trustAssociation>

<library id="simpleTAI">
  <fileset dir="{server.config.dir}" includes="simpleTAI.jar"/>
</library>
```

## Configuring a custom form login page

8.5.5.4

Liberty provides the ability to define a custom form login page for users to submit authentication credentials.

## About this task

You can customize your own custom form login page, but you must implement this page in the required form-based authentication format as specified in the Servlet 3.0 specification. In all forms, the action on the form element must be `j_security_check`. The action must use the `j_username` input field to get the user name and the `j_password` input field to get the user password in forms supporting authentication schemes that require a user name and password. The custom form login page must be provided as an unprotected web resource. You can set this login page at the global server level, which applies to all applications deployed to the server. Alternatively, you can specify the login page for individual applications.

**Note:** Make sure that any files included in your form-login page (such as external style sheets, or images) are unprotected.

## Procedure

1. Specify the following form elements in the form login page that expects a user name and password.

```
<FORM action="j_security_check" method="POST">  
  User name: <INPUT type="text" name="j_username"><br>  
  Password: <INPUT type="password" name="j_password"><br>  
  <INPUT type="submit" name="action" value="Login">  
</FORM>
```

2. Configure the login form for use by applications on the server. There are two possible configurations to use a form login page in an application that is deployed to the server. You can configure the custom login page for use in a single application, or you can configure the page as a global login form that is used for all applications that are deployed to the server.

- a. Configure a login form for a single application. You can configure individual applications to direct users to a specific form login page by configuring the `web.xml` file that is packaged with the application.

Specify the path to the login page in the `web.xml` file that is packaged with the application; for example:

```
<login-config>  
  <auth-method>FORM/<auth-method>  
  <realm-name>MyRealm/<realm-name>  
  <form-login-config id="FormLoginConfig_1">  
    <form-login-page>/login.jsp/<form-login-page>  
    <form-error-page>/loginError.jsp/<form-error-page>  
  </form-login-config>  
</login-config>
```

To see how to customize and package a form login page, refer to [Customizing web application login](#).

- b. Configure a global login form. You can omit the form login page from the `web.xml` files that are packaged with each application and instead, specify in the `server.xml` configuration that the login form is for global use among applications that are deployed to the server.

In the `server.xml` file, include a `webAppSecurity` element with the `loginFormURL` attribute that is specified with a value of the path of the login form page; for example:

```
<webAppSecurity loginFormURL="myGlobalFormLogin/myLogin.jsp" />
```

Ensure that the form login page is packaged as a web application archive (WAR) file deployed to the server.

If the `form-login-page` element within an application's `web.xml` file does not exist, use the global login page that is specified in the server configuration.

3. **Optional:** Configure a custom form login page for OpenID.
4. **Optional:** Configure a custom form login page for OAuth.

## Configuring a custom form login page for OpenID

8.5.5.4

Login pages for Liberty must have a certain configuration in order to support OpenID Authentication.

### About this task

If you have configured the `providerIdentifier` attribute of the `<openid>` element in your `server.xml` file, you can skip this task.

Unlike standard form login pages that require a user name and password, form login for OpenID only requires submitting an OpenID Identifier. You must therefore configure form login pages to accept this OpenID Identifier.

### Procedure

1. Configure the login form to specify `j_security_check` as the value for the action.
2. Add an input field to the login form and set the `name` attribute to `openid_identifier` for users to input an OpenID Identifier. The resulting form is similar to the following HTML example:

```
<FORM action="j_security_check" method="POST">  
  OpenID: <INPUT type="text" name="openid_identifier"><br>  
  <INPUT type="submit" name="action" value="Login">  
</FORM>
```

No user name or password inputs are required if authentication is only performed using OpenID.

## Configuring a custom form login page for OAuth

8.5.5.4

You can configure custom form login pages for specific OAuth service providers.

### About this task

To use a custom form login page for a specific OAuth service provider, you must update the service provider definition in the `server.xml` file.

### Procedure

In the provider configuration, add the `customLoginURL` attribute and specify the login page URL as the value.

The following is an example custom login page entry in the provider definition:

```
<oauthProvider id="OAuthConfigSample"  
  customLoginURL="https://acme.com:9043/oauth20/login.jsp">
```

The login form that is used for OAuth must be configured to accept a user name and password.

## Configuring SAML Web Browser SSO in Liberty

8.5.5.7

You can configure a Liberty server to function as a SAML web browser Single-Sign-On (SSO) service provider.

## About this task

You can configure a Liberty server as a SAML web SSO service provider by enabling the `samlWeb-2.0` feature in Liberty, and in addition to other configuration information.

### Procedure

1. Add the `samlWeb-2.0` Liberty feature to your `server.xml` file by adding the following element declaration inside the `featureManager` element.

```
<feature>samlWeb-2.0</feature>
```

2. Liberty provides a default `samlWebSso20` element.

```
<samlWebSso20 id="defaultSP">
```

```
</samlWebSso20>
```

In this default configuration, the following default values are assumed:

- AssertionConsumerService URL:  
`https://<hostname>:<sslport> /ibm/saml20/defaultSP/acs`
- Service Provider (SP) metadata URL:  
`https://<hostname>:<sslport> /ibm/saml20/defaultSP/samlmetadata`

You can use a browser to download the metadata for this service provider (SP) by using this URL, and provide the URL to the SAML identity provider to establish federation between this SP and Identity Provider (IdP).

- The IdP metadata file must be copied to the `resources/security` directory on the server, and named `idpMetadata.xml`.
- The issuer name for SAML assertion is used as the security realm, and `NameID` is used as the principal to create an authenticated subject from the SAML assertion.
- The SAML `AuthnRequest` is signed with a private key in the default keystore of the server if the attribute `KeyStoreRef` is not specified. If the `keyAlias` is not configured, then `samlsp` is the default key alias. If the `keyAlias` is not configured, and the keystore only contains one private key, the private key is used in the signature.

**Note:** If you create a new service provider instance, and the `defaultSP` is no longer required, then you must explicitly disable the `defaultSP` instance, by adding the following to the `server.xml` file.

```
<samlWebSso20 id="defaultSP" enabled="false">  
</samlWebSso20>
```

**Note:** It is required that you specify a URL safe String that is not null as the `id` for `samlWebSso20`. If the `id` is missing, then the configuration element is omitted, and is not handled as the `defaultSP`.

**Note:** When SAML is configured and enabled, all unauthenticated requests will use SAML authentication. To configure the types of requests that should and should not use SAML authentication, you must configure an authentication filter as described in step 15.

3. Optional: You can add `<samlWebSso20 id="defaultSP">` to the `server.xml` file, and customize the `defaultSP` service provider. For example:
  - `idpMetadata`: Add this parameter to change the IdP metadata location and file name from the default location and file name (`${server.config.dir}/resources/security/idpMetadata.xml`).
  - `userIdentifier`: Add this parameter to select a SAML attribute name whose value is used as the principal name.
  - `groupIdIdentifier`: Add this parameter to select a SAML attribute name whose values are included as group members in the subject.
  - `realmName`: Use this parameter to explicitly specify the realm name to identify a SAML principal in this service provider. The default realm name is the SAML issuer name.

- Optional: You can create one or more new `samlWebSso20` elements with a different ID. For example, if you create a new element with an ID as `mySP`, you effectively create a new SAML SP instance that has a new `AssertionConsumerService` URL:

`https://<hostname>:<sslport>/ibm/saml20/mySP/acs`

**Note:** The ID you choose for `samlWebSso20` is included in URL of the SP, including the `AssertionConsumerService` URL and metadata URL. The `samlWebSso20` ID must be non-empty and must not contain unsafe URL characters.

- Optional: You can configure a trust engine. The Liberty SAML SP supports two types of trust engines:

- **Metadata trust engine:** Validates the signature against information that is provided in the configured IdP metadata.
- **PKIX trust engine:** Validates the trustworthiness of the certificate in the signature through PKIX validation. Certificates that pass this validation are assumed to be trusted.

Metadata is the default trust engine. If you want to use the PKIX trust engine, you need to add the `PKIXTrustEngine` element, and define the proper `trustAnchor`.

- Optional: You can configure how to create an authenticated subject from SAML. By default the Liberty SP creates a subject from SAML assertion directly without the requirement of a local user registry, which is equivalent to the configuration `mapToUserRegistry=No`. The other configuration options are `mapToUserRegistry=User` or `mapToUserRegistry=Group`.

- `mapToUserRegistry=No`: The SAML issuer's name is `realm`, and the `NameID` is used to create a principal name and unique security name in the subject, and no group member is included. You can configure the attributes: `userIdentifier`, `realmIdentifier`, `groupIdentifier`, and `userUniqueIdentifier` to create an authenticated subject with a customized user name, realm name, group memberships, and unique security identifier.
- `mapToUserRegistry=User`: Choose this option if you want to validate a SAML user against your on-premises user registry, and create the user subject based on the on-premises registry.
- `mapToUserRegistry=Group`: Choose this option if you want to validate a SAML group against your local user registry, and create a subject to contain those validated groups. This option is similar to `mapToUserRegistry=No`, except for group memberships are verified against the on-premises user registry.

- Optional: You can implement the Liberty SAML SPI, `com.ibm.wsspi.security.saml2.UserCredentialResolver` as a user feature to dynamically map a SAML assertion to a Liberty subject.
- Optional: You can define rules to tell the IdP how to authenticate a user by configuring one or more of the following attributes when using an SP-initiated Web SSO flow: `forceAuthn`, `isPassive`, `allowCreate`, `authnContextClassRef`, and `authnContextComparisonType`.
- Optional: You can define a required `NameID` format in the `AuthnRequest` by using the `nameIDFormat` attribute. You can specify any `NameID` format that is defined in the SAML specification, or use the keyword `customize` to specify the custom `NameID` format.
- Optional: You can configure multiple SP and IdP federation partners by creating multiple `samlWebSso20` elements, and each `samlWebSso20` refers to one unique `authFilter` element. All `authFilters` must exclude each other. With multiple `samlWebSso20` configured, each can perform single-sign-on with its federated identity provider, and has its own authentication policy and consuming rules.
- Optional: Add support for IdP-initiated unsolicited SSO. Liberty SAML SP supports IdP-initiated unsolicited SSO with and without the requirement of IdP metadata on-premises. If you do not have IdP metadata, or if you intend to use unsolicited SSO to federate with multiple identity providers with one Liberty SP, you must add the following configurations:
  - Configure `<PKIXTrustEngine>`, and import all the IdP signer certificates to the default truststore of the Liberty server, or to the `trustAnchor` of the `PKIXTrustEngine`.

- Configure the trustedIssuers to list the issuer name of the IdP as it appears in the SAML assertion. The issuer name is used as the EntityID in the metadata.
  - If you intend to support unsolicited SSO only, you can configure SP-initiated unsolicited SSO as documented in the next step. This scenario is useful if the user's security context in the SP that is associated with SAML becomes invalid, the SP can redirect the user back to the IdP to start unsolicited SSO again automatically.
12. Optional: Add support for SP-initiated unsolicited SSO. The Liberty SAML SP uses configured IdP metadata to perform a solicited SAML AuthnRequest. It is possible for the Liberty SP to redirect unauthenticated requests to a preconfigured login application without using AuthnRequest. This scenario is useful if a business application performs pre-authentication processing before a user can authenticate to the SAML IdP, or the SAML IdP must be hidden from the Liberty SP. To configure this scenario, you add the loginPageURL attribute, and set its value to a URL that can instruct a user to authenticate to the SAML IdP.
  13. Optional: Configure signature requirements with the following considerations:
    - SAML assertion. All SAML assertions must be digitally signed by the SAML IdP. In the rare case that you want to accept an unsigned assertion, you can explicitly configure wantAssertionsSigned=false.
    - The default signature algorithm is SHA256. If you must change the algorithm, use the signatureMethodAlgorithm attribute to modify it.
    - If you do not want to sign the SAML AuthnRequest, you can set authnRequestsSigned=false.
  14. Optional: You can configure an SP authentication session and cookie. After SAML assertion is verified and processed, the Liberty SAML SP maintains an authenticated session between the browser and the SP without using an LTPA cookie. The authenticated session timeout is set to SessionNotOnOrAfter in the <saml:AuthnStatement> if presented, or to sessionNotOnOrAfter as configured in the server.xml file, with the default being 120 minutes. The session cookie name is automatically generated, and you can customize the cookie name by using the attribute spCookieName to specify the wanted name.

If you want the Liberty SP to create an LTPA cookie from the SAML assertion and use the LTPA cookie for subsequent authentication requests, you can add the configuration disableLtpaCookie=false. If you want to share the LTPA cookie with other servers, you must add the configuration attribute allowCustomCacheKey="false".

**Note:** If you configure disableLtpaCookie="false" and allowCustomCacheKey="false", ensure that a SAML user name is not directly authenticating to an on-premises user registry that prevents a user from having two accounts.

15. Optional: Configure the Authentication Filter.
 

When the samlWeb-2.0 feature is enabled, any unauthenticated request is authenticated through one SAML SP. If you define a customized samlWebSso20 element, all authentication requests are handled by this samlWebSso20 SP instance; otherwise, all authentication is handled by the default instance defaultSP. You can use authnFilter to define which SP instance to handle the authentication request.

For more information on configuring the authentication filter, see Authentication Filters.
16. Optional: Configure the SAML SP in a cluster.
 

If application servers are cluster members, and you use a router or reverse proxy server to route your requests, then you need to perform the following tasks:

  - The router and proxy server must be configured to support session affinity.
  - Add the configuration attribute spHostAndPort to each application server, and set its value to the router or proxy server host name and port. For example, spHostAndPort="https://myRouter.com:443".
  - Generate an X509 certificate for signing the SAML AuthnRequest, and use this certificate on all application servers. For example, you can create a keystore to contain this certificate only, and add the KeyStoreRef to reference this keystore on all application servers.

- If `createSession="true"` is not set in a cluster environment, then the following error is encountered during the stress execution:

E CWWKS5029E: The relay state [sp\_initial\_KGe22fCWKG11D9VkoMuDz0Ji8pBxFPnU] in the response from the identity pro

Here is a sample cluster configuration:

```
<keyStore id="samlKeyStore" password="<password>"
  location="{server.config.dir}/resources/security/<samlKey.jks>" />

  <samlWebSso20 id="defaultSP"
    spHostAndPort="https://<IHS host>:<port>"
    keyStoreRef="samlKeyStore"
    createSession="true"
    allowCustomCacheKey="false"
    disableLtpaCookie="false"
    mapToUserRegistry="User">
</samlWebSso20>
```

## Results

You have now established the configuration that is required to configure a Liberty server as a SAML service provider capable of single-signing on with SAML identity providers.

## Using OpenID Connect

8.5.5.4

OpenID Connect in the Liberty server is implemented as an OAuth 2.0 extension. In addition to providing OpenID Connect functions, the OpenID Connect provider supports all OAuth 2.0 functions.

### OpenID Connect endpoint URLs

8.5.5.4

Learn about OpenID Connect endpoint URLs that are available for communicating with the OpenID Connect provider.

After OpenID Connect is configured, several endpoint URLs are available on Liberty so that OpenID Connect clients can communicate with the OpenID Connect provider before accessing protected resources. By default, all communications must be over Transport Layer Security (TLS).

The following endpoint URLs are available for communicating with the OpenID Connect provider:

- “Authorization endpoint URL”
- “Token endpoint URL” on page 1898
- “Introspection endpoint URL” on page 1898
- “UserInfo endpoint URL” on page 1898
- “Discovery endpoint URL” on page 1898
- “Coverage map endpoint URL” on page 1899
- “Registration endpoint URL” on page 1899

### Authorization endpoint URL

`https://<host_name>:<port_number>/oidc/endpoint/<provider_name>/authorize`

where

#### **host\_name**

The host name of the OpenID Connect provider.

#### **port\_number**

The secure port number that is configured on the Liberty server.

**provider\_name**

The OpenID Connect provider name.

For more information, see  [8.5.5.4](#) Invoking the Authorization Endpoint for OpenID Connect.

**Token endpoint URL**

`https://<host_name>:<port_number>/oidc/endpoint/<provider_name>/token`

where

**host\_name**

The host name of the OpenID Connect provider.

**port\_number**

The secure port number that is configured on the Liberty server.

**provider\_name**

The OpenID Connect provider name.

For more information, see  [8.5.5.4](#) Invoking the Token Endpoint for OpenID Connect.

**Introspection endpoint URL**

`https://<host_name>:<port_number>/oidc/endpoint/<provider_name>/introspect`

where

**host\_name**

The host name of the OpenID Connect provider.

**port\_number**

The secure port number that is configured on the Liberty server.

**provider\_name**

The OpenID Connect provider name.

For more information, see  [8.5.5.4](#) Invoking the Introspection Endpoint for OpenID Connect.

**UserInfo endpoint URL**

`https://<host_name>:<port_number>/oidc/endpoint/<provider_name>/userinfo`

where

**host\_name**

The host name of the OpenID Connect provider.

**port\_number**

The secure port number that is configured on the Liberty server.

**provider\_name**

The OpenID Connect provider name.

For more information, see  [8.5.5.4](#) Invoking the UserInfo Endpoint for OpenID Connect.

**Discovery endpoint URL**

`https://<host_name>:<port_number>/oidc/endpoint/<provider_name>/.well-known/openid-configuration`

where

**host\_name**

The host name of the OpenID Connect provider.

**port\_number**

The secure port number that is configured on the Liberty server.

**provider\_name**

The OpenID Connect provider name.

For more information, see  [8.5.5.4](#) Configuring an OpenID Connect Provider to accept discovery requests.

**Coverage map endpoint URL**

`https://<host_name>:<port_number>/oidc/endpoint/<provider_name>/coverage_map`

where

**host\_name**

The host name of the OpenID Connect provider.

**port\_number**

The secure port number that is configured on the Liberty server.

**provider\_name**

The OpenID Connect provider name.

For more information, see  [8.5.5.4](#) Invoking the coverage map service.

**Registration endpoint URL**

`https://<host_name>:<port_number>/oidc/endpoint/<provider_name>/registration`

where

**host\_name**

The host name of the OpenID Connect provider.

**port\_number**

The secure port number that is configured on the Liberty server.

**provider\_name**

The OpenID Connect provider name.

For more information, see  [8.5.5.4](#) Configuring an OpenID Connect Provider to accept client registration requests.

**Configuring an OpenID Connect Provider in Liberty**

[8.5.5.4](#)

You can configure a Liberty server to function as an OpenID Connect Provider, or authorization server, to take advantage of web single sign-on.

**About this task**

You can configure a Liberty server to act as an OpenID Connect Provider by enabling the `openidConnectServer-1.0` feature in Liberty, and in addition to other configuration information.

## Procedure

1. Add the openidConnectServer-1.0 Liberty feature and any other needed features to the server.xml file. The ssl-1.0 feature is also required for the openidConnectServer-1.0 feature.

```
<feature>openidConnectServer-1.0</feature>
<feature>ssl-1.0</feature>
```

2. Define an OAuth service provider. OpenID Connect is built on top of the OAuth 2.0 protocol and you must configure a valid OAuth service provider. The configuration of an OAuth service provider includes the appropriate oauth-roles, oauthProvider, and user registry elements. Any user that is authorized to use OpenID Connect must also be mapped to the authenticated oauth-role. See Defining an OAuth service provider for more information.

The OAuth metadata is updated for OpenID Connect, and the main additions are in the client metadata. If you use the databaseStore mode for client registration, see “Configuring an OpenID Connect Provider to accept client registration requests” on page 1915 for more information. It is suggested that you follow the document to manage clients. If you use the localStore mode for client registration, you can register the scope, preAuthorizedScope, grantTypes, responseTypes, introspectTokens, and functionalUserId, as well as other attributes.

3. Add an openidConnectProvider element whose oauthProviderRef attribute references the configured oauthProvider. Each oauthProvider can only be referenced by one openidConnectProvider, and two or more openidConnectProvider elements cannot reference to the same oauthProvider. The name attribute and the secret attribute of the client element must match the client ID and the client secret of the corresponding OpenID Connect Client. This example works with the default Liberty server OpenID Connect Client.

**Note:** In this example, the OP expects the client's SSL port to be set to 443.

```
<openidConnectProvider id="OidcConfigSample" oauthProviderRef="OAuthConfigSample" />

<oauthProvider id="OAuthConfigSample">
<localStore>
<client name="client01" secret="{xor}LDo8LTor"
displayname="client01"
scope="openid profile email"
redirect="https://server.example.com:443/oidcclient/redirect/client01"/>
</localStore>
</oauthProvider>
```

**Note:** A valid client must register its name, redirect, scope, and secret for authorization\_code grant type.

4. Configure the truststore of the server to include the signer certificates of the OpenID Connect Relying Parties, or clients, that are supported. For information about keystores, see “Enabling SSL communication in Liberty” on page 1834
5. Modify the SSL configuration of the server to use the configured truststore.

```
<sslDefault sslRef="DefaultSSLSettings" />
<ssl id="DefaultSSLSettings" keyStoreRef="myKeyStore" trustStoreRef="myTrustStore" />
<keyStore id="myKeyStore" password="{xor}Lz4sLCgwLTs=" type="jks" location="{server.config.dir}/resources/security/Bas
<keyStore id="myTrustStore" password="{xor}Lz4sLCgwLTs=" type="jks" location="{server.config.dir}/resources/security/B
```

OpenID Connect is configured to use the default SSL configuration that is specified by the server. Therefore, the default SSL configuration for the server must use the truststore that is configured for OpenID Connect.

The user consent form in OpenID Connect is pluggable, which allows providers to create and maintain their own consent form. Because this form is retrieved over SSL, you must configure the truststore to include the signer certificate of the server on which the consent form is hosted. If the default consent form is used and the truststore that is used for OpenID Connect is configured to be different from the keystore that is used by the Liberty server, you must import the Liberty server's signer certificate into the OpenID Connect truststore.

For more OpenID Connect Provider configuration options, see .

**Note:** In order to use OpenID Connect, the scope attribute must include openid in the scope list.

## Results

You have now completed the minimum configuration that is required to configure a Liberty server as an OpenID Connect Provider capable of communicating with other Liberty servers configured as OpenID Connect Clients.

### Using an OpenID Connect provider as an OAuth 2.0 authorization server: 8.5.5.4

An OpenID Connect provider can be used as a normal OAuth 2.0 authorization provider to issue an OAuth 2.0 access\_token, and support all OAuth 2.0 grant types.

An OpenID Connect provider supports JSON Web Token (JWT) Bearer Token as a grant for requesting an OAuth 2.0 access token, see  JSON Web Token (JWT) for OAuth Client Authorization Grants and  Configuring an OpenID Connect Provider to accept JSON Web Tokens (JWT) for authorization grants.

If an authorization request is made with an authorization code grant or implicit grant type, and if openid scope is not included or approved, the request is handled as a normal OAuth authorization request. An id\_token is not issued, and an access\_token and refresh\_token can be issued.

An OpenID Connect provider can support OAuth authorization flow with Resource Owner Password Credentials Grant or Client Credentials Grant, see  Configuring an OpenID Connect Provider to enable 2-legged OAuth requests.

### JSON Web Token (JWT) for OAuth Client Authorization Grants: 8.5.5.4

JWT for OAuth Client Authorization Grants enables a client to send a signed JWT token to the OpenID Connect Provider in exchange for an OAuth 2.0 access token.

JWT for OAuth Client Authorization Grants is included in the openidConnectServer-1.0 feature. It enables a client to send a signed JWT token to the OpenID Connect Provider in exchange for an OAuth 2.0 access token.

An example usage scenario of this functionality might be a customer of an electric company who authorizes automatic monthly payments from an online bank. Assuming the electric company and the online bank have established a trusted relationship for the purposes of fulfilling such requests. The electric company can send a signed JWT Token with proper claims to the token endpoint URI of the OpenID Connect Provider that are configured for the online bank in order to request an OAuth 2.0 access token each month. The electric company can then use the access token to cash monthly payments from the online bank.

Portions of the JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants specification are supported for Liberty servers that are configured as OpenID Connect Providers. Users that want to support the JWT client functionality must do so by using their own application.

- Authorized scopes
- Claims in a JSON Web Token
- Submitting JSON Web Token requests

## Authorized scopes

The OpenID Connect Client sends an HTTPS request with a JWT to the token endpoint of the OpenID Connect Provider to request an access token. During this process, the user sees no consent form for authorizing the use of scopes. The JWT handler will handle the authorized scopes that are based on the following criteria:

1. If no scope parameter is specified in the request, the OpenID Connect Provider will not specify any scopes in the access token.
2. When an OpenID Connect Client is qualified as an autoAuthorized client in the OpenID Connect Provider configuration, any scope that is specified by the client in the request is specified in the scope list of the access token.
3. When an OpenID Connect Client is not qualified as an autoAuthorized client, the scope that is included in the request needs to be filtered by the list of scopes in the client configuration and must also be specified in the preAuthorizedScope list. If a scope in the HTTPS request is in the scope and preAuthorizeScope list of the client configuration, the scope can be specified in the scope list of the access token.

When a client is not qualified as an autoAuthorized client, scopes that can be included in the scope list of the access token must be properly configured in the client configuration. The scope must be included in the values for the scope and preAuthorizedScope attributes in the client configuration for the OpenID Connect Provider. In the example that is shown, the scopes profile and email are specified in the scope list of the access token because both are included in the scope and preAuthorizedScope value list. If a scope is not listed in the scope attribute of the client configuration, it is omitted from the scope list of the access token. If a scope is listed in the scope attribute but is not included in the preAuthorizedScope list within the client configuration, the authorization request triggers an invalid\_grant error in the response from the OpenID Connect Provider.

```
<openidConnectProvider id="OidcConfigSample" oauthProviderRef="OAuthConfigSample" />
<oauthProvider id="OAuthConfigSample" ... >
  ...
  <localStore>
    <client name="client01" secret="{xor}..."
      displayname="client01"
      scope="profile email phone"
      preAuthorizedScope="profile email"
      enabled="true"/>
    ...
  </localStore>
</oauthProvider>
```

## Claims in a JSON Web Token

A valid JSON Web Token must be signed. A Liberty server that is configured as an OpenID Connect Provider only supports HMAC-SHA256 as the token signing algorithm. The signing key for each OpenID Connect Client is the secret attribute in the client configuration of the OpenID Connect Provider. In the example that is shown, the signing key that is used would be "{xor}LDo8LTor".

```
<client name="client01" displayname="client01" secret="{xor}LDo8LTor" ... />
```

The OpenID Connect Provider also verifies the following claims in a JWT:

### 'iss' (issuer)

This claim is required in a JWT. The iss claim must match the name attribute or the redirect attribute of the client configuration in the OpenID Connect Provider. In the following example, the iss claim must match either client01 or http://op201406.ibm.com:8010/oauthclient/redirect.jsp.

```
<client name="client01" redirect="http://op201406.ibm.com:8010/oauthclient/redirect.jsp" scope="openid profile email" />
```

**'sub' (subject)**

This claim is required in a JWT. The value of the subject must be a valid user name in the user registry of the OpenID Connect Provider server.

**'aud' (audience)**

This claim is required in a JWT. The value of the audience claim is the name of the issuerIdentifier when the issuerIdentifier attribute is specified in the openidConnectProvider configuration. If the issuerIdentifier attribute is not specified in the openidConnectProvider configuration, the audience must be the token endpoint URI of the OpenID Connect Provider. In the following example, the value of the audience claim would be "OpenIDConnectProviderID1".

```
<openidConnectProvider id="OidcConfigSample" oauthProviderRef="OAuthConfigSample" issuerIdentifier="OpenIDConnectProviderID1">
```

**'exp' (expiration)**

This claim is required in a JWT and limits the time window that the JWT can be used. The OpenID Connect Provider verifies the exp against its system clock, plus some allowable clock skew.

**'nbf' (not before)**

This is an optional claim. When present, the token is only valid after the time specified by this claim. The OpenID Connect Provider verifies this time against its system clock, plus some allowable clock skew.

**'iat' (issued at)**

By default, this is an optional claim. However, if the iatRequired attribute of the jwtGrantType element is set to true, then all JWTs are required to contain the iat claim. When present, the iat claim indicates the time at which the JWT was issued. A JWT cannot be issued longer than the maxTokenLifetime.

**'jti' (JWT ID)**

This is an optional claim and is the unique identifier of a JWT Token. When present, the same JWT ID cannot be reused by an issuer. For example, if client01 issues a JWT whose jti is id6098364921, then no other JWT issued by client01 can have a jti value of id6098364921. A JWT with a jti claim identical to another JWT is considered to be a replay attack. Liberty servers that are configured as OpenID Connect Providers set up a jti cache on the server. The size of the cache is specified by the maxJtiCacheSize in the jwtGrantType configuration. The jti IDs that are kept in the cache are checked against any new incoming jti ID. The jti IDs stored in the cache are not discarded unless the cache is full.

**Submitting JSON Web Token requests**

It is a best practice to use the HTTPS protocol instead of HTTP to submit a JWT request. The token endpoint of the OpenID Connect Provider is used for handling HTTPS JWT requests. To determine the token endpoint for the OpenID Connect Provider, see Invoking the Token Endpoint for OpenID Connect or OAuth endpoint URLs.

The request must contain the following parameters:

- grant\_type - The value of this parameter must be "urn:ietf:params:oauth:grant-type:jwt-bearer"
- assertion - The value of this parameter must contain a single signed JWT Token.
- scope - This parameter is optional. If scope is omitted, the access token that is returned does not contain any scopes. The scope values listed in the scope parameter are checked against the OpenID Connect Provider configuration. For more information, see the previous Authorized Scopes section.
- client\_id - The value of this parameter must match the name attribute in the client configuration of the OpenID Connect Provider.
- client\_secret - The value of this parameter must match the secret attribute in the client configuration of the OpenID Connect Provider.

An example HTTPS request:

```

POST /token.oauth2 HTTP/1.1
Host: oidc.ibm.com
Content-Type: application/x-www-form-urlencoded

client_id=client01
&client_secret=secret
&grant_type=urn%3Aietf%3Aparams%3Aoauth%3Agrant-type%3Ajwt-bearer
&assertion=eyJhbGciOiJIcGkiLCJ0eSI6ImF4fQ.MB6ZF1CsHg5MJ-weiHZYz6xgF1jdSZn7ErchHs8-8Rk
&scope=profile email

```

A Java example to create a signed JWT Token:

```

package com.ibm.sample;

import java.security.SignatureException;
import com.google.gson.JsonObject;
import net.oauth.jsontoken.crypto.HmacSHA256Signer;

import net.oauth.jsontoken.SystemClock;
import net.oauth.jsontoken.JsonToken;
import org.joda.time.Duration;
import org.joda.time.Instant;

public class SampleJWTToken {
    private static final Duration SKEW = Duration.standardMinutes(5);

    JsonToken jwtToken = null;
    String[] allPayloadKeys = { "iss", "sub", "aud", "exp", // required
                               "nbf", "iat", "jti" }; // optional

    public SampleJWTToken(String clientId,
                          String keyId,
                          String signKey,
                          String audience,
                          String subject, // user
                          String jtiId) throws Exception { // InvalidKeyException

        byte[] hs256Key = signKey.getBytes();
        HmacSHA256Signer hmacSha256Signer = new HmacSHA256Signer(
            clientId, keyId, hs256Key);
        // _rsaSha256Signer = new RsaSHA256Signer(clientId, _keyId,
        //   _privateKey);
        SystemClock clock = new SystemClock(SKEW);
        jwtToken = new JsonToken(hmacSha256Signer, clock);
        JsonObject headerObj = jwtToken.getHeader();
        JsonObject payloadObj = jwtToken.getPayloadAsJsonObject();

        headerObj.addProperty("alg", "HS256");

        Instant instantExp = clock.now().plus(600000); // 10 minutes
        jwtToken.setExpiration(instantExp);
        jwtToken.setAudience(audience);
        payloadObj.addProperty("iss", clientId);
        payloadObj.addProperty("sub", subject);

        // optional
        payloadObj.addProperty("jti", jtiId);
        jwtToken.setIssuedAt(clock.now()); // issued at time
    }

    public String getJWTTokenString() throws Exception {
        String signedAndSerializedString = null;
        try {
            signedAndSerializedString = jwtToken.serializeAndSign();
        } catch (SignatureException e) {
            throw e;
        }
    }
}

```

```

    }
    return signedAndSerializedString;
}
}

```

## Configuring an OpenID Connect Provider to accept discovery requests: 8.5.5.4

The discovery configuration endpoint makes information available about the capabilities that are supported by the OpenID Connect Provider (OP) server.

### About this task

The metadata that is returned by this service is based on and extends the OIDC Discovery 1.0 specification provider metadata. The service returns a set of default configurations if nothing is specified. Otherwise, refer to the list of properties to understand their purpose and possible configurable options.

### Procedure

You can override the default values for selected properties in the discovery configuration service. This action is performed by specifying the values in the `server.xml` file. Refer to the following table of properties to view the configurable properties and possible configuration options.

*Table 130. Discovery request parameters*

Attribute Name	Data Type	Required/Optional	Description
responseTypesSupported	Input	Optional	The response types that are supported by the OpenID Connect Provider (OP) server. Unless specified, the default values are code, token, and id_token token. More than 1 value can be specified. These values are strings. For example, possible values are: <ul style="list-style-type: none"> <li>code</li> <li>token</li> <li>id_token token</li> </ul>
subjectTypesSupported	Output only	N/A	The subject types that are supported by the OP server. This value is set to public. This value is a string.

Table 130. Discovery request parameters (continued)

Attribute Name	Data Type	Required/Optional	Description
idTokenSigningAlgValuesSupported	Output only	Optional	<p>The ID token signing algorithms that are supported by the OP server. This value is specified as the server attribute <code>signatureAlgorithm</code> in the <code>openidConnectProvider</code> server configuration. Unless specified, the default value is HS256. Only 1 value can be specified. This is a string. For example, possible values for attribute <code>signatureAlgorithm</code> in the <code>openidConnectProvider</code> configuration:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• RS256</li> <li>• HS256</li> </ul>
scopesSupported	Input	Optional	<p>The scope values supported by the OP server. Unless specified, the default values are <code>openid</code>, <code>general</code>, <code>profile</code>, <code>email</code>, <code>address</code>, and <code>phone</code>. More than 1 value can be specified. These values are strings. For example, possible values are:</p> <ul style="list-style-type: none"> <li>• <code>openid</code></li> <li>• <code>general</code></li> <li>• <code>profile</code></li> <li>• <code>email</code></li> <li>• <code>address</code></li> <li>• <code>phone</code></li> </ul>

Table 130. Discovery request parameters (continued)

Attribute Name	Data Type	Required/Optional	Description
claimsSupported	Input	Optional	<p>The claims values that are supported by the OP server. Unless specified, the default values are sub, groupIds, name, preferred_username, picture, locale, email, and profile. More than 1 value can be specified. These values are strings. For example, possible values are:</p> <ul style="list-style-type: none"> <li>• sub</li> <li>• groupIds</li> <li>• name</li> <li>• preferred_username</li> <li>• picture</li> <li>• locale</li> <li>• email</li> <li>• profile</li> </ul>
responseModesSupported	Input	Optional	<p>The response modes that are supported by the OP server. Unless specified, the default values are query and fragment. More than 1 value can be specified. These values are strings.</p> <ul style="list-style-type: none"> <li>• query</li> <li>• fragment</li> </ul>
grantTypesSupported	Input	Optional	<p>The grant types that are supported by the OP server. Unless specified, the default values are authorization_code, implicit, refresh_token, client_credentials, password, and urn:iETF:params:oauth:grant-type:jwtbearer. More than 1 value can be specified. These values are strings. For example, possible values are:</p> <ul style="list-style-type: none"> <li>• authorization_code</li> <li>• implicit</li> <li>• refresh_token</li> <li>• client_credentials</li> <li>• password</li> <li>• urn:iETF:params:oauth:grant-type:jwtbearer</li> </ul>

Table 130. Discovery request parameters (continued)

Attribute Name	Data Type	Required/Optional	Description
tokenEndpointAuthMethodsSupported	Input	Optional	The token endpoint authorization methods that are supported by the OP server. Unless specified, the default values are <code>client_secret_post</code> , and <code>client_secret_basic</code> . More than 1 value can be specified. These values are strings. For example, possible values are: <ul style="list-style-type: none"> <li>• none</li> <li>• <code>client_secret_post</code></li> <li>• <code>client_secret_basic</code></li> </ul>
displayValuesSupported	Output only	N/A	The display values supported by the OP server. This value is set to page. This value is a string.
claimTypesSupported	Output only	N/A	The claim type values that are supported by the OP server. This value is set to normal. This value is a string.
claimsParameterSupported	Input	Optional	Indication of whether claims parameter is supported by the OP server. Unless specified, the default value is false. Only 1 value can be specified. This is a Boolean value. For example, possible values are: <ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul>
requestParameterSupported	Input	Optional	Indication of whether a request parameter is supported by the OP server. Unless specified, the default value is false. Only 1 value can be specified. This is a Boolean value. For example, possible values are: <ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul>

Table 130. Discovery request parameters (continued)

Attribute Name	Data Type	Required/Optional	Description
requestUriParameterSupported	Input	Optional	Indication of whether request URI parameter is supported by the OP server. Unless specified, the default value is false. Only 1 value can be specified. This is a Boolean value. For example, possible values are: <ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul>
requireRequestUriRegistration	Input	Optional	Indication of whether require request URI registration is supported by the OP server. Unless specified, the default value is false. Only 1 value can be specified. This is a Boolean value. For example, possible values are: <ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul>

### Examples of discovery configuration

The following example assumes that the Liberty OP is configured with SSL on port 443.

`https://server.example.com:443/oidc/endpoint/<provider_name>/`

The discovery configuration endpoint is accessible at:

`https://server.example.com:443/oidc/endpoint/<provider_name>/.well-known/openid-configuration`

For example, in the `server.xml` file, a user can customize their OpenID Connect discovery configuration properties in the following manner:

```
<openidConnectProvider id="OidcConfigSample" oauthProviderRef="OAuthConfigSample">
  <discovery
    responseTypeSupported="token, id_token token"
    subjectTypesSupported="public"
    scopesSupported="openid, general, profile"
    claimsSupported="sub, groupIds, name"
    responseModesSupported="query"
    grantTypesSupported="implicit"
    tokenEndpointAuthMethodsSupported="client_secret_basic"
    displayValuesSupported="page"
    claimTypesSupported="normal"
    claimsParameterSupported="true"
    requestParameterSupported="true"
    requestUriParameterSupported="true"
    requireRequestUriRegistration="true"
  />
</openidConnectProvider>
<oauthProvider id="OAuthConfigSample">
</oauthProvider>
```

## Example of customized discovery configuration

Request Headers:

GET https://server.example.com:443/oidc/endpoint/<provider\_name>/.well-known/openid-configuration

Response Headers:

Status: 200

Content-Type: application/json

Cache-Control: public, max-age=3600

Response Body:

```

}
```

## Configuring claims returned by the UserInfo endpoint: 8.5.5.4

You can configure a Liberty OpenID Connect Provider to customize the claims that are returned by the UserInfo endpoint.

### About this task

You can configure the claims that are returned from a Liberty server OpenID Connect Provider by using the `scopeToClaimMap` and `claimToUserRegistryMap` subelements of the `openidConnectProvider` element in the `server.xml` file.

The OpenID Connect UserInfo endpoint accepts an access token as input and returns a set of claims about the user for whom the access token was created. The claims that are returned are determined by:

1. The scopes in the access token  
An access token can have multiple scopes. The scopes in an access token are the scopes that are supplied on the authorization endpoint invocation that created the access token.
2. The claims that are associated with the scopes  
Each scope can have multiple claims that are associated with it.
3. The federated repository properties that are associated with the claims  
A claim can have only one federated repository property that is associated with it.
4. The user registry attributes that are associated with the federated repository properties  
A federated repository property can have only one user registry attribute that is associated with it.

**Note:** The only user registry type that supports the retrieval of UserInfo claims is LDAP.

Liberty defines default scopes, claims, federated registry properties, and default mappings.

*Table 131. Default mappings for scopes, claims, and federated registry properties*

Scope	Claims	Federated registry property
profile	name, given_name, picture	displayName, givenName, photoURL
email	email	mail
address	address	postalAddress
phone	phone_number	telephoneNumber

Each of the following steps is optional. The Liberty server defines default scopes, claims, federated registry properties, and default mappings. The only time that you need to perform any of the following steps is if you want to change a default mapping or define a custom scope or claim.

### Procedure

1. Configure the claims that are associated with scopes. A scope can be mapped to multiple claims, and multiple claims must be comma-separated.

In the following example, the scope `CUSTOM_SCOPE1` is associated with two claims, `CUSTOM_CLAIM1` and `language`, and the scope `CUSTOM_SCOPE2` is associated with the claim `CUSTOM_CLAIM2`.

```
<scopeToClaimMap CUSTOM_SCOPE1="CUSTOM_CLAIM1, language"
CUSTOM_SCOPE2="CUSTOM_CLAIM2" />
```

**Note:** Claim and scope names are case-sensitive, `CUSTOM_SCOPE1`, and `custom_scope1` are different scopes.

- a. To define scopes with the same spelling but different case, you must use the property subelement. In the following example, the scopes `CUSTOM_SCOPE1` and `custom_scope1` are defined.

```

<scopeToClaimMap CUSTOM_SCOPE1="CUSTOM_CLAIM1, language" >
  <property name="custom_scope1" value="custom_claim1,mobile"/>
</scopeToClaimMap>

```

2. Configure the federated repository properties that are associated with claims. A claim can be mapped to only one federated repository property.

In the following example, the claim CUSTOM\_CLAIM1 is associated with the federated repository property departmentNumber. The claim language is associated with the federated repository property preferredLanguage, and the claim CUSTOM\_CLAIM2 is associated with the federated repository property mail.

```

<claimToUserRegistryMap CUSTOM_CLAIM1="departmentNumber"
  language="preferredLanguage"
  CUSTOM_CLAIM2="mail" />

```

- a. To define claims with the same spelling but different case, you must use the property subelement. In the following example, the claims CUSTOM\_CLAIM1 and custom\_claim1 are defined.

```

<claimToUserRegistryMap CUSTOM_CLAIM1="departmentNumber" >
  <property name="custom_claim1" value="employeeType" />
</claimToUserRegistryMap>

```

3. Configure the user registry attributes that are associated with federated repository properties.

In the following example, the federated repository property photoURL is associated with the LDAP registry attribute ldapPersonPicture

```

<ldapRegistry...>
  ...
  <attributeConfiguration>
    <attribute name="ldapPersonPicture"
      propertyName="photoURL"
      entityType="PersonAccount" />
  </attributeConfiguration>
  ...
</ldapRegistry>

```

**Note:** The LDAP attribute must be defined in the schema of the LDAP registry.

## Results

You have now completed the configuration that is required to customize the claims that are returned by the UserInfo endpoint.

## Configuring an OpenID Connect Provider to enable 2-legged OAuth requests:

8.5.5.4

The typical OAuth flow consists of three “legs”, or stages of interaction between a client and an authorization server. In 2-legged OAuth scenarios, the client uses pre-authorized scopes so that no interaction with the user is necessary, removing the need to perform one of the legs in the typical flow. Specifically, the user does not need to authenticate to the authorization server or give consent for sharing the information that is specified by the requested scopes. Instead, all requested scope parameters are considered pre-authorized and are automatically added to the request token, which is then sent to the authorization server.

### Before you begin

This task expects you to have a Liberty server that is properly configured as an OpenID Connect Provider.

### About this task

In scenarios with two legs or stages, an Open ID Connect client can send a 2-legged HTTP request with a **grant type** of client\_credential or resource owner password. These requests do not go through the

authorization endpoint, so there is no scope consent form for users to confirm and approve the requested scopes; however the OpenID Connect Provider still needs to deal with the authorized scopes in its `access_token` content.

Liberty servers that are configured as OpenID Connect Providers that are equipped to handle 2-legged OAuth requests approve the pre-authorized scopes by using the following criteria:

1. If the **grant\_type** parameter value of a request is `client_credential` or `resource owner password` and the request is an OAuth 2.0 request, then all the scopes that are defined in the request are approved and are copied into the content of the access token. This is the existing behavior of the OAuth 2.0 feature.
2. If the request is an OpenID Connect request or a JWT Token OAuth, or OpenID Connect request, the following criteria is used:
  - If there is no scope parameter that is specified in the request, the OpenID Connect Provider will not accept the request.
  - The requested scopes must be present in the list of scopes that are defined by the scope attribute of the client configuration and must also be specified in the `preAuthorizedScope` list of the client configuration.

This task demonstrates how to configure a Liberty server that is acting as an OpenID Connect Provider to enable 2-legged OAuth requests.

## Procedure

To specify the list of pre-authorized scopes for a client, add the necessary scopes to the `scope` and `preAuthorizedScope` attributes of the client configuration within the appropriate `<oauthProvider>` element in your `server.xml` file. In the example that is shown, the scopes `profile` and `email` are qualified to be specified in the scope list of an access token that is returned by the OpenID Connect Provider. The `phone` scope is not considered a pre-authorized scope because it is missing from the `preAuthorizedScope` list.

```
<oauthProvider id="OAuthConfigSample" ...>
  ....
  <localStore>
    <client name="client01" secret="{xor}..."
      displayName="client01"
      scope="profile email phone"
      preAuthorizedScope="profile email"
      enabled="true"/>
    ....
  </localStore>
</oauthProvider>
```

**Note:** If a requested scope is not listed in the `scope` attribute of the client configuration, it is omitted from the scope of the access token that is returned. If a requested scope is listed in the `scope` attribute of the client configuration but is not included in the `preAuthorizedScope` list of the client configuration, it triggers an `invalid_grant` error in the response from the OpenID Connect Provider.

## Configuring an OpenID Connect Provider to use the RSA-SHA256 algorithm for signing of ID

tokens:  8.5.5.4

You can configure an OpenID Connect Provider to use the RS256 algorithm for the signing of ID tokens.

### About this task

You can configure an OpenID Connect Provider to use the RSA-SHA256 signature algorithm for signing ID tokens by setting the `signatureAlgorithm` to `RS256` and configuring a keystore with the private key used for signing.

## Procedure

1. In the `server.xml` file, create a `keystore` element that refers to the physical keystore that contains the private key that is capable of performing a RSA-SHA256 signature algorithm. For example:  

```
<keystore id="opTestKeyStore" location="{server.config.dir}/opKeyStore.jks" type="JKS" password="keystorePwd" />
```
2. Set the OpenID Connect Provider `signatureAlgorithm` attribute to `RS256`, set the `keyStoreRef` attribute to the `id` value of the keystore element that is used in step 1, and set the `keyAliasName` to locate the private key in the keystore. Setting the `keyStoreRef` is optional if the keystore element `id` used in step 1 is `opKeyStore`. For example:  

```
<openidConnectProvider id="OAuthConfigSample" oauthProviderRef="OAuthConfigSample" signatureAlgorithm="RS256" keyStoreRef="opTestKeyStore" />
```

## Results

You have now configured an OpenID Connect Provider for signing ID tokens with RSA-SHA256.

## Configuring an OpenID Connect Provider to accept JSON Web Tokens (JWT) for authorization

grants:  8.5.5.4

You can configure a Liberty server that acts as an OpenID Connect Provider to accept a JSON Web Token in exchange for an access token.

### About this task

You can configure a Liberty server that acts as an OpenID Connect Provider to accept JSON Web Tokens by enabling the `openidConnectServer-1.0` and `ssl-1.0` features, in addition to other optional configuration information.

## Procedure

1. Ensure the `ssl-1.0` and `openidConnectServer-1.0` features are included in the feature manifest in the `server.xml` file.  

```
<featureManager>  
  <feature>ssl-1.0</feature>  
  <feature>openidConnectServer-1.0</feature>  
</featureManager>
```
2. Optional: Configure a `jwtGrantType` element inside of the appropriate `oauthProvider` element. The `jwtGrantType` element is optional. If no `jwtGrantType` element is included, the default values for all attributes are used; for example:  

```
<oauthProvider id="OAuthConfigSample" ...>  
  <jwtGrantType clockSkew="5m" iatRequired="false" tokenMaxLifetime="120m" maxJtiCacheSize="10000"/>  
  ...  
</oauthProvider>
```

For more JWT configuration options, see the section for the `jwtGrantType` element in the topic.

## Configuring an OpenID Connect Provider to accept client registration requests: 8.5.5.4

The client registration endpoint is an administrator managed service that is used to register, update, delete, and retrieve information about an OpenID Connect Relying Party that intends to use the OpenID Connect Provider. In turn, the registration process can provide information for the Relying Party to use it, including the OAuth 2.0 Client ID and Client Secret, if not specified.

## Before you begin

The client registration service operates in one of two modes: local store or database store. These modes are determined by how the Liberty server configures its client store, whether clients are defined with the `oauthProvider localStore` attributes (local store) in the `server.xml` file or are configured with a database (database store).

In a local store configuration, the client registration service is limited to only retrieving OpenID Connect Relying Party information. You can modify the `server.xml` file to add more operations to register, update, or delete an OpenID Connect Relying Party.

In a database store configuration, there is no limitation on the client registration service and all operations are functional through the REST interface.

**Note:** A Liberty server must not configure its client store with both local store and database store. Choose only one configuration route.

The client registration endpoint is a protected administration endpoint with the `clientManager` role. To access this endpoint, the user must be granted the `clientManager` role by the administrator.

The `clientManager` role is one of the `oauth-roles` defined for an `oauthProvider`. The following is a sample configuration that shows a grant of the `clientManager` role to the user Alice or members in the `clientAdministrator` group.

```
<oauth-roles>
<authenticated>
<special-subject type="ALL_AUTHENTICATED_USERS" />
</authenticated>
<clientManager>
<group name="clientAdministrator" />
<user name="Alice" />
</clientManager>
</oauth-roles>
```

## About this task

Client registration information about an OpenID Connect Relying Party is largely used to define the usage scenario constraints of the client. Additionally, other operations of the OP that are opaque to the client use the client registration metadata to make authorization decisions.

The following example assumes that the Liberty OP is configured with SSL on port 443.

`https://server.example.com:443/oidc/endpoint/<provider_name>/registration`

The previous example also assumes that the `server.xml` file is configured with a user name: `clientAdmin` and password: `clientAdminPassword`, that uses the `oauth-role: clientManager`.

The client registration metadata consists of the following parameters:

*Table 132. Client registration parameters*

Attribute Name	Data Type	Required/Optional	Description
<code>client_id</code>	Input/Output	Optional	The client identifier that is being registered with the OP. Unless specified, this parameter value is generated during registration by default. This is a string.

Table 132. Client registration parameters (continued)

Attribute Name	Data Type	Required/Optional	Description
client_secret	Input/Output	Optional	The client secret that is being registered with the OP. Unless specified, this parameter value is generated during registration by default. This is a string. During an update operation, the parameter value '*' preserves the existing value. A blank parameter value generates a new client_secret. A non-blank parameter value overrides the existing value with the newly specified value.
client_name	Input/Output	Optional	A description for the client that is being registered with the OP. Unless specified, this parameter is set to the client_id parameter value by default. This is a string.
application_type	Input	Optional	The application type that describes the client. Unless specified, the default value is web. This is a string. For example, possible values: <ul style="list-style-type: none"> <li>• &lt;an empty value is valid&gt;</li> <li>• web</li> <li>• native</li> </ul>
response_types	Input	Optional	The response type constraints that are used by this client. Unless specified, the default value is code. This is a JSON array. For example, possible values are: <ul style="list-style-type: none"> <li>• &lt;an empty value is valid&gt;</li> <li>• code</li> <li>• token</li> <li>• id_token token (order reversible)</li> </ul> <p>For a specific response_type, the corresponding grant_types must be specified. For more information, see response_types at the Client Metadata website.</p>

Table 132. Client registration parameters (continued)

Attribute Name	Data Type	Required/Optional	Description
grant_types	Input	Optional	The grant type constraints that are used by this client. Unless specified, the default value is authorization_code. This is a JSON array. For example, the possible values are: <ul style="list-style-type: none"> <li>• &lt;an empty value is valid&gt;</li> <li>• authorization_code</li> <li>• implicit</li> <li>• refresh_token</li> <li>• client_credentials</li> <li>• urn:iETF:params:oauth:grant-type:jwtbearer</li> <li>• password</li> </ul>
redirect_uris	Input	Optional	The array of redirect URIs to which the client is constrained to. This is a JSON array.
post_logout_redirect_uris	Input	Optional	The array of post logout redirect URIs to which the client is constrained. This is a JSON array.
trusted_uri_prefixes	Input	Optional	The array of trusted URI prefixes that the client has deemed safe for sending access tokens. This is a JSON array.
scope	Input	Optional	The space delimited scope values to which the client is constrained. This is a string. If the client is allowed to request any scope, a value of ALL_SCOPES can be used.
preauthorized_scope	Input	Optional	The space delimited scope values that the client is preauthorizing that does not require user consent. This is a string.
subject_type	Input	Optional	The subject type constraint that is described by the client. This is a string. For example, possible values are: <ul style="list-style-type: none"> <li>• &lt;an empty value is valid&gt;</li> <li>• public</li> </ul>

Table 132. Client registration parameters (continued)

Attribute Name	Data Type	Required/Optional	Description
token_endpoint_auth_method	Input	Optional	<p>The token endpoint authentication method constraint that is used by the client. Unless specified, the default value is <code>client_secret_basic</code>. This is a string. For example, possible values are:</p> <ul style="list-style-type: none"> <li>• <code>&lt;an empty value is valid&gt;</code></li> <li>• <code>client_secret_basic</code></li> <li>• <code>client_secret_post</code></li> <li>• <code>none</code></li> </ul>
functional_user_id	Input	Optional	<p>This parameter indicates which user ID to associate with a request made on behalf of a client in a <code>client_credentials</code> grant type. This is a string.</p>
functional_user_groupIds	Input	Optional	<p>A list of group IDs to associate with access tokens obtained by this client using the client credentials grant type. The value is a list of group IDs to which the functional user is a member, where the group IDs are case-sensitive strings. The strings are defined by the authorization server. If the value contains multiple group IDs, their order does not matter. If the list is empty, the claim is omitted. When this client metadata parameter is specified, the value is returned in the <code>functional_user_groupIds</code> response parameter from the introspection endpoint for access tokens that are issued to this client with a client credentials grant. If the <code>functional_user_id</code> parameter is not used, this parameter is ignored.  <b>Note:</b> Authorization Servers must not trust the client to self-assert this parameter.</p>

Table 132. Client registration parameters (continued)

Attribute Name	Data Type	Required/Optional	Description
introspect_tokens	Input	Optional	A parameter value that indicates whether the specified client has the privilege to introspect an access token that is issued by the OP. This is a Boolean value.
registration_client_uri	Output only	N/A	A parameter that is returned in a response with the value that indicates the unique URL for a registered client. This is a string.
client_secret_expires_at	Output only	N/A	A parameter that is returned in a response with the value that indicates the number of seconds from 1970-01-01T0:0:0Z as measured in UTC, at which the client secret expires. The value 0 indicates no expiration time.
client_id_issued_at	Output only	N/A	A parameter that is returned in a response with the value that indicates the number of seconds from 1970-01-01T0:0:0Z as measured in UTC, at which the client ID was issued. The value 0 indicates that no client ID issue time was identified.

## Procedure

1. Register a client, as shown in the following example:

Request Headers:

```
POST https://server.example.com:443/oidc/endpoint/<provider_name>/registration
Accept: application/json
Content-Type: application/json
Authorization: Basic Y2xpZW50QWRtaW46Y2xpZW50QWRtaW5QYXNzd29yZA==
```

Request Payload:

```
{
  "token_endpoint_auth_method": "client_secret_basic",
  "scope": "openid profile email general",
  "grant_types": [
    "authorization_code",
    "client_credentials",
    "implicit",
    "refresh_token",
    "urn:iETF:params:oauth:grant-type:jwt-bearer"
  ],
  "response_types": [
    "code",
    "token",
    "id_token token"
  ],
}
```

```

"application_type":"web",
"subject_type":"public",
"post_logout_redirect_uris":[
  "https://server.example.com:9000/logout/",

  "client_secret": "*",
  "client_name": "updated client",
}
```

```

    "redirect_uris":[
      "https://server.example.com:443/resource/redirect1"
    ]
  }
}

```

3. Retrieve a client, as shown in the following example:

**Request Headers:**

```

GET https://server.example.com:443/oidc/endpoint/<provider_name>/registration/registration/b0a376ec4b694b67b6baeb0604a312d8
Accept: application/json
Authorization: Basic Y2xpZW50QWRtaW46Y2xpZW50QWRtaW5QYXNzd29yZA==

```

**Response Headers:**

```

Status: 200
Cache-Control: private
ETag: "3DD7affTGS91mfhPZ83B39Y=="
Content-Type: application/json

```

**Response Body:**

```

{
  "client_id_issued_at":1401776782,
  "registration_client_uri":"https://server.example.com:8020/oidc/endpoint/OIDC/registration/b0a376ec4b694b67b6baeb0604a312d8",
  "client_secret_expires_at":0,
  "token_endpoint_auth_method":"client_secret_basic",
  "scope":"openid profile",
  "grant_types":[
    "authorization_code"
  ],
  "response_types":[
    "code"
  ],
  "application_type":"native",
  "subject_type":"public",
  "post_logout_redirect_uris":[
    "https://server.example.com:9000/logout/"
  ],
  "preauthorized_scope":"openid",
  "introspect_tokens":false,
  "trusted_uri_prefixes":[
    "https://server.example.com:9003/trusted/"
  ],
  "client_id":"b0a376ec4b694b67b6baeb0604a312d8",
  "client_secret":"*",
  "client_name":"updated client",
  "redirect_uris":[
    "https://server.example.com:443/resource/redirect1"
  ]
}

```

4. Retrieve a client (head request), as shown in the following example:

**Request Headers:**

```

HEAD https://server.example.com:443/oidc/endpoint/<provider_name>/registration/registration/b0a376ec4b694b67b6baeb0604a312d8
Accept: application/json
Authorization: Basic Y2xpZW50QWRtaW46Y2xpZW50QWRtaW5QYXNzd29yZA==

```

**Response Headers:**

```

Status: 200
Cache-Control: private, no-cache=set-cookie
ETag: "3DD7affTGS91mfhPZ83B39Y=="
Content-Type: application/json

```

5. Delete a client, as shown in the following example:

**Request Headers:**

```

DELETE https://server.example.com:443/oidc/endpoint/<provider_name>/registration/registration/b0a376ec4b694b67b6baeb0604a312d8
Authorization: Basic Y2xpZW50QWRtaW46Y2xpZW50QWRtaW5QYXNzd29yZA==

```

**Response Headers:**

Status: 204  
Content-Length: 0  
Content-Language: en-US

**Note:** The information in this topic also applies to client registration services of OAuth 2.0 clients, and OpenID Connect Relying parties.

### OpenID Connect custom forms: 8.5.5.4

You can replace the default form login page for user authentication, or develop your own user consent form to collect client authorization data.

### Authenticating a user: 8.5.5.4

OpenID Connect provider supports traditional Java Platform, Enterprise Edition (J2EE) FormLogin for user authentication.

You can customize the login form, see  8.5.5.4 OpenID Connect custom forms.

The OpenID Connect provider can be configured to support other authentication methods.

### OpenId Connect provider delegates user authentication to third-party authentication service

If you configure Trust Association Interceptor (TAI) to intercept a request to an OpenID Connect authorization endpoint (`/oidc/<provider name>/authorize`), the login form is not presented, and the user authentication is performed by the configured TAI.

### OpenId Connect provider authenticates user with HTTP Basic Authentication

If you want an OpenID Connect provider to authenticate a user with HTTP Basic Authentication, the openid connect authorization request must include a user id and password as defined in the Basic Authentication Scheme.

### OpenID Connect provider authenticates user with a client certificate

If you want an OpenID Connect provider to authenticate a user with a client certificate, you need to explicitly add the attribute `certAuthentication=true` inside the `oauthProvider` configuration element that is referenced by the `openidConnectProvider` configuration, and the user agent must be able to provide a client certificate for an OpenID Connect authorization request.

### OpenId Connect provider delegates user authentication to a third-party OpenId Connect provider

You can configure an OpenID Connect provider to delegate user authentication to a third-party OpenID Connect provider. To enable this authentication delegation, you configure the OP as an OpenID Connect relying party. Optionally, you can add an authentication filter to limit the `openidConnectClient-1.0` feature to protect an OpenID Connect authorization endpoint (`/oidc/<provider name>/authorize`) only.

## Configuring an OpenID Connect Client in Liberty

### 8.5.5.4

You can configure a Liberty server to function as an OpenID Connect Client, or Relying Party, to take advantage of web single sign-on and to use an OpenID Connect Provider as an identity provider.

## About this task

You can configure a Liberty server to act as an OpenID Connect Client by enabling the `openidConnectClient-1.0` feature in Liberty, and in addition to other configuration information.

## Procedure

1. Add the `openidConnectClient-1.0` Liberty feature and any other needed features to the `server.xml` file. The `ssl-1.0` feature is also required for the `openidConnectClient-1.0` feature. Add the following element declaration inside the `featureManager` element in your `server.xml` file:

```
<feature>openidConnectClient-1.0</feature>
<feature>ssl-1.0</feature>
```

2. Configure an `openidConnectClient` element. The following is an example of a minimal configuration that works with the default Liberty server OpenID Connect Provider.

The client must have a configured application available at the given URL pattern that can handle redirect requests from an OpenID Connect Provider. This URL must also precisely match the redirect URL registered for the client with the OP.

**Avoid trouble:** In this example, the client expects the SSL port to be set to 443.

```
<openidConnectClient id="client01"
  clientId="client01"
  clientSecret="{xor}LDo8LTor"
  authorizationEndpointUrl="https://server.example.com:443/oidc/endpoint/OidcConfigSample/authorize"
  tokenEndpointUrl="https://server.example.com:443/oidc/endpoint/OidcConfigSample/token">
</openidConnectClient>
```

In this sample minimal configuration, the following default values are assumed:

- `scope=openid profile`: The scope of `openid` is required, and you can use the `scope` attribute to edit required scopes. For example, you can change the required scope to `openid profile email`.
  - This RP registers its redirect URL with the OP as `https://<host name>:<ssl port>/oidcclient/redirect/client01`, where both the host name and ssl port are automatically resolved, and `client01` is the ID of the `openidConnectClient` configuration element. If there is a proxy in front of the RP, you can override the host name and port with the attribute `redirectToRPHostAndPort`, and set `redirectToRPHostAndPort` to `https://<host name>:<ssl port>`.
3. Configure a user registry. User identities that are returned by the OP are not mapped to a registry user by default, so no users are required to be configured in the registry. However, if the `mapIdentityToRegistryUser` attribute of the `openidConnectClient` element is set to `true`, there must be a user entry for the appropriate identity that is returned from the OP in order for authentication and authorization to succeed. For more information about configuring a user registry, see “Configuring a user registry for Liberty” on page 1851.
  4. Configure the truststore of the server to include the signer certificates of the OpenID Connect Providers that are supported. For information about keystores, see “Enabling SSL communication in Liberty” on page 1834.
  5. Modify the SSL configuration of the server to use the configured truststore.

```
<sslDefault sslRef="DefaultSSLSettings" />
<ssl id="DefaultSSLSettings" keyStoreRef="myKeyStore" trustStoreRef="myTrustStore" />
<keyStore id="myKeyStore" password="{xor}EzY90i0rJg==" type="jks" location="{server.config.dir}/resources/security/
<keyStore id="myTrustStore" password="{xor}EzY90i0rJg==" type="jks" location="{server.config.dir}/resources/security/
```

OpenID Connect is configured to use the default SSL configuration that is specified by the server. Therefore, the default SSL configuration for the server must use the truststore that is configured for OpenID Connect.

6. **8.5.5.5** Optional: Configure a third party OpenID Connect provider.

To configure the Liberty OpenID Connect client to use a third party OpenID Connect Provider such as (Microsoft Azure or Google), you must configure the following attributes. The attribute values can be obtained by calling the OP's discovery endpoint, which provides a JSON document at the path that is formed by concatenating the string `/.well-known/openid-configuration` to the issuer.

- a. Set the `jwkEndpointUrl` attribute to the URL of the OP's JSON Web Key Set JWK document that is defined as `asjwks_uri` in the discovery file. For example, to use Google's OP, you can set `jwkEndpointUrl = "https://www.googleapis.com/oauth2/v2/certs"`.
- b. Set the `issuerIdentifier` attribute to the issuer as defined in the discovery file. An ID Token that does not contain this value as an `iss` claim is rejected. For example, you can set `issuerIdentifier="accounts.google.com"` if you are using Google as your OP.
- c. Set `signatureAlgorithm="RS256"`. The Liberty OpenID Connect client's default signature algorithm is HS256.
- d. Set the `userIdentityToCreateSubject` attribute to a claim name used by the vendor's ID Token that represents a user's unique identifier. For example, you can set `userIdentityToCreateSubject="email"` if you are using Google's OP, and `userIdentityToCreateSubject="upn"` or `userIdentityToCreateSubject="unique_name"` if you are using Microsoft Azure.
- e. Set the `groupIdentifier` attribute to the claim name that represents the user's group memberships or roles. For example, you can set `groupIdentifier="groups"` if you are using Microsoft Azure.

For more OpenID Connect Client configuration options, see .

#### 7. Optional: Authentication Filter.

When the `openidConnectClient-1.0` feature is enabled and the `openidConnectClient` element is not configured with an `authFilterRef` attribute, any unauthenticated request is authenticated through the OpenID Connect provider.

For more information on configuring the authentication filter, see  [“Authentication Filters”](#) on page 1937.

#### 8. Support multiple OpenID Connect Providers.

You can configure Liberty as an OpenID Connect Relying Party to multiple OpenID Connect Providers by creating multiple `openidConnectClient` elements and multiple Authentication Filters. Each `openidConnectClient` element defines one Single-Sign-On relationship with one OpenID Connect Provider, and use the `authFilterRef` attribute to reference to one Authentication Filter.

#### 9. Configure a supported ID Token signature algorithm.

You can configure a Liberty OpenID Connect client to support the RS256 signature algorithm in an ID Token. The Liberty OpenID Connect client's default signature algorithm is HS256. If you configure RS256 as the ID Token's signature algorithm by setting `signatureAlgorithm="RS256"`, you must configure both the `trustStoreRef` and `trustAliasName`, unless the OP supports a JWK endpoint.

#### 10. Optional: Configure an “implicit” grant type.

The `openidConnectClient-1.0` feature uses an Authorization Code grant type to request a user authentication token, and you can configure the Liberty `openidConnectClient-1.0` feature to use an “implicit” grant type by adding `grantType="implicit"` to the `server.xml` file. If your Liberty server and OpenID Connect provider are in different firewalls, you must use this configuration option.

## Results

You have now established the minimum configuration that is required to configure a Liberty server as an OpenID Connect Client capable of communicating with other Liberty servers configured as OpenID Connect Providers.

### Invoking the Authorization Endpoint for OpenID Connect: [8.5.5.4](#)

In OpenID Connect the authorization endpoint handles authentication and authorization of a user.

## Before you begin

When starting the authorization endpoint from an in-browser client application or a client application implemented in a scripting language such as Javascript, for example, no configuration of a Liberty server as an OpenID Connect Client is necessary.

## About this task

The authorization endpoint accepts an authentication request that includes parameters that are defined by both the OAuth 2.0 and OpenID Connect 1.0 specifications.

In the Authorization Code Flow, the authorization endpoint is used for authentication and authorization and returns an authorization grant to the client. This authorization grant can then be passed in a request by the client to the token endpoint in exchange for an ID token, access token, and refresh token. In the Implicit Flow, the authorization endpoint still performs authentication and authorization but also directly returns an ID token and access token to the client in its response; no interaction is performed with the token endpoint.

A Liberty server with OpenID Connect enabled has access to the OpenID Connect authorization endpoint at the following URL:

```
https://server.example.com:443/oidc/endpoint/<provider_name>/authorize
```

**Avoid trouble:** In this example, the client expects the SSL port to be set to 443.

## Procedure

1. Prepare an HTTP GET or POST request that includes the following required and recommended parameters.
  - **scope:** (Required) OpenID Connect requests must contain the `openid` scope value. Other scopes may also be present
  - **response\_type:** (Required) Determines the authorization processing flow to be used. When using the Authorization Code Flow, this value is `code`. When using the Implicit Flow, this value is `id_token` token or `id_token`. No access token is returned when the value is `id_token`
  - **client\_id:** (Required) Client identifier that is valid at the OpenID Connect Provider.
  - **redirect\_uri:** (Required) Redirection URI to which the response will be sent. This value must exactly match one of the redirection URI values for the registered client at the OP.
  - **state:** (Recommended) Opaque value used to maintain state between the request and the callback.
  - **nonce:** (Required for the Implicit Flow) String value used to associate a client session with an ID token and to mitigate replay attacks.

You can include more parameters in the request. For a description of other supported parameters, see the OpenID Connect Core 1.0 specification.

We do not support only an `id_token` `response_type`. Using the implicit flow must always use `id_token` token and will return an access token.

2. Send the GET or POST request to the authorization endpoint URL.

## Results

After completing these steps, you have a valid HTTP request that is being sent to the authorization endpoint. The authorization endpoint returns a response in the manner described in the Examples section.

The OpenID Connect Provider attempts to authenticate and authorize the user once it receives a request from the client.

In the Authorization Code Flow, if authentication and authorization succeed, the OpenID Connect Provider issues an authorization code and includes it as a parameter in an OAuth 2.0 Authorization Response to the client. If the initial request included **state**, the authorization response will also include the exact **state** value that was included in the initial request. Using the application/x-www-form-urlencoded format, the **code** and **state** parameters are added as query parameters to the **redirect\_uri** value that was specified in the authorization request.

In the Implicit Flow, if authentication and authorization succeed, the following parameters are returned from the authorization endpoint.

- **access\_token**: Access token. This is returned unless the **[response\_type]** value in the initial request is **[id\_token]**.
- **token\_type**: OAuth 2.0 Token Type. For OpenID Connect, this value is Bearer.
- **id\_token**: ID token.
- **state**: Required if included in authorization request.
- **expires\_in**: (Optional) Expiration time of the access token in seconds since the response was generated.

These parameters are added to the fragment component of the **redirect\_uri** value that is specified in the authorization request, not as query parameters such as in the Authorization Code Flow.

## Example

The following examples show forms of Authorization and Implicit code flow.

An example request for the Authorization Code Flow is shown here:

```
GET /authorize?  
  response_type=code  
  &scope=openid profile email  
  &client_id=client01  
  &state=af0ifjsldkj  
  &redirect_uri=https://server.example.com:443/oidcclient/redirect/client01 HTTP/1.1
```

An example request for the Implicit Flow is shown here:

```
GET /authorize?  
  response_type=id_token token  
  &scope=openid profile  
  &client_id=client01  
  &state=af0ifjsldkj  
  &redirect_uri=https://server.example.com:443/oidcclient/redirect/client01  
  &nonce=n-0S6_wzA2Mj HTTP/1.1
```

An example response from the authorization endpoint in the Authorization Code Flow is shown here:

```
HTTP/1.1 302 Found  
Location: https://server.example.com:443/oidcclient/redirect/client01  
  code=Sp1x10BeZQQYbYS6WxSbIA  
  &state=af0ifjsldkj
```

An example response from the authorization endpoint in the Implicit Flow is shown here:

```
HTTP/1.1 302 Found  
Location: https://server.example.com:443/oidcclient/redirect/client01  
  access_token=S1AV32hkKG  
  &token_type=Bearer  
  &id_token=eyJ0 ... NiJ9.eyJ1c ... I6IjIifX0.DeWt4Qu ... ZXso  
  &expires_in=3600  
  &state=af0ifjsldkj
```

## Invoking the Token Endpoint for OpenID Connect: 8.5.5.4

In the OpenID Connect Authorization Code Flow, the token endpoint is used by a client to obtain an ID token, access token, and refresh token.

### Before you begin

When starting the token endpoint from an in-browser client application or a client application implemented in a scripting language such as Javascript, for example, no configuration of a Liberty server as an OpenID Connect Client is necessary.

### About this task

The token endpoint accepts a request from the client that includes an authorization code that is issued to the client by the authorization endpoint. When the authorization code is validated, the appropriate tokens are returned in a response to the client.

The token endpoint is not used in the OpenID Connect Implicit Flow.

A Liberty server with OpenID Connect enabled has access to the OpenID Connect token endpoint at the following URL:

```
https://server.example.com:443/oidc/endpoint/<provider_name>/token
```

**Avoid trouble:** In this example, the client expects the SSL port to be set to 443. All communication with the token endpoint must use TLS.

### Procedure

1. Prepare an HTTP POST request with the following parameters.
  - **grant\_type:** The value of this parameter must be `authorization_code`.
  - **code:** The authorization code received from the authorization endpoint.The parameters must be added by using the `application/x-www-form-urlencoded` format.
2. POST the request to the token endpoint URL.

### Results

After completing these steps you have a valid HTTP POST request that is being sent to the token endpoint. The token endpoint returns a response as described in the Examples section.

When the OpenID Connect Provider validates the token request that is received from the client, the OpenID Connect Provider returns an HTTP 200 response back to the client with a JSON object in `application/json` format. The response includes the ID token, access token, and refresh token, along with the following additional parameters:

- **token\_type:** OAuth 2.0 Token Type. For OpenID Connect, this value is `Bearer`.
- **expires\_in:** Expiration time of the access token in seconds since the response was generated.

All responses from the token endpoint that contain tokens, secrets, or other sensitive information have their **Cache-Control** header value set to **no-store** and **Pragma** header value set to **no-cache**.

## Example

The following shows examples of an HTTP POST request and response

An example request is shown here:

```
POST /token HTTP/1.1
Content-Type: application/x-www-form-urlencoded
Authorization: Basic czZCaGRSa3F0MzpnWDFmQmF0M2JW
    grant_type=authorization_code
    &code=Sp1x10BeZQYbYS6WxSbIA
    &redirect_uri=https%3A%2F%2Fclient.example.org%2Fcb
```

An example response is shown here:

```
HTTP/1.1 200 OK
Content-Type: application/json
Cache-Control: no-store
Pragma: no-cache
{
  "access_token": "S1AV32hkKG",
  "token_type": "Bearer",
  "refresh_token": "8xL0xBtZp8",
  "expires_in": 3600,
  "id_token": "eyJ ... zcifQ.ewo ... NzAKfQ.ggW8h ... Mzqg"
}
```

## Invoking the Introspection Endpoint for OpenID Connect:

8.5.5.4

The introspection endpoint enables holders of access tokens to request a set of metadata about an access token from the OpenID Connect Provider that issued the access token. The access token must be one that was obtained through OpenID Connect or OAuth authentication.

### Before you begin

When a resource service or a client application invokes the introspection endpoint, it must register itself as a normal OAuth 2.0 client to the OpenID Connect server. The registered client metadata must include the attribute `introspectTokens = true`.

### About this task

Information that is contained within access tokens that are used in OpenID Connect and OAuth 2.0 is opaque to clients. This can enable protected resources or clients to make authorization decisions that are based on the metadata that is returned from the OpenID Connect Provider about the access token.

A Liberty server with OpenID Connect enabled has access to the OpenID Connect introspection endpoint at the following URL:

```
https://server.example.com:443/oidc/endpoint/<provider_name>/introspect
```

**Avoid trouble:** In this example, the client expects the SSL port to be set to 443.

### Procedure

1. Set up client authentication with the client ID and password for a registered OpenID Connect Client in the HTTP Basic Authorization header of a GET or POST request. The client ID and password are encoded by using the `application/x-www-form-urlencoded` encoding algorithm. The encoded client ID is used as the username and the encoded password is used as the password.
2. Include the string value for the access token as a parameter in the GET or POST request to the introspection endpoint.
3. Send the GET or POST request to the introspection endpoint URL.

## Results

After completing these steps you have a valid HTTP request that is being sent to the introspection endpoint as shown in the Examples section.

For valid requests, the introspection endpoint returns an HTTP 200 response with a JSON object in application/json format that includes the following information, depending upon whether the access token is active or expired.

When the access token is active, the endpoint returns active:true, as well as the following additional information in the JSON object:

**active** Boolean indicator of whether the access token is active.

**client\_id**

Client identifier of the OpenID Connect Client who requested the access token.

**sub** Resource owner who authorized the access token.

**scope** Space-separated list of scopes that are associated with the access token.

**iat** Integer timestamp, measured in seconds since January 1, 1970 UTC, indicating when the access token was issued.

**exp** Integer timestamp, measured in seconds since January 1, 1970 UTC, indicating when the access token will expire.

**realmName**

Realm name of the resource owner.

**uniqueSecurityName**

Unique security name of the resource owner.

**tokenType**

Access token type. For OpenID Connect, this value is Bearer.

**grant\_type**

String indicating the type of grant that generated the access token. Possible values are: authorization\_code, password, refresh\_token, client\_credentials, resource\_owner, implicit, and urn:iETF:params:oauth:grant-type:jwt-bearer.

If the access token is expired, but the provided authentication is valid, or if the provided access token is of the wrong type, the endpoint returns active:false in the JSON object.

**Note:** For a client or resource service to perform access token introspection, the client or resource service must register itself as a client to the OpenID Connect provider, and the client metadata must have introspect\_tokens set to true.

## Example

The following shows examples of an active and expired access token along with a request.

An example request is shown here:

```
POST /register HTTP/1.1
Accept: application/x-www-form-urlencoded
Authorization: Basic czZCaGRSa3F0Mzo3RmpmcDBaQnIxS3REUmJuZlZkbU13
token=SOYleDziTitHeKcodp6vqEmRwKPjz31FZTcsQtVC
```

An example response for an active access token:

```

HTTP/1.1 200 OK
Content-Type: application/json
Cache-Control: no-store
{
  "exp"           : 1415307710,
  "realmName"    : "BasicRealm",
  "sub"          : "testuser",
  "scope"        : "openid scope2 scope1",
  "grant_type"   : "authorization_code",
  "uniqueSecurityName" : "testuser",
  "active"       : true,
  "token_type"   : "Bearer",
  "client_id"    : "pclient01",
  "iat"          : 1415307700
}

```

Example response for an expired access token:

```

HTTP/1.1 200 OK
Content-Type: application/json
Cache-Control: no-store
{
  "active":"false"
}

```

## Invoking the coverage map service: 8.5.5.4

The coverage map service is an unprotected endpoint that returns a JavaScript Object Notation (JSON) array of slash-terminated URI prefixes. The array of URI prefixes designates which web contexts are part of a Single Sign On (SSO) group, thus enabling clients to know whether a URI destination is deemed safe to send an access token.

### Before you begin

The coverage map service returns a JSON array of URI prefixes, which are a unique set that is derived from the aggregation of the **trusted\_uri\_prefixes** parameter values that are specified in the registered clients. Therefore, a typical case for populating the coverage map service is to register clients and specify the **trusted\_uri\_prefixes** value.

### About this task

The following example assumes that the Liberty OpenID Connect provider is configured with SSL on port 443.

```
https://server.example.com:443/oidc/endpoint/<provider_name>/coverage_map
```

Additionally, this example assumes that a client is registered with the specified **trusted\_uri\_prefixes**.

### Procedure

1. Specify a **token\_type URI** query parameter on the coverage\_map endpoint. The following is an example request that assumes that the client is registered with the specified trusted\_uri\_prefixes  

```
https://server.example.com:443/oidc/endpoint/<provider_name>/coverage_map?token_type=bearer
```

The only token\_type value that is supported is **token\_type=bearer**.
2. Get the coverage map for the bearer token type, as shown in the following example.  

Request Headers:

```
GET https://server.example.com:443/oidc/endpoint/<provider_name>/coverage_map?token_type=bearer
```

Response Headers:

```
Status: 200
CacheControl: public, maxage=600
ETag:"vvhkgXkRx+BzR3Q4kwCCqw=="
ContentType: application/json

Response Body:
[
  "http://res1.ibm.com/",
  "https://trusted.server.ibm.com:9554/resources/"
]
```

## Invoking the UserInfo Endpoint for OpenID Connect: 8.5.5.4

The UserInfo endpoint returns claims about a user that is authenticated with OpenID Connect authentication.

### About this task

To obtain the claims for a user, a client makes a request to the UserInfo endpoint by using an access token as the credential. The access token must be one that was obtained through OpenID Connect authentication. The claims for the user who is represented by the access token are returned as a JSON object that contains a collection of name-value pairs for the claims. The UserInfo endpoint is an OAuth 2.0 protected resource, which means that the credential required to access the endpoint is the access token.

The claims that are returned by the UserInfo endpoint can be customized with the OpenID Connect Provider configuration, see [Configuring claims returned by the UserInfo endpoint](#).

A Liberty profile server with OpenID Connect enabled has access to the OpenID Connect UserInfo endpoint at the following URL:

```
https://server.example.com:443/oidc/endpoint/<provider_name>/userinfo
```

**Avoid trouble:** In this example, the client expects the SSL port to be set to 443.

### Procedure

1. Set up authentication with an access token that was obtained through OpenID Connect authentication. The access token can be provided in the HTTP Basic Authorization header or with the `access_token` request parameter. In either case, the access token does not need to be encoded.
2. Send the GET or POST request to the UserInfo endpoint URL.

### Results

After completing these steps you have a valid HTTP request that is being sent to the UserInfo endpoint as shown in the Examples section.

For valid requests, the UserInfo endpoint returns an HTTP 200 response with a JSON object in `application/json` format that includes the claims that are configured for the OpenID Connect Provider.

### Example

The following examples illustrate requests with a valid token and invalid tokens.

- Request that uses the HTTP Bearer Authorization header to pass the access token
- Response for a valid access token
- Invalid access tokens

An example request that uses the HTTP Bearer Authorization header to pass the access token:

```
POST /register HTTP/1.1
Accept: application/x-www-form-urlencoded
Authorization: Bearer fAAAdL01c6QWDbPs9HrWHz5e7nRWVAnxqTTP7i88G
```

The token can also be passed by using the `access_token` request parameter:

```
POST /register HTTP/1.1
Accept: application/x-www-form-urlencoded
access_token=fAAAdL01c6QWDbPs9HrWHz5e7nRWVAnxqTTP7i88G
```

It is a best practice to use the HTTP Authorization header instead of the `access_token` request parameter because HTTP request parameters, which can include sensitive information, can be saved in the browser history or cache.

Here is an example response for a valid access token. The `sub` and `groupIds` claims are always returned. The other claims that are shown here are the default claims for an OpenID Connect Provider.

```
HTTP/1.1 200 OK
Content-Type: application/json
Cache-Control: no-store
Pragma: no-cache
{
  "sub"      : "bob",
  "groupIds" : [ "bobsdepartment","administrators" ],
  "given_name" : "Bob",
  "name"      : "Bob Smith",
  "email"     : "bob@mycompany.com",
  "phone_number" : "+1 (604) 555-1234;ext5678",
  "address"   : { "formatted" : "123 Main St., Anytown, TX 77777" },
  "picture"   : "http://mycompany.com/bob_photo.jpg"
}
```

For an invalid access token, the `UserInfo` endpoint returns an HTTP 401 status code with an error message in the `WWW-AUTHENTICATE` header.

```
HTTP/1.1 401 Unauthorized
CONTENT-LENGTH : 0
WWW-AUTHENTICATE : Bearer error=invalid_token,
  error_description=CWwKS1617E: A userinfo request was made with
  an access token that was not recognized. The request URI was
  /oidc/endpoint/MyOAuthProvider/userinfo.
```

## Invoking the Session Management Endpoint for OpenID Connect:

8.5.5.4

The session management endpoint enables OpenID Connect Relying Parties to monitor the login status of a user with a particular OpenID Connect Provider (OP) while minimizing network traffic. With the help of the session management endpoint, a Relying Party (RP) can log out a user who logged out of the OpenID Connect Provider.

### Before you begin

The OP session management endpoint URL is obtained from the `check_session_iframe` attribute in the discovery information that is returned from the discovery endpoint of the OP. This URL must be used as the target of an `iframe` in the RP application that requires session management functionality. The RP application must also know the `id` attribute of the `iframe` in order to submit `Window.postMessage()` requests to it.

### About this task

To help determine the login status of a user, the RP loads an `iframe` with its `src` target set to the session management endpoint of the OP. The session management endpoint has access to a cookie that stores the login status, or browser state, of a user. This browser state cookie is updated when a user logs out of the

OP. The RP can then use client side scripting to invoke the `Window.postMessage()` function of the OP iframe, sending the client ID and the currently known session state in the text of the message. If the RP receives a `postMessage` back from the OP frame with a value of `changed`, then the login status of the user at the OP has changed and the RP can decide whether to log out the user. If a value of `unchanged` is returned, the user is still logged in at the OP.

A Liberty server with OpenID Connect enabled has access to the OpenID Connect session management endpoint at the following URL:

```
https://server.example.com:443/oidc/endpoint/<provider_name>/check_session_iframe
```

**Avoid trouble:** In this example, the client expects the SSL port to be set to 443.

### Procedure

1. Create a web resource in an appropriate RP application capable of loading an iframe that targets the OP session management endpoint. The web resource also needs to have access to the session state value that is returned in the `session_state` parameter of the authorization response. The session state value can be stored in a cookie, for example, or in any other way that allows client-side scripting in the web resource to know what the value is. The following is a sample HTML snippet for such an iframe.

```
<iframe id="iframeOP" src="https://server.example.com:443/oidc/endpoint/0idcConfigSample/check_session_iframe" frameborder="0"></iframe>
```

2. To check the login status of a user, invoke the `Window.postMessage()` function of the OP iframe, passing the client ID and session state as the message parameter in the format `Client ID + " " + Session State` and the host name of the OP as the target origin parameter. In the following JavaScript sample function, the script expects the session state value to be stored in a cookie that is named `session_state`, and the `getCookieValue()` function returns the value that is stored in the `session_state` cookie.

```
var targetOP = "https://server.example.com:443";
function checkStatus() {
    var client = "client01";
    var sessionState = getCookieValue("session_state");
    var text = client + " " + sessionState;
    var iframe = document.getElementById("iframeOP");
    iframe.contentWindow.postMessage(text, targetOP);
}
```

3. Configure the web resource to listen for `postMessages` from the OP that contain the value `changed` or `unchanged` to reflect the respective login status of the user. The RP can then decide whether to log the user out of the RP based on the value that is returned from the OP. The function must ensure that the origin of the `postMessage` matches the expected OP host name. Any messages that do not match are rejected. The following JavaScript example shows how to add an event listener to the web resource to listen for such messages.

```
var targetOP = "https://server.example.com:443";
window.addEventListener("message", receiveMessage, false);
function receiveMessage(event) {
    if (event.origin !== targetOP) {
        // Origin did not come from the OP; this message must be rejected.
        return;
    }
    if (event.data === "unchanged") {
        // User is still logged in to the OP
    } else {
        // User has logged out of the OP
    }
}
```

### Results

You now have a web resource on the RP that is capable of utilizing the session management functionality of OpenID Connect on a Liberty server OP. The browser state that is maintained in the OP iframe is

updated when users log in or log out of the OP. After successful login at the OP, a new session state value is provided in the authorization response to the RP. The RP can then use client-side scripting to validate the session state of the user to determine whether the login status of the user changed on the OP without broadcasting extra network traffic.

## Example

The following HTML example shows a complete HTML page that uses OpenID Connect Session Management. The src attribute of the OP iframe is set to the session management endpoint URL obtained from the OP. The startChecking() function is automatically called every 60 seconds and checks the login status of the user. The page has a message event listener that calls the receiveMessage() function when a postMessage is received. This function makes sure the postMessage comes from the expected domain for the OP and checks the value of the returned message to see whether the login status of the user is changed or unchanged.

You can load this HTML page, itself, as an invisible iframe in another web resource within the RP. This enables any web resource that loads this iframe to monitor the login status of the user on the client side.

```
<!DOCTYPE html>
<html>
<head>
<meta charset="ISO-8859-1">
<title>iFrame RP Page</title>
</head>
<body onload="javascript:startChecking()">
  <iframe id="iframeOP" src="https://localhost:8999/oidc/endpoint/OidcConfigSample/check_session_iframe" frameborder="0">
</body>
<script>
  var targetOP = "https://server.example.com:443";

  window.addEventListener("message", receiveMessage, false);

  function startChecking() {
    checkStatus();
    // Check status every 60 seconds
    setInterval("checkStatus()", 1000*60);
  }

  function getCookieValue(cookieName) {
    var name = cookieName + "=";
    var cookies = document.cookie.split(';');
    if (!cookies) {
      return null;
    }
    for (var i = 0; i < cookies.length; i++) {
      var cookie = cookies[i].trim();
      if (cookie.indexOf(name) == 0) {
        return cookie.substring(name.length, cookie.length);
      }
    }
    return null;
  }

  function checkStatus() {
    var client = "client01";
    var sessionState = getCookieValue("session_state");
    var text = client + " " + sessionState;
    var iframe = document.getElementById("iframeOP");
    iframe.contentWindow.postMessage(text, targetOP);
  }

  function receiveMessage(event) {
    if (event.origin !== targetOP) {
      // Origin did not come from the OP; this message must be rejected
    }
  }
</script>
</body>
</html>
```

```

        return;
    }
    if (event.data === "unchanged") {
        // User is still logged in to the OP
    } else {
        // User has logged out of the OP
    }
}
</script>
</html>

```

## Authentication Filters

8.5.5.5

You can use the authentication filter to determine whether certain HTTP servlet requests are processed by certain providers.

Liberty server authentication filter uses the filter criteria that are specified in the `authFilter` element in the `server.xml` file to determine whether certain HTTP servlet requests are processed by certain providers, such as OpenID, OpenID Connect, or SPNEGO, for authentication.

If all conditions in the `authFilter` element are met, the HTTP servlet request is processed by the particular provider that references that `authFilter` element. If any of the conditions within the `authFilter` element are not met, the HTTP servlet request is not processed by the provider.

### Supported elements

The `authFilter` element supports the following elements: `userAgent`, `host`, `webApp`, `remoteAddress`, and `requestUrl`.

- The `userAgent` element is compared against a corresponding header value that is extracted from the incoming HTTP servlet request. The `userAgent` element is compared against the “User-Agent” HTTP request header, which identifies the client software that is used by the originating request. For web client browsers, this value reflects the browser type that is used to initiate the request (Internet Explorer, Firefox, Safari, etc.).
- The `host` element is used similarly to the `userAgent` element. The `host` element is compared against the “Host” HTTP request header, which identifies the target host name of the request.
- The `webApp` element is used to specify the application, or list of applications, hosted on the Liberty server that is protected by this authentication filter.
- The `remoteAddress` element is compared against the remote TCP/IP address of the client application that sent the HTTP request. You can configure wildcards for specifying subnets and ranges by using the `lessThan` or `greaterThan` values of the `matchType` attribute, as shown among the examples that follow later in this topic.
- The `requestUrl` element is compared against the URL that is used by the client application to make the request. Single URL patterns are configured or piped lists of values are configured, as shown among the examples that follow later in this topic.

### Authentication Filter examples

#### Request URL contains a pattern

The following example shows a typical configuration for an authentication filter. Here, any incoming request with a request URL containing `/SimpleServlet` is processed by the service that is configured to use this filter.

```

<authFilter id="myAuthFilter">
    <requestUrl id="myRequestUrl" urlPattern="/SimpleServlet" matchType="contains"/>
</authFilter>

```

### Request URL contains one of a set of patterns

In the following example, a piped list of request URL patterns is specified. To process an incoming request with the service configured to use this filter, the incoming request URL must contain any one of "/SimpleServlet", "/EmployeeRoleServlet", or "/AllRoleServlet".

```
<authFilter id="myAuthFilter">
    <requestUrl id="myURL" urlPattern="/SimpleServlet|/EmployeeRoleServlet|/AllRoleServlet" matchType="contains"/>
</authFilter>
```

### Web application name contains a pattern

In the following example, a web application name is specified in the authentication filter. Incoming requests must target the "myApp" application to be processed by the service that is configured to use this filter.

```
<authFilter id="myAuthFilter">
    <webApp id="myWebApp" name="myApp" matchType="contains"/>
</authFilter>
```

### Web application name contains one of a set of patterns

In the following example, a piped list of web applications is specified. To process an incoming request with the service configured to use this filter, the incoming request must target any one of the "myApp1", "myApp2", or "myApp3" applications.

```
<authFilter id="myAuthFilter">
    <webApp id="myWebApp" name="myApp1|myApp2|myApp3" matchType="contains"/>
</authFilter>
```

### Request originates from a certain IP address

The following example shows how to use wildcards in the `remoteAddress` element. With this configuration, the service that is configured to use this filter processes the incoming request if the request comes from an IP address anywhere in the 127.0.0.\* range.

```
<authFilter id="myAuthFilter">
    <remoteAddress id="myRemoteAddress" ip="127.0.0.*" matchType="equals"/>
</authFilter>
```

### Excluding patterns

The following example shows how to use a piped list of values for the `requestUrl` element. Matching any of the patterns in the list is sufficient to satisfy the requirements of that particular element. In this example, the request URL must contain either "/SimpleServlet", "/EmployeeRoleServlet", or "/AllRoleServlet". In addition, the request URL must not contain "/ManagerRoleServlet" and the request must come from an Internet Explorer user agent.

```
<authFilter id="myAuthFilter">
    <requestUrl id="myURL1" urlPattern="/SimpleServlet|/EmployeeRoleServlet|/AllRoleServlet" matchType="contains"/>
    <requestUrl id="myURL2" urlPattern="/ManagerRoleServlet" matchType="notContains" />
    <userAgent id="myAgent" agent="IE" matchType="contains" />
</authFilter>
```

### Example using all sub-elements

To process an incoming request with the service configured to use this filter, the request must meet the following conditions:

- Contains the pattern "/SimpleServlet" in the request URL
- Targets a domain that contains "host.example.com"
- Comes from the IP address 127.0.0.1
- Comes from a Firefox browser
- The name of the target application is myApp

```
<authFilter id="myAuthFilter">
    <requestUrl id="myRequestUrl" urlPattern="/SimpleServlet" matchType="contains"/>
    <host id="myHost" name="host.example.com" matchType="contains"/>
    <remoteAddress id="myAddress" ip="127.0.0.1" matchType="equals" />
    <userAgent id="myUserAgent" agent="Firefox" matchType="equals"/>
    <webApp id="myWebApp" name="myApp" matchType="contains"/>
</authFilter>
```

---

## Authorizing access to resources in Liberty

The purpose of authorization is to determine whether a user or group has the necessary privileges to access a resource.

### About this task

To learn about how authorization works in Liberty, see “Liberty: Authorization” on page 999.

The following topics are covered in this section:

### Procedure

- Configure authorization for applications in a Liberty server
- **z/OS** Configure security authorization for users on z/OS(r)

## Configuring authorization for applications in Liberty

Configuring authorization for your application is to verify whether a user or group belongs to a specified role, and whether this role has the privilege to access a resource.

### About this task

The Liberty server extracts user and group mapping information from a user registry, then checks the authorization configuration for the application to determine whether a user or group is assigned to one of the required roles. Then the server reads the deployment descriptor of the application, to determine whether the user or group has the privilege to access the resource.

**z/OS** When using System Authorization Facility (SAF) authorization, roles are mapped to EJBROLE resource profiles using the SAF role mapper. The server queries SAF to determine if the user has the required READ access to the EJBROLE resource profile.

### Procedure

1. Enable the `appSecurity-2.0` Liberty feature in the `server.xml` file.

For example:

```
<featureManager>
  <feature>appSecurity-2.0</feature>
</featureManager>
```

**Note:** **z/OS**

- If you are using the SAF authorization provider, include the `zosSecurity-1.0` feature and define a `safAuthorization` configuration element in your `server.xml` file. For example:

```
<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>zosSecurity-1.0</feature>
</featureManager>
```

```
<safAuthorization id="saf" />
```

2. Configure a user registry for authentication on the Liberty server.  
See “Authenticating users in Liberty” on page 1850.

**z/OS** If you are using the SAF authorization provider, you must use the SAF registry and the server must be authorized to use SAF authorized services. See “Activating and configuring the SAF registry on z/OS” on page 1857.

3. Ensure that the deployment descriptor for your application includes security constraints and other security related information.

**Note:** You can also use a tool such as Rational Application Developer to create the deployment descriptor.

4. Configure the authorization information such as the user and group to role mapping.

You can configure the authorization table in the following ways:

- If you have an EAR file, you can add the authorization configuration definition to the `ibm-application-bnd.xml` or `ibm-application-bnd.xmi` file.
- If you have standalone WAR files, you can add the authorization table definitions to the `server.xml` file under the respective application element. You can use the WebSphere Application Server Developer Tools for Eclipse to do this.

**Notes:**

- If you have an EAR file, the authorization configuration might already exist. In EAR files that are written to the current specification, this information is stored in an `ibm-application-bnd.xml` file; in older EAR files, this information is stored in an `ibm-application-bnd.xmi` file.
- If your EAR file does not already contain an `ibm-application-bnd.xml` file, it is not a straightforward task to create one and you might prefer to add the authorization configuration to the `server.xml` file.
- If the authorization configuration for the EAR file is defined in an `ibm-application-bnd.xml` file and also in the `server.xml` file, then the two tables are merged. If there are any conflicts, the information from the `server.xml` file is used.
- If you modify your user registry, be sure to review the authorization table for necessary changes. For example, if you are specifying an `access-id` element and change the realm name of the registry, you must also change the realm name in the `access-id` element.
- If you specify the `application-bnd` element in the `server.xml` file, your application must not be in the `dropins` folder. If you leave it in the `dropins` folder, then you must disable application monitoring by setting the following in your `server.xml` file:

```
<applicationMonitor dropinsEnabled="false" />
```

A role can be mapped to a user, a group, or a special subject. The two types of special subject are `EVERYONE` and `ALL_AUTHENTICATED_USERS`. When a role is mapped to the `EVERYONE` special subject, there is no security because everyone is allowed access and you are not prompted to enter credentials. When a role is mapped to the `ALL_AUTHENTICATED_USERS` special subject, then any user who has been authenticated by the application server can access the protected resource.

Here is example code for configuring the user and group to role mapping in the `server.xml` file:

```
<application type="war" id="myapp" name="myapp" location="${server.config.dir}/apps/myapp.war">
  <application-bnd>
    <security-role name="user">
      <group name="students" />
    </security-role>
    <security-role name="admin">
      <user name="gjones" />
      <group name="administrators" />
    </security-role>
    <security-role name="AllAuthenticated">
      <special-subject type="ALL_AUTHENTICATED_USERS" />
    </security-role>
  </application-bnd>
</application>
```

In this example, the **admin** role is mapped to the user ID `gjones` and all users in the group `administrators`. The **AllAuthenticatedRole** is mapped to the special subject `ALL_AUTHENTICATED_USERS`, meaning that any user has access as long as they provide valid credentials for authentication.

**z/OS** If you are using SAF authorization, roles are mapped to EJBROLE resource profiles using the SAF role mapper. The SAF role mapper pattern can be configured using the **safRoleMapper**

element in the `server.xml` file. See “Liberty: Controlling how roles are mapped to SAF Profiles.” By default, the role is mapped to a resource profile using the pattern `profile_prefix.resource.role`, where

- `profile_prefix` is defined by the `profilePrefix` attribute on the `safCredentials` configuration element. By default, the value of `profilePrefix` is `BBGZDFLT`.
- `resource` is the resource name; for example, the application name.
- `role` is the role name.

To access the protected resource, the user must have `READ` access to the `EJBROLE` resource profile. For example, for user ID `gjones` to access a protected resource under the role `admin` for the application `myapp`, the user `gjones` must have `READ` access to the resource profile `BBGZDFLT.myapp.admin` in the `EJBROLE` class in the SAF product.

**Note:** `EJBROLE` resource profiles are case sensitive.

The following example code shows sample RACF commands for authorizing a user:

```
rdef EJBROLE BBGZDFLT.myapp.admin uacc(none)
permit BBGZDFLT.myapp.admin class(EJBROLE) access(read) id(gjones)
```

## Liberty: Controlling how roles are mapped to SAF Profiles

z/OS

The System Authorization Facility (SAF) role mapper determines how `EJBROLE` profile names are generated from application-defined role names. The mapper is invoked whenever SAF authorization is performed for an application role. The authorization check for the application role is made against the underlying SAF security product using the mapped profile name generated by the SAF role mapper.

The SAF role mapper can be configured by using the `<safRoleMapper>` configuration element.

```
<safRoleMapper profilePattern="myprofile.%.resource%.role%" toUpperCase="true" />
```

### Attributes

#### `profilePattern="<string>"`

The pattern used to map application roles to profile names.

- `%role%` is substituted at run time with the value of the application role
- `%resource%` is substituted with the resource name. For example, the application name.

For example, for `profilePattern="myprofile.%.resource%.role%"`, the profile generated for an access check to the resource `"myapp"` for the `"admin"` role, is `myprofile.myapp.admin`.

The list of supported substitution variables:

#### `%role%`

The application role name. For the administrator role, the value is `Administrator`.

#### `%resource%`

The protected resource name. For security administration, the resource name is `com.ibm.ws.management.security.resource`.

#### `%profilePrefix%`

The `profilePrefix`, defined by the `profilePrefix` attribute in the `<safCredentials>` config element. The default value is `BBGZDFLT`.

If not specified, the default is `profilePattern="%.profilePrefix%.resource%.role%"`

#### `toUpperCase="true|false"`

Indicates whether the mapped profile name should be folded to uppercase.

If not specified, the default is `false`.

**Note:** The SAF role mapper will automatically substitute any wildcard characters (%&\*) and whitespaces in the mapped profile name with the '#' character.

## Enabling z/OS authorized services in Liberty for z/OS

z/OS

Liberty on z/OS offers the ability for your applications to take advantage of z/OS authorized services for System Authorization Facility (SAF) authorization, Workload Manager (WLM), Resource Recovery services (RRS), and SVCDUMP. If your application requires these services, set up a Liberty angel process and grant access for your Liberty server to use these services.

### About this task

To use the z/OS Authorized Services, you can set up the following types of profiles by using a SAF security product such as RACF:

- SAF STARTED profile is required if you plan on running the Liberty server or the Liberty angel process as a z/OS Started Task. For more information about the Liberty angel process, see “Liberty profile: Process types on z/OS” on page 1019.
- SAF SERVER profile is required if you plan on having the Liberty server access any of the z/OS Authorized Services for your applications. You can find the description of each service in the following content.

**Note:** You do not need to set up RACF if you are not planning to run the Liberty server as a Started Task and you are not planning to use any of the authorized services.

### Procedure

- Create STARTED profiles for the PROCs for the angel and Liberty server processes. This action enables the angel and Liberty server to run as Started Tasks.

- To cause the angel to run under the user ID *WLPUSER0*:

```
rdef started bbgzangl.* uacc(none) stdata(user(WLPUSER0) group(wasuser) privileged(no) trusted(no) trace(yes))
```

- To cause a server that is running under the BBGZSRV procedure name to run under the user ID *WLPUSER1*:

```
rdef started bbgzsrv.* uacc(none) stdata(user(WLPUSER1) group(wasuser) privileged(no) trusted(no) trace(yes))
```

- Create a SERVER profile for the angel process and permit the *WLPUSER1* user ID. This action grants a Liberty server access to the angel process, which is required for the z/OS authorized services. To enable a server that is running as *WLPUSER1* to connect to the angel:

```
RDEF SERVER BBG.ANGEL UACC(NONE)  
PERMIT BBG.ANGEL CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

- Create a SERVER profile for the authorized module BBGZSAFM and permit the Started Task user ID of the Liberty server to the profile. This action enables a Liberty server to use the z/OS Authorized services. To enable a server that is running as *WLPUSER1* to access the authorized module:

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM UACC(NONE)  
PERMIT BBG.AUTHMOD.BBGZSAFM CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

- Create SERVER profiles for the individual authorized services provided for the z/OS platform. These profiles enable the server to invoke the individual authorized services and these services are grouped by function:

- To enable the SAF authorized user registry services and SAF authorization services (SAFCRED):

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.SAFCRED UACC(NONE)  
PERMIT BBG.AUTHMOD.BBGZSAFM.SAFCRED CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

- To enable the WLM services (ZOSWLM):

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.ZOSWLM UACC(NONE)  
PERMIT BBG.AUTHMOD.BBGZSAFM.ZOSWLM CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

- To enable the RRS transaction services (TXRRS):

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.TXRRS UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.TXRRS CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

- To enable the SVCDUMP services (ZOSDUMP):

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.ZOSDUMP UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.ZOSDUMP CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

-  **8.5.5.2** To enable optimized local adapter services:

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.LOCALCOM UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.LOCALCOM CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.WOLA UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.WOLA CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

- **8.5.5.2** To enable the IFAUSAGE services (PRODMGR):

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.PRODMGR UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.PRODMGR CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

- To enable the AsyncIO services (ZOSAIO):

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.ZOSAIO UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.ZOSAIO CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

-  **8.5.5.2** Create a SERVER profile for the authorized client module BBGZSCFM and permit the Started Task user ID of the Liberty server to the profile. This action enables a Liberty server to load the z/OS Authorized client services. To enable a server that is running as WLPUSER1 to access the authorized client module:

```
RDEF SERVER BBG.AUTHMOD.BBGZSCFM UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSCFM CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

-  **8.5.5.2** Create SERVER profiles for the individual authorized client services provided for the z/OS platform. These profiles enable clients to invoke the individual authorized services provided by the server. These services are grouped by function:

- To enable optimized local adapter services:

```
RDEF SERVER BBG.AUTHMOD.BBGZSCFM.WOLA UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSCFM.WOLA CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

## Liberty: Accessing z/OS security resources using WZSSAD

z/OS

The WebSphere Liberty z/OS System Security Access Domain (WZSSAD) refers to the permissions granted to the Liberty server. These permissions control which System Authorization Facility (SAF) application domains and resource profiles the server is permitted to query when authenticating and authorizing users.

For example, if you want to set up two Liberty server instances, one for production and one for test and you want your role access to be different between production and test, you can set up two different System Security Access Domains.

The Liberty server is an unauthorized program that can be configured and run by non-administrator or non-privileged users, so it is important for system security and integrity purposes that the user is prevented from leveraging the server to run security operations for which they have not been explicitly granted permission.

**Note:** The WZSSAD is in effect only when the server is using authorized SAF services for authentication and authorization. This means the angel process is running, and the server has been granted permission to use the SAFCREED authorized service routines.

There are three SAF operations that are protected by the WZSSAD:

- Authenticating a user

- Authorizing a Subject to a Java EE role
- Authorizing a Subject to other SAF resources

By default, the WZSSAD is not configured, which means the server has no permission to authenticate or authorize anything. For example, the Liberty server cannot use authorized SAF services for authentication or authorization until an administrator grants it permission to perform some or all of the operations.

## Authenticating a user

The server authenticates users to a particular SAF domain that is configured by defining a resource, which is referred to as the APPLID in the APPL class. In order to authenticate a user to the domain, the user must have READ access to the APPLID resource in the APPL class. In addition, whenever the APPL class is active, the unauthenticated user ID (which is WSGUEST by default) also requires READ access to the APPLID resource in the APPL class.

The APPLID resource name used by the server is specified by the **profilePrefix** attribute in the <saxCredentials> configuration element. If you do not specify this element, then the default profilePrefix of BBGZDFLT is used.

The following example shows how to configure a **profilePrefix** of BBGZDFLT in the server.xml file:

```
<saxCredentials profilePrefix="BBGZDFLT"/>
```

The following example shows how to use RACF commands to configure the APPLID as BBGZDFLT:

```
// Define the BBGZDFLT APPLID to RACF.
RDEFINE APPL BBGZDFLT UACC(NONE)

// Activate the APPL class.
//If not active, the domain is not restricted, which means anyone can authenticate to it.
SETROPTS CLASSACT(APPL)

//All users to be authenticated by the server must have READ access to the APPLID in the APPL class:
PERMIT BBGZDFLT CLASS(APPL) ACCESS(READ) ID(UserID)

//The unauthenticated user ID requires READ access to the APPLID in the APPL class:
PERMIT BBGZDFLT CLASS(APPL) ACCESS(READ) ID(WSGUEST)
```

In addition, the server must be granted permission within the WZSSAD to make authentication calls in the given APPLID domain. This prevents an unauthorized user from leveraging the server's use of authorized SAF services to discover information about which APPLIDs can and cannot be authenticated. To grant the server permission to authenticate in a particular APPLID domain, the started task ID of the Liberty server must be granted READ access to the BBG.SECPFX.<APPLID> profile in the SERVER class:

```
RDEFINE SERVER BBG.SECPFX.BBGZDFLT UACC(NONE)
PERMIT BBG.SECPFX.BBGZDFLT CLASS(SERVER) ACCESS(READ) ID(serverUserId)
```

## Authorizing a Subject to a Java EE role

The server authorizes a subject against a Java EE application security role name by checking whether the subject is authorized to a SAF resource profile defined in the EJBROLE class. The SAF resource profile name is mapped from the application role name via the SAF role mapper. The SAF role mapper generates a SAF profile name for a given application role name and application resource name. By default, it generates the SAF profile name using the pattern *{profilePrefix}.{resource}.{role}*. For example:

```
profilePrefix="BBGZDFLT"
```

```
Application resource name = "MYAPP"
```

Application role name = "ADMIN"

Mapped profile name = "BBGZDFLT.MYAPP.ADMIN"

For more information, see “Liberty: Controlling how roles are mapped to SAF Profiles” on page 1941

The WZSSAD restricts which SAF profiles in the EJBROLE class the server is allowed to perform authorization against. This prevents an unauthorized user from leveraging the server's use of authorized SAF services to discover information about which EJBROLE profiles can or cannot be authorized to. The server must be granted permission to run authorization checks against the HLQ of the EJBROLE profile name. The HLQ of the profile name is the first segment of the profile name, up to but not including the first '.'. For example:

EJBROLE profile name = "BBGZDFLT.ADMIN"

HLQ = "BBGZDFLT"

To grant the server permission to run authorization checks against the profile HLQ, the user associated with the server process must be granted READ access to the BBG.SECPFX.<HLQ> profile in the SERVER class:

```
RDEFINE SERVER BBG.SECPFX.BBGZDFLT UACC(NONE)
PERMIT BBG.SECPFX.BBGZDFLT CLASS(SERVER) ACCESS(READ) ID(serverUserId)
```

In the example, because the SAF role mapper sets the HLQ of the mapped profile to the profilePrefix, the same profile BBG.SECPFX.BBGZDFLT governs both the APPLID authentication permissions, and the EJBROLE profile authorization permissions.

## Authorizing a Subject to other SAF resources

Java EE applications can perform access control checks against SAF classes other than EJBROLE. The WZSSAD restricts which SAF classes outside of EJBROLE the server is allowed to authorize against. This prevents an unauthorized user or application from leveraging the server's use of authorized SAF services to discover information about which resource profiles in non-EJBROLE SAF classes the user or application is or is not authorized to.

To grant the server permission to perform authorization checks against non-EJBROLE SAF classes, the user associated with the server process must be granted READ access to the BBG.SECCLASS.<SAF-CLASS> profile in the SERVER class. For example, to authorize against a profile in the FACILITY class:

```
RDEFINE SERVER BBG.SECCLASS.FACILITY UACC(NONE)
PERMIT BBG.SECCLASS.FACILITY CLASS(SERVER) ACCESS(READ) ID(serverUserId)
```

**Note:** There are no restrictions on which resource profiles within the non-EJBROLE class the server is allowed to authorize against. If the server has been granted permission to perform authorization checks against a non-EJBROLE class, then it can authorize against any profile in that class.

## Enabling Asynchronous TCP/IP sockets I/O for Liberty on z/OS

z/OS

You can use the Asynchronous TCP/IP sockets I/O for Liberty (AsyncIO) on z/OS service to provide the basic capabilities of an Asynchronous I/O package at the operating system level. The AsyncIO on z/OS service uses native services to provide improvements in performance and scalability in many environments.

### About this task

To enable the AsyncIO on z/OS service, you define the security setup to permit the Authorized AsyncIO Service(ZOSAIO):

## Procedure

- Start the Angel process:

```
START bbgzangl
```

For more information, see [Administering Liberty on z/OS](#).

- Define the security setup to permit the Authorized AsyncIO Service(ZOSAIO):

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.ZOSAIO UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.ZOSAIO CLASS(SERVER) ACCESS(READ) id(wlpuser1)
```

For more information, see [Enabling z/OS authorized services in Liberty for z/OS](#).

## What to do next

This procedure enables the AsyncIO on z/OS service by default. However, if the AsyncIO z/OS service is enabled, you can disable it within a particular server by adding the following to the `server.xml`:

```
<zosaio id="defaultZOSAIO" zosaio.enable="false"/>
```

You must then restart the server to override the default behavior.

## Liberty: Unauthorized services used by the SAF registry

z/OS

The System Authorization Facility (SAF) registry uses a number of unauthorized services from the C environment provided by LE (Language Environment<sup>®</sup>).

The following table lists the unauthorized services from LE C that the SAF registry uses, and provides links to additional information in the z/OS V2R1 information center. These services are subject to BPX.DAEMON restrictions which are detailed in the documentation linked to from the service calls associated with each method listed in the table.

Method	Link to further information
<code>checkPassword(String, String)</code> <code>__passwd_applid()</code>	Verify/Change User Password
<code>getGroups(String, int)</code> <code>setgrent()</code>	Reset Group Database to First Entry
<code>getgrent()</code>	Get Group Database Entry
<code>endgrent()</code>	Get Group Database Entry Functions
<code>getGroupsForUser(String)</code>	Get Supplementary Group IDs by User Name
NOTE: This method only works for users with defined OMVS segments.	
<code>getgroupsbyname()</code>	Get Supplementary Group IDs by User Name
<code>getgrgid()</code>	Access the Group Database by ID
<code>getUsers(String, int)</code> <code>setpwent()</code>	Reset User Database Search
<code>getpwent()</code>	Get User Database Entry
<code>endpwent()</code>	User Database Functions
<code>isValidGroup(String)</code> <code>getgrnam_r()</code>	Search Group Database for a Name
<code>isValidUser(String)</code> <code>getpwnam_r()</code>	Search User Database for a Name

Method	Link to further information
mapCertificate(X509Certificate) __certificate()	Register/Deregister/Authenticate a Digital Certificate

**Note:** If the Liberty server is configured to use SAF authorized services (see “Activating and configuring the SAF registry on z/OS” on page 1857), then the following unauthorized services are not used:

- checkPassword: \_\_passwd\_applid
- isValidUser: getpwnam\_r
- mapCertificate: \_\_certificate

Instead, the Liberty server will use the authorized SAF service initACEE.

## Liberty: Setting up the System Authorization Facility (SAF) unauthenticated user

z/OS

If you are using a SAF user registry, it is necessary to specify a SAF user ID that represents the unauthenticated state. The name of the unauthenticated user ID is specified on the `unauthenticatedUser` attribute of the `SAFCredentials` element in `server.xml`. It is important to define this user ID correctly in your SAF registry. If you are using a RACF SAF user registry, the unauthenticated user (default WSGUEST) needs a unique default group (DFLTGRP) with no other user IDs connected to that group, an OMVS segment, but not a TSO segment, and the options NOPASSWORD, NOOIDCARD, and RESTRICTED. If you have another SAF user registry, instead of RACF, then find the user ID options that are provided by that SAF registry that are equivalent to these RACF options.

### About this task

By running the appropriate commands, you can correctly set up an unauthenticated user in your SAF user registry. An unauthenticated user that is incorrectly setup might cause a security exposure.

### Procedure

1. Run the **ADDGROUP** command. Use WSGUESTG as the group name.

```
ADDGROUP WSGUESTG SUPGROUP(SYS1)OWNER(SYS1)
        DATA('WAS Unauthenticated User Group')
        OMVS(AUTOGID)
```

2. Run the **ADDUSER** command. Use WSGUEST as the user ID name.

```
ADDUSER WSGUEST DFLTGRP(WSGUESTG) OWNER(SYS1)
        OMVS(AUTOUID)
        HOME(/u/WSGUEST)
        PROGRAM(/bin/sh)
        NAME('WAS unauth')
        NOPASSWORD NOOIDCARD
        RESTRICTED
```

The options NOPASSWORD and NOOIDCARD protect this user ID from being revoked by repeated attempts to guess the password.

The option RESTRICTED means that this user ID cannot gain access to protected resources unless it is explicitly permitted to that resource, even is that resource has a general access setting of UACC(READ).

- 3.

**Note:** After the unauthenticated user ID (WSGUEST) is defined to the SAF registry, ensure that the user ID is permitted to only the minimum number of SAF resources. If the Liberty server is using SAF APPL resource check to control which users can connect to the Liberty z/OS System Security Access Domain, then the unauthenticated user ID must be given access to the APPL profile. Run the **PERMIT** command.

```
PERMIT BBGZDFLT CLASS(APPL) ID(WSGUEST) ACCESS(READ)
```

## What to do next

If you receive the RACF authorization failure message ICH408I because the unauthenticated user (WSGUEST) does not have access to a RACF resource, such as an EJBROLE profile. It is nearly always incorrect to permit the unauthenticated user ID to the resource profile to resolve the problem. It usually means that the request is running in an unauthenticated state when it should be running in an authenticated state. The actual problem is probably a failure to authenticate properly. Whenever it appears necessary to permit the unauthenticated user ID to a SAF resource profile you should consider carefully whether that is the correct action to take. Permitting the unauthenticated user ID to any SAF resource profile makes that resource available to everyone, including users that are not authenticated. There are almost no instances where that is required, however, the APPL profile that controls access to the WZSSAD is one exception.

## Configuring distributed identity filters in z/OS security

z/OS

Distributed identity filters must be configured when the `mapDistributedIdentities` attribute in the `safCredentials` configurations element is set to true.

### About this task

Before you map distributed identities to System Authorization Facility (SAF) users, you must first configure distributed identity filters in z/OS security.

The distributed identity filter in the SAF class RACMAP consists of the distributed user name and the realm name of the distributed user name. You can configure the filters to map many distributed identities to one SAF user or you can have a one-to-one mapping.

The following example illustrates the syntax for creating a distributed identity filter that uses the RACMAP command:

```
RACMAP ID(<SAFUser>) MAP USERDIDFILTER(NAME('<distributedUserId>'))
REGISTRY(NAME('<distributedRealmName>'))
    WITHLABEL('<someLabel>')
```

In the example:

- The *SAFUser* element is the SAF user in z/OS security.
- The *distributedUserID* element is the distributed identity.
- The *distributedRealmName* element is the realm name of the distributed identity.
- The *someLabel* element is a field that describes this distributed identity filter.

### Procedure

1. Activate the IDIDMAP class. This command needs to be run only once at the beginning. SETROPTS CLASSACT(IDIDMAP) RACLIST(IDIDMAP)
2. After you edit the RACMAP profiles, you must use the following command for the changes to take effect: SETROPTS RACLIST(IDIDMAP) REFRESH

### Example

The following example illustrates the LDAP user (LDAPUser1) mapped to the SAF user (USER1):

```
RACMAP ID(USER1) MAP USERDIDFILTER(NAME('CN=LDAPUser1,o=ibm,c=us'))
REGISTRY(NAME('ccwin12.austin.ibm.com:389'))
WITHLABEL('Mapping LDAP LDAPUser1 to USER1')
```

## Securing optimized local adapters on Liberty for z/OS

z/OS

8.5.5.2

In addition to configuring security on your Liberty server, you can further secure WebSphere optimized local adapters (WOLA) connections with the System Authorization Facility (SAF) CBIND class, security parameters on the optimized local adapter APIs, and more.

## Securing optimized local adapters for inbound support in Liberty for z/OS

z/OS

8.5.5.2

Secure your WebSphere optimized local adapters (WOLA) connections that make inbound calls to the Liberty server.

### Before you begin

Run the Liberty servers on z/OS with server security. For more information, see “Liberty: Security” on page 971.

Local access to Liberty for z/OS servers is protected by the System Authorization Facility (SAF) CBIND class. When enabled, this class is used to protect Liberty servers when optimized local adapters requests are made. Before you run any application that uses the Register API, grant READ access for the user ID for the job, UNIX System Services process, or Customer Information Control System (CICS) region to the CBIND class for the target server.

All inbound requests to the Liberty server run under the authority of the current user on thread. This identity is automatically propagated and asserted in the Enterprise JavaBeans (EJB) container, and the application starts under this identity. Inbound requests that drive into a target enterprise bean arrive in the same manner as method invocations do for local EJB requests, and the security options for RunAs work in the same way as local EJB requests.

When inbound or outbound transaction work passes between CICS and Liberty for z/OS, you must take into account some special security considerations. For example, you must determine if the authentication for inbound to the Liberty server work should run with the authority of the specific CICS application or the overall CICS region authority. There are similar concerns when the Liberty server sends outbound work to a CICS application; you must determine if CICS should honor the originating application authority or its own CICS current security profile.

**Attention:** You must make sure that the client applications are authenticated for CICS to process the request.

For passing requests in to the Liberty server from CICS, you can indicate that you want to use the current CICS application identity by setting a flag for this with the Register API call.

### Procedure

- Create SERVER profiles for z/OS.
  1. Create SERVER profiles for the optimized local adapter authorized service. Use the following Time Sharing Option (TSO) commands:

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.LOCALCOM UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.LOCALCOM CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.WOLA UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.WOLA CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

2. Create a SERVER profile for the authorized client module BBGZSCFM and permit the Started Task user ID of the Liberty server to the profile. This action enables a Liberty server to load the z/OS Authorized client services. To enable a server that is running as WLPUSER1 to access the authorized client module:

```
RDEF SERVER BBG.AUTHMOD.BBGZSCFM UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSCFM CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

3. Create SERVER profiles for optimized local adapter authorized client service. Use the following TSO commands:

```
RDEF SERVER BBG.AUTHMOD.BBGZSCFM.WOLA UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSCFM.WOLA CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

For more information, see “Enabling z/OS authorized services in Liberty for z/OS” on page 1942.

- If you have CBIND enabled in System Authorization Facility (SAF), grant access to the clients that will use optimized local adapters.

1. Define a profile for the Liberty server in the CBIND class. The profile name is BBG.WOLA.<WOLA1>.<WOLA2>.<WOLA3>, where WOLA1,WOLA2, and WOLA3 are the three parts of the optimized adapter group name that are specified in the <zosLocalAdapters> element in the server.xml file. You can define a profile by using the SAF **RDEFINE** TSO command. For example, the following command creates a profile in the CBIND class for a WOLA group named LIB1.LIB2.LIB3:

```
RDEF CBIND BBG.WOLA.LIB1.LIB2.LIB3 UACC(NONE)
```

2. Permit READ access to the profile. For example, the following command permits read access for the *username* user name on the bbg.wola.lib1.lib2.lib3 profile:

```
PERMIT BBG.WOLA.LIB1.LIB2.LIB3 CLASS(CBIND) ACCESS(READ) ID(USERNAME)
```

You can use asterisks to permit a user access to multiple profiles. The following example permits READ access to the *username* user for all profiles that start with bbg.wola in the CBIND class:

```
RDEF CBIND BBG.WOLA.* UACC(NONE)
PERMIT BBG.WOLA.* CLASS(CBIND) ACCESS(READ) ID(USERNAME)
```

For more information about SAF commands and syntax, see the documentation for your version of z/OS.

- Configure the security settings. The security identity propagation type is specified in registration flags when the optimized local adapters connection request is made in the call to the Register API. For more information, see “Optimized local adapters APIs on Liberty for z/OS” on page 2079. You can select either the CICS region or application security profile.

**Attention:** For security propagation to function, you must enable security at the CICS application level by setting the SEC=Y CICS startup option.

## Securing optimized local adapters for outbound support in Liberty for z/OS

Secure your WebSphere optimized local adapters (WOLA) connections that make outbound calls from the Liberty server.

### Procedure

1. Optional: Set up server-side security.
  - a. Run the Liberty servers on z/OS with server security. For more information, see “Configuring authorization for applications in Liberty” on page 1939 and “Enabling z/OS authorized services in Liberty for z/OS” on page 1942.
  - b. If you are calling from a Liberty server to Customer Information Control System (CICS) and security is enabled on the CICS link server, choose a user ID to run the target CICS program.

By default, the invocation subject obtains the MVS user ID that runs the target CICS program. The invocation subject is the subject that runs the application component that makes the optimized local adapters request. In many cases, this subject is the run-as identity that is configured in the application deployment descriptor.

You can define an alternative subject to the invocation subject in three ways:

- In the connection factory configuration, specify a user ID and password in an `authData` element, and reference the element in the `connectionFactory` element. In the following example, the optimized local adapter connection factory references the `auth2` `authData` element, which specifies a user ID of `user2` and an associated password.

```
<connectionFactory jndiName="eis/ola" containerAuthDataRef="auth2">
  <properties.ola RegisterName="OLASERVER"/>
</connectionFactory>
<authData id="auth2" user="user2" password="{xor}Lz4sLCgwLTtt"/>
```

For more information about configuring connection factories, see “Configuring JCA connection factories” on page 1618.

- The system administrator can provide a user ID and password on the optimized local adapters connection factory. For more information, see “Connection factory properties for optimized local adapters on Liberty” on page 1699.
- The application developer can provide a user ID and password on the `ConnectionSpec` object that obtains a connection from the optimized local adapters connection factory.

The security service attempts to authenticate with the provided user ID and password. If authentication is successful, the new subject obtains the MVS user ID that runs the target CICS program.

- c. If you are calling from a Liberty server to IBM Information Management System (IMS) by using OTMA, the Liberty server can propagate the current user ID to the IMS region if the Liberty server and the application are both configured to use `sync-to-OS-thread`. The IMS region must also be running with the option `OTMASE=FULL` in the `IMSPBxxx PROCLIB` member.
2. Set up client-side security.
    - a. If you have `CBIND` enabled in System Authorization Facility (SAF), grant access to the clients that will use optimized local adapters.
      - 1) Define a profile for the Liberty server in the `CBIND` class. The profile name is `BBG.WOLA.<WOLA1>.<WOLA2>.<WOLA3>`, where `WOLA1`, `WOLA2`, and `WOLA3` are the three parts of the optimized adapter group name that are specified in the `<zosLocalAdapters>` element in the `server.xml` file. You can define a profile by using the SAF **RDEFINE** TSO command. For example, the following command creates a profile in the `CBIND` class for a `WOLA` group that is named `LIB1.LIB2.LIB3`:
 

```
rdef cbind bbg.wola.lib1.lib2.lib3 uacc(none)
```
      - 2) Permit `READ` access to the profile. For example, the following command permits read access for the `username` user name on the `bbg.wola.lib1.lib2.lib3` profile:
 

```
permit bbg.wola.lib1.lib2.lib3 class(cbind) access(read) id(username)
```

You can use asterisks to permit a user access to multiple profiles. The following example permits `READ` access to the `username` user for all profiles that start with `bbg.wola` in the `CBIND` class:

```
rdef cbind bbg.wola.* uacc(none)
permit bbg.wola.* class(cbind) access(read) id(username)
```
- For more information about SAF commands and syntax, see the documentation for your version of z/OS.
- b. If you are running a CICS link server with security enabled, configure CICS to enable user identity assertion.
    - 1) Ensure that the CICS region is running with security enabled and `EXEC CICS START` checking enabled.
      - Enable security at CICS startup by specifying the parameter `SEC=YES`.

- Enable EXEC CICS START checking at startup by specifying the parameter XUSER=YES.

For more information about CICS system initialization parameters, see the documentation for your version of CICS.

- 2) Create a System Authorization Facility (SAF) SURROGAT class definition that permits the user ID of the link server to issue the EXEC CICS START TRAN('BBO#') USERID(<propagated\_id>) command.

The following example shows a SURROGAT class that is defined for the USER1 user ID. The class enables user ID OLASERVE to run the EXEC CICS START TRANS(BBO#) USERID(USER1) command and process optimized local adapters CICS link transactions that run with the identity of USER1.

```
RDEFINE SURROGAT USER1.DFHSTART UACC(NONE) OWNER(USER1)
PERMIT USER1.DFHSTART CLASS(SURROGAT) ID(USER1)
PERMIT USER1.DFHSTART CLASS(SURROGAT) ID(OLASERVE)
SETROPTS RACLIST(SURROGAT) REFRESH
```

For more information about defining a SURROGAT class, see the documentation for your version of CICS.

## Configuring security authorization for Liberty servers on IBM i

IBM i

Using the iAdmin GRANTAUTH command, you can authorize the QEJBSVR user profile to access the required resources for running the Liberty server.

### Before you begin

Servers run under the QEJBSVR user profile if one of the following is true:

- The Liberty environment was installed as a feature of a product offering using the IBM Installation Manager.
- The iAdmin POSTINSTALL command was called after Installing Liberty by extracting an archive file.

Also, QEJBSVR is granted authorization to files in the \$WLP\_USER\_DIR and \$WLP\_OUTPUT\_DIR locations in all of these installation scenarios. Additionally, when servers are created, QEJBSVR is granted authorization to server definition files and the \$WLP\_OUTPUT\_DIR location.

### About this task

This task provides example commands that show you how to authorize the QEJBSVR user profile to access the required resources for running the server after doing the following tasks:

- Creating files manually or modifying the authorities on shared resources and server definitions files.
- Configuring a server to access resources the QEJBSVR user profile is not yet authorized to.

### Example

- Granting the server role to the QEJBSVR user profile for the shared resources, server definitions and output locations configured for the Liberty environment installed at /WAS/wlp directory.  

```
/WAS/wlp/lib/native/os400/bin/iAdmin GRANTAUTH -rolename server -userprofilename QEJBSVR
```
- Granting the server role to the QEJBSVR user profile for shared resources and server definitions in /WAS/myWlpServers/usr, and for any server output locations defined by the WLP\_OUTPUT\_DIR variable in files matching the definition in the /WAS/myWlpServers/usr/servers/\*/server.env file.  

```
/WAS/wlp/lib/native/os400/bin/iAdmin GRANTAUTH -rolename server -userprofilename QEJBSVR
-userdir /WAS/myWlpServers/usr
```
- Granting the server role to the QEJBSVR user profile for output location /WAS/myWlpOutput/servers.

```
/WAS/wlp/lib/native/os400/bin/iAdmin GRANTAUTH -rolename server -userprofilename QEJBSVR  
-outputdir /WAS/myWlpOutput/servers
```

## OAuth

8.5.5.0

OAuth is an open standard for delegated authorization. With the OAuth authorization framework, a user can grant a third-party application access to their information stored with another HTTP service without sharing their access permissions or the full extent of their data.

In OAuth, the client, or third-party application, requests access to resources controlled by the resource owner and hosted by the resource server, and is issued a different set of credentials than those of the resource owner. Instead of using the credentials of the resource owner to access protected resources, the client obtains an access token, which is a string denoting a specific scope, lifetime, and other access attributes. Access tokens are issued to third-party clients by an authorization server with the approval of the resource owner. The client uses the access token to access the protected resources hosted by the resource server.

OAuth 2.0 is not compatible with OAuth 1.0. OAuth 2.0 provides ease of use for client application developers, and authorization flows for different types of client applications.

WebSphere Application Server supports OAuth 2.0, and can be used as an OAuth service provider endpoint and an OAuth protected resource enforcement endpoint.

WebSphere Application Server supports the following OAuth standard specifications:

- The OAuth 2.0 Authorization Framework
- The OAuth 2.0 Authorization Framework: Bearer Token Usage

The following list shows a summary of features within WebSphere Application Server OAuth 2.0 services.

- WebSphere Application Server acts as an OAuth Service Provider (SP) to handle OAuth 2.0 protocol requests.
- WebSphere Application Server acts as protected resource enforcement endpoint to authorize or deny requests for deployed web resources.
- Allow multiple service providers to co-exist.
- Allow administrator to revoke access tokens.
- Allow client to revoke its authorization given by a user.
- Optionally provide a Subject for a resource application to make an authenticated downstream call or perform programmatic J2EE security.
- Support 4 typical OAuth 2.0 flows as defined in the protocol.
- Support persistent OAuth services.

### OAuth 2.0 services

8.5.5.0

WebSphere Application Server OAuth services include both the OAuth authorization service and the web resource authorization decision service.

The OAuth 2.0 authorization service provides all OAuth 2.0 protocol endpoint URLs, and is responsible for client authorization and token issuing.

The web resource authorization decision service is built into the Liberty web authentication code. When a client accesses an OAuth protected web resource, the OAuth token is validated and mapped to a WebSphere Application Server platform security subject that the web request then runs under.

## Defining an OAuth service provider: **8.5.5.0**

An OAuth service provider is a named set of configuration options for OAuth. The id or name of the provider is specified in the URL of inbound requests to the authorization and token endpoints. The set of configuration options for that provider is used when the request is handled. This process allows one server with one endpoint servlet to effectively provide multiple OAuth configurations. For example, the `https://my.company.com:8021/oauth2/endpoint/photoShare/authorize` URL is handled by using the set of OAuth configuration options that are defined for the OAuth provider named `photoShare`. The `https://my.company.com:8021/oauth2/endpoint/calendarAuthz/authorize` URL is handled by using the set of OAuth configuration options that are defined for the OAuth provider named `calendarAuthz`.

### About this task

An OAuth service provider is defined with the `oauthProvider` element in the `server.xml` file. You can define an OAuth service provider by editing the `server.xml` file or by using the WebSphere Application Server Development Tools for Liberty. This task describes how to define a minimal OAuth configuration.

### Procedure

1. Add the `oauth-2.0` and `ssl-1.0` features. OAuth is a secure protocol so SSL is required. On Liberty, you must supply a keystore password for SSL by using the `keyStore` element. There is no default keystore password.

```
<featureManager>
  <feature>oauth-2.0</feature>
  <feature>ssl-1.0</feature>
</featureManager>
```

2. Set up the role mapping for the OAuth web application by using the `oauth-roles` element. OAuth is an HTTP-based protocol and a web application is supplied to handle the authorization and token endpoints. The web application is built in and is started automatically when you specify the `oauth-2.0` feature. However, you must map the authenticated role to one or more users, groups, or special subjects. Another role, `clientManager`, is supplied for managing client configuration, but it is not necessary to map that role for OAuth authorization to function.

```
<oauth-roles>
  <authenticated>
    <user>testuser</user>
  </authenticated>
</oauth-roles>
```

3. Define one or more providers with the `oauthProvider` element. The provider must have at least one client defined. Clients can be defined locally with the `localStore` and `client` elements. Clients can also be defined in a relational database with the `databaseStore` element.

```
<oauthProvider id="SampleProvider" filter="request-url%=ssodemo">
  <localStore>
    <client name="client01" secret="{xor}LDo8LTor"
      displayname="Test client number 1"
      redirect="http://localhost:1234/oauthclient/redirect.jsp"
      enabled="true" />
  </localStore>
</oauthProvider>
```

4. **8.5.5.0** Define a user registry, either an LDAP registry by specifying the `ldapRegistry-3.0` feature and the `ldapRegistry` configuration element, or a basic registry by specifying the `basicRegistry` configuration element.

```

<basicRegistry id="basic" realm="BasicRealm">
  <user name="testuser" password="testuserpwd" />
</basicRegistry>

```

5. Set the `allowFailOverToBasicAuth` web application security property to `true`.

```

<webAppSecurity allowFailOverToBasicAuth="true" />

```

## Results

You have defined a minimal OAuth configuration.

## Example

The following example shows a sample `server.xml` file that defines a simple OAuth provider with one client:

```

<server>

  <featureManager>
    <feature>oauth-2.0</feature>
    <feature>ssl-1.0</feature>
  </featureManager>

  <keyStore password="keyspass" />

  <oauth-roles>
    <authenticated>
      <user>testuser</user>
    </authenticated>
  </oauth-roles>

  <oauthProvider id="SampleProvider" filter="request-url%ssodemo">
    <localStore>
      <client name="client01" secret="{xor}LDo8LTor"
        displayname="Test client number 1"
        redirect="http://localhost:1234/oauthclient/redirect.jsp"
        enabled="true" />
    </localStore>
  </oauthProvider>

  <webAppSecurity allowFailOverToBasicAuth="true" />

  <basicRegistry id="basic" realm="BasicRealm">
    <user name="testuser" password="testuserpwd" />
  </basicRegistry>

</server>

```

## OAuth full profile provider configuration equivalents: **8.5.5.0**

The following tables map the Liberty `server.xml` file elements and attributes to the equivalent full profile provider parameters in the provider configuration file.

The following table illustrates the Liberty profile attributes and the equivalent full profile parameters for the `oauthProvider` element.

*Table 133. Liberty `oauthProvider` element*

Liberty attribute name	Full profile equivalent parameter
<code>authorizationGrantLifetime</code>	<code>oauth20.max.authorization.grant.lifetime.seconds</code>
<code>authorizationCodeLifetime</code>	<code>oauth20.code.lifetime.seconds</code>

Table 133. Liberty oauthProvider element (continued)

Liberty attribute name	Full profile equivalent parameter
authorizationCodeLength	oauth20.code.length
accessTokenLifetime	oauth20.token.lifetime.seconds
accessTokenLength	oauth20.access.token.length
issueRefreshToken	oauth20.issue.refresh.token
refreshTokenLength	oauth20.refresh.token.length
mediatorClassname	oauth20.mediator.classnames
allowPublicClients	oauth20.allow.public.clients
grantType	oauth20.grant.types.allowed
authorizationFormTemplate	oauth20.authorization.form.template
authorizationErrorTemplate	oauth20.authorization.error.template
customLoginURL	oauth20.authorization.loginURL
autoAuthorizeParam	oauth20.autoauthorize.param
autoAuthorizeClient	oauth20.autoauthorize.clients
clientURISubstitutions	oauth20.client.uri.substitutions
filter	Filter
oauthOnly	oauthOnly
includeTokenInSubject	includeToken
characterEncoding	characterEncoding
clientTokenCacheSize	oauth20.token.userClientTokenLimit

The following table illustrates the Liberty attributes and the equivalent full profile parameters for the databaseStore element.

Table 134. Liberty databaseStore element

Liberty attribute name	Full profile equivalent parameter
cleanupExpiredTokenInterval	oauthjdbc.CleanupInterval

## Configuring automatic authorization: 8.5.5.0 Before you begin

Ensure that you enabled the OAuth 2.0 feature and configured an OAuth service provider by following Defining an OAuth service provider.

### About this task

You can authorize an OAuth client without the approval of the resource owner by enabling the automatic authorization feature of the WebSphere Application Server OAuth service provider.

### Procedure

To configure auto consent, use the autoAuthorizeParam attribute and the <autoAuthorizeClient> subelement of the <oauthProvider> element in the server.xml file:

```
<oauthProvider id="OAuthConfigSample" autoAuthorizeParam="autoauthz" ...>
  ...
  <autoAuthorizeClient>client01</autoAuthorizeClient>
  <autoAuthorizeClient>client02</autoAuthorizeClient>
</oauthProvider>
```

## Results

The `client01` and `client02` OAuth clients are configured for automatic authorization.

### OAuth endpoint URLs: **8.5.5.0**

After OAuth 2.0 is enabled, several endpoint URLs are configured on your WebSphere Application Server so that OAuth clients can communicate with the OAuth service provider before accessing OAuth protected resources.

The following endpoint URLs are configured for the OAuth service provider:

- Authorization endpoint URL

`https://host_name:port_number/oauth2/endpoint/provider_name/authorize`

where

- `host_name` is the host name of the OAuth service provider.
- `port_number` is the secure port number that is configured on the WebSphere Application Server.
- `provider_name` is the OAuth provider name.

- Token endpoint URL

`https://host_name:port_number/oauth2/endpoint/provider_name/token`

where

- `host_name` is the host name of the OAuth service provider.
- `port_number` is the secure port number that is configured on the WebSphere Application Server.
- `provider_name` is the OAuth provider name.

- Authorization endpoint URL of trust association interceptor (TAI) based user authentication

`https://host_name:port_number/oauth2/declaritiveEndpoint/provider_name/authorize`

where

- `host_name` is the host name of the OAuth service provider.
- `port_number` is the secure port number that is configured on the WebSphere Application Server.
- `provider_name` is the OAuth provider name.

By using this authorization endpoint, the applicable user authentication includes TAI.

### OAuth 2.0 service invocation

#### **8.5.5.0**

A registered OAuth client can invoke the WebSphere Application Server OAuth service authorization endpoint to request an access token. A registered OAuth client can also invoke the WebSphere Application Server OAuth service token endpoint to request an access token. The client then can use the access token to request protected web resources from WebSphere Application Server.

WebSphere Application Server OAuth 2.0 service supports the following flows.

#### Authorization code flow

Invoke authorization endpoint to request authorization code.

The OAuth client redirects the resource owner or user to the WebSphere Application Server OAuth 2.0 Authorization Service by adding its client id, client secret, state, redirect URI, and the optional scopes.

`https://host_name:port_number/oauth2/endpoint/provider_name/authorize`

or

`https://host_name:port_number/oauth2/declarativeEndpoint/provider_name/authorize`

Invoke OAuth token endpoint to request access token.

The OAuth client requests an access token from the WebSphere Application Server OAuth 2.0 token endpoint by adding `authorization_code` grant type, authorization code, `redirect_url`, and `client_id` as request parameters.

`https://host_name:port_number/oauth2/endpoint/provider_name/token`

The following example shows the constructions of the URIs when using authorization code, and the use of the access token to access web resources:

```
String charset = "UTF-8";
String param1 = "code";

if (isAuthorizationCode){
    String query = String.format("response_type=%s&
                                client_id=%s&
                                client_secret=%s&
                                state=%s&
                                redirect_uri=%s&
                                scope=%s",
                                URLEncoder.encode(param1, charset),
                                URLEncoder.encode(clientId, charset),
                                URLEncoder.encode(clientSecret, charset),
                                URLEncoder.encode(state, charset),
                                URLEncoder.encode(redirectURI, charset),
                                URLEncoder.encode(scope, charset));

    String s = authorizationEndPoint + "?" + query;
    System.out.println("Visit: " + s + "\nand grant permission");
    System.out.print("Now enter the OAuth code you have received in redirect uri :");
    BufferedReader br = new BufferedReader(new InputStreamReader(System.in));
    String code = br.readLine();
    param1 = "authorization_code";
    query = String.format("grant_type=%s&
                            code=%s&
                            client_id=%s&
                            client_secret=%s&
                            state=%s&
                            redirect_uri=%s&
                            scope=%s",
                            URLEncoder.encode(param1, charset),
                            URLEncoder.encode(code, charset),
                            URLEncoder.encode(clientId, charset),
                            URLEncoder.encode(clientSecret, charset),
                            URLEncoder.encode(state, charset),
                            URLEncoder.encode(redirectURI, charset),
                            URLEncoder.encode(scope, charset));

    URL url = new URL(tokenEndPoint);
    HttpURLConnection con = (HttpURLConnection)url.openConnection();
    con.setRequestProperty("Content-Type", "application/x-www-form-urlencoded;charset=" + charset);
    con.setDoOutput(true);
    con.setRequestMethod("POST");
    OutputStream output = null;
    try {
        output = con.getOutputStream();
        output.write(query.getBytes(charset));
        output.flush();
    } finally {
        if (output != null) try {
            output.close();
        } catch (IOException logOrIgnore) {}
    }
    con.connect();
    System.out.println("response message is = " + con.getResponseMessage());
    // read the output from the server
    BufferedReader reader = null;
    StringBuilder stringBuilder;
    reader = new BufferedReader(new InputStreamReader(con.getInputStream()));
    stringBuilder = new StringBuilder();
    String line = null;
    try {
        while ((line = reader.readLine()) != null) {
```

```

        stringBuilder.append(line + "\n");
    }
} finally {
    if (reader != null) try {
        reader.close();
    } catch (IOException logOrIgnore) {}
}
String tokenResponse = stringBuilder.toString();
System.out.println ("response is = " + tokenResponse);
JSONObject json = JSONObject.parse(tokenResponse);
if (json.containsKey("access_token")) {
    accessToken = (String)json.get("access_token");
    this.accessToken = accessToken;
}
if (json.containsKey("refresh_token")) {
    refreshToken = (String)json.get("refresh_token");
}
//sendRequestForAccessToken(query);
if (accessToken != null) {
    String query = String.format("access_token=%s",
        URLEncoder.encode(accessToken, charset));
    URL urlResource = new URL(resourceEndPoint);
    HttpURLConnection conn = (HttpURLConnection) urlResource.openConnection();
    conn.setRequestMethod("POST");
    conn.setRequestProperty("Content-type", "application/x-www-form-urlencoded");
    conn.setDoOutput(true);
    output = null;
    try {
        output = conn.getOutputStream();
        output.write(query.getBytes(charset));
        output.flush();
    } finally {
        if (output != null) try {
            output.close();
        } catch (IOException logOrIgnore) {}
    }
    conn.connect();
    System.out.println("response to the resource request is = " + conn.getResponseMessage ());
    reader = null;
    if(conn.getResponseCode()>=200 && conn.getResponseCode() < 400) {
        reader = new BufferedReader(new InputStreamReader(conn.getInputStream()));
        stringBuilder = new StringBuilder();
        String line = null;
        try {
            while ((line = reader.readLine()) != null) {
                stringBuilder.append(line + "\n");
            }
        } finally {
            if (reader != null) try {
                reader.close();
            } catch (IOException logOrIgnore) {}
        }
        System.out.println ("response message to the request resource is = " + stringBuilder.toString());
    } else {
        isValidResponse = false;
    }
}
}
}

```

## Implicit grant flow

The OAuth client requests an access token from the WebSphere Application Server OAuth 2.0 authorization endpoint by adding token response\_type, redirect\_url, client\_id, scope, and state as request parameters.

`https://host_name:port_number/oauth2/endpoint/provider_name/authorize`

or

`https://host_name:port_number/oauth2/declarativeEndpoint/provider_name/authorize`

The following example shows the construction of the URI when using implicit grant:

```

if (isImplicit) {
    param1 = "token";
    String query = String.format("response_type=%s&
                                client_id=%s&
                                state=%s&
                                redirect_uri=%s&
                                scope=%s",
                                URLEncoder.encode(param1, charset),
                                URLEncoder.encode(clientId, charset),
                                URLEncoder.encode(state, charset),
                                URLEncoder.encode(redirectURI, charset),
                                URLEncoder.encode(scope, charset));

    String s = authorizationEndPoint + "?" + query;
    System.out.println("Visit: " + s + "\nand grant permission");
    System.out.print("Now enter the access token you have received in redirect uri :");
    BufferedReader br = new BufferedReader(new InputStreamReader(System.in));
    accessToken = br.readLine();
    if (accessToken != null) {
        // send Resource Request using the access token
    }
}
}

```

## Client credential flow

The OAuth client accesses the token endpoint by using the client ID and client secret, and exchanges for an access token for future resource requests. In this flow, the client accesses the token endpoint by adding `client_credentials` grant type, `client_id`, and `client_secret` as request parameters.

[https://host\\_name:port\\_number/oauth2/endpoint/provider\\_name/token](https://host_name:port_number/oauth2/endpoint/provider_name/token)

The following example shows the construction of the URI when using client credential:

```

if (isClientCredentials){
    param1 = "client_credentials";
    String query = String.format("grant_type=%s&
                                scope=%s&
                                client_id=%s&
                                client_secret=%s",
                                URLEncoder.encode(param1, charset),
                                URLEncoder.encode(scope, charset),
                                URLEncoder.encode(clientId, charset),
                                URLEncoder.encode(clientSecret, charset));

    accessToken = sendRequestForAccessToken(query);
    if (accessToken != null) {
        //send Resource Request using (accessToken);
    }
}
}

```

## Resource owner password credentials flow

The Resource Owner Password Credentials flow passes the user ID and password of the resource owner to the token endpoint directly. In this flow, The OAuth client accesses the token endpoint by adding `password` grant type, `client_id`, `client_secret`, `username`, `password`, `scope`, and `state` as request parameters.

[https://host\\_name:port\\_number/oauth2/endpoint/provider\\_name/token](https://host_name:port_number/oauth2/endpoint/provider_name/token)

The following example shows the construction of the URI when using resource owner password:

```

if (isResourceOwnerCredentials) {
    param1 = "password";
    String query = String.format("grant_type=%s&
                                username=%s&

```

```

        password=%s&
        scope=%s&
        client_id=%s&
        client_secret=%s",
        URLEncoder.encode(param1, charset),
        URLEncoder.encode(resOwnerName, charset),
        URLEncoder.encode(resOwnerPassword, charset),
        URLEncoder.encode(scope, charset),
        URLEncoder.encode(clientId, charset),
        URLEncoder.encode(clientSecret, charset));
    accessToken = sendRequestForAccessToken(query);
    if (accessToken != null) {
        //send Resource Request using (accessToken);
    }
}

```

If the access token is expired, then the refresh token can be sent to get a valid access token. The following example shows how to send a refresh token:

```

if(isAccessToken) {
    if (this.accessToken != null) {
        if (!sendResourceRequest(this.accessToken)) {
            // resource request failed...
            //get refresh token
            param1 = "refresh_token";
            String query = String.format("grant_type=%s&
                client_id=%s&
                client_secret=%s&
                refresh_token=%s&
                scope=%s",
                URLEncoder.encode(param1, charset),
                URLEncoder.encode(clientId, charset),
                URLEncoder.encode(clientSecret, charset),
                URLEncoder.encode(this.refreshToken, charset),
                URLEncoder.encode(scope, charset));

            accessToken = sendRequestForAccessToken(query);
            if (accessToken != null) {
                sendResourceRequest(accessToken);
            }
        }
    }
}
}

```

## Customizing an OAuth provider

**8.5.5.0**

The WebSphere Application Server OAuth service provider has plug-in points for customization. You can replace the default form login page for user authentication, or develop your own user consent form to collect client authorization data. WebSphere Application Server OAuth providers also allow customized post processing for major events in OAuth token issuing by using mediators.

### Custom mediator: **8.5.5.0**

An OAuth 2.0 mediator is used as a callback during the OAuth 2.0 message processing to perform customized post processing.

## Write an OAuth 2.0 mediator

To write a mediator, you must implement the interface named `com.ibm.oauth.core.api.oauth20.mediator.OAuth20Mediator`. You can implement one or more of the following methods to perform custom post processing.

```
void init(OAuthComponentConfiguration config)
```

This method is called by a factory when an instance of this object is created.

```
void mediateAuthorize(AttributeList attributeList)
```

This method is called by the core component after basic message validation and processing to allow any post custom processing by the component consumer in the `processAuthorization` method.

```
void mediateAuthorizeException(AttributeList attributeList, OAuthException exception)
```

This method is called by the core component when the protocol exception happens to allow any post custom processing by the component consumer in the `processAuthorization` method.

```
void mediateResource(AttributeList attributeList)
```

This method is called by the core component after basic message validation and processing to allow any post custom processing by the component consumer in the `processResourceRequest` method.

```
void mediateResourceException(AttributeList attributeList, OAuthException exception)
```

This method is called by the core component when protocol exception happens to allow any post custom processing by the component consumer in the `processResourceRequest` method.

```
void mediateToken(AttributeList attributeList)
```

This method is called by the core component after basic message validation and processing to allow any post custom processing by the component consumer in the `processTokenRequest` method.

```
void mediateTokenException(AttributeList attributeList, OAuthException exception)
```

This method is called by the core component when protocol exception happens to allow any post custom processing by the component consumer in the `processTokenRequest` method.

## Enable OAuth 2.0 mediator for an OAuth provider

To add a customized mediator to a specific OAuth 2.0 service provider, update the provider definition in the `server.xml` file. Add the `mediatorClassname` attribute of the `oauthProvider` element and specify the class name for the mediator. You can also specify multiple class names for mediators by using the `mediatorClassname` subelement of the `oauthProvider` element. If multiple mediators are specified, those mediators are started in the order they are specified. You must also define a `library` element that contains the mediator class and refer to the library with the `libraryRef` attribute.

The following example shows a sample custom mediator entry in the provider definition in the `server.xml` file:

```
<oauthProvider id="OAuthConfigSample" libraryRef="myLib"
  mediatorClassname="com.ibm.ws.security.oauth20.mediator.ResourceOwnerValidationMediator" ...>
  ...
</oauthProvider>

<library id="myLib">
  <fileset dir="C:\mydir" includes="myLib.jar" />
</library>
```

The following code sample implements the credential validation by using the WebSphere Application Server user registry in the resource owner password credentials flow.

```

package com.ibm.ws.security.oauth20.mediator;

import com.ibm.oauth.core.api.attributes.AttributeList;
import com.ibm.oauth.core.api.config.OAuthComponentConfiguration;
import com.ibm.oauth.core.api.error.OAuthException;
import com.ibm.oauth.core.api.error.oauth20.OAuth20MediatorException;
import com.ibm.oauth.core.api.oauth20.mediator.OAuth20Mediator;
import com.ibm.oauth.core.internal.oauth20.OAuth20Constants;
import com.ibm.websphere.security.CustomRegistryException;
import com.ibm.websphere.security.PasswordCheckFailedException;
import com.ibm.websphere.security.UserRegistry;

import java.rmi.RemoteException;
import java.util.logging.Level;
import java.util.logging.Logger;

import javax.naming.InitialContext;
import javax.naming.NamingException;

public class ResourceOwnerValidationMediator implements OAuth20Mediator {
    private static final String CLASS = ResourceOwnerValidationMediator.class.getName();
    private static final Logger LOG = Logger.getLogger(CLASS);
    private UserRegistry reg = null;

    public void init(OAuthComponentConfiguration config) {
        try {
            InitialContext ctx = new InitialContext();
            reg = (UserRegistry) ctx.lookup("UserRegistry");
        } catch (NamingException ne) {
            LOG.log(Level.SEVERE, "Cannot lookup UserRegistry", ne);
        }
    }

    public void mediateAuthorize(AttributeList attributeList)
        throws OAuth20MediatorException {
        // nothing to do here
    }

    public void mediateAuthorizeException(AttributeList attributeList,
        OAuthException exception)
        throws OAuth20MediatorException {
        // nothing to do here
    }

    public void mediateResource(AttributeList attributeList)
        throws OAuth20MediatorException {
        // nothing to do here
    }

    public void mediateResourceException(AttributeList attributeList,
        OAuthException exception)
        throws OAuth20MediatorException {
        // nothing to do here
    }

    public void mediateToken(AttributeList attributeList)
        throws OAuth20MediatorException {
        final String methodName = "mediateToken";
        LOG.entering(CLASS, methodName, attributeList);
        if("password".equals(attributeList.getAttributeValueByName("grant_type"))) {
            String username = attributeList.getAttributeValueByName("username");
            String password = attributeList.getAttributeValueByName("password");
            try {

```

```

        reg.checkPassword(username, password);
    } catch (PasswordCheckFailedException e) {
        throw new OAuth20MediatorException("User doesn't exist or the
   password doesn't match.", e);
    } catch (CustomRegistryException e) {
        throw new OAuth20MediatorException("Cannot validate resource owner.", e);
    } catch (RemoteException e) {
        throw new OAuth20MediatorException("Cannot validate resource owner.", e);
    }
}
LOG.exiting(CLASS, methodName);
}

public void mediateTokenException(AttributeList attributeList,
                                 OAuthException exception)
    throws OAuth20MediatorException {
    final String methodName = "mediateTokenException";
    LOG.entering(CLASS, methodName, new Object[] {attributeList, exception});
    if("password".equals(attributeList.getAttributeValueByName("grant_type"))) {
        // clear sensitive data
        attributeList.setAttribute("access_token",
                                   OAuth20Constants.ATTRTYPE_RESPONSE_ATTRIBUTE,
                                   new String[0]);
        attributeList.setAttribute("refresh_token",
                                   OAuth20Constants.ATTRTYPE_RESPONSE_ATTRIBUTE,
                                   new String[0]);
    }
    LOG.exiting(CLASS, methodName);
}
}
}

```

### Custom consent form template: **8.5.5.0**

The OAuth authorization server provides a template to acquire user consent information about which OAuth clients are authorized to access the protected resource in given scopes. The authorization request from the OAuth client includes a list of requested scopes from the template.

WebSphere Application Server allows the consent form template to be either a static HTML page or a dynamic web page. In both cases, the template must be provided as an unprotected web resource. The form retriever in WebSphere Application Server integration does not perform any authentication when accessing this template URL.

The WebSphere Application Server OAuth provider includes a sample consent form template, and allows customization by using `oauthFormData` variable.

To customize the consent form, you must edit the `oauthFormData` variable by using JavaScript. The following variables are included in the form data:

- `authorizationUrl` - the authorization URL where the form is being submitted
- `clientDisplayName` - the display name of the client
- `nonce` - random generated number to prevent cross-site request forgery (CSRF)
- `client_id` - see the OAuth 2.0 specification
- `response_type` - see the OAuth 2.0 specification
- `redirect_uri` - see the OAuth 2.0 specification
- `state` - see the OAuth 2.0 specification
- `scope` - see the OAuth 2.0 specification

The developer of a form template must include the content of the `oauthFormData` variable, by using JavaScript. The developer must interpret the scope value to be a meaningful value to a user. When a user authorizes the request, the developer can call the `submitForm(oauthFormData)` method to perform the authorization. The `submitForm` method is provided by default. However, if developers are familiar with OAuth 2.0 protocol, they can implement their own function to submit the OAuth authorization request.

8.5.5.4

A `cancel(oauthFormData)` method is provided by default and can be used to allow a user to cancel the authorization request.

8.5.5.4

The consent form can also be modified to allow the user's consent selection to be cached. This means that if the same OpenID Connect client makes a new authorization request with the same approved scopes or reduced scopes, the user is not be prompted with the consent form. Instead, the previously allowed scopes are considered authorized and passed to the protected resource accordingly.

8.5.5.4

If client registration is in `localStorage` mode, the user's consent selection is cached in the browser session. The approved scopes remain cached for the given user until the session is closed or until a set amount of time (specified in the server configuration) has elapsed.

8.5.5.4

If client registration is in `databaseStore` mode, the user's consent selection can be persistent in a database table, `OAuthDBSchema.OAUTH20CONSENTCACHE`. The scopes remain cached for the given user until a set amount of time (specified in the server configuration) has elapsed. The OpenID Connect provider tries to create the consent cache table automatically, but it is suggested that the user explicitly create the consent table when configuring a database for an OAuth2.0 provider and OpenID Connect provider, see [Persistent OAuth service configuration](#) for further details.

8.5.5.4

To use this functionality, the developer of a form template must include a `prompt` value within the `oauthFormData` JavaScript object. In order to cache the user's affirmative response and prevent the consent form from being displayed again in the same session, the `prompt` value is set to the string `none`. To allow the user to submit an affirmative response without caching the approval, the `prompt` value is set to the string `consent`.

You can use a dynamic page that returns globalized content according to the `Accept-Language` header in the request. When retrieving the template, the `Accept-Language` header is forwarded, and the template developer must decide which content to return regarding the preferred language.

**Note:** The `clientDisplayName` variable is not escaped in HTML. The template developer must sanitize the value, as the value is input by a user during client registration.

To use a custom consent form template page for a specific OAuth 2.0 service provider, you must update the service provider definition in the `server.xml` file. In the provider configuration, you must use the `authorizationFormTemplate` attribute of the `oauthProvider` element and add the template URL as the value. The following example shows a sample template entry in the provider configuration:

```
<oauthProvider id="OAuthConfigSample"
  authorizationFormTemplate="https://acme.com:9043/oath20/template.html
  ...>
```

The following example illustrates a sample consent form:

```
<oauthProvider id="OAuthConfigSample"
  authorizationLoginURL="https://acme.com:9043/oath20/login.jsp"
  ...>
```

```
function escapeHTML(str) {
  var ele = document.createElement("div");
  ele.innerText = ele.textContent = str;
  return ele.innerHTML;
```

```

}
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN" "http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
<meta http-equiv="Content-Type" content="text/html; charset=UTF-8">
<title>OAuth authorization form</title>
<script language="javascript">
function init() {
  var scope = oauthFormData.scope;
  var scopeEle = document.getElementById("oauth_scope");
  var ul = document.createElement("ul");
  if(scope) {
    for(var i=0; i< scope.length; i++) {
      var n = document.createElement("li");
      n.innerHTML = scope[i];
      ul.appendChild(n);
    }
  }
  scopeEle.appendChild(ul);
  // set client name
  var clientEle = document.getElementById("client_name");
  clientEle.innerHTML = escapeHTML(oauthFormData.clientDisplayName);
}

function escapeHTML(str) {
  var ele = document.createElement("div");
  ele.innerText = ele.textContent = str;
  return ele.innerHTML;
}
</script>
</head>
<body onload="init()">
  <div>Do you want to allow client <span id=client_name style="font-weight:bold">xxxxxxx</span> to access your data?</div>
  <div id="oauth_scope">
  </div>
  <div>
    <form action="javascript:submitForm(oauthFormData);">
      <input type="submit" value="Allow, remember my decision" onclick="javascript:oauthFormData.prompt = 'none';"/>
      <input type="submit" value="Allow once" onclick="javascript:oauthFormData.prompt = 'consent';"/>
      <input type="button" value="Cancel" onclick="javascript:cancel(oauthFormData);"/>
    </form>
  </div>
</body>
</html>

```

## Custom user login form: **8.5.5.0**

The WebSphere Application Server OAuth service provider includes a form login page for a user to submit a user name and password.

You can customize your own form login page, but it must be implemented as required in the form-based authentication in the servlet specification. In this form, the action must be `j_security_check`, and use the `j_username` input field to get the user name. The action must also use the `j_password` input field to get the user password. The custom form login page must be provided as an unprotected web resource.

To use the custom form login page for a specific OAuth20 service provider, you must update the service provider definition in the `server.xml` file. In the provider configuration, you must add the `customLoginURL` attribute and specify the login page URL as the value.

The following is an example custom login page entry in the provider definition:

```

<oauthProvider id="OAuthConfigSample"
  customLoginURL="https://acme.com:9043/oauth20/login.jsp"
  ...>

```

**Note:** Make sure that any files included in your form-login page (such as external style sheets, or images) are unprotected.

## Persistent OAuth service configuration

8.5.5.0

WebSphere Application Server supports a persistent OAuth 2.0 service by persisting OAuth tokens and clients in a database. With persistent OAuth 2.0 services, an authorized client can access OAuth 2.0 service after OAuth services are restarted.

To configure persistent OAuth 2.0 services, complete the following steps:

### 1. Configure the OAuth 2.0 service provider.

To use a database store, you must specify the `<databaseStore>` subelement of the `<oauthProvider>` element. The only required attribute on the `<databaseStore>` element is `<dataSourceRef>`, whose value must be the id of the `<dataSource>` element.

The following example is a sample `server.xml` file for an OAuth provider that uses a Derby database store:

```
<server>

  <featureManager>
    <feature>oauth-2.0</feature>
    <feature>ssl-1.0</feature>
    <feature>jdbc-4.0</feature>
    <feature>jndi-1.0</feature>
  </featureManager>

  <keyStore password="keyspass" />

  <oauth-roles>
    <authenticated>
      <user>testuser</user>
    </authenticated>
  </oauth-roles>

  <oauthProvider id="OAuthConfigDerby" filter="request-uri%ssodemo"
    oauthOnly="false">
    <databaseStore dataSourceRef="OAuthFvtDataSource" />
  </oauthProvider>

  <jdbcDriver id="DerbyEmbedded" libraryRef="DerbyLib" />

  <library id="DerbyLib" fileSetRef="DerbyFileset" />

  <fileset id="DerbyFileset" dir="{DERBY_JDBC_DRIVER_PATH}"
    includes="derby.jar" />

  <dataSource id="OAuthFvtDataSource" jndiName="jdbc/OAuth2DB"
    jdbcDriverRef="DerbyEmbedded">
    <properties.derby.embedded databaseName="D:\oauth2db"
      createDatabase="create" />
  </dataSource>

  <webAppSecurity allowFailOverToBasicAuth="true" />

  <basicRegistry id="basic" realm="BasicRealm">
    <user name="testuser" password="testuserpwd" />
  </basicRegistry>

</server>
```

### 2. Set up a database and table to store the OAuth token and client.

- a. Create a database for persistent OAuth service. See the vendor documentation for database creation. In this example, the database name is `D:\oauth2db`.

b. Create 3 OAuth tables as defined by the following SQL statements:

```
----- CREATE TABLES -----
CREATE TABLE OAuthDBSchema.OAUTH2OCACHE
(
  LOOKUPKEY VARCHAR(256) NOT NULL,
  UNIQUEID VARCHAR(128) NOT NULL,
  COMPONENTID VARCHAR(256) NOT NULL,
  TYPE VARCHAR(64) NOT NULL,
  SUBTYPE VARCHAR(64),
  CREATEDAT BIGINT,
  LIFETIME INT,
  EXPIRES BIGINT,
  TOKENSTRING VARCHAR(2048) NOT NULL,
  CLIENTID VARCHAR(64) NOT NULL,
  USERNAME VARCHAR(64) NOT NULL,
  SCOPE VARCHAR(512) NOT NULL,
  REDIRECTURI VARCHAR(2048),
  STATEID VARCHAR(64) NOT NULL,
  EXTENDEDFIELDS CLOB NOT NULL DEFAULT '{}')
);

CREATE TABLE OAuthDBSchema.OAUTH2OCLIENTCONFIG
(
  COMPONENTID VARCHAR(256) NOT NULL,
  CLIENTID VARCHAR(256) NOT NULL,
  CLIENTSECRET VARCHAR(256),
  DISPLAYNAME VARCHAR(256) NOT NULL,
  REDIRECTURI VARCHAR(2048),
  ENABLED INT,
  CLIENTMETADATA CLOB NOT NULL DEFAULT '{}')
);

CREATE TABLE OAuthDBSchema.OAUTH2OCONSENTCACHE
(
  CLIENTID VARCHAR(256) NOT NULL,
  USERID VARCHAR(256),
  PROVIDERID VARCHAR(256) NOT NULL,
  SCOPE VARCHAR(1024) NOT NULL,
  EXPIRES BIGINT,
  EXTENDEDFIELDS CLOB NOT NULL DEFAULT '{}')
);

----- ADD CONSTRAINTS -----
ALTER TABLE OAuthDBSchema.OAUTH2OCACHE
  ADD CONSTRAINT PK_LOOKUPKEY PRIMARY KEY (LOOKUPKEY);

ALTER TABLE OAuthDBSchema.OAUTH2OCLIENTCONFIG
  ADD CONSTRAINT PK_COMPIDCLIENTID PRIMARY KEY (COMPONENTID,CLIENTID);

----- CREATE INDEXES -----
CREATE INDEX OAUTH2OCACHE_EXPIRES ON OAUTHDBSCHEMA.OAUTH2OCACHE (EXPIRES ASC);
```

3. Configure WebSphere Application Server.

Configure the WebSphere Application Server data source. You must set the data source Java Naming and Directory Interface (JNDI) name to be jdbc/OAuth2DB. The JNDI name must match the jndiName attribute of the <dataSource> element in the server.xml file. Enter the database name, for example, D:\oauth2db.

For more information about the configuration of DB2 and Derby for OAuth persistent services, see IBM DB2 for persistent OAuth services and Derby database for persistent OAuth services. You can use them as a sample template to configure other databases.

4. Add the registered OAuth clients to the database.

To persist a client in a database, you must save the client to the database. The following SQL statements add the dbclient01 and dbclient02 OAuth clients to a Derby database:

```

CONNECT 'jdbc:derby:D:\oauth2db';
INSERT INTO OAuthDBSchema.OAUTH2CLIENTCONFIG VALUES
(
  'OAuthConfigDerby',
  'dbclient01',
  'secret',
  'dbclient01',
  'http://localhost:9080/oauthclient/redirect.jsp',
  1
),
(
  'OAuthConfigDerby',
  'dbclient02',
  'secret',
  'dbclient02',
  'http://localhost:9080/oauthclient/redirect.jsp',
  1
);
DISCONNECT CURRENT;

```

**Note:** **8.5.5.2** The Componentid must be the same as the id of the oauthProvider element in the server.xml file.

### Derby database for persistent OAuth services: **8.5.5.0**

Derby database can be used for persistent OAuth services. For convenience and reference purposes, this topic documents the steps you need to configure Derby database, either remote or local to the OAuth service, for OAuth persistent service.

To configure Derby database for persistent OAuth services, complete the following steps:

1. Create a database and tables.

Edit and run the following SQL statement to create an OAuth database and table:

```

--- Change oauth2db to the name you want for the database
--- Connect to Derby, choose one connection option to uncomment
--- if connecting to Derby as network server
--- CONNECT 'jdbc:derby://localhost:1527/oauth2db;create=true';

--- if connecting to embedded derby, you can change D:\oauth2db to location of database
--- CONNECT 'jdbc:derby:D:\oauth2db;create=true';

--- if creating tables in existing Derby database, remove the create=true parameter.

----- CREATE TABLES -----
CREATE TABLE OAuthDBSchema.OAUTH2OCACHE (
  LOOKUPKEY VARCHAR(256) NOT NULL,
  UNIQUEID VARCHAR(128) NOT NULL,
  COMPONENTID VARCHAR(256) NOT NULL,
  TYPE VARCHAR(64) NOT NULL,
  SUBTYPE VARCHAR(64),
  CREATEDAT BIGINT,
  LIFETIME INT,
  EXPIRES BIGINT,
  TOKENSTRING VARCHAR(2048) NOT NULL,
  CLIENTID VARCHAR(64) NOT NULL,
  USERNAME VARCHAR(64) NOT NULL,
  SCOPE VARCHAR(512) NOT NULL,
  REDIRECTURI VARCHAR(2048),
  STATEID VARCHAR(64) NOT NULL,
  EXTENDEDFIELDS CLOB NOT NULL DEFAULT '{}')
);

```

```

CREATE TABLE OAuthDBSchema.OAUTH2CLIENTCONFIG (
  COMPONENTID VARCHAR(256) NOT NULL,
  CLIENTID VARCHAR(256) NOT NULL,
  CLIENTSECRET VARCHAR(256),
  DISPLAYNAME VARCHAR(256) NOT NULL,
  REDIRECTURI VARCHAR(2048),
  ENABLED INT,
  CLIENTMETADATA CLOB NOT NULL DEFAULT '{}')
);

CREATE TABLE OAuthDBSchema.OAUTH2CONSENTCACHE (
  CLIENTID VARCHAR(256) NOT NULL,
  USERID VARCHAR(256),
  PROVIDERID VARCHAR(256) NOT NULL,
  SCOPE VARCHAR(1024) NOT NULL,
  EXPIRES BIGINT,
  EXTENDEDFIELDS CLOB NOT NULL DEFAULT '{}')
);

----- ADD CONSTRAINTS -----
ALTER TABLE OAuthDBSchema.OAUTH2CACHE
  ADD CONSTRAINT PK_LOOKUPKEY PRIMARY KEY (LOOKUPKEY);

ALTER TABLE OAuthDBSchema.OAUTH2CLIENTCONFIG
  ADD CONSTRAINT PK_COMPIDCLIENTID PRIMARY KEY (COMPONENTID,CLIENTID);

----- CREATE INDEXES -----
CREATE INDEX OAUTH2CACHE_EXPIRES ON OAUTHDBSCHEMA.OAUTH2CACHE (EXPIRES ASC);

DISCONNECT CURRENT;

```

Run the createTables.sql file by starting **ij** with the following command:

```
ij createTables.sql
```

## 2. Configure the WebSphere Application Server Liberty server.

The following example is a sample server.xml file for an OAuth provider that uses a Derby database store:

```

<server>

  <featureManager>
    <feature>oauth-2.0</feature>
    <feature>ssl-1.0</feature>
    <feature>jdbc-4.0</feature>
    <feature>jndi-1.0</feature>
  </featureManager>

  <keyStore password="keyspass" />

  <oauth-roles>
    <authenticated>
      <user>testuser</user>
    </authenticated>
  </oauth-roles>

  <oauthProvider id="OAuthConfigDerby" filter="request-url%ssodemo"
    oauthOnly="false">
    <databaseStore dataSourceRef="OAuthDerbyDataSource" />
  </oauthProvider>

  <jdbcDriver id="DerbyEmbedded" libraryRef="DerbyLib" />

  <library id="DerbyLib" filesetRef="DerbyFileset" />

  <fileset id="DerbyFileset" dir="${DERBY_JDBC_DRIVER_PATH}"

```

```

        includes="derby.jar" />

<dataSource id="OAuthDerbyDataSource" jndiName="jdbc/OAuth2DB"
            jdbcDriverRef="DerbyEmbedded">
    <properties.derby.embedded databaseName="D:\oauth2db"
                            createDatabase="create" />
</dataSource>

<webAppSecurity allowFailOverToBasicAuth="true" />

<basicRegistry id="basic" realm="BasicRealm">
    <user name="testuser" password="testuserpwd" />
</basicRegistry>
</server>

```

**Note:** **8.5.5.2** The Componentid must be the same as the id of the oauthProvider element in the server.xml file.

### IBM DB2 for persistent OAuth services: **8.5.5.0**

IBM DB2 can be used for persistent OAuth services. For convenience and reference purposes, this topic documents the steps you need to configure DB2 for OAuth persistent service.

To configure DB2 for persistent OAuth services, complete the following steps:

1. Create a database and tables.

Edit and run the following SQL statement to create an OAuth database and table:

```

-- Change oauth2db to the name you want for the database

CREATE DATABASE oauth2db USING CODESET UTF8 TERRITORY US;
CONNECT TO oauth2db;

---- CREATE TABLES ----
CREATE TABLE OAuthDBSchema.OAUTH20CACHE
(
    LOOKUPKEY VARCHAR(256) NOT NULL,
    UNIQUEID VARCHAR(128) NOT NULL,
    COMPONENTID VARCHAR(256) NOT NULL,
    TYPE VARCHAR(64) NOT NULL,
    SUBTYPE VARCHAR(64),
    CREATEDAT BIGINT,
    LIFETIME INT,
    EXPIRES BIGINT,
    TOKENSTRING VARCHAR(2048) NOT NULL,
    CLIENTID VARCHAR(64) NOT NULL,
    USERNAME VARCHAR(64) NOT NULL,
    SCOPE VARCHAR(512) NOT NULL,
    REDIRECTURI VARCHAR(2048),
    STATEID VARCHAR(64) NOT NULL
    EXTENDEDFIELDS CLOB NOT NULL DEFAULT '{}';
);

CREATE TABLE OAuthDBSchema.OAUTH20CLIENTCONFIG
(
    COMPONENTID VARCHAR(256) NOT NULL,
    CLIENTID VARCHAR(256) NOT NULL,
    CLIENTSECRET VARCHAR(256),
    DISPLAYNAME VARCHAR(256) NOT NULL,
    REDIRECTURI VARCHAR(2048),
    ENABLED INT
    CLIENTMETADATA CLOB NOT NULL DEFAULT '{}';
);

```

```

CREATE TABLE OAuthDBSchema.OAUTH20CONSENTCACHE (
  CLIENTID VARCHAR(256) NOT NULL,
  USERID VARCHAR(256),
  PROVIDERID VARCHAR(256) NOT NULL,
  SCOPE VARCHAR(1024) NOT NULL,
  EXPIRES BIGINT,
  EXTENDEDFIELDS CLOB NOT NULL DEFAULT '{}')
);

---- ADD CONSTRAINTS ----
ALTER TABLE OAuthDBSchema.OAUTH20CACHE
  ADD CONSTRAINT PK_LOOKUPKEY PRIMARY KEY (LOOKUPKEY);

ALTER TABLE OAuthDBSchema.OAUTH20CLIENTCONFIG
  ADD CONSTRAINT PK_COMPIDCLIENTID PRIMARY KEY (COMPONENTID,CLIENTID);

---- CREATE INDEXES ----
CREATE INDEX OAUTH20CACHE_EXPIRES ON OAUTHDBSCHEMA.OAUTH20CACHE (EXPIRES ASC);

---- GRANT PRIVILEGES ----
---- UNCOMMENT THE FOLLOWING IF YOU USE AN ACCOUNT OTHER THAN ADMINISTRATOR FOR DB ACCESS ----

-- Change dbuser to the account you want to use to access your database
-- GRANT ALL ON OAuthDBSchema.OAUTH20CACHE TO USER dbuser;
-- GRANT ALL ON OAuthDBSchema.OAUTH20CLIENTCONFIG TO USER dbuser;

---- END OF GRANT PRIVILIGES ----

DISCONNECT CURRENT;

```

The default DB2 listening port is 50000. If you want to find it, run the following command and find the value of the SVCENAME parameter. If it is a number, then it is the port number. If it is a name, look for the name in the /etc/services file or the Windows equivalent if you are using Windows.

```

Linux/Unix: db2 get dbm cfg | grep SVCENAME
Windows:   db2 get dbm cfg | findstr SVCENAME

```

You can create a database and tables in DB2 by running the following statement:

```
db2 -tvf createTables.sql
```

## 2. Configure the WebSphere Application Server Liberty server.

The following example is a sample server.xml file for an OAuth provider that uses a DB2 store:

```

<server>
  <featureManager>
    <feature>oauth-2.0</feature>
    <feature>ssl-1.0</feature>
    <feature>jdbc-4.0</feature>
    <feature>jndi-1.0</feature>
  </featureManager>

  <keyStore password="keyspass" />

  <oauth-roles>
    <authenticated>
      <user>testuser</user>
    </authenticated>
  </oauth-roles>

  <oauthProvider id="DBOAuth20Provider" oauthOnly="true"
    filter="request-url%=AnnuityOAuthWeb/index.jsp">
    <databaseStore dataSourceRef="OAUTH2DBDS" />
  </oauthProvider>

```

```

<jdbcDriver id="db2Universal" libraryRef="DB2JCC4LIB" />
<library apiTypeVisibility="spec,ibm-api,third-party" filesetRef="db2jcc4"
  id="DB2JCC4LIB" />
<fileset dir="${shared.resource.dir}/db2" id="db2jcc4"
  includes="db2jcc4.jar db2jcc_license_cu.jar" />
<dataStore id="OAUTH2DBDS" jdbcDriverRef="db2Universal"
  jndiName="jdbc/oauthProvider">
  <properties.db2.jcc databaseName="OAUTH2DB" driverType="4"
    user="bob" password="abcdefg"
    portNumber="50000"
    serverName="db2.server.mycompany.com" />
</dataStore>
<webAppSecurity allowFailOverToBasicAuth="true" />
<basicRegistry id="basic" realm="BasicRealm">
  <user name="testuser" password="testuserpwd" />
</basicRegistry>
</server

```

The following example adds a client to DB2:

```

INSERT INTO OAuthDBSchema.OAUTH2CLIENTCONFIG
(
  COMPONENTID,
  CLIENTID,
  CLIENTSECRET,
  DISPLAYNAME,
  REDIRECTURI,
  ENABLED
)
VALUES
(
  'DBOAuth20Provider',
  'key',
  'secret',
  'My Client',
  'https://localhost:9443/oauth/redirect.jsp',
  1
)

```

**Note:** **8.5.5.2** The Componentid must be the same as the id of the oauthProvider element in the server.xml file.

---

## Configuring Common Secure Interoperability version 2 (CSIv2) in Liberty

**8.5.5.6**

Liberty supports CSIv2 security at various levels such as the message authentication (authentication layer), identity assertion (attribute layer), and client certificate authentication (transport layer). Using the CSIv2 feature, you can specify the type of authentication for both inbound and outbound requests to downstream servers. CSIv2 features are enabled automatically when the appSecurity-2.0 and ejbRemote-3.2 features are configured in the server.xml file. You can configure CSIv2 in Liberty to enable interoperability between Java Platform, Enterprise Edition vendors.

## Procedure

The following is the default configuration that is used without having to specify it in the `server.xml` file when the `appSecurity-2.0` and `ejbRemote-3.2` features are configured.

```
<orb id="defaultOrb">
  <serverPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Required"/>
      <transportLayer/>
    </layers>
  </serverPolicy.csiv2>
  <clientPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Supported"/>
      <transportLayer/>
    </layers>
  </clientPolicy.csiv2>
</orb>
```

You can change each of the layers in `serverPolicy.csiv2` and in `clientPolicy.csiv2` for customizing the inbound and outbound CSIV2 settings.

## Configuring inbound CSIV2 in Liberty

8.5.5.6

Common Secure Interoperability, version 2 (CSIV2) feature inbound configuration determines the type of accepted authentication for inbound requests. The CSIV2 feature is enabled automatically when the `appSecurity-2.0` and `ejbRemote-3.2` features are configured in the `server.xml` file.

### Before you begin

Understand the CSIV2 concepts, see [Common Secure Interoperability version 2 \(CSIV2\)](#) for further information.

### About this task

The following layers of security are available for inbound requests:

#### Procedure

1. Configure the inbound CSIV2 attribute layer.
2. Configure the inbound CSIV2 authentication layer.
3. Configure the inbound CSIV2 transport layer.

### Configuring inbound CSIV2 attribute layer

8.5.5.6

You can configure a Liberty server to claim support for identity assertion for inbound CSIV2 requests.

### About this task

The inbound CSIV2 attribute layer for a Liberty server has identity assertion that is disabled by default. The server supports Anonymous, Principal Name, X509 Certificate Chain, and Distinguished Name identity assertions from an upstream server that is acting as a client after the identity assertion is enabled through the `identityAssertionEnabled` attribute. You can use the `identityAssertionTypes` attribute to

specify the identity token types that the server supports. The `trustedIdentities` attribute can be used to specify the identity of the trusted upstream servers that are able to assert an identity to this server.

#### CAUTION:

Ensure that only trusted entities communicate with the server if presumed trust is set.

#### Procedure

1. Add the `appSecurity-2.0` and `ejbRemote-3.2` features in the `server.xml` file.

```
<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>ejbRemote-3.2</feature>
</featureManager>
```

The following is the default configuration without having to specify it in the `server.xml` file.

```
<orb id="default0rb">
  <serverPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Required"/>
      <transportLayer/>
    </layers>
  </serverPolicy.csiv2>
  <clientPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Supported"/>
      <transportLayer/>
    </layers>
  </clientPolicy.csiv2>
</orb>
```

2. Optional: If you need to change the default inbound attribute layer configuration, then add an `<orb>` element in the `server.xml` file as follows or add the `attributeLayer` element to an existing one. Replace the sample values in the example with your values.

```
<orb id="default0rb">
  <serverPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="true"/>
    </layers>
  </serverPolicy.csiv2>
</orb>
```

**Note:** The ID value `default0rb` in the `<orb>` element is predefined and cannot be modified.

3. Set the `trustedIdentities` attribute by changing the example values to the `trustedIdentity` of each of the upstream servers. The pipe character (`|`) must be used to separate the values when there are more than one asserting client.

```
<attributeLayer identityAssertionEnabled="true" trustedIdentities="yourAssertingUpstreamServer|anotherAssertingUpstreamServer"/>
```

4. Alternative: Instead of setting a named value for the `trustedIdentities` in step 2, you can set the `trustedIdentities` attribute with the character (`*`) to indicate that the server supports presumed trust. With presumed trust, any upstream server is able to assert an identity and must be used only when the upstream servers can be limited to a set of trusted servers. Therefore, use this value with caution.

```
<attributeLayer identityAssertionEnabled="true" trustedIdentities="*/>
```

5. When an upstream server that sends a certificate chain is trusted, add the issuer distinguished name of the certificate chain to the `trustedIdentities` attribute. For example,

```
<attributeLayer identityAssertionEnabled="true" trustedIdentities="CN=localhost,0=ibm,C=us"/>
```

6. Optional: If you need to change the default identity assertion token types that are supported by the server, then add the `identityAssertionTypes` attribute to the `attributeLayer` element in the `server.xml` file and specify a comma-separated list of values. The valid values are `ITTAnonymous`, `ITTPrincipalName`, `ITTX509CertChain`, and `ITTDistinguishedName`. For example, you can configure the

server to support identity assertions with X509 Certificate Chains or Distinguished Names. Replace the sample values in the example with your values.

```
<orb id="defaultOrb">
  <serverPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="true" identityAssertionTypes="ITTX509CertChain, ITTDistinguish
    </layers>
  </serverPolicy.csiv2>
</orb>
```

**Note:** The upstream server identity is obtained from the security information that the server sent in either the authentication layer or the transport layer. The authentication layer identity takes precedence over the transport identity, and the transport identity is used if no security information is sent at the authentication layer. For sample syntax and more information about `authenticationLayer` and `transportLayer` elements, see [Configuring inbound CSiv2 authentication layer](#) and [Configuring inbound CSiv2 transport layer](#).

Omitting a layer uses the default values for that layer.

## Results

Your inbound CSiv2 attribute layer is now configured for identity assertion.

## Configuring inbound CSiv2 authentication layer

8.5.5.6

You can configure a Liberty server to use a specific authentication mechanism for inbound CSiv2 requests.

### About this task

The inbound CSiv2 authentication layer for a Liberty server is enabled with the support for the LTPA and GSSUP authentication mechanisms by default. The `establishTrustInClient` association option of the authentication layer is set to `Required` by default to indicate that the authentication mechanisms specified are required. When you are using the LTPA mechanism, ensure that the communicating Liberty servers and other servers share the same LTPA keys.

### Procedure

1. Add the `appSecurity-2.0` and `ejbRemote-3.2` features in the `server.xml` file.

```
<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>ejbRemote-3.2</feature>
</featureManager>
```

The following example shows the default configuration without having to specify it in the `server.xml` file.

```
<orb id="defaultOrb">
  <serverPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Required"/>
      <transportLayer/>
    </layers>
  </serverPolicy.csiv2>
  <clientPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Supported"/>
    </layers>
  </clientPolicy.csiv2>
</orb>
```

```

        <transportLayer/>
    </layers>
</clientPolicy.csiv2>
</orb>

```

- Optional: If you need to change the default inbound authentication layer configuration, then add an <orb> element in the server.xml file as follows or add the authenticationLayer element to an existing one. Replace the sample values in the example with your values.

```

<orb id="default0rb">
  <serverPolicy.csiv2>
    <layers>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Required"/>
    </layers>
  </serverPolicy.csiv2>
</orb>

```

**Note:** The ID value default0rb in the <orb> element is predefined and cannot be modified.

- Optional: Set the mechanisms attribute to LTPA or GSSUP to use either LTPA or GSSUP (user name and password) only as the authentication mechanism.

```

<authenticationLayer mechanisms="LTPA" establishTrustInClient="Supported"/>
or
<authenticationLayer mechanisms="GSSUP" establishTrustInClient="Supported"/>

```

- Optional: Set the establishTrustInClient attribute to Required, Supported, or Never to indicate that the server requires, supports (optional), or never claims authentication with the specified mechanisms.

#### Notes:

- When the establishTrustInClient attribute is set to Required, only clients that either require or support compatible (at least one) authentication mechanisms are able to send a security context to the server.
- When the establishTrustInClient attribute is set to Supported, a client might choose whether to send the authentication information in the authentication layer.
- When the establishTrustInClient attribute is set to Never, the inbound CSIV2 authentication layer is disabled and at least one other CSIV2 layer must be enabled to authenticate.

Omitting a layer uses the default values for that layer.

For more information about the attributeLayer and transportLayer elements, see [Configuring inbound CSIV2 attribute layer](#) and [Configuring inbound CSIV2 transport layer](#).

## Results

Your inbound CSIV2 authentication layer is now configured.

## Configuring inbound CSIV2 transport layer

8.5.5.6

You can configure a Liberty server to claim support for client certificate authentication for inbound CSIV2 requests.

### About this task

The inbound CSIV2 transport layer for a Liberty server has client certificate authentication that is disabled by default. You can configure the transportLayer to specify the SSL configuration to use. You can configure the SSL element to either support or require the client certificate authentication. The certificate that is received is authenticated against the server user registry, and its identity is only used if no other form of authentication was sent in the CSIV2 request, like an identity assertion in the attribute layer or an authentication token in the authentication layer.

When you use the client certificate authentication, ensure that SSL is supported by the server.

## Procedure

1. Add the appSecurity-2.0 and ejbRemote-3.2 features in the server.xml file.

```
<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>ejbRemote-3.2</feature>
</featureManager>
```

The following example is the default configuration without having to specify it in the server.xml file.

```
<orb id="default0rb">
  <serverPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Required"/>
      <transportLayer/>
    </layers>
  </serverPolicy.csiv2>
  <clientPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Supported"/>
      <transportLayer/>
    </layers>
  </clientPolicy.csiv2>
</orb>
```

2. Configure SSL support as described in the “Enabling SSL communication in Liberty” on page 1834 page.
3. Configure the SSL element to use clientAuthentication or clientAuthenticationSupported. For example,

```
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore"
  trustStoreRef="defaultTrustStore" clientAuthentication="true" />
```

or

```
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore"
  trustStoreRef="defaultTrustStore" clientAuthenticationSupported="true" />
```

- If you specify clientAuthentication="true", then the server requests that a client sends a certificate. However, if the client does not have a certificate or if the certificate is not trusted by the server, then the handshake does not succeed.
  - If you specify clientAuthenticationSupported="true", then the server requests that a client sends a certificate. However, if the client does not have a certificate or if the certificate is not trusted by the server, then the handshake might still succeed.
  - If you do not specify either clientAuthentication or clientAuthenticationSupported, or if you specify clientAuthentication="false" or clientAuthenticationSupported="false", then the server does not request the client to send a certificate during the handshake.
4. Optional: If you need to change the default inbound transport layer configuration, then add an <orb> element in the server.xml file as follows or add the transportLayer element to an existing one. Replace the sample values in the example with your values.

```
<orb id="default0rb">
  <serverPolicy.csiv2>
    <layers>
      <transportLayer sslRef="defaultSSLConfig"/>
    </layers>
  </serverPolicy.csiv2>
</orb>
```

**Note:** The ID value default0rb in the <orb> element is predefined and cannot be modified.

5. Make sure the server trusts any client certificates that are used.

6. Make sure any client certificates that are used for client authentication are mapped to a user identity in your registry.
  - For the basic registry, the user identity is the common name (CN) from the distinguished name (DN) of the certificate.
  - For a Lightweight Directory Access Protocol (LDAP) registry, the DN from the client certificate must be in the LDAP registry.

Omitting a layer uses the default values for that layer. For more information about `attributeLayer` and `authenticationLayer` elements, see [Configuring inbound CSIV2 attribute layer](#) and [Configuring inbound CSIV2 authentication layer](#).

## Results

Your inbound CSIV2 transport layer is now configured for client certificate authentication.

## Configuring outbound CSIV2 in Liberty

8.5.5.6

The Common Secure Interoperability, version 2 (CSIV2) feature outbound configuration determines the type of authentication information sent for outbound requests. The CSIV2 feature is enabled automatically when the `appSecurity-2.0` and `ejbRemote-3.2` features are configured in the `server.xml` file.

### Before you begin

Understand the CSIV2 concepts, see [Common Secure Interoperability version 2 \(CSIV2\)](#) for further information.

### About this task

The following layers of security are available for outbound requests:

#### Procedure

1. Configure the outbound CSIV2 attribute layer.
2. Configure the outbound CSIV2 authentication layer.
3. Configure the outbound CSIV2 transport layer.

### Configuring outbound CSIV2 attribute layer

8.5.5.6

You can configure a Liberty server to perform identity assertions for outbound CSIV2 requests.

### About this task

Identity assertion is disabled by default in the outbound CSIV2 attribute layer for a Liberty server. The server that is acting as a client supports sending the Principal Name and Anonymous identity assertions to a downstream server after the identity assertion is enabled through the `identityAssertionEnabled` attribute. You can use the `identityAssertionTypes` attribute to specify more or different identity token types that the server supports for outbound requests. The `trustedIdentity` and `trustedPassword` attributes can be used to specify the identity of the client to be verified for trust by the downstream server when the authentication layer mechanism is GSSUP. The `trustedIdentity` attribute can be set without a `trustedPassword` if the authentication mechanism in the authentication layer is LTPA. You must also configure the upstream server along with enabling the identity assertion so that the client can assert an identity.

## Procedure

1. Add the appSecurity-2.0 and ejbRemote-3.2 features in the server.xml file.

```
<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>ejbRemote-3.2</feature>
</featureManager>
```

The following example is the default configuration without having to specify it in the server.xml file.

```
<orb id="default0rb">
  <serverPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Required"/>
      <transportLayer/>
    </layers>
  </serverPolicy.csiv2>
  <clientPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Supported"/>
      <transportLayer/>
    </layers>
  </clientPolicy.csiv2>
</orb>
```

2. Optional: If you need to change the default outbound attribute layer configuration, then add an <orb> element in the server.xml file as follows or add the attributeLayer element to an existing one. Replace the sample values in the example with your values.

```
<orb id="default0rb">
  <clientPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="true"/>
    </layers>
  </clientPolicy.csiv2>
</orb>
```

**Note:** The ID value default0rb in the <orb> element is predefined and cannot be modified.

3. Specify the upstream server identity for trust validation by the downstream server. The trustedIdentity specified must exist in the user registry of the target server.
  - When you are using the GSSUP mechanism in the authentication layer, you must set the trustedIdentity and trustedPassword attributes by changing the example values to the identity and password of the upstream server that is acting as a client.

```
<attributeLayer identityAssertionEnabled="true" trustedIdentity="yourTrustedId" trustedPassword="yourTrustedIdPwd"/>
```

Encode the password within the configuration. You can get the encoded value by using the securityUtility encode command.

- When you are using the LTPA mechanism in the authentication layer, you must set the trustedIdentity attribute by changing the example value to the identity of the upstream server that is acting as a client.

```
<attributeLayer identityAssertionEnabled="true" trustedIdentity="yourTrustedId"/>
```

4. Optional: If you need to change the default identity assertion token types that are supported by the server, then add the identityAssertionTypes attribute to the attributeLayer element in the server.xml file and specify a comma-separated list of values. The valid values are ITTAnonymous, ITTPrincipalName, ITTX509CertChain, andITTDistinguishedName. For example, you can configure the server to support identity assertions with X509 Certificate Chains or Distinguished Names. Replace the sample values in the example with your values.

```
<orb id="default0rb">
  <clientPolicy.csiv2>
    <layers>
```

```

        <attributeLayer identityAssertionEnabled="true" identityAssertionTypes="ITTX509CertChain, ITTDistingu
    </layers>
</clientPolicy.csiv2>
</orb>

```

#### Notes:

- If both LTPA and GSSUP are configured in the authentication layer and the downstream server supports LTPA, then LTPA takes precedence over GSSUP.
- If both LTPA and GSSUP are configured in the authentication layer and the downstream server supports only GSSUP, then GSSUP is used and the `trustedIdentity` and `trustedPassword` attributes must be specified.
- The `trustedIdentity` attribute is not required if you are using the transport certificate chain to identify the server to the downstream server. (The `identityAssertionEnabled` attribute is set to `true` and `establishTrustInClient` is set to `Never` in the `authenticationLayer`).
- Omitting a layer uses the default values for that layer.

For more information about `authenticationLayer` and `transportLayer` elements, see [Configuring outbound CSiv2 authentication layer](#) and [Configuring outbound CSiv2 transport layer](#).

## Results

Your outbound CSiv2 attribute layer is now configured for identity assertion.

## Configuring outbound CSiv2 authentication layer

8.5.5.6

You can configure a Liberty server to use specific authentication mechanisms for outbound CSiv2 requests.

### About this task

The outbound CSiv2 authentication layer for a Liberty server is enabled with support for the LTPA and GSSUP authentication mechanisms by default. The `establishTrustInClient` association option of the authentication layer is set to `Supported` by default to indicate that the authentication mechanisms specified are supported and optional.

When the LTPA mechanism is used, ensure that the communicating Liberty servers and other servers share the same LTPA keys.

### Procedure

1. Add the `appSecurity-2.0` and `ejbRemote-3.2` features in the `server.xml` file.

```

<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>ejbRemote-3.2</feature>
</featureManager>

```

The following example is the default configuration without having to specify it in the `server.xml` file.

```

<orb id="default0rb">
  <serverPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Required"/>
      <transportLayer/>
    </layers>
  </serverPolicy.csiv2>
</clientPolicy.csiv2>
  <layers>
    <attributeLayer identityAssertionEnabled="false"/>

```

```

        <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Supported"/>
        <transportLayer/>
    </layers>
</clientPolicy.csiv2>
</orb>

```

- Optional: If you need to change the default outbound authentication layer configuration, then add an <orb> element in the server.xml file as follows or add the authenticationLayer element to an existing one. Replace the sample values in the example with your values.

```

<orb id="default0rb">
  <clientPolicy.csiv2>
    <layers>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Supported"/>
    </layers>
  </clientPolicy.csiv2>
</orb>

```

**Note:** The ID value default0rb in the <orb> element is predefined and cannot be modified.

- Optional: Set the mechanisms attribute to LTPA or GSSUP to use either LTPA or GSSUP (user name and password) only as the authentication mechanism.

```
<authenticationLayer mechanisms="LTPA" establishTrustInClient="Supported"/>
```

or

```
<authenticationLayer mechanisms="GSSUP" establishTrustInClient="Supported"/>
```

- Optional: Set the establishTrustInClient attribute to Required, Supported, or Never to indicate that the server that is acting as a client requires, supports(optional), or never performs authentication with the specified mechanisms.

#### Notes:

- When the establishTrustInClient attribute is set to Required, the client is able to send an authentication token of one of the specified mechanisms only to servers that either require or support the same authentication mechanisms.
- When the establishTrustInClient attribute is set to Supported, the client might choose whether to send the authentication information in the authentication layer. If the downstream server is configured with Supported or Required, then the client sends a compatible authentication token.
- When the establishTrustInClient attribute is set to Never, the outbound CSiv2 authentication layer is disabled and at least one other CSiv2 layer must be enabled to authenticate to the downstream server.
- Omitting a layer uses the default values for that layer.

For more information about the attributeLayer and transportLayer elements, see [Configuring outbound CSiv2 attribute layer](#) and [Configuring outbound CSiv2 transport layer](#). For an example of a programmatic login when using GSSUP as the authentication mechanism, see [Example: Using the WSLogin configuration to create a basic authentication subject](#).

## Results

Your outbound CSiv2 authentication layer is now configured.

## Configuring outbound CSiv2 transport layer

8.5.5.6

You can configure a Liberty server to perform client certificate authentication for outbound CSiv2 requests.

## About this task

The client certificate authentication of the outbound CSiv2 transport layer for a Liberty server is disabled by default. You can configure the transportLayer to specify the SSL configuration to use.

You can configure the SSL element to support client certificate authentication or require it. The certificate sent to the downstream server is authenticated against the downstream server user registry and its identity is only used if no other form of authentication is sent in the CSiv2 request, like an identity assertion in the attribute layer or an authentication token in the authentication layer.

When the client certificate authentication is used, ensure that SSL is supported by this server.

## Procedure

1. Add the appSecurity-2.0 and ejbRemote-3.2 features in the server.xml file.

```
<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>ejbRemote-3.2</feature>
</featureManager>
```

The following example is the default configuration without having to specify it in the server.xml file.

```
<orb id="defaultOrb">
  <serverPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Required"/>
      <transportLayer/>
    </layers>
  </serverPolicy.csiv2>
  <clientPolicy.csiv2>
    <layers>
      <attributeLayer identityAssertionEnabled="false"/>
      <authenticationLayer mechanisms="LTPA,GSSUP" establishTrustInClient="Supported"/>
      <transportLayer/>
    </layers>
  </clientPolicy.csiv2>
</orb>
```

2. Configure SSL support as described in Enabling SSL communication for Liberty.
3. Optional: Configure the SSL element to use clientAuthentication or clientAuthenticationSupported. For example,

```
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore"
  trustStoreRef="defaultTrustStore" clientAuthentication="true" />
```

or

```
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore"
  trustStoreRef="defaultTrustStore" clientAuthenticationSupported="true" />
```

4. Optional: If you need to change the default outbound transport layer configuration, then add an <orb> element in the server.xml file as follows or add the transportLayer element to an existing one. Replace the sample values in the example with your values.

```
<orb id="defaultOrb">
  <clientPolicy.csiv2>
    <layers>
      <transportLayer sslRef="defaultSSLConfig"/>
    </layers>
  </clientPolicy.csiv2>
</orb>
```

**Note:** The id value *defaultOrb* in the <orb> element is predefined and cannot be modified.

5. Make sure the downstream server trusts any client certificates that are sent from this server.

6. Make sure that any client certificates used for client authentication are mapped to a user identity in the downstream server user registry.
  - For the basic registry, the user identity is the common name (CN) from the distinguished name (DN) of the certificate.
  - For a Lightweight Directory Access Protocol (LDAP) registry, the DN from the client certificate must be in the LDAP registry.

**Notes:**

- When the `clientAuthentication` attribute is set to `true` in the `<ssl>` element, the client sends a client certificate only to servers that either require or support the client certificate authentication.
- When the `clientAuthenticationSupported` attribute is set to `true` in the `<ssl>` element, the client might choose whether to send a client certificate based on the `<ssl>` element configuration that is used by the downstream server.
- When the `clientAuthentication` and `clientAuthenticationSupported` attributes are not set in the `<ssl>` element, then the server that is acting as a client is not enabled with the client certificate authentication.

Omitting a layer uses the default values for that layer. For more information about the `attributeLayer` and `authenticationLayer` elements, see [Configuring outbound CSIV2 attribute layer](#) and [Configuring outbound CSIV2 authentication layer](#).

## Results

Your outbound CSIV2 transport layer is now configured for client certificate authentication.

---

## Configuring security for the Liberty application client container and its applications

8.5.5.6

Configure security on the Liberty application client container and its applications to ensure communications between the client and server are secure. You can also configure security to ensure that credentials of clients flow to the server.

### Enabling SSL communication for the Liberty application client container

8.5.5.6

The Liberty application client container might require some SSL configuration for the client container to communicate with a server. Configuring SSL for the application client container requires the use of the same SSL feature, `ssl-1.0`, that the server requires for SSL enablement. The configuration elements and attributes are the same for the application client as for the server; however, for the application client container, these values are specified in the `client.xml` file.

### About this task

The SSL handshake is a series of messages that are exchanged over the SSL protocol between a client and a server to negotiate for connection-specific protection. To enable SSL for the Liberty application client container the SSL feature, `ssl-1.0`, must include the minimal information that is needed to form an SSL configuration that is used by the client. The minimal information that is required to form an SSL configuration is a keystore and a password.

You can use the securityUtility **createSSLCertificatecommand** to create the keystore of the client and to provide you with information about the configuration. Using the tool is optional, because you can also create a keystore and the associated configuration for other customer-defined purposes.

## Procedure

Add the keystore element to the `client.xml` file. The `id` attribute must be `defaultKeyStore` and the `password` attribute contains the keystore password. The password can be entered in clear text or encoded. Use the securityUtility `encode` option to encode the password.

```
<keyStore id="defaultKeyStore" password="yourPassword" />
```

This is the minimum configuration that is needed to create an SSL configuration. In this configuration, the client creates the keystore and certificate if it does not exist during SSL initialization. The password that is provided must be at least 6 characters long. JKS is the default keystore type and the default keystore is called `key.jks` and these defaults are in the `<client home>/resources/security` directory. The client will create the `defaultKeyStore` the first time it starts when using the previous configuration, however having the client create the default certificate comes with a performance cost. To avoid the performance cost it is recommended that the **securityUtility createSSLCertificate** command be used to create the default keystore used in the `defaultKeyStore` configuration. If you need a custom SSL configuration, see SSL configuration attributes.

### Accepting signer certificates

If the client does not have an established trust relationship with the server the communication with the client prompts the user and asks if they accept the certificate from the server. If the user responds with yes, the certificate is taken and stored in the client keystore configuration and the command proceeds. If the user specifies no then there is no trust that is established and the call ends in an error.

Example of what the prompt looks like:

```
*** SSL SIGNER EXCHANGE PROMPT ***
```

```
The SSL signer from target host is not found in trust store C:/liberty/workspace/build.image/wlp/usr/clients/myT
```

Here is the signer information (verify the digest value matches what is displayed at the server):

```
Subject DN: CN=localhost, O=ibm, C=us
Issuer DN: CN=localhost, O=ibm, C=us
Serial number: 1327582458
Expires: Sun Jan 04 06:54:18 CST 2099
SHA-1 Digest: 00:6F:25:F1:78:5D:EB:00:B1:E2:99:DB:E8:D7:DF:3B:F8:E0:20:9A
Add signer to the trust store now? (y/n)
```

You might receive the following error message if the user specifies no when asked to add the signer to the truststore:

```
[ERROR ] CWPKI0022E: SSL HANDSHAKE FAILURE: A signer with SubjectDN CN=localhost, O=ibm, C=us
sent from the target host. The signer might need to be added to local trust store C:/liberty/workspace/build.im
    java.security.cert.CertPathValidatorException: The certificate issued by SubjectDN CN=localhost, O=ibm, C
    java.security.cert.CertPathValidatorException: Certificate chaining error
throw able: javax.net.ssl.SSLHandshakeException: java.security.cert.CertificateException: PKIX path building fai
: PKIXCertPathBuilderImpl could not build a valid CertPath.; internal cause is:

    java.security.cert.CertPathValidatorException: The certificate issued by
SubjectDN CN=localhost, O=ibm, C=us is not trusted; internal cause is:
    java.security.cert.CertPathValidatorException: Certificate chaining error
```

### Auto accept signer certificate

If the client does not want to be prompted for the signer certificate and chooses to accept the server signer certificate without examining the certificate, the user can provide the `-autoAcceptSigner` flag to the client container command line.

```
client run client_name --autoAcceptSigner
```

### Client authentication

If the client is communicating with a server that has client authentication that is enabled, then the

server needs to trust the client as well as the client trusting the server. The client must have a key, and personal certificate, in its keystore. If you use the `securityUtility createSSLCertificate` command, the keystore contains a personal certificate. The server that the client application container is communicating with must trust the client, so the signer from the client needs to be added to the truststore of the server. You can use the `java` tool, `keytool`, to extract the signer from the keystore of the application client container and add the certificate from the client to the truststore of the server.

## Configuring a JAAS programmatic login on the Liberty application client container

8.5.5.6

The Liberty application client container can be configured to use a JAAS programmatic login.

### Before you begin

Review the different ways of authenticating users on the application client container, and decide whether the programmatic login option is best for your environment. For further details, see [Authentication on the Liberty application client container](#).

### About this task

A programmatic login is a type of form login that supports application presentation login forms for authentication. This approach requires the application developer to collect the user's credentials and authenticate that user. This method takes advantage of the JAAS framework to send a user's credentials to the server for authentication. The JAAS framework consists of creating a login context by specifying a JAAS login configuration and by using a callback handler to gather the user's credentials. When a subject is obtained from the login context, you can use a Liberty security API to set that Subject on the thread, and it is used for your outbound call to the server.

The JAAS login configuration specifies how and which login modules are used for authentication. Here are the JAAS login configurations that are provided by Liberty on the client:

- **WSLogin JAAS login configuration:** A generic JAAS login configuration that a Liberty application client container application can use to perform authentication that is based on a user ID and password. However, this configuration does not support the `CallbackHandler` handler that is specified in the deployment descriptor of the client application module.
- **ClientContainer JAAS login configuration:** This JAAS login configuration recognizes the `CallbackHandler` handler that is specified in the client application module's deployment descriptor, if one is specified. If a handler is not specified in the deployment descriptor, then the handler that was specified programmatically is used.

The login modules that are specified by the JAAS login configuration implement a certain authentication technology. A login module can gather credentials from the user by using the `javax.security.auth.callback.CallbackHandler` interface. Liberty provides a non-prompt implementation of the `CallbackHandler` interface, which is called `com.ibm.websphere.security.auth.callback.WSCallbackHandlerImpl`. This implementation enables an application developer to specify the credentials directly in the application without having to prompt the user. There are two ways to specify your `CallbackHandler` implementation:

- Specify your implementation programmatically, as an argument to the `javax.security.auth.login.LoginContext` constructor; for example:

```
LoginContext logincontext = new LoginContext("ClientContainer", new WSCallbackHandlerImpl("user", "password"));
```
- Specify your implementation name in the client application module's deployment descriptor (`application-client.xml`); for example:

```
<callbackhandler>com.acme.callbackhandler.WSCallbackHandlerImpl</callbackhandler>
```

**Note:** The WSLgin login configuration does not recognize the second option of specifying a CallbackHandler handler in the deployment descriptor.

## Procedure

1. Add the appSecurityClient-1.0 feature to your client.xml file.  

```
<feature>appSecurityClient-1.0</feature>
```
2. Configure SSL for your client:
  - a. **Optional:** Use the **securityUtility** command to create an SSL certificate for the client; for example:  

```
securityUtility createSSLCertificate --client=myClient --password=liberty
```
  - b. **Recommended:** Use the **securityUtility** command to generate an xor encoded password. For example, to encode the password liberty:  

```
securityUtility encode liberty
```
  - c. Add a keyStore element to your client.xml file. The following example uses the default SSL configuration:  

```
<keyStore id="defaultKeyStore" password="{xor}MzY90i0rJg==" /> <!-- pwd: liberty -->
```
3. In the application code, create a Subject using the ClientContainer JAAS login configuration and the WSCallbackHandlerImpl callback handler.
  - a. Before the application makes an outbound request, add the following code. Change the userName and userPassword to valid credentials for a user that exists in the user registry of the target server.

```
CallbackHandler wscbh = new WSCallbackHandlerImpl("userName", "userPassword");
LoginContext ctx = null;
try {
    ctx = new LoginContext("ClientContainer", wscbh);
} catch (LoginException le) {
    le.printStackTrace();
}
try {
    ctx.login();
} catch (LoginException le) {
    le.printStackTrace();
}
Subject subject = ctx.getSubject();
```
4. Set the Subject obtained in the previous step on the thread and use that Subject to look up an EJB. Use the WSSubject.doAs, or doAsPrivileged APIs to accomplish this action. The Subject within the com.ibm.websphere.security.auth.WSSubject.doAs or com.ibm.websphere.security.auth.WSSubject.doAsPrivileged code block is used for Java Platform, Enterprise Edition (J2EE) resources authorization checks.

```
WSSubject.doAs(subject, new PrivilegedAction() {
    public Object run() {
        try {
            //Perform EJB lookup and invocation
        } catch (Exception ex) {
            ex.printStackTrace();
        }
        return null;
    }
});
```
5. 8.5.5.7 If Java 2 security is enabled on your client and your application code is calling JAAS or Liberty security APIs, add the necessary Java 2 Security permissions to either the permissions.xml file or the client.xml file of the application. For more details on which Liberty security APIs are protected by Java 2 Security permissions, see Programming Interfaces (APIs). For further details, see Java 2 Security.

## What to do next

As on the server, you can use a custom login module to either make more authentication decisions or add information to the subject to make finer-grained authorization decisions inside your client application. For further details, see [Configuring a JAAS custom login module for the Liberty application client container](#).

## Configuring a JAAS custom login module for the Liberty application client container

8.5.5.6

You can configure the Liberty application client container to use a custom Java Authentication and Authorization Service (JAAS) login module.

### Before you begin

Make sure that you have a JAR file that contains the JAAS custom login module, which implements the `javax.security.auth.spi.LoginModule` interface.

### About this task

You can use a custom login module to either make additional authentication decisions or add information to the subject to make finer-grained authorization decisions inside your application. To configure a JAAS custom login module, complete the following steps.

### Procedure

1. Add the `appSecurityClient-1.0` feature to your `client.xml` file.  

```
<feature>appSecurityClient-1.0</feature>
```
2. Create a class `com.sample.CustomLoginModule` that implements the `LoginModule` interface and package it into the `CustomLoginModule.jar` file.
3. Create a `<library>` element that uses a `<fileset>` element that indicates where the `CustomLoginModule.jar` file is. In this example, the file is in the client's configuration directory, and the library id is `customLoginLib`.

```
<library id="customLoginLib">  
  <fileset dir="{server.config.dir}" includes="CustomLoginModule.jar"/>  
</library>
```

4. Create a `<jaasLoginModule>` element. In this example, the id is `myCustom`.
  - a. Configure the custom login module to require a successful authentication by setting the `controlFlag` attribute to `REQUIRED`.
  - b. Set the `libraryRef` attribute to `customLoginLib`, the id of the `<library>` element that is configured in the previous step.

```
<jaasLoginModule id="myCustom" className="com.sample.CustomLoginModule" controlFlag="REQUIRED" libraryRef="customLO
```

5. Create a `<jaasLoginContextEntry>` element with the id and name of the system-defined JAAS configuration on the application client container: `ClientContainer`. You can also set this JAAS configuration to `WSLogin`, or your own JAAS configuration. In the `loginModuleRef` attribute, add `proxy`, the id for the proxy login module and `myCustom`, the id of the `jaasLoginModule` element that is created in the previous step.

```
<jaasLoginContextEntry id="ClientContainer" name="ClientContainer"  
  loginModuleRef="proxy, myCustom"/>
```

# Configuring Common Secure Interoperability version 2 (CSiv2) in the Liberty application client container

8.5.5.6

The WebSphere Application Server Liberty application client container supports CSiv2 security at various levels such as the message authentication (message layer), and client certificate authentication (transport layer). Using the CSiv2 feature, you can specify the type of authentication for outbound requests to the servers. CSiv2 features are enabled by default. You can configure CSiv2 in the Liberty application client container to enable interoperability between Java Platform, Enterprise Edition vendors.

## Configuring outbound CSiv2 in the Liberty application client container

8.5.5.6

CSiv2 features are enabled by default. You can configure CSiv2 in the Liberty application client container to enable interoperability between Java Platform, Enterprise Edition vendors.

### Before you begin

Understand the CSiv2 concepts, see Common Secure Interoperability version 2 (CSiv2) for further information.

### Configuring the outbound CSiv2 authentication layer in the Liberty application client container:

8.5.5.6

You can configure a Liberty application client container to use specific authentication mechanisms for outbound CSiv2 requests.

### About this task

The outbound CSiv2 authentication layer for a Liberty application client container is enabled with support for the GSSUP authentication mechanism by default. The `establishTrustInClient` association option of the authentication layer is set to `Supported` by default to indicate that the authentication mechanisms specified are supported and optional.

### Procedure

1. Configure the `orb` element in the `client.xml` file as follows or add the `authenticationLayer` element to an existing one, replacing the sample values in the example with your values:

```
<orb id="default0rb">
  <clientPolicy.clientContainerCsiv2>
    <layers>
      <authenticationLayer user="userId" password="{xor}PDC+MTg6Ejo="/>
    </layers>
  </clientPolicy.clientContainerCsiv2>
</orb>
```

**Note:** The `id` value `default0rb` in the `orb` element is predefined and cannot be modified.

**Note:** Hash encoding cannot be used for encrypting the password because the original password cannot be decoded from the hashed value.

The `mechanisms` and `establishTrustInClient` attributes are optional. The only supported value, and the default value, for the `mechanisms` attribute is `GSSUP`.

Without specifying an `<orb>` element, the following configuration is implicit.

```

<orb id="defaultOrb">
  <clientPolicy.clientContainerCsiv2>
    <layers>
      <authenticationLayer mechanisms="GSSUP" establishTrustInClient="Supported"/>
      <transportLayer/>
    </layers>
  </clientPolicy.clientContainerCsiv2>
</orb>

```

2. **Optional:** Set the user and password attributes with a valid user ID and password to access the server. By default, a server requires the GSSUP mechanism for inbound connections, meaning that the server must receive a user and password and because of this requirement, the user, and password values are required in the client.xml file, unless a programmatic login is implemented by the application.
3. **Optional:** Set the establishTrustInClient attribute to Required, Supported (default), or Never for performing authentication with the specified mechanisms. For example,

```

<orb id="defaultOrb">
  <clientPolicy.clientContainerCsiv2>
    <layers>
      <authenticationLayer user="userId" password="{xor}PDC+MTg6Ejo=" establishTrustInClient="Required" />
    </layers>
  </clientPolicy.clientContainerCsiv2>
</orb>

```

**Note:**

- When the establishTrustInClient attribute is set to Required, the client is able to send an authentication token of one of the specified mechanisms only to servers that either require or support the same authentication mechanisms.
- When the establishTrustInClient attribute is set to Supported (default), the client can choose whether to send the authentication information in the authentication layer. If the server is configured with Supported or Required of the same authentication mechanisms, then the client sends a compatible authentication token.
- When the establishTrustInClient attribute is set to Never, the outbound CSiv2 authentication layer is disabled and the CSiv2 transport layer must be enabled to authenticate to the server.

**Results**

Your outbound CSiv2 authentication layer is now configured.

**Configuring the outbound CSiv2 transport layer in the Liberty application client container:** 

8.5.5.6

You can configure the Liberty application client container to perform client certificate authentication for outbound CSiv2 requests.

**About this task**

The client certificate authentication of the outbound CSiv2 transport layer for a Liberty application client container is not used by default. You can configure the transportLayer to specify the SSL configuration to use.

You can configure the SSL element to support client certificate authentication or require it. The certificate sent to the server is authenticated against the server user registry and its identity is only used if no other form of authentication is sent in the CSiv2 request, like an identity assertion in the attribute layer or an authentication token in the authentication layer.

## Procedure

1. Configure SSL support as described in Enabling SSL communication for the Liberty application client container.
2. Optional: Configure the SSL element to use `clientAuthentication` or `clientAuthenticationSupported`. For example,

```
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore"
    trustStoreRef="defaultTrustStore" clientAuthentication="true" />
```

or

```
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore"
    trustStoreRef="defaultTrustStore" clientAuthenticationSupported="true" />
```

3. Configure the `<orb>` element in the `client.xml` file as follows or add the `transportLayer` element to an existing one and replace the sample values in the sample with your values:

```
<orb id="defaultOrb">
  <clientPolicy.clientContainerCsi2>
    <layers>
      <transportLayer sslRef="defaultSSLConfig"/>
    </layers>
  </clientPolicy.clientContainerCsi2>
</orb>
```

Without specifying an `<orb>` element, the following configuration is implicit.

```
<orb id="defaultOrb">
  <clientPolicy.clientContainerCsi2>
    <layers>
      <authenticationLayer mechanisms="GSSUP" establishTrustInClient="Supported"/>
      <transportLayer/>
    </layers>
  </clientPolicy.clientContainerCsi2>
</orb>
```

4. Make sure the server trusts any client certificates that are sent from this server.
  - When the `clientAuthentication` attribute is set to `true` in the `ssl` element, the client sends a client certificate only to servers that either require or support the client certificate authentication.
  - When the `clientAuthenticationSupported` attribute is set to `true` in the `ssl` element, the client might choose whether to send a client certificate based on the `ssl` element configuration used by the server.
  - When the `clientAuthentication` and `clientAuthenticationSupported` attributes are not set in the `ssl` element, the server that is acting as a client is not enabled with the client certificate authentication.

## Results

Your outbound CSIv2 transport layer is now configured for client certificate authentication.

---

## Configuring Java Servlet 3.1 support for security

8.5.5.4

Liberty supports all security updates as defined in the Java Servlet 3.1 specification.

### About this task

Take advantage of the Java Servlet 3.1 features on Liberty.

## Procedure

1. Add the servlet-3.1 feature in the server.xml file:

```
<feature>servlet-3.1</feature>
```

2. Determine which of the following Java Servlet 3.1 functions that you want to use:

- Specify autocomplete=off in the login form.

When you use HTML for a form login page, set the password form field to autocomplete="off" to disable automatically filling in passwords in the web browser. For example:

```
<form method="POST" action="j_security_check">
<input type="text" name="j_username">
<input type="password" name="j_password" autocomplete="off">
</form>
```

- Specify the all authenticate security constraint (\*\*).

The special role name \*\* indicates any authenticated user. When \*\* displays in an authorization constraint, if the user is authenticated, that user has access to the methods that are specified in the constraint. Users do not have to be mapped to this role in the application bindings. For example:

```
<security-constraint id="SecurityConstraint_1">
  <web-resource-collection id="WebResourceCollection_1">
    <web-resource-name>Protected with ** role</web-resource-name>
    <url-pattern>/AnyAuthSecurityConstraint</url-pattern>
    <http-method>GET</http-method>
    <http-method>POST</http-method>
  </web-resource-collection>
  <auth-constraint id="AuthConstraint_1">
    <role-name>**</role-name>
  </auth-constraint>
</security-constraint>
```

When the isUserInRole() method is called with a role name of \*\*, isUserInRole() returns true if the user is authenticated. If \*\* is a defined role in the configuration in a security-role, it is not treated like the special any authenticated user role. The user must be mapped to that role in application bindings for isUserInRole to return true.

- Specify the deny-uncovered-http-methods flag in web.xml files.

If the deny-uncovered-http-methods element is specified within the web.xml file, the container denies any uncovered HTTP methods that are not enumerated within the combined security constraint for a URL pattern that is the best match for the request URL. A 403 (SC\_FORBIDDEN) status code is returned. For example:

```
<servlet-mapping id="ServletMapping_1">
  <servlet-name>MyServlet</servlet-name>
  <url-pattern>/MyURLPattern</url-pattern>
</servlet-mapping>
```

```
<deny-uncovered-http-methods/>
```

```
<!-- SECURITY CONSTRAINTS -->
```

```
<security-constraint id="SecurityConstraint_1">
  <web-resource-collection id="WebResourceCollection_1">
    <web-resource-name>Protected with Employee or Manager roles</web-resource-name>
    <url-pattern>/MyURLPattern</url-pattern>
    <http-method>GET</http-method>
    <http-method>POST</http-method>
  </web-resource-collection>
  <auth-constraint id="AuthConstraint_1">
    <role-name>Employee</role-name>
    <role-name>Manager</role-name>
  </auth-constraint>
</security-constraint>
```

If the deny-uncovered-http-methods element is specified in the web.xml file, a message is logged in the messages.log file for each URL pattern in each servlet, indicating the uncovered methods with a note that those uncovered methods are unprotected and not accessible. For example:

For URL MyURLPattern in servlet MyServlet, the following HTTP methods are uncovered, and not accessible: DELETE OPTION  
If the deny-uncovered-http-methods element is not specified in the web.xml file, a message is logged in the messages.log file for each URL pattern in each servlet, indicating the uncovered methods with a note that those uncovered methods are unprotected and accessible. For example:

For URL MyURLPattern in servlet MyServlet, the following HTTP methods are uncovered, and accessible: DELETE OPTION

## Results

You have now secured your application.

---

## Configuring secure JMX connection to Liberty

You can access the secured Java Management Extensions (JMX) connectors on Liberty by using SSL. The secured JMX connection is enabled by the Liberty feature restConnector-1.0.

### About this task

The REST connector is enabled through the Liberty feature restConnector-1.0. Remote access through the REST connector is protected by a single administrator role. In addition, SSL is required to keep the communication confidential. The restConnector-1.0 feature already includes the ssl-1.0 feature.

**Note:** An application deployed on Liberty has unrestricted access to its MBeanServer directory.

The following section describes how to configure and access the REST connector on Liberty.

### Procedure

1. Enable the REST connector using the following code in the server.xml file.

```
<featureManager>  
  <feature>restConnector-1.0</feature>  
</featureManager>
```

2. Configure SSL certificates in the server.xml file.

Ensure that the CN value of the certificate's subjectDN is the host name of the machine where the server is running, and that the truststore contains the certificate of the server in the jConsole connection.

3. Configure a user or group to the administrator role in the server.xml file.

- Map to the administrator role for Liberty
-  Map to the administrator role for Liberty on z/OS

4. Access the REST connector.

 You can access a Liberty REST connector from a Java client or directly through an HTTPS call. A Java client uses the client-side of the connector, which is in wlp/clients/restConnector.jar and implements the javax.management.MBeanServerConnection interface. HTTPS calls use the server-side of the connector. As to HTTPS calls on the server-side, any programming language that can make HTTPS calls, such as C++, JavaScript, curl, Ruby, and Perl, can use the REST APIs. The REST APIs contain endpoints for management (JMX), file transfer, collective routing and collective deployment.

- Access the REST connector from a JMX client application or by using the jConsole tool provided in the Java SDK. Use -J flags to pass the system properties as Java options and set the class path to include the connector class files. The connector class files are packed in the clients/restConnector.jar file.

– Use the following properties for SSL certificates:

```
-J-Djavax.net.ssl.trustStore=<location of your client trust store>  
-J-Djavax.net.ssl.trustStorePassword=<password for the trust store>  
-J-Djavax.net.ssl.trustStoreType=<type of trust store>
```

The following example shows the jConsole tool being used with SSL configurations:

```
jconsole -J-Djava.class.path=%JAVA_HOME%/lib/jconsole.jar;  
          %JAVA_HOME%/lib/tools.jar;  
          %WLP_HOME%/clients/restConnector.jar  
-J-Djavax.net.ssl.trustStore=key.jks  
-J-Djavax.net.ssl.trustStorePassword=Liberty  
-J-Djavax.net.ssl.trustStoreType=jks
```

After the jConsole starts, select **Remote Process**, and enter the JMX service URL:  
service:jmx:rest://<host>:<port>/IBMJMXConnectorREST. The port number is the HTTPS port.  
You must also provide the user name and password.

- **z/OS** For z/OS, use the following system properties:

```
-J-Djava.protocol.handler.pkgs=com.ibm.crypto.provider  
-J-Djavax.net.ssl.trustStore=<SAF keyring>  
-J-Djavax.net.ssl.trustStorePassword=<password to SAF>  
-J-Djavax.net.ssl.trustStoreType=JCERACFKS
```

- **8.5.5.4** Access the REST connector directly using an HTTPS call.

To use HTTPS calls to access REST connectors, you need WebSphere Application Server Liberty 8.5.5.4 or later.

- a. Open a browser at `https://<host>:<port>/IBMJMXConnectorREST/api`, and enter the administrative credentials you specified in step 3.
- b. Examine the available REST APIs. Each item has a description of its behavior, input, output, query parameters, and header.

**Note:** You can specify some JMX REST connection options as system properties. See the Liberty API - WebSphere JMX REST Connector API.

---

## Configuring web security related properties in Liberty

You can configure web security related properties for Liberty, such as SSO and client certificate authentication.

### About this task

You can use the `webAppSecurity` element to configure web container application security for Liberty.

Make sure you add the `appSecurity-2.0` **8.5.5.0**, `servlet-3.0` and other required Liberty features to the `server.xml` file.

For all available attributes in the `webAppSecurity` element, see .

You can choose to complete one or more of the following tasks according to your requirements.

### Procedure

- “Customizing SSO configuration using LTPA cookies in Liberty” on page 1887
- “Configuring your web application and server for client certificate authentication” on page 1847

## Customizing SSO configuration using LTPA cookies in Liberty

With single sign-on (SSO) configuration support, web users can authenticate once when accessing Liberty resources such as HTML, JavaServer Pages (JSP) files, and servlets, or accessing resources in multiple Liberty servers that share the same Lightweight Third Party Authentication (LTPA) keys.

### Example

When a user passes authentication on one of Liberty servers, authentication information generated by the server is transported to the web browser in a cookie. The cookie is used to propagate the authentication information to other Liberty servers.

The LTPA is configured and ready for immediate use. The default cookie name used to store the SSO token is called `ltpaToken2`. If you want to use a different name for the cookie, you can customize the cookie name using the **ssoCookieName** attribute of the `<webAppSecurity>` element. If you customize the cookie name, make sure that all the servers that participate in SSO use the same cookie name.

For more information about SSO, see SSO concept in Liberty.

The following example code sets the user to be logged out after the HTTP session expires and the name of the SSO cookie as `myCookieName`:

```
<webAppSecurity logoutOnHttpSessionExpire="true" ssoCookieName="myCookieName" />
```

**Note:** For SSO to work across Liberty servers, full profile servers, or both, set the following resources:

- The servers must use the same LTPA keys and share the same user registry.
- If the servers are not in the same domain, use the **ssoDomainNames** attribute of the `<webAppSecurity>` element to list the domains. The following example code sets the domain name to `domain.com`:

```
<webAppSecurity ssoDomainNames="domain.com" />
```

- If the servers are in the same domain, set the **ssoUseDomainFromURL** attribute of the `<webAppSecurity>` element to `true`, or specify the domain name in the **ssoDomainNames** attribute. The following example code sets **ssoUseDomainFromURL** to `true` so that the domain name is taken from the request URL:

```
<webAppSecurity ssoUseDomainFromURL="true" />
```

For details of all the available SSO settings, see the `<webAppSecurity>` element in .

## Configuring your web application and server for client certificate authentication

You can configure your web application on Liberty using SSL client authentication.

### Before you begin

This topic assumes that you have already created the SSL certificates, for example as described in “Creating SSL certificates from the command line” on page 1844.

### About this task

Client certificate authentication occurs if the server-side requests that the client-side send a certificate. A WebSphere server can be configured for client certificate authentication on the SSL configuration. To do this, you add the `ssl-1.0` Liberty feature to the `server.xml` file, along with code that tells the server the keystore information for authentication.

For details of which aspects of SSL are supported, see “Liberty features” on page 826.

### Procedure

1. Ensure that the deployment descriptor for your web application specifies client certificate authentication as the authentication method to use.

Check that the deployment descriptor includes the following element:

```
<auth-method>CLIENT-CERT</auth-method>
```

**Note:** You can use a tool such as Rational Application Developer to create the deployment descriptor.

2. Optional: Generate an SSL certificate using the command line. See “Liberty:securityUtility command” on page 1844.
3. Configure your server to enable SSL client authentication by adding the following lines to the `server.xml` file:

```
<featureManager>
  <feature>ssl-1.0</feature>
</featureManager>
```

```
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore"
  trustStoreRef="defaultTrustStore" clientAuthenticationSupported="true" />
<keyStore id="defaultKeyStore" location="key.jks" type="JKS" password="defaultPWD" />
<keyStore id="defaultTrustStore" location="trust.jks" type="JKS" password="defaultPWD" />
```

- If you specify `clientAuthentication="true"`, the server requests that a client sends a certificate. However, if the client does not have a certificate, or the certificate is not trusted by the server, the handshake does not succeed.
  - If you specify `clientAuthenticationSupported="true"`, the server requests that a client sends a certificate. However, if the client does not have a certificate, or the certificate is not trusted by the server, the handshake might still succeed.
  - If you do not specify either `clientAuthentication` or `clientAuthenticationSupported`, or you specify `clientAuthentication="false"` or `clientAuthenticationSupported="false"`, the server does not request that a client send a certificate during the handshake.
4. Add a client certificate to your browser. See the documentation of your browser for adding client certificates.
  5. Make sure the server trusts any client certificates that are used.
  6. Make sure any client certificates used for client authentication are mapped to a user identity in your registry.
    - For the basic registry, the user identity is the common name (CN) from the distinguished name (DN) of the certificate.
    - For a Lightweight Directory Access Protocol (LDAP) registry, the DN from the client certificate must be in the LDAP registry.
  7. To use basic authentication, user ID and password only, if client certificate authentication does not succeed, add the following line to your `server.xml` file.

```
<webAppSecurity allowFailOverToBasicAuth="true" />
```

**Note:** If you specify `allowFailOverToBasicAuth="false"` or do not specify `allowFailOverToBasicAuth`, and the client certificate authentication does not succeed, the request generates a 403 Authentication error message, and the client is not prompted for basic authentication.

## Configuring the Liberty server to track logged out LTPA tokens

8.5.5.4

You can configure a Liberty server to track logged out Lightweight Third Party Authentication (LTPA) tokens.

### About this task

When a user is logged out by using either form logout or programmatic logout, the LTPA token that is used for Single Sign On is removed from the cookie. The LTPA token that is used for SSO is also removed from the local Authentication cache and the session is invalidated. If the token was persisted and presented again, it is validated based on the expiration time and the LTPA encryption keys.

With this element enabled, the LTPA SSO tokens that were logged out on the server are tracked and if presented again on the same server are not used.. A logout is performed and the user needs to authenticate again.

This configuration only works on the same server. This means that the LTPA token can only be tracked on the server where the user logged out, and if that same LTPA token is presented to another server it is

used and if the LTPA keys are shared and the token has not expired it is used until it is also logged out on that server.

## Procedure

To track the tokens that are logged out on a particular Liberty server, you can enable the following element in the `server.xml`:

```
<webAppSecurity trackLoggedOutSSOCookies="true"/>
```

When this element is enabled, it might affect your Single Sign On (SSO) scenarios. For example, if the user 'bob' logs in from multiple browsers to the same server and logs out from one browser and tries to access the resource by using another browser, the user must log in as the token presented is discarded.

---

## Configuring authentication aliases for Liberty

You can configure an authentication data alias to use with a resource reference for authentication in Liberty.

### About this task

You can use an authentication data alias by defining a user and password for authentication in Liberty. To do this, add the `jdbc-4.0` Liberty feature to the `server.xml` file and add at least one `authData` element.

**Note:** There is no authentication alias principal mapping module support.

## Procedure

1. Add the `jdbc-4.0` Liberty features in the `server.xml` file.

```
<featureManager>  
  <feature>jdbc-4.0</feature>  
</featureManager>
```

2. Configure the `authData` element in the `server.xml` file as follows. If the `authData` element is used as a top-level configuration element, you must set the `id` attribute value to a unique authentication alias.

```
<authData id="auth1" user="dbuser1" password="dbuser1pwd"/>
```

3. Configure the IBM deployment descriptor, for example, the `ibm-web-bnd.xml` file, of your application by using the `authentication-alias` element in the resource reference. The `name` attribute value must match the `id` attribute defined in the `server.xml` file.

```
<resource-ref name="jdbc/mydbresource" binding-name="jdbc/mydbresource">  
  <authentication-alias name="auth1"/>  
</resource-ref>
```

---

## Configuring JAAS for database authentication

8.5.5.9

You can use Java Authentication and Authorization Service (JAAS) for database authentication.

### About this task

You can use a JAAS login context entry to specify a custom login module to use for setting the user name and password to authenticate to a database.

## Procedure

1. Add the `appSecurity-2.0`, `jdbc-4.0`, and `jca-1.6` features in the `server.xml` file. You can also add `appSecurity-2.0`, `jdbc-4.1`, and `jca-1.7`. For example:

```

<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>jdbc-4.0</feature>
  <feature>jca-1.6</feature>
</featureManager>

```

2. Configure a `jaasLoginContextEntry` element in the `server.xml` file with the login module to use. For example:

```

<jaasLoginContextEntry id="myJAASLoginEntry" name="myJAASLoginEntry" loginModuleRef="myLoginModule" />
<jaasLoginModule id="myLoginModule" className="my.package.MyLoginModule" controlFlag="REQUIRED" libraryRef="customLogin" />

<library id="customLoginLib">
  <fileset dir="${server.config.dir}" includes="MyLoginModule.jar"/>
</library>

```

3. Configure the `dataSource` element's `jaasLoginContextEntry` attribute with the id of the `jaasLoginContextEntry` element configured in step 2. For example:

```

<dataSource id="ds1" jndiName="jdbc/ds1" jdbcDriverRef="DB2"
  jaasLoginContextEntry="myJAASLoginEntry" .../>

```

4. As an alternative to step 3, you can configure a `custom-login-configuration` element in the deployment descriptor `ibm-web-bnd.xml` file of your application. The name attribute must match the id attribute for `jaasLoginContextEntry` that is defined in the `server.xml` file. For example:

```

<resource-ref name="jdbc/ds1ref" binding-name="jdbc/ds1">
  <custom-login-configuration name="myJAASLoginEntry">
    <property name="property1" value="value1"/>
  </custom-login-configuration>
</resource-ref>

```

---

## Developing extensions to the Liberty security infrastructure

The Liberty server provides various plug-in points so that you can extend the security infrastructure.

### About this task

The following topics are covered in this section:

#### Procedure

- Follow the instructions in “Developing a custom TAI for Liberty” to develop custom trust association interceptors (TAI) to extend the security infrastructure of Liberty server.
- Follow the instructions in “Developing JAAS custom login modules for a system login configuration” on page 2002 to develop JAAS custom login modules to extend the security infrastructure of Liberty server.

## Developing a custom TAI for Liberty

You can develop a custom trust association interceptor (TAI) class by implementing the `com.ibm.wsspi.security.tai.TrustAssociationInterceptor` interface provided in the Liberty server.

### About this task

The trust association interface is a service provider API that enables the integration of third-party security services with a Liberty server. When processing the web request, the Liberty server calls out and passes the `HttpServletRequest` and `HttpServletResponse` to the trust association interceptors. The `HttpServletRequest` calls the `isTargetInterceptor` method of the interceptor to see whether the interceptor can process the request. After an appropriate trust association interceptor is selected, the `HttpServletRequest` is processed by the `negotiateValidateandEstablishTrust` method of the interceptor, and the result is returned in a `TAIResult` object. You can add your own logic code to each method of the custom TAI class.

See also the Java API document for the TAI interface. The Java API documentation for each Liberty API is available in a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

**Avoid trouble:** **Distributed operating systems** **8.5.5.0** There are several security configuration examples on the WASdev.net website for reference when configuring security for your applications on Liberty. See “Configuring TAI on Liberty by using developer tools” on page 1891.

## Example

Here is a sample TAI class called SimpleTAI, which also lists all available methods from the TrustAssociationInterceptor interface.

```
package com.ibm.websphere.security.sample;

import java.util.Properties;

import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import com.ibm.websphere.security.WebTrustAssociationException;
import com.ibm.websphere.security.WebTrustAssociationFailedException;
import com.ibm.wsspi.security.tai.TAIResult;
import com.ibm.wsspi.security.tai.TrustAssociationInterceptor;

public class SimpleTAI implements TrustAssociationInterceptor {
    public SimpleTAI() {
        super();
    }

    /**
     * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#isTargetInterceptor
     * (javax.servlet.http.HttpServletRequest)
     */
    public boolean isTargetInterceptor(HttpServletRequest req)
        throws WebTrustAssociationException {
        //Add logic to determine whether to intercept this request
        return true;
    }

    /**
     * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#negotiateValidateandEstablishTrust
     * (javax.servlet.http.HttpServletRequest, javax.servlet.http.HttpServletResponse)
     */
    public TAIResult negotiateValidateandEstablishTrust(HttpServletRequest req,
        HttpServletResponse resp) throws WebTrustAssociationFailedException {
        // Add logic to authenticate a request and return a TAI result.
        String tai_user = "taiUser";
        return TAIResult.create(HttpServletResponse.SC_OK, tai_user);
    }

    /**
     * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#initialize(java.util.Properties)
     */
    public int initialize(Properties arg0)
        throws WebTrustAssociationFailedException {
        return 0;
    }

    /**
     * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#getVersion()
     */
}
```

```

    public String getVersion() {
        return "1.0";
    }

    /*
    * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#getType()
    */
    public String getType() {
        return this.getClass().getName();
    }

    /*
    * @see com.ibm.wsspi.security.tai.TrustAssociationInterceptor#cleanup()
    */
    public void cleanup()

    {}
}

```

## What to do next

Add the TAI class to the Liberty server.

Use one of the following methods to add the TAI class to the Liberty server:

- Put the custom TAI class in a JAR file, for example `simpleTAI.jar`, then make the JAR file available as a shared library. See “Configuring TAI in Liberty” on page 1889.
- Package the custom TAI class as a feature. See “Developing a custom TAI as a Liberty feature” on page 1820.

## Developing a custom SIP TAI

8.5.5.7

When you develop Session Initiation Protocol (SIP) applications, you can create a custom trust association interceptor (TAI).

### Before you begin

Developing a SIP TAI is similar to developing any other custom interceptors used in trust associations. In fact, a custom TAI for a SIP application is an extension of the trust association interceptor model.

### About this task

TAI can be invoked by a SIP servlet request or a SIP servlet response. To implement a custom SIP TAI, you need to write your own Java class.

### Procedure

1. Write a Java class that extends the `com.ibm.wsspi.security.tai.extension.BaseTrustAssociationInterceptor` class and implements the `com.ibm.websphere.security.tai.extension.SIPTrustAssociationInterceptor` interface. Those classes are defined in the `${wlp.install.dir}/dev/api/ibm/ccom.ibm.websphere.appserver.api.sipServletSecurity.1.0_1.0.10.jar` file.
2. Declare the following Java methods:

```
public int initialize(Properties properties) throws WebTrustAssociationFailedException;
```

This is invoked before the first message is processed so that the implementation can allocate any resources that it needs. For example, it might establish a connection to a database.

WebTrustAssociationFailedException is defined in the `{wlp.install.dir}/lib/com.ibm.websphere.security_1.0.10.jar` file. The value of the properties argument comes from the `<trustAssociation>` configuration.

**public void cleanup();**

This is invoked when the TAI can free any resources that it holds. For example, it could close a connection to a database.

**public boolean isTargetProtocolInterceptor(SipServletMessage sipMsg) throws WebTrustAssociationFailedException;**

Your custom TAI can use this method to handle the sipMsg message. If the method returns false, WebSphere ignores your TAI for sipMsg.

**public TAIResult negotiateValidateandEstablishProtocolTrust (SipServletRequest req, SipServletResponse resp) throws WebTrustAssociationFailedException;**

This method returns a TAIResult that indicates the status of the message that is being processed and a user ID or the unique ID for the user who is trying to authenticate. If authentication succeeds, the TAIResult contains the status `HttpServletResponse.SC_OK` and a principal. If authentication fails, the TAIResult will contain a return code of `HttpServletResponse.SC_UNAUTHORIZED (401)`, `SC_FORBIDDEN (403)`, or `SC_PROXY_AUTHENTICATION_REQUIRED (407)`. This only indicates whether the container should accept a message for further processing. To challenge an incoming request, the TAI implementation must generate and send its own `SipServletResponse` containing a challenge. The exception can be thrown for internal TAI errors. Table 1 describes the argument values and resultant actions for the `negotiateValidateandEstablishProtocolTrust` method.

Table 135. Description of negotiateValidateandEstablishProtocolTrust arguments and actions.

This table provides a description of the `negotiateValidateandEstablishProtocolTrust` arguments and actions

Argument or action	For a SIP request	For a SIP response
Value of req argument	The incoming request	Null
Value of resp argument	Null	The incoming response
Action for valid response credentials	Return <code>TAIResult.status</code> containing <code>SC_OK</code> and a user ID or unique ID	Return <code>TAIResult.status</code> containing <code>SC_OK</code> and a user ID or unique ID
Action for incorrect response credentials	Return the <code>TAIResult</code> with the 4xx status	Return the <code>TAIResult</code> with the 4xx status

The sequence of events is as follows:

- a. The SIP container maps initial requests to applications by using the rules in each applications deployment descriptor; subsequent messages are mapped based on JSR289 mechanisms.
- b. If any of the applications require security, the SIP container invokes any defined TAI implementations for the message.
- c. If the message passes security, the container invokes the corresponding applications.

Your TAI implementation can modify a SIP message, but the modified message will not be usable within the request mapping process, because it finishes before the container invokes the TAI.

The `com.ibm.wsspi.security.tai.TAIResult` class, which is defined in the `{wlp.install.dir}/lib/com.ibm.ws.security.authentication.tai_1.0.10.jar` file, has three static methods for creating a `TAIResult`. The `TAIResult` create methods take an `int` type as the first parameter. The WebSphere Application Server expects the result to be a valid HTTP request return code and is interpreted as follows:

If the value is `HttpServletResponse.SC_OK`, this response tells WebSphere that the TAI has completed its negotiation. The response also tells WebSphere to use the information in the `TAIResult` to create a user identity.

The created `TAIResults` have the meanings that are shown in Table 2.

Table 136. Meanings of `TAIResults`.

This table lists the meanings of `TAIResults`

TAIResult	Explanation
<code>public static TAIResult create(int status);</code>	Indicates a status to the WebSphere Application Server. The status should not be <code>SC_OK</code> because the identity information is provided.
<code>public static TAIResult create(int status, String principal);</code>	Indicates a status to the WebSphere Application Server and provides the user ID or the unique ID for this user. WebSphere creates credentials by querying the user registry.
<code>public static TAIResult create(int status, String principal, Subject subject);</code>	Indicates a status to the WebSphere Application Server, the user ID or the unique ID for the user, and a custom Subject. If the Subject contains a Hashtable, the principal is ignored. The contents of the Subject becomes part of the eventual user Subject.

**public String getVersion();**

This method returns the version number of the current TAI implementation.

**public String getType();**

This method's return value is implementation-dependent.

3. Compile the implementation after you have implemented it to create your own SIP TAI jar file.
4. Follow steps 3-4 described in the topic [Configuring TAI for Liberty](#) to configure the Liberty server to use the SIP TAI.

## Developing JAAS custom login modules for a system login configuration

For a Liberty server, multiple Java Authentication and Authorization Service (JAAS) plug-in points exist for configuring system logins. The Liberty uses system login configurations to authenticate incoming requests. You can develop a custom JAAS login module to add information to the **Subject** of a system login configuration.

### About this task

Application login configurations are called by servlet applications for obtaining a Subject that is based on specific authentication information. When you write a login module that plugs into a Liberty profile application login or system login configuration, you must develop login configuration logic that knows when specific information is present, and how to use the information. See ["JAAS configuration"](#) on page 978 and ["JAAS login modules"](#) on page 979 for more details.

To develop a JAAS custom login module for a system login configuration, follow the steps in the procedure:

### Procedure

- Understand usable callbacks and how they work.

See [Programmatic login for JAAS](#) for more information about usable callbacks.

**Note:** Liberty only supports the following callbacks:

```
callbacks[0] = new javax.security.auth.callback.NameCallback("Username: ");
callbacks[1] = new javax.security.auth.callback.PasswordCallback("Password: ", false);
callbacks[2] = new com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl("Credential Token: ");
```

```

callbacks[3] = new com.ibm.websphere.security.auth.callback.WSServletRequestCallback("HttpServletRequest: ");
callbacks[4] = new com.ibm.websphere.security.auth.callback.WSServletResponseCallback("HttpServletResponse: ");
callbacks[5] = new com.ibm.websphere.security.auth.callback.WSAppContextCallback("ApplicationContextCallback: ");
callbacks[6] = new WSRealmNameCallbackImpl("Realm Name: ", default_realm);
callbacks[7] = new WSX509CertificateChainCallback("X509Certificate[]: ");
callbacks[8] = wsAuthMechOidCallback = new WSAuthMechOidCallbackImpl("AuthMechOid: ");

```

- Understand shared state variables and how they work.

If you want to access the objects that the WebSphere Application Server traditional creates during a login, refer to the following shared state variables. For more information about these variables, see the “System Programming Interfaces” subtopic of Programming Interfaces

#### **com.ibm.wsspi.security.auth.callback.Constants.WSPRINCIPAL\_KEY**

Specifies an implemented object of the java.security.Principal interface. This shared state variable is for read-only purposes. Do not set this variable in the shared state for custom login modules. The default login module sets this variable.

#### **com.ibm.wsspi.security.auth.callback.Constants.WSCREDENTIAL\_KEY**

Specifies the com.ibm.websphere.security.cred.WSCredential object. This shared state variable is for read-only purposes. Do not set this variable in the shared state for custom login modules. The default login module will set this variable.

#### **com.ibm.wsspi.security.auth.callback.Constants.WSSSOTOKEN\_KEY**

Specifies the com.ibm.wsspi.security.token.SingleSignonToken object. Do not set this variable in the shared state for custom login modules. The default login module sets this variable.

- Optional: Understand hashtables for custom JAAS login modules in Liberty. See “Hash table login module” on page 985 for more details.
- Develop a sample custom login module using callbacks and shared state.

You can use the following sample to learn on how to use some of the callbacks and shared state variables.

```

public class CustomCallbackLoginModule implements LoginModule {

    protected Map<String, ?> _sharedState;
    protected Subject _subject = null;
    protected CallbackHandler _callbackHandler;
    private final String customPrivateCredential = "CustomLoginModuleCredential";

    /**
     * Initialization of login module
     */
    public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map<String, ?> sharedState, Map<String, ?> options) {
        _sharedState = sharedState;
        _subject = subject;
        _callbackHandler = callbackHandler;
    }

    public boolean login() throws LoginException {
        try {
            AccessController.doPrivileged(new PrivilegedExceptionAction<Object>() {
                public Object run() throws Exception {
                    _subject.getPrivateCredentials().add(customPrivateCredential);
                    return null;
                }
            });
        } catch (PrivilegedActionException e) {
            throw new LoginException(e.getLocalizedMessage());
        }

        String username = null;
        char passwordChar[] = null;
        byte[] credToken = null;
        HttpServletRequest request = null;
        HttpServletResponse response = null;
        Map appContext = null;
        String realm = null;
        String authMechOid = null;
        java.security.cert.X509Certificate[] certChain = null;

```

```

NameCallback nameCallback = null;
PasswordCallback passwordCallback = null;
WSCredTokenCallbackImpl wsCredTokenCallback = null;
WSServletRequestCallback wsServletRequestCallback = null;
WSServletResponseCallback wsServletResponseCallback = null;
WSAppContextCallback wsAppContextCallback = null;
WSRealmNameCallbackImpl wsRealmNameCallback = null;
WSX509CertificateChainCallback wsX509CertificateCallback = null;
WSAuthMechOidCallbackImpl wsAuthMechOidCallback = null;

Callback[] callbacks = new Callback[9];
callbacks[0] = nameCallback = new NameCallback("Username: ");
callbacks[1] = passwordCallback = new PasswordCallback("Password: ", false);
callbacks[2] = wsCredTokenCallback = new WSCredTokenCallbackImpl("Credential Token: ");
callbacks[3] = wsServletRequestCallback = new WSServletRequestCallback("HttpServletRequest: ");
callbacks[4] = wsServletResponseCallback = new WSServletResponseCallback("HttpServletResponse: ");
callbacks[5] = wsAppContextCallback = new WSAppContextCallback("ApplicationContextCallback: ");
callbacks[6] = wsRealmNameCallback = new WSRealmNameCallbackImpl("Realm name:");
callbacks[7] = wsX509CertificateCallback = new WSX509CertificateChainCallback("X509Certificate[]: ");
callbacks[8] = wsAuthMechOidCallback = new WSAuthMechOidCallbackImpl("AuthMechOid: ");

try {
    _callbackHandler.handle(callbacks);
} catch (Exception e) {
    // handle exception
}

if (nameCallback != null)
    username = nameCallback.getName();

if (passwordCallback != null)
    passwordChar = passwordCallback.getPassword();

if (wsCredTokenCallback != null)
    credToken = wsCredTokenCallback.getCredToken();

if (wsServletRequestCallback != null)
    request = wsServletRequestCallback.getHttpServletRequest();

if (wsServletResponseCallback != null)
    response = wsServletResponseCallback.getHttpServletResponse();

if (wsAppContextCallback != null)
    appContext = wsAppContextCallback.getContext();

if (wsRealmNameCallback != null)
    realm = wsRealmNameCallback.getRealmName();

if (wsX509CertificateCallback != null)
    certChain = wsX509CertificateCallback.getX509CertificateChain();

if (wsAuthMechOidCallback != null)
    authMechOid = wsAuthMechOidCallback.getAuthMechOid();

_subject.getPrivateCredentials().add("username = " + username);
_subject.getPrivateCredentials().add("password = " + String.valueOf(passwordChar));
_subject.getPrivateCredentials().add("realm = " + realm);
_subject.getPrivateCredentials().add("authMechOid = " + authMechOid.toString());

return true;
}

public boolean commit() throws LoginException {
    return true;
}

public boolean abort() {
    return true;
}

public boolean logout() {
    return true;
}
}

```

- Optional: Develop a sample custom login module using hashtable login. You can use the following sample to learn on how to use hashtable login.

```

package com.ibm.websphere.security.sample;

import java.util.Map;

import javax.security.auth.Subject;
import javax.security.auth.callback.CallbackHandler;
import javax.security.auth.login.LoginException;
import javax.security.auth.spi.LoginModule;

import com.ibm.wsspi.security.token.AttributeNameConstants;

/**
 * Custom login module that adds another PublicCredential to the subject
 */
@SuppressWarnings("unchecked")
public class CustomHashtableLoginModule implements LoginModule {

    protected Map<String, ?> _sharedState;
    protected Map<String, ?> _options;

    /**
     * Initialization of login module
     */
    public void initialize(
        Subject subject, CallbackHandler callbackHandler, Map<String, ?> sharedState, Map<String, ?> options) {
        _sharedState = sharedState;
        _options = options;
    }

    public boolean login() throws LoginException {
        try {
            java.util.Hashtable<String, Object> customProperties = (java.util.Hashtable<String, Object>)
                _sharedState.get(AttributeNameConstants.WSCREDENTIAL_PROPERTIES_KEY);
            if (customProperties == null) {
                customProperties = new java.util.Hashtable<String, Object>();
            }

            customProperties.put(AttributeNameConstants.WSCREDENTIAL_USERID, "userId");
            // Sample of creating custom cache key
            customProperties.put(AttributeNameConstants.WSCREDENTIAL_CACHE_KEY, "customCacheKey");

            /*
             * Sample for creating user ID and security name
             * customProperties.put(AttributeNameConstants.WSCREDENTIAL_UNIQUEID, "userId");
             * customProperties.put(AttributeNameConstants.WSCREDENTIAL_SECURITYNAME, "securityName");
             * customProperties.put(AttributeNameConstants.WSCREDENTIAL_REALM, "realm");
             * customProperties.put(AttributeNameConstants.WSCREDENTIAL_GROUPS, "groupList");
             */
            /*
             * Sample for creating user ID and password
             * customProperties.put(AttributeNameConstants.WSCREDENTIAL_USERID, "userId");
             * customProperties.put(AttributeNameConstants.WSCREDENTIAL_PASSWORD, "password");
             */
            Map<String, java.util.Hashtable> mySharedState = (Map<String, java.util.Hashtable>) _sharedState;
            mySharedState.put(AttributeNameConstants.WSCREDENTIAL_PROPERTIES_KEY, customProperties);
        } catch (Exception e) {
            throw new LoginException("LoginException: " + e.getMessage());
        }

        return true;
    }

    public boolean commit() throws LoginException {
        return true;
    }

    public boolean abort() {
        return true;
    }

    public boolean logout() {
        return true;
    }
}

```

## What to do next

Add your custom login module into the WEB\_INBOUND, and DEFAULT Java Authentication and Authorization Service (JAAS) system login configurations of the server.xml file. Put the custom login module class in a JAR file, for example, customLoginModule.jar, then make the JAR file available to the Liberty server. See “Configuring a JAAS custom login module for Liberty” on page 1868.

## Developing a custom JASPIC authentication provider for Liberty

8.5.5.6

You can develop a custom Java Authentication SPI for Containers (JASPIC) authentication provider by creating classes that implement the required interfaces noted in the JSR 196: Java Authentication Service Provider Interface for Containers specification.

### Before you begin

Review the specific interface implementation requirements for JASPIC authentication providers and modules in the JSR 196: Java Authentication Service Provider Interface for Containers specification.

### About this task

WebSphere Application Server Liberty supports the use of third-party authentication providers that are compliant with the servlet container profile specified in Java Authentication SPI for Containers (JASPIC) Version 1.1.

The servlet container profile defines interfaces that are used by the security runtime environment in collaboration with the web container in the WebSphere Application Server to invoke authentication modules before and after a web request is processed by an application. Authentication that uses JASPIC modules is performed only when JASPIC is enabled in the security configuration.

To develop a custom authentication provider, create classes that implement the required interfaces noted in the JSR 196: Java Authentication Service Provider Interface for Containers specification. A provider can use one or more authentication modules for authentication. Modules can use callbacks to perform authentication, or they can manually add the necessary user identity information to the client subject.

### Procedure

1. Create a class that implements the `javax.security.auth.message.config.AuthConfigProvider` interface.

The `AuthConfigProvider` implementation class must define a public two-argument constructor and the `getServerAuthConfig` public method:

```
import java.util.Map;
import javax.security.auth.callback.CallbackHandler;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.config.AuthConfigFactory;
import javax.security.auth.message.config.AuthConfigProvider;
import javax.security.auth.message.config.ServerAuthConfig;

public class SampleAuthConfigProvider implements AuthConfigProvider {

    public SampleAuthConfigProvider(Map<String, String> properties, AuthConfigFactory factory) {
        ...
    }
    public ServerAuthConfig getServerAuthConfig(String layer, String appContext, CallbackHandler handler)
        throws AuthException {
        ...
    }
}
```

An instance of the `AuthConfigProvider` implementation class is used by WebSphere Application Server when a request arrives to be processed by the web module of the application. The `getServerAuthConfig` method is used to obtain a `ServerAuthConfig` instance. The `CallbackHandler` argument in the method call is used by the authentication module.

2. Create a class that implements the `javax.security.auth.message.config.ServerAuthConfig` interface. The `ServerAuthConfig` implementation class must define the `getAuthContextID` and `getAuthContext` public methods:

```
import java.util.Map;
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.config.ServerAuthConfig;
import javax.security.auth.message.config.ServerAuthContext;

public class SampleServerAuthConfig implements ServerAuthConfig {

    public String getAuthContextID(MessageInfo messageInfo) throws IllegalArgumentException {
        ...
    }
    public ServerAuthContext getAuthContext(String authContextID, Subject serviceSubject, Map properties)
        throws AuthException {
        ...
    }
}
```

The `getAuthContextID` and `getAuthContext` methods in the `ServerAuthConfig` implementation class are used to obtain a `ServerAuthContext` instance.

3. Create a class that implements the `javax.security.auth.message.config.ServerAuthContext` interface. The `ServerAuthContext` implementation class must define the `validateRequest` and `secureResponse` public methods:

```
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.config.ServerAuthContext;

public class SampleServerAuthContext implements ServerAuthContext {

    public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
        throws AuthException {
        ...
    }
    public AuthStatus secureResponse(MessageInfo messageInfo, Subject serviceSubject)
        throws AuthException {
        ...
    }
}
```

The `validateRequest` method in the `ServerAuthContext` implementation class is used to invoke the module that authenticates the received web request message. If the authentication result is successful, the web container dispatches the received web request message that the target web module processes in the application. If the authentication result is not successful, the request is rejected with the appropriate response status.

4. Create a class that implements the `javax.security.auth.message.module.ServerAuthModule` interface. The `ServerAuthModule` implementation class must define the `initialize`, `validateRequest`, and `secureResponse` public methods:

```
import javax.security.auth.Subject;
import javax.security.auth.callback.CallbackHandler;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.MessagePolicy;
```

```

import javax.security.auth.message.module.ServerAuthModule;

public class SampleAuthModule implements ServerAuthModule {

    public void initialize(MessagePolicy requestPolicy, MessagePolicy responsePolicy, CallbackHandler handler, Map<String, Object> context) throws AuthException {
        ...
    }

    public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject) throws AuthException {
        ...
    }

    public AuthStatus secureResponse(MessageInfo messageInfo, Subject serviceSubject) throws AuthException {
        ...
    }

    public void cleanSubject(MessageInfo messageInfo, Subject subject) throws AuthException {
        ...
    }
}

```

The `initialize` method in the `ServerAuthModule` implementation class is called by the `ServerAuthContext` implementation class to initialize the authentication module and to associate it with the `ServerAuthContext` instance.

The `validateRequest` and `secureResponse` methods in this class are used to authenticate the `javax.servlet.http.HttpServletRequest` and `javax.servlet.http.HttpServletResponse` contained in the `javax.security.auth.message.MessageInfo` that is received. These methods can use the `CallbackHandler` instance that is received in the `initialize` method to interact with the WebSphere security run time to validate a user password, and the active user registry to retrieve a unique id and group membership for a user. The retrieved data is placed in a `Hashtable` in the set of private credentials in the client subject. The WebSphere Application Server implementation of the `CallbackHandler` supports the following three callbacks:

- `CallerPrincipalCallback`
- `GroupPrincipalCallback`
- `PasswordValidationCallback`

WebSphere Application Server expects the name values obtained with `PasswordValidationCallback.getUsername()` and `CallerPrincipalCallback.getName()` to be identical. If they are not, unpredictable results occur. The `handle()` method of the `CallbackHandler` processes each callback that is given in the argument array of the method sequentially. Therefore, the name value set in the private credentials of the client subject is the one obtained from the last callback processed.

If `CallbackHandler` is not used by the authentication module, and `validateRequest` returns a successful status, WebSphere Application Server requires that a `Hashtable` instance be included in the `clientSubject` with user identity information so that a custom login can be performed to obtain the credentials for the user. This `Hashtable` can be added to the client subject as in the following example:

```

import java.util.Hashtable;
import java.util.String;
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import com.ibm.wsspi.security.registry.RegistryHelper;
import com.ibm.wsspi.security.token.AttributeNameConstants.AttributeNameConstants;

public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject) throws AuthException {
    ...
}

```

```

UserRegistry reg = RegistryHelper.getUserRegistry(null);
String uniqueid = reg.getUniqueUserID(username);

Hashtable hashtable = new Hashtable();
hashtable.put(AttributeConstants.WSCREDENTIAL_UNIQUEID, uniqueid);
hashtable.put(AttributeConstants.WSCREDENTIAL_SECURITYNAME, username);
hashtable.put(AttributeConstants.WSCREDENTIAL_PASSWORD, password);
hashtable.put(AttributeConstants.WSCREDENTIAL_GROUPS, groupList); //optional
clientSubject.getPrivateCredentials().add(hashtable);
...
}

```

For more information about the Hashtable requirements and custom login, see Developing JAAS custom login modules for a system login configuration.

## Developing a Java Authorization Contract for Containers (JACC) Authorization Provider

8.5.5.6

You can develop a JACC provider to have custom authorization decisions for Java Platform, Enterprise Edition (J2EE) applications by implementing the `com.ibm.wsspi.security.authorization.jacc.ProviderService` interface that is provided in the Liberty server.

### Before you begin

By default, the application module loading is deferred until the request to the application is being processed, however the security constraint of the entire module in the application needs to be processed before the application is ready to be processed. The deferred module loading needs to be disabled. The following shows you how to disable it:

1. For the WebContainer:

In the `server.xml` file, the following element needs to be set:

```
<webContainer deferServletLoad="false"/>
```

2. For the EJBContainer:

In the `server.xml` file, the following element needs to be set:

```
<ejbContainer startEJBsAtAppStart="true"/>
```

**Note:** If the previous elements are not set, the complete security constraint information may not be propagated to the third party JACC provider upon starting the server. As a result, the correct authorization decision may not be enforced by the third party JACC provider.

### About this task

The Java Authorization Contract for Containers specification, JSR 115, defines an interface for authorization providers. In the Liberty server, you must package your JACC provider as a user feature. Your feature must implement the `com.ibm.wsspi.security.authorization.jacc.ProviderService` interface.

### Procedure

1. Create an OSGi component that provides a service that implements the `com.ibm.wsspi.security.authorization.jacc.ProviderService` interface.

The `ProviderService` interface defines two methods, `getPolicy`, which the Liberty server run time invokes to retrieve an instance of your `Policy` class that implements the `java.security.Policy` abstract class, and `getPolicyConfigFactory`, which the Liberty server run time invokes to retrieve an instance

of your PolicyConfigurationFactory class that implements the javax.security.jacc.PolicyConfigurationFactory abstract class. The following example uses OSGi declarative services annotations:

```

package com.mycompany.jacc;

import com.mycompany.jacc.MyAuthConfigProvider;
import com.ibm.wsspi.security.authorization.jacc.ProviderService;
import java.security.Policy;
import java.util.Map;
import javax.security.jacc.PolicyConfigurationFactory;
import org.osgi.service.component.ComponentContext;
import org.osgi.service.component.annotations.Activate;
import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Deactivate;

// The property value of javax.security.jacc.policy.provider which defines the implementation class of Policy and
// javax.security.jacc.PolicyConfigurationFactory.provider which defines the implementation class of PolicyConfiguration
@Component(service = ProviderService.class,
    immediate = true,
    property = {
        "javax.security.jacc.policy.provider=com.myco.jacc.MyPolicy",
        "javax.security.jacc.PolicyConfigurationFactory.provider="
        + "com.myco.jacc.MyFactoryImpl"
    }
)

public class MyJaccProviderService implements ProviderService {
    Map<String, String> configProps;

    // This method called by the Liberty runtime
    // to get an instance of Policy class
    @Override
    public Policy getPolicy() {
        return new myPolicy();
    }

    // This method called by the Liberty runtime
    // to get an instance of PolicyConfigurationFactory class
    @Override
    public PolicyConfigurationFactory getPolicyConfigurationFactory() {
        ClassLoader cl = null;
        PolicyConfigurationFactory pcf = null;
        System.setProperty(
            "javax.security.jacc.PolicyConfigurationFactory.provider",
            "com.myco.jacc.MyFactoryImpl");
        try {
            cl = Thread.currentThread().getContextClassLoader();
            Thread.currentThread().setContextClassLoader(
                this.getClass().getClassLoader());
            pcf = PolicyConfigurationFactory.getPolicyConfigurationFactory();
        } catch (Exception e) {
            return null;
        } finally {
            Thread.currentThread().setContextClassLoader(cl);
        }
        return pcf;
    }

    @Activate
    protected void activate(ComponentContext cc) {
        // Read provider config properties here if needed,
        // then pass them to the Provider ctor.
        // This example reads the properties from the OSGi
        // component definition.
        configProps = (Map<String, String>) cc.getProperties();
    }
}

```

```

    }

    @Deactivate
    protected void deactivate(ComponentContext cc) {}
}

```

2. Package the component into an OSGi bundle that is part of your user feature, along with your JACC provider.
3. Ensure that your feature includes the OSGi subsystem content: `com.ibm.ws.javaee.jacc.1.5; version="[1,1.0.100)"; location="dev/api/spec/"`.
4. After the feature is installed into the user product extension location, configure the `server.xml` file with the feature name. For example:

```

<featureManager>
    ...
    <feature>usr:myJaccProvider</feature>
</featureManager>

```

## Developing a customPasswordEncryption Provider

8.5.5.9

You can develop a `customPasswordEncryption` provider to have custom authorization decisions for Java Platform, Enterprise Edition (J2EE) applications by implementing the `com.ibm.wsspi.security.crypto.CustomPasswordEncryption` interface that is provided in the Liberty server.

### About this task

#### Procedure

1. Create an OSGi component that provides a service that implements the `com.ibm.wsspi.security.crypto.CustomPasswordEncryption` interface.

The `CustomPasswordEncryption` interface defines three methods, `decrypt`, which the Liberty server run time invokes to decrypt the string, `encrypt`, which the Liberty server run time invokes to encrypt the string, and `initialize`, which is reserved for future use.

The following example uses OSGi declarative services annotations:

```

package com.mycompany.custom;

import org.osgi.service.component.ComponentContext;
import org.osgi.service.component.annotations.Activate;
import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.ConfigurationPolicy;
import org.osgi.service.component.annotations.Deactivate;
import org.osgi.service.component.annotations.Modified;

import com.ibm.wsspi.security.crypto.CustomPasswordEncryption;
import com.ibm.wsspi.security.crypto.EncryptedInfo;
import com.ibm.wsspi.security.crypto.PasswordDecryptException;
import com.ibm.wsspi.security.crypto.PasswordEncryptException;

/**
 */
@Component(service = CustomPasswordEncryption.class,
           immediate = true,
           name = "com.mycompany.CustomPasswordEncryptionImpl",
           configurationPolicy = ConfigurationPolicy.OPTIONAL,
           property = { "someKey=someValue" })
public class CustomPasswordEncryptionImpl implements CustomPasswordEncryption {

    @Activate
    protected synchronized void activate(ComponentContext cc, Map<String, Object> props) {
    }
}

```

```

@Modified
protected synchronized void modify(Map<String, Object> props) {
}

@Deactivate
protected void deactivate(ComponentContext cc) {
}

/**
 * The encrypt operation takes a UTF-8 encoded String in the form of a byte[].
 * The byte[] is generated from String.getBytes("UTF-8"). An encrypted byte[]
 * is returned from the implementation in the EncryptedInfo object.
 * Additionally, a logically key alias is returned in EncryptedInfo so which
 * is passed back into the decrypt method to determine which key was used to
 * encrypt this password. The WebSphere Application Server runtime has no
 * knowledge of the algorithm or key used to encrypt the data.
 *
 * @param decrypted_bytes
 * @return com.ibm.wsspi.security.crypto.EncryptedInfo
 * @throws com.ibm.wsspi.security.crypto.PasswordEncryptException
 */
@Override
public EncryptedInfo encrypt(byte[] input) throws PasswordEncryptException {
    byte[] output = null;
    String key = null;
    try {
        :
        <do some encryption>
        :
        return new EncryptedInfo(output, key);
    } catch (Exception e) {
        throw new PasswordEncryptException("Exception is caught", e);
    }
}

/**
 * The decrypt operation takes the EncryptedInfo object containing a byte[]
 * and the logical key alias and converts it to the decrypted byte[]. The
 * WebSphere Application Server runtime will convert the byte[] to a String
 * using new String (byte[], "UTF-8");
 *
 * @param info
 * @return byte[]
 * @throws PasswordEncryptException
 * @throws com.ibm.wsspi.security.crypto.PasswordDecryptException
 */
@Override
public byte[] decrypt(EncryptedInfo info) throws PasswordDecryptException {
    byte[] input = info.getEncryptedBytes();
    String key = info.getKeyAlias();
    byte[] output = null;
    try {
        :
        <do some decryption>
        :
        return output;
    } catch (Exception e) {
        throw new PasswordEncryptException("Exception is caught", e);
    }
}

/**
 * This is reserved for future use and is currently not called by the
 * WebSphere Application Server runtime.
 *
 * @param initialization_data

```

```

    **/
    @SuppressWarnings("rawtypes")
    @Override
    public void initialize(Map initialization_data) {}
}

```

2. Package the component into an OSGi bundle that is part of your user feature. Make sure that the bundle includes the OSGi service manifest.

The following example shows the contents of OSGi service manifest:

```

<?xml version="1.0" encoding="UTF-8"?>
<scr:component xmlns:scr="http://www.osgi.org/xmlns/scr/v1.1.0" name="com.mycompany.custom.CustomPasswordEncryptionImpl">
  <implementation class="com.mycompany.custom.CusomPasswordEncryptionImpl"/>
  <service>
    <provide interface="com.ibm.wsspi.security.crypto.CustomPasswordEncryption"/>
  </service>
  <property name="<someKey>" type="String" value="<someValue>"/>
</scr:component>

```

3. Ensure that your feature manifest includes the OSGi subsystem content with start-phase:="SERVICE\_EARLY". For example:

```

Manifest-Version: 1.0
IBM-Feature-Version: 2
IBM-ShortName: customPasswordEncryption-1.0
Subsystem-Type: osgi.subsystem.feature
Subsystem-Version: 1.0.0
Subsystem-ManifestVersion: 1.0
Subsystem-SymbolicName: customPasswordEncryption-1.0;visibility:=public
Subsystem-Content:
com.mycompany.custom; version="[1,1.0.100)"; start-phase:="SERVICE_EARLY"

```

4. After the feature is installed into the user product extension location, configure the server.xml file with the feature name.

```

<featureManager>
  ...
  <feature>usr:customPasswordEncryption-1.0</feature>
</featureManager>

```

## Customizing an application login to perform an identity assertion by using JAAS

You can use the Java Authentication and Authorization Service (JAAS) login framework to create a JAAS login configuration that can be used to perform login to an identity assertion on Liberty.

### About this task

By configuring identity assertion with trust validation, an application can use the JAAS login configuration to perform a programmatic identity assertion. See `IdentityAssertionLoginModule` for more detail.

**Avoid trouble:** Distributed operating systems 8.5.5.0 There are several security configuration examples on the WASdev.net website for reference when configuring security for your applications on Liberty. See “Configuring JAAS on Liberty by using developer tools” on page 1870.

### Procedure

1. Delegate trust validation to a user-implemented plug-in point.

Trust validation is accomplished by a custom login module. This custom login module performs any trust validation required, then sets the trust and identity information in the shared state to be passed on to the identity assertion login module. A map is required in the following shared state key:

```
com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state
```

If the state is missing then a `WSLoginFailedException` problem is reported by the `IdentityAssertionLoginModule` class.

The map in the shared state key must include a trust key with the following key name:

```
com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trust
```

If this key is set to true, then trust is established. If the key is set to false, then no trust is established and `IdentityAssertionLoginModule` class creates a `WSLoginFailedException` problem.

The map in the shared state key must also set one of the following resources:

- An identity key. A `java.security.Principal` can be set in the following key:  
`com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal`
- A `java.security.cert.X509Certificate[]`. This certificate can be set in the following key:  
`com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates`

If both a principal and certificate are supplied, then the principal is used and a warning is reported.

2. Create a JAAS configuration for application logins. The JAAS configuration will contain the user-implemented trust validation custom login module and `IdentityAssertionLoginModule` class. Then to configure an application login configuration, add the following code in the `server.xml` file:

```
<jaasLoginContextEntry id="CustomIdentityAssertion" name="CustomIdentityAssertion"
    loginModuleRef="customIdentityAssertion,identityAssertion" />
<jaasLoginModule id="customIdentityAssertion"
    className="com.ibm.ws.security.authentication.IdentityAssertionLoginModule"
    controlFlag="REQUIRED" libraryRef="customLoginLib"/>
<library id="customLoginLib">
    <fileset dir="{server.config.dir}" includes="IdentityAssertionLoginModule.jar"/>
</library>
```

This JAAS configuration is used by the application to perform an identity assertion.

3. Perform the programmable identity assertion. A program can now use the JAAS login configuration to perform a programmatic identity assertion. The application program can create a login context for the JAAS configuration created in step 2, then log in to that login context with the identity that would assert to. If the login is successful then that identity can be set in the current running process. The following example illustrates this process:

```
NameCallback handler = new NameCallback(new MyPrincipal("Joe"));
LoginContext lc = new LoginContext("customIdentityAssertion", handler);
lc.login(); //assume successful
Subject s = lc.getSubject();
WSSubject.setRunAsSubject(s);
// From here on , the runas identity is "Joe"
```

**Note:** The `MyPrincipal` class is the implementation of the `java.security.Principal` interface in the example.

## Results

Using the JAAS login framework and two user-implemented login modules, you can create a JAAS login configuration that can be used to log in to an identity assertion.

## Developing a custom user registry in Liberty

8.5.5.0

You can develop a custom user registry class by implementing the `com.ibm.websphere.security.UserRegistry` interface provided in the Liberty server.

## About this task

The `UserRegistry` interface is a Service Programming Interface (SPI) that enables support to virtually any type of account repository. For a general view of stand-alone custom registries, see [Stand-alone custom registries](#).

### Procedure

1. Implement the custom user registry. For more information, see [Developing the UserRegistry interface for using custom registries](#).
2. Convert the implementation class into an OSGi service. You can do the conversion in the following ways:
  - Convert your `UserRegistry` class into a Declarative Service (DS) component. For more information, see [“Declaring your services to OSGi Declarative Services”](#) on page 1794.
  - Write a new `UserRegistry` class that is a DS component and delegate it to your `UserRegistry` class.
  - Register your `UserRegistry` class directly in the Service Registry (SR) using the OSGi core APIs. For more information, see [“Working with the OSGi service registry”](#) on page 1789.
3. Package the custom user registry as an OSGi bundle and export the `UserRegistry` service. For information on creating an OSGi bundle, see [Creating an OSGi service bundle](#).
4. Create a feature manifest to include the OSGi bundle. For more information, see [“Liberty profile: Product extension”](#) on page 967.
5. After the feature is installed into the user product extension location, configure the `server.xml` file with the feature name. For example:

```
<featureManager>
  ...
  <feature>usr:customRegistrySample-1.0</feature>
</featureManager>
```

For a downloadable custom user registry sample, see [https://developer.ibm.com/wasdev/downloads/#asset/samples-Custom\\_User\\_Registry](https://developer.ibm.com/wasdev/downloads/#asset/samples-Custom_User_Registry).

For more information, see <https://www.ibm.com/docs/wasdev/docs/creating-a-custom-user-registry-as-a-liberty-user-feature/>.

## Developing JAAS custom login modules for database authentication

8.5.5.9

You can develop a Java Authentication and Authorization Service (JAAS) custom login module for adding a user name and password to authenticate to a database.

### About this task

You can develop a JAAS custom login module that can be invoked when a database connection that requires authentication is created. The JAAS custom login module is responsible of creating a password credential that contains the user name, password, and managed connection factory. The login module must add the password credential to the subject's private credentials set to be used to authenticate to the database.

### Procedure

1. Create a class that implements the `javax.security.auth.spi.LoginModule` interface.
2. Save the necessary fields in the initialize method. For example:

```
/** {@inheritDoc} */
@SuppressWarnings("unchecked")
@Override
public void initialize(Subject subject, CallbackHandler callbackHandler, Map<String, ?> sharedState, Map<String, ?> o
    this.callbackHandler = callbackHandler;
```

```

    this.subject = subject;
    this.sharedState = (Map<String, Object>) sharedState;
    this.options = options;
}

```

3. Handle the `WSManagedConnectionFactoryCallback` and `WSMappingPropertiesCallback` callbacks in the login method. For example:

```

/** {@inheritDoc} */
@Override
public boolean login() throws LoginException {
    ...
    Callback callbacks[] = new Callback[2];
    callbacks[0] = new WSManagedConnectionFactoryCallback("Target ManagedConnectionFactory: ");
    callbacks[1] = new WSMappingPropertiesCallback("Mapping Properties (HashMap): ");
    callbackHandler.handle(callbacks);
}

```

4. Obtain the managed connection factory and properties in the login method. For example:

```

// The method getManagedConnectionFactory must be used as shown for compatibility with WAS Classic
ManagedConnectionFactory managedConnectionFactory = ((WSManagedConnectionFactoryCallback) callbacks[0]).getManagedConnectionFactory();
Map properties = ((WSMappingPropertiesCallback) callbacks[1]).getProperties();

```

5. Obtain the user name and password based on the authentication data alias or some other criteria. For example:

```

String alias = (String) properties.get(com.ibm.wsspi.security.auth.callback.Constants.MAPPING_ALIAS);
String user = getUser(alias); // Implementation specific
char[] password = getPassword(alias); // Implementation specific

```

6. Create a `javax.resource.spi.PasswordCredential` object with the user name and password and set the managed connection factory. For example:

```

javax.resource.spi.security.PasswordCredential passwordCredential = new PasswordCredential(user, password);
passwordCredential.setManagedConnectionFactory(managedConnectionFactory);

```

7. Add the password credential to the subject in the commit method. For example:

```

/** {@inheritDoc} */
@Override
public boolean commit() throws LoginException {
    // Verify that the login was successful before adding the PasswordCredential to the subject.
    subject.getPrivateCredentials().add(passwordCredential);
    return true;
}

```

## Developing a programmatic login for obtaining authentication data

8.5.5.9

You can use the Java Authentication and Authorization Service (JAAS) login framework to obtain the authentication data from your application.

### About this task

Your application can perform a JAAS programmatic login using the `DefaultPrincipalMapping` JAAS context entry name to obtain a `Subject` object with a `javax.resource.spi.security.PasswordCredential` instance in the private credentials set that contains the user name and password configured for an `authData` element.

### Procedure

1. Add the `appSecurity-2.0`, `passwordUtilities-1.0`, and `jca-1.7` features in the `server.xml` file. You can also add `appSecurity-2.0`, `passwordUtilities-1.0`, and `jca-1.6`. For example:

```

<featureManager>
  <feature>appSecurity-2.0</feature>
  <feature>passwordUtilities-1.0</feature>
  <feature>jca-1.7</feature>
</featureManager>

```

2. Configure an `authData` element in the `server.xml` file. For example:

```
<authData id="myAuthData" user="myUser" password="myPassword"/> <!-- password can also be encoded -->
```

Encode the password within the configuration. You can get the encoded value by using the `securityUtility` `encode` command.

3. Perform a programmatic login with the `DefaultPrincipalMapping` JAAS login context entry name from your application servlet or enterprise bean, replacing the mapping alias with the one you need. For example:

```
HashMap map = new HashMap();
map.put(com.ibm.wsspi.security.auth.callback.Constants.MAPPING_ALIAS, "myAuthData"); // Replace value with your alias
CallbackHandler callbackHandler = new com.ibm.wsspi.security.auth.callback.WSMappingCallbackHandler(map, null);
LoginContext loginContext = new LoginContext("DefaultPrincipalMapping", callbackHandler);
loginContext.login();
Subject subject = loginContext.getSubject();
Set<javax.resource.spi.security.PasswordCredential> creds = subject.getPrivateCredentials(javax.resource.spi.security.PasswordCredential passwordCredential = creds.iterator().next());
```

**Note:** The error handling is not shown for simplicity. A `javax.security.auth.login.LoginException` is returned if the authentication alias requested does not exist or is malformed.

4. Obtain the user name and password from the `PasswordCredential`. For example:

```
String userName = passwordCredential.getUserName();
char[] password = passwordCredential.getPassword();
// Do something with the userName and password.
```

5. If Java 2 Security is enabled, then the application must be granted the `javax.security.auth.PrivateCredentialPermission`. For example, grant the permission in the application's `META-INF/permissions.xml` file to access the `PasswordCredential` object:

```
<?xml version="1.0" encoding="UTF-8"?>
<permissions xmlns="http://xmlns.jcp.org/xml/ns/javaee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:schemaLocation="http://xmlns.jcp.org/xml/ns/javaee http://xmlns.jcp.org/xml/ns/javaee/xsi.xsd">

  <permission>
    <class-name>javax.security.auth.PrivateCredentialPermission</class-name>
    <name>javax.resource.spi.security.PasswordCredential * "*"</name>
    <actions>read</actions>
  </permission>

  <!-- Other permissions -->

</permissions>
```

For more information about Java 2 Security, see [Liberty: Java 2 Security](#).

## Developing a custom thread identity service

You can develop a custom thread identity service class by implementing the `com.ibm.wsspi.kernel.security.thread.ThreadIdentityService` interface that is provided in the Liberty server. The `ThreadIdentityService` interface is a Service Programming Interface (SPI) that enables support to receive notifications of user identity switches.

### Procedure

1. Create a custom thread identity service by implementing the `ThreadIdentityService` interface.
2. Convert the implementation class into an OSGi service. You can do the conversion in either of two ways:
  - a. Convert your `ThreadIdentityService` class into a Declarative Service (DS) component. For more information, see “Declaring your services to OSGi Declarative Services” on page 1794.
  - b. Write a new `ThreadIdentityService` class that is a DS component and delegate it to your `ThreadIdentityService` class. Register your `ThreadIdentityService` class directly in the Service Registry (SR) by using the OSGi core APIs. For more information, see “Working with the OSGi service registry” on page 1789.

3. Package the custom thread identity service as an OSGi bundle and export the ThreadIdentityService service. For information on creating an OSGi bundle, see [Creating an OSGi service bundle](#).
4. Create a feature manifest to include the OSGi bundle. For more information, see “Liberty profile: Product extension” on page 967.
5. After the feature is installed into the user product extension location, configure the server.xml file with the feature name.

```
<featureManager>
  ...
  <feature>usr:sampleThreadIdentityService-1.0</feature>
</featureManager>
```

---

## Web services security

### 8.5.5.0

Security is a major quality of service (QoS) requirement for QoS enabled web services. You can provide security for web services in several ways, two of which include transport layer security and message level security.

### Securing web services at the transport layer

Transport-level security is based on a Secure Sockets Layer (SSL) or Transport Layer Security (TLS) and is used to protect HTTP message contents point to point.

### Securing web services at the message level

Message-level security protects the SOAP contents that are contained within an HTTP message for a web service.

## Securing web services at the transport level

### 8.5.5.0

Transport-level security is a well-known and often used mechanism to secure HTTP Internet and intranet communications. Transport-level security can be used to secure web services messages. Transport-level security functionality is independent from functionality that is provided by message-level security (WS-Security) or HTTP basic authentication. You can use the transport-level security binding to secure the communication between your web service client and web service provider.

### Before you begin

The `ibm-ws-bnd.xml` file must be in the `/WEB-INF` directory of a web-based web services application (WAR file), or in the `/META-INF` directory of an EJB-based web service application (JAR file).

**Note:** 8.5.5.6 If the client is running in the Liberty application client container, the `ibm-ws-bnd.xml` file must be in the `/META-INF` directory of the JAR file in the client EAR.

### About this task

Transport-level security is based on Secure Sockets Layer (SSL) or Transport Layer Security (TLS) that runs beneath HTTP.

SSL and TLS provide security features including authentication, data protection, and cryptographic token support for secure HTTP connections. To run with HTTPS, the service port address must be in the form

https://. The integrity and confidentiality of transport data, including SOAP messages and HTTP basic authentication, is confirmed when you use SSL and TLS.

Liberty uses the Java Secure Sockets Extension (JSSE) package to support SSL and TLS. The following security configurations are supported for web services protection in Liberty:

- Secured HTTP
- Basic authentication
- Client certification

For all available elements that you can configure within the `ibm-ws-bnd.xml` file, see “Liberty:The `ibm-ws-bnd.xml` file” on page 2186.

## Procedure

- Enable SSL communications between a web service client and service provider
- Optional: Enable basic authentication between a web service client and service provider
- Optional: Enable client certificate authentication between a web service client and service provider

## Enabling SSL communication for web services access

0.5.5.0

You can configure SSL communication for your client applications to access web services.

### Before you begin

You must complete the following prerequisites before enabling the SSL communication for web services access:

- Generate a pair of self-signed public and private keys for client and provider:

```
keytool -genkey -alias default -keystore myKey.jks -dname "CN=myServer, O=IBM, C=CN"
        -storepass passw0rd -keypass passw0rd -storetype jks -validity 1000 -keyalg RSA
```
- Copy the `myKey.jks` file to the `${server.config.dir}/resources/security` directory of the Liberty server.

**Note:** The `keytool` utility can be found in your Java installation directory.

### About this task

If you need to use your web service client application with the secured HTTP protocol to access the protected web service resources, all the message are encrypted according to the SSL specification.

## Procedure

1. Enable the `jaxws-2.2`, `servlet-3.0`(or `servlet-3.1`) and `appSecurity-2.0` features in the `server.xml` file.

```
<featureManager>
  <feature>jaxws-2.2</feature>
  <feature>servlet-3.0</feature>
  <feature>appSecurity-2.0</feature>
</featureManager>
```

2. Configure the SSL elements in the `server.xml` file.

```
<sslDefault sslRef="customizeSSLConfig" />
<ssl id="customizeSSLConfig" keyStoreRef="serverKeyStore" trustStoreRef="serverTrustStore" />
<keyStore id="serverKeyStore" location="myKey.jks" type="JKS" password="passw0rd" />
<keyStore id="serverTrustStore" location="myKey.jks" type="JKS" password="passw0rd" />
```

3. Configure the service provider by specifying the web service endpoints.

a. Create web services.

```
@WebService(serviceName = "SayHelloPojoService",
             portName = "SayHelloPojoPort")
public class SayHelloPojoService implements SayHelloService {
    ...
}

@WebService(serviceName = "SayHelloStatelessService",
            portName = "SayHelloStatelessPort",
            endpointInterface = "com.ibm.ws.jaxws.transport.server.security.SayHelloService")
@Stateless(name = "SayHelloSessionBean")
public class SayHelloStatelessService implements SayHelloLocal {
    ...
}
```

b. Configure the `ibm-ws-bnd.xml` file for the service provider.

```
<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee
    http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0.xsd "
  version="1.0">
<http-publishing>
<webservice-security>
<security-constraint>
<web-resource-collection>
<web-resource-name>All</web-resource-name>
<url-pattern>*/*/url-pattern>
<http-method>GET</http-method>
<http-method>POST</http-method>
</web-resource-collection>
<user-data-constraint>
<transport-guarantee>CONFIDENTIAL</transport-guarantee>
</user-data-constraint>
</security-constraint>
</webservice-security>
</http-publishing>
</webservices-bnd>
```

**Note:** The `ibm-ws-bnd.xml` file must be in the `/WEB-INF` directory of a web application, or the `/META-INF` directory of a EJB-based web service application (JAR archive).

4. Configure the service client by specifying the web service endpoints. For example, the client application is a web application named `TransportSecurityClient.war`.

a. Configure the client application in the `server.xml` file.

```
<application id="TransportSecurityClient" name="TransportSecurityClient"
  location="TransportSecurityClient.war"
  context-root="TransportSecurityClient" type="war" />
```

b. Configure the `ibm-ws-bnd.xml` file for the client application.

```
<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd id="idvalue0" version="1.0" xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee
    http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0.xsd " >
<!-- POJO service reference binding-->
<service-ref name="service/SayHelloPojoService">
<port name="SayHelloPojoPort"
  namespace="http://ibm.com/ws/jaxws/transport/security/"
  ssl-ref="customizeSSLConfig"/>
<properties http.conduit.tlsClientParameters.disableCNCheck="true" />
</service-ref>
<!-- Stateless service reference binding-->
<service-ref name="service/SayHelloStatelessService">
<port name="SayHelloStatelessPort"
  namespace="http://ibm.com/ws/jaxws/transport/security/"
```

```

        ssl-ref="customizeSSLConfig"/>
        <properties http.conduit.tlsClientParameters.disableCNCheck="true" />
    </service-ref>
</webservices-bnd>

```

**Note:**

- The `ibm-ws-bnd.xml` file must be in the `/WEB-INF` directory of the client web application.
- The value of `ssl-ref` attribute must match the ID value of `ssl` element in `server.xml` file.
- If the `ssl-ref` attribute is not specified in the `ibm-ws-bnd.xml` file, the default SSL configuration in Liberty is used by the web services engine if the configuration is present.
- The `http.conduit.tlsClientParameters.disableCNcheck` attribute is used to control whether to validate the remote server. Use *false* for this attribute in a production environment because the `hostName` verification will be ignored if this attribute is *true*.

c. Generate the client stubs through WSDL location.

```

@WebServiceClient(name = "SayHelloPojoService",
    targetNamespace = "http://ibm.com/ws/jaxws/transport/security/",
    wsdlLocation = "https://localhost:8020/TransportSecurityProvider/Unauthorized/employPojoService?wsdl")
public class SayHelloPojoService
    extends Service
{...}

@WebServiceClient(name = "SayHelloStatelessService",
    targetNamespace = "http://ibm.com/ws/jaxws/transport/security/",
    wsdlLocation = "https://localhost:8020/TransportSecurityProvider/Unauthorized/EmployStatelessService?wsdl")
public class SayHelloStatelessService
    extends Service
{...}

```

d. Use the `@WebServiceRef` annotation to inject the web service into the servlet. For example, the `TestJaxWsTransportSecurityServlet`.

```

@WebServiceRef(name = "service/SayHelloPojoService")
SayHelloPojoService pojoService;

@WebServiceRef(name = "service/SayHelloStatelessService")
SayHelloStatelessService statelessService;

```

## Enabling basic authentication for web services access

**8.5.5.0**

You can configure basic authentication for your client applications to access web services.

### About this task

If you need to use your web service client application with the basic authentication to access the protected web service resources, the client must provide the user name and password in the request when communicating with the service provider.

### Procedure

1. Enable the `jaxws-2.2`, `servlet-3.0`(or `servlet-3.1`) and `appSecurity-2.0` features in the `server.xml` file.

```

<featureManager>
    <feature>jaxws-2.2</feature>
    <feature>servlet-3.0</feature>
    <feature>appSecurity-2.0</feature>
</featureManager>

```

2. Configure the login realm in the `server.xml` file and bind the realm to the service provider.

```

<application id="TransportSecurityProvider" name="TransportSecurityProvider"
    location="TransportSecurityProvider.war" type="ear">
    <application-bnd>
        <security-role name="Employee">

```

```

        <user name="employee0" />
        <group name="employeeGroup" />
    </security-role>
    <security-role name="Manager">
        <user name="manager0" />
    </security-role>
    <security-role name="AllAuthenticated">
        <special-subject type="ALL_AUTHENTICATED_USERS" />
    </security-role>
</application-bnd>
</application>

<basicRegistry id="basic" realm="BasicRealm">
    <user name="employee0" password="emp0pwd" />
    <user name="employee1" password="emp1pwd" />
    <user name="manager0" password="mgr0pwd" />
    <group name="employeeGroup">
        <member name="employee0" />
        <member name="employee1" />
    </group>
</basicRegistry>

```

### 3. Configure the service provider by specifying the web service endpoints.

#### a. Create web services.

```

@WebService(serviceName = "SayHelloPojoService",
            portName = "SayHelloPojoPort")
public class SayHelloPojoService implements SayHelloService {
    ...
}

@WebService(serviceName = "SayHelloStatelessService",
            portName = "SayHelloStatelessPort",
            endpointInterface = "com.ibm.ws.jaxws.transport.server.security.SayHelloService")
@Stateless(name = "SayHelloSessionBean")
public class SayHelloStatelessService implements SayHelloLocal {
    ...
}

```

#### b. Configure the ibm-ws-bnd.xml file for the service provider.

```

<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0.xsd"
    version="1.0">
<http-publishing>
<webservice-security>
<security-constraint>
<web-resource-collection>
<web-resource-name>Only Managers</web-resource-name>
<url-pattern>/manager/*</url-pattern>
<http-method>GET</http-method>
<http-method>POST</http-method>
</web-resource-collection>
<auth-constraint id="AuthConstraint_manager">
<role-name>Manager</role-name>
</auth-constraint>
</security-constraint>
<security-constraint>
<web-resource-collection>
<web-resource-name>Employees</web-resource-name>
<url-pattern>/employee/*</url-pattern>
<http-method>GET</http-method>
<http-method>POST</http-method>
</web-resource-collection>
<auth-constraint id="AuthConstraint_employee">
<role-name>Employee</role-name>
</auth-constraint>
</security-constraint>
<!-- SECURITY ROLES -->
<security-role id="Staff">
<role-name>Employee</role-name>

```

```

    <role-name>Manager</role-name>
  </security-role>
  <!-- AUTHENTICATION METHOD: Basic authentication -->
  <login-config id="LoginConfig">
    <auth-method>BASIC</auth-method>
    <realm-name>Authentication</realm-name>
  </login-config>
</webservice-security>
</http-publishing>
</webservices-bnd>

```

**Note:**

- The `ibm-ws-bnd.xml` file must be in the `/WEB-INF` directory of a web application, or the `/META-INF` directory of an EJB-based web service application (JAR archive).
- The `login-config` element in the `ibm-ws-bnd.xml` file takes effect only in an EJB-based web service application (JAR archive). For a web application, the `login-config` element is ignored and the value of the same element in the `web.xml` file is used.

4. Configure the service client by specifying the web service endpoints. For example, the client application is a web application named `TransportSecurityClient.war`.

a. Configure the client application in the `server.xml` file.

```

<application id="TransportSecurityClient" name="TransportSecurityClient"
  location="TransportSecurityClient.war"
  context-root="TransportSecurityClient" type="war" />

```

b. Configure the `ibm-ws-bnd.xml` file for the client application.

```

<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0.xsd"
  version="1.0">
  <!-- POJO service reference binding-->
  <service-ref name="service/SayHelloPojoService">
    <port name="SayHelloPojoPort"
      namespace="http://ibm.com/ws/jaxws/transport/security/"
      username="employee1"
      password="{xor}0jIvbi8o0w=="
    />
  </service-ref>
  <!-- Stateless service reference binding-->
  <service-ref name="service/SayHelloStatelessService">
    <port name="SayHelloStatelessPort"
      namespace="http://ibm.com/ws/jaxws/transport/security/"
      username="employee1"
      password="{xor}0jIvbi8o0w=="
    />
  </service-ref>
</webservices-bnd>

```

**Note:**

- The `ibm-ws-bnd.xml` file must be in the `/WEB-INF` directory of the client web application.
- The values of **username** and **password** attributes must match the user name and password of `basicRegistry` element in `server.xml` file. The password can be encoded by using the `securityUtility` command.

c. Generate the client stubs by using the `wsdl` location.

```

@WebServiceClient(name = "SayHelloPojoService",
  targetNamespace = "http://ibm.com/ws/jaxws/transport/security/",
  wsdlLocation = "https://localhost:8020/TransportSecurityProvider/authorized/employPojoService?wsdl")
public class SayHelloPojoService
  extends Service
{...}

@WebServiceClient(name = "SayHelloStatelessService",
  targetNamespace = "http://ibm.com/ws/jaxws/transport/security/",
  wsdlLocation = "https://localhost:8020/TransportSecurityProvider/authorized/EmployStatelessService?wsdl")
public class SayHelloStatelessService
  extends Service
{...}

```

- d. Use the `@WebServiceRef` annotation to inject the web service into the servlet. For example, the `TestJaxWsTransportSecurityServlet`.

```
@WebServiceRef(name = "service/SayHelloPojoService")
SayHelloPojoService pojoService;

@WebServiceRef(name = "service/SayHelloStatelessService")
SayHelloStatelessService statelessService;
```

## Enabling client certificate authentication for web services access

0.5.5.0

You can configure client certificate authentication for your client applications to access web services.

### Before you begin

You must complete the following prerequisites before enabling client certificate authentication for web services access:

- Generate a pair of self-signed public and private keys for provider.  

```
keytool -genkey -alias default -keystore serverKey.jks -dname "CN=myServer, O=IBM, C=CN"
-storepass passw0rd -keypass passw0rd -storetype jks -validity 1000 -keyalg RSA
```
- Export the certificate of the default and import the certificate into the trust store.  

```
keytool -export -alias default -file myserver.cer -keystore serverKey.jks
-storepass passw0rd -storetype jks
keytool -import -file myserver.cer -alias default -keystore clientTrust.jks
-storepass passw0rd -keypass passw0rd -storetype jks
```
- Generate two pairs of self-signed public and private for client.  

```
keytool -genkey -alias user0 -keystore clientKey.jks -dname "CN=employee0, O=IBM, C=CN"
-storepass passw0rd -keypass passw0rd -storetype jks -validity 1000 -keyalg RSA
keytool -genkey -alias admin0 -keystore clientKey.jks -dname "CN=manager0, O=IBM, C=CN"
-storepass passw0rd -keypass passw0rd -storetype jks -validity 1000 -keyalg RSA
```
- Export the certificates of the two alias and import the certificate into the trust store.  

```
keytool -export -alias user0 -file user0.cer -keystore clientKey.jks -storepass passw0rd -storetype jks
keytool -export -alias admin0 -file admin0.cer -keystore clientKey.jks -storepass passw0rd -storetype jks
keytool -import -file user0.cer -alias user0 -keystore serverTrust.jks -storepass passw0rd -keypass passw0rd -storetype jks
keytool -import -file admin0.cer -alias admin0 -keystore serverTrust.jks -storepass passw0rd -keypass passw0rd -storetype jks
```
- Copy the `serverKey.jks`, `serverTrust.jks`, `clientKey.jks`, and `clientTrust.jks` files to the `${server.config.dir}/resources/security` directory.

**Note:** The `keytool` utility can be found in your Java installation directory.

### About this task

If you need to use the web service client application with the Client Certificate Authentication to access the protected web service resources, the client must provide the valid certificate in the request and must use the HTTPS to communicate with the service provider.

### Procedure

1. Enable the `jaxws-2.2`, `servlet-3.0`(or `servlet-3.1`) and `appSecurity-2.0` features in the `server.xml` file.  

```
<featureManager>
  <feature>jaxws-2.2</feature>
  <feature>servlet-3.0</feature>
  <feature>appSecurity-2.0</feature>
</featureManager>
```
2. Configure the SSL element and client customized SSL element in the `server.xml` file.

```

<!-- Server SSL configuration -->
<ssl id="defaultSSLConfig" keyStoreRef="serverKeyStore" trustStoreRef="serverTrustStore"
  clientAuthenticationSupported="true"/>
<keyStore id="serverKeyStore" location="serverKey.jks" type="JKS" password="passw0rd" />
<keyStore id="serverTrustStore" location="serverTrust.jks" type="JKS" password="passw0rd" />

<!-- customize SSL configuration -->
<ssl id="customizeSSLConfig" keyStoreRef="clientKeyStore" trustStoreRef="clientTrustStore" />
<keyStore id="clientKeyStore" location="clientKey.jks" type="JKS" password="passw0rd" />
<keyStore id="clientTrustStore" location="clientTrust.jks" type="JKS" password="passw0rd" />

```

### 3. Configure the login realm in the server.xml file and bind the realm to the service provider.

```

<application id="TransportSecurityProvider" name="TransportSecurityProvider"
  location="TransportSecurityProvider.war" type="ear">
  <application-bnd>
    <security-role name="Employee">
      <user name="employee0" />
      <group name="employeeGroup" />
    </security-role>
    <security-role name="Manager">
      <user name="manager0" />
    </security-role>
    <security-role name="AllAuthenticated">
      <special-subject type="ALL_AUTHENTICATED_USERS" />
    </security-role>
  </application-bnd>
</application>

<basicRegistry id="basic" realm="BasicRealm">
  <user name="employee0" password="emp0pwd" />
  <user name="employee1" password="emplpwd" />
  <user name="manager0" password="mgr0pwd" />
  <group name="employeeGroup">
    <member name="employee0" />
    <member name="employee1" />
  </group>
</basicRegistry>

```

### 4. Configure the service provider.

#### a. Create web services.

```

@WebService(serviceName = "SayHelloPojoService",
  portName = "SayHelloPojoPort")
public class SayHelloPojoService implements SayHelloService {
  ...
}

@WebService(serviceName = "SayHelloStatelessService",
  portName = "SayHelloStatelessPort",
  endpointInterface = "com.ibm.ws.jaxws.transport.server.security.SayHelloService")
@Stateless(name = "SayHelloSessionBean")
public class SayHelloStatelessService implements SayHelloLocal {
  ...
}

```

#### b. Configure the ibm-ws-bnd.xml file for the service provider.

```

<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0.xsd"
  version="1.0">

<http-publishing>
<webservice-security>
<security-constraint>
<web-resource-collection>
  <web-resource-name>Only Managers</web-resource-name>
  <url-pattern>/manager/*</url-pattern>
  <http-method>GET</http-method>

```

```

    <http-method>POST</http-method>
  </web-resource-collection>
  <auth-constraint id="AuthConstraint_manager">
    <role-name>Manager</role-name>
  </auth-constraint>
  <user-data-constraint>
    <transport-guarantee>CONFIDENTIAL</transport-guarantee>
  </user-data-constraint>
</security-constraint>
<security-constraint>
  <web-resource-collection>
    <web-resource-name>Employees</web-resource-name>
    <url-pattern>/employee/*</url-pattern>
    <http-method>GET</http-method>
    <http-method>POST</http-method>
  </web-resource-collection>
  <auth-constraint id="AuthConstraint_employee">
    <role-name>Employee</role-name>
  </auth-constraint>
  <user-data-constraint>
    <transport-guarantee>CONFIDENTIAL</transport-guarantee>
  </user-data-constraint>
</security-constraint>
<!-- SECURITY ROLES -->
<security-role id="Staff">
  <role-name>Employee</role-name>
  <role-name>Manager</role-name>
</security-role>
<!-- AUTHENTICATION METHOD: client-cert authentication -->
<!-- login configuration -->
<login-config id="LoginConfig">
  <auth-method>CLIENT-CERT</auth-method>
  <realm-name>Authentication</realm-name>
</login-config>
</webservice-security>
</http-publishing>
</webservices-bnd>

```

**Note:**

- The `ibm-ws-bnd.xml` file must be in the `/WEB-INF` directory of a web application, or the `/META-INF` directory of an EJB-based web service application (JAR archive).
- The `login-config` element in the `ibm-ws-bnd.xml` file takes effect only in an EJB-based web service application (JAR archive). For a web application, the `login-config` element is ignored and the value of the same element in the `web.xml` file is used.

5. Configure the service client by specifying the web service endpoints. For example, the client application is a web application named `TransportSecurityClient.war`.

a. Configure the client application in the `server.xml` file.

```

<application id="TransportSecurityClient" name="TransportSecurityClient"
  location="TransportSecurityClient.war"
  context-root="TransportSecurityClient" type="war" />

```

b. Configure the `ibm-ws-bnd.xml` file for the client application.

```

<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0.xsd"
  version="1.0">
  <!-- POJO service reference binding-->
  <service-ref name="service/SayHelloPojoService">
    <port name="SayHelloPojoPort"
      namespace="http://ibm.com/ws/jaxws/transport/security/"
      ssl-ref="customizeSSLConfig"
      key-alias="user0"/>
    <properties http.conduit.tlsClientParameters.disableCNCheck="true" />
  </service-ref>
  <!-- Stateless service reference binding-->
  <service-ref name="service/SayHelloStatelessService">
    <port name="SayHelloStatelessPort"
      namespace="http://ibm.com/ws/jaxws/transport/security/"
      ssl-ref="customizeSSLConfig"

```

```

    key-alias="user0"/>
    <properties http.conduit.tlsClientParameters.disableCNCheck="true" />
  </service-ref>
</webservices-bnd>

```

#### Note:

- The `ibm-ws-bnd.xml` file must be in the `/WEB-INF` directory of the client web application.
- The **key-alias** attribute specifies the valid client certificate in client key store that is defined in the `server.xml` file. In this example, the client keystore is defined as follows:
 

```
<keyStore id="clientKeyStore" location="clientKey.jks" type="JKS" password="passw0rd" />
```
- The **ssl-ref** attribute in the `ibm-ws-bnd.xml` file must match the correct **id** attribute of the `ssl` element in the `server.xml` file. In this example, the `ssl` element is defined as follows:
 

```
<ssl id="customizeSSLConfig" keyStoreRef="clientKeyStore" trustStoreRef="clientTrustStore" />
```
- The value of **key-alias** attribute can also override the value of **clientKeyAlias** attribute of the `ssl` element in the `server.xml` file.

#### c. Generate the client stubs through WSDL location.

```

@WebServiceClient(name = "SayHelloPojoService",
    targetNamespace = "http://ibm.com/ws/jaxws/transport/security/",
    wsdlLocation = "https://localhost:8020/TransportSecurityProvider/unauthorized/employPojoService?wsdl")
public class SayHelloPojoService
    extends Service
{...}

@WebServiceClient(name = "SayHelloStatelessService",
    targetNamespace = "http://ibm.com/ws/jaxws/transport/security/",
    wsdlLocation = "https://localhost:8020/TransportSecurityProvider/unauthorized/EmployStatelessService?wsdl")
public class SayHelloStatelessService
    extends Service
{...}

```

- d. Use the `@WebServiceRef` annotation to inject the web service into the servlet. For example, the `TestJaxWsTransportSecurityServlet`.

```

@WebServiceRef(name = "service/SayHelloPojoService")
SayHelloPojoService pojoService;

@WebServiceRef(name = "service/SayHelloStatelessService")
SayHelloStatelessService statelessService;

```

## Web Services Security at the message level

### 8.5.5.0

Web services message level security (Web Services Security or WS-Security) is a security quality of service (QoS) for web services applications. WS-Security standards and profiles describe how to provide security and protection for SOAP messages that are exchanged in a web services environment.

### 8.5.5.0

WS-Security is provided as a Liberty feature. The WS-Security run time that is provided in Liberty is based on the Apache CXF open source services framework. The WS-Security feature in Liberty is limited by the features and function of the Apache CXF framework. WS-Security must be explicitly enabled by enabling the `wsSecurity-1.1` feature. Make sure you also add the `appSecurity-2.0`, `servlet-3.0`(or `servlet-3.1`) and `jaxws-2.2` features, and other required Liberty features to the `server.xml` file of the Liberty.

WS-Security is configured by using the `WS-SecurityPolicy` within the WSDL file of a web service application. To protect your web service application with WS-Security, your JAX-WS application must contain a `wsdl` that has an embedded WS-Security policy. There must be a `PolicyReference` to the embedded WS-Security policy in either the `wsdl:binding` or `wsdl:operation` sections or both.

## Web Services Security specifications and standards

### 8.5.5.0

Liberty supports a number of Organization for the Advancement of Structured Information Standards (OASIS) standards.

- Web Services Security SOAP Message Security 1.1: <http://docs.oasis-open.org/wss/v1.1/wss-v1.1-spec-os-SOAPMessageSecurity.pdf>
- Web Services Security Username Token Profile 1.1: <http://docs.oasis-open.org/wss/v1.1/wss-v1.1-spec-os-UsernameTokenProfile.pdf>
- Web Services Security X.509 Certificate Token Profile 1.1: <http://docs.oasis-open.org/wss/v1.1/wss-v1.1-spec-os-x509TokenProfile.pdf>
- WS-SecurityPolicy 1.3: <http://docs.oasis-open.org/ws-sx/ws-securitypolicy/v1.3/os/ws-securitypolicy-1.3-spec-os.pdf>

## WS-Security behavior differences between traditional and Liberty

### 8.5.5.0

The WS-Security constraints that can be added to a web service application in Liberty may behave differently from the same constraints applied to a service in traditional.

### WS-Security enablement and configuration

WS-Security in Liberty is configured by using the WS-SecurityPolicy within the WSDL file of a web service application, and is enabled by adding the wsSecurity-1.1 feature in the server.xml file.

WS-Security in traditional is configured by using a policysset and enabled by attaching a policysset. If you deploy a WS-Security enabled Liberty web service application to traditional, you must create and attach an equivalent policysset and bindings to get the same level of web service security.

### WS-Security Policy

- Namespaces
  - The Liberty CXF WS-Security supports the following WS-Security Policy namespaces:  
<http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702>  
<http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200802>
  - The following namespace is also supported, with limitations:  
<http://schemas.xmlsoap.org/ws/2005/07/securitypolicy>
  - The WS-Security of traditional supports the following WS-Security Policy namespaces:  
<http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200512>

- Assertions

Liberty supports more assertions in the WS-Security Policy 1.2 than traditional. Some policy assertions in traditional WS-Security are implemented through XPath or bindings. The following list shows some important differences:

- Supporting Tokens

To sign or encrypt a SupportingToken such as a UsernameToken in Liberty, you assert the token as SignedSupportingTokens, SignedEncryptedSupportingTokens, or EncryptedSupportingTokens. In traditional, you must use an XPath expression to sign or encrypt a SupportingToken.

All endorsing tokens are not supported in traditional, including EndorsingSupportingTokens, SignedEndorsingSupportingTokens, EndorsingEncryptedSupportingTokens, and SignedEndorsingEncryptedSupportingTokens.

- Security Binding Assertion

Liberty supports the SymmetricBinding, AsymmetricBinding, and TransportBinding assertions. The traditional application server does not support the TransportBinding assertion.

- IncludeToken Assertion

The IncludeToken assertion is enforced in Liberty, but is ignored in the WS-Security runtime environment of traditional.

- UsernameToken Assertion

Liberty supports PasswordDigest and key derivation in the UsernameToken assertion. The traditional application server supports only PasswordText in a UsernameToken.

## Unrecognized elements in the Security headers

- An unrecognized element in the Security header is rejected by traditional, while it is accepted by Liberty.

## Encrypted header

- The WS-Security 1.1 specification recommends using the <wsse11:EncryptedHeader> element for encrypting SOAP header blocks.
  - The CXF WS-Security that is used in Liberty does not generate an EncryptedHeader element. Instead, the CXF WS-Security generates an <xenc:EncryptedData> element. However, the CXF WS-Security that is used in Liberty can process and consume an incoming <wsse11:EncryptedHeader> element if mustUnderstand in the <security> header is set to 0.
  - The WebSphere Application Server traditional always sets mustUnderstand to 1 in the <security> header. In order for Liberty to process the EncryptedHeader element successfully, you must explicitly set mustUnderstand to 0 by setting the following property in the outbound bindings configuration:  
`<properties name="com.ibm.wsspi.wssecurity.config.request.setMustUnderstand" value="false"/>`

## Intermediate non-trusted certificates

- There is no way to specify intermediate non-trusted certificates to allow the certificate path validator to build a certificate path from an inbound certificate to a trusted certificate in a trust store. Either the inbound certificate or its immediate issuer must be in the trust store for the certificate to be trusted.

## Known issues

- There are some known issues in Liberty CXF WS-Security. Some of the issues have work-arounds. To find known issues and work-arounds, see WS-Security known issues and work-arounds.

## Not tested and not supported features

- Liberty WS-Security includes all of the WS-Security runtime environment code from the CXF project. However, not all functions and features in the CXF WS-Security were tested or verified. To see a list of the specifications that were not verified, see Untested WS-Security specifications.

## WS-Security known issues and work-arounds: **8.5.5.0**

The following items are issues with the WS-Security implementation in the Apache CXF open source services framework.

- If your SupportingToken is being encrypted when you intended to encrypt nothing, try removing any encryption-related token assertions to resolve the issue. If there are no EncryptedParts and no EncryptedElements in an AsymmetricBinding with SupportingToken assertion, then the SupportingToken is encrypted unexpectedly.
- XML Signature with Enveloped Signature Transformation does not work. There is no work-around.
- Although the PolicyReference within <wsdl:output> is honored, the PolicyReference within <wsdl:input> is ignored. If you must distinguish PolicyReference between input and output, the work-around is to attach PolicyReference at the binding level and then override PolicyReference in <wsdl:output>.
- sp:requireEmbeddedTokenReference policy assertion is not supported.

- When the `org.apache.ws.security.crypto.merlin.truststore.*` properties exist in the `signatureProperties` element and the `org.apache.ws.security.crypto.merlin.keystore.*` properties exist in the `encryptProperties` element in the `wsSecurityProvider` or `wsSecurityClient` section of the `server.xml` file, the `org.apache.ws.security.crypto.merlin.keystore.*` values in the `encryptProperties` element overrides the `org.apache.ws.security.crypto.merlin.truststore.*` properties in the `signatureProperties` element. This behavior means that your encryption keystore is used for your signature trust store. The work-around is to use the same keystore for both encryption and signature trust store; separate keystores cannot be used.
- The `X509PKIPathv1` and `PKCS#7` token types are not supported.
- In the WS-Security policy, the `Require*` assertions within the `X509Token` assertion are only used when generating an X509 token. They are not enforced when consuming an X509 token. These assertions include, but are not limited to, `RequireKeyIdentifierReference`, `RequireIssuerSerialReference`, and `RequireThumbprintReference`.
- In the `SymmetricBinding` assertion, neither the `SignatureToken` nor the `EncryptionToken` assertions can be specified. The only supported assertion that can be used within a `SymmetricBinding` assertion is the `ProtectionToken` assertion. The `ProtectionToken` specified is used for both signature and encryption.
- The `ProtectTokens` assertion in the WS-Security policy is not supported and is ignored.
- The `KeyValueToken` assertion in the WS-Security policy is not supported.
- `X509Token` within `EndorsingEncryptedSupportingTokens` or `SignedEndorsingEncryptedSupportingTokens` is not supported.
- WS-Security in Liberty supports the version 1.1 specification, which is compatible with an earlier version with the version 1.0 specification. This means that URIs and schema elements that are defined in 1.0 remain unchanged, while new schema elements and constants are defined with 1.1 namespaces and URIs.

WS-Security options and properties in the WS-Security policy is defined with the `wss10` assertion or the `wss11` assertion. If you must configure a policy to support the WS-Security 1.1 properties, you must configure only the `wss11` policy assertion that already includes the `wss10` assertion, and you must not configure both the `wss11` and the `wss10` policy assertions.

Examples of `wss11` policy assertions that contain the `wss10` assertion include, but are not limited to, `RequireSignatureConfirmation`, `MustSupportRefKeyIdentifier` and `MustSupportRefIssuerSerial`.

- WS-Security and MTOM cannot be configured together for the same service at this time. When MTOM is used and WS-Security is also configured, the SOAP message is not sent properly. The user must make a choice to either use MTOM or configure WS-Security. If MTOM is required, you must remove the WS-Security policy from the WSDL file to disable WS-Security.
- If you are using a Liberty profile client and a WebSphere Application Server traditional provider and receive a `CWWS6001E: Key object was not obtained.` response from the provider, the issue might be resolved by WebSphere Application Server traditional APAR PM88011. This issue specifically relates to configurations that include both asymmetric digital signature and encryption of the Body.

**Untested WS-Security specifications:** **8.5.5.0** The following list of specifications are not verified. However, this list does not include all specifications that are not yet verified.

1. Web Services Security SAML Token Profile 1.1: <http://docs.oasis-open.org/wss/v1.1/wss-v1.1-spec-os-SAMLSAMLTokenProfile.pdf>
2. Web Services Security Kerberos Token Profile 1.1: <http://docs.oasis-open.org/wss/v1.1/wss-v1.1-spec-os-KerberosTokenProfile.pdf>
3. WS-SecureConversation 1.3: <http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/ws-secureconversation-1.3-os.html>
4. WS-Trust 1.3: <http://docs.oasis-open.org/ws-sx/ws-trust/200512/ws-trust-1.3-os.html>

## Web Services Security default configuration

**8.5.5.0**

A Web Services Security (WS-Security) configuration is complementary to the WS-Security policy at run time. The WS-Security configuration follows the CXF name and value pair style, and preserves the CXF property name. Some of the properties have default values and some do not.

In the `server.xml` file, the WebSphere Application Server Liberty profile provides a server-level configuration that is applied to all services. This configuration is known as the default WS-Security configuration.

The `server.xml` file has two default WS-Security configurations: one for client applications and one for provider applications. No other WS-Security configurations can exist in the `server.xml` file. If you need a custom WS-Security configuration for your application that deviates from the default, the configuration must be done programmatically.

The following example shows a default client configuration:

```
<wsSecurityClient id="default"
  ws-security.username="user2"
  ws-security.password="security">
  <signatureProperties org.apache.ws.security.crypto.merlin.keystore.type="jks"
    org.apache.ws.security.crypto.merlin.keystore.password="LibertyX509Client"
    org.apache.ws.security.crypto.merlin.keystore.alias="x509ClientCert"
    org.apache.ws.security.crypto.merlin.file="{server.config.dir}/x509ClientDefault.jks"/>
</wsSecurityClient>
```

The following example shows a default provider configuration:

```
<wsSecurityProvider id="default"
  ws-security.username="user2">
  <encryptionProperties org.apache.ws.security.crypto.merlin.keystore.type="jks"
    org.apache.ws.security.crypto.merlin.keystore.password="LibertyX509Server"
    org.apache.ws.security.crypto.merlin.keystore.alias="x509ServerCert"
    org.apache.ws.security.crypto.merlin.file="{server.config.dir}/x509ServerDefault.jks"/>
</wsSecurityProvider>
```

The following table shows the default WS-Security user properties in Liberty. These same properties can be found in CXF.

*Table 137. Default WS-Security user properties in Liberty and CXF*

Liberty profile/CXF property	Default value
<code>ws-security.username</code>	none
<code>ws-security.password</code>	none
<code>ws-security.signature.username</code>	none
<code>ws-security.encryption.username</code>	none

The following table shows the WS-Security callback handler class and crypto properties in Liberty and the equivalent CXF properties, if different.

*Table 138. WS-Security callback handler class and crypto properties in Liberty and the equivalent CXF properties*

Liberty profile property	CXF property	Default value
<code>ws-security.callback-handler</code>		none
<code>&lt;signatureProperties&gt;</code>	<code>ws-security.signature.properties</code>	none
<code>&lt;encryptionProperties&gt;</code>	<code>ws-security.encryption.properties</code>	none

In the WebSphere Application Server, the `wss4j` properties are specified as attributes of the `signatureProperties` or `encryptionProperties` elements. The following example shows the `wss4j` properties:

```

<signatureProperties org.apache.ws.security.crypto.merlin.keystore.type="jks"
                    org.apache.ws.security.crypto.merlin.keystore.password="LibertyX509Client"
                    org.apache.ws.security.crypto.merlin.keystore.alias="x509ClientDefault"
                    org.apache.ws.security.crypto.merlin.file="${server.config.dir}/x509ClientDefault.jks">
</signatureProperties>

```

The following table shows the wss4j crypto properties in Liberty. These same properties can be found in CXF.

*Table 139. wss4j crypto properties in Liberty and CXF*

Liberty profile/CXF property	Default value
org.apache.ws.security.crypto.provider	org.apache.ws.security.components.crypto.Merlin
org.apache.ws.security.crypto.merlin.keystore.provider	defaults to the installed provider
org.apache.ws.security.crypto.merlin.cert.provider	defaults to the keystore provider
org.apache.ws.security.crypto.merlin.x509crl.file	none

The following table shows the wss4j keystore properties in Liberty. These same properties can be found in CXF.

*Table 140. wss4j keystore properties in Liberty and CXF*

Liberty profile/CXF property	Default value
org.apache.ws.security.crypto.merlin.keystore.file	none
org.apache.ws.security.crypto.merlin.keystore.password	none
org.apache.ws.security.crypto.merlin.keystore.type	none
org.apache.ws.security.crypto.merlin.keystore.alias	none
org.apache.ws.security.crypto.merlin.keystore.private.password	none

The following table shows the wss4j truststore properties in Liberty. These same properties can be found in CXF.

*Table 141. wss4j truststore properties in Liberty and CXF*

Liberty profile property	Default value
org.apache.ws.security.crypto.merlin.truststore.file	none
org.apache.ws.security.crypto.merlin.truststore.password	none
org.apache.ws.security.crypto.merlin.truststore.type	none

The following table shows the WS-Security miscellaneous properties in Liberty. These same properties can be found in CXF.

*Table 142. WS-Security miscellaneous properties in Liberty and CXF*

Liberty profile/CXF property	Default value
ws-security.enable.nonce.cache	true
ws-security.cache.config.file	none

The following table shows the properties that are supported only in Liberty.

Table 143. Properties that are supported only in Liberty

Liberty profile property	CXF property	Default value
callerToken	none	none

## Configuring additional properties

You can set several extra properties to provide additional configuration information to the WS-Security runtime environment. See the following links for detailed information regarding these properties:

- <http://cxf.apache.org/docs/ws-securitypolicy.html>
- <http://ws.apache.org/wss4j/config.html>

Any of the additional properties can be specified in the default WS-Security configuration in the `server.xml` file.

For example, to specify any additional properties, specify them in either the `wsSecurityClient` or `wsSecurityProvider` sections, or both.

```
<wsSecurityProvider id="default"
  <signatureProperties ... />
  <encryptionProperties ... />
  ws-security.cache.config.file = "${server.config.dir}/resources/ws-security/new_cxf-ehcache.xml"
</wsSecurityProvider>

<wsSecurityClient id="default"
  <signatureProperties ... />
  <encryptionProperties ... />
  ws-security.username-token.always.encrypted="false"
</wsSecurityClient>
```

## Configuring cache

WS-Security provides a default caching implementation for nonce in a UsernameToken, the created Timestamp, and security tokens. The default cache implementation is based on ehCache with the following default settings:

```
maxEntriesLocalHeap="5000"
timeToIdleSeconds="3600"
timeToLiveSeconds="3600"
overflowToDisk="true"
maxElementsOnDisk="10000000"
diskPersistent="false"
diskExpiryThreadIntervalSeconds="120"
memoryStoreEvictionPolicy="LRU"
```

To modify the default cache settings, you can provide an ehCache configuration XML file. Use the `ws-security.cache.config.file` custom property to specify a file name with customized properties to deviate from the default settings. You must put this file somewhere in the server profile. You can find an additional sample cache setting configuration file from <http://svn.apache.org/viewvc/cxf/trunk/rt/ws/security/src/main/resources/cxf-ehcache.xml?view=markup>.

## Configuring a stronger signature algorithm

Because of the weakness of the SHA1 signature algorithm, the US National Institute of Standards and Technology (NIST) recommends that you use stronger signature algorithms.

However, WS-Security policy 1.3 defines HmacSha1 or RsaSha1 (collectively called sha1) as the only signature algorithm. WS-Security in Liberty has a configuration option to use the following stronger signature algorithm:

- RSA-SHA-256
- RSA-SHA-384
- RSA-SHA-512
- HMAC-SHA-256
- HMAC-SHA-384
- HMAC-SHA-512

To configure WS-Security in Liberty to support the stronger signature algorithm, you use the `signatureAlgorithm` attribute to define the required algorithm within the `<signatureProperties>` element in the `server.xml` file. The valid values for the `signatureAlgorithm` attribute are `sha256`, `sha384`, and `sha512`. For example, if you specify `sha512` as the value of the `signatureAlgorithm` attribute, the signature algorithm that is used in the signature with an asymmetric key is RSA-SHA-512, and the signature algorithm that is used in the signature with a symmetric key is HMAC-SHA-512.

The following example shows a sample client side configuration that requires the `sha256` signature algorithm:

```
<wsSecurityClient id="default"
  ws-security.password="security"
  ws-security.username="user1"
  ws-security.callback-handler="com.ibm.ws.wssecurity.example.cbh.CommonPasswordCallback"
  ws-security.signature.username="soaprequester">
  <signatureProperties
    signatureAlgorithm="sha256"
    org.apache.ws.security.crypto.merlin.keystore.type="jks"
    org.apache.ws.security.crypto.merlin.keystore.password="client"
    org.apache.ws.security.crypto.merlin.keystore.alias="soaprequester"
    org.apache.ws.security.crypto.merlin.file="${server.config.dir}/dsig-sender.ks" />
</wsSecurityClient>
```

The following example shows a sample provider side configuration that requires the `sha256` signature algorithm:

```
<wsSecurityProvider id="default"
  ws-security.callback-handler="com.ibm.ws.wssecurity.example.cbh.CommonPasswordCallback"
  ws-security.signature.username="soapprovider">
  <signatureProperties
    signatureAlgorithm="sha256"
    org.apache.ws.security.crypto.merlin.keystore.type="jks"
    org.apache.ws.security.crypto.merlin.keystore.password="server"
    org.apache.ws.security.crypto.merlin.keystore.alias="soapprovider"
    org.apache.ws.security.crypto.merlin.file="${server.config.dir}/dsig-receiver.ks" />
</wsSecurityProvider>
```

## Authentication of web services clients with a UsernameToken

### 8.5.5.0

The WebSphere Application Server Liberty profile supports the OASIS Web Services Security UsernameToken Profile 1.1 specification. The specification describes how a web services client supplies a UsernameToken as a means of identifying the requestor by using a user name, and optionally by using a password or password-equivalent to the web services provider. The Web Services Security (WS-Security) run time in Liberty that processes the policy for the web services provider can use this identifying information to authenticate the user.

The requirement of a UsernameToken is expressed as one of the supporting tokens in the WS-Security policy. You can add a UsernameToken requirement as a required token in one of supporting token assertions, including `SupportingTokens`, `SignedSupportingTokens`, `SignedEndorsingSupportingTokens`, `SignedEncryptedSupportingTokens`, and `EncryptedSupportingTokens`.

The following example shows a sample policy fragment that requires a UsernameToken with password text to be sent in the Security header of a SOAP message to a web services provider:

```

<sp:SupportingTokens>
  <wsp:Policy>
    <sp:UsernameToken
      sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
      <wsp:Policy>
        <sp:WssUsernameToken11 />
      </wsp:Policy>
    </sp:UsernameToken>
  </wsp:Policy>
</sp:SupportingTokens>

```

In addition to the requirement of providing a user name or a password, you can configure a policy to include a nonce and created timestamp in a UsernameToken.

The following example shows a sample policy fragment that requires a UsernameToken with password text, nonce, and created timestamp to be sent in the Security header of a SOAP message to a web services provider:

```

<sp:SupportingTokens>
  <wsp:Policy>
    <sp:UsernameToken
      sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
      <wsp:Policy>
        <sp:WssUsernameToken11 />
        <sp13:Created />
        <sp13:Nonce />
      </wsp:Policy>
    </sp:UsernameToken>
  </wsp:Policy>
</sp:SupportingTokens>

```

The following example shows a sample policy fragment that requires a UsernameToken with password digest instead of password text:

```

<sp:SupportingTokens>
  <wsp:Policy>
    <sp:UsernameToken
      sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
      <wsp:Policy>
        <sp:WssUsernameToken11 />
        <sp:HashPassword />
      </wsp:Policy>
    </sp:UsernameToken>
  </wsp:Policy>
</sp:SupportingTokens>

```

For more information about nonce, created, and different password types, see the OASIS WS-Security policy 1.3 specification.

## Providing a user name and password in a web services client

The WS-Security feature in Liberty provides more than one method for indicating the user name and password for a client application when generating a UsernameToken. You can set the user name and password programmatically or in the `server.xml` file.

A client can generate a UsernameToken with the user name and password provided in the `server.xml` file. The user name and password that is in the `server.xml` file is considered the default configuration and is overridden by what is provided on the `RequestContext` for the client's web service invocation.

The following example shows a sample default configuration:

```

<wsSecurityClient id="default"
  ws-security.username="alice"
  ws-security.callback-handler="com.acme.PasswordCallback"
</wsSecurityClient>

```

To generate a UsernameToken with the user name and password determined programmatically, you can set the following CXF properties on the `RequestContext` for the client's web service invocation:

- `ws-security.username` - user name
- `ws-security.password` - user password if `ws-security.callback-handler` is not defined
- `ws-security.callback-handler` - the `CallbackHandler` implementation class used to obtain passwords

The following code sample shows how to provide a user name and password on the request context:

```
Map<String, Object> requestCtx = ((BindingProvider)port).getRequestContext();
requestCtx.put("ws-security.username", "bob_username");
requestCtx.put("ws-security.password", "bob_password");
```

## Consuming a UsernameToken in a web services provider

When a `UsernameToken` is received, WS-Security automatically uses Liberty security user registry to validate the user name and password, if the password is required. If the password type in the `UsernameToken` is `PasswordDigest` or is using derived keys, you must provide the `ws-security.callback-handler` implementation of a password callback handler by configuring it in the `server.xml` file. This callback handler must return valid passwords for all expected user names so that the WS-Security run time can calculate digest values for comparison with the value in the SOAP message. After the digest value comparison completes successfully, the user name and password is validated against the user registry.

The following example illustrates a sample configuration in the `server.xml` file for password digest:

```
<wsSecurityProvider id="default"
  ws-security.callback-handler="com.acme.PasswordCallback"
</wsSecurityProvider>
```

## Password CallbackHandler

The password `CallbackHandler` is used by WS-Security to retrieve a user password. In Liberty, this password `CallbackHandler` class must be packaged as a Liberty feature. For more information about the password `CallbackHandler`, see [Developing a password callback handler for WS-Security](#).

For more information on requirements and limitations of a callback handler implementation, refer to the [Private key password CallbackHandler](#) section of [Protection of web services with an X.509 token](#).

## Protecting a UsernameToken in a SOAP message

When a `UsernameToken` is specified in a policy, the password type is password text (`PasswordText`) by default. When a password is sent with password text, it is sent in the message as-is. The following example shows a `UsernameToken` with a password type of `PasswordText`:

```
<UsernameToken>
  <Username>myusername</Username>
  <Password
    Type="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#PasswordText">
    mypassword
  </Password>
</UsernameToken>
```

When you want to send a `UsernameToken` with `PasswordText`, you should consider additional protections on the message, such as using HTTPS or encrypting the token using the `EncryptedSupportingToken` policy assertion. For more information on requiring the use of the HTTPS transport in the policy, see [Liberty Profile: Web services security HTTPS transport policy assertions](#).

## UsernameToken key derivation

As stated in the [Web Services Security UsernameToken Profile 1.1](#) specification:

*The password associated with a username may be used to derive a shared secret key for the purposes of integrity or confidentiality protecting message contents.*

*It must be noted that passwords are subject to several kinds of attack, which in turn will lead to the exposure of any derived keys. This key derivation procedure is intended to minimize the risk of attacks on the keys, to the extent possible, but it is ultimately limited by the insecurity of a password that it is possible for a human being to remember and type on a standard keyboard.*

*Two additional elements are required to enable to derivation of a key from a password. They are <wsse11:Salt> and <wsse11:Iteration>. These values are not secret and must be conveyed in the Username token when key derivation is used. When key derivation is used the password must not be included in the Username token. The receiver will use its knowledge of the password to derive the same key as the sender.*

If a UsernameToken is using key derivation, for a provider application, you must provide the `ws-security.callback-handler` implementation of a password callback handler by configuring it in the `server.xml` file.

The following example shows a policy fragment for a UsernameToken as a protection token with key derivation:

```
<sp:SymmetricBinding>
  <wsp:Policy>
    <sp:ProtectionToken>
      <wsp:Policy>
        <sp:UsernameToken
          sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
          <wsp:Policy>
            <sp:WssUsernameToken10 />
            <sp:RequireDerivedKeys />
          </wsp:Policy>
        </sp:UsernameToken>
      </wsp:Policy>
    </sp:ProtectionToken>
  </wsp:Policy>
</sp:SymmetricBinding>
```

The following example shows a sample UsernameToken in the security header when key derivation is used:

```
<wsse:UsernameToken wsse:Id="...">
  <wsse:Username>...</wsse:Username>
  <wsse11:Salt>...</wsse11:Salt>
  <wsse11:Iteration>...</wsse11:Iteration>
</wsse:UsernameToken>
```

## Protection of web services with an X.509 token

### 8.5.5.0

Liberty supports the Oasis Web Services Security X.509 Certificate Token Profile 1.1. An X.509 token can be used to provide message integrity and confidentiality by signing and encrypting messages.

### WS-Security policy

To protect an XML message with an X.509 token, a contract that is specified in a Web Services Description Language (WSDL) must be created first. The web service must have a WS-Security policy included in the WSDL file. The WS-Security policy can contain `AsymmetricBinding` or `SymmetricBinding` assertions.

The requirement of an X.509 token is expressed as an `X509Token` assertion type in the WS-Security policy. The following example shows a sample `X509Token` assertion:

```

<sp:X509Token sp:IncludeToken=
  "http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
  <wsp:Policy>
    <sp:WssX509V3Token10 />
  </wsp:Policy>
</sp:X509Token>

```

In an AsymmetricBinding assertion:

- The initiator X509Token is used for message signature from the requestor to the provider and message encryption from the provider to the requestor.
- The recipient X509Token is used for message signature from the provider to the requestor and message encryption from the requestor to the provider.

The following table shows how the initiator and recipient tokens are used for each part of the request/response chain:

*Table 144. Initiator and recipient token use for each part of the request/response chain*

*	Initiator token	Recipient token
request out (requestor)	sign	encrypt
request in (provider)	verify signature	decrypt
response out (provider)	encrypt	sign
response in (requestor)	decrypt	verify signature

Private keys are used to sign and decrypt messages. Public certificates are used to encrypt messages and verify signatures. Private keys belong to the user of the key (the signer or decrypter).

In a SymmetricBinding assertion, a secret key or ephemeral key that is protected for an X.509 token is shared by both the initiator and the recipient, and the key is used for both encryption and decryption.

The following example shows a sample WS-Security policy with an X.509 token in an AsymmetricBinding assertion. This policy enables signing and encryption of the body for both the request and response with Timestamp.

```

<wsp:Policy wsu:Id="SampleAsymmetricX509TokensPolicy">
  <wsp:ExactlyOne>
    <wsp>All>
      <sp:AsymmetricBinding>
        <wsp:Policy>
          <sp:InitiatorToken>
            <wsp:Policy>
              <sp:X509Token sp:IncludeToken=
                "http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
                <wsp:Policy>
                  <sp:WssX509V3Token10 />
                </wsp:Policy>
              </sp:X509Token>
            </wsp:Policy>
          </sp:InitiatorToken>
          <sp:RecipientToken>
            <wsp:Policy>
              <sp:X509Token sp:IncludeToken=
                "http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/Never">
                <wsp:Policy>
                  <sp:WssX509V3Token10 />
                </wsp:Policy>
              </sp:X509Token>
            </wsp:Policy>
          </sp:RecipientToken>
          <sp:AlgorithmSuite>
            <wsp:Policy>
              <sp:Basic128 />
            </wsp:Policy>
          </sp:AlgorithmSuite>
          <sp:Layout>
            <wsp:Policy>
              <sp:Strict />
            </wsp:Policy>
          </sp:Layout>
          <sp:IncludeTimestamp />
          <sp:ProtectTokens />
          <sp:OnlySignEntireHeadersAndBody />
        </wsp:Policy>
      </wsp>All>
    </wsp:ExactlyOne>
  </wsp:Policy>

```

```

    </wsp:Policy>
  </sp:AsymmetricBinding>
<sp:SignedParts>
  <sp:Body />
</sp:SignedParts>
<sp:EncryptedParts>
  <sp:Body />
</sp:EncryptedParts>
<sp:Wss10>
  <wsp:Policy>
    <sp:MustSupportRefKeyIdentifier />
  </wsp:Policy>
</sp:Wss10>
</wsp:All>
</wsp:ExactlyOne>
</wsp:Policy>

```

The following example shows a sample WS-Security policy with an X.509 token in a SymmetricBinding assertion. This policy enables signing of the Body for both the request and response with Timestamp.

```

<wsp:Policy wsu:Id="SampleSymmetricX509TokensPolicy">
  <wsp:ExactlyOne>
    <wsp:All>
      <sp:SymmetricBinding>
        <wsp:Policy>
          <sp:ProtectionToken>
            <wsp:Policy>
              <sp:X509Token sp:IncludeToken=
                "http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/Never">
                <wsp:Policy>
                  <sp:WssX509V3Token11 />
                  <sp:RequireThumbprintReference />
                </wsp:Policy>
              </sp:X509Token>
            </wsp:Policy>
          </sp:ProtectionToken>
          <sp:Layout>
            <wsp:Policy>
              <sp:Lax />
            </wsp:Policy>
          </sp:Layout>
          <sp:IncludeTimestamp />
          <sp:OnlySignEntireHeadersAndBody />
          <sp:SignBeforeEncrypting />
          <sp:AlgorithmSuite>
            <wsp:Policy>
              <sp:Basic128 />
            </wsp:Policy>
          </sp:AlgorithmSuite>
        </wsp:Policy>
      </sp:SymmetricBinding>
      <sp:EncryptedParts>
        <sp:Body />
      </sp:EncryptedParts>
      <sp:SignedParts>
        <sp:Body />
      </sp:SignedParts>
    </wsp:All>
  </wsp:ExactlyOne>
</wsp:Policy>

```

## Token reference and token inclusion

A token assertion can carry an `sp:IncludeToken` attribute that requires that the token be included in the message. Several token assertions support mechanisms for referencing tokens in addition to direct references. If a token assertion contains multiple reference assertions, then the references to that token are required to contain all the specified reference types. For example, if a token assertion carries an `sp:IncludeToken` attribute with a value of `../Always` and that token assertion also contains a nested `sp:RequireIssuerSerialReference` assertion, then the token must be included twice in the message. While such combinations are not errors, they are best avoided for efficiency reasons.

The `IncludeToken` assertion is enforced in Liberty, but is ignored in the WS-Security runtime environment of WebSphere Application Server traditional.

The WS-Security policy supports the following token reference mechanisms:

- `KeyIdentifier`: `<sp:RequireKeyIdentifierReference... />`
- `IssuerSerial`: `<sp:RequireIssuerSerialReference ... />`

- Thumbprint: <sp:RequireThumbprintReference ... />

These references are used when generating an X.509 token on the client/generator side, and are not enforced on the server/consumer side.

## Runtime configuration

The WS-Security feature run time in Liberty provides more configuration options for message protection with an X.509 token than are covered by the WS-Security policy. The runtime configuration is defined in the server.xml file. The runtime configuration includes cryptographic properties such as signatureProperties and encryptionProperties, key, and keystores.

The following example shows a client configuration for an X509Token assertion:

```
<wsSecurityClient id="default"
  ws-security.callback-handler="com.ibm.ws.wssecurity.example.cbh.KeyPasswordCallbackHandler">
  <signatureProperties org.apache.ws.security.crypto.merlin.keystore.type="jks"
    org.apache.ws.security.crypto.merlin.keystore.password="LibertyX509Client"
    org.apache.ws.security.crypto.merlin.keystore.alias="x509ClientDefault"
    org.apache.ws.security.crypto.merlin.file="{server.config.dir}/x509ClientDefault.jks" />
  <encryptionProperties org.apache.ws.security.crypto.merlin.keystore.type="jks"
    org.apache.ws.security.crypto.merlin.keystore.password="LibertyXClient"
    org.apache.ws.security.crypto.merlin.keystore.alias="x509DefaultCert"
    org.apache.ws.security.crypto.merlin.file="{server.config.dir}/x509ClientDefault.jks" />
</wsSecurityClient>
```

The following example shows a server configuration for an X509Token assertion:

```
<wsSecurityProvider id="default"
  ws-security.callback-handler="com.ibm.ws.wssecurity.example.cbh.KeyPasswordCallbackHandler">
  <signatureProperties org.apache.ws.security.crypto.merlin.keystore.type="jks"
    org.apache.ws.security.crypto.merlin.keystore.password="LibertyX509Server"
    org.apache.ws.security.crypto.merlin.keystore.alias="x509ServerDefault"
    org.apache.ws.security.crypto.merlin.file="{server.config.dir}/x509ServerDefault.jks" />
  <encryptionProperties org.apache.ws.security.crypto.merlin.keystore.type="jks"
    org.apache.ws.security.crypto.merlin.keystore.password="LibertyX509Server"
    org.apache.ws.security.crypto.merlin.keystore.alias="x509ServerDefault"
    org.apache.ws.security.crypto.merlin.file="{server.config.dir}/x509ServerDefault.jks" />
</wsSecurityProvider>
```

In the runtime configuration, the signatureProperties and encryptionProperties properties are equivalent to the crypto properties in the WSS4J configuration. See WSS4J configuration for additional details. Many crypto properties have valid default values so there is no need to specify them. But other properties, such as keystore and key related properties, must be specified.

For more information about these properties, see Web services security default configuration.

## Keystore files, keys, and certificates

Message signature and encryption requires the use of public certificates and private keys. These public certificates and private keys are stored in keystore files. Keystore files are required when you use X509Token assertions. The client-side keystore file contains the private key of the client, and a chain of certificates corresponding to the public key of the server. The server-side keystore file contains the private key of the server, and a chain of certificates corresponding to the public key of the client.

When a SOAP message is signed and encrypted, the signatureProperties and encryptionProperties properties are interpreted by the WS-Security runtime environment as follows:

- AsymmetricBinding assertion

The key specified by the signatureProperties property is used as the private key for signing the outbound message, and is also used for decrypting the inbound message.

The key specified by the encryptionProperties property is used as the public key for encrypting the outbound message, and is also used for verifying the signature in the inbound message.

- SymmetricBinding assertion

The key specified by the `encryptionProperties` properties is used, while the `signatureProperties` property is ignored.

## Private key password CallbackHandler

To access a private key in a keystore, you must know two different passwords. One password is for the keystore where the private key is stored. The other password is for the private key itself. While the password for the keystore is specified in one of the crypto properties, either `signatureProperties` or `encryptionProperties`, the `CallbackHandler` class is normally used by WS-Security to access the private key in a keystore. In Liberty, this `CallbackHandler` class must be packaged as a Liberty feature and its class name specified as the value for the `ws-security.callback-handler` custom property in the `security.xml`.

This `CallbackHandler` class is required by WS-Security to access the private key in a keystore.

For more information about the password `CallbackHandler` class, see [Developing a password callback handler for WS-Security](#).

If the `CallbackHandler` class does not provide the private key password, the `ws-security` runtime first tries the `CallbackHandler` so it must be provided, then the password that is specified in the crypto properties is used as the default password for the private key. This property is configured as `org.apache.ws.security.crypto.merlin.keystore.private.password`.

Because there is only one `ws-security.callback-handler` custom property supported in each of the `wsSecurityClient` and `wsSecurityProvider` sections of the `security.xml` file, a single password callback handler must support all of the required passwords for each application type (client or server) that use the default. All provider applications must use the default password callback handler. Client applications can override the default callback handler by specifying the `ws-security.callback-handler` custom property on the request context for the web service invocation of the client.

If you need to provide passwords for an X.509 private key and a `UsernameToken` for a single web service invocation, you cannot provide separate callback handlers for each use. In this case, you must implement a single callback handler that handles both kinds of passwords. As illustrated in the previous example, you must use the `WSPasswordCallback.getUsage()` method to determine which kind of password that you should return. See the `WSPasswordCallback` API documentation for the supported usage codes: <http://ws.apache.org/wss4j/apidocs/org/apache/wss4j/common/ext/WSPasswordCallback.html>.

### 8.5.5.0

## Certificate revocation list

A certificate revocation list (CRL) is a list of serial numbers for certificates that have been revoked. A CRL can be a stand-alone file or it can be packaged in a PKCS#7 wrapper. You can use a CRL in conjunction with a trust store to control access to a service.

There are two steps required to configure the WS-Security feature in Liberty to perform revocation checking with a CRL file. To enable certificate revocation checking with a CRL file, you must modify the WS-Security runtime configuration in the `server.xml` file.

1. Within the `wsSecurityProvider` or `wsSecurityClient` element, add the following property:  
`ws-security.enableRevocation="true"`
2. Within the `signatureProperties` element, add the following property and set the value to a CRL file:  
`org.apache.ws.security.crypto.merlin.x509crl.file`

The following example shows a sample WS-Security provider configuration that enables certificate revocation checking with a CRL file:

```

<wsSecurityProvider id="default"
  ws-security.callback-handler="com.acme.example.cbh.CommonPasswordCallback"
  ws-security.signature.username="x509ServerDefault"
  ws-security.enableRevocation="true">
  <signatureProperties
    org.apache.ws.security.crypto.merlin.keystore.type="jks"
    org.apache.ws.security.crypto.merlin.keystore.password="LibertyX509Server"
    org.apache.ws.security.crypto.merlin.keystore.alias="x509ServerDefault"
    org.apache.ws.security.crypto.merlin.file="${server.config.dir}/x509ServerDefault.ks"
    org.apache.ws.security.crypto.merlin.truststore.password="LibertyX509Server"
    org.apache.ws.security.crypto.merlin.truststore.file="${server.config.dir}/x509DefaultServer.ks"
    org.apache.ws.security.crypto.merlin.x509crl.file="${server.config.dir}/revokedCerts.crl"/>
</wsSecurityProvider>

```

## Protection of web services with endorsing tokens

**8.5.6.0**

An endorsing token is used to sign the SOAP message signature. An endorsing token is usually used to sign the entire <Signature> element and optionally to sign additional message parts. If transport security is used, the endorsing token must be used to sign the Timestamp in the SOAP Security header.

### Endorsing supporting token assertions

Endorsing tokens are SupportingTokens in WS-Security, and can be signed and encrypted. There are four types of endorsing tokens.

- EndorsingSupportingTokens - The token is not required to be signed or encrypted.
- SignedEndorsingSupportingTokens - The token must be signed.
- EndorsingEncryptedSupportingTokens - The token must be encrypted.
- SignedEndorsingEncryptedSupportingTokens - The token must be signed.

### X509Token as an endorsing token

You can configure an X509Token as an endorsing token. Configuring an X509Token as an endorsing token is similar to configuring an X509Token as an InitiatorToken in an AsymmetricBinding. To configure an X509Token as an endorsing token, you need a policy that has an X509Token contained within one of the endorsing token assertions described previously, and a <SignatureProperties> element in the server.xml file.

The following example shows a policy fragment for an X509 endorsing supporting token:

```

<sp:EndorsingSupportingTokens xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702">
  <wsp:Policy>
    <sp:X509Token sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
      <wsp:Policy>
        <sp:WssX509V3Token10/>
      </wsp:Policy>
    </sp:X509Token>
  </wsp:Policy>
</sp:EndorsingSupportingTokens>

```

After configuring the X509Token as an endorsing token, you must define the <signatureProperties> element in the server.xml file to identify the keystore and the signing key. The configuration for the <signatureProperties> element is the same as the configuration of the X509Token for the message signature. For more information, see Protection of web services with an X.509 token.

### UsernameToken as an endorsing token

The configuration of a UsernameToken as an endorsingToken is similar to the configuration of a UsernameToken with PasswordDigest, except there is no HashPassword in the policy. To configure a

UsernameToken as an endorsing token, you need a policy that has a UsernameToken contained within one of the endorsing token assertions described in the Endorsing supporting token assertions section.

The following example shows a policy fragment for a UsernameToken signed and encrypted endorsing supporting token. Key derivation is used:

```
<sp:SignedEndorsingEncryptedSupportingTokens>
  <wsp:Policy>
    <sp:UsernameToken
      sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
      <wsp:Policy>
        <sp:WssUsernameToken10 />
        <sp:RequireDerivedKeys />
      </wsp:Policy>
    </sp:UsernameToken>
  </wsp:Policy>
</sp:SignedEndorsingEncryptedSupportingTokens>
```

In this sample policy fragment, the UsernameToken is signed and encrypted with the rest of the message. Then the key that is derived from the password from the UsernameToken is used to sign the message signature.

Since a UsernameToken endorsing token uses derived keys, you must implement and configure a password CallbackHandler for a provider application. For more information, see Authentication of web services clients with a UsernameToken.

## Web services security caller configuration

### 8.5.5.0

You can run a web service in authenticated or unauthenticated mode. When you want to restrict access to resources based on the identity of a user, the web service must run in authenticated mode. When a web service is run in authenticated mode, the identity of the user is placed on the same thread on which the web service runs.

There are two ways that a web service can run in the authenticated mode:

#### HTTP basic authentication

The identity from the HTTP header is placed on the thread by the web container.

#### WS-Security caller configuration

The identity of one of the tokens in the SOAP security header is placed on the thread by the WS-Security runtime.

The WS-Security specification allows more than one token to be passed in the security header of a SOAP message. When a web service is required to run in authenticated mode by using WS-Security, some mechanism is required to tell the WS-Security runtime environment which token to use for the identity. This mechanism is called a caller configuration.

The WS-Security caller configuration is specified in the `server.xml` file with the `<callerToken>` element.

The following example shows a sample WS-Security provider configuration that includes a caller configuration for a UsernameToken:

```
<wsSecurityProvider ...>
  ...
  <callerToken name="UsernameToken" />
  ...
</wsSecurityProvider>
```

The following values can be specified for the `<callerToken>` element:

- UsernameToken

- X509Token
- **8.5.5.8** SamlToken

If you configure an X509Token as a caller token, make sure only one client's X509Certificate can be resolved from the security header. For example, ensure that only one client certificate is resolved from the initiator token in an AsymmetricBinding, or that only one client certificate that is resolved from an endorsing token.

If you configure a UsernameToken as a caller token, the security header must contain only one UsernameToken.

**8.5.5.8** If you configure a SamlToken as a caller token, the security header must contain only one SAML token. There are additional configuration options such as `userIdentifier`, `groupIdentifier` or `realmIdentifier` that is used to specify a SAML attribute that can be used as a principal, group or realm when an authenticated subject is created. For more information about the optional SAML callerToken configuration, see "Creating a WS-Security SAML caller configuration."

### Creating a WS-Security SAML caller configuration: **8.5.5.8**

A WS-Security provider configuration that includes a caller for a SAML token can be configured with the `<callerToken>` element in the `server.xml` file.

#### Procedure

1. Configure the WS-Security Security Assertion Markup Language (SAML) caller configuration in the `server.xml` file with the `<callerToken>` element. The following example shows a sample WS-Security provider configuration that includes a caller for a SAML Token:

```
<wsSecurityProvider ...>
  ...
  <callerToken name="SamlToken" userIdentifier="userIdentifierString" groupIdentifier="groupIdentifierString" userUniqueIdentifier="userUniqueIdentifierString"
    includeTokenInSubject="false" mapToUserRegistry="User" realmName="customRealmName" allowCustomCacheKey="true" ... />
  ...
</wsSecurityProvider>
```

The only required attribute in this configuration is `name`. By default, the authenticated subject is created by using the information from the SAML assertion and it does not require a local user registry to do the authentication.

2. Optional: You can configure the following optional attributes to help create an authenticated subject from SAML assertion. The default values for some of these optional attributes are:

```
includeTokenInSubject=true
mapToUserRegistry="No"
allowCustomCacheKey="true"
```

- When `mapToUserRegistry` is `"No"`, the name of the SAML issuer is used as realm, and the `NameID` is used as the principal name and unique security name in the subject, and the group member is not included.
- When `mapToUserRegistry` is `"User"`, the SAML user is validated against your on-premises user registry, and then the runtime creates the user subject based on the on-premises registry.
- When `mapToUserRegistry` is `"Group"`, SAML group is validated against your on-premises user registry, and then the runtime creates the subject with the validated groups. This option is similar to `mapToUserRegistry=No`, except for the verification of the group memberships against the on-premises user registry.

You can configure additional attributes such as `userIdentifier`, `realmIdentifier`, `groupIdentifier`, and `userUniqueIdentifier` to create an authenticated subject with a customized user name, realm name, group memberships, and unique security identifier.

- `userIdentifier`: Use this attribute to select a SAML attribute name whose value is used as the principal name.

- `groupId`: Use this attribute to select a SAML attribute name whose values are included as group members in the subject.
  - `realmName`: Use this attribute to explicitly specify the realm name to identify a SAML principal for the authenticated subject. The default realm name is the SAML issuer name.
3. Optional: You can implement the Liberty SAML SPI, `com.ibm.wsspi.security.saml2.UserCredentialResolver` as a user feature to dynamically map a SAML assertion to a Liberty subject.

## WS-SecurityPolicy and templates

### 8.5.5.0

Web Services Security (WS-Security) in Liberty is configured by using the WS-SecurityPolicy in either Web Services Description Language (WSDL) or policy attachment file of a web service application. To protect your web service application with WS-Security, your JAX-WS application must contain a WSDL or policy attachment file that has an embedded WS-Security Policy. WS-SecurityPolicy templates contain several commonly used WS-Security policy samples. These templates can be modified to satisfy many different usage scenarios.

The following list of commonly used WS-SecurityPolicy templates are provided, and can be modified to satisfy many different usage scenarios:

- Scenario 1: UsernameToken with password digest (HashPassword) and timestamp over SSL
- Scenario 2: UsernameToken with password text, nonce, and created timestamp over SSL
- Scenario 3: UsernameToken as an EndorsingToken and an X509Token symmetric for message protection
- Scenario 4: UsernameToken with X509Token asymmetric message protection (mutual authentication)
- Scenario 5: Client X509Token as an EndorsingToken and a server X509Token symmetric for message protection
- Scenario 6: UsernameToken authentication and an X509Token symmetric for message protection
- Scenario 7: UsernameToken with password text, nonce, and created timestamp over HTTP
- **8.5.5.8** Scenario 8: SAMLToken as SupportingToken over SSL
- **8.5.5.8** Scenario 9: SAMLToken with X509Token asymmetric for message signature
- **8.5.5.8** Scenario 10: SAMLToken with X509Token asymmetric message protection (mutual authentication)
- **8.5.5.8** Scenario 11: SAMLToken with X509Token symmetric for message protection

### UsernameToken with password digest (HashPassword) and timestamp over SSL: **8.5.5.0**

This policy requires that you protect the message with HTTPS, and that a UsernameToken is used for authentication. The UsernameToken password is hashed with the created timestamp and nonce. There is also a message Timestamp.

The following policy shows a UsernameToken with password digest (HashPassword) and timestamp over SSL:

```
<wsp:Policy wsu:Id="UserNameTokenPasswordHashOverSSL">
  <wsp:ExactlyOne>
    <wsp:All>
      <sp:TransportBinding>
        <wsp:Policy>
          <sp:TransportToken>
            <wsp:Policy>
              <sp:HttpsToken>
                <wsp:Policy />
              </sp:HttpsToken>
            </wsp:Policy>
          </sp:TransportToken>
        </wsp:Policy>
      </sp:Layout>
    </wsp:Policy>
  </wsp:ExactlyOne>
</wsp:Policy>
```

```

        <sp:Lax />
    </wsp:Policy>
</sp:Layout>
<sp:IncludeTimestamp />
<sp:AlgorithmSuite>
    <wsp:Policy>
        <sp:Basic128 />
    </wsp:Policy>
</sp:AlgorithmSuite>
</wsp:Policy>
</sp:TransportBinding>
<sp:SupportingTokens>
    <wsp:Policy>
        <sp:UsernameToken
            sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
            <wsp:Policy>
                <sp:WssUsernameToken10 />
                <sp:HashPassword/>
            </wsp:Policy>
        </sp:UsernameToken>
    </wsp:Policy>
</sp:SupportingTokens>
</wsp>All>
</wsp:ExactlyOne>
</wsp:Policy>

```

The namespaces used in this example are:

- xmlns:wsp="http://www.w3.org/ns/ws-policy"
- xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
- xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702"

To validate the UsernameToken in the Liberty profile server, you must provide a password callback handler class on the provider side by setting the ws-security.callback-handler attribute. The password from the callback handler must match the password that is used in the PasswordDigest. The password must also match the password in the user registry in the Liberty profile.

### UsernameToken with password text, nonce, and created timestamp over SSL: **8.5.5.0**

This policy requires that you protect the message with HTTPS, and that a UsernameToken is used for authentication. The user password within the UsernameToken is sent as clear text, and a timestamp and nonce are included. There is also a message Timestamp. You can modify this policy to remove the requirement of nonce and timestamp. For testing purposes, you can also remove the TransportBinding to send the UsernameToken over HTTP for simplicity.

The following policy shows a UsernameToken with password text, nonce, and created timestamp over SSL:

```

<wsp:Policy wsu:Id="UserNameTokenPasswordTextOverSSL">
    <wsp:ExactlyOne>
        <wsp>All>
            <sp:TransportBinding>
                <wsp:Policy>
                    <sp:TransportToken>
                        <wsp:Policy>
                            <sp:HttpsToken>
                                <wsp:Policy>
                                    </wsp:Policy>
                                </sp:HttpsToken>
                            </wsp:Policy>
                        </sp:TransportToken>
                    </wsp:Policy>
                </sp:Layout>
                <wsp:Policy>
                    <sp:Lax />
                </wsp:Policy>
            </sp:Layout>
            <sp:IncludeTimestamp />
            <sp:AlgorithmSuite>
                <wsp:Policy>

```

```

        <sp:Basic128 />
    </wsp:Policy>
</sp:AlgorithmSuite>
</wsp:Policy>
</sp:TransportBinding>
<sp:SupportingTokens>
  <wsp:Policy>
    <sp:UsernameToken
      sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
      <wsp:Policy>
        <sp:WssUsernameToken10 />
        <sp13:Created />
        <sp13:Nonce />
      </wsp:Policy>
    </sp:UsernameToken>
  </wsp:Policy>
</sp:SupportingTokens>
</wsp:All>
</wsp:ExactlyOne>
</wsp:Policy>

```

The namespaces used in this example are:

- xmlns:wsp="http://www.w3.org/ns/ws-policy"
- xmlns:wss="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
- xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702"

This policy is analogous to the Username WSHTTPS default policy set in WebSphere Application Server traditional.

#### UsernameToken as an EndorsingToken and an X509Token symmetric for message protection:

##### 8.5.5.0

With X509Token symmetric protection, an ephemeral key is created to sign and encrypt the message. The ephemeral key is encrypted using the receiver's public certificate. A UsernameToken with derived keys is used for authentication. The message signature is signed using the UsernameToken's derived key. There is also a message Timestamp.

This policy template can be used if HTTP transport is not supported, the service has an X509 token and supports a UsernameToken, and the service requires the client to endorse the message.

The following policy shows a UsernameToken as an EndorsingToken and an X509Token symmetric for message protection:

```

<wsp:Policy wsu:Id="UsernameTokenAsEndorsingAndX509Symmetric">
  <wsp:ExactlyOne>
    <wsp:All>
      <sp:SymmetricBinding>
        <wsp:Policy>
          <sp:ProtectionToken>
            <wsp:Policy>
              <sp:X509Token
                sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
                <wsp:Policy>
                  <sp:WssX509V3Token10 />
                </wsp:Policy>
              </sp:X509Token>
            </wsp:Policy>
          </sp:ProtectionToken>
          <sp:Layout>
            <wsp:Policy>
              <sp:Lax />
            </wsp:Policy>
          </sp:Layout>
          <sp:IncludeTimestamp />
          <sp:OnlySignEntireHeadersAndBody />
          <sp:AlgorithmSuite>
            <wsp:Policy>

```

```

        <sp:Basic128 />
    </wsp:Policy>
</sp:AlgorithmSuite>
</wsp:Policy>
</sp:SymmetricBinding>
<sp:SignedEndorsingEncryptedSupportingTokens>
    <wsp:Policy>
        <sp:UsernameToken
            sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
            <wsp:Policy>
                <sp:WssUsernameToken10 />
                <sp:RequireDerivedKeys />
            </wsp:Policy>
        </sp:UsernameToken>
    </wsp:Policy>
</sp:SignedEndorsingEncryptedSupportingTokens>
<sp:SignedParts>
    <sp:Body />
</sp:SignedParts>
<sp:EncryptedParts>
    <sp:Body />
</sp:EncryptedParts>
</wsp>All>
</wsp:ExactlyOne>
</wsp:Policy>

```

The namespaces used in this example are:

- xmlns:wsp="http://www.w3.org/ns/ws-policy"
- xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
- xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702"

### UsernameToken with X509Token asymmetric message protection (mutual authentication):

**8.5.5.0**

An X509Token with issuer/serial representation of the sender's public certificate is included in the message. The UsernameToken in the request and the SOAP body in the request and response are signed and encrypted with X509Token asymmetric message protection. There is also a message Timestamp and signature confirmation. A UsernameToken with clear text password is used for authentication.

This policy template is best used if the client must authenticate itself to the service with both an X509 client certificate and a UsernameToken.

The following policy shows a UsernameToken with X509Token asymmetric message protection:

```

<wsp:Policy wsu:Id="AsymmetricX509MutualAuthenticationWithUnt">
    <wsp:ExactlyOne>
        <wsp>All>
            <sp:SignedEncryptedSupportingTokens
                xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702">
                <wsp:Policy>
                    <sp:UsernameToken
                        sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
                        <wsp:Policy>
                            <sp:WssUsernameToken10 />
                        </wsp:Policy>
                    </sp:UsernameToken>
                </wsp:Policy>
            </sp:SignedEncryptedSupportingTokens>
            <sp:AsymmetricBinding>
                <wsp:Policy>
                    <sp:InitiatorToken>
                        <wsp:Policy>
                            <sp:X509Token
                                sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
                                <wsp:Policy>
                                    <sp:WssX509V3Token10 />
                                    <sp:RequireIssuerSerialReference />
                                </wsp:Policy>
                            </sp:X509Token>

```

```

    </wsp:Policy>
  </sp:InitiatorToken>
  <sp:RecipientToken>
    <wsp:Policy>

</wsp:Policy>

```

The namespaces used in this example are:

- xmlns:wsp="http://www.w3.org/ns/ws-policy"
- xmlns:wssu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
- xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702"

This policy is analogous to the Username WSSecurity default policy set in WebSphere Application Server traditional.

#### Client X509Token as an EndorsingToken and a server X509Token symmetric for message protection:

##### 8.5.5.0

The client and server X509 certificates are used for mutual authentication and message protection. With X509Token symmetric protection, an ephemeral key is created to sign and encrypt the message. The ephemeral key is encrypted using the receiver's public certificate. An X509Token with the thumbprint representation of the client's public certificate is included in the message. The message signature is signed using the client's private key.

This policy template is best used if the client must authenticate itself to the service with both an X509 client certificate and a UsernameToken.

The following policy shows a client X509Token as an EndorsingToken and a server X509Token symmetric for message protection:

```
<wsp:Policy wsu:Id="X509SymmetricAndEndorsing">
  <wsp:ExactlyOne>
    <wsp>All>
      <sp:SymmetricBinding>
        <wsp:Policy>
          <sp:ProtectionToken>
            <wsp:Policy>
              <sp:X509Token
                sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/Never">
                <wsp:Policy>
                  <sp:RequireDerivedKeys />
                  <sp:RequireThumbprintReference />
                  <sp:WssX509V3Token11 />
                </wsp:Policy>
              </sp:X509Token>
            </wsp:Policy>

        <wsp:Policy>
          <sp:MustSupportRefKeyIdentifier />
          <sp:MustSupportRefIssuerSerial />
          <sp:MustSupportRefThumbprint />
          <sp:MustSupportRefEncryptedKey />
          <sp:RequireSignatureConfirmation />
        </wsp:Policy>
      </sp:Wss11>
    </wsp>All>
  </wsp:ExactlyOne>
</wsp:Policy>
```

The namespaces used in this example are:

- xmlns:wsp="http://www.w3.org/ns/ws-policy"
- xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
- xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702"

## UsernameToken authentication and X509Token symmetric for message protection: 8.5.5.0

A UsernameToken with clear text password is used for authentication. The UsernameToken in the request and the SOAP body in the request and response are signed and encrypted with X509Token symmetric message protection. There is also a message Timestamp.

With X509Token symmetric protection, an ephemeral key is created to sign and encrypt the message. The ephemeral key is encrypted using the receiver's public certificate.

In this sample, the token reference is using a RequireThumbprintReference. You can change the policy to use a RequireIssuerSerialReference or RequireKeyIdentifierReference. You can also modify this policy to use derived keys from an ephemeral key to secure the message exchange by adding an `<sp:RequireDerivedKeys />` assertion.

This policy template is best used if the client can use only a UsernameToken to authenticate itself, and if the message exchange must be signed and encrypted.

The following policy shows a UsernameToken authentication and X509Token symmetric for message protection:

```
<wsp:Policy wsu:Id="X509SymmetricForMessageAndUntForClient">
  <wsp:ExactlyOne>
    <wsp:All>
      <sp:SignedEncryptedSupportingTokens
        xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702">

### UsernameToken with password text, nonce, and created timestamp over HTTP: 8.5.5.0

This policy requires that a client must send a UsernameToken with clear text password, nonce, and created timestamp. Transport security is not required. This simple policy is only suitable if password confidentiality is not a concern or is provided by other means. This policy can be used in a pre-production environment for testing purposes.

The following policy shows a UsernameToken with password text, nonce, and created timestamp over HTTP:

```

<wsp:Policy wsu:Id="UsernameTokenOverHTTP">
  <sp:SupportingTokens>
    <wsp:Policy>
      <sp:UsernameToken
        sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
        <wsp:Policy>
          <sp13:Created />
          <sp13:Nonce />
          <sp:WssUsernameToken11 />
        </wsp:Policy>
      </sp:UsernameToken>
    </wsp:Policy>
  </sp:SupportingTokens>
</wsp:Policy>

```

The namespaces used in this example are:

- xmlns:wsp="http://www.w3.org/ns/ws-policy"
- xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
- xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702"

### Sam1Token as SupportingToken over SSL: 8.5.5.8

This policy requires that you protect the message with HTTPS, and that a SAML 2.0 token is used for authentication.

The following policy shows a SAML 2.0 token over SSL:

```

<wsp:Policy wsu:Id="Sam120TokenOverSSL">
  <wsp:ExactlyOne>
    <wsp:All>
      <sp:TransportBinding>
        <wsp:Policy>
          <sp:TransportToken>
            <wsp:Policy>

</wsp>All>
</wsp:ExactlyOne>
</wsp:Policy>

```

### SAMLToken with X509Token asymmetric for message signature: 8.5.5.6

An X509Token with the sender's public certificate is included in the message. The SAML token in the request and the SOAP body in the request and response are signed with X509Token asymmetric message protection. A Timestamp is also included in the message. A SAML 2.0 token is used for authentication.

The following policy shows a SAMLToken with X509Token asymmetric for message signature:

```

<wsp:Policy wsu:Id="SamlTokenWithMessageSignature">
  <wsp:ExactlyOne>
    <wsp>All>
      <sp:SignedSupportingTokens>
        <wsp:Policy>
          <sp:SamlToken
            sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">

    <sp:Body/>
</sp:SignedParts>
</wsp>All>
</wsp:ExactlyOne>
</wsp:Policy>

```

### SamlToken with X509Token asymmetric message protection (mutual authentication): 8.5.5.8

An X509Token with issuer and serial representation of the sender's public certificate is included in the message. The SAML token in the request and the SOAP body in the request and response are signed and encrypted with X509Token asymmetric message protection. There is also a message timestamp and signature confirmation. A SAML 2.0 token is used for authentication. This policy template is best used if the client must authenticate itself to the service with both an X509 client certificate and a SAML token.

The following policy shows a SAML token with X509Token asymmetric message protection:

```

<wsp:Policy wsu:Id="AsymmetricX509MutualAuthenticationWithSam1">
  <wsp:ExactlyOne>
    <wsp>All>
      <sp:SignedEncryptedSupportingTokens
xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702">
        <wsp:Policy>
          <sp:Sam1Token
            sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
              <wsp:Policy>
                <sp:WssSam1V20Token11/>
              </wsp:Policy>
            </sp:Sam1Token>
          </wsp:Policy>
        </sp:SignedEncryptedSupportingTokens>
        <sp:AsymmetricBinding>
          <wsp:Policy>
            <sp:InitiatorToken>
              <wsp:Policy>

<sp:EncryptedParts>
  <sp:Body />
</sp:EncryptedParts>
</wsp>All>
</wsp:ExactlyOne>
</wsp:Policy>

```

### SAMLToken with X509Token symmetric for message protection: 8.5.5.8

A SAML token is used for authentication. The SAML token in the request and the SOAP body in the request and response are signed and encrypted with X509Token symmetric message protection. There is also a message timestamp.

With X509Token symmetric protection, an ephemeral key is created to sign and encrypt the message. The ephemeral key is encrypted by using the receiver's public certificate.

In the following sample, the token reference is using a RequireThumbprintReference. You can change the policy to use a RequireIssuerSerialReference or RequireKeyIdentifierReference. You can also modify this policy to use derived keys from an ephemeral key to secure the message exchange by adding a <sp:RequireDerivedKeys /> assertion. This policy template is best used if the client can only use a SAML token to authenticate itself, and if the message exchange must be signed and encrypted.

The following policy shows a SAML token for authentication and X509Token symmetric for message protection:

```

<wsp:Policy wsu:Id="X509SymmetricForMessageAndSamlForClient">
  <wsp:ExactlyOne>
    <wsp>All>
      <sp:SignedEncryptedSupportingTokens
xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702">
        <wsp:Policy>
          <sp:SamlToken
            sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
              <wsp:Policy>
                <sp:WssSamlV20Token11/>
              </wsp:Policy>
            </sp:SamlToken>

## Developing a password callback handler for WS-Security

**8.5.5.0**

In Liberty, password callback handlers can be used in many WS-Security scenarios to retrieve passwords. For example, passwords can be retrieved for generating UsernameTokens, opening keystores, or accessing private keys. A password callback handler is required for the provider when you use PasswordDigest. A password callback handler must be packaged as a user feature in Liberty.

### About this task

This task describes how to develop a password callback handler to retrieve user name and keystore key passwords.

### Procedure

1. Develop a password callback handler. The following example shows a callback handler:

```

package com.ibm.ws.wssecurity.example.cbh;

import java.util.HashMap;
import java.util.Map;
import javax.security.auth.callback.Callback;
import javax.security.auth.callback.CallbackHandler;
import org.apache.ws.security.WSPasswordCallback;

public class SamplePasswordCallback implements CallbackHandler {

    private Map<String, String> userPasswords = new HashMap<String, String>();
    private Map<String, String> keyPasswords = new HashMap<String, String>();
    public SamplePasswordCallback() {
        // some example user passwords
        userPasswords.put("user1", "user1pswd");
        userPasswords.put("admin", "adminpswd");
        // some example key passwords
        keyPasswords.put("alice", "keypswd");
        keyPasswords.put("bob", "keypswd");
    }
}

```

```

    }
    public void handle(Callback[] callbacks) throws IOException, UnsupportedOperationException {
        for (int i = 0; i < callbacks.length; i++) {
            WSPasswordCallback pwcb = (WSPasswordCallback)callbacks[i];
            String id = pwcb.getIdentifier();
            String pass = null;
            switch (pwcb.getUsage()) {
                case WSPasswordCallback.USERNAME_TOKEN_UNKNOWN:
                case WSPasswordCallback.USERNAME_TOKEN:
                    pass = userPasswords.get(id);
                    pwcb.setPassword(pass);
                    break;
                case WSPasswordCallback.SIGNATURE:
                case WSPasswordCallback.DECRYPT:
                    pass = keyPasswords.get(id);
                    pwcb.setPassword(pass);
                    break;
            }
        }
    }
}

```

2. Create a MANIFEST.MF file for the callback handler. The following example shows a MANIFEST.MF file:

```

Manifest-Version: 1.0
Bnd-LastModified: 1359415594428
Build-Identifier: SNAPSHOT-Mon Jan 28 17:26:34 CST 2013
Bundle-Copyright: The Program materials contained in this file are IBM
copyright materials. 5724-I63, 5724-J08, 5724-H89, 5724-H88, 5655-W65
Copyright International Business Machines Corp. 1999, 2012 All Rights
Reserved * Licensed Materials - Property of IBM US Government Users
Restricted Rights - Use, duplication or disclosure restricted by GSA ADP
Schedule Contract with IBM Corp.
Bundle-Description: An PasswordCallbackHandler; version=1.0.0
Bundle-ManifestVersion: 2
Bundle-Name: wssecuritycbh
Bundle-SymbolicName: com.ibm.ws.wssecurity.example.cbh
Bundle-Vendor: IBM
Bundle-Version: 1.0.0
Created-By: 1.6.0 (IBM Corporation)
Export-Package: com.ibm.ws.wssecurity.example.cbh;uses="com.ibm.websphe
re.ras.annotation,java.security.auth.callback";version="1.0.0"
Import-Package: com.ibm.websphere.ras,com.ibm.websphere.ras.annotation,c
om.ibm.ws.ffdc,java.security.auth.callback,org.apache.ws.security;version="[1.6,2)"
Require-Capability: osgi.ee;filter="(&(osgi.ee=JavaSE)(version>=1.6))"
Tool: Bnd-2.1.0.20120920-170235
WS-TraceGroup: WSSecurity

```

3. Package the callback handler into a JAR file. Create a JAR file with the callback handler class and the MANIFEST.MF file that you created in the previous steps. The following example shows the contents of a sample JAR file that is called SampleCbh.jar:

```

META-INF/MANIFEST.MF
com/ibm/ws/wssecurity/example/cbh/SamplePasswordCallback.class

```

4. Create a feature manifest file. The following example shows a sample feature manifest file that is called wssecdbh-1.0.mf:

```

Subsystem-ManifestVersion: 1
Subsystem-SymbolicName: wssecdbh-1.0; visibility:=public
Subsystem-Version: 1.0.0
Subsystem-Content: com.ibm.ws.wssecurity.example.cbh; version="[1,1.0.100)";
    location="lib/"; type="osgi.bundle"; start-phase:=APPLICATION_EARLY

```

```

Subsystem-Type: osgi.subsystem.feature
IBM-Feature-Version: 2

```

```

IBM-API-Package: com.ibm.ws.wssecurity.example.cbh; version="1.0"; type="internal"

```

5. Install the callback handler as a user feature in Liberty. Copy the callback handler JAR file and the feature manifest file to the Liberty user directory. The following example shows where to copy the files:

```
build.image/wlp/usr/extension/lib/SampleCbh.jar  
build.image/wlp/usr/extension/lib/features/wssecbh-1.0.mf
```

6. Configure the callback handler as a user feature in the `server.xml` file. Define the callback handler as a user feature in the `server.xml` file. The following example shows how to define the callback handler as a user feature:

```
<featureManager>  
  <feature>usr:wssecbh-1.0</feature>  
  <feature>servlet-3.0</feature>

  <feature>jaxws-2.2</feature>  
  <feature>wsSecurity-1.1</feature>  
</featureManager>
```

## Results

You successfully developed the password callback handler and installed the callback handler to Liberty.

## What to do next

You can now use this callback handler to retrieve passwords for UsernameTokens and private keys that are used in WS-Security configuration.

## Securing a web service by using a WS-Security policy

0.5.5.0

You can develop and secure a Java API for XML Web Services (JAX-WS) web service by using a WS-Security policy in the IBM WebSphere Application Server Liberty. The examples are provided as a tutorial to explain the general steps that are involved in developing and securing a web service in Liberty. Do not use the examples in a production environment. Review your own security requirements to develop the Web Services Description Language (WSDL) contract and the WS-Security policy for protecting your web service applications.

## About this task

This task describes how to develop a simple JAX-WS web service application and secure the application by using a WS-Security policy.

This task uses two keystores: `enc-sender.jceks` and `enc-receiver.jceks`. These are WS-Security sample keystores that are shipped in traditional. If you have access to a traditional installation, you can obtain the sample keystores from one of the following directories:

```
profile_root/etc/ws-security/samples
```

```
WASHOME/profileTemplates/defaultdocuments/etc/ws-security/samples
```

If you do not have access to traditional, a zip file that contains all of the WS-Security sample keystores can be found here: <http://www-01.ibm.com/support/docview.wss?uid=swg21507405&aid=1>

## Procedure

1. Create the WSDL contract and WS-Security policy. In this sample, a WSDL contract with a WS-Security policy for a JAX-WS web service provider application is created. The WS-Security policy template called UsernameToken with X509Token asymmetric message protection (mutual authentication) is used. The client signs and encrypts the SOAP body and signs and encrypts the

UsernameToken in the request message. In the response message, the provider signs and encrypts the SOAP body. For a complete description of the security constraints in this example, see UsernameToken with X509Token asymmetric message protection (mutual authentication).

a. Create a WSDL contract for your service. The following example shows a sample WSDL contract:

```
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions xmlns:wSDL="http://schemas.xmlsoap.org/wsdl/"
  xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
  xmlns:tns="http://com.ibm/was/wssample/sei/echo/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="WSSampleSei"
  targetNamespace="http://com.ibm/was/wssample/sei/echo/">
  <wsdl:types>
    <xsd:schema targetNamespace="http://com.ibm/was/wssample/sei/echo/"
      xmlns:xsd="http://www.w3.org/2001/XMLSchema">
      <xsd:element name="echoStringResponse">
        <xsd:complexType>
          <xsd:sequence>
            <xsd:element name="echoResponse" type="xsd:string" />
          </xsd:sequence>
        </xsd:complexType>
      </xsd:element>
      <xsd:element name="echoStringInput">
        <xsd:complexType>
          <xsd:sequence>
            <xsd:element name="echoInput" type="xsd:string" />
          </xsd:sequence>
        </xsd:complexType>
      </xsd:element>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="echoOperationRequest">
    <wsdl:part element="tns:echoStringInput" name="parameter" />
  </wsdl:message>
  <wsdl:message name="echoOperationResponse">
    <wsdl:part element="tns:echoStringResponse" name="parameter" />
  </wsdl:message>
  <wsdl:portType name="EchoServicePortType">
    <wsdl:operation name="echoOperation">
      <wsdl:input message="tns:echoOperationRequest" />
      <wsdl:output message="tns:echoOperationResponse" />
    </wsdl:operation>
  </wsdl:portType>
  <wsdl:binding name="EchoISOAP" type="tns:EchoServicePortType">
    <soap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http" />
    <wsdl:operation name="echoOperation">
      <soap:operation soapAction="echoOperation" style="document" />
      <wsdl:input>
        <soap:body use="literal" />
      </wsdl:input>
      <wsdl:output>
        <soap:body use="literal" />
      </wsdl:output>
    </wsdl:operation>
  </wsdl:binding>
  <wsdl:service name="Echo1Service">
    <wsdl:port binding="tns:EchoISOAP" name="Echo1ServicePort">
      <soap:address location="http://localhost:8010/WSSampleSei/Echo1Service" />
    </wsdl:port>
  </wsdl:service>
</wsdl:definitions>
```

b. Add the namespaces that are needed to support the security policy to your WSDL in the wsdl:definitions element. The following example shows the added namespaces:

```
xmlns:wsp="http://www.w3.org/ns/ws-policy"
xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702"
xmlns:sp13="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200802"
xmlns:wsaws="http://www.w3.org/2005/08/addressing"
```

c. Add the WS-Security policy fragment to your WSDL just before the wsdl:binding element. The policy template from UsernameToken with X509Token asymmetric message protection (mutual authentication) is used in this example.

d. Add a wsp:PolicyReference for your security policy to your wsdl:binding element. The following example shows the wsp:PolicyReference:

```
<wsp:PolicyReference URI="#AsymmetricX509MutualAuthenticationWithUnt" />
```

e. Verify that your final WSDL looks like the example. The following example shows the final WSDL:

```
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
  xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
  xmlns:tns="http://com.ibm/was/wssample/sei/echo/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="WSSampleSei"
  xmlns:wsp="http://www.w3.org/ns/ws-policy"
  xmlns:wssu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
  xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702"
  xmlns:sp13="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200802"
  xmlns:wsa="http://www.w3.org/2005/08/addressing"
  targetNamespace="http://com.ibm/was/wssample/sei/echo/">
  <wsdl:types>
    <xsd:schema targetNamespace="http://com.ibm/was/wssample/sei/echo/"
      xmlns:xsd="http://www.w3.org/2001/XMLSchema">
      <xsd:element name="echoStringResponse">
        <xsd:complexType>
          <xsd:sequence>
            <xsd:element name="echoResponse" type="xsd:string" />
          </xsd:sequence>
        </xsd:complexType>
      </xsd:element>
      <xsd:element name="echoStringInput">
        <xsd:complexType>
          <xsd:sequence>
            <xsd:element name="echoInput" type="xsd:string" />
          </xsd:sequence>
        </xsd:complexType>
      </xsd:element>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="echoOperationRequest">
    <wsdl:part element="tns:echoStringInput" name="parameter" />
  </wsdl:message>
  <wsdl:message name="echoOperationResponse">
    <wsdl:part element="tns:echoStringResponse" name="parameter" />
  </wsdl:message>
  <wsdl:portType name="EchoServicePortType">
    <wsdl:operation name="echoOperation">
      <wsdl:input message="tns:echoOperationRequest" />

</wsp:Policy>
<wsdl:binding name="Echo1SOAP" type="tns:EchoServicePortType">
    <wsp:PolicyReference URI="#AsymmetricX509MutualAuthenticationWithUnt" />
    <soap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http" />
    <wsdl:operation name="echoOperation">
        <soap:operation soapAction="echoOperation" style="document" />
        <wsdl:input>
            <soap:body use="literal" />
        </wsdl:input>
        <wsdl:output>
            <soap:body use="literal" />
        </wsdl:output>
    </wsdl:operation>
</wsdl:binding>
<wsdl:service name="Echo1Service">
    <wsdl:port binding="tns:Echo1SOAP" name="Echo1ServicePort">
        <soap:address location="http://localhost:8010/WSSampleSei/Echo1Service" />
    </wsdl:port>
</wsdl:service>
</wsdl:definitions>

```

2. Create the web service application by using WSDL. This step can be done before or after the WS-Security policy is added to the WSDL. You can use supported tools to create a JAX-WS web service application from the WSDL that was developed in the previous section.

The following example shows a web service application that is developed from the WSDL by using the Rational Application Developer (RAD) tool:

```

@javax.jws.WebService (endpointInterface="com.ibm.was.wssample.sei.echo.EchoServicePortType",
    targetNamespace="http://com.ibm.was.wssample/sei/echo/",
    serviceName="Echo1Service",
    wsdlLocation = "WEB-INF/wsdl/Echo.wsdl",
    portName="Echo1ServicePort")
public class Echo1SOAPImpl {

    public EchoStringResponse echoOperation(EchoStringInput parameter) {
        String strInput = (parameter == null ? "input_is_null" : parameter.getEchoInput() );
        try {
            com.ibm.was.wssample.sei.echo.EchoStringResponse strOutput = new EchoStringResponse();
            strOutput.setEchoResponse( "Echo1SOAPImpl>>" + strInput );
            return strOutput;
        } catch (java.lang.Exception ex) {
            ex.printStackTrace();
        }
    }
}

```

```

@WebService (name = "EchoServicePortType",
            targetNamespace = "http://com/ibm/was/wssample/sei/echo/")
@SOAPBinding (parameterStyle = SOAPBinding.ParameterStyle.BARE)
@XmlSeeAlso ({
    ObjectFactory.class
})

public interface EchoServicePortType {

    @WebMethod (action = "echoOperation")
    @WebResult (name = "echoStringResponse", targetNamespace = "http://com/ibm/was/wssample/sei/echo/", partName = "parameter")
    public EchoStringResponse echoOperation(
        @WebParam (name = "echoStringInput", targetNamespace = "http://com/ibm/was/wssample/sei/echo/", partName = "parameter")
        EchoStringInput parameter);

}

```

The following code shows a managed web service client that invokes a web service provider application:

```

@WebServlet("ClientServlet")
public class ClientServlet extends HttpServlet {

    @WebServiceRef (value=Echo1Service.class, wsdlLocation="Echo.wsdl")
    Echo1Service echo1Service;

    public ClientServlet() {
        super ();
    }

    protected void doGet(HttpServletRequest request,
                        HttpServletResponse response) throws ServletException, IOException {
        processRequest(request, response);
    }

    protected void doPost(HttpServletRequest request,
                        HttpServletResponse response) throws ServletException, IOException {
        processRequest(request, response);
    }

    private void processRequest(HttpServletRequest req,
                        HttpServletResponse resp) throws ServletException, IOException {

        String endpointURL = "http://localhost:8010/WSSampleSei/Echo1Service";

        Echo1ServicePortProxy proxy = new Echo1ServicePortProxy(echo1Service);
        proxy._getDescriptor().setEndpoint(endpointURL);

        echoParm = new ObjectFactory().createEchoStringInput();
        echoParm.setEchoInput("Hello");

        String retval = proxy.echoOperation(echoParm).getEchoResponse();
    }
}

```

The following example shows the file structure of the web service provider application war file:

```

WEB-INF/web.xml
WEB-INF/wsdl/Echo.wsdl
WEB-INF/classes/com/ibm/was/wssample/sei/echo/Echo1SOAPImpl.class
WEB-INF/classes/com/ibm/was/wssample/sei/echo/EchoServicePortType.class
WEB-INF/classes/com/ibm/was/wssample/sei/echo/EchoStringInput.class
WEB-INF/classes/com/ibm/was/wssample/sei/echo/EchoStringResponse.class
WEB-INF/classes/com/ibm/was/wssample/sei/echo/ObjectFactory.class
WEB-INF/classes/com/ibm/was/wssample/sei/echo/package-info.class

```

The following example shows the file structure of the web service client application war file:

```

WEB-INF/web.xml
WEB-INF/wsdl/Echo.wsdl
WEB-INF/classes/com/ibm/was/wssample/client/ClientServlet.class
WEB-INF/classes/com/ibm/was/wssample/client/SampleClient.class
WEB-INF/classes/com/ibm/was/wssample/sei/echo/Echo1Service.class
WEB-INF/classes/com/ibm/was/wssample/sei/echo/Echo1ServicePortProxy.class
WEB-INF/classes/com/ibm/was/wssample/sei/echo/EchoStringInput.class

```

```

WEB-INF/classes/com/ibm/was/wssample/sei/echo/EchoStringResponse.class
WEB-INF/classes/com/ibm/was/wssample/sei/echo/ObjectFactory.class
WEB-INF/classes/com/ibm/was/wssample/sei/echo/package-info.class

```

3. Develop the callback handler. You must develop a callback handler to retrieve the user name and keystore key passwords. The user name password is used when you generate the UsernameTokens. The keystore passwords are used for accessing the private keys in the keystore. The callback handler must return plaintext passwords and be packaged and installed as a Liberty user feature.

The following sample code illustrates a callback handler:

```

package com.ibm.ws.wsssecurity.example.cbh;

import java.util.HashMap;
import java.util.Map;
import javax.security.auth.callback.Callback;
import javax.security.auth.callback.CallbackHandler;
import org.apache.ws.security.WSPasswordCallback;

public class SamplePasswordCallback implements CallbackHandler {
    private Map<String, String> userPasswords = new HashMap<String, String>();
    private Map<String, String> keyPasswords = new HashMap<String, String>();
    public SamplePasswordCallback() {
        // some example user passwords
        userPasswords.put("user1", "user1pswd");
        userPasswords.put("admin", "adminpswd");
        // some example key passwords
        keyPasswords.put("alice", "keypswd");
        keyPasswords.put("bob", "keypswd");
    }
    public void handle(Callback[] callbacks) throws IOException, UnsupportedCallbackException {
        for (int i = 0; i < callbacks.length; i++) {
            WSPasswordCallback pwcb = (WSPasswordCallback)callbacks[i];
            String id = pwcb.getIdentifier();
            String pass = null;
            switch (pwcb.getUsage()) {
                case WSPasswordCallback.USERNAME_TOKEN_UNKNOWN:
                case WSPasswordCallback.USERNAME_TOKEN:
                    pass = userPasswords.get(id);
                    pwcb.setPassword(pass);
                    break;
                case WSPasswordCallback.SIGNATURE:
                case WSPasswordCallback.DECRYPT:
                    pass = keyPasswords.get(id);
                    pwcb.setPassword(pass);
                    break;
            }
        }
    }
}

```

The following example shows the MANIFEST.MF file that is packaged with the callback handler:

```

Manifest-Version: 1.0
Bnd-LastModified: 1359415594428
Build-Identifier: SNAPSHOT-Mon Jan 28 17:26:34 CST 2013

Schedule Contract with IBM Corp.
Bundle-Description: An PasswordCallbackHandler; version=1.0.0
Bundle-ManifestVersion: 2
Bundle-Name: wsssecuritycbh
Bundle-SymbolicName: com.ibm.ws.wsssecurity.example.cbh
Bundle-Vendor: IBM
Bundle-Version: 1.0.0
Created-By: 1.6.0 (IBM Corporation)
Export-Package: com.ibm.ws.wsssecurity.example.cbh;uses:="com.ibm.websphe
re.ras.annotation,javax.security.auth.callback";version="1.0.0"
Import-Package: com.ibm.websphere.ras,com.ibm.websphere.ras.annotation,c

```

```
om.ibm.ws.ffdc, javax.security.auth.callback, org.apache.ws.security; version="[1.6,2)"
Require-Capability: osgi.ee; filter:="(&(osgi.ee=JavaSE)(version>=1.6))"
Tool: Bnd-2.1.0.20120920-170235
WS-TraceGroup: WSSecurity
```

- a. Create a JAR file with the callback handler and the feature manifest file - wssecdbh-1.0.mf. Create a JAR file that is called SampleCbh.jar with the following contents:

```
META-INF/MANIFEST.MF
com/ibm/ws/wssecurity/example/cbh/SamplePasswordCallback.class
```

The following example shows the wssecdbh-1.0.mf file:

```
Subsystem-ManifestVersion: 1
Subsystem-SymbolicName: wssecdbh-1.0; visibility:=public
Subsystem-Version: 1.0.0
Subsystem-Content: com.ibm.ws.wssecurity.example.cbh; version="[1,1.0.100)";
    location:="lib/"; type="osgi.bundle"; start-phase:=APPLICATION_EARLY
```

```
Subsystem-Type: osgi.subsystem.feature
IBM-Feature-Version: 2
```

```
IBM-API-Package: com.ibm.ws.wssecurity.example.cbh; version="1.0"; type="internal"
```

- b. Copy the callback handler JAR file and the feature manifest file under the Liberty user directory. The following example shows where the callback handler JAR file and the feature manifest file are copied:

```
build.image/wlp/usr/extension/lib/SampleCbh.jar
build.image/wlp/usr/extension/lib/features/wssecdbh-1.0.mf
```

4. Configure WS-Security in the Liberty server. Enable the WS-Security feature in the Liberty server configuration file: server.xml and configure WS-Security for the sample web service client and provider application that is developed in the previous sections.

The following example shows how to configure WS-Security:

```
<server>
  <featureManager>
    <feature>usr:wssecdbh-1.0</feature>
    <feature>servlet-3.0</feature>
    <feature>appSecurity-2.0</feature>
    <feature>jsp-2.2</feature>
    <feature>jaxws-2.2</feature>
    <feature>wsSecurity-1.1</feature>
  </featureManager>
  <basicRegistry id="basic" realm="customRealm">
    <user name="user1" password="user1pswd" />
    <user name="user2" password="user2pswd" />
  </basicRegistry>
  <wsSecurityProvider id="default"
    ws-security.callback-handler="com.ibm.ws.wssecurity.example.cbh.SamplePasswordCallback"
    ws-security.signature.username="bob">
    <signatureProperties org.apache.ws.security.crypto.merlin.keystore.type="jceks"
      org.apache.ws.security.crypto.merlin.keystore.password="storepswd"
      org.apache.ws.security.crypto.merlin.keystore.alias="bob"
      org.apache.ws.security.crypto.merlin.file="{server.config.dir}/enc-receiver.jceks" />
    <encryptionProperties org.apache.ws.security.crypto.merlin.keystore.type="jceks"
      org.apache.ws.security.crypto.merlin.keystore.password="storepswd"
      org.apache.ws.security.crypto.merlin.keystore.alias="alice"

## What to do next

You can now develop your own WSDL file and protect the web service application by using a WS-Security policy that matches your security requirements.

## Migrating CXF WS-Security to Liberty

**8.5.5.0**

Migrating CXF WS-Security to Liberty is easy and straightforward. The migration work includes migrating the Spring or Spring-like configuration to the `server.xml` file. If a `CallbackHandler` is required, you must also package and install a password `CallbackHandler` as a Liberty user feature.

### Before you begin

Ensure that you have a working knowledge of CXF WS-Security enabled web services outside Liberty.

### About this task

To protect your web service application with WS-Security, your JAX-WS application must contain a `wsdl` that has an embedded WS-Security policy. There must be a `PolicyReference` to the embedded WS-Security policy in either the `wsdl:binding` or `wsdl:operation` sections or both. After you migrate your web service to Liberty, you can enable a WS-Security policy-driven WS-Security configuration. This task describes how you can migrate an Apache CXF WS-Security configuration to Liberty.

### Procedure

1. Add the `wsSecurity-1.1` feature to the `server.xml` file to enable WS-Security in Liberty.
2. Add the WS-Security configuration to the `server.xml` file. CXF WS-Security in Liberty does not support the Spring configuration file, or its equivalent configuration file from other vendors. You must migrate extra configurations that are defined outside the policy from the Spring or its equivalent configuration file to the `server.xml` file in Liberty.

Create the `<wsSecurityClient>` element to hold the client-side configuration, and the `<wsSecurityProvider>` element to hold the server-side configuration. All configuration property name and value pairs from CXF and WSS4J must be preserved. You can use the same name and value pairs from the Spring or equivalent configuration files. For crypto properties, you must create the `<signatureProperties>` and `<encryptionProperties>` subelements to hold all the required properties. For more information, see [Web services security default configuration](#).

3. Package your password callback handler as a Liberty profile user feature if you have a password callback handler in your Spring configuration files. For more information about the password `CallbackHandler`, see [Developing a password callback handler for WS-Security](#).

## Results

You migrated a WSDL-first web service to Liberty.

## Authenticate web service clients with a SAML (Security Markup Assertion Language) Token

8.5.5.8

Web Services Security SAML Token Profile 1.1 defines how to use Security Assertion Markup Language (SAML) V1.1 and V2.0 assertions with the Web Services Security (WSS): SOAP Message Security V1.1 specification. Liberty supports Web Services Security SAML Token Profile 1.1 for SAML v2.0 assertion with bearer confirmation method.

### About this task

Liberty supports SAML v2.0 with bearer confirmation method (<SubjectConfirmation Method="urn:oasis:names:tc:SAML:2.0:cm:bearer">). A web services client propagates a SAML token to the web services provider as a means of identifying the requester, and the web services provider can use this SAML token information to authenticate the requester.

The requirement of a SAML token is expressed as one of the supporting tokens in the WS-Security policy. You can add a SamlToken requirement as a required token in one of the supporting token assertions, including SupportingTokens, SignedSupportingTokens, SignedEncryptedSupportingTokens, and EncryptedSupportingTokens.

### Procedure

1. Configure a web services client to propagate the SAML token.

It is required that a Saml20Token (com.ibm.websphere.security.saml2.Saml20Token) exists in the RunAs Subject. If a SamlToken policy assertion is configured, the Liberty WS-Security runtime will automatically extract the Saml20Token from the RunAs Subject, and attach a SAML assertion to the <wsse:Security> SOAP header. The following steps are required:

- a. Add wsSecuritySaml-1.1 to the featureManager in the server.xml file.

```
<featureManager>
  <feature>wsSecuritySaml-1.1</feature>
</featureManager>
```

- b. The application must specify the SAML token as a supporting token (including SupportingTokens, SignedSupportingTokens, SignedEncryptedSupportingTokens, and EncryptedSupportingTokens token assertion) in the policy in the .wsdl file.

```
<wsp:Policy wsu:Id="CallerHttpPolicy">
  <sp:SupportingTokens>
    <wsp:Policy>
      <sp:SamlToken
        sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken/AlwaysToRecipient">
        <wsp:Policy>
          <sp:WssSamlV20Token11 />
        </wsp:Policy>
      </sp:SamlToken>
    </wsp:Policy>
  </sp:SupportingTokens>
</wsp:Policy>
```

2. Authenticate the Web Service with a SAML token.

When the web services provider receives the SOAP message with the SAML token, it validates the token first and then uses the SAML token attributes to complete the authentication process. The following are the steps that are involved in validating the SAML token:

- a. Add wsSecuritySaml-1.1 to the featureManager in the server.xml file.

```

<featureManager>
  <feature>wsSecuritySaml-1.1</feature>
</featureManager>

```

- b. The application must specify the SAML token as a supporting token in the policy inside the .wsdl file.
- c. The following attributes in the server configuration are used when validating the token.

```

<wsSecurityProvider id="default"
  ..
  ..
  <saml token
    wantAssertionsSigned="true"
    clockSkew="5m"
    timeToLive="30m"
    requiredSubjectConfirmationMethod="bearer"
    audienceRestrictions="https://../aud1"
    audienceRestrictions="aud2" .. />

</wsSecurityProvider>

```

- wantAssertionsSigned - Specify whether the <saml:Assertion> element in the SOAP message received by the WS-Security provider is signed.
- clockSkew - The time difference that is allowed between systems that generated the SAML token and received the SAML token. The default is 5 minutes.
- timeToLive - The life time of a SAML Assertion. This setting is required when the NoOnOrAfter condition is missing in the SAML assertion. The default is 30 minutes.
- requiredSubjectConfirmationMethod - Subject confirmation method in the SAML assertion. The default is bearer.
- audienceRestrictions - The allowed audiences of the SAML assertion. The default is all audiences allowed.

For further details on the steps involved in authenticating, see *Creating a WS-Security SAML caller configuration*.

## Web Services Security HTTPS transport policy assertions

### 8.5.5.0

You can use assertions in the Web Services Security (WS-Security) policy defined in the WSDL file to ensure that SOAP messages are protected with the HTTPS secure transport. When used with security tokens such as UsernameTokens with clear text passwords, HTTPS can help to ensure confidentiality.

The assertions for the HTTPS transport in the WS-Security policy do not set up the HTTPS transport between the requestor and provider. They ensure only that the HTTPS transport is used when the web services application with the defined policy is called. **8.5.5.0** To enable the transport security for web services, see “Securing web services at the transport level” on page 2018.

Ensure that HTTPS is set up between the web services client and provider. To protect your SOAP messages with the HTTPS secure transport, complete the following extra steps.

1. **8.5.5.0** WS-Security must be explicitly enabled by adding the wsSecurity-1.1 feature. Make sure you also add the appSecurity-2.0, servlet-3.0(or servlet-3.1) and jaxws-2.2 features, and other required Liberty features to the server.xml file of the Liberty profile.
2. The WS-Security policy attached to your web services application must include a TransportBinding assertion, and must match the HTTPS configuration. The following example illustrates a sample TransportBinding assertion:

```

<wsp:Policy xmlns:wsp="..." xmlns:sp="...">
  <sp:TransportBinding>
    <wsp:Policy>
      <sp:TransportToken>
        <wsp:Policy>
          <sp:HttpsToken />
        </wsp:Policy>
      </sp:TransportToken>
      <sp:AlgorithmSuite>
        <wsp:Policy>
          <sp:Basic256 />
        </wsp:Policy>
      </sp:AlgorithmSuite>
      <sp:Layout>
        <wsp:Policy>
          <sp:Strict />
        </wsp:Policy>
      </sp:Layout>
      <sp:IncludeTimestamp />
    </wsp:Policy>
  </sp:TransportBinding>
</wsp:Policy>

```

By completing these extra steps after the HTTPS configuration, SOAP messages are required to be sent over HTTPS from a web services client to a web services provider.

---

## Liberty:Security considerations

### 8.5.6.0

Consider the following when you configure Security for Liberty.

#### LTPA

- Protect file access to the LTPA keys file because it contains the cryptographic material that is used to encrypt and decrypt the user data. Ensure that only the server and administrators have access to this file.
- Ensure that all servers use the same LTPA keys. In addition, make sure that the all the servers have their time and date synchronized.
- When you specify a password, ensure that it is the same password for all servers that use the same set of LTPA keys. The password is not used to generate the keys, but rather it is used to encrypt the LTPA keys file to prevent the keys from being read. If you copy the LTPA keys file to another Liberty server to achieve Single Sign-On (SSO), the password is required to gain access to the keys in the LTPA keys file. For more information about LTPA, see Configuring LTPA on Liberty topic.

#### Passwords

- Encrypt passwords by using the securityUtility encode command.
- If you override the default encryption key with the wlp.password.encryption.key property, set the property in a separate configuration file that is stored outside the normal configuration directory for the server.

#### Authorization

- If you specify an auth-constraint with no roles in an application, then no one is allowed to access the resource.
- Be cautious when you specify the EVERYONE special subject, as this specification is equivalent to not protecting a resource.

## Authentication

- The timeout value for the authentication cache that is specified in the <authCache> element must be smaller than the expiration value for the LTPA token that is specified in the <ltpa> element.

---

## Securing Liberty by using HTTP Strict Transport Security (HSTS)

You can secure Liberty by first setting up HTTP Strict Transport Security (HSTS) in IBM HTTP Server. Then, add IBM HTTP Server as a front end to Liberty so that connections between Liberty and a client are over HTTPS.

### Procedure

1. Set up HSTS in IBM HTTP Server.
2. Add IBM HTTP Server as a front end to Liberty.

---

## Chapter 9. Developing applications in the Liberty environment

WebSphere Application Server Liberty is a lightweight, composable application server that provides a convenient application development environment for your web and OSGi applications. Applications that run on Liberty also run on the WebSphere Application Server traditional server.

### About this task

Liberty simplifies application development by providing the following key benefits and more:

- Frictionless download, at no cost, for development purposes
- Ultra lightweight modular runtime environment, with an install size of under 50 MB
- Very fast startup time; for example, less than 5 seconds for simple web applications
- Simplified configuration for quick time to productivity
- Java EE and OSGi application deployment support for web applications
- LDAP registry support
- Deployment, as a package, of an application and configured server
- Managed, centralized deployment of a packaged application and server
- Availability of WebSphere Application Server Developer Tools as Eclipse plug-ins for broad tools support
- Platform support for distributed platforms, z/OS, and Mac OS

Very fast restart times, coupled with its small size, dynamic behavior, and ease of use, make Liberty a good option for developers building web applications that do not require the full Java EE environment of traditional enterprise application server profiles. Familiar WebSphere Application Server enterprise qualities of service, such as security and transaction integrity, are enabled as required.

---

### Developing applications that interact with z/OS resources

To interact between Liberty applications and resources in your z/OS environment, you can use features such as z/OS Connect and the optimized local adapters.

### Developing applications that use optimized local adapters on Liberty

Optimized local adapters enable high-performance calling between native-language applications on z/OS and business logic in a Liberty server environment.

### Using Liberty to Invoke an API to call an enterprise bean from an external address space

Use the WebSphere optimized local adapter (WOLA) Invoke API to call from an external address space to a stateless session bean that is deployed on a local Liberty server for z/OS.

## Before you begin

To identify your enterprise bean as a potential target of an optimized local adapter call, your Enterprise JavaBean (EJB) application must implement the `com.ibm.websphere.ola.ExecuteLocalBusiness` interface as a local business interface. The interface is located in the `wlp/dev/api/ibm/com.ibm.websphere.appserver.api.zosLocalAdapters_1.0.0.jar` file.

The Liberty server must be active on the same z/OS image that the register request originates from. Ensure that the current address space is already registered and bound to the target optimized local adapter group using the Register API. For more information about registering an external address space, see “Registering an external address space with a local Liberty server using optimized local adapters” on page 1711.

## About this task

This method of calling an enterprise bean provides a simplified path for when you know the response area length before you call the bean. If you do not know the response area length or want more flexibility when you call the bean, see “Using the Liberty optimized local adapters APIs to invoke an enterprise bean from an external address space” on page 2075.

## Procedure

1. Decide which parameters to use when you call the bean using the Invoke API, which is BBOA1INV.

The API accepts parameters for the following items:

- The register name that you specified when you called the Register API
- The request type, which must be set to 1 for local EJB work requests
- The name of the service to invoke, which must be the Java Naming and Directory Interface (JNDI) local business interface path name of the stateless session bean
- The length of the service name
- A pointer to the address of the start of the request data to send
- The length of the request data to send
- A pointer to the address of the start of the response data area
- The length of the response data to send
- The number of seconds until the connection times out

For more information about API parameters, see “Optimized local adapters APIs on Liberty for z/OS” on page 2079.

2. Call the Invoke API for your caller with your selected parameters from a native-language application in the client address space. In the target Enterprise JavaBeans (EJB) application, the execute method runs and then starts any business logic that is required before returning the response data as a serialized byte array back to the native-language caller.
3. Review the response data. A 0 return code and reason code indicates that the client Invoke API call completed successfully and the response data and response data length are saved in the areas designated by the caller.
4. The client application repeats these steps using the same register name call, calling as many stateless session beans as needed, as often as needed.

**Attention:** With the Invoke API, the three primitive functions, `Send_Request`, `Receive_RespLen`, and `Get_Data` are all completed. The calling thread is blocked until the response data is received and copied to the response area.

## Results

The client starts a stateless session bean from the Liberty server using the optimized local adapter Invoke API.

## Using the Liberty optimized local adapters APIs to invoke an enterprise bean from an external address space

z/OS

8.5.5.2

Use the WebSphere optimized local adapter (WOLA) APIs to connect an external address space to a Liberty server and invoke a local stateless session bean.

### Before you begin

To identify your enterprise bean as a potential target of an optimized local adapter call, your Enterprise JavaBean (EJB) application must implement the `com.ibm.websphere.ola.ExecuteLocalBusiness` interface as a local business interface. The interface is located in the `wlp/dev/api/ibm/com.ibm.websphere.appserver.api.zosLocalAdapters_1.0.0.jar` file.

For programs that are running under Customer Information Control System (CICS), the optimized local adapters task-related user exist (TRUE) program must be activated before a connection is made between CICS and the Liberty server. For more information, see “Liberty server transactions for CICS: BBOC, BBO\$, and BBO#” on page 1705.

The Liberty server must be active on the same z/OS image that the register request originates from. Ensure that the current address space is already registered and bound to the target optimized local adapter group using the Register API. For more information about registering an external address space, see “Registering an external address space with a local Liberty server using optimized local adapters” on page 1711.

### About this task

This method of invoking a stateless session bean provides more flexibility and is for situations when you might not know the response area maximum length before you call. For a simplified method of invoking the bean when the response area length is known, see “Using Liberty to Invoke an API to call an enterprise bean from an external address space” on page 2073.

### Procedure

1. Call the Connection Get API, `BBOA1CNG`, from the native-language application in the client address space, passing the register name that you used when you called the Register API, `BBOA1REG`. The call returns a connection handle that must be used for all future API calls.
2. Call the Send Request API, `BBOA1SRQ`, from the native-language application in the client address space. For the **requestservicename** parameter, specify the Java Naming and Directory Interface (JNDI) local business interface path name for the enterprise bean that you want to invoke. Use the JNDI name in the global JNDI namespace. The Liberty server then invokes the execute method for the local business interface that the EJB application implements.

If you set the Send Request API **async** parameter to 0, the API returns the response length and the return value. You can then directly call the Get Message Data API.

If you set the Send Request API **async** parameter to 1, control returns to the client application so you can call the Receive Response Length API.

3. If you called the Send Request API with the **async** parameter set to 1, call the Receive Response Length API, `BBOA1RCL`, setting the **async** parameter to 0 or 1. The client application uses the response length that is returned by Receive Response Length API to ensure that it has an area large enough to hold the response data.

If you set the Receive Response Length API **async** parameter to 0, the API blocks the thread until a response is received.

If you set the Receive Response Length API **async** parameter to 1, the API returns immediately regardless of whether it received a response.

4. Call the Get Message Data API, BBOA1GET, to copy the response data into the client application's buffer.
5. The client application can continue to send requests and receive message data using the same connection handle until it sends all requests and is ready to release the connection. To release the connection, the application calls the Connection Release API, BBOA1CNR. Connection handles must be released before they can be retained on a Connection Get API call and used again.

## Using the optimized local adapters to connect to an application in an external address space from a Liberty application

Use the WebSphere optimized local adapters (WOLA) APIs to connect to an application in an external address space from an application that is deployed on the Liberty server.

### Before you begin

Register the external address space with the WOLA group. For more information, see “Registering an external address space with a local Liberty server using optimized local adapters” on page 1711.

Set up the application in the external address space as an optimized local adapters server task by calling either the Receive Request Any, Receive Request Specific, or Host Service APIs. For more information, see “Optimized local adapters APIs on Liberty for z/OS” on page 2079.

### Procedure

1. Enable the Liberty Enterprise JavaBeans (EJB) application to access the connection factory by using either resource injection or a JNDI lookup.
  - For resource injection, use the @Resource annotation to reference the connection factory that you defined in the server.xml file. The following example references the eis/ola connection factory:
 

```
@Resource(lookup = "eis/ola",
            authenticationType = Resource.AuthenticationType.APPLICATION,
            shareable = false)
private ConnectionFactory cf;
```
  - For JNDI lookup, create a resource reference in your application that you then look up in the enterprise bean.
    - a. Create a resource reference in the META-INF/ibm-ejb-jar-bnd.xml file for the application, where the binding-name matches the JNDI name of the connection factory in the server.xml file.
 

```
<session name="HSCBC016Bean">
  <resource-ref name="eis/ola" binding-name="eis/ola"/>
</session>
```
    - b. In the EJB implementation, create a connection factory object that looks up the resource reference that you defined. Prefix the name of the resource reference with java:comp/env/ as shown in the following example:
 

```
Context ctx = new InitialContext();
ConnectionFactory cf = ctx.lookup("java:comp/env/eis/ola");
```
2. Create a connection specification by creating a ConnectionSpecImpl object. Provide the register name of the external address space that you want to connect to in either of the following ways:
  - Add the register name as an attribute on the connection factory
  - Call the ConnectionSpecImpl method, setRegisterName, with the register name

The following example creates the ConnectionSpecImpl object and provides the MyRES1 register name:

```
ConnectionSpecImpl csi = new ConnectionSpecImpl();
csi.setRegisterName ("MyRES1");
```
3. Create a connection with the connection factory, as shown in the following example:
 

```
Connection con = cf.getConnection(csi);
```

## Results

The Liberty application is connected to an external address space and can call services that are hosted on the external address space. For more information, see “Using the Liberty optimized local adapters APIs to call services in an external address space.”

## Using the Liberty optimized local adapters APIs to call services in an external address space

Use the WebSphere optimized local adapters (WOLA) APIs to call services on an external address space or subsystem from a Liberty server.

### Before you begin

Connect the application to an external address space or subsystem as described in “Using the optimized local adapters to connect to an application in an external address space from a Liberty application” on page 2076.

If you want to pass record data that is generated by the Rational Application Developer CICS/IMS Java Data Binding wizard, you must first enable the connection to use the generated record data. For more information, see “Enabling generated record data in outbound optimized local adapter connections in Liberty” on page 2078

### Procedure

1. In the application, create an interaction from the Connection object that you created. The following example creates the `int` interaction from the `con` Connection object:  

```
Interaction int = con.createInteraction();
```
2. Create an interaction specification by creating an `InteractionSpecImpl` object and providing the service name, which is the name of the method that you want to call in the external address space or subsystem. The service name must be the name that you set when you called the Receive Request Any, Receive Request Specific, or Host Service APIs, or, if you are using a Customer Information Control System (CICS) server task, the name of the CICS program. The following example provides the `MYSERVICE` service name on the `isi` `InteractionSpecImpl` object:  

```
InteractionSpecImpl isi = new InteractionSpecImpl();
isi.setServiceName("MYSERVICE");
```
3. Run the interaction with the interaction specification. The following example runs the `int` interaction with the `isi` interaction specification and sends no data:  

```
int.execute(isi, null);
```

### Example

The following example shows how to start an interaction with input and output data as a byte array (`byte[]`):

```
public byte[] driveInteraction(javax.resource.cci.ConnectionFactory cf,
    javax.resource.cci.Connection con,byte[] inputDataBytes),throws javax.resource.ResourceException
{
    // Create an interaction using the optimized local adapter connection
    javax.resource.cci.Interaction i = con.createInteraction();
    // The InteractionSpec describes the service we want to call
    com.ibm.websphere.ola.InteractionSpecImpl isi = new com.ibm.websphere.ola.InteractionSpecImpl();
    isi.setServiceName("MYSERVICE");
    // The input data is specified using an IndexedRecord. The first
    // slot in the indexed record contains the input data bytes.
    javax.resource.cci.RecordFactory rf = cf.getRecordFactory();
    javax.resource.cci.IndexedRecord ir = rf.createIndexedRecord(null);
    ir.add(inputDataBytes);
```

```

// The interaction returns another IndexedRecord, whose first
// slot contains the output data bytes.
javax.resource.cci.Record or = i.execute(isi, ir);
byte[] outputDataBytes = null;

if (or != null)
{
    outputDataBytes = (byte[])((javax.resource.cci.IndexedRecord)or).get(0);
}

// Return the output data to the caller
return outputDataBytes;
}

```

The following example shows how to start an interaction using a Rational Application Developer generated copybook Record object. .

```

/**
 * An example of driving an optimized local adapter interaction, using a Rational
 * Application Developer copybook mapping class as input (inputRecord) and receiving
 * a Rational Application Developer copybook mapping as output.
 */
public javax.resource.cci.Record driveInteraction(
    javax.resource.cci.Connection con,
    javax.resource.cci.Record inputRecord)
    throws javax.resource.ResourceException
{
    // Create an interaction using the OLA connection
    javax.resource.cci.Interaction i = con.createInteraction();
    // The InteractionSpec describes the service we want to call com.ibm.websphere.ola.InteractionSpecImpl isi =
    new com.ibm.websphere.ola.InteractionSpecImpl();
    isi.setServiceName("MYSERVICE");
    // The Rational Application Developer generated copybook implements
    // javax.resource.cci.Record and can be passed directly to the interaction.
    // The interaction returns an IndexedRecord, whose first slot contains
    // the output data bytes.
    javax.resource.cci.Record or = i.execute(isi, inputRecord);
    javax.resource.cci.Record outputRecord = null;
    if (or != null)
    {
        // In this example, RADGeneratedOutputType is the name of the Rational Application Developer
        // generated copybook mapping class.
        outputRecord = new RADGeneratedOutputType();
        // The output bytes are stored in the output record returned on the
        // interaction, which is an IndexedRecord.
        byte[] outputDataBytes =
            (byte[])((javax.resource.cci.IndexedRecord)or).get(0);

        // To convert the output bytes to another Rational Application Developer generated copybook,
        // call the setBytes(byte[]) method of that class. The class will
        // implement the com.ibm.etools.marshall.RecordBytes interface.
        ((com.ibm.etools.marshall.RecordBytes)outputRecord)
            .setBytes(outputDataBytes);
    }

    // Return the output data to the caller
    return outputRecord;
}

```

## Enabling generated record data in outbound optimized local adapter connections in Liberty: z/OS

### 8.5.5.2

If you are passing data by using one of the Java EE Connector Architecture (JCA) record interfaces that the WebSphere optimized local adapters (WOLA) support, you can generate the Record classes by using the Rational Application Developer CICS/IMS Java Data Binding wizard.

## About this task

You can use the Rational Application Developer CICS/IMS Java Data Binding wizard to generate a `javax.resource.cci.Record` object that can replace the byte array that sends and receives data in the `IndexRecordImpl` and `MappedRecordImpl` objects. To use the generated Record classes, you must set up an extra library in the Liberty server instance to enable the server instance to serialize and deserialize the data in the Record object.

## Procedure

1. Copy the marshalling JAR file from Rational Application Developer into a `lib` subdirectory underneath the server configuration directory, which contains the `server.xml` file. The licensed, redistributable `marshall.jar` file is located in the `com.ibm.ccl.commonj.connector.metadata_version.timestamp` plug-in in the `runtime` folder. The exact name of the plug-in folder varies depending on the Rational Application Developer version.
2. In the `server.xml` file, create a `library` element that points to the new location of the marshalling JAR file, as shown in the following example. Replace `marshall.jar` with the actual name of your marshalling JAR file.

```
<!-- Library required by RAD generated application classes. -->
<library id="MarshallLib">
  <file name="{server.config.dir}/lib/marshall.jar"/>
</library>
```

3. In the `server.xml` file, add the new library to the application definition that contains the generated Record class by specifying the library ID that you created on a `classloader` element. The following example adds the `MarshallLib` library to the `WolaApp` application.

```
<!-- Application installed in {server.config.dir}/apps. -->
<application id="WolaApp" name="WolaApp" location="OLA.ear">
  <classloader commonLibraryRef="MarshallLib"/>
</application>
```

## Results

You can now use the Rational Application Developer CICS/IMS Java Data Binding wizard to generate record data for your outbound connection. For more information, see “Using the Liberty optimized local adapters APIs to call services in an external address space” on page 2077.

## Optimized local adapters APIs on Liberty for z/OS

WebSphere optimized local adapters (WOLA) on Liberty are supported by a set of z/OS native-language callable services application programming interfaces (APIs) and the Java EE Connector Architecture (JCA).

You can use the callable services from the following native programming languages:

- Cobol
- C/C++
- PL/I
- High-level assembly languages

The term *local connection* refers to a cross-memory link that is created for communication between an external address space on the z/OS system and the Liberty server on the same z/OS system. The client address space must be running on the same z/OS image. The adapter API manages these local connections in pools that are associated with each uniquely registered caller. The 12-character registration name can be used for only one set of connection pools per address space. The number of unique registrations in a single address space is limited only by the amount of available storage.

The Liberty supports the following optimized local adapters APIs:

- Register - BBOA1REG
- Unregister - BBOA1URG
- Connection Get - BBOA1CNG
- Connection Release - BBOA1CNR
- Send Request - BBOA1SRQ
- Send Response - BBOA1SRP
- Send Response Exception - BBOA1SRX
- Receive Request Any - BBOA1RCA
- Receive Request Specific - BBOA1RCS
- Receive Response Length - BBOA1RCL
- Get Message Data - BBOA1GET
- Invoke - BBOA1INV
- Host Service - BBOA1SRV
- JCA Adapter APIs

## Register

Using the BBOA1REG API, you can register with a local Liberty server. The BBOA1REG API requests that a group of optimized connections to a local Liberty server be allocated and registered under the specified register name.

*Table 145. BBOA1REG API syntax*

API	Syntax
BBOA1REG	BBOA1REG (wologroupnamepart1, wologroupnamepart2, wologroupnamepart3, registername, minconn, maxconn, registerflags, rc, rsn)

The BBOA1REG API accepts the following input parameters:

### **wologroupnamepart1**

An entry variable or entry constant that contains the first part of the name of the optimized local adapter group to be joined. It must be a null-terminated string of exactly 8 characters, and it must be passed by reference.

### **wologroupnamepart2**

An entry variable or entry constant that contains the second part of the name of the optimized local adapter group to be joined. It must be a blank-padded string of exactly 8 characters, and it must be passed by reference.

### **wologroupnamepart3**

An entry variable or entry constant that contains the third part of the name of the optimized local adapter group to be joined. It must be a blank-padded string of exactly 8 characters, and it must be passed by reference.

### **registername**

An entry variable or entry constant that contains the name that is used to register a set of local connections. Later calls require this name to identify the pool of connections to use. It must be a blank-padded string of exactly 12 characters, and it cannot be used in the current address space.

### **minconn**

An integer that contains the initial minimum number of connections to allocate for this registration. The adapter attempts to reserve this number of connections with the associated server during registration.

**Important:** At minimum, one connection is allocated to bind with the target server even if the `minconn` parameter is specified as 0, so specifying 0 is the same as specifying 1.

#### **maxconn**

An integer that contains the maximum number of connections to allocate for this registration. The adapter attempts to extend the local connection pool up to this number during a Connection Get API request when the minimum number of connections are all in use.

#### **registerflags**

A 32-bit flag word that contains registration flags.

- **reg\_flag\_W2Cprop** - bit 31

The `reg_flag_W2Cprop` flag controls outbound transaction security propagation from the Liberty server to CICS.

- **reg\_flag\_C2Wprop** - bit 29

The `reg_flag_C2Wprop` flag propagates the identity on the calling task from CICS to the Liberty server. For transactions that are inbound from CICS, the flag controls how the identity is determined. When this bit is turned *on*, the CICS application task identity is used in the Liberty server authorization process. When this bit is turned *off*, the CICS region identity is used.

- **reg\_flag\_trcmod** - bit 0

Set the `reg_flag_trcmod` flag if you want to modify the optimized local adapter trace settings for the requested registration. If you do not set this flag, no change to the trace setting is made, and the system defaults or predefined trace settings that apply to the registration name or job name are used.

- **reg\_flag\_trcmore** - bit 1 and **reg\_flag\_trcsome** - bit 2

If you set `reg_flag_trcmod` flag to 1, you must also specify the level of tracing for the registration by setting the `reg_flag_trcmore` flag for detailed tracing or the `reg_flag_trcsome` flag for coarse-level tracing. If `reg_flag_trcmod` is set to 1, setting both the `reg_flag_trcmore` flag and the `reg_flag_trcsome` flag to 0 forces no tracing for the registration regardless of what pre-definitions or defaults are set.

The BBOA1REG API accepts the following output parameters:

**rc** An integer return code that indicates success or failure of this call.

#### **rsn**

An integer reason code that describes the reason for a failure on this call.

Usage notes:

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.
- The minimum connections requested is validated against the server maximum connections. A minimum connection (`minconn`) value of 3 means that three connections are reserved during the register call. If more than three connections are requested at a given time, the connection pool can increase to the maximum connection (`maxconn`) value. When the number of all connections to a server reaches the maximum that is permitted, all subsequent Connection Get API requests for that server are rejected, even if the `maxconn` value is not yet reached.

**Important:** Use caution in setting the minimum connections value. Except in specific instances, do not set a large value because resources in the Liberty server are reserved for each connection.

- Multiple calls to the Register API can be made under the same address space, thread, or Customer Information Control System (CICS) task; however, they cannot share the same register name. The register name must be a unique name.
- Use the Unregister API call to remove this registration and release the connection pool associated with it.

- When the address space that makes a register call terminates, the registration is automatically terminated and the connections are released.

Return and reason codes:

Table 146. BBOA1REG API return and reason codes

Return Code	Reason Code	Description	Action
0	-	Success	
4	8.5.5.2 <sup>4</sup>	The transactional register flag was set to 1 in an environment where the adapter does not support global transactions.	This setting is ignored and processing continues.
8	-	Error - see reason code	
	8	The registration name token already exists.	Unregister this name before you call the Register API.
	12	The specified minimum connections parameter is larger than the maximum.	Ensure that the minimum connections setting is less than, or equal to, the maximum setting.
	14	Out of shared memory while trying to create registration.	Increase the shared memory allocation for the optimized local adapter or issue unregister calls to reduce resource consumption.
	74	Input register name contains a null.	Before you call the Register API, pad the register name with blank spaces so that the name is exactly 12 characters long.
	8.5.5.9 236	WOLA name part 2 or 3 is empty or missing.	Ensure that WOLA name part 2 and 3 are specified on the BBOA1REG call.
	8.5.5.9 480	The client cannot become authorized to invoke the register function.	This condition is unexpected. Ensure that the target server is running and that the zosLocalAdapters service is configured in the server instance.
	8.5.5.9 481	The client could not find the authorized function table for zosLocalAdapters services.	Ensure that the zosLocalAdapters feature is configured on the target server instance.
12	10	The API could not locate the selected optimized local adapters group.	Ensure that the Liberty server and target server are started, verify that the optimized local adapters support is active, and try again.
	14	The user ID is not authorized for the requested Liberty server.	Ensure that the user ID is authorized to the CBIND SAF class for the requested Liberty server.
	16	Part 2 or part 3 of the optimized local adapters group name is not found.	Ensure that the optimized local adapter group name parameters that are being passed are valid and that the server is active.
	23	An error occurred while naming the token.	See the problem determination information on the WebSphere Application Server Support site.
	24	An error occurred while establishing the initial Liberty server local communication connection.	Refer to the Liberty server region logs for details on the local communication connect call.
	28	The registration identified with this name is not valid.	The specified register name is already registered, but the registration is missing. As a workaround, call the Unregister API and attempt to call the Register API again. If the problem continues, see the problem determination information on the WebSphere Application Server Support site.
	68	An attachment to shared memory failed.	See the problem determination information on the WebSphere Application Server Support site.
	86	The Liberty server master BGVT cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	8.5.5.9 232	An out of memory condition occurred during a register call.	Ensure that memory is available to the client in subpool 0. Try the BBOA1REG call again.
	8.5.5.9 234	The client could not bind to the Liberty server instance.	Ensure that the Liberty server instance started and that the zosLocalAdapters service is configured in the server instance.

Table 146. BBOA1REG API return and reason codes (continued)

Return Code	Reason Code	Description	Action
	8.5.5.9 238	The client could not locate the target server's registration.	This condition is unexpected. Ensure that the target server instance started and that the zosLocalAdapters feature is configured. If the server stopped, start it and try the BBOA1REG call again.

## Unregister

Unregister from the local optimized local adapter group and Liberty server using the BBOA1URG API.

*Table 147. BBOA1URG API syntax.* This API requests that a group of optimized connections to a local optimized local adapter group and Liberty server be released using the specified register name.

API	Syntax
BBOA1URG	BBOA1URG (registername, unregflags, rc, rsn)

The BBOA1URG API accepts the following input parameters:

### registername

An entry variable or entry constant that contains the name to use to unregister a set of local connections. The value must be exactly 12 characters, blank padded, and the same name that is used on the Register API call.

### unregisterflags

A 32-bit flag word that contains unregistration flags.

- **Reserved** - bit 0-30
- **Force (0|1)** - bit 31

Specify 1 to force the unregister request. By default, an unregister request is complete if all connections are returned to the connection pool. If all the connections are not returned to the pool, a warning is returned to the caller. The unregister process is complete when the last connection is returned to the pool. Make a second register request with the force bit set to 1 to force the unregister process to complete and invalidate all remaining connection handles for that registration.

The BBOA1URG API accepts the following output parameters:

**rc** An integer return code that indicates success or failure of this call.

### rsn

An integer reason code that describes the reason for a failure on this call.

Usage notes:

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.
- If the Unregister API is not called and the address space that made a register call terminates, an unregister call is done automatically and the connections are released.
- Any connection handles for this registration that are active when the unregister call occurs might continue to be valid until they are returned to the connection pool by using the Connection Release API. To force the connection handles to be cleaned up, a second unregister call must be made, specifying the force flag. This invalidates all outstanding connection handles.

Return and reason codes:

Table 148. BBOA1URG API return and reason codes

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	

Table 148. BBOA1URG API return and reason codes (continued)

Return Code	Reason Code	Description	Action
	66	The unregister call is delayed until all the connections are returned to the pool.	Unregistration completes when the last connection is returned to the free pool.
8	-	Error - see reason code	
	8	The registration token name does not exist.	You must register this name before calling the Unregister API for it.
	64	The <i>force</i> option cannot be specified until a normal unregister is issued.	Call the Unregister API without specifying the <i>force</i> option.
	82	An attempt to unregister this registration was already made.	Wait for the previous unregister request to complete or reissue this unregister with the <i>force</i> option.
	8.5.5.9 228	The unregister call could not complete because the registration has already been reused.	No action is required.
	8.5.5.9 230	The connection pool could not be cleaned up on an unregister force call.	No action is required. To avoid using an unregister force call, ensure that your application returns all of the connection handles back to the pool before calling unregister.
	8.5.5.9 480	The client could not become authorized to call the unregister function.	This condition is unexpected. Ensure that the target server is running and that the zosLocalAdapters service is configured in the server instance.
12	86	The Liberty server master BGVV cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Connection Get

This API requests that an available connection from the pool that was created with the selected registration name is returned.

Table 149. BBOA1CNG API syntax

API	Syntax
BBOA1CNG	BBOA1CNG (registername, connectionhandle, waittime, rc, rsn)

The BBOA1CNG API accepts the following input parameters:

### registername

An entry variable or entry constant that contains the name to be used to locate the connection pool from which to retrieve a connection. This must be a blank padded string of exactly 12 characters.

### connectionhandle

A 12-byte connection handle that must be passed on later requests for actions on this connection.

### waittime

An integer that contains the number of seconds to wait for the connection to complete before returning a connection unavailable reason code. A value of 0 implies there is no wait time and the API waits indefinitely. The *waittime* parameter applies only to the process of obtaining a WOLA connection from the connection pool. When the connection is obtained, it is used to receive a request from the server with an unlimited wait time.

The BBOA1CNG API accepts the following output parameters:

**rc** An integer return code that indicates success or failure of this call.

**rsn**

An integer reason code that describes the reason for a failure on this call.

Usage notes:

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.
- Ensure that a successful Register API call was completed in the current address space with a matching name before you use the Connection Get API.

Return and reason codes:

*Table 150. BBOA1CNG API return and reason codes*

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	The registration name token does not exist.	Register this name before you call the name with the Connection Get API.
	10	The connection is unavailable. The wait time expired before the connection request could be obtained.	The application behavior varies. Wait and try again, or issue the abend macro to terminate the task that called the Connection Get API. You can also increase the maximum connections setting on the Register API call.
	24	After a successful register call, an error occurred when getting a connection from the pool.	Verify that the server is started. If it is not working, restart the server and try the API request again.
	28	The registration was found, but it is inactive.	
	8.5.5.9 224	An incomplete registration was found.	This condition is unexpected. Use the BBOA1URG service to unregister, and use the BBOA1REG service to register again.
	8.5.5.9 480	The client could not become authorized to call the get connection function.	This condition is unexpected. Ensure that the target server is running and that the zosLocalAdapters service is configured in the server instance.
	8.5.5.9 482	The client could not reconnect to the target server instance after the server was restarted.	This condition is unexpected. Use the BBOA1URG service to remove the registration, and use the BBOA1REG service to create a new one.
	8.5.5.9 483	The client could not reconnect to the target server instance after the server was restarted.	This condition is unexpected. Use the BBOA1URG service to remove the registration, and use the BBOA1REG service to create a new one.
12	10	The API could not locate the selected optimized local adapters group.	Ensure that the Liberty server and target server are started, verify that the optimized local adapters support is active, and try again.
	8.5.5.9 14	The user ID is not authorized for the requested Liberty server.	Ensure that the user ID is authorized to the CBIND SAF class for the requested Liberty server.
	86	The Liberty server master BGVT cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Connection Release

The Connection Release API requests that a connection is returned to the pool that it was retrieved from and is made available for another requester.

Table 151. BBOA1CNR API syntax

API	Syntax
BBOA1CNR	BBOA1CNR (connectionhandle, rc, rsn)

The BBOA1CNR API accepts the following input parameter:

### connectionhandle

A 12-byte connection handle that indicates the previously obtained connection that is to be released back into the connection pool.

The BBOA1CNR API accepts the following output parameters:

**rc** An integer return code that indicates success or failure of this call.

### rsn

An integer reason code that describes the reason for a failure on this call.

### Usage notes

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.
- Before you use the Connection Release API, ensure that a successful Register API call is completed in the current address space with a matching name, and a successful Connection Get API call is completed to obtain the connection that is now to be released.

Table 152. BBOA1CNR API return and reason codes

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Unable to locate the optimized local adapter group and Liberty server. Any resources that are related to this connection were cleared.	None
8	-	Error-see reason code	
	36	The connection state is not valid.	The connection handle that is used for this request is in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle that is used for this request is not valid. Refer to the API documentation for information about client connection handles.
12	86	The Liberty server master BGVT cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Send Request

These APIs send a request into the local Liberty server for processing.

Table 153. BBOA1SRQ API syntax

API	Syntax
BBOA1SRQ	BBOA1SRQ (connectionhandle, requesttype, request servicename, request servicename1, requestdata, requestdatalen, async(0 1), responsedatalen, rc, rsn)

The BBOA1SRQ API accepts the following input parameters:

### connectionhandle

A 12-byte connection handle that is to be used for this request.

### requesttype

An integer that contains the request type that indicates the type of work request to process. The only supported value is 1 for local EJB work requests.

### request servicename

An EBCDIC character string up to 256 bytes in length that contains the name of the service to invoke. This parameter specifies the JNDI name of the local business interface.

### request servicename1

An integer that contains the length of the service name to start or 0 (zero) if the service name is null terminated.

### requestdata

A 31-bit pointer to the address of the start of the request data to send.

### requestdatalen

A 32-bit unsigned value that contains the length of the data to send.

### async(0|1)

Set **async** to 1 to indicate that the caller wants control returned immediately, even though the response length might not yet be known. If you set **async** to 0, the current thread waits for the Liberty server to return the response, and the API returns the response length in the **responsedatalen** output parameter.

The BBOA1SRQ API accepts the following output parameters:

### responsedatalen

A 32-bit unsigned value that contains the length of the response. The caller can use this length to acquire storage before you call the Get Data API to copy the data in. When you set **async** to 1, indicating the caller wants control back immediately, the value is set to 0xFFFFFFFF if the response is not yet received.

**rc** An integer return code that indicates success or failure of this call.

### rsn

An integer reason code that describes the reason for a failure on this call.

Usage notes:

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.
- Ensure that a successful Register API call was completed in the current address space with a matching name before you use the Send Request API.

Return and reason codes:

Table 154. BBOA1SRQ API return and reason codes

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	The register name token already exists.	Ensure that the register name passed is valid.
	16	The request service name length is not valid.	Correct the program and try again.
	18	The request length exceeds the system limits.	The message size is larger than the Liberty server size can support. Verify that the size is valid. If the size is valid, ensure that the Liberty server size is large enough to accommodate the message size.
	32	The API call request type is not valid.	The request type is not valid. Correct the program and try the call again.
	34	The target service is not found.	Ensure that the application that contains the target enterprise bean is installed and started in the target server for the Liberty server.
	36	The connection state is not valid.	The connection handle that is used for the request is in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle that is used for the request is not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the Liberty server log for any local communication error messages.
	44	An exception or unexpected condition occurred in the target enterprise bean.	Refer to the Liberty server logs to review the exception data.
	46	An error occurred in the local communication send request call.	Check the Liberty server logs to determine the error.
	98	The beginning of the supplied request buffer cannot be accessed.	Ensure that the supplied request buffer address and length are correct.
	100	The end of the supplied request buffer cannot be accessed.	Ensure that the supplied request buffer address and length are correct.
12	10	The API could not locate the selected optimized local adapters group.	Ensure that the Liberty server and target server are started, verify that the optimized local adapters support is active, and try again.
	86	The Liberty server master BGVV cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Send Response

This API sends a response to a request back to the local Liberty server.

Table 155. BBOA1SRP API syntax

API	Syntax
BBOA1SRP	BBOA1SRP (connectionhandle, responsedata, responsedatalen, rc, rsn)

The BBOA1SRP API accepts the following input parameters:

**connectionhandle**

A 12-byte connection handle that is to be used for this response.

**responsedata**

A 31-bit pointer to the address of the start of the response data to send.

**requestdatalen**

A 32-bit unsigned value that contains the length of the data to send.

The BBOA1SRP API accepts the following output parameters:

**rc** An integer return code that indicates success or failure of this call.

**rsn**

An integer reason code that describes the reason for a failure on this call.

## Usage notes:

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.
- Ensure that a successful Register API call was completed in the current address space with a matching name before you use the Send Response API.
- Ensure that a successful Connection Get API call completed and the handle is provided as input on this call.
- Ensure that a successful receive Request Any, Receive Request Specific, or Host API call was issued and returned with request data for the connection handle. The connection must be in a state where the Send Response API is valid.

## Return and reason codes:

*Table 156. BBOA1SRP API return and reason codes*

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	The register name token already exists.	Ensure that the register name passed is valid.
	18	The request length exceeds the system limits.	The message size is larger than the Liberty server size can support. Verify that the size is valid. If the size is valid, ensure that the Liberty server size is large enough to accommodate the message size.
	34	The target service is not found.	Ensure that the application that contains the target enterprise bean is installed and started in the target server for the Liberty server.
	36	The connection state is not valid.	The connection handle that is used for the request is in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle that is used for the request is not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the Liberty server log for any local communication error messages.
	46	An error occurred in the local communication send request call.	Check the Liberty server logs to determine the error.
	102	The beginning of the supplied response buffer cannot be accessed.	Ensure that the supplied response buffer address and length are correct.
	104	The end of the supplied response buffer cannot be accessed.	Ensure that the supplied response buffer address and length are correct.
	8.5.5.9 480	The client could not become authorized to call the send response function.	This condition is unexpected. Ensure that the target server is running and that the <code>zosLocalAdapters</code> service is configured in the server instance.

Table 156. BBOA1SRP API return and reason codes (continued)

Return Code	Reason Code	Description	Action
12	10	The API could not locate the selected optimized local adapters group.	Ensure that the Liberty server and target server are started, verify that the optimized local adapters support is active, and try again.
	86	The Liberty server master BGVV cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Send Response Exception

This API sends a ResourceException exception that contains response data back to the JCA caller in the local Liberty server.

Table 157. BBOA1SRX API syntax

API	Syntax
BBOA1SRX	BBOA1SRX (connectionhandle, excrespondata, excrespondatalen, rc, rsn)

The BBOA1SRX API accepts the following input parameters:

### connectionhandle

A 12-byte connection handle that is to be used for this response.

### excrespondata

A 31-bit pointer to the address of the start of the exception response data to send.

### excrespondatalen

A 32-bit unsigned value that contains the length of the exception response data to send. Exception response data is an EBCDIC string that describes the error.

The BBOA1SRX API accepts the following output parameters:

**rc** An integer return code that indicates success or failure of this call.

### rsn

An integer reason code that describes the reason for a failure on this call.

Usage notes:

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.
- Ensure that a successful Register API call completed in the current address space with a matching name before you use the send response call.
- Ensure that a successful Connection Get API call completed, and provide the handle as input on this API call.
- Ensure that a successful Receive Request Any, Receive Request Specific, or Host Service API call was issued and returned with request data for the connection handle. The connection must be in a state where the Send Response and Send Response Exception APIs are valid.

Return and reason codes:

Table 158. BBOA1SRX API return and reason codes

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	The register name token already exists.	Ensure that the register name passed is valid.
	10	The connection handle is in a released or not valid state.	Ensure that a valid connection handle was passed.
	16	One or more parameters are not valid.	Verify that all the parameters are valid and try the call again.
	18	The request length exceeds the system limits.	The message size is larger than the Liberty server size can support. Verify that the size is valid. If the size is valid, ensure that the Liberty server size is large enough to accommodate the message size.
	36	The connection state is not valid.	The connection handle used for this request is in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle used for this request is not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the Liberty server log for any local communication error messages.
	46	An error occurred in the local communication send request call.	Check the Liberty server logs to determine the error.
	102	The beginning of the supplied response buffer cannot be accessed.	Ensure that the supplied response buffer address and length are correct.
	104	The end of the supplied response buffer cannot be accessed.	Ensure that the supplied response buffer address and length are correct.
	8.5.5.9 480	The client could not become authorized to call the send exception function.	This condition is unexpected. Ensure that the target server is running and that the zosLocalAdapters service is configured in the server instance.
12	10	The API could not locate the selected optimized local adapters group.	Ensure that the Liberty server and target server are started, verify that the optimized local adapters support is active, and try again.
	86	The Liberty server master BGVt cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Receive Request Any

This API receives a request and related data from a local Liberty server on any connection in the pool for the passed register name. The API returns request data length and a connection handle as output parameters. Calling the Get Data API with the returned connection handle returns the received message data.

Table 159. BBOA1RCA API syntax

API	Syntax
BBOA1RCA	BBOA1RCA (registername, connectionhandle, requestservername, requestservername1, requestdatalen, waittime, rc, rsn)

The BBOA1RCA API accepts the following input parameters:

**registername**

An entry variable or entry constant that contains the name to be used to locate the connection pool from which to retrieve a connection. The value must be a blank padded string of exactly 12 characters.

**waittime**

An integer that contains the number of seconds to wait for the connection to complete before it returns a connection unavailable reason code. A value of 0 indicates that there is no wait time and that the API waits indefinitely. The `waittime` parameter applies only to the process of obtaining a WOLA connection from the connection pool. When the connection is obtained, it is used to receive a request from the server with an unlimited wait time.

The BBOA1RCA API accepts the following input or output parameters:

**requestservicename**

An EBCDIC character string up to 256 bytes that contains the name of the service. This parameter is the name of the target service that is specified on the `InteractionSpec` interface by the Liberty server application. A value of \* indicates a receive request for all service names that arrive under the current register name.

**requestservicename1**

An integer that contains the length of the service name to start or 0 if the service name is null terminated.

The BBOA1RCA API accepts the following output parameters:

**connectionhandle**

A 12-byte connection handle that is returned and must be passed on later requests for actions on this connection.

**requestdatalen**

A 32-bit unsigned value is returned with the length of the data to receive.

**rc** An integer return code that indicates success or failure of this call.

**rsn**

An integer reason code that describes the reason for a failure on this call.

Usage notes:

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.
- Ensure that a successful Register API call was completed in the current address space with a matching name before you use this API.

Return and reason codes:

*Table 160. BBOA1RCA API return and reason codes*

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	The register name token already exists.	Ensure that the register name passed is valid.
	10	The connection is unavailable. The wait time expired before the connection request could be obtained.	The application behavior varies. Wait and try again, or issue the <code>abend</code> macro to terminate the task that called the Connection Get API. You can also increase the maximum connections setting on the Register API call.

Table 160. BBOA1RCA API return and reason codes (continued)

Return Code	Reason Code	Description	Action
	16	The request service name length is not valid.	Correct the program and try the call again.
	19	A call to a local communication service received a non-zero return code.	
	21	A call to a local communication service received a non-zero return code.	
	38	The client connection handle is not valid.	The client connection handle used for this request was determined to be not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the Liberty server log for any local communication error messages.
	46	An error occurred in the local communication send request call.	Check the Liberty server logs to determine the error.
	8.5.5.9 224	An incomplete registration was found.	This condition is unexpected. Use the BBOA1URG service to unregister, and use the BBOA1REG service to register again.
	8.5.5.9 226	An incomplete connection handle was found.	This condition is unexpected. Use the BBOA1RCA service to try the request again.
	8.5.5.9 480	The client could not become authorized to call the receive request function.	This condition is unexpected. Ensure that the target server is running and that the zosLocalAdapters service is configured in the server instance.
	8.5.5.9 482	The client could not reconnect to the target server instance after the server was restarted.	This condition is unexpected. Use the BBOA1URG service to remove the registration, and use the BBOA1REG service to create a new one.
	8.5.5.9 483	The client could not reconnect to the target server instance after the server was restarted.	This condition is unexpected. Use the BBOA1URG service to remove the registration, and use the BBOA1REG service to create a new one.
12	10	The API could not locate the selected optimized local adapters group.	Ensure that the Liberty server and target server are started, verify that the optimized local adapters support is active, and try again.
	8.5.5.9 14	The user ID is not authorized for the requested Liberty server.	Ensure that the user ID is authorized to the CBIND SAF class for the requested Liberty server.
	24	After a successful registration call, an error occurred when getting a connection from the pool.	Verify that the server is started. If the server is not started, restart the server and try the API request again.
	86	The Liberty server master BGVTT cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Receive Request Specific

This API receives a request and related data from a local Liberty server for the specified connection handle. The API returns request data length as an output parameter. Calling the Get Data API with the specified connection handle returns the received message data.

Table 161. BBOA1RCS APIs syntax

API	Syntax
BBOA1RCS	BBOA1RCS (connectionhandle, requestservername, requestservername1, requestdatalen, async(0 1), rc, rsn)

The BBOA1RCS API accepts the following input parameters:

**connectionhandle**

A 12-byte connection handle that is to be used for the receive request.

**async(0|1)**

Set **async** to 1 to indicate that the caller wants control returned immediately, even though the response length might not yet be known. If you set **async** to 0, this call waits to receive a request from the Liberty server.

The BBOA1RCS API accepts the following input or output parameters:

**requestservername**

An EBCDIC character string up to 256 bytes that contains the name of the service. This parameter is the name of the target service that is specified on the InteractionSpec interface by the Liberty server application. A value of \* indicates that set up as a server for all service names that arrive under the current register name.

**requestservername1**

An integer that contains the length of the service name to start or 0 if the service name is null terminated.

The BBOA1RCS API accepts the following output parameters:

**requestdatalen**

A 32-bit unsigned value is returned that contains the length of the request data received. The caller can then use this length to acquire storage before you call the Get Data API to copy the data in. When **async** is set to 1, indicating the caller wants control back immediately, the value is set to 0xFFFFFFFF if the request data is not yet received. In this case, you must call the API again to retrieve an inbound request.

**rc** An integer return code that indicates success or failure of this call.

**rsn**

An integer reason code that describes the reason for a failure on this call.

Usage notes:

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.
- Ensure that a successful Register API call was completed in the current address space with a matching name before you use this API.

Return and reason codes:

Table 162. BBOA1RCS API return and reason codes

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	The register name token already exists.	Ensure that the register name passed is valid.
	10	The connection handle is in a released state improper state.	Ensure that a valid connection handle passed.

Table 162. BBOA1RCS API return and reason codes (continued)

Return Code	Reason Code	Description	Action
	16	The request service name length is not valid.	Correct the program and try the call again.
	19	A call to a local communication service received a non-zero return code.	
	21	A call to a local communication service received a non-zero return code.	
	36	The connection state is not valid.	The connection handle used for this request is in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle used for this request is not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the Liberty server log for any local communication error messages.
	46	An error occurred in the local communication send request call.	Check the Liberty server logs to determine the error.
	76	An attempt to communicate with the server failed because the server is no longer running.	Start the server and try the communication again.
	78	An internal error occurred that caused the connection to select a request that was not a part of the transaction being processed by this connection.	Return the connection to the connection pool. If the problem continues, see the problem determination information on the WebSphere Application Server Support site.
	80	The transaction that is active on this connection timed out and the connection state cannot be reset so that another request is processed.	Return the connection to the connection pool. If the problem continues, see the problem determination information on the WebSphere Application Server Support site.
	8.5.5.9 226	An incomplete connection handle was found.	This condition is unexpected. Use the BBOA1CNR service to release the connection, and use the BBOA1CNG service to obtain a new connection.
	8.5.5.9 480	The client could not become authorized to call the receive request function.	This condition is unexpected. Ensure that the target server is running and that the zosLocalAdapters service is configured in the server instance.
12	10	The API could not locate the selected optimized local adapters group.	Ensure that the Liberty server and target server are started, verify that the optimized local adapters support is active, and try again.
	86	The Liberty server master BGVV cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Receive Response Length

The receive response length API retrieves the length of the response data from a prior send request call.

Table 163. BBOA1RCL API syntax

API	Syntax
BBOA1RCL	BBOA1RCL (connectionhandle, async(0 1), responsedatalen, rc, rsn)

The BBOA1RCL API accepts the following input parameters:

**connectionhandle**

A 12-byte connection handle that is to be used for this request.

**async(0|1)**

Set **async** to 1 to indicate that the caller wants control returned immediately, even though the response length might not be known. If you set **async** to 0, this call waits for the Liberty server to return the response, and the API returns the response length in the **responsedatalen** parameter.

The BBOA1RCL API accepts the following output parameters:

**requestdatalen**

A 32-bit unsigned value with the length of the received data is returned. The caller can use this length to acquire storage before you call the Get Data API to copy the data in. If you set **async** to 1, the value is set to 0xFFFFFFFF if the response data is not yet received.

**rc** An integer return code that indicates success or failure of this call.

**rsn**

An integer reason code that describes the reason for a failure on this call.

Usage notes:

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.
- Ensure that a successful Register API call was completed in the current address space with a matching name before you use this API.
- Ensure that a successful Connection Get API call completed and the handle is provided as input on this call.
- Ensure that a successful Send Request API call was completed before you make this call.

Return and reason codes:

*Table 164. BBOA1RCL API return and reason codes*

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	The register name token already exists.	Ensure that the register name passed is valid.
	19	A call to a local communication service received a non-zero return code.	
	21	A call to a local communication service received a non-zero return code.	
	36	The connection state is not valid.	The connection handle used for this request was determined to be in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle used for this request was determined to be not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the Liberty server log for any local communication error messages.
	8.5.5.9 226	An incomplete connection handle was found.	This condition is unexpected. Use the BBOA1CNR service to release the connection, and use the BBOA1CNG service to obtain a new connection.
	8.5.5.9 480	The client could not become authorized to call the receive length function.	This condition is unexpected. Ensure that the target server is running and that the zosLocalAdapters service is configured in the server instance.

Table 164. BBOA1RCL API return and reason codes (continued)

Return Code	Reason Code	Description	Action
12	10	The API could not locate the selected optimized local adapters group.	Ensure that the Liberty server and target server are started, verify that the optimized local adapters support is active, and try again.
	86	The Liberty server master BGVT cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Get Message Data

This API copies the received message data. When this API call returns, the message is removed from the adapter message cache.

Table 165. BBOA1GET API syntax

API	Syntax
BBOA1GET	BBOA1GET (connectionhandle, msgdata, msgdatalen, rc, rsn, rv)

The BBOA1GET API accepts the following input parameters:

### connectionhandle

A 12-byte connection handle that is to be used for this request.

### msgdata

A 31-bit pointer to the address of the start of the data area to copy into. The storage that this parameter points to must be in a key that the caller can write in.

### msgdatalen

A 32-bit unsigned value that contains the length of the data to copy.

The BBOA1GET API accepts the following output parameters:

**rc** An integer return code that indicates success or failure of this call.

### rsn

An integer reason code that describes the reason for a failure on this call.

**rv** A 32-bit integer return value that contains the size of the context buffer for this request.

Usage notes:

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.
- Ensure that a successful Register API call was completed in the current address space with a matching name before you use the Send Request API.
- Ensure that a successful Connection Get API call completed and the handle is provided as input on this call.
- If the API caller input **msgdatalen** parameter is larger than the actual message response, the return code contains a 0 and the actual message length is provided to the return value.
-

**Important:** After the get message data call returns to the caller, the message data does not persist and the connection is returned to a state where it can be used for another send or receive request call. A subsequent call to get message data or receive response length is returned in error.

Return and reason codes:

*Table 166. BBOA1GET API return and reason codes*

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	The register name token already exists.	Ensure that the register name passed is valid.
	36	The connection state is not valid.	The connection handle used for this request was determined to be in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle used for this request was determined to be not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the Liberty server log for any local communication error messages.
	48	An error occurred in the local communication read request.	Check the Liberty server logs to determine the error.
	72	Response length input parameter is not large enough to contain the response message.	Only a portion of the message is returned. The remainder is discarded. Refer to the return value for the size of the message response.
	98	The beginning of the supplied request buffer cannot be accessed.	Ensure that the supplied request buffer address and length are correct.
	100	The end of the supplied request buffer cannot be accessed.	Ensure that the supplied request buffer address and length are correct.
	102	The beginning of the supplied response buffer cannot be accessed.	Ensure that the supplied response buffer address and length are correct.
	104	The end of the supplied response buffer cannot be accessed.	Ensure that the supplied response buffer address and length are correct.
	8.5.5.9 226	An incomplete connection handle was found.	This condition is unexpected. Use the BBOA1CNR service to release the connection, and use the BBOA1CNG service to obtain a new connection.
	8.5.5.9 480	The client could not become authorized to call the get data function.	This condition is unexpected. Ensure that the target server is running and that the zosLocalAdapters service is configured in the server instance.
12	10	The API could not locate the selected optimized local adapters group.	Ensure that the Liberty server and target server are started, verify that the optimized local adapters support is active, and try again.
	86	The Liberty server master BGVT cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Invoke

This API uses other underlying primitive API functions to call a method in a local Liberty server. It is designed to be used in situations where the response output area maximum size is known in advance.

Table 167. BBOA1INV API syntax

API	Syntax
BBOA1INV	BBOA1INV (registername, requesttype, request servicename, request servicename1, requestdata, requestdatalen, responsedata, responsedatalen, waittime, rc, rsn, rv)

The BBOA1INV API accepts the following input parameters:

### **registername**

An entry variable or entry constant that contains the name to be used to locate the connection pool to retrieve a connection for this invocation. The value must be a blank padded string of exactly 12 characters.

### **requesttype**

An integer that contains the request type, which indicates the type of work request to process. The only supported value is 1 for local EJB work requests.

### **request servicename**

An EBCDIC character string up to 256 bytes in length that contains the name of the service to invoke. This parameter specifies the JNDI name of the local business interface.

### **request servicename1**

An integer that contains the length of the service name to start or 0 if the service name is null terminated.

### **requestdata**

A 31-bit pointer to the address of the start of the request data to send.

### **requestdatalen**

A 32-bit unsigned value that contains the length of the request data to send.

### **responsedata**

A 31-bit pointer to the address of the start of the response data area to copy into. The storage this parameter points to must be in a key that the caller can write in.

### **responsedatalen**

A 32-bit unsigned value that contains the length of the response data to send.

### **waittime**

An integer that contains the number of seconds to wait for the connection to complete before it returns a connection unavailable reason code. A value of 0 (zero) indicates that there is no timeout and that this API waits indefinitely. The waittime parameter applies only to the process of obtaining a WOLA connection from the connection pool. When the connection is obtained, it is used to receive a request from the server with an unlimited wait time.

The BBOA1INV API accepts the following output parameters:

**rc** An integer return code that indicates success or failure of this call.

### **rsn**

An integer reason code that describes the reason for a failure on this call.

**rv** A 32-bit integer return value that contains the size of the message data that was received and copied into the caller response area.

Usage notes:

- Ensure that the Liberty server that you specified on this call is started and the support for local adapters is enabled.

- Ensure that a successful Register API call was completed in the current address space with a matching name before you use the Send Request API.
- If the API caller input **responseDataLen** parameter is larger than the actual message response, the return code contains a 0 (zero) and the actual message length is provided in the return value.

Return and reason codes:

*Table 168. BBOA1INV API return and reason codes*

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	The register name token does not exist.	Ensure that the register name passed is valid.
	10	The connection is unavailable. The wait time expired before the connection request is obtained.	The application behavior varies. Wait and retry, or accept this failed Invoke API call. Another option is to increase the maximum connections setting on the Register API call.
	16	The request service name length is not valid.	Correct the program and try the call again.
	18	The response length exceeded the system limits.	The message size is larger than the Liberty server size can support. Verify that the size is valid. If the size is valid, ensure that the Liberty server size is large enough to accommodate the message size.
	19	A call to a local communication service received a non-zero return code.	
	21	A call to a local communication service received a non-zero return code.	
	24	After a successful register call, an error occurred when getting a connection from the pool.	Verify that the server is started. If it is not working, restart the server and try the API request again.
	26	The global transaction cannot begin.	
	28	The registration was found, but it is inactive.	
	32	The request type on the API call is not valid.	The request type parameter is not valid. Correct the program and try the call again.
	34	The target service not found.	Ensure the application that contains the target enterprise bean is installed and started in the target Liberty server.
	36	The connection state is not valid.	The connection handle used for this request was determined to be in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle used for this request was determined to be not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the Liberty server log for any local communication error messages.
	44	An exception or unexpected condition occurred in the target enterprise bean.	Refer to the Liberty server logs to review the exception data.
	46	An error occurred in the local communication send request.	Refer to the Liberty server logs to determine the error.
	48	An error occurred in the local communication read request.	Check the Liberty server logs to determine the error.
	72	Response length input parameter is not large enough to contain the response message.	Only a portion of the message is returned. The remainder is discarded. Refer to the return value for the size of the message response.

Table 168. BBOA1INV API return and reason codes (continued)

Return Code	Reason Code	Description	Action
	98	The beginning of the supplied request buffer could not be accessed.	Ensure that the supplied request buffer address and length are correct.
	100	The end of the supplied request buffer could not be accessed.	Ensure that the supplied request buffer address and length are correct.
	102	The beginning of the supplied response buffer could not be accessed.	Ensure that the supplied response buffer address and length are correct.
	104	The end of the supplied response buffer could not be accessed.	Ensure that the supplied response buffer address and length are correct.
	8.5.5.9 224	An incomplete registration was found.	This condition is unexpected. Use the BBOA1URG service to unregister, and use BBOA1REG to register again.
	8.5.5.9 226	An incomplete connection handle was found.	This condition is unexpected. Use the BBOA1INV service to try the request again.
	8.5.5.9 480	The client could not be authorized to call the invoke function.	This condition is unexpected. Ensure that the target server is running and that the zosLocalAdapters service is configured in the server instance.
	8.5.5.9 482	The client was not able to reconnect to the target server instance after the server was restarted.	This condition is unexpected. Use the BBOA1URG service to remove the registration, and use the BBOA1REG service to create a new one.
	8.5.5.9 483	The client was not able to reconnect to the target server instance after the server was restarted.	This condition is unexpected. Use the BBOA1URG service to remove the registration, and use the BBOA1REG service to create a new one.
12	10	The API could not locate the selected optimized local adapters group.	Ensure that the Liberty server and target server are started, verify that the optimized local adapters support is active, and try again.
	8.5.5.9 14	The user ID is not authorized for the requested Liberty server.	Ensure that the user ID is authorized to the CBIND SAF class for the requested Liberty server.
	24	After a successful register call, an error occurred while getting a connection from the connection pool.	Verify that the server is started. If it is not started, restart the server and try the API request again.
	86	The Liberty server master BGVT cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Host Service

The Host Service API uses other underlying primitive API functions to set up a native language z/OS program as a server and target for optimized local adapter calls from a local Liberty server. Use the API when you know the request area maximum size before you call the API.

Table 169. BBOA1SRV API syntax

API	Syntax
BBOA1SRV	BBOA1SRV (registername, requestservername, requestservername1, requestdata, requestdatalen, connectionhandle, waittime, rc, rsn, rv)

The BBOA1SRV API accepts the following input parameters:

**registername**

An entry variable or entry constant that contains the name to be used to locate the connection pool to retrieve a connection from for this call. The value must be a blank-padded string of exactly 12 characters.

**requestdata**

A 31-bit pointer to the address of the start of the request data received. The storage that this parameter points to must be in a key that the caller can write in.

**requestdatalen**

A 32-bit unsigned value that contains the length of the data area into which the message is received.

**connectionhandle**

A 12-byte connection handle that is returned to the caller and used for sending a response for this request.

**waittime**

An integer that contains the number of seconds to wait for the connection to complete before it returns a connection unavailable reason code. A value of 0 (zero) implies that there is no timeout, and the API waits indefinitely. The `waittime` parameter applies only to the process of obtaining a WOLA connection from the connection pool. When the connection is obtained, it is used to receive a request from the server with an unlimited wait time.

The BBOA1SRV API accepts the following input or output parameters:

**request servicename**

An EBCDIC character string up to 256 bytes that contains the name of the service. This parameter is the name of the target service that is specified on the InteractionSpec interface by the Liberty server application. A value of \* indicates set up as a server for all service names that arrive under the current register name.

**request servicename1**

An integer that contains the length of the service name to start or 0 if the service name is null terminated.

The BBOA1SRV API accepts the following output parameters:

**rc** An integer return code that indicates success or failure of this call.

**rsn**

An integer reason code that describes the reason for a failure on this call.

**rv** A 32-bit integer return value that contains the size of the message data that was received and copied into the caller response area.

Usage notes:

- Ensure that the Liberty server that you specified on this call are started and the support for local adapters is enabled.
- Ensure that a successful Register API call was completed in the current address space with a matching name before you use this API.
- If the API caller input **requestdatalen** parameter is larger than the actual message response, the return code contains a 0 (zero) and the actual message length is provided in the return value.
- The returned connection handle must be supplied on any response for this Host Service call using the Send Response API.

Return and reason codes:

Table 170. BBOA1SRV API return and reason codes

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	The register name token already exists.	Ensure that the register name passed is valid.
	10	The connection handle is in a released state.	Ensure that a correct connection handle is passed.
	12	The connection handle is not in the connection that is in the registration name.	Correct to program and try the call again.
	16	The request service name length is not valid.	Correct the program and try the call again.
	18	The response length exceeded the system limits.	The message size is larger than the Liberty server size can support. Verify that the size is valid. If the size is valid, ensure that the Liberty server size is large enough to accommodate the message size.
	40	A local communication error occurred.	Check the Liberty server log for any local communication error messages.
	46	An error occurred in the local communication send request.	Refer to the Liberty server logs to determine the error.
	48	An error occurred in the local communication read request.	Check the Liberty server logs to determine the error.
	72	Response length input parameter is not large enough to contain the response message.	Only a portion of the message is returned. The remainder is discarded. Refer to the return value for the size of the message response.
	98	The beginning of the supplied request buffer cannot be accessed.	Ensure that the supplied request buffer address and length are correct.
	100	The end of the supplied request buffer cannot be accessed.	Ensure that the supplied request buffer address and length are correct.
	8.5.5.9 224	An incomplete registration was found.	This condition is unexpected. Use the BBOA1URG service to unregister, and use BBOA1REG service to register again.
	8.5.5.9 226	An incomplete connection handle was found.	This condition is unexpected. Use the BBOA1SRV service to try the request again.
	8.5.5.9 480	The client could not become authorized to call the host function.	This condition is unexpected. Ensure that the target server is running and that the zosLocalAdapters service is configured in the server instance.
	8.5.5.9 482	The client was not able to reconnect to the target server instance after the server was restarted.	This condition is unexpected. Use the BBOA1URG service to remove the registration, and use the BBOA1REG service to create a new one.
	8.5.5.9 483	The client was not able to reconnect to the target server instance after the server was restarted.	This condition is unexpected. Use the BBOA1URG service to remove the registration, and use the BBOA1REG service to create a new one.
12	10	The API could not locate the selected optimized local adapters group.	Ensure that the Liberty server and target server are started, verify that the optimized local adapters support is active, and try again.
	8.5.5.9 14	The user ID is not authorized for the requested Liberty server.	Ensure that the user ID is authorized to the CBIND SAF class for the requested Liberty server.
	86	The Liberty server master BGVV cannot be located.	The Liberty server was not started on the current z/OS operating system image. Ensure that the server is started before you start any optimized local adapters client processes.
	88	The Liberty server master client stub table cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.
	90	The master client stub table slot for the Liberty server optimized local adapters cannot be located.	A Liberty server was started on the current z/OS operating system image, but the server is not running at the level where the optimized local adapters client stub table is supported. Ensure that your application is running with the level of the optimized local adapters stubs that are compatible with the Liberty server on this z/OS system.

## Java EE Connector Architecture (JCA) adapters APIs

For calls from the Liberty server into a batch program or subsystem, the Liberty server application uses the standard JCA APIs. The following interfaces are customized for use with optimized local adapters:

- ConnectionSpec
- InteractionSpec
- Record I/O

### ConnectionSpec

Use the ConnectionSpec interface to pass connection-specific parameters when you obtain a connection from a connection factory. These parameters can override the parameters of the same name that are defined in the connection factory. For optimized local adapters, this interface is implemented as the `com.ibm.websphere.ola.ConnectionSpecImpl` class. The ConnectionSpecImpl class enables you to specify which optimized local adapters register name that you want to communicate with.

When you communicate with a CICS link server, the ConnectionSpecImpl class provides methods that you can use to override values that the link server uses. For example, you can specify the four-character transaction ID of the link server invocation transaction, BBO#. You can also specify whether to store request data in a CICS COMMAREA or CONTAINER object.

For information about methods in the ConnectionSpecImpl class, see the generated API documentation.

### InteractionSpec

Use the InteractionSpec interface to specify request-specific parameters to the resource adapter instance that you are connected to. For optimized local adapters, this interface is implemented as the `com.ibm.websphere.ola.InteractionSpecImpl` class. You can use the InteractionSpecImpl class to set the service name for the application to communicate with. The service name is hosted by the register name that was specified when the connection was obtained.

For information about methods in the InteractionSpecImpl class, see the generated API documentation.

### Record I/O

Use the Record interface to pass request and response data to the resource adapter instance that you are connected to. The optimized local adapters provide two implementations of the Record interface, IndexedRecord and MappedRecord. You can create both implementations by obtaining a reference to the RecordFactory from the JCA connection instance that the application uses.

Use an IndexedRecord object if you are passing data to a Batch or UNIX System Services program or if you are communicating with CICS using a COMMAREA or a single CONTAINER object. Add a byte array (`byte[]`) to the IndexedRecord object to represent the data that the program sends on the request. The response is also received into an IndexedRecord object. You can obtain the response data by retrieving the first entry from the IndexedRecord object and casting it to a byte array.

Use a MappedRecord object if you are passing data to CICS in multiple CONTAINER objects. The MappedRecord object contains name-value pairs, similar to what Map objects store. In the name-value pairs, the name is the name of the container that the data is transferred to, and the value is the actual data, specified as a byte array (`byte[]`). When you use a MappedRecord object to send a request, the response is also sent back using a MappedRecord object. The response contains the name of each container that contained response data and the associated data.

# Developing applications for use with z/OS Connect to reach z/OS assets

## IBM z/OS Connect overview

The IBM z/OS Connect offering is a Liberty feature that encapsulates calling z/OS target applications using REST (Representation State Transfer) calls.

z/OS Connect is designed to provide a fast, secure, reliable connector to reach any z/OS asset. z/OS Connect provides a standard way to identify these assets and reach the assets using REST technology. Where these assets run is specified in the z/OS Connect configuration, relieving clients applications in the cloud, mobile, and web worlds of the need to understand the details about how to reach them and how to convert payloads to and from the formats that the applications require.

### Benefits of using z/OS Connect

z/OS Connect adds value for z/OS customers by enabling users to consolidate multiple client connect pathways into a single common gateway or concentrator for synchronous calls to reach business assets and data on z/OS operating systems. Virtually any z/OS asset, applications and data, can be reached by using standard REST HTTP calls. This feature also provides the ability to inquire about, or discover, all assets that are defined in the z/OS Connect configuration repository. The following is a summary of the benefits of z/OS Connect:

- Provides RESTful access to identify and invoke z/OS-based business assets in CICS, IMS, UNIX System Services, and traditional batch environments, opening up these assets to cloud and mobile-based system of engagement environments.
- Functionality that is based on Liberty server technology, is lightweight and easily configurable, and provides z/OS differentiation with System Authorization Facility (SAF) security integration, z/OS Workload Manager (WLM), and Resource Recovery Services (RRS) integration. WLM integration means different URIs can have varying levels of priority and performance criteria.
- As a feature in the Liberty server on z/OS, you can integrate z/OS Connect with z/OS standard system management, which can run as a started task and integrate with z/OS automated operations.
- Provides the ability to secure individual or groups of z/OS Connect services with SAF security in which only specific users or groups can have access to specific services.
- Provides the ability to uniformly track requests from cloud, mobile, and web environments by using z/OS System Management Facility (SMF) services. This tracking means that z/OS customers can use their existing processes for auditing and chargeback for requests from these environments.
- Enables the ability to do an automatic conversion of the request payload from JavaScript Object Notation (JSON) form on input to binary form consumable by z/OS applications such as Cobol, PL/I, and C. The reverse for the response from the z/OS application, converting the output from binary to JSON form is also true.

### Using z/OS Connect REST APIs

z/OS<sup>®</sup> Connect provides a set of RESTful APIs that you can use to discover services, check service status, start or stop services, get statistics, and other operations.

### About this task

You can use z/OS Connect REST APIs from a client running in a web, mobile, or cloud environment.

## Procedure

1. Discover services in the z/OS Connect configuration.

Sample HTTP GET request:

```
https://host:port/zosConnect/services
```

Sample JSON payload returned:

```
{
  zosConnectServices: [
    {
      ServiceName: "recordOpsCreate"
      ServiceDescription: "Creates a new record"
      ServiceProvider: "SAMPLE-1.0"
      ServiceURL: "https://host:port/zosConnect/services/recordOpsCreate"
    },
    {
      ServiceName: "recordOpsDelete"
      ServiceDescription: "Deletes an existing record"
      ServiceProvider: "SAMPLE-1.0"
      ServiceURL: "https://host:port/zosConnect/services/recordOpsDelete"
    }
  ]
}
```

2. Retrieve configuration data for a service. Sample HTTP GET request:

```
https://host:port/zosConnect/services/recordOpsCreate
```

The output is returned in two parts: the first part contains the z/OS Connect configuration parameters and the second part has the configuration returned by the service provider implementation. The following is a sample of JSON payload that was returned:

```
{
  zosConnect: {
    serviceName: "recordOpsCreate"
    serviceDescription: "Creates a new record"
    serviceProvider: "SAMPLE-1.0"
    serviceURL: "https://host:port/zosConnect/services/recordOpsCreate"
    serviceInvokeURL: "https://host:port/zosConnect/services/recordOpsCreate?action=invoke"
    dataXformProvider: "jsonByte-1.0"
  },
  recordOpsCreate: {
    targetProgram: "CREATREC"
    timeout: "300ms"
  }
}
```

3. Retrieve service status. Sample HTTP GET request:

```
https://host:port/zosConnect/services/recordOpsCreate?action=status
```

Sample JSON payload returned.

```
{
  zosConnect:
  {
    serviceName: "recordOpsCreate"
    serviceDescription: "Creates a new record"
    serviceProvider: "SAMPLE-1.0"
    serviceURL: "https://host:port/zosConnect/services/recordOpsCreate"
    serviceInvokeURL: "https://host:port/zosConnect/services/recordOpsCreate?action=invoke"
    dataXformProvider: "jsonByte-1.0"
    serviceStatus: "Started"
  }
}
```

4. Retrieve request schema. Sample HTTP GET request:

```
https://host:port/zosConnect/services/recordOpsCreate?action=getRequestSchema
```

Sample JSON payload returned.

```
{
  <Request schema as returned by the data configured data transformer>
}
```

- Retrieve response schema. Sample HTTP GET request:

`https://host:port/zosConnect/services/recordOpsCreate?action=getResponseSchema`

Sample JSON payload returned.

```
{
  <Request schema as returned by the data configured data transformer>
}
```

- Retrieve statistics.

Statistics include z/OS Connect data for a service such as `InvokeRequestCount`, and a `TimeOfRegistrationWithZosConnect`, along with any other statistics returned by the service provider using the `getStatistics()` SPI implementation in the provider. Statistics for a particular service can be retrieved through a `/zosConnect/operation` or an `action=` request call. `/zosConnect/operations` requests offer more flexibility because the product can retrieve statistics for all services. If the authorization interceptor is enabled, then the product returns statistics for only those services that the user can request. See the documentation about z/OS Connect security for more details.

Sample HTTP GET request to return statistics using `action=getStatistics`:

`https://host:port/zosConnect/services/recordOpsCreate?action=getStatistics`

Sample JSON payload returned.

```
{
  recordOpsCreate:
  {
    ServiceProvider: "SAMPLE-1.0"
    InvokeRequestCount: 100
    TimeOfRegistrationWithZosConnect: "xxx-xx-xx xx:xx:xx:xxx xxx"
    ServiceStatistics:
    {
      <JSON name value pairs showing statistical information the service returned>
    }
  }
}
```

- Retrieving statistics for a service can be also accomplished using the `zosConnect/operations/getStatistics` REST API.

Information returned includes statistics for all services that the current user can request.

Sample HTTP GET request using `/zosConnect/operation/getStatistics` :

`https://host:port/zosConnect/operations/getStatistics`

Sample JSON payload returned.

```
{
  zosConnectStatistics:
  [
    {
      recordOpsCreate:
      {
        ServiceProvider: "SAMPLE-1.0"
        InvokeRequestCount: 100
        TimeOfRegistrationWithZosConnect: "xxx-xx-xx xx:xx:xx:xxx xxx"
        ServiceStatistics:
        {
          <JSON name value pairs showing statistical information the service returned>
        }
      }
    },
    {
      recordOpsDelete:
      {
        ServiceProvider: "SAMPLE-1.0"
        InvokeRequestCount: 100
      }
    }
  ]
}
```

```

        TimeOfRegistrationWithZosConnect: "xxx-xx-xx xx:xx:xx:xxx xxx"
    ServiceStatistics:
    {
    <JSON name value pairs showing statistical information the service returned>
    }
    }
}
]
}

```

If there are no services registered with z/OS Connect, the output resembles:

```

{
zosConnectStatistics:[]
}

```

- Retrieve statistics for all services that are defined for a specific service provider using the `zosConnect/operations/getStatistics` REST API.

Sample HTTP GET request:

```
https://host:port/zosConnect/operations/getStatistics?provider=SAMPLE-1.0
```

Sample format/output:

```

{
  recordOpsCreate:
  {
    ServiceProvider: "SAMPLE-1.0"
    InvokeRequestCount: 100
    TimeOfRegistrationWithZosConnect: "xxx-xx-xx xx:xx:xx:xxx xxx"
    ServiceStatistics:
    {
      .. JSON name value pairs showing statistical information the service returned.
    }
  }
}

```

- Retrieve statistics for a single service using the `zosConnect/operations/getStatistics?service=<service name>` REST API. This operation is equivalent to specifying `action=getStatistics` on a service.

HTTP GET request on:

```
https://host:port/zosConnect/operations/getStatistics?service=recordOpsCreate
```

Sample JSON payload returned:

```

{
  recordOpsCreate:
  {
    ServiceProvider: "SAMPLE-1.0"
    InvokeRequestCount: 100
    TimeOfRegistrationWithZosConnect: "xxx-xx-xx xx:xx:xx:xxx xxx"
    ServiceStatistics:
    {
      <JSON name value pairs showing statistical information the service returned>
    }
  }
}

```

- Stop z/OS Connect services by using an HTTP POST or PUT request with `action=stop`, or start the services by using HTTP POST or PUT with the `action=start` query string.  
Stop and start actions do not require a payload. If one is provided, it is ignored. A user can retrieve the status of a z/OS Connect service using HTTP GET on the service name with the `action=status` query string to retrieve the service status. If the authorization interceptor provided by z/OS Connect is enabled, the user that is requesting the status or state change must be in the operator or administrator group required for the service. For each, the Service Provider SPI is called by z/OS Connect to notify it that these actions have been requested. The method names that are in the SPI for this are `stop()`, `start()`, and `status()`.

**Note:** z/OS Connect does not persist any state that is related to the service and instead delegates this to the service provider.

The service provider can send responses other than stop or start. z/OS Connect allows for a custom status to be returned.

Stop a service sample using HTTP POST or PUT:

```
https://host:port/zosConnect/services/recordOpsCreate?action=stop
```

Sample JSON payload returned:

```
{
  zosConnect:
  {
    serviceName: "recordOpsCreate"
    serviceDescription: "Creates a new record"
    serviceProvider: "SAMPLE-1.0"
    serviceURL: "https://host:port/zosConnect/services/recordOpsCreate"
    serviceInvokeURL: "https://host:port/zosConnect/services/recordOpsCreate?action=invoke"
    dataXformProvider: "jsonByte-1.0"
    serviceStatus: "Stopped"
  }
}
```

11. Start a service sample using HTTP POST or PUT:

```
https://host:port/zosConnect/services/recordOpsCreate?action=start
```

Sample JSON payload returned:

```
{
  zosConnect:
  {
    serviceName: "recordOpsCreate"
    serviceDescription: "Creates a new record"
    serviceProvider: "SAMPLE-1.0"
    serviceURL: "https://host:port/zosConnect/services/recordOpsCreate"
    serviceInvokeURL: "https://host:port/zosConnect/services/recordOpsCreate?action=invoke"
    dataXformProvider: "jsonByte-1.0"
    serviceStatus: "Started"
  }
}
```

12. Invoke services using the z/OS Connect query string: `action=invoke`, which runs the `invoke()` method of the Service Provider SPI implementation.

The sample in this step runs the `invoke` method for the service named `recordOpsCreate` and passes a JSON object payload in the request body.

The z/OS Connect `invoke` method supports an input payload in JSON object form for this request. In the code example, it is assumed that z/OS Connect looked up the Service Provider and identified a service reference for the service called `SAMPLE-1.0`. There is also a data transformation reference in the z/OS Connect service definition with a provider called `jsonByte-1.0`. With this in place, when the `invoke` method of the service provider gets control and it calls the `getBytes()` method, the data transformation implementation gets control and converts the request payload from JSON to a byte array and returns it to the service provider.

If the URL that the `invoke` action request came in with contains query parameters, these parameters along with other HTTP request information are passed to the service provider using the `com.ibm.wsspi.zos.connect.HttpZosConnectRequest` SPI interface provided by z/OS Connect. Interceptors processed for actions or operations also receive HTTP request information through the same object.

Another invocation style that is supported by z/OS Connect provides a means to define a user-defined URI as the `invokeURI` in the z/OS Connect service definition. With this style, the HTTP request does not have to contain `zosConnect/services` and can instead be a user-defined string.

When this style is employed, z/OS Connect supports use of other HTTP methods, such as GET, PUT, POST, and DELETE. Requests arriving with this URI, regardless of the HTTP method employed, pass through z/OS Connect interceptors and are passed to the `invoke()` method of the service provider.

Sample using HTTP POST or PUT:

```
https://host:port/zosConnect/services/recordOpsCreate?action=invoke
{
<JSON object passed in for the service invocation>
}
```

Sample JSON payload returned:

```
{
<JSON object returned from the service invocation>
}
```

## Creating a z/OS Connect service provider

8.5.5.2

z/OS<sup>®</sup> Connect provides the `com.ibm.wsspi.zos.connect.Service` SPI that supports the creation of service providers that you can use to process requests arriving in to the z/OS Connect servlet.

### About this task

z/OS Connect service providers can be written and delivered by any component to plug into the framework. A WOLA service provider is included with z/OS Connect.

A service provider implemented for z/OS Connect is an OSGi service that connects and interacts with z/OS Connect through the OSGi framework.

### Procedure

1. Create a service provider that implements the z/OS Connect `com.ibm.wsspi.zos.connect.Service` SPI.
2. Edit the service metatype configuration so that it specifies the following attribute definition:

```
<AD id="com.ibm.ws.zos.connect.serviceType" required="false" type="String"ibm:final="true"name="internal"description="i
```

The `ibm:final` attribute indicates that the value cannot be specified in the configuration, and the `name="internal"` attribute indicates that tools do not display this property.

The Java™ API documentation for each Liberty SPI is available in a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

For more information, see the documentation on extending Liberty.

**Note:** The Java API documentation for each Liberty SPI is detailed in the Programming Interfaces (APIs) section of the documentation, and is also available as a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

## Creating a z/OS Connect service at run time

8.5.5.7

To process incoming requests, you can create a z/OS connect service at run time by using the `com.ibm.wsspi.zos.connect.ServiceController` service programming interface (SPI).

### About this task

You can dynamically create a z/OS Connect service provider at run time based on the configuration that is stored in an external repository.

### Procedure

1. Create a service provider that implements the z/OS Connect `com.ibm.wsspi.zos.connect.ServiceController` SPI.
2. At run time, register the service with the OSGi framework that is using the `theregisterService` method on the `BundleContext` attribute.

```
Dictionary<String, Object> dynamicServiceProps = new Hashtable<String, Object>();
dynamicServiceProps.put(ServiceControllerConstants.SERVICE_NAME, "myNewService");
dynamicServiceProps.put(ServiceControllerConstants.INVOKE_URI, new String[] { "/u/my/ur11",
"/u/myur12", "/u/my/ur13*" });
ServiceRegistration<ServiceController> dynamicServiceReg =
    bundleContext.registerService(com.ibm.wsspi.zos.connect.ServiceController.class, new
MyServiceController(), dynamicServiceProps);
```

**Important:** The Java API documentation for each Liberty SPI is detailed in the Programming Interfaces (APIs) section of the documentation, and is also available as a separate .zip file in one of the subdirectories of the `${wlp.install.dir}/dev` directory. For more information, see the documentation on extending Liberty.

## Creating a z/OS Connect interceptor

8.5.5.2

Use z/OS® Connect SPI to create interceptor `preInvoke` and `postInvoke` implementations that manage service requests such as `invoke`, `status`, `start`, and `stop`. Interceptors are OSGi services that implement the `com.ibm.wsspi.zos.connect.Interceptor` SPI provided by z/OS Connect.

### About this task

z/OS Connect includes several interceptors. The `com.ibm.wsspi.zos.connect.AuthorizationInterceptor` provides z/OS SAF and LDAP authorization checks z/OS Connect operations, such as `start`, `stop`, and `invoke`. The `com.ibm.wsspi.zos.connect.Audit` implementation, records z/OS SMF recording of request data on z/OS Connect operations.

You can use interceptors for various purposes. z/OS Connect has no visibility into uses of interceptors. For example, an interceptor might be written to do some infrastructure setup that is based on the message payload before the request is processed. z/OS Connect provides a copy of the input request payload to all interceptors.

An interceptor implemented for z/OS Connect is an OSGi service that connects and interacts with z/OS Connect through the OSGi framework.

### Procedure

1. The interceptor must implement the z/OS Connect `com.ibm.wsspi.zos.connect.Interceptor` SPI.
2. Edit the service metatype configuration so that it specifies following attribute definition:

```
<AD id="com.ibm.ws.zos.connect.interceptorType" required="false" type="String"ibm:final="true"name="internal"description
```

The `ibm:final` attribute indicates that the value cannot be specified in the configuration, and the `name="internal"` attribute indicates that tools do not display this property.

The Java™ API documentation for each Liberty SPI is available in a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

For more information, see the documentation on extending Liberty.

**Note:** The Java API documentation for each Liberty SPI is detailed in the Programming Interfaces (APIs) section of the documentation, and is also available as a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

## Creating a z/OS Connect data transformer

8.5.5.2

You can use the z/OS® Connect SPI to create a custom data transformer. Data transformers are OSGi services that implement the `com.ibm.wsspi.zos.connect.DataXform` SPI that is provided by z/OS Connect.

## About this task

z/OS Connect data transformers are written and delivered by any component to plug into the framework. A data transformer is included with z/OS Connect and provides both to and from JSON byte arrays that are consumable by COBOL, PL/I, and C programs on z/OS.

A data transformer that is implemented for z/OS Connect is an OSGi service that connects and interacts with z/OS Connect through the OSGi framework.

## Procedure

1. Implement the z/OS Connect `com.ibm.ws.zos.connect.DataXform` SPI in the service.
2. Edit the metatype configuration so that it specifies the following attribute definition:

```
<AD id="com.ibm.ws.zos.connect.dataXformType" required="false" type="String" ibm:final="true" name="internal" description="Data Xform Type" />
```

The `ibm:final` attribute indicates that the value cannot be specified in the configuration, and the `name="internal"` attribute indicates that tools do not display this property.

The Java™ API documentation for each Liberty SPI is available in a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

For more information, see the documentation on extending Liberty.

**Note:** The Java API documentation for each Liberty SPI is detailed in the Programming Interfaces (APIs) section of the documentation, and is also available as a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

## Conversion for z/OS Connect data transformation

8.5.5.2

The z/OS Connect feature runs in a WebSphere Application Server for z/OS, Liberty environment. You can use the BBGLS2JS and BBGJS2LS Job Control Language (JCL) tools to generate the necessary z/OS Connect artifacts to facilitate data conversion.

### BBGLS2JS: High-level language to binding and schema file conversion for z/OS Connect data transformation

The BBGLS2JS Job Control Language procedure generates a JavaScript Object Notation (JSON) schema and binding files from a high-level data structure. The files that are generated are used by the z/OS Connect data transformation process. It is based on DFHLS2JS from the Customer Information Control Center (CICS) Transaction Server Mobile Extensions feature pack.

See the documentation for usage information and examples on using the BBGLS2JS tool. Where the documentation refers to DFHLS2JS, use BBGLS2JS. [http://www-01.ibm.com/support/knowledgecenter/SSGMCP\\_5.1.0/com.ibm.cics.ts.mobileextensions.doc/reference/dfhws\\_ls2js.html](http://www-01.ibm.com/support/knowledgecenter/SSGMCP_5.1.0/com.ibm.cics.ts.mobileextensions.doc/reference/dfhws_ls2js.html)

#### Symbolic parameters

The following symbolic parameters are defined in BBGLS2JS:

**WLPDIR=path** A required parameter that specifies the name of the WebSphere Application Server Liberty directory in the UNIX System Services file system.

**TMPDIR=tmpdir** Specifies the location of a directory in IBM z/OS Unix System Services that BBGLS2JS uses as a temporary workspace. The user ID used to run the job must have read and write permission to this directory. It is an optional parameter and if it is not specified, the default value is `/tmp`.

You specify an absolute path for a Java API to use a new temporary workspace when you code the `java.io.tmpdir` custom property. For scripts, you specify the environment variable **TMPDIR** to point to this new temporary directory.

**TMPFILE=tmpprefix** Specifies a prefix that BBGLS2JS uses to construct the names of the temporary workspace files. It is an optional parameter and if it is not specified, the default value is LS2JS.

## Input Parameters

The input parameters that are documented for DFHLS2JS are also applicable to BBGLS2JS. The value that is specified for the **PGMNAME** parameter is used in the generated JSON schema.

The following example shows how to create the JCL to run the BBGLS2JS tool:

```
//LS2JS JOB 'accounting information',name,MSGCLASS=A
//JCLLIB JCLLIB ORDER=EXAMPLE.DSNAME
//JAVAPROG EXEC BBGLS2JS,
// WLPDIR='/opt/IBM/wlp'
//INPUT.SYSUT1 DD *
PDSLIB=TEST.DSNAME
REQMEM=CDATA2
RESPMEM=CDATA2
MAPPING-LEVEL=3.0
MINIMUM-RUNTIME-LEVEL=3.0
CHAR-VARYING=COLLAPSE
STRUCTURE=(requestData,requestData)
JSON-SCHEMA-REQUEST=/u/user1/json/getcustc_request.json
JSON-SCHEMA-RESPONSE=/u/user1/json/getcustc_response.json
LANG=C
LOGFILE=/u/user1/wsbinding/getcustc.log
URI=http://myserver.example.org:8080/exampleApp/example
PGMINT=COMMAREA
PGMNAME=GETCUSTC
WSBIND=/u/user1/getcustc.wsbinding
/*
```

## BBGJS2LS: JSON schema to high-level language conversion for z/OS Connect data transformation

The BBGJS2LS JCL procedure generates a high-level language data structure and binding file from a JSON schema. The files that are generated are used by the z/OS Connect data transformation process. It is based on DFHJS2LS from the CICS Transaction Server Mobile Extensions feature pack.

See the documentation for usage information and examples on using the BBGJS2LS tool. Where the documentation refers to DFHJS2LS, use BBGJS2LS. [http://www-01.ibm.com/support/knowledgecenter/SSGMCP\\_5.1.0/com.ibm.cics.ts.mobileextensions.doc/reference/dfhws\\_js2ls.html](http://www-01.ibm.com/support/knowledgecenter/SSGMCP_5.1.0/com.ibm.cics.ts.mobileextensions.doc/reference/dfhws_js2ls.html)

## Symbolic parameters

The following symbolic parameters are defined in BBGJS2LS:

**WLPDIR=path** A required parameter that specifies the name of the WebSphere Application Server Liberty directory in the UNIX System Services file system.

**TMPDIR=tmpdir** Specifies the location of a directory in z/OS UNIX that BBGJS2LS uses as a temporary workspace. The user ID used to run the job must have read and write permission to this directory. It is an optional parameter and if it is not specified, the default value is /tmp.

**TMPFILE=tmpprefix** Specifies a prefix that BBGJS2LS uses to construct the names of the temporary workspace files. It is an optional parameter and if it is not specified, the default value is JS2JS.

## Input Parameters

The input parameters that are documented for DFHJS2LS are also applicable to BBGJS2LS. The value that is specified for the **PGMNAME** parameter is used in the name of the generated high-level language structure.

The following example shows how to create the JCL to run the BBGJS2LS tool:

```
//JS2LS JOB 'accounting information',name,MSGCLASS=A
// SET QT=''
//JCLLIB JCLLIB ORDER= EXAMPLE.DSNAME
//JAVAPROG EXEC BBGJS2LS,
// WLPDIR='/opt/IBM/wlp'
//INPUT.SYSUT1 DD *
PDSLIB=TEST.DSNAME
REQMEM=CPYBK1
RESPMEM=CPYBK2
JSON-SCHEMA-REQUEST=example.json
JSON-SCHEMA-RESPONSE=example.json

MAPPING-LEVEL=3.0
CHAR-VARYING=NULL
INLINE-MAXOCCURS-LIMIT=2
PGMNAME=DFH0XCMN
URI=exampleApp/example
PGMINT=COMMAREA
SYNCONRETURN=YES
WSBIND=/u/exampleapp/wsbinding/example.wsbinding
/*
```

## Auditing and tracking with z/OS Connect

Audit and track requests with z/OS<sup>®</sup> Connect, which includes an interceptor that records data to the z/OS SMF data store.

### About this task

You can enable the interceptor in z/OS Connect on a single or group of z/OS Connect services. The z/OS Connect audit interceptor records request activity to the SMF data store on z/OS operating systems. SMF type 120, subtype 11 records are generated.

The SMF data in the 120-11 record contains the standard header for SMF records. Then, there are two triplets. The first triplet points to the server identification section of which there is one instance. The second triplet points to the user data section of which there can be multiple instances.

**The server data section consists of the following parameters: (values in decimal)**

- Offset Length Data
- 0 4 Version (1)
- 4 8 System name
- 12 8 Sysplex name
- 20 8 Job id(jsabjbid)
- 28 8 Job name (jsabjbnm)
- 36 8 SToken (assbstkn)

**The user data consists of the following parameters (values in decimal):**

- Offset Length Data
- 0 4 Version (1)

- 4 4 Type
- 8 4 Length of data (user data sections are 2 K, this field indicates how much of that is used)
- 12 ? Data

**The user data consists of the following parameters (values in decimal):**

For z/OS Connect the user data type is 102 (decimal). The data contains the following parameters:

- Offset length Data
- 0 4 Version (3)
- 4 8 Arrival time (STCK format)
- 12 8 Completion time (STCK format)
- 20 64 Target URI (EBCDIC, right-padded with blanks)
- 84 4 Input payload length in bytes
- 88 64 Service name (EBCDIC, right-padded with blanks)
- 152 8 Method (EBCDIC)
- 160 4 Respond length in bytes
- 164 64 User name (EBCDIC, right-padded with blanks)
- 228 23 Request id (bytes, right-padded with zeros)
- 251 1 Boundary padding (zero)
- 252 64 Service grouping name (EBCDIC, right-padded with blanks)
- 316 8 Mapped user name (EBCDIC, right-padded with blanks) Only valid on version 3 or later.

**Procedure**

1. Enable the z/OS Connect-provided audit interceptor for a service or set of services. The z/OS Connect-supplied audit interceptor implements the `com.ibm.wsspi.zos.connect.Interceptor` SPI to store auditing/tracking information in the z/OS System Management Facility (SMF) data sets. The following is an example that shows how to enable the audit interceptor for a single service:

```
<!-- Audit interceptor configuration -->
<auditInterceptor id="auditInterceptor" sequence="1"/>

<!-- Interceptor list configuration -->
<zosConnectInterceptors id="interceptorList1" interceptorRef="auditInterceptor"/>

<!-- z/OS Connect service definitions -->
<zosConnectService id="zcs1" serviceName="recordOpsCreate" serviceRef="wolaOpsCreateService"
interceptorsRef="interceptorList1"/>
```

2. Retrieve live statistic data. Feature start time, total number of service requests and the distribution of requests are available by using this operational capability. Valid authenticated clients are able to use a HTTP GET for one of the following URIs to retrieve statistics about the z/OS Connect server:

- Get statistics for a single service:  
`https://<hostname:port>/zosConnect/services/HelloWorld?action=getStatistics`
- Get statistics for all services in the server:  
`https://<hostname:port>/zosConnect/operations/getStatistics`
- Get statistics for all services under a single service provider by specifying the `provider=<service provider name>` query parameter. For example to retrieve statistics for all services associated with the provider name of **WOLA-1.0** use the following URL:  
`https://<hostname:port>/zosConnect/operations/getStatistics?provider=WOLA-1.0`
- The response data is returned in JSON object format.

---

## Developing EJB applications on Liberty

8.5.5.6

An Enterprise JavaBeans (EJB) application is a set of beans that are packaged a combination of a Java archive file (jar), web application archive file (war), or Java EE enterprise application archive file (EAR).

### About this task

The WebSphere® Application Server Liberty provides full support for the Enterprise JavaBeans specification. The EJB Specification also defines a lite subset, which is also a configurable feature provided in Liberty in addition to several other optional features that enable server configurations that only support subsets of the full EJB specification. These subsets enable the use of server configurations that use fewer resources when all capabilities of the EJB specification are not used by the installed applications.

For information about developing EJB applications by using WebSphere Developer Tools, see [Developing EJB 3.x applications](#).

### Enterprise JavaBeans core features

#### ejbLite

This feature enables the lite subset of the EJB technology as defined in the EJB specification. This subset includes support for local session beans that are written to the EJB 3.x APIs. Beginning with the `ejbLite-3.2` feature, the subset also includes support for non-persistent EJB timers and asynchronous local interface methods.

Other than enabling the `ejbLite-3.2` feature in the `server.xml` file, no additional configuration is required for this feature.

#### mdb

This feature enables the message-driven bean subset of the EJB technology, which is similar to the support that the `ejbLite` feature enables for session beans. The feature does not enable session beans, so if both session and message-driven beans are needed, then both features need to be enabled in the `server.xml` file.

The following features provide the minimum set of capabilities for the EJB APIs:

**Note:** EJB 2.x API entity beans are not supported by Liberty. For persistence, the Java Persistence API (JPA) must be used instead.

### Enterprise JavaBeans extension features

The following features provide extensions to the core EJB features, which, when they are combined, provide support for the full set of EJB APIs:

#### ejbHome

Enables support of the EJB 2.x APIs, specifically, support for the `javax.ejb.EJBLocalHome` interface. The `javax.ejb.EJBHome` interface is also supported when combined with the `ejbRemote` feature. Since this feature is not useful without the `ejbLite` feature, enabling this feature automatically enables the corresponding `ejbLite` feature.

Other than enabling the feature in the `server.xml` file, no additional configuration is available for this feature.

#### ejbPersistentTimer

Enables support for persistent EJB timers. Enabling this feature automatically enables the corresponding `ejbLite` feature.

In addition to enabling this feature in the `server.xml` file, a data source must also be configured to provide the persistent store for the timers. By default, the `DefaultDataSource` is used, so that configuration is all that is required.

### **ejbRemote**

Enables support for remote EJB interfaces. Enabling this feature automatically enables the corresponding `ejbLite` feature.

Other than enabling the feature in the `server.xml` file, no additional configuration is required for this feature.

### **Enterprise JavaBeans convenience feature**

The following feature provides a convenient way to enable the full set of EJB APIs:

#### **ejb**

Enables all of the core and extension features for the specification level of the configured feature. For example, `ejb-3.1` enables `ejbLite-3.1` and `mdb-3.1`. This feature provides no additional support beyond what is provided by enabling all of the core and extension EJB features.

Other than enabling the feature in the `server.xml` file, no additional configuration is required for this feature.

### **Procedure**

Enable the feature in the `server.xml` file. For example:

```
<featureManager>
  <feature>ejbLite-3.2</feature>
</featureManager>
```

## **Developing Enterprise bean (EJB) persistent timer applications**

8.5.5.6

EJB persistent timers are created either automatically by the container or programmatically by an application. Both types of persistent timers are stored in tables in the database that is configured for the EJB timer service in the `server.xml` file.

### **About this task**

After the persistent timer is created, it exists in the database until one of the following occurs:

- The timer is not scheduled for further expirations; for example, after a single-action timer expires and runs successfully.
- The timer is canceled by the application.
- The timer is canceled by using the EJB timer service MBean (`EJBPersistentTimerServiceMBean`)
- The timer is manually removed from the database. For example, if the timer service database is cleared or removed.

Also, note that EJB persistent timers are associated with an EJB based on the application name, module name, and bean name. If an application is updated, and any of these names change, then the timer continues to exist in the database, but appears to no longer exist as it no longer expires and runs.

The Enterprise JavaBeans specification declares that automatic timers are created by the container when an application is deployed. For Liberty, this occurs the first time that an application starts within a server process. During the first application start, the automatically created persistent timers are stored in the persistent timer database along with an indication that the application has been deployed. The container does not create the automatic persistent timers again until both the timers and the indication that the

application has been deployed is removed from the EJB persistent timer database.

## Procedure

Enable the EJB persistent timer feature in the `server.xml` file; for example:

```
<featureManager>
  <feature>ejbPersistentTimer-3.2</feature>
</featureManager>
```

## Managing enterprise beans (EJB) persistent timers

8.5.5.6

Applications or modules can create EJB persistent timers either automatically or programmatically that are stored in a database. An MXBean is provided for viewing the persistent timers that exist in the database and removing some or all persistent timers that are associated with an application.

### About this task

The best way to manage EJB persistent timers is through the application that created the timers. The application that created the timer is able to provide the context of why the timer was created and exactly what action the timer performs when the timer reaches the expiration. However, for application development and diagnostic purposes the EJB timer service does provide an MXBean capable of performing basic timer management functions, `com.ibm.websphere.ejbcontainer.mbean.EJBPersistentTimerServiceMXBean`.

The MXBean provides operations to find the EJB persistent timers that are associated with an application, module, or specific bean. The viewable information includes the name of the bean that the timer is associated with and the schedule when the timer expires. Application-specific data that is associated with the timer might not be viewable. Operations are also provided to cancel a specific timer or all timers that are associated with an application, module, or bean.

The EJB APIs do not provide a mechanism for providing a unique identity when creating timers, however when the timer is stored in the database a unique identity is associated with the timer and used as the primary key into the database. There is no way to programmatically obtain the timer identity, but the identity is part of the viewable information provided by the MXBean 'get' operations. The identity appears in logs when an error is encountered involving the timer. And, the identity is the value that is used to cancel a specific timer through the '`cancelTimer`' MXBean operation.

Note: All MXBean operations perform the same for both automatic and programmatic persistent timers.

## Procedure

1. Configure the application server to include an EJB feature that supports persistent timers and the rest connector in the `server.xml` file.

```
<featureManager>
  <feature>servlet-3.1</feature>
  <feature>ejbPersistentTimer-3.2</feature>
  <feature>jdbc-4.1</feature>
  <feature>restConnector-1.0</feature>
</featureManager>
```

2. Start the JConsole from the JVM bin directory and connect to the Liberty server process.
3. Navigate to the EJB timer service MXBean.
4. Enter the application name in the **String** field of the first '`getTimers`' operation and submit to receive information about the persistent timers for the application.

## Managing automatically created EJB persistent timers

8.5.5.6

Applications or modules use the `javax.ejb.Schedule` annotation or the `schedule` element in the XML deployment descriptor to instruct the application server to automatically create EJB timers. An MBean is provided for managing the creation of the automatically created EJB persistent timers.

## About this task

The Liberty server creates the EJB automatic persistent timers for an application the first time the application is started within the server process. The timers, and an indication that they have been created, are stored in the database associated with the `PersistentExecutor`, configured for the EJB timer service. Once created, the automatically created persistent timers for an application will not be created again until an action is taken to specifically clear the indication that they have been created from the database. Even if all of the automatically created timers for an application are removed, the Liberty server will not create any of them again until the indication that they have been created is also removed.

Clearing the indication that the automatically created timers have been created may be done by either manually clearing the timer database or using the EJB timer service MBean. The EJB timer service MBean can be used either programmatically or through a tool such as JConsole. The interface for the EJB timer service MBean is: `com.ibm.websphere.ejbcontainer.mbean.EJBPersistentTimerServiceMXBean`.

## Procedure

1. Configure the application server to include an EJB feature that supports persistent timers and the rest connector in the `server.xml` file.

```
<featureManager>
  <feature>servlet-3.1</feature>
  <feature>ejbPersistentTimer-3.2</feature>
  <feature>jdbc-4.1</feature>
  <feature>restConnector-1.0</feature>
</featureManager>
```

2. Configure the application server to include a datasource for the EJB timer service in the `server.xml` file.

```
<dataSource id="DefaultDataSource" jdbcDriverRef="DerbyEmbedded">
  <properties.derby.embeddedcreateDatabase="create" databaseName="\${server.config.dir}/data/EJBTimerDB"/>
</dataSource>
<jdbcDriver id="DerbyEmbedded" libraryRef="DerbyLib"/>
<library id="DerbyLib">
  <filename="\${server.config.dir}/derby/derby.jar"/>
</library>
```

3. Obtain the MBean server connection.

4. Obtain the EJB persistent timer service MBean.

```
import javax.management.MBeanServerConnection;
import javax.management.ObjectName;
import com.ibm.websphere.ejbcontainer.mbean.EJBPersistentTimerServiceMXBean;
...
MBeanServerConnection mbsc = <step #3>;
ObjectName on = new
ObjectName("WebSphere:feature=ejbPersistentTimer,type=EJBPersistentTimerService,name=EJBPersistentTimerService");
EJBPersistentTimerServiceMXBean timerServiceMBean =
    JMX.newMXBeanProxy(mbsc, on, EJBPersistentTimerServiceMXBean.class);
```

5. Remove the automatically created persistent timers for the application.

```
timerServiceMBean.removeAutomaticTimers("<application name>");
```

The `removeAutomaticTimers()` method on the MBean removes both the automatically created timers and the indication that they were created. The next time that the server starts the application, the automatically created persistent timers are created.

## Configuring the enterprise JavaBeans timer service for persistent timers

8.5.5.6

For persistent EJB timers, you can configure the EJB timer service to control the data source where the timers are stored, the interval between timer retries and the number of retry attempts for failed calls to the timeout callback method.

## About this task

When the `ejbPersistentTimer` feature is enabled, a data source must be configured for persisting the timers or any attempt to use persistent timers fails. The EJB timer service uses the `DefaultDataSource` if it is configured and no other specific data source is configured for use by the EJB timer service.

Also, the EJB timer service retries failed calls to the timeout callback method for persistent timers every 5 minutes until the timeout callback method completes successfully.

Use the following options to configure persistent timers.

### EJB Persistent Timers Scheduled Executor

Specifies a reference to a persistent executor that controls the behavior of persistent timers. A default instance, `defaultEJBPersistentTimerExecutor`, is provided which uses the `DefaultDataSource` as the persistent store. The EJB persistent timers scheduled executor reference might be changed to a custom configuration, or the default instance might be overridden to change specific values. The following options are available for the persistent executor:

#### Retry limit

Specifies the maximum number of times that the failing timeout callback method might be retried. If the timeout callback method is successful upon retry, the server stops attempting to run it. If a retry fails, the server continues to attempt retries until the timeout callback method succeeds, or the retry limit is reached. After the retry limit is reached, the server does not attempt to run the timeout callback method, even if prior attempts did not succeed. The default value of -1 indicates unlimited retries. A value of 0 indicates no retries, and is not compliant with the EJB specification. A value of 1 or greater indicates the specific number of retries.

Changing the configuration of the number of times a timeout callback method is retried for non-persistent timers is useful for applications that do not require non-persistent timers to complete at each of the scheduled times. For example, if an application creates a non-persistent interval timer that is scheduled to run every 5 minutes, then configuring the number of retries to 0 results in the timer, running one time every 5 minutes, regardless of whether it succeeds or fails.

#### Retry interval

Specifies the interval between retry attempts for a failed timeout callback method. The first retry always occurs immediately, regardless of the interval that is configured for this value. All additional retries wait for the interval that is specified for this value. A value of 0 indicates that all retries are immediate. A value of 1 or greater indicates that retries must wait for that specific number of seconds. The default is 300 seconds.

Configuring a different time interval between retries for non-persistent timers is useful for applications where it is important for the timeout callback method to complete before the scheduled time. This approach is also applicable for applications where it is acceptable to delay the timer completion to a later time, such as a later retry interval, to enable the timeout callback method so the application can have a better chance to run successfully.

#### Persistent Task Store

Specifies which data source is used. A default instance, `defaultDatabaseStore`, is provided which uses the `DefaultDataSource` as the persistent store.

## Procedure

1. Configure the application server to include an EJB feature that supports persistent timers in the `server.xml` file.

```
<featureManager>
  <feature>ejbPersistentTimer-3.2</feature>
</featureManager>
```

2. Configure the EJB timer service to use a specific maximum number of retry values and retry interval values for persistent timers in the `server.xml` file. For example, use the following configuration to specify that the persistent timers retry up to 3 times, with 10 seconds between retries:

```
<persistentExecutor id="defaultEJBPersistentTimerExecutor" retryInterval="10s"
  retryLimit="3"/>
```

With this configuration, the timeout callback method for a timer can be called up to 4 times. The first call occurs at the scheduled time. If the first call fails, then the first retry occurs immediately after the failure. If the timeout callback method continues to fail, then the second and third retries occur 10 and 20 seconds later.

In the following example, a failed timeout callback method is only retried one time. The callback interval is irrelevant because the first retry is always started immediately.

```
<persistentExecutor id="defaultEJBPersistentTimerExecutor" retryLimit="1"/>
```

3. Configure the EJB timer service to use a specific data source for persistent timers in the `server.xml` file. For example, use the following configuration to specify that the persistent timers must be stored by using the `jdbc/timerDataSource`.

```
<databaseStore id="EJBTimerDatabaseStore" tablePrefix="EJBTimer_"/>
<persistentExecutor id="defaultEJBPersistentTimerExecutor"
  taskStoreRef="EJBTimerDatabaseStore"/>
```

## Configuration options for persistent enterprise JavaBeans timers: 8.5.5.6

Persistent EJB timers do not require any configuration beyond enabling the `ejbPersistentTimer` feature and setting up the default data source, which has an ID of `DefaultDataSource`, to point to a database. Optional configuration settings are available to control behaviors such as choosing a different data source, controlling when and how often the database is polled to look for persisted timer tasks, and whether and how often to retry failed or rolled back timer tasks.

EJB timer configuration is specified by an optional `timerService` configuration element. Configuration attributes for persistent EJB timers are further grouped under a `persistentExecutor` configuration. By default, the EJB timer service uses a persistent executor instance named `defaultEJBPersistentTimerExecutor`. It is possible to customize the EJB persistent timer configuration by configuring the timer service to use a different persistent executor instance. However, the best practice for customizing the EJB persistent timer configuration is to override the `defaultEJBPersistentTimerExecutor` instance so that you inherit default values from the `defaultEJBPersistentTimerExecutor` instance.

For example, to override only the retry limit,

```
<persistentExecutor id="defaultEJBPersistentTimerExecutor" retryLimit="50"/>
```

### Customizing the database store for persistent timer tasks

Persistent EJB timer tasks are persisted to a database. Configuration related to the database is grouped under the `databaseStore` configuration element. Unless configured otherwise, an instance of `databaseStore` named `defaultDatabaseStore` is used for persistent EJB timers as well as by other product features that require a database. An example of overriding the `defaultDatabaseStore` instance,

```
<databaseStore id="defaultDatabaseStore" dataSourceRef="DB2DataSource" tablePrefix="MYTIMERS"/>
```

An example of configuring the `defaultEJBPersistentTimerExecutor` instance to use a different `databaseStore` instance,

```
<persistentExecutor id="defaultEJBPersistentTimerExecutor" taskStoreRef="MyDBStore"/>
<databaseStore id="MyDBStore" dataSourceRef="DB2DataSource" tablePrefix="MYTIMERS">
  <authData user="user1" password="password1"/>
</databaseStore>
```

### Enabling and disabling persistent timer task execution

Persistent EJB timer tasks are enabled to run upon commit of the transaction from which they are scheduled. To prevent persistent timer tasks from running, you can configure the `enableTaskExecution` attribute with a value of `false`, in which case the EJB timer service still writes persistent timer tasks to the database but does not run them. If the value is switched to `true`, the EJB timer service will start running the timers that were previously scheduled as well as any new timers that are scheduled.

### Customizing polling of the persistent store for timer tasks

A single initial poll of the persistent store is performed upon startup to locate any previously scheduled timer tasks. When tasks are scheduled, information about the scheduled next run time is persisted as well as kept in memory, making it unnecessary to do further polling of the persistent store. This behavior is ideal in many cases, but might not always be desirable.

- If the timer tasks have external dependencies on other services, the initial poll might occur too soon and timer tasks might fail due to the external services they require being unavailable. If this happens, an initial poll delay can be used to defer the initial poll by a fixed amount of time.
- If a large number of EJB persistent timers are scheduled, they might consume too much memory. In this case, you can configure a poll interval to periodically poll the persistent store for only the timer tasks that you want to run within the interval up until the next poll. The poll size further limits the number of timer tasks that can be read from the database each poll interval, which might cause some tasks to run late.

Example configuration:

```
<persistentExecutor id="defaultEJBPersistentTimerExecutor" initialPollDelay="5m" pollInterval="10m" pollSize="200"/>
```

### Retries for failed and rolled back persistent timer tasks

When persistent EJB timer executions fail or are marked to roll back, they are retried one time immediately. If the immediate retry fails, they are retried at a fixed interval until successful. It is possible to limit the number of retry attempts by specifying a retry limit in the configuration. You can also control the interval between retries by specifying a retry interval in the configuration.

Example configuration:

```
<persistentExecutor id="defaultEJBPersistentTimerExecutor" retryLimit="100" retryInterval="2m"/>
```

## Using enterprise JavaBeans with remote interfaces on Liberty

8.5.5.6

You can remotely access Enterprise Java™ Bean (EJB) methods with remote interfaces when the EJB is hosted by another Java virtual machine (JVM) or another application within the same JVM. WebSphere® Application Server implements remote EJB interfaces by using RMI-IIOP technologies. You can enable remote EJB support with the `ejbRemote-3.2` feature.

### About this task

To configure a Liberty server to run an application with remote EJB support enabled, you must set the `ejbRemote-3.2` feature.

When you use remote EJB interfaces, review the following considerations:

#### Naming

## Using the java: namespace

The EJB specification requires that remote interfaces are bound to the java: namespace; for example:

```
java:global/ExampleApp/ExampleModule/ExampleBean!com.ibm.example.ExampleRemoteInterface
java:app/ExampleModule/ExampleBean!com.ibm.example.ExampleRemoteInterface
java:module/ExampleBean!com.ibm.example.ExampleRemoteInterface
```

EJB components are not bound to the default Java Naming and Directory Interface (JNDI) namespace as in WebSphere Application Server traditional, so @EJB lookups and bindings in ibm-\*.bnd.xml files must not use this namespace. These lookups must use the java: names for EJB components that are hosted within the same server, and corbaname: URLs for EJB components that are hosted in another server.

## Using corbaname: URLs

Interfaces are also bound to the ORB CosNaming name service in similar contexts to those interfaces used in the java:global namespace. These interfaces can be accessed through JNDI by using corbaname: URLs; for example:

```
corbaname::test.ibm.com:2809#ejb/global/ExampleApp/ExampleModule/ExampleHomeBean!com.ibm.example.ExampleEJBHome
corbaname:rir:#ejb/global/ExampleApp/ExampleModule/ExampleHomeBean!com.ibm.example.ExampleEJBHome
```

On the server, the rir: form of the URL uses the local name service. On the client, it uses the default or configured remote name service.

## Escaping corbaname: URLs

According to the Object Management Group (OMG) Naming Service specification, some characters in corbaname: URLs must be escaped. Liberty tries to determine whether a corbaname: URL that is derived from the java:global namespace needs to be escaped, and then escapes it automatically. It is not possible to do the escape in all cases. For example, if a name contains a single dot (.), and has no invalid characters, it cannot be escaped automatically. To force a name to be interpreted in a particular way, it is necessary to escape the URL manually as described in the OMG Naming Service specification.

Consider the following java:global name for an enterprise bean:

```
java:global/TestApp/TestModule/TestBean!test.TestRemoteInterface
```

The simple form of the corbaname: URL cannot be escaped automatically because it represents a different, but valid location. Therefore, the following URL does not work as expected:

```
corbaname:rir:#ejb/global/TestApp/TestModule/TestBean!test.TestRemoteInterface
```

Instead, this URL must be manually escaped as follows:

```
corbaname:rir:#ejb/global/TestApp/TestModule/TestBean!test%5c.TestRemoteInterface
```

The syntax for escaping corbaname: URLs is described fully in OMG Naming Service specification.

## Using JNDI names programmatically

All of the URLs and JNDI names in these examples can be looked up programmatically from an InitialContext. When you look up a java: name, the resulting object can be cast directly to the expected type; for example:

```
Object found = new InitialContext().lookup("java:global/ExampleApp/ExampleModule/ExampleBean!com.ibm.example.ExampleRemoteInterface");
ExampleRemoteInterface bean = (ExampleRemoteInterface) found;
```

However, when you retrieve objects by using corbaname: URLs, the RMI style of casting, called narrowing, must be used; for example:

```
Object found = new InitialContext().lookup("corbaname:rir:#ejb/global/ExampleApp/ExampleModule/ExampleBean!com.ibm.example.ExampleRemoteInterface");
ExampleRemoteInterface bean = (ExampleRemoteInterface) PortableRemoteObject.narrow(found, ExampleRemoteInterface.class);
```

## Interoperability

Any product that supports the IIOP protocol can call enterprise beans that use the EJB 2.x remote

programming model with EJBHome and EJBObject when it is packaged in an EJB JAR module with a version 2.0 deployment descriptor. The `WLP_INSTALL_DIR/clients/ejbRemotePortable.jar` file must be included on the class path of the remote client. This file contains system value classes that are required for communication with a Liberty server. This file is not required when you remotely access EJB components from Liberty or WebSphere Application Server traditional. EJB components that use the EJB 3 remote programming model on Liberty can be remotely accessed by WebSphere Application Server processes. Liberty does not provide a thin client to start EJB components from a stand-alone Java process. Liberty does not provide workload management or failover capabilities for remote EJB components, including when you start EJB components that are hosted from WebSphere Application Server traditional.

### Stub classes

A client must include stub classes when you start a remote EJB that is hosted on an WebSphere Application Server. In some cases, if the client is WebSphere Application Server, the product automatically generates the correct stub classes:

- If a client application starts a remote EJB that is contained within the same application, then Liberty automatically generates stub classes.
- If the target EJB is running in a separate application and is using the EJB 2.x remote programming model with EJBHome and EJBObject, then the client must include stub classes on its classpath. If the EJB is hosted on WebSphere Application Server traditional, you can copy the EJB client JAR from the application from the EAR after it is processed by the `ejbdeploy` command. If the EJB is hosted on WebSphere Application Liberty, you must use the `rmic` program that is included with your Java SDK to generate the stub classes for the target EJB, and then you must include the stub classes with the client.
- If the target EJB is running in a separate application and is using the EJB 3 remote programming model, then the client WebSphere Application Server Liberty or WebSphere Application Server traditional process automatically generates stub classes. EJB components that use the EJB 3 remote programming model on Liberty can be remotely accessed by WebSphere Application Server or WebSphere Application Client processes only.

### Transaction propagation

Liberty does not support outbound or inbound transaction propagation. Additionally, the EJB specification requires that, even if a product supports outbound transaction propagation, it must still send a null transaction context. This context must be rejected by EJB components that use the Required (default), Mandatory, or Supports transaction attributes. A client with an active global transaction cannot start an EJB with default transaction attributes if either the client or server is in Liberty. The client can start the EJB if the EJB is changed to use the RequiresNew or NotSupported transaction attributes. However, the transactional work that is done by the EJB is not committed as part of the transactions of the client.

### Asynchronous methods

An EJB remote interface can have an asynchronous method with a return value of type Future. The server will return a Future object to the client, which is used to retrieve the value. Remote asynchronous methods are not recommended because accumulation of unclaimed results can exhaust memory. To mitigate this problem, the server results expire if the client does not retrieve the result within 24 hours or if the maximum number of unclaimed results exceeds 1000. These values can be adjusted in the `server.xml` file; for example:

```
<ejbContainer>
  <async maxUnclaimedRemoteResults="10"unclaimedRemoteResultTimeout="10m"/>
</ejbContainer>
```

### Procedure

1. To enable this feature, update the `server.xml` file to add the `ejbRemote-3.2` feature; for example:

```
<featureManager>
  <feature>ejbRemote-3.2</feature>
</featureManager>
```

2. Configure your application binding files, `ibm-*-bnd.xml` files, for remote EJB references that have been defined either in the deployment descriptor `<ejb-ref>` or with source code annotations, `@EJB`. A binding is not required for EJB references that provide a lookup name, either on the annotation or in the deployment descriptor. In the binding file, the EJB reference can be bound using one of the `java:` names for an EJB or with one of the `corbaname:names`; for example:

For an EJB reference:

```
@EJB(name="TestBean")
    TestRemoteInterface testBean;
```

The binding is defined:

```
<ejb-ref name="TestBean" binding-name="corbaname:rir:#ejb/global/TestApp/TestModule/TestBean!test%5c.TestRemoteInter
```

3. Configure your application client to include stub classes.
4. (Optional) Configure interoperability for applications that support the IIOP protocol to use EJB remote interfaces by adding the `WLP_INSTALL_DIR/clients/ejbRemotePortable.jar` file on the class path of the remote client.

## Using enterprise JavaBeans applications that call local EJB components in another application

8.5.5.6

The Enterprise JavaBeans (EJB) specification requires that local client views are supported for EJB components that are packaged within the same application. This includes local homes, local business interfaces, and the no-interface view. Local client views are also supported for EJB components that are not packaged within the same application, but additional configuration is required.

### About this task

The product supports access to local client views to EJB components packaged within a separate application with some restrictions:

- The local interface and all parameter, return, and exception types that are used by the local interface must be visible to the class loader of both the calling application and the target EJB application. You can ensure that they are visible by either using a shared library that is associated with a server class loader or by using a common library reference with both applications.
- When the target EJB application is stopped, any cached references to the EJB must be refreshed by restarting the calling application. The simplest solution is to restart the calling application whenever you restart a target EJB application on which it relies.

### Procedure

Add the configuration to the `server.xml` file; for example:

```
<library id="ejbInterfaceLib">
  <file name="${server.config.dir}/lib/ejbInterfaceLib.jar"/>
</library>
<webApplication id="ejbClient" location="ejbClient.war">
  <classloader commonLibraryRef="ejbInterfaceLib"/>
</webApplication>
<ejbApplication id="ejbApp" location="ejbApp.ear">
  <classloader commonLibraryRef="ejbInterfaceLib"/>
</ejbApplication>
```

---

## Developing SIP applications on Liberty

8.5.5.7

A Session Initiation Protocol (SIP) application is a set of SIP servlets that are packaged in a SIP application archive file (SAR).

## About this task

A SIP servlet is an application component that is managed by the SIP container that performs SIP signaling. The programming and deployment models are analogous to web servlets and are therefore mapped to the Liberty administrative model. You can include web servlets in a SAR file (along with the required web.xml deployment descriptor) to create what is known as a converged application. See JSR 116 and JSR 289 for details on SIP applications, servlets, converged applications, and status codes.

You can use developer tools, such as the IBM WebSphere Application Server Developer Tools for Eclipse, to develop SIP servlets using graphical deployment descriptor editors and basic wizards. The developer tools also include other features that integrate with Liberty deployments, such as tools for server automation and application packaging. For more information, see WebSphere Developer Tools > Developing > Developing SIP applications.

## Developing SIP applications that support PRACK on the Liberty

8.5.5.7

A SIP response to an INVITE request can be final or provisional. Final responses are always sent reliably, but provisional responses typically are not. For cases where you need to send a provisional response reliably, you can use the PRACK (Provisional response acknowledgment) method.

### Before you begin

To develop applications that support PRACK, the following criteria must be met:

- To indicate that the client supports PRACK, the client that sends the INVITE request must put a 100rel tag in the Supported or the Require header.
- The SIP servlet must respond by invoking the sendReliably() method instead of the send() method.

### About this task

PRACK is described in the following standards:

- RFC 3262 (“Reliability of Provisional Responses in the Session Initiation Protocol (SIP)”), which extends RFC 3261 (“SIP: Session Initiation Protocol”), adding PRACK and the option tag 100rel.
- Section 5.7.1 (“Reliable Provisional Responses”) of JSR 289 (“SIP Servlet Specification Version 1.1”).

### Procedure

- If you are developing an application that acts as a proxy, make your application generate and send a reliable provisional response for any INVITE request that has no tag in the To field.
- If you are developing an application that acts as a user agent client (UAC), perform the following actions:
  - Make your application add the 100rel tag to outgoing INVITE requests. The option tag must appear in either the Supported header or the Require header.
  - To create a PRACK request and send the request to the user agent server (UAS), invoke the createPrack() method on the incoming response within your application's doProvisionalResponse(...) method. The container handles the RAck header as defined in JSR 289 Section 5.7.1.
  - The application that acts as an UAC receives a final 2xx-6xx response on the PRACK, which the UAC can handle with a doResponse() method.
- If you are developing an application that acts as a user agent server (UAS), perform the following actions:
  -

**Note:** If an incoming INVITE request requires the 100rel tag, trying to send a 101-199 response unreliably by using the send() method causes an exception.

- In the application, declare a SipErrorListener object to receive noPrackReceived() events when a reliable provisional response is not acknowledged within 64\*T1 seconds, where T1 is a SIP timer. Within the noPrackReceived() event processing, the application generates and sends a 5xx error response for the associated INVITE request per JSR 116 Section 6.7.1.
- The application can have at most one outstanding, unacknowledged reliable provisional response. Trying to send another one before the first is acknowledged results in an exception.
- Make sure that the application enforces the RFC 3262 offer/answer semantics for PRACK requests containing session descriptions. Specifically, a servlet must not send a 2xx final response if any unacknowledged provisional responses contained a session description.

## Developing back-to-back (B2B) applications

8.5.5.7

You can use the javax.servlet.sip.B2buaHelper interface to develop a Back-to-Back User Agent (B2BUA) application.

### Before you begin

Read the JSR289 specification, section 12, which provides detailed information about the B2BUA operations. The SIP Servlet 1.1 specification defines a helper class, javax.servlet.sip.B2buaHelper, for creating B2BUA applications. For more information, see the documentation on the B2buaHelper methods.

### About this task

The B2BUA is a Session Initiation Protocol (SIP) application that sits in the middle of a SIP call, and forwards requests and responses between two or more SIP dialogs. A typical B2BUA application manages SIP sessions between two user agents. However, the B2BUA application can also handle more complex scenarios where it needs to manage responses from different branches of downstream forking. Downstream forking occurs when the request is split into different branches and the message is forwarded from the user agent client to the user agent server. The B2buaHelper class contains all the necessary methods for creating such B2BUA applications. The behavior of the B2buaHelper class and the rules that are used to create new requests are defined in the JSR289 specification, section 12.2. You can use the B2buaHelper class functions for linking two legs, the incoming call leg and the outgoing call leg, of the SIP back-to-back user agent call.

### Procedure

1. Retrieve the B2buaHelper instance by calling the SipServletRequest.getB2buaHelper() method.
2. After you retrieve this instance, you can create a new SIP request by calling B2buaHelper.createRequest().

```
private void doInvite(SipServletRequest req) {  
    B2buaHelper b2buaHelper = req.getB2buaHelper();  
    SipServletRequest newRequest = b2buaHelper.createRequest(req, true, headerMap);  
}
```

The newRequest that is created is identical to the SipServletRequest req that is provided as an original request in the first parameter of this method. The **Boolean** parameter indicates whether the original request req and the newRequest are linked. The headerMap provides a map of non-system headers to override in the newRequest.

3. Ensure that the two legs are linked. If you called the createRequest method with false attribute, you can link the SIP sessions explicitly by calling:  
B2buaHelper.linkSipSessions(session1, session2)
4. After the SIP sessions and SIP requests are linked, you can retrieve the linked session by calling:

```
SipSession linkedSession = B2buaHelper.getLinkedSession(req.getSession());
```

**Note:** In B2BUA forking scenario, the application creates more than one SIP request, so not all SIP sessions are linked. You must link them explicitly.

5. After you receive a response from the User Agent Server (UAS), create a response to its leg. Check to determine whether a linked session on the response exists and if it does, use the linked request to create a response to the User Agent Client (UAC).

```
SipServletRequest linked = b2bHelper.getLinkedSipServletRequest(resp.getRequest());  
linked.createResponse(resp.getStatus(), resp.getReasonPhrase()).send();
```

If there is no linked session that is associated with the response, the application needs to call `B2buaHelper.createResponseToOriginalRequest` and create a new derived session, which is a copy of the `SipSession` that is associated with the original request.

**Note:** The JSR289 specification, section 12.5 provides a way to create more than one successful response to the original request. If there is more than one `SipSession` that is associated with the original INVITE message and there is a need to send more than one successful response to the INVITE message, then use the `B2buaHelper.createResponseToOriginalRequest` method.

6. If you use the `createResponseToOriginalRequest` method, ensure that the two legs are linked. Your application is responsible for linking the new derived session to its pair session so it can retrieve the linked session for sending subsequent responses on it.

## Developing applications that use the Asynchronous Invocation API on the Liberty profile

8.5.5.7

You can use the Asynchronous Invocation API to transfer events that require processing in the context of a Session Initiation Protocol (SIP) application session to any server in a cluster based on the related application session ID. The Asynchronous Invocation API transfers the event task to the correct server.

### Before you begin

Read the API documentation for information on the following asynchronous work classes:

- `com.ibm.websphere.sip.AsynchronousWork`
- `com.ibm.websphere.sip.AsynchronousWorkListener`

### About this task

When running code outside of a SIP thread, application developers can use the Asynchronous Invocation API to create an object. They can then configure the server to run that object either on a different thread in the same container, or on a different server, if that is where the session exists.

The following example shows the class structure for the `AsynchronousWork` class, which is the abstract base class that is extended when you use the API.

```
public abstract class AsynchronousWork implements Serializable  
{  
    private String sessionId;  
    public AsynchronousWork(String sessionId)  
    {  
        this.sessionId = sessionId;  
        ....  
    }  
    public void dispatch (AsynchronousWorkListener listener)  
    {
```

```

.....
}
public abstract Serializable doAsyncTask();
}

```

## Procedure

1. Extend the abstract class `AsynchronousWork` with the SIP-related code. The extended implementation of the `doAsyncTask()` method is invoked on the target server that contains the `SipApplicationSession`, and whose ID was set in the constructor that implements the `AsynchronousWork` class. The implementation class must pass the session ID to the base class by calling `super` in the constructor.

```

public class MyClass extends AsynchronousWork
{
String _sessionId;

public MyClass(String sessionId) {
super(sessionId);
_sessionId = sessionId;
}

// This code is invoked on the target machine or thread
public Serializable doAsyncTask() {
// Application code goes here; for instance:
appSession = sessionUtils.getApplicationSession(_sessionId);
appSession.createRequest().....

Serializable myResponse = new MyResponse();
myResponse.setStatus(200);
return (myResponse);
}
}

```

2. To receive information about the task completion, implement the `AsynchronousWorkListener` class, as in the following example. The code in these methods is invoked on the source server.

```

public class MyListener implements AsynchronousWorkListener
{
public void workCompleted(Serializable myResponse)
{
.....
}
public void workFailed(int reasonCode, String reason)
{
}
}

```

3. Invoke the asynchronous call; for example, when you receive the proprietary message, use this sample code as an example.

```

public void onMyMessage()
{
// Obtain the session ID from the message or
// somewhere else
String sessionId = obtainIdFromMessage();

// Create the runnable
MyClass myClass = new MyClass(sessionId);

// Create the listener
MyListener myListener = new MyListener();

// Dispatch it
myClass.dispatch(myListener);
}

```

## Results

The SIP container ensures that the task is invoked in the correct server and on the correct thread, so that the application can avoid synchronization on the session level.

### Asynchronous Invocation API on Liberty

8.5.5.7

Use the Asynchronous Invocation API to transfer events that require processing in a Session Initiation Protocol (SIP) application session to any server in a cluster based on an application session ID.

The Asynchronous Invocation API, also referred to as the asynchronous work dispatcher, can transfer events that require processing in the context of a SIP application session to any server in a cluster, using the related application session ID. These transfers are usually triggered by events that cause a state change to SIP sessions on another server. The asynchronous work dispatcher transfers the event task to the correct server to be run.

On Liberty, all related SIP messages are delivered to the same server in the cluster, and sessions are always in the same SIP container. To prevent synchronicity issues and locking, tasks in the same application session cannot be processed simultaneously (that is, on different threads or processes), which limits handling of certain types of events.

For more in-depth information about SIP sessions and SIP application sessions, see Section 6 of Java Specification Request (JSR) 289.

The following two scenarios are resolved by implementing the Asynchronous Invocation API.

1. Two requests that are related to the same SIP application session are simultaneously run on two different threads.

For example, a Java Platform, Enterprise Edition. application that works with a message-driven bean (MDB) can retrieve an event to send a SIP message on a certain SIP application session. At the same time, the SIP container receives an incoming SIP message on another session that is connected to the same application session and handles that on a different thread. It is necessary to synchronize the session access to avoid race conditions and to ensure that all session attributes are synchronized. To employ the locking mechanism in this case would not be effective, because the SIP application session might contain multiple SIP sessions.

2. A server that does not own a certain SIP application session receives a request, through non-SIP protocol, to send a message in the context of that session.

For example, a web service that initiates SIP dialogs can be in a server different from the server that owns the SIP application session it must use.

The Asynchronous Invocation API ensures that the specific application code is run on the correct server and correct thread according to the SIP application session ID.

The Asynchronous Invocation API provides the following benefits:

1. No more than two servers are involved in the asynchronous invocation process: one is the server that retrieves the work task, and the other is the target server that handles the SIP application session for that task and to which the task is transferred.
2. The asynchronous invocation allows working in a thread-safe manner. This approach ensures that only one thread processes the messages that are related to the SIP application session, so you do not need to synchronize access to the session.
3. The asynchronous invocation provides a scalable solution so performance is not impacted when more servers are added to the cluster.
4. Cross-server invocation is used only when required, which results in better performance.

## Performing DNS lookups in Session Initiation Protocol (SIP) applications on the Liberty profile

8.5.5.7

Use the Domain Resolver API in your application to perform Domain Name System (DNS) lookups of SIP URIs using the RFC 3263 protocol. You can perform synchronous lookups to avoid having to preserve state, which is required for an asynchronous callback. Alternatively, you can perform asynchronous lookups if you need a better performing interface.

### Before you begin

In your `server.xml` file, install and configure the `sipServlet-1.1` feature with a `domainResolver` element. For more information, see “Administering Session Initiation Protocol (SIP) on Liberty” on page 1728.

### Procedure

1. Access the Domain Resolver API in your application.

- Get an attribute from the ServletContext method using `com.ibm.websphere.sip.resolver` as a key.  
`getServletContext().getAttribute("com.ibm.websphere.sip.resolver ")`

- Use resource injection.

```
@resource
DomainResolver resolver
```

2. Perform the URI lookup.

- To use the API synchronously, call the `locate(SIPURI)` method, which returns the result of the URI resolve request response.

```
DomainResolver
locate(SIPURI)
```

- To use the API asynchronously, call the `locate(SIPURI, Listener)` method, which signals the listener after it finishes. When the result is cached, the listener is triggered on the same caller thread.

```
DomainResolver
locate(SIPURI, Listener)
```

## Receiving unmatched messages in Session Initiation Protocol (SIP) on Liberty

8.5.5.7

Use the `UnmatchedMessageListener` API to receive incoming Session Initiation Protocol (SIP) request or response messages that the SIP container cannot process.

### Before you begin

In your `server.xml` file, install and configure the `sipServlet-1.1` feature. For more information, see “Administering Session Initiation Protocol (SIP) on Liberty” on page 1728.

### About this task

The SIP container provides an interface that enables an application to receive all incoming request or response messages that cannot be matched to any existing dialogs. Any request or response messages that are not matched to an existing dialog are known as unmatched messages.

An *unmatched request* is a request that has `To` and `From` tags, but the related dialog is not found in the SIP container because it was never created or this dialog is in the invalidated state. When an incoming unmatched request is received by the SIP container, the container responds with a `481 Call/Transaction Does Not Exist` response, and then forwards the incoming request to the listener class. The incoming

request is forwarded as part of the `UnmatchedRequestEvent` event, which is defined in the `com.ibm.websphere.sip.unmatchedMessages.events` package. The event contains an interface to get the incoming unmatched request and the `ServletContext` related to the application that receives the event. The application can use the `ServletContext` to create new SIP activity. The listener cannot create a response for the received unmatched request or proxy the request. When this condition occurs, an `IllegalStateException` exception occurs in the SIP container.

An *unmatched response* is a response that is received in the SIP container, but the response is not matched to any outgoing requests. Before the SIP container discards the unmatched response, the unmatched response is sent to the `UnmatchedMessageListener` listener as part of the `UnmatchedResponseEvent` event. Similar to the unmatched request, the application gets access to the unmatched response and to the related application `ServletContext`.

If an application has more than one defined `UnmatchedMessageListener` listener, each listener is started independent of each other. If you have more than one application on a single application server and multiple applications have `UnmatchedMessageListener` listeners, all listeners are started in a random order. If one application sends a request to another application on the same server as part of application composition, and the SIP container determines that this request is a request that cannot be handled by the SIP container, then all of the `UnmatchedMessageListener` listeners on that server are activated.

The `UnmatchedMessageListener` API is defined in the `com.ibm.websphere.appserver.api.sipServlet` file in the `com.ibm.websphere.sip.unmatchedMessages` package.

## Procedure

You can use one of the following methods in the application code to access the `UnmatchedMessageListener` API:

- Add the `UnmatchedMessageListener` implementation class explicitly as a listener deployment descriptor element in the `sip.xml` file.

```
<listener>
  <listener-class>com.example.MyTimerListener</listener-class>
</listener>
```

- Use the `@javax.servlet.sip.annotation.SipListener` annotation.

```
@SipListener
public class MySipUnmatchedMessagesListener
    implements UnmatchedMessageListener {
    ....
}
```

## SIP proprietary header fields on Liberty

8.5.5.7

You can create a Session Initiation Protocol (SIP) servlet request that includes proprietary header fields. SIP proprietary header fields enable certain SIP settings to be implemented on a per message basis. SIP settings set at the SIP container level apply to all SIP messages handled by that SIP container.

To include one or more proprietary header fields in a message, set up your SIP servlet request such that it includes one or more `SipServletMessage.setHeader(string_name, string_value)` methods. When the application calls `SipServletRequest.send()` to send the request, the message object that is passed to the SIP stack for transmission includes the propriety header information. The SIP stack then creates a client transaction to send out the request and adjusts the SIP configuration settings for this specific request based on any proprietary header fields that are included in the message object. The stack removes the proprietary header fields before the message is sent out to the network.

## Proprietary header fields used to specify timer values

The following proprietary header fields are available for specifying timer values for a specific message. The application can set multiple timer values in one message instance, but cannot specify multiple values for the same proprietary header field.

### IBM-TransactionTimeout

Use this header field to specify, in milliseconds, the length of the client transaction timeout. This header is equivalent to specifying a value for timer B in INVITE client transactions, and timer F in non-INVITE client transactions.

### IBM-RetransmissionInterval

Use this header field to specify, in milliseconds, the length of the request retransmission interval. This header is equivalent to specifying a value for timer A in INVITE client transactions, and timer E in non-INVITE client transactions.

### IBM-RetransmissionMaxInterval

Use this header field to specify, in milliseconds, the maximum retransmission interval. This header is equivalent to specifying a value for timer T2 in non-INVITE client transactions, and timer B in INVITE client transactions.

## SIP SipServletRequest and SipServletResponse classes on Liberty

8.5.5.7

The `SipServletRequest` and `SipServletResponse` classes are similar to the `HttpServletRequest` and `HttpServletResponse` classes that are used when you develop web applications.

Each class gives you the capability to access the headers in the SIP message and manipulate them. Because of the asynchronous nature of the requests and responses, the `SipServletRequest` class also creates new responses for the requests. When you extend the `doInvite` method, only the `SipServletRequest` class is passed to the method. To send a response to the client, you must call the `createResponse` method on the `Request` object to create a response as shown in the following example:

```
protected void doInvite(SipServletRequest req) throws
    javax.servlet.ServletException, java.io.IOException {

    //send back a provisional Trying response
    SipServletResponse resp = req.createResponse(100);
    resp.send();
}
```

Because of their asynchronous nature, SIP servlets can seem complicated; however, something as simple as the previous code sample sends a response to a client.

The following example shows a more complex SIP servlet. With the following method included in a SIP servlet, the servlet blocks all of the calls that do not come from the *example.com* domain.

```
protected void doInvite(SipServletRequest req) throws
    javax.servlet.ServletException, java.io.IOException {

    //check to make sure that the URI is a SIP URI
    if (req.getFrom().getURI().isSipURI()){
        SipURI uri = (SipURI)req.getFrom().getURI();
        if (!uri.getHost().equals("example.com")) {
            //send forbidden response for calls outside domain
            req.createResponse(SipServletResponse.SC_FORBIDDEN).send();
            return;
        }
    }
    //proxy all other requests on to their original destination
    req.getProxy().proxyTo(req.getRequestURI());
}
```

For more information on these classes, see the SIP Servlet Specification 1.1, JSR 289.

## SIP SipSession and SipApplicationSession classes on Liberty

8.5.5.7

Both the SipSession and SipApplicationSession classes can act as the primary place to store data in applications that are designed for distributed or highly available environments.

The SipSession class is the best representative of a specific point-to-point communication between two entities and is the closest to the HttpSession object. Because historically no proxying or forking existed for the HTTP request in HTTP servlets, the need for something higher than a single point-to-point session did not exist. The SIP users expect the proxying and forking activities that require multiple layers of SIP session management. The SipSession class is the lowest point-to-point layer.

The SipApplicationSession class represents the higher layer of SIP session management. One SipApplicationSession class can own one or more SipSession objects. However, each SipSession class can be related to one SipSession object only. The SipApplicationSession class also supports the attachment of any number of other protocol sessions. Currently, only HTTP sessions are supported by any implementations. The SipApplicationSession class has a getSession method, which takes the requested protocol type as an argument.

In many applications, it can be useful to combine HTTP and SIP. For example, you might use this approach to tie together HTTP and SIP sessions to monitor a phone call or to start a phone call through a rich HTTP graphical user interface.

For more information on these classes, see the SIP Servlet Specification 1.1, JSR 289.

---

## Developing OSGi applications in Liberty

8.5.5.5

8.5.5.7

### About this task

This section includes the OSGi application features that are specific to Liberty. Currently a WebSocket application can be deployed in an OSGi Web Application Bundle on Liberty. For more information on creating an application in an OSGi application on WebSphere Application Server traditional, see [http://www-01.ibm.com/support/knowledgecenter/SSEQTP\\_8.5.5/com.ibm.websphere.wdt.doc/topics/tcrtbundleprj.htm?lang=en](http://www-01.ibm.com/support/knowledgecenter/SSEQTP_8.5.5/com.ibm.websphere.wdt.doc/topics/tcrtbundleprj.htm?lang=en).

For information about developing OSGi applications by using WebSphere Developer Tools, see Developing OSGi applications.

## Enable OSGi Applications with Java EE 7 technologies

8.5.5.6

You can enable OSGi Applications with key Java Platform, Enterprise Edition (Java EE) 7 technologies. WebSphere Application Server Liberty Version 8.5.5.6 and later, is a production ready server certified for Java EE 7 Full Platform.

To achieve zero migrations, new features are created and existing features remain unaltered. For example, when support for servlet 3.1 was added, a servlet-3.1 feature was created, and servlet-3.0 was kept to ensure behavior did not change for an existing server deployment.

In an environment before Java EE 7 support, you were required to configure `blueprint-1.0`, or something that depends on it, to be able to deploy OSGi applications. You then either configured other OSGi-specific features, like `wab-1.0`, or generic ones, like `jpa-2.0`, to get other capabilities.

In a Java EE 7 environment, OSGi configuration is in two steps:

1. Decide you want to deploy OSGi Bundles.
2. Decide what technologies you want to use to implement those OSGi Bundles.

## Telling the server you want to deploy OSGi Bundles

The first step is to add the `osgiBundle-1.0` feature to your `server.xml`:

```
<featureManager>
  <feature>osgiBundle-1.0</feature>
</featureManager>
```

Adding the `osgiBundle-1.0` feature enables OSGi Bundles to be deployed as part of an OSGi application.

## Telling the server what component models you want to use

Rather than having OSGi-specific features, like `wab-1.0`, you now configure the same component models you would for Java EE. This configuration enables the use of servlets in Bundles, for example, Web Application Bundles or Http Whiteboard servlets:

```
<featureManager>
  <feature>osgiBundle-1.0</feature>
  <feature>servlet-3.1</feature>
</featureManager>
```

For more information, see [OSGi Web Application Bundles](#), and [OSGi Http Whiteboard](#).

This server configuration adds the ability to use `jpa-2.1` in a Persistence Bundle:

```
<featureManager>
  <feature>osgiBundle-1.0</feature>
  <feature>servlet-3.1</feature>
  <feature>jpa-2.1</feature>
</featureManager>
```

For more information, see [Accessing data using Java Persistence API](#).

Optionally, you can still include `blueprint-1.0`:

```
<featureManager>
  <feature>osgiBundle-1.0</feature>
  <feature>servlet-3.1</feature>
  <feature>jpa-2.1</feature>
  <feature>blueprint-1.0</feature>
</featureManager>
```

## Which Java EE 7 component models are supported?

You can see the full list of Java EE 7 technologies that are enabled for OSGi applications.

## Enabling integration of OSGi application services

8.5.5.5

Using the `osgiAppIntegration-1.0` feature, the OSGi applications that are available within the same Java virtual machine (JVM) can share their services with each other. To enable communication between the OSGi applications, you must declare the appropriate service headers in the application manifest file,

META-INF/APPLICATION.MF. An application that wants to import services from other applications must include the `Application-ImportService` header, and an application that wants to export services to other applications must include the `Application-ExportService` header. If an application wants to export and import services, then both headers must be used.

## About this task

To enable the `osgiAppIntegration-1.0` feature, you must include the feature in the `server.xml` file. To use the feature, you need to use the appropriate headers, such as the `Application-ImportService` and `Application-ExportService`. For more information, see `Application manifest files`. You must add the `binding:=local` directive in the headers to specify the integration of applications that are within the same JVM. The binding directive is specific only to the `osgiAppIntegration-1.0` Liberty feature.

## Procedure

1. Based on your requirement, add one or both application headers to your `MANIFEST.MF` file as given in the following example:

```
Application-ExportService: com.acme.Foo;binding:=local
Application-ImportService: com.acme.Foo;binding:=local
```

where `com.acme.Foo` is the name of the Java interface or class associated with the OSGi service.

**Note:** You must add the `binding:=local` directive along with the application import and export service headers to allow the applications within the same JVM to communicate with each other.

2. Add the feature in the `server.xml` file.  

```
<feature>osgiAppIntegration-1.0</feature>
```

## Custom blueprint namespace handlers

8.5.5.4

The Blueprint Container specification, introduced in the OSGi Enterprise Specification Release 5, provides a simple and easy programming model for creating dynamic applications in the OSGi environment without adding complexity to the Java code.

For more information about the OSGi Enterprise Release specification, see [OSGi specification download](#).

The Blueprint Container specification defines a Dependency injection framework for OSGi. It is designed to handle the dynamic nature of OSGi, where services can become available and unavailable at any time. The specification is also designed to work with plain old Java objects (POJOs) so that the same objects can be used within and outside the OSGi framework. The Blueprint XML files that define and describe the various components of an application are key to the Blueprint programming model. The specification describes how the components get instantiated and wired together to form a running application. For more information, see [OSGi Blueprint Container Specification](#).

Each blueprint bundle must contain a blueprint XML file in order for the blueprint runtime to process the blueprint component of the bundle. The standard blueprint element is defined by the OSGi blueprint specification, and required in every blueprint xml document. It sets the default document namespace to `http://www.osgi.org/xmlns/blueprint/v1.0.0`, for example:

```
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0">
```

Other namespaces can be added to the blueprint by using standard XML rules, either as prefixed entries, or directly within the custom XML elements. These namespaces can be added either at the top level or they can be inline with the custom XML elements. If it is valid XML, it is parsed correctly. For example, defined in the top-level blueprint element:

```
<blueprint
  xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
  xmlns:tx="http://aries.apache.org/xmlns/transactions/v1.0.0">
```

For example, inline in a custom element:

```
<transaction method="*" value="Required"
  xmlns:tx="http://aries.apache.org/xmlns/transactions/v1.0.0"/>
```

The Blueprint runtime implementation that is provided by Apache Aries project is used to support Blueprint bundles that are contained in OSGi Applications for Liberty. For more information, see Apache Aries. The Aries Blueprint runtime provides an extension mechanism called namespace handlers. A namespace handler provides a processor for custom blueprint extensions or namespaces. A namespace handler implements the `org.apache.aries.blueprint.NamespaceHandler` interface and must be registered in the OSGi service registry with an associated `osgi.service.blueprint.namespace` service property. This property denotes the namespace URIs this handler can process. For example: `http://aries.apache.org/xmlns/transactions/v1.0.0`. The service property value can either be a single String or URI, or a Collection, or an array of String or URI.

The blueprint runtime parses the blueprint descriptors twice. The first pass is fast, and finds only every namespace that is used by the blueprint bundle. If the blueprint bundle uses a non-standard namespace, then the blueprint container attempts to locate `NamespaceHandler` services in the OSGi service registry for each custom namespace. A `NamespaceHandler` service advertises every xml namespace that it can process by using OSGi service properties. The blueprint runtime does not parse the blueprint xml until `NamespaceHandler` services can be found for every custom namespace that is used in the bundle. Unless `NamespaceHandler` services can be found for every custom namespace, the blueprint container is unable to process the bundle. This result can mean that the blueprint container waits indefinitely if no `NamespaceHandler` exists. If this situation is encountered, then the blueprint container issues a warning to the log. When the blueprint parser begins to parse the blueprint xml files, it parses any standard blueprint elements. When the parser reaches a custom element, the parser calls out to the `NamespaceHandler` that advertised support for the namespace of the custom element. Here, the `NamespaceHandler` has the opportunity to process the information in the custom element, modify the runtime blueprint model, or do any other operation. If there is a typing error in any of the namespace definitions, then the blueprint almost certainly fails to start.

A custom `NamespaceHandler` service can be provided by any bundle that is running in Liberty, including Liberty Feature bundles , and OSGi Applications bundles.

---

## Developing WebSocket applications in Liberty

You can configure Liberty to use the WebSocket protocol to enable applications to communicate by using a full duplex connection.

### About this task

To configure a Liberty server to run an application that is enabled for WebSocket 1.0, you must set the `websocket-1.0` feature for WebSocket 1.0 or the `websocket-1.1` feature for WebSocket 1.1.

**Note:** 8.5.5.7

In addition to the WebSocket API which is defined in JSR 356 (Java API for WebSocket version 1.1), an API was added to the WebSphere implementation which allows a servlet or filter to request that the current HTTP Request be "upgraded" to start a WebSocket session. This new API is documented here:

Interface `WsWsocServerContainer`

WebSocket endpoints can make use of templates to match an endpoint to a URI. URIs that should not map to websocket endpoints, even though they match a websocket template, can also be used by a web application. The distinction between mapping a websocket endpoint to a URI or allowing the URI to be treated as a "non-websocket" HTTP Request, is made by the presence or absence of an "Upgrade" header with a value of "websocket" in the HTTP Request.

For information about developing WebSocket applications by using WebSphere Developer Tools, see [Developing WebSocket applications](#).

## WebSocket

8.5.5.4

WebSocket is a standard protocol that enables a web browser or client application and a web server application to communicate by using one full duplex connection.

HTTP was not designed for long-lived, real-time, full duplex communication between two applications. In many instances, a user's web server application or servlet wants to communicate with a client browser or application in a long-lived, real-time, full duplex conversation. In other words, the two applications want to freely read and write data back and forth. An example of this type of application is one that constantly displays changing currency exchange rates on the web browser of a stock trader. Current solutions that involve existing HTTP technology to accomplish this type of communication are cumbersome and inefficient. HTTP solutions, for constant two-way communication between a browser and a server, mostly consists of either polling or two open HTTP connections that handle one-way traffic only, or both.

WebSocket uses a standard HTTP request-response sequence to establish a connection. When the connection is established, the WebSocket API provides a read and write interface for reading and writing data over the established connection in an asynchronous full duplex manner. WebSocket also provides an interface for asynchronously closing the connection from either side.

Because WebSocket uses a standard HTTP request-response sequence to establish a connection, the connection initiation connects through firewalls and proxies in the same manner as an HTTP connection. WebSocket requires full duplex communication, including simultaneous reads and writes on the same connection. Version 8.5.5.3 and later of the WebSphere web server plug-in support full duplex communication, but other firewalls and proxies might require modification to enable this support. WebSocket can also use SSL for secure connections and transmission of data. This protocol uses SSL in the same way that the HTTP protocol uses SSL.

The Liberty WebSocket feature implements the following specifications:

- The WebSocket Protocol - RFC 6455
- Java API for WebSocket - JSR 356

8.5.5.5

Liberty supports the WebSocket 1.0 and WebSocket 1.1 specifications. Compared to WebSocket 1.0, WebSocket 1.1 supports a more robust way of specifying message handlers.

You can download sample programs that implement the WebSocket protocol from [WASdev.net](#). For a walkthrough of using WebSocket on Liberty, see [WebSocket sample application on WASdev.net](#).

---

## Chapter 10. Deploying applications in Liberty

You can deploy web applications, enterprise applications, and OSGi applications in Liberty. You deploy an application by either dropping the application into a previously-defined dropins directory, or by adding an application entry to the server configuration.

### Before you begin

**Distributed operating systems** You can deploy applications as described in this topic, or as described in “Adding and running an application on Liberty by using developer tools” on page 2141.

This topic assumes that you have not disabled dynamic updates to the runtime configuration, as described in “Controlling dynamic updates” on page 1594.

### About this task

By default, the “dropins” directory is automatically monitored. If you drop an application into this directory, the application is automatically deployed on the server. Similarly, if the application is deleted from the directory, the application is automatically removed from the server. The “dropins” directory can be used for applications that do not require additional configuration, such as security role mapping. If you put your applications in the “dropins” directory, you must not include an entry for the application in the server configuration. Otherwise, the server will try to load the application twice and an error might occur. For applications that are not in the “dropins” directory, you specify the location using an application entry in the server configuration. The location can be on the file system or at a URL.

Your application can be packaged as an archive file, a directory, [8.5.5.4](#) or as a loose application where files are in multiple locations. For more information about loose applications, see “Loose applications” on page 2255.

For applications in the “dropins” directory, the file name and file extension are used by the application monitor to determine the type of application, and to generate the application id and application name. For example, if the archive file or directory is named snoop.war, the application monitor assumes that the application is a web application and that the application id and application name is “snoop”. For configured applications, the application type and name are specified.

For more information about the default directory structure and the properties that are associated with directories (for example `server.config.dir`), see “Liberty:Directory locations and properties” on page 1434.

**Note:** Restrictions apply when using the “dropins” directory in a production environment. See “Versioning is not possible for applications in the “dropins” directory” on page 2336.

### Procedure

- Deploy an application by dropping it into the dropins directory.

For example, using the default directory structure, to deploy an application you drop it into the `${server.config.dir}/dropins` directory (that is, `wlp/usr/servers/server_name/dropins`).

You can deploy your application in any of the following ways:

- Place the archive file with its identifying suffix (`.ear`, `.war`, and so on) directly into the `/dropins` directory. For example, `${server.config.dir}/dropins/myApp.war`
- Extract the archive file into a directory named with the application name and the identifying suffix. For example, `${server.config.dir}/dropins/myApp.war/WEB-INF/...`

- Place the archive file or the extracted archive into a subdirectory named with the identifying suffix. For example, `${server.config.dir}/dropins/war/myApp/WEB-INF/...`
- Deploy an application by adding it to the server configuration file.

Configure the application element in the `server.xml` configuration file. See . You must configure the following attributes for the application:

**id** Must be unique and is used internally by the server.

**name** Must be unique and depending on the application. The value of **name** might be used as the context-root of the application. For more information on how the context-root is set for an application, see “Deploying a web application to Liberty” on page 2155.

**type** Specifies the type of application.

- For web applications, the supported type is **war**.
- For enterprise applications, the supported type is **ear**.

**location**

Specifies the location of the application. It can be an absolute path or a URL which you can download the application from. It can also be the file name of your application (including file extension if any).

If the application is available on the file system, the location can either be the full path name or a simple file name. If the location does not include the full path, the application manager looks for the application in `${server.config.dir}/apps` and `${shared.app.dir}`. If the application is available at a URL, the application manager downloads the application to a temporary folder inside the server work area, then starts the application.

**Note:** The location that you specify for a configured application should not be in the “dropins” directory. If you drop an application into the “dropins” directory, and also specify the location in the `server.xml` file, you are telling the server to deploy the application twice.

In the following two examples, the location is the file system. If the location is a URL, enter the URL in the location field.

```
<osgiApplication location="D:/apps/ImpactEBA.eba"/>
<webApplication location="ImpactWeb.war"/>
```

The second example does not include the full path. In this case, you must put the application in one of the following locations:

- `${server.config.dir}/apps` (that is, *server\_directory/user/servers/server\_name/apps*)
- `${shared.app.dir}` (that is, *liberty\_install\_location/usr/shared/apps*)

You can deploy your application to the file system in either of the following ways:

- Place the archive file with its identifying suffix (`.ear`, `.war`, and so on) directly into the chosen location. For example, *application\_directory\_path/myApp.war*
- Extract the archive file into a subdirectory of the chosen location, named with the application name and the identifying suffix. For example, *application\_directory\_path/myApp.war/WEB-INF/...*

**Note:**

- You must create the server-level apps directory, whereas the shared apps directory is present by default. See “Liberty:Directory locations and properties” on page 1434 for more information about the properties associated with the server directories.
- The **application** element can be set before or after the server has started. If the element is set after the server has started, the changes are picked up dynamically.

-  **8.5.5.6** Deploying Contexts and Dependency (CDI) applications in Liberty

A Liberty server can be used to deploy CDI applications by configuring the server for the CDI 1.2 Liberty feature. See “Configuring Liberty for Contexts and Dependency Injection 1.2” on page 1725 for more information.

Applications that use contexts and dependency injection must have CDI enabled. For the CDI 1.2 Liberty feature, CDI is enabled if either:

- There is a `beans.xml` file with a bean discovery mode of `all`.
- There is no `beans.xml` file or a blank `beans.xml` file and classes with bean defining annotations. In this case, there must be a bean deployment archive.

For more information on the different types of bean deployment archive recognized by the CDI 1.2 feature, see “Contexts and Dependency Injection 1.2 behavior changes” on page 1726.

- Remove an application.

For applications that are included in the server configuration, remove the reference to the application from the `server.xml` file. The application is then automatically removed from the server.

For applications that are deployed to the “dropins” directory, delete the application from the directory. The application is then automatically removed from the server.

To uninstall all applications that are in the “dropins” directory, set the application monitor `dropinsEnabled` property to `false` as described in “Controlling dynamic updates” on page 1594.

## What to do next

For all deployed applications, you can configure whether application monitoring is enabled and how often to check for updates to applications. For the “dropins” directory, you can also configure the name and location of the directory and choose whether to deploy the applications that are in the directory. See “Controlling dynamic updates” on page 1594.

---

## Adding and running an application on Liberty by using developer tools

### Distributed operating systems

You can add applications to the server by right-clicking on the server in the Servers view then selecting Add and Remove from the menu.

### Before you begin

This task assumes that your application is in your Eclipse workspace. If you have a prebuilt application archive file that you want to add and run, you must first import the file into your Eclipse workspace. Alternatively, you can use the steps described in Chapter 10, “Deploying applications in Liberty,” on page 2139.

### About this task

When you add an application to the server, the workbench tries to determine which features are required by the application and enables them in the server configuration for you if they are not already enabled.

### Procedure

1. In the Servers view, right-click the server and select **Add and Remove**.
2. In the **Add and Remove** wizard, under the **Available** list, select the applications you want to add then click **Add**. Or click **Add All** to add all available applications to the server.
3. Alternatively, you can right-click on an application in the **Project Explorer** view and select **Run As > Run on Server**, or **Debug As > Debug on Server**. This adds the application to the server (if not already added), starts the server (if not already started) and runs the application.

## Results

**Tip:** If you are using **Run on Server** or **Debug on Server** and the server is already started, the browser might try to load the application before the server has finished loading it. If this happens, wait for the message in the console view that displays the application has been started and then refresh the browser if necessary.

## Publishing your application by using developer tools

### Distributed operating systems

Publishing involves copying files (projects, resource files, and server configurations) to the correct location for the server to find and use them. You can either publish your application automatically or manually.

### About this task

If you choose to publish your application automatically, the publishing frequency is controlled by a configurable publishing interval. If you do not want to wait for the automatic publishing interval to pass, or the **Never publish automatically** option is enabled, at anytime you can manually request the workbench to issue a publish command to the server. Each manual publish command causes a single publishing request to the server.

### Procedure

- To publish your application to a server automatically, complete the following steps:
  1. Open the Server preferences page by clicking **Window > Preferences > Server > Launching**, and select the **Automatically publish when starting servers** check box. The workbench checks to see if your project and files on the server are synchronized. If they are not, the project and the files are automatically updated when the server is either started or restarted.
  2. (optional) Modify the Publishing settings. To modify the Publishing settings, right-click the server in the Servers view and select **Open**. In the Overview page of the server editor, under the Publishing settings, you will find the following settings:
    - **Never publish automatically:** Specifies the workbench should never publish files to the server.
    - **Automatically publish when resources change:** Specifies the workbench to issue a publish after changes on a file that is associated with the server are saved and a full time interval has passed in the **Publishing interval** setting. In the workbench, the default setting is the **Automatically publish when resources change** option is enabled with a value set in the publishing interval.
    - **Automatically publish after a build event:** Specifies the workbench to issue a publish after changes on a file that requires a build and is associated with the server are saved, and a full time interval has passed in the **Publishing interval** setting.
    - **Publishing interval (in seconds):** Specifies the number of seconds required before the workbench calls a publish to happen on the server. However, if you make a subsequent change to the files before this time interval has completed, the publish is delayed as the timer is reset. The workbench makes a publish to the server only after the full time interval has passed. If you set the publishing interval to 0 seconds, an immediate publish should happen after changes on a file are saved.
- To publish your application to a server manually, complete the following steps:
  1. Select the server and then click the **Publish to the server** icon located on the toolbar.
  2. Right-click the server and then select **Publish**.

## Publishing settings for a WebSphere Application Server Liberty

*Publishing* involves copying files such as application, resource files, and deployment descriptor files to the correct location for the server to find and use them. You can choose whether you want to publish your application on the server or run your application within the development environment without copying the application into the directories of the server.

### About this task

#### Run applications directly from the workspace

The **Run applications directly from the workspace** publishing option requests the server to run your application from the workspace.

This publishing option publishes faster when an application contains a single root, as opposed to containing multiple roots. The workbench might require additional processing time to publish an application with multiple roots. To determine whether the structure of your application contains a single or multiple roots, use the Project Structure Validator. For details, see *Creating and configuring Java EE projects using wizards*.

#### CAUTION:

**When you are using the Run applications directly from the workspace publishing option, the server can lose track of your application under the following scenarios:**

- If you delete your workspace, the server can no longer find your application. As a result, if you did not put your application under source control management and the workspace is deleted, you can lose your application from your file system.
- If you delete an application from the workspace without removing it from the server, the server can no longer find your application. As a result, you might encounter errors when starting the server because the server tries to start the missing application from the workspace.

### Procedure

1. In the Servers view, double-click your WebSphere Application Server Liberty server to open the server editor.
2. In Liberty Settings, configure publishing settings by choosing any or none of the following options:
  - You can select **Run applications directly from the workspace**.  
This option is selected by default.
  -  You can select **Allow publishing of applications containing errors**.  
If you do not select this option, then when you attempt to publish an application that contains errors, you receive a warning. You can choose to cancel publishing and fix your errors, or you can choose to publish your application without correcting the errors. If you select this option, then you do not receive a warning when you attempt to publish an application that contains errors.
3. Save and close the editor.

## Restart requirements for a modified application on Liberty

When you change an application on Liberty, whether an application or server restart is required depends on whether the Liberty server is started in run mode or debug mode.

### Modifying an application when the server is started in debug mode

In debug mode, some changes require an application restart. For details of which changes require an application restart, use the IBM Rational Application Developer documentation, and see the “Hot Method Replace” section in WebSphere Application Server debug limitations.

If an application restart is required, a Hot Code Replace Failed dialog box is displayed, giving you an option to restart the application. If you click **Yes**, the application is restarted automatically; if you click **No**, you must restart the application manually.

For details on how to start the server in debug mode, use the IBM Rational Application Developer documentation, and see [Debug on server](#).

## Modifying an application when the server is started in run mode

In run mode, most changes require an application restart. If an application restart is required, the application is restarted automatically as part of the application publish operation from the developer tools. Some changes require a server restart.

---

## Customizing automatic feature detection

Control which features are added to each project and resolve feature conflicts.

### About this task

Automatic feature detection selects and enables features that an application needs. However, the automatic process can lead to conflicts among features. Customize automatic feature detection to fit your preferences and resolve conflicts.

### Procedure

1. Right-click the project and select **Properties**.
2. Expand **Liberty** and select **Required Features**.
3. Set the action for each feature to **Always add**, **Prompt before adding**, or **Never add**. **Always add** is the default. See [Disabling automatic feature detection](#) to set the default for all projects or to disable automatic feature detection.
4. Resolve or ignore feature conflicts by using the Feature Conflict dialog box.
  - a. The Feature Conflict dialog box appears when features conflict. New features are marked with **new**.
  - b. Click **Add...** to add a feature, or select a feature and click **Remove** to remove it.
  - c. Click **OK** after you resolve the conflicts.

**Note:** Click **Ignore** to avoid conflict resolution. If conflicts are ignored, the server might not work as expected.

---

## Packaging a Liberty server from the command line

From the command line, you can create a compressed file that contains a Liberty runtime environment, the files in the shared resources directory, a specific server, and the applications that are embedded in the server. You can also choose to exclude the runtime binary files from the compressed file.

### About this task

The Liberty server is lightweight, and therefore you can easily package a server installation in a compressed file. You can store this package, distribute it to colleagues, and then use it to deploy the installation to a different location or to another machine, or even embed the installation in a product distribution.

The server installation that you want to package cannot already be joined to a collective. You can only package a stand-alone server.

**Note:** **Distributed operating systems** The resulting file is created by using UTF-8 encoding for entry names, so the tool that you use to open the file must be able to use UTF-8 encoding for entry names. The `jar` command in a Java SDK uses this format.

## Procedure

To package a Liberty server from the command line, complete the following steps:

1. Open a command line, then change directory to the `wlp/bin` directory.
2. Stop the server.
3. Run the **package** command to create a package.

**8.5.5.5** You can package the Liberty profile server or the runtime.

- Package the Liberty server.

The default archive format is `.zip` on all platforms apart from z/OS where it is `.pax`. You can also generate a `.jar` archive.

If you do not specify a server name, `defaultServer` is used. If you do not specify the **--archive** parameter, the value of `server_name` is used for `package_file_name`, and the compressed file is created in the `${server.output.dir}` directory.

Choose the correct command for your environment.

**Distributed operating systems**

IBM i

Use this command to generate a `.zip` archive.

```
server package server_name --archive=package_file_name.zip --include=all
```

where `package_file_name.zip` is a file name that you choose. This file name can include a full path name. If the full path is omitted, a compressed file called `package_file_name.zip` is created in the `${server.output.dir}` directory.

**Distributed operating systems**

IBM i

Use this command to generate a `.jar` archive. The advantage of a `.jar` archive is that the scripts in the `bin` directory keep their permissions, so they are executable when the package is installed.

```
server package server_name --archive=package_file_name.jar --include=all
```

where `package_file_name.jar` is a file name that you choose.

For more information about extraction options with this archive file, see “Java archive file extraction options” on page 1376.

**z/OS**

Use this command to generate a `.pax` archive.

```
server package server_name --archive=package_file_name.pax --include=all
```

where `package_file_name.pax` is a file name that you choose. This file name can also include a full path. If the full path is omitted, a compressed file called `package_file_name.pax` is created in the `${server.output.dir}` directory.

The pax archive format saves the extended attributes that are required for the Liberty to work as designed in all supported scenarios. If a compressed file in ZIP format is required, specify the target archive name and include the `.zip` extension. If the specified name ends with `.zip`, then a compressed file in ZIP format is generated, instead of the z/OS default PAX format.

An archive format of `.jar` is not valid on z/OS.

You can also use the **--include** option with this command. For example, the `--include=all` option packages the runtime binaries and the relevant files in the `${WLP_USER_DIR}` directory; the `--include=usr` option packages only relevant files in the `${WLP_USER_DIR}` directory, effectively excluding the runtime binaries from the compressed file.

The `--include=usr` option is not valid with an archive format of `.jar`.

#### 8.5.5.0

If you use the `--include=minify` option, the **server** command packages only those parts of the runtime environment, and files in the `${WLP_USER_DIR}` directory, that are required to run the server. This option significantly reduces the size of the resulting archive.

The parts of the runtime environment that are retained by the `minify` operation depend on the features that are configured in the server that you are packaging. Only those features that are required to run the server are retained, and the remaining features are removed. Therefore, you cannot later enable a feature that has been removed. For example, if only the `servlet-3.0` feature is retained, you cannot later enable the `jpa-2.0` feature.

You can repeat the `minify` operation to further reduce the size of the archive if the configuration is changed. There is, however, no reverse operation for the `minify` operation, so if you later require one or more features that have been removed, you must begin again with a complete Liberty server.

While the `minify` operation is running, the server is temporarily started, and you see the associated messages. For this reason, you cannot use the `--include=minify` option with a server that is not able to be started, but you can package it with the `--include=all` or `--include=usr` options.

You can specify the operating systems that you want the packaged server to support by using the `--os` option with the `--include=minify` option.

For example, to package a server with `z/OS` support removed, use the following command:

```
server package --archive="nozoz.zip" --include=minify --os=-z/OS
```

To package a server with `OS/400` support retained, but `z/OS` support removed, use the following command:

```
server package --archive="small.zip" --include=minify --os=OS/400,-z/OS
```

To package a server that supports only Linux, use the following command:

```
server package --archive="linux.zip" --include=minify --os=Linux
```

**Note:** `z/OS` To unpackage a file on `z/OS`, go to the location where you want to unpackage the file and then run the following command. The `-ppx` option is used to preserve the extended attributes.

```
pax -ppx -rf location filename.pax
```

Where *location* is the path where the file exists and *filename.pax* is the name of the file.

- **8.5.5.5** Package the Liberty runtime.

Create a runtime archive that contains the `wlp` directory, but does not contain the `usr` directory. The naming convention for a server package is *package\_name.zip*; for example, `CustomerPortalApp.zip`. To create a runtime archive, run the **package** command without a server name and with the `--include=wlp` option:

```
server package --include=wlp
```

To specify a package file name and target location, add the `--archive=package_path_name` option; for example:

```
server package --include=wlp --archive=c:\temp\myPackage.zip
```

If you do not specify a valid package name or target location with the `--archive` option, then the command creates the `wlp.zip` runtime archive in the `$WLP_OUTPUT_DIR` location, which is the `${wlp.install.dir}/usr/servers` directory by default. The target location must exist before running the command. Thus, if the target location is `c:\temp`, the `C:\temp` directory must exist and have write permission for the command to write the archive to the `C:\temp` directory.

---

## Using JNDI binding for constants from the server configuration files

You can bind constants into the default Java Naming and Directory Interface (JNDI) namespace from the server configuration files by using the `<jndiEntry>` element on Liberty.

## About this task

The default JNDI namespace is available in the Liberty profile to provide bindings to miscellaneous objects required by applications. Any data sources declared in the server configuration files are available in the default JNDI namespace. Additionally, you can bind Java strings and primitive data types in the configuration file into JNDI namespace. These constants are then made available to an application at run time, providing a simple and portable way to pass configuration values into the application.

For more information about the JNDI naming, see Naming.

## Procedure

1. Add a constant into the default JNDI namespace by specifying the `jndi-1.0` Liberty feature in the `server.xml` file of the Liberty server.

```
<featureManager>
  <feature>jndi-1.0</feature>
</featureManager>
```

2. Bind constants into the JNDI namespace by specifying the `<jndiEntry>` elements with **jndiName** and **value** attributes in the `server.xml` file.

```
<jndiEntry jndiName="schoolOfAthens/defaultAdminUserName" value="plato" />
<jndiEntry jndiName="schoolOfAthens/defaultAdminPassword" value="republic" />
```

If you want to bind an instance of `java.net.URL` into the JNDI namespace, use the `jndiURLEntry` configuration:

```
<jndiURLEntry jndiName="urls/IBMKnowledgeCenter" value="http://www-01.ibm.com/support/knowledgecenter/" />
<jndiURLEntry jndiName="urls/WASDevNet" value="http://wasdev.net" />
```

3. Look up the constants from an application by using a JNDI context with the following code:

```
Object jndiConstant = new InitialContext().lookup("schoolOfAthens/defaultAdminUserName");
String defaultAdmin = (String) jndiConstant;
```

### Note:

- The `lookup()` method returns an object to the application. The type of the object is determined by interpreting the value stored in the `jndiEntry` element as a Java literal string or primitive data type. If the parsing fails, the exact value is provided as an unmodified string.
- The `jndiEntry` element supports the integer, floating-point, boolean, character, and string literals as described in Java Language Specification, Java SE 7 Edition, section 3.10. String and character literals might contain unicode escaped sequences (see section 3.3: Unicode Escaped Sequences), and the octal and character escape sequences (see section 3.10.6: Escape Sequences for Character and String Literals). Null literals and class literals are not supported; for more information see section 3.10.7: The null literal and section 15.8.2: Class Literals.

See the following examples of Java literals:

- The string "Hello, world" followed by a newline character:

```
<jndiEntry jndiName="a" value="'Hello, world.\n'" />
```

- The integer with a binary value 1010101:

```
<jndiEntry jndiName="b" value="0b1010101" />
```

- The single character 'X':

```
<jndiEntry jndiName="c" value="'X'" />
```

- The double-precision floating point number 1.0:

```
<jndiEntry jndiName="d" value="1.0D" />
```

For more information about `<jndiEntry>` element, see .

---

## Using JNDI binding for dynamic values from the server configuration files

8.5.5.4

You can bind a reference for dynamic values into the default Java Naming and Directory Interface (JNDI) namespace from the server configuration files by using the `jndiReferenceEntry` element on the Liberty profile.

### About this task

The default JNDI namespace is available in Liberty to provide bindings to miscellaneous objects that are required by applications. Based on the features that are enabled in your server, you can bind a predetermined set of objects to the default JNDI namespace. Additionally, you can bind a reference to an object factory, which dynamically determines the value that it returns. You can also use this object factory to return custom object types to an application.

For more information about the JNDI naming, see [Naming](#).

### Procedure

1. Add the `jndi-1.0` Liberty feature to the `server.xml` file.

```
<featureManager>
  <feature>jndi-1.0</feature>
</featureManager>
```

2. Create an `ObjectFactory` class that returns a programmatically defined value.

```
import javax.naming.spi.ObjectFactory;

public class MyObjectFactory implements ObjectFactory {
    @Override
    public Object getObjectInstance(Object o, Name n, Context c, Hashtable<?, ?> envmt) throws Exception {
        Properties p = new Properties();
        p.put("abc", 123);
        return p;
    }
}
```

3. Include the `ObjectFactory` in a `library` element in the `server.xml` file:

```
<library id="objectFactoryLib">
  <fileset dir="${server.config.dir}/lib" includes="factory.jar"/>
</library>
```

4. Declare the factory in a `jndiObjectFactory` element in the `server.xml` file and reference the previously declared library.

```
<jndiObjectFactory id="objectFactory" libraryRef="objectFactoryLib"
  className="com.ibm.example.factory.MyObjectFactory"/>
```

You can also declare the type of object that the factory returns. The type is returned by the `javax.naming.Context.list()` method.

```
<jndiObjectFactory id="objectFactory" libraryRef="objectFactoryLib"
  className="com.ibm.example.factory.MyObjectFactory"
  objectClassName="java.util.Properties"/>
```

5. Declare the entry in a `jndiReferenceEntry` element in the `server.xml` file and reference the previously declared factory.

```
<jndiReferenceEntry id="refEntry" jndiName="ref/entry" factoryRef="objectFactory"/>
```

6. To declare more properties for the `jndiReferenceEntry` element in the `server.xml` file:

```
<jndiReferenceEntry id="refEntry" jndiName="ref/entry" factoryRef="objectFactory">
  <properties abc="123"/>
</jndiReferenceEntry>
```

These additional properties are represented as `javax.naming.StringRefAddr` on the `javax.naming.Reference` that is passed to the factory:

```
import javax.naming.spi.ObjectFactory;

public class MyObjectFactory implements ObjectFactory {
    @Override
    public Object getObjectInstance(Object o, Name n, Context c, Hashtable<?, ?> envmt) throws Exception {
        Properties p = new Properties();
        Reference ref = (Reference) o;
        RefAddr refAddr = ref.get("abc");
        p.put("abc", refAddr == null ? 123 : refAddr.getContent());
        return p;
    }
}
```

7. You can inject the resulting object to an application by using a resource environment reference:

```
@Resource(name="ref/entry")
private Properties properties;
```

---

## Deploying OSGi applications to Liberty

You can deploy OSGi applications to Liberty by enabling a list of server features in the `server.xml` file.

### About this task

By providing a list of OSGi-specific server features, Liberty provides OSGi support for your applications. These features are as follows:

- `blueprint-1.0`
- `osgi.jpa-1.0`
- `wab-1.0`

For a full list of server features in Liberty, see “Liberty features” on page 826.

## Sharing common OSGi bundles for Liberty

You can share common OSGi bundles by placing them in a directory and configuring the `server.xml` file for your server, so that those common OSGi bundles are available to your OSGi applications.

### Procedure

- Create a directory in your file system and place all the common OSGi bundles into the directory.
- Add the following lines into the `server.xml` file.

```
<bundleRepository>
  <fileset dir="directory_path" include="*.jar"/>
</bundleRepository>
```

Where *directory\_path* is the path to the directory that contains the common OSGi bundles.

- Define a dependency on the common bundle using `import` phrase in the `manifest.mf` file of your OSGi application.

---

## Deploying data access applications to Liberty

Deploying a data access application includes more than installing your web application archive (WAR) or enterprise archive (EAR) file onto Liberty. Deployment can include tasks for configuring the data access resources of the server and overall runtime environment.

## About this task

This following topics are covered in this section:

### Procedure

- Configure a data source and JDBC driver for database connectivity in a Liberty profile
- Deploy an JDBC application to Liberty
- Optional: Configure connection pooling in Liberty
- Optional: Develop an application-defined data source on Liberty
- Optional: Configure transaction recovery for data sources on Liberty
- Migrating data access applications to Liberty

## Deploying an existing JDBC application to Liberty

You can take an existing application that uses Java Database Connectivity (JDBC) and a data source, and deploy the application to a server.

### About this task

You can take an existing JDBC application and deploy it to Liberty. To complete this deployment, you add the `jdbc-4.0` Liberty feature to the `server.xml` file. You must also add code that tells the server the JDBC driver location and specifies properties that the JDBC driver uses to connect to the database.

In this example, you can extend your servlet application, or use the one provided here to test the interactivity that is used through the JDBC driver is working as expected.

### Procedure

1. Create a server.
2. Start the server.
3. Add the `jdbc-4.0` and the `servlet-3.0` Liberty features to the `server.xml` file.

```
<server>
  <featureManager>
    <feature>jdbc-4.0</feature>
    <feature>servlet-3.0</feature>
  </featureManager>
</server>
```

To check that the server is working and that the features are enabled successfully, see the `console.log` file, which is stored in the `logs` directory of the server. You can view it using any text editor. You should see something like this example:

```
[AUDIT ] CWWKF0012I: The server installed the following features: [jdbc-4.0, jndi-1.0].
[AUDIT ] CWWKF0008I: Feature update completed in 0.326 seconds.
```

4. Specify the database type and the data source location in the `server.xml` file.

Where `path_to_derby` is the location where `derby` is installed on your operating system, `lib` is the folder where `derby.jar` is located, and `data/exampleDB` is the directory that is created if it does not exist.

For example:

```
<jdbcDriver id="DerbyEmbedded" libraryRef="DerbyLib"/>

<library id="DerbyLib">
  <fileset dir="C:/path_to_derby/lib" includes="derby.jar"/>
</library>

<dataSource id="ds1" jndiName="jdbc/exampleDS" jdbcDriverRef="DerbyEmbedded">
  <properties.derby.embedded
```

```

        databaseName="C:/path_to_derby/data/exampleDB"
        createDatabase="create"
    />
</dataSource>

```

For information about other options for coding data source definitions, see “Using Ref tags in configuration files” on page 1592.

5. Add some SQL create, read, update, and delete statements to your JDBC application to test the interactivity with the database.

```
package wasdev;
```

```

import java.io.*;
import java.sql.Connection;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;
import javax.annotation.Resource;
import javax.servlet.*;
import javax.servlet.http.*;
import javax.servlet.annotation.WebServlet;
import javax.sql.DataSource;

```

```
@WebServlet("/HelloWorld")
```

```
public class HelloWorld extends HttpServlet {
```

```
    @Resource(name = "jdbc/exampleDS")
```

```
    private DataSource ds1;
```

```
    private Connection con = null;
```

```
    private static final long serialVersionUID = 1L;
```

```
    public HelloWorld() {
```

```
        super();
```

```
    }
```

```
    public void doGet(HttpServletRequest request, HttpServletResponse response)
        throws ServletException, IOException {
```

```
        response.setContentType("text/html");
```

```
        PrintWriter out = response.getWriter();
```

```
        out.println("<H1>Hello World Liberty</H1>\n");
```

```
        try {
```

```
            con = ds1.getConnection();
```

```
            Statement stmt = null;
```

```
            stmt = con.createStatement();
```

```
            // create a table
```

```
            stmt.executeUpdate("create table cities (name varchar(50) not null primary key, population int, county var");
```

```
            // insert a test record
```

```
            stmt.executeUpdate("insert into cities values ('myHomeCity', 106769, 'myHomeCounty')");
```

```
            // select a record
```

```
            ResultSet result = stmt.executeQuery("select county from cities where name='myHomeCity'"); would result.ne
```

```
            // display the county information for the city.
```

```
            out.println("The county for myHomeCity is " + result.getString(1));
```

```
            // drop the table to clean up and to be able to rerun the test.
```

```
            stmt.executeUpdate("drop table cities");
```

```
        }
```

```
    catch (SQLException e) {
```

```
        e.printStackTrace();
```

```
    }
```

```
    finally {
```

```
        if (con != null){
```

```
            try{
```

```
                con.close();
```

```
            }
```

```
        catch (SQLException e) {
```

```
            e.printStackTrace();
```

```
        }
```

```
    }  
  }  
}
```

## 6. Compile your application.

Where *path\_to\_liberty* is the location you installed Liberty on your operating system, and *path\_to\_app* is the location of the Java file of the application you want to compile.

Example on Windows:

```
C:\> javac -cp  
path_to_liberty\wlp\dev\api\spec\com.ibm.ws.javaee.servlet.3.0_1.0.1.jar  
path_to_App\HelloWorld.java
```

Example on Linux:

```
mo@machine01:~> javac -cp  
path_to_liberty/wlp/dev/api/spec/com.ibm.ws.javaee.servlet.3.0_1.0.1.jar  
path_to_App/HelloWorld.java
```

If the **javac** command is not recognized, ensure that you have the Java bin directory in the PATH environment variable of your operating system.

## 7. Add the application to the server.

In this example, the JDBC application is put in the dropins directory of the server:

```
...\dropins\HelloWorldApp.war\WEB-INF\classes\wasdev\HelloWorld
```

The wasdev directory uses the same package name that is used in HelloWorld.java.

## 8. Check that your JDBC application is working.

For this example, go to this URL:

```
http://localhost:9080/HelloWorldApp/HelloWorld
```

Port 9080 is the default HTTP port that is used by the Liberty server. You can check which HTTP port your server is set on by looking in the server.xml file.

The output on the browser for this example looks like:

```
Hello World Liberty  
The county for myHomeCity is myHomeCounty
```

## Enabling JDBC Tracing for Liberty

JDBC tracing for Liberty is enabled either through a driver-specific custom trace setting, or using the application server supplemental JDBC tracing option.

### About this task

There are two ways of using driver-specific custom trace facilities:

- Using the Java built-in logging mechanism, `java.util.logging`, if the driver supports it.
- Configuring a custom trace setting as a vendor property.

If your JDBC driver does not provide its own custom tracing or logging facilities, or the facilities it provides are minimal, you can use supplemental JDBC tracing from the application server.

If you enable tracing by using either a custom vendor property or supplemental JDBC tracing, you must add the logwriter name to the trace specification in the `bootstrap.properties` file. You can use any of the following logwriters:

**DB2** `com.ibm.ws.db2.logwriter`

**Derby** `com.ibm.ws.derby.logwriter`

**Informix JCC (uses the same driver as DB2)**  
`com.ibm.ws.db2.logwriter`

## Informix JDBC

com.ibm.ws.informix.logwriter

## Microsoft SQL Server JDBC Driver

com.ibm.ws.sqlserver.logwriter

## DataDirect Connect for JDBC for Microsoft SQL Server

com.ibm.ws.sqlserver.logwriter

## Sybase

com.ibm.ws.sybase.logwriter

## Other databases (for example solidDB and MySQL)

com.ibm.ws.database.logwriter

Because changes to trace enablement involve altering the `bootstrap.properties` file, you must restart the server for the changes to take effect.

The following examples illustrate the use of the various JDBC trace methods.

## Procedure

- Use `java.util.logging`.

If the driver you are using supports `java.util.logging`, you can enable it by appending the driver's trace level to `com.ibm.ws.logging.trace.specification` in the `bootstrap.properties` file. See the JDBC vendor documentation for levels and other trace information specific to your driver.

Here is an example for Microsoft SQL Server JDBC Driver:

- Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:com.microsoft.sqlserver.jdbc=FINE
```

Here is an example for Oracle JDBC:

- Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:oracle=FINE
```

- For Oracle, you must also enable the tracing using the system property `oracle.jdbc.Trace`, using one of the following two options:

- In the `bootstrap.properties` file, add the setting `oracle.jdbc.Trace=true`

- In a Java program, add the setting `System.setProperty("oracle.jdbc.Trace", "true");`

- Use custom trace settings.

If the driver you are using has custom trace settings, you set them as JDBC driver vendor properties in the `server.xml` file. You also add the logwriter name to the trace specification in the `bootstrap.properties` file.

Here is an example for DB2 JCC, using the custom property `traceLevel`:

- Example code for the `server.xml` file:

```
<dataSource id="db2" jndiName="jdbc/db2" jdbcDriverRef="DB2Driver" >  
  <properties.db2.jcc databaseName="myDB" traceLevel="-1"/>  
</dataSource>
```

- Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:com.ibm.ws.db2.logwriter=all=enabled
```

Here is an example for Derby Network Client:

- Example code for the `server.xml` file:

```
<dataSource id="derbyNC" jndiName="jdbc/derbyNC" jdbcDriverRef="DerbyNC" >  
  <properties.derby.client databaseName="myDB" createDatabase="create" traceLevel="1"/>  
</dataSource>
```

- Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:com.ibm.ws.derby.logwriter=all=enabled
```

Here is an example for Informix JCC. This database uses the DB2 drivers for JCC connectivity.

– Example code for the `server.xml` file:

```
<dataSource id="informixJCC" jndiName="jdbc/informixJCC" jdbcDriverRef="InformixDriverJCC" >
  <properties.informix.jcc databaseName="myDB" traceLevel="-1"/>
</dataSource>
```

– Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:com.ibm.ws.db2.logwriter=all=enabled
```

- Use supplemental JDBC tracing.

If your JDBC driver does not provide suitable tracing or logging facilities, you can use supplemental JDBC tracing from the application server. The application server automatically determines whether to enable supplemental JDBC tracing, based on the JDBC driver being used. To override this, set the data source property `supplementalJDBCTrace` to true or false.

1. Enable supplemental tracing.

Here is an example for enabling supplemental tracing with the embedded Derby database.

Supplemental JDBC tracing is enabled by default for this database, so you only need to set the logwriter in the `bootstrap.properties` file:

– Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:com.ibm.ws.derby.logwriter=all=enabled
```

Here is an example for enabling supplemental tracing with Informix JDBC. Supplemental JDBC tracing is enabled by default for this database.

– Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:com.ibm.ws.informix.logwriter=all=enabled
```

Here is an example for enabling supplemental tracing, and `java.util.logging`, with Microsoft SQL Server JDBC Driver:

– Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:com.ibm.ws.sqlserver.logwriter=all=enabled:
com.microsoft.sqlserver.jdbc=all
```

Here is an example for enabling supplemental tracing with DataDirect Connect for JDBC for Microsoft SQL Server:

– Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:com.microsoft.sqlserver.jdbc=all
```

Here is an example for enabling supplemental tracing with solidDB. Supplemental JDBC tracing is enabled by default for this database.

– Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:com.ibm.ws.database.logwriter=all=enabled
```

Here is an example for enabling supplemental tracing with Sybase. Supplemental JDBC tracing is enabled by default for this database.

– Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:com.ibm.ws.sybase.logwriter=all=enabled
```

Here is an example for enabling supplemental tracing with other databases:

– Example code for the `bootstrap.properties` file:

```
com.ibm.ws.logging.trace.specification==audit=enabled:com.ibm.ws.database.logwriter=all=enabled
```

2. Disable supplemental tracing

To disable supplemental JDBC tracing, either set the `supplementalJDBCTrace` data source property to false in the `server.xml` file, or remove the logwriter name from the

`com.ibm.ws.logging.trace.specification` property in the `bootstrap.properties` file:

– Example code for the `server.xml` file for solidDB:

```

<dataSource id="soliddb" jndiName="jdbc/soliddb"
    jdbcDriverRef="solidDBDriver" supplementalJDBCTrace="false">
    <properties databaseName="dba" URL="jdbc:solid://localhost:2315/dba/dba" />
</dataSource>

```

- Example code for the bootstrap.properties file for solidDB:  
com.ibm.ws.logging.trace.specification=\*\*audit=enabled

**Note:** If you are not seeing JDBC trace, a feature might be activating JDBC immediately. Check bootstrap.properties and edit it to add JDBC trace specifications.

---

## Deploying a web application to Liberty

By deploying a helloworld.war application, you can learn how server configurations change in Liberty.

### Before you begin

The helloworld.war application uses a simple servlet to display a message on your browser. You can create any other messages to be displayed. The coding of the application is not described within Liberty documents.

### About this task

When you deploy a web application to Liberty by using the developer tools, all configurations that are related to the application are automatically enabled in the server.xml file. However, you can also configure the server.xml file manually by completing the following steps.

This example uses the helloworld.war application and can be accessed by using http://localhost:9090/helloworld. In this example, a Liberty server instance is created, and then its default HTTP port is changed to 9090, and then an application is deployed to it.

### Procedure

1. Create a server named hwserver by using the command `server create hwserver`.
2. Copy the helloworld.war application into the `/usr/servers/hwserver/apps` directory; this directory was created by the `server create` command in step 1.
3. In the server.xml file that was created by the `server create` command, change the default HTTP port of the server hwserver to 9090 by replacing the attribute value `httpPort="9080"` with `httpPort="9090"`:

```

<server description="new server">

    <!-- Enable features -->
    <featureManager>
        <feature>jsp-2.2</feature>
    </featureManager>

    <httpEndpoint id="defaultHttpEndpoint"
        host="localhost"
        httpPort="9090"
        httpsPort="9443" />
</server>

```

4. Configure the application by updating the server.xml in either of the following ways:

- **8.5.5.0** Define the application by using a `webApplication` element:  

```

<server description="Hello World Server">

    <featureManager>
        <feature>servlet-3.0</feature>
    </featureManager>

```

```

<httpEndpoint id="defaultHttpEndpoint" host="*" httpPort="9090" />

<webApplication contextRoot="helloworld" location="helloworld.war" />

</server>

```

- Define the application by using an application element:

```

<server description="Hello World Server">

  <featureManager>
    <feature>servlet-3.0</feature>
  </featureManager>

  <httpEndpoint id="defaultHttpEndpoint" host="*" httpPort="9090" />

  <application context-root="helloworld" type="war" id="helloworld"
    location="helloworld.war" name="helloworld"/>

</server>

```

#### 8.5.5.0

The `webApplication` element can use the same child elements as the `application` element, except for `context-root` and `type`. The two elements do not work together for a `context-root`, and if both an `application` and `webApplication` element define the same `context-root`, only one is used and an error is displayed.

The `context-root` attribute specifies the entry point of the deployed application. The entry point of a deployed application is determined in the following precedence:

- `context-root` in the `server.xml` file
- `application.xml`, if an EAR application
- `ibm-web-ext.xml`, if a web application
- `name` of the application in the `server.xml` file, if a web application
- `Manifest.MF`, if a WAB application
- Directory name or the file name relative to the drop-ins directory of Liberty

**Note:** In an application server `server.xml` configuration, the `application` element can contain a `context-root` tag. This `context-root` tag is applicable in combination with the tag `type="war"`. For all other application types, the `context-root` element has no effect.

It is not possible to override the `context-root` for either an EAR application, or an EBA application. It is only possible to do an override for a stand-alone war file, or `webApplication`.

5. Start the server in foreground by using the command `server run hwserver`.
6. Test the application at `http://localhost:9090/helloworld`.
7. Optional: Stop the server if you don't need it.

---

## Deploying SIP applications to Liberty

#### 8.5.5.7

Session Initiation Protocol (SIP) applications are Java applications that contain at least one SIP servlet. SIP applications are deployed the same way as other web applications.

### Before you begin

Install the `sipServlet-1.1` feature in your Liberty server. For more information, see “Adding and removing Liberty features” on page 1587.

Configure the SIP container. For more information, see “Administering Session Initiation Protocol (SIP) on Liberty” on page 1728.

## About this task

To deploy a SIP application, the application must be packaged in a web archive (WAR) file, a servlet archive (SAR) file, or an enterprise archive (EAR) file that contains a WAR or SAR file.

This task describes how to manually deploy a SIP application. Alternatively, you can deploy a SIP application to Liberty by using the developer tools, which automatically enable all configurations related to the application in the `server.xml` file. For more information, see [WebSphere Developer Tools > Developing > Developing SIP applications](#).

## Procedure

Add your SIP application WAR, SAR, or EAR file to the Liberty server in one of the following ways:

- Move the archive file to the folder for drop-in artifacts in the server configuration directory at `wlp/usr/servers/server_name/dropins`. The Liberty server monitors the `dropins` folder for new applications and automatically installs the application with the default configuration.
- Move the archive file to the folder for applications in the server configuration directory at `wlp/usr/servers/server_name/apps`. Then, install the SIP application in the Liberty server by configuring an `application` element in the `server.xml` file.

The following example installs the `appName.ear` file. The `context-root` attribute specifies the entry point of the deployed application.

```
<application id="appId" name="appName" type="ear" location="appName.ear" context-root="/sip289"/>
```

---

## Deploying a JPA application to Liberty

To enable Liberty to support an application that uses the Java Persistence API (JPA), you add the `jpa-2.0` or `jpa-2.1` feature to the `server.xml` file, depending on which specification level you need. You also need to define persistence contexts and persistence units, and configure access to the entity manager and entity manager factory.

## Before you begin

This task assumes that you have created a Liberty server, on which you want to deploy an application that uses JPA. See “Creating a Liberty server manually” on page 1423.

## About this task

**8.5.5.6** There are two JPA features available in Liberty:

- The `jpa-2.0` feature provides support for applications that use application-managed and container-managed JPA written to the JPA 2.0 specification. The support is built on Apache OpenJPA with extensions to support the container-managed programming model.
- The `jpa-2.1` feature provides support for applications that use application-managed and container-managed JPA written to the JPA 2.1 specification. The support is built on EclipseLink

For information about developing JPA applications by using WebSphere Developer Tools, see [Developing JPA applications](#).

## Procedure

- Add the `jpa-2.0` or `jpa-2.1` feature to the `server.xml` file.
- Add persistence context and persistence unit definitions to the `web.xml` file.

For example:

```
<persistence-context-ref>
  <persistence-context-ref-name>example/em</persistence-context-ref-name>
  <persistence-unit-name>ExamplePersistenceUnit</persistence-unit-name>
</persistence-context-ref>
```

```
<persistence-unit-ref>
  <persistence-unit-ref-name>example/emf</persistence-unit-ref-name>
  <persistence-unit-name>ExamplePersistenceUnit</persistence-unit-name>
</persistence-unit-ref>
```

- Configure access to the entity manager.

For example:

```
Context ctx = new InitialContext();
UserTransaction tran = (UserTransaction) ctx.lookup("java:comp/UserTransaction");
tran.begin();
EntityManager em = (EntityManager) ctx.lookup("java:comp/env/example/em");
Thing thing = new Thing();
em.persist(thing);
tran.commit();
```

- Configure access to the entity manager factory.

For example:

```
Context ctx = new InitialContext();
EntityManagerFactory emf = (EntityManagerFactory) ctx.lookup("java:comp/env/example/emf");
EntityManager em = emf.createEntityManager();
EntityTransaction tx = em.getTransaction();
tx.begin();
Thing thing = new Thing();
em.persist(thing);
tx.commit();
int id = thing.getId();
em.close();
```

## Liberty: Enhancement of JPA entities for JPA 2.0

### 8.5.5.0

The JPA 2.0 specification provider that is included in Liberty is based on Apache OpenJPA. OpenJPA uses Java bytecode enhancement of JPA persistent types (Entity, Embeddable, MappedSuperclass) to add state tracking, and other necessary information to enable persistence and other optimized features within JPA classes. In an application server environment, enhancement of your JPA entities occurs automatically when the application is loaded by the Liberty server.

Pre-enhancement of JPA classes (or build time enhancement) is necessary when a persistence JAR is used in both application server, and non-application server environments. The most common ways to perform build time enhancement are the OpenJPA enhancer Ant task, and PCEnhancer. These build time enhancement options require the OpenJPA library and dependent libraries to be on the classpath. The **wsenhancer** command, in the WebSphere Application Server traditional install, can also be used.

**Note:** The JPA 2.1 specification provider for Liberty is EclipseLink. EclipseLink does not require entity enhancement.

---

## Deploying web services applications to Liberty

By configuring Liberty features in the `server.xml` file, you can deploy web services applications to Liberty.

## Deploying JAX-RS 2.0 applications to Liberty

You can use Java API for RESTful Web Services (JAX-RS) to develop services that follow Representational State Transfer (REST) principles. RESTful services are based on manipulating resources. Resources can contain static or dynamically updated data. By identifying the resources in your application, you can make the service more useful and easier to develop. Liberty provides two Liberty features, `jaxrs-1.1`  and `jaxrs-2.0`, to support the JAX-RS programming model.

8.5.5.6

### Asynchronous processing

You can use the asynchronous processing technique in JAX-RS 2.0 to process threads. Asynchronous processing is supported both in the Client API and in the Server API. For more information about asynchronous processing in Client and Server APIs, see Chapter 8 of JSR 339: JAX-RS 2.0: The Java API for RESTful Web Services (the "Specification").

The following two examples show asynchronous processing in the Client and Server APIs:

- Asynchronous processing in the Client API:

```
Client client = ClientBuilder.newClient();
WebTarget target = client.target("http://example.org/customers/{id}");
target.resolveTemplate("id", 123).request().async().get(
    new InvocationCallbackCustomer() {
        @Override
        public void completed(Customer customer) {
            // Do something
        }
        @Override
        public void failed(Throwable throwable) {
            // Process error
        }
    });
```

- Asynchronous processing in the Server API:

```
@Path("/async")
public class MyResource{

    @GET
    public void getAsync(@Suspended final AsyncResponse asyncResponse){
        CompletionCallback callBack = new CompletionCallback(){
            @Override
            public void onComplete(Throwable throwable) {
                ...
            }
        };
        asyncResponse.register(callBack);
        asyncResponse.resume("some Response");
    }
}
```

The JAX-RS 2.0 implementation in Liberty supports EJB and the use of stateless and singleton session beans as root resource classes. When an EJB method is annotated with `@Asynchronous`, the EJB container automatically allocates the necessary resources for its execution. Thus, in this scenario, it is unnecessary to use an `Executor` to generate an asynchronous response. For example,

```
@Stateless
@Path("/")
class EJBResource {

    @GET @Asynchronous
    public void longRunningOp(@Suspended AsyncResponse ar) {
        executeLongRunningOp();
        ar.resume("Hello async world!");
    }
}
```

Explicit thread management is not needed in this case because that is under the control of the EJB container. The response is produced by calling `resume` on the injected `AsyncResponse`. Hence, the return type of `longRunningOp` is `void`.

## Configuring a resource to receive multipart/form-data parts from an HTML form submission in JAX-RS 2.0

HTML forms that transmit file data must be configured with the `POST` method and the `"multipart/form-data"` action. This data can be received in one of the two ways by the JAX-RS resource method that accepts it with the IBM Java API for RESTful Web Services (JAX-RS) implementation.

### About this task

This task provides instructions for configuring a JAX-RS method to use and produce `multipart/form-data`. The following example illustrates an HTML form:

```
<form action="http://www.example.com/" method="POST" enctype="multipart/form-data">
  <input type="text" name="fileid" />
  <br />
  <input type="text" name="description" />
  <br />
  <input type="file" name="thefile" />
  <br />
  <input type="submit" name="submit" value="submit"/>
</form>
```

You can implement the IBM JAX-RS to receive the data in parts, so you can process these parts yourself, if needed.

### Procedure

Create a resource method. You must declare one of the following resource methods to receive and echo `multipart/form-data` content from an HTTP `POST`:

```
package com.example.jaxrs;
@POST
@Consumes("multipart/form-data")
@Produces("multipart/form-data")

public Response postFormData(IMultipartBody multipartBody) {
    List<IAttachment> attachments = multipartBody.getAllAttachments();
    String formElementValue = null;
    InputStream stream = null;
    for (Iterator<IAttachment> it = attachments.iterator(); it.hasNext(); ) {
        IAttachment attachment = it.next();
        if (attachment == null) {
            continue;
        }
        DataHandler dataHandler = attachment.getDataHandler();
        stream = dataHandler.getInputStream();
        MultivaluedMap<String, String> map = attachment.getHeaders();
        String fileName = null;
        String formElementName = null;
        String[] contentDisposition = map.getFirst("Content-Disposition").split(";");
        for (String tempName : contentDisposition) {
            String[] names = tempName.split("=");
            formElementName = names[1].trim().replaceAll("\\\\", "");
            if ((tempName.trim().startsWith("filename"))) {
                fileName = formElementName;
            }
        }
        if (fileName == null) {
            StringBuffer sb = new StringBuffer();
            BufferedReader br = new BufferedReader(new InputStreamReader(stream));
            String line = null;
            try {
                while ((line = br.readLine()) != null) {
                    sb.append(line);
                }
            } catch (IOException e) {
                e.printStackTrace();
            } finally {
                if (br != null) {
                    try {
                        br.close();
                    } catch (IOException e) {
                        e.printStackTrace();
                    }
                }
            }
        }
    }
}
```

```

        }
        formElementValue = sb.toString();
        System.out.println(formElementName + ":" + formElementValue);
    } else {
        //handle the file as you want
        File tempFile = new File(fileName);
        ...
    }
}
if (stream != null) {
    stream.close();
}
return Response.ok("test").build();
}

```

Or

```

package com.example.jaxrs;
@POST
@Consumes("multipart/form-data")
@Produces("multipart/form-data")

public Response postFormData(List<IAttachment>attachments) {
    List<IAttachment> attachments = multipartBody.getAllAttachments();
    String formElementValue = null;
    InputStream stream = null;
    for (Iterator<IAttachment> it = attachments.iterator(); it.hasNext();) {
        IAttachment attachment = it.next();
        if (attachment == null) {
            continue;
        }
        DataHandler dataHandler = attachment.getDataHandler();
        stream = dataHandler.getInputStream();
        MultivaluedMap<String, String> map = attachment.getHeaders();
        String fileName = null;
        String formElementName = null;
        String[] contentDisposition = map.getFirst("Content-Disposition").split(";");
        for (String tempName : contentDisposition) {
            String[] names = tempName.split("=");
            formElementName = names[1].trim().replaceAll("\\\\", "");
            if ((tempName.trim().startsWith("filename"))) {
                fileName = formElementName;
            }
        }
        if (fileName == null) {
            StringBuffer sb = new StringBuffer();
            BufferedReader br = new BufferedReader(new InputStreamReader(stream));
            String line = null;
            try {
                while ((line = br.readLine()) != null) {
                    sb.append(line);
                }
            } catch (IOException e) {
                e.printStackTrace();
            } finally {
                if (br != null) {
                    try {
                        br.close();
                    } catch (IOException e) {
                        e.printStackTrace();
                    }
                }
            }
            formElementValue = sb.toString();
            System.out.println(formElementName + ":" + formElementValue);
        } else {
            //handle the file as you want
            File tempFile = new File(fileName);
            ...
        }
    }
    if (stream != null) {
        stream.close();
    }
    return Response.ok("test").build();
}

```

The originator of the form POST submission can generate a Content-Transfer-Encoding header for one or more parts of the multipart message. The IBM JAX-RS implementation attempts to auto-decode the payload of the part according to this header when the header is of base64 or quoted-printable encoding type.

## Results

- You have received and echoed data from an HTTP POST with multipart/form-data Content-Type, by allowing the IBM JAX-RS implementation to split and auto-decode the parts for you, and by receiving the still encoded parts to process yourself.

## Configuring JAX-RS 2.0 client

8.5.5.6

For Java API for XML RESTful Web Services 2.0, you can configure the client to access REST endpoints. JAX-RS 2.0 introduces a new and standardized Client API so that you can make HTTP requests to your remote RESTful web services.

### About this task

An instance of `Client` is required to access a Web resource using the Client API. The default instance of `Client` can be obtained by calling `newClient` or `build` on `ClientBuilder`.

### Procedure

1. Enable the `jaxrsClient-2.0` or `jaxrs-2.0` feature in your `server.xml` file:

```
<featureManager>
  <feature>jaxrs-2.0</feature>// If you only need the JAX-RS 2.0 client feature, you can enable jaxrsClient-2.0 instead
</featureManager>
```

2. Create a JAX-RS 2.0 client and send the request to the server:

```
javax.ws.rs.client.ClientBuilder cb = ClientBuilder.newBuilder();

javax.ws.rs.client.Client c = cb.build();
String res = null;

try {
  res = c.target("<Resource_URL>")
    .path("<PATH>")
    .request()
    .get(String.class);
} catch (Exception e) {
  res = "[Error]:" + e.toString();
} finally {
  c.close();
}
```

For more information about the asynchronous JAX-RS 2.0 client, see “Asynchronous processing” on page 2159.

### What to do next

-  **8.5.5.6** Use the `com.ibm.ws.jaxrs.client.timeout` client property to set the timeout value.

```
javax.ws.rs.client.ClientBuilder cb = ClientBuilder.newBuilder();
  cb.property("com.ibm.ws.jaxrs.client.timeout", "1000");
Client c = cb.build();
```

**Tip:** The value of the timeout property is milliseconds, and the type must be long or int. If the type of the value is invalid, the following message is displayed:

CWWKW0700E: The timeout value {0} that you specified in the property `com.ibm.ws.jaxrs.client.timeout` on the JAX-RS Client is invalid.

-  **8.5.5.7** Use the `com.ibm.ws.jaxrs.client.connection.timeout` client property and the `com.ibm.ws.jaxrs.client.receive.timeout` client property to set the timeout values.

- `com.ibm.ws.jaxrs.client.connection.timeout`  

```
javax.ws.rs.client.ClientBuilder cb = ClientBuilder.newBuilder();
    cb.property("com.ibm.ws.jaxrs.client.connection.timeout", "1000");
    Client c = cb.build();
```
- `com.ibm.ws.jaxrs.client.receive.timeout`  

```
javax.ws.rs.client.ClientBuilder cb = ClientBuilder.newBuilder();
    cb.property("com.ibm.ws.jaxrs.client.receive.timeout", "1000");
    Client c = cb.build();
```

**Tip:** The value of the timeout property is millisecond, and the type must be long or int. If the type of the value is invalid, the following message is displayed:

CWWKW0700E: The timeout value {0} that you specified in the property `com.ibm.ws.jaxrs.client.receive.timeout` on the

- Use the following client properties for client proxy support:

```
ClientBuilder cb = ClientBuilder.newBuilder();
cb.property("com.ibm.ws.jaxrs.client.proxy.host", "hostname");
cb.property("com.ibm.ws.jaxrs.client.proxy.port", "8888");
cb.property("com.ibm.ws.jaxrs.client.proxy.type", "HTTP");
```

```
Client c = cb.build();
```

- `com.ibm.ws.jaxrs.client.proxy.host`
- `com.ibm.ws.jaxrs.client.proxy.port`

**Tip:** The type of the proxy server port value must be int. The default value is 80. If the value type is invalid, the following message is displayed:

CWWKW0701E: The proxy server port value {0} that you specified in the property `com.ibm.ws.jaxrs.client.proxy.port` o

- `com.ibm.ws.jaxrs.client.proxy.type`

**Tip:** The value of the proxy server type must be HTTP or SOCKS. The default value is HTTP. If the type of the proxy server is invalid, the following message is displayed:

CWWKW0702E: The proxy server type value {0} that you specified in the property `com.ibm.ws.jaxrs.client.proxy.type` o

- Use the `com.ibm.ws.jaxrs.client.ltpa.handler` client property to set the SSO cookie and set the value to true.

```
ClientBuilder cb = ClientBuilder.newBuilder();
    Client c = cb.build();
    c.property("com.ibm.ws.jaxrs.client.ltpa.handler", "true");
```

If you want to use the Secure Sockets Layer (SSL) function in JAX-RS 2.0, you need to enable the `ssl-1.0` or `appSecurity-2.0` feature. For the LTPA token function, you must enable the `appSecurity-2.0` feature.

For more information about how to configure the environment to run the JAX-RS 2.0 client with SSL through IHS, see [Configuring IBM HTTP server SSL support](#).

**Note:** The `ssl-1.0` feature is a subfeature of the `appSecurity-2.0` feature. If you enable the `jaxrsClient-2.0` feature and the `ssl-1.0` feature, the `appSecurity-2.0` feature is enabled automatically.

- Use the `com.ibm.ws.jaxrs.client.ssl.config` client property to set the SSL reference id of your `server.xml` file.

```
ClientBuilder cb = ClientBuilder.newBuilder();
    cb.property("com.ibm.ws.jaxrs.client.ssl.config", "mySSLRefId");
    Client c = cb.build();
```

For more information about establishing trust by extracting the certificate from the IHS key file and adding it to the Liberty JKS file, see [Create a key database file and certificates needed to authenticate the Web server during an SSL handshake](#).

**Note:** The configuration in the `server.xml` file shows as follows:

```
<ssl id="mySSLRefId" keyStoreRef="clientKeyStore" trustStoreRef="clientTrustStore" />
```

- **8.5.5.9** Use the `com.ibm.ws.jaxrs.client.disableCNCheck` client property to disable the common name check.

```
ClientBuilder cb = ClientBuilder.newBuilder();
cb.property("com.ibm.ws.jaxrs.client.disableCNCheck", true);
```

## Deploying EJB in an EAR file for JAX-RS 2.0

**8.5.5.6**

In Liberty, JAX-RS 2.0 supports EJB JAX-RS in EJB JAR file that must be included in an EAR file.

### Procedure

1. Deploy the new `myearfile.ear` file to Liberty.
2. Use the following URL pattern to access the JAX-RS service:  
`http://<host>:<port>/<context root>/<path of jaxrs resource>`

For example, you can access EJB JAX-RS in `<myejbjaxrs.jar>`:

`http://<host>:<port>/myejbjaxrs/<path of jaxrs resource>`

**Note:** If there are EJB JAX-WS classes in the same EJB-jar and the JAX-WS 2.2 feature is enabled, that means JAX-WS router module also exists, then the default context root should be the short file name of EJB jar+ ".jaxrs" like "myejbjaxrs.jaxrs" for `<myejbjaxrs.jar>`.

### Liberty: Implementation of JAX-RS 2.0 web applications

You can use Java API for RESTful Web Services (JAX-RS) to develop services that follow Representational State Transfer (REST) principles. Using JAX-RS, development of RESTful services is simplified.

JAX-RS is a Java API for developing REST applications quickly. This standard API continues to gain support throughout the Java community. While JAX-RS provides a faster way of developing web

applications than servlets, the primary goal of JAX-RS is to build RESTful services. `jaxrs-1.1` and  **8.5.5.6** `jaxrs-2.0` define a server-side component API to build REST applications. IBM JAX-RS provides an implementation of the JAX-RS (JSR 311) specification.

By using the principles of REST, your business applications can benefit from several advantages. RESTful services are generally simpler to develop and consume. Most RESTful services use well-defined standards for delivery such as HTTP. Because HTTP is a protocol that has RESTful properties, RESTful services gain scalability advantages that enable the service to serve different clients and interoperate with multiple services, while permitting future growth. Additionally, clients for RESTful services generally are not difficult to develop, yielding interoperability advantages because most RESTful services use common data representations such as XML and JSON.

By using JAX-RS technology, REST applications are simpler to develop, simpler to consume, and simpler to scale when compared to other types of distributed systems. Many popular and widely used Internet services have successfully provided RESTful APIs to their applications. Third parties have used various REST APIs to build their own businesses and applications.

JAX-RS capabilities are provided by the use of a servlet or a filter. When you configure the `web.xml` file of your web application and assemble the IBM JAX-RS implementation that is based on the Apache Wink framework into the library directory of your web application, your business application is now ready to use JAX-RS capabilities.

For more information, see

- Define the resources in JAX-RS web applications
- Configure the JAX-RS application

- Assemble JAX-RS web applications
- Deploy JAX-RS web applications

**Note:** The context root value in Liberty is either the name of the web module, or the user-defined context root found in the EAR file.

## Liberty: Implementation of secure JAX-RS 2.0 applications

The JAX-RS 1.1 runtime environment from IBM is driven by a servlet derived from the Apache Wink

project.  **8.5.5.6** The JAX-RS 2.0 runtime environment is driven by a servlet derived from the Apache CXF 3.0.2. Within the WebSphere Application Server environment, the lifecycle of servlets is managed in the web container. Therefore, the security services offered by the web container are applicable to REST resources that are deployed in WebSphere Application Server.

You can define and add security constraints on the REST resources using the same tools that is used to assemble REST applications. These constraints are captured in the J2EE web deployment descriptor that is associated with your application. The following list describes security definitions that you can include in the deployment descriptor:

- User authentication when invoking REST resources embodied in the application, including
  - HTTP basic authentication.
  - Form login authentication.
- Authorization control over REST resources as defined by the URL patterns for the resources.
- Use of SSL for transport when invoking REST resources.
- Programmatic use of the SecurityContext object to determine user identity and roles.

All the security mechanisms supported by the web container are applicable to REST resources, including the use of the Kerberos-based SPNEGO authentication mechanism.

For more information, see:

- Securing JAX-RS applications within the web container
- Securing JAX-RS resources using annotations
- Securing downstream JAX-RS resources

**Note:** In Liberty, the default context root is the name of the WAR file. For more information about options when configuring context roots, see “Deploying a web application to Liberty” on page 2155.

### Securing downstream JAX-RS resources:

You can secure downstream Java API for RESTful Web Services (JAX-RS) resources by configuring the BasicAuth method for authentication and by using the LTPA JAX-RS security handler to take advantage of single sign-on for user authentication.

### Before you begin

This task assumes that you have completed the following steps:

- You have installed your JAX-RS application onto the application server.
- You have enabled security for your JAX-RS application.
- You have secured your JAX-RS applications within the web container by configuring downstream JAX-RS applications to use the basic authentication (BasicAuth) method for user authentication.

### About this task

When composing JAX-RS resources, a new LTPA JAX-RS security handler can be used to seamlessly authenticate on downstream resource invocations.

When invoking downstream secure JAX-RS resources, the calling application is required to authenticate to the target resource. If the target resource on a downstream server uses the BasicAuth method for security, the calling application can take advantage of single sign-on (SSO) for JAX-RS resources. Using single sign-on, an authenticated context is propagated along downstream calls. You can use the LTPA-based security client handler to authenticate to downstream resources that are distributed across servers.

To illustrate this scenario, assume that you have two servers in your cell and that you have deployed JAX-RS resources on both of these servers. Suppose from one resource on server1 you need to invoke another resource that is deployed on server2. When server2 resources are secured using the BasicAuth method for authentication, use the LTPA JAX-RS security handler to take advantage of single sign-on and seamlessly propagate user authentication on downstream calls without having to provide or manage user identities and passwords in the application.

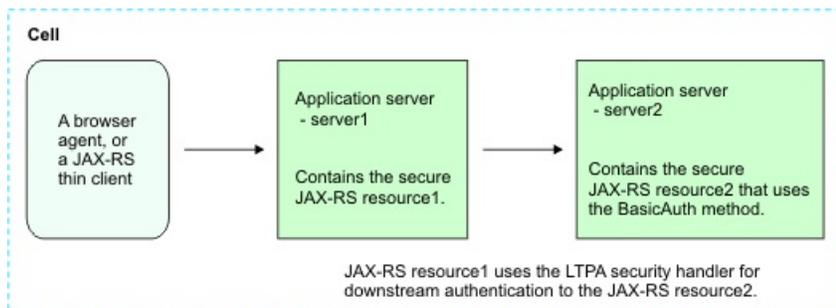

Figure 29. Securing JAX-RS downstream resources

Use the following steps to configure user authentication to a downstream server using the JAX-RS security handler at application build time.

### Procedure

- At application build time, use the LTPA-based security client handler, `LtpaAuthSecurityHandler`, to authenticate to downstream resources that are distributed across servers.
  - For JAX-RS 1.1, when using the `LtpaAuthSecurityHandler` class, ensure that you target resources using the `https` scheme for your URLs, and that the target application is SSL-enabled. It is highly recommended to use SSL connections when sending user credentials, including LTPA cookies. You may explicitly turn off the requirement for SSL in the `LtpaAuthSecurityHandler` class by invoking the `setSSLRequired` method on the security handler with the `false` value. The default value is `true`.

```
yourLtpaAuthSecHandler.setSSLRequired(false);
```

-  **8.5.5.6** For JAX-RS 2.0, you can use the `com.ibm.ws.jaxrs.client.ltpa.handler` client property to set SSO cookie and set the value to `true`:

```
ClientBuilder cb = ClientBuilder.newBuilder();
```

```

Client c = cb.build();
c.property("com.ibm.ws.jaxrs.client.ltpa.handler", "true");
WebTarget t = c.target("http://" + serverIP + ":" + serverPort + "/" + moduleName + "/ComplexClientTest/ComplexReso
String res = t.path("echo1").path("test1").request().get(String.class);
c.close();
ret.append(res);
  
```

-  **8.5.5.6** If you want to use the Secure Sockets Layer (SSL) function in JAX-RS 2.0, you need to enable the `ssl-1.0` or `appSecurity-2.0` feature. For the LTPA token function, the `appSecurity-2.0` feature is must.

**Note:** The `ssl-1.0` feature is a subfeature of the `appSecurity-2.0` feature. If you enable the `jaxrsClient-2.0` feature and the `ssl-1.0` feature, the `appSecurity-2.0` feature is enabled automatically.

- Add the security handler to the handlers chain.

3. Create the REST client instance.
4. Create the resource instance that you want to interact with.
5. Substitute a value representing your resource address.

## Results

You have defined secure JAX-RS resources such that when downstream resources are invoked, you can use single sign-on and seamlessly propagate user authentication on downstream calls without having to provide or manage user identities and passwords in the application.

## Example

For JAX-RS 1.1, the following code snippet demonstrates how to use this security handler that is packaged as part of the JAX-RS client.

```
import org.apache.wink.client.Resource;
import org.apache.wink.client.RestClient;
import org.apache.wink.client.ClientConfig;
import org.apache.wink.client.handlers.LtpaAuthSecurityHandler;

ClientConfig config = new ClientConfig();
LtpaAuthSecurityHandler secHandler = new LtpaAuthSecurityHandler();

// Add this security handler to the handlers chain.
config.handlers(secHandler);

// Create the REST client instance.
RestClient client = new RestClient(config);

// Create the resource instance that you want to interact with.
// Substitute a value representing your resource address
resource =
    client.resource("http://localhost:8080/path/to/resource");

// Now you are ready to begin calling your resource.
```

8.5.5.6

For JAX-RS 2.0, the following code snippet demonstrates how to use this security handler that is packaged as part of the JAX-RS client.

```
ClientBuilder cb = ClientBuilder.newBuilder();
Client c = cb.build();
c.property("com.ibm.ws.jaxrs.client.ltpa.handler", "true");

String res = "";
res = c.target("http://" + serverIP + ":" + serverPort + "/" + moduleName + "/rest/ltpa")
    .request()

c.close();
return res;
```

## JAX-RS 2.0 behavior changes

8.5.5.6

The JAX-RS 2.0 implementation contains some behavior changes. These changes might cause applications to behave differently or fail on JAX-RS 2.0 if the applications are upgraded from JAX-RS 1.1.

The following list describes the differences between JAX-RS 1.1 and JAX-RS 2.0:

- In JAX-RS 1.1 and Jersey, if an EJB or CDI class creates a new instance that is returned by the JAX-RS `application.getSingletons()` method, the engine uses the returned instance and does not try to access the instance from the EJB or CDI container. In JAX-RS 2.0, for the same scenario, the engine tries to access

the instance from the EJB or CDI container. If the instance can be accessed, the retrieved instance is used. But if the instance cannot be accessed, the returned instance from the `getSingletons()` method is used. For example:

```
@Override
public SetObject getSingletons() {
    SetObject objs = new HashSetObject();
    objs.add(new CDIInjectResource());
    objs.add(new EJBInjectResource());
    return objs;
}
```

- | • JAX-RS 2.0 includes many API changes when it handles the MultiPart file. For example, in JAX-RS 1.1, the `@FormParam` can be used to handle the MultiPart file, but in JAX-RS 2.0, only `@IMultipartBody` or `@IAttachment` can be used to handle the MultiPart file. For more information, see [Configuring a resource to receive multipart/form-data parts from an HTML form submission in JAX-RS 2.0](#).
- | • The jackson packages that are displayed as a third-party API in JAX-RS 1.1 are no longer displayed in JAX-RS 2.0. If you want to use any `org.codehaus.jackson` APIs in your application, you need to compress the jackson packages in your application.
- | • If you specify `javax.ws.rs.core.Application` for the servlet name in the `web.xml` file, the `getClasses` method in the Application object, which is injected by `@Context`, does not return the resource classes.

```
<servlet>
  <servlet-name>javax.ws.rs.core.Application</servlet-name>
</servlet>
<servlet-mapping>
  <servlet-name>javax.ws.rs.core.Application</servlet-name>
  <url-pattern>/*</url-pattern>
</servlet-mapping>
```

- The JAX-RS 2.0 specification states that a provider is a class that implements one or more JAX-RS interfaces and that can be annotated with `@Provider` for automatic discovery. In the scenario, a class has `@Local` annotation that refers to a provider interface, but it does not implement any POJO provider interface, and then it is an invalid provider. For example:

```
@Stateless
@Local(OneLocalInterfaceMyOtherStuffMessageBodyWriter.class)
public class OneLocalInterfaceMyOtherStuffProvide
```

- If you use the `MessageBodyReader` and `MessageBodyWriter` `@Consumes` and `@Produces` annotations, some supported media types might be restricted. Use the `isReadable` method or `isWriteable` method to check the media type. For example:

```
@Provider
@Consumes("<custom/type>")
@Produces("<custom/type>")
@Singleton
public class MyMessageBodyReaderAndWriter implements MessageBodyReader,MessageBodyWriter {

    public boolean isReadable(Class<?> type,
                             Type genericType,
                             Annotation[] annotations,
                             MediaType mediaType) {
        if (mediaType.toString().equals("<custom/type>"))
            return true;
        return false;
    }

    public boolean isWriteable(Class<?> type,
                              Type genericType,
                              Annotation[] annotations,
                              MediaType mediaType) {
        if (mediaType.toString().equals("<custom/type>"))
            return true;
    }
}
```

```

        return false;
    }
    ...
}

```

- You can use asynchronous processing in JAX-RS 2.0 to process threads. For more information, see “Asynchronous processing” on page 2159.
- None of the Wink APIs that are displayed as third-party APIs in JAX-RS 1.1 are supported in JAX-RS 2.0. Here is a partial list:

- `org.apache.wink.common.model.atom.AtomEntry`. For more information about integrating JAX-RS 2.0 with Atom, see “JAX-RS 2.0 integration with Atom” on page 2170.
- `org.apache.wink.client.handlers.BasicAuthSecurityHandler`. If you want to use basic authentication in JAX-RS 2.0, see the following code snippets:

1. Use `ClientRequestFilter` through the JAX-RS 2.0 standard Client API as shown in the code example:

```

import java.io.IOException;
import java.io.UnsupportedEncodingException;
import javax.ws.rs.client.ClientRequestContext;
import javax.ws.rs.client.ClientRequestFilter;
import javax.ws.rs.core.MultivaluedMap;
import javax.xml.bind.DatatypeConverter;

public class BasicAuthFilter implements ClientRequestFilter {

    private final String usr;
    private final String pwd;

    public BasicAuthFilter(String usr, String pwd) {
        this.usr = user;
        this.pwd = pwd;
    }

    public void filter(ClientRequestContext requestContext) throws IOException {
        MultivaluedMap<String, Object> headers = requestContext.getHeaders();

        String token = this.usr + ":" + this.pwd;
        final String basicAuthentication = "Basic " + DatatypeConverter.printBase64Binary(token.getBytes("UTF-8"));
        headers.add("Authorization", basicAuthentication);
    }
}

```

2. Register to the `ClientBuilder`:

```

ClientBuilder cb = ClientBuilder.newBuilder();
cb.register(new BasicAuthFilter("user","password"));

```

- `org.apache.wink.client.handlers.LtpaAuthSecurityHandler`. If you want to use the LTPA-based security client to secure downstream resources, see “Securing downstream JAX-RS resources” on page 2165.
- `org.apache.wink.server.internal.providers.exception.EJBAccessExceptionHandler`. This API is no longer supported because it is the Wink-specified `ExceptionHandler`. You can define your own `ExceptionHandler` to map the `EJBAccessException`.
- `com.ibm.websphere.jaxrs.server.IBMRestFilter`. This API is no longer supported because it is based on Wink Filter.

**Note:** Detect if there are wink jar packages in your application. If there are any wink packages in your application, you must do the following steps:

1. Make sure that there is `Application` subclass defined.
2. At least one of `getClasses` and `getSingletons` must not return null.

- For more information about the supported client properties that can be used in the JAX-RS 2.0 client, see [Configuring JAX-RS 2.0 client](#).

- If you want to use the Secure Sockets Layer (SSL) function in JAX-RS 2.0, do the following steps:
  1. Enable either the `ssl-1.0` feature or the `appSecurity-2.0` feature. For the LTPA token function, the `appSecurity-2.0` feature is required.

**Note:** The `ssl-1.0` feature is a sub-feature of the `appSecurity-2.0` feature. If you enable the `jaxrsClient-2.0` feature and the `ssl-1.0` feature, the `appSecurity-2.0` feature is automatically enabled.

2. Enable the `com.ibm.ws.jaxrs.client.ssl.config` property in the JAX-RS 2.0 client code as follows:

```
ClientBuilder cb = ClientBuilder.newBuilder();
Client c = cb.build();
c.property("com.ibm.ws.jaxrs.client.ssl.config", "mySSLConfig"); //mySSLConfig is the ssl ref id in Liberty server.xml
```

**Note:** This property can bind the Liberty SSL configuration to scopes of `ClientBuilder`, `Client`, and `WebTarget`.

- If you want to use the Wink Client in the JAX-RS 2.0 server run time, do the following steps:
  1. Download the following files that can enable Wink Client in the JAX-RS 2.0 server run time.
    - Download the Apache Wink and related JAR files from <http://wink.apache.org/downloads.html>.
    - Download the Apache HTTP and related JAR files from <http://hc.apache.org/>.

**Note:** If the JAX-RS 2.0 feature is not enabled, you must also download and add the JAX-RS API to the third-party lib. Download the JAX-RS API from <https://jax-rs-spec.java.net/nonav/>.

2. Save all JAR files into the `<third-party lib>` directory.
3. Add the location of `<third-party lib>` to the `server.xml` file:

```
<library id="thirdPartyLib">
  <fileset dir=" <third-party lib>" includes="*.jar" scanInterval="5s"/>
</library>
<enterpriseApplication id="<Your Ear ID>" location="<Your Ear Name>" name="<Your Ear Name>">
  <classloader commonLibraryRef="thirdPartyLib"/>
</enterpriseApplication>
```

**Note:** For more information about asynchronous processing in Client and Server APIs, see Chapter 8 of JSR 339: JAX-RS 2.0: The Java API for RESTful Web Services (the "Specification").

## JAX-RS 2.0 integration with Atom

8.5.5.8

JAX-RS 2.0 can use Apache Abdera to add Atom support.

You can register the following Apache Abdera-based providers with a JAX-RS endpoint and use resource methods to explicitly deal with Abdera Feed or Entry classes:

- Apache Abdera-based Feed provider: `net.wasdev.wlp.sample.abdera.jaxrs.atom.AtomFeedProvider`
- Apache Abdera-based Entry provider: `net.wasdev.wlp.sample.abdera.jaxrs.atom.AtomEntryProvider`

**Note:** Both `AtomFeedProvider` and `AtomEntryProvider` support a formatted Output property.

Now the JAX-RS 2.0 sample on GitHub supports both Maven and Gradle. The online instruction on GitHub also shows you how to use commands or WebSphere Development Tools (WDT) for Eclipse to build or test Liberty sample. For more information, see <https://github.com/WASdev/sample.abdera.jaxrs>.

**Note:** Apache CXF offers you other ways of integrating JAX-RS 2.0 with Atom. For more information, see <https://cxf.apache.org/docs/jax-rs-data-bindings.html#JAX-RSDataBindings-Atom>.

## JAX-RS 2.0 integration with EJB and CDI

8.5.5.6

JAX-RS 2.0 in Liberty integrates with Enterprise JavaBeans (EJB) and Contexts and Dependency Injection (CDI).

For JAX-RS 2.0 to work with enterprise beans, you need to use `@Path` to annotate the class of a bean and convert it to a root resource class.

By integrating with EJB, you can annotate the EJB beans to expose them as REST endpoints. You can also use the JTA and security functions of EJB. JAX-RS 2.0 in Liberty supports the use of stateless and singleton session beans as root resource classes, providers, and application subclasses. By integrating with CDI, you can annotate CDI beans or Managed beans as REST endpoints and use CDI injection for web services. JAX-RS 2.0 in Liberty supports CDI-style beans as root resource classes, providers, and application subclasses. Providers and application subclasses must be singletons or use the application scope. CDI specification makes it easier to integrate Java EE components of different types. It provides a common mechanism to inject component such as EJB components or Managed beans into other components such as JSPs or other EJBs.

For EJB, you can use annotation with stateless session beans and singleton POJO beans.

- For a stateless session bean, use the `@Stateless` annotation as is shown in the following example:

```
@Stateless
@Path("stateless-bean")
public class StatelessResource {...}
```

- For a singleton bean, use the `@Singleton` annotation as is shown in the following example:

```
@Singleton
@Path("singleton-bean")
public class SingletonResource {...}
```

For CDI, you can use the `@ApplicationScoped` and `@Inject` annotations with application scoped beans.

**Tip:** If the CDI feature is disabled, JAX-RS reports no errors, but the instances are obtained by using POJO.

```
@ApplicationScoped
@Path("/ApplicationScopedResource")
public class ApplicationScopedResource {

    private @Inject
    SimpleBean injected;

    ...
}
```

### Restrictions on JAX-RS 2.0 with EJB and CDI

See the following items for the restrictions of JAX-RS 2.0 in Liberty:

- If you use EJB as JAX-RS resource, provider or application, you cannot use the `@Context` injection on constructor of the EJB bean. The reason is that the EJB with default constructor can only be used for JAX-RS according to EJB and JAX-RS specification.
- If you use EJB or CDI annotation in a Java class, but the Liberty feature for EJB (such as `ejbLite-3.2`) or CDI (such as `cdi-1.0`) is not configured in the `server.xml` file, which means there are no EJB or CDI supports in Liberty run time, then the JAX-RS 2.0 engine uses the Java class as POJO class.
- For an Application class, if it implements no interface or it has `@LocalBean` annotation, it is seen as EJB; if it implements local or POJO interfaces, it is not seen as EJB.

- For a Provider:
  - If a class implements POJO provider interfaces only without the `@Local` annotation, it is seen as a valid EJB provider.
  - If a class has the `@LocalBean` annotation and it implements the POJO provider interface, then it is seen as a valid EJB provider.
  - If a class has the local interface with the `@Local` annotation, the local interface is a provider interface. If this class implements the provider interface, then it is a valid EJB provider.
  - If a class has a local interface with `@Local` annotation, and if the local interface is not a provider interface, then it is not a valid provider.  
The reason is that in this case, EJB container can generate EJB stub for the local interface only rather than the POJO provider interface.
  - If a class has the `@Local` annotation only that refers a provider interface, but it does not implement this provider interface, then it is not a valid provider according to the JAX-RS 2.0 specification: A provider is a class that implements one or more JAX-RS interfaces that are introduced in this specification and that might be annotated with `@Provider` for automatic discovery.
- For Resource:
  - If EJB-based resource does not implement any interface, all of the methods that are declared in this class are available as JAX-RS resources.
  - If EJB-based resource implements one interface (local or POJO), then all the methods that are declared in this interface are available as JAX-RS resources.
  - If EJB-based resource implements multiple interface,
    1. If all the interfaces are POJO interfaces without the `@Local` annotation, then all the methods that are declared in interface are available as JAX-RS resources.
    2. If all the interfaces are local interfaces with the `@Local` annotation, then all the methods that are declared in the interface are available as JAX-RS resources.
    3. If some of the interfaces are local interfaces with the `@Local` annotation while others are not local interfaces, then only the methods declared in the local interfaces are available as JAX-RS resources. The reason is that the EJB container can generate EJB stub for local interfaces only in this scenario.
    4. If the EJB-based resource has the `@LocalBean` annotation, then all the methods that are declared in class are available as JAX-RS resource.
    5. If EJB-based resource implements an interface, then JAX-RS resource method must be declared in the interface. If the interface is a provider that can't be modified, then you must create a new interface for the resource class to add the resource method. Otherwise, it is not seen as EJB resource.
  - If a resource class with the `@Path` annotation implements JAX-RS provider interface or it declares with the `@Provider` annotation, this class works as both a resource and a provider. In this case, by default, the JAX-RS 2.0 engine uses only one instance of this class that is shared by the resource and the provider, and the lifecycle of the instance is singleton.
  - If a class is registered in both the `getClasses` and `getSingletons` methods of the application class, then by default, the JAX-RS 2.0 engine uses the instance from the `getSingletons` method and ignore the registration in the `getClasses` method.
  - If a RESTful resource is also a CDI managed bean and its scope is `javax.enterprise.context.Dependent`, the `PreDestroy` method cannot be called because of the CDI restriction.

## JAX-RS 2.0 bean and EJB bean lifecycle

JAX-RS bean and EJB bean have different lifecycle. If the bean lifecycle of JAX-RS and EJB conflicts, the lifecycle is managed by EJB container in Liberty. So the EJB instance is applied while the JAX-RS lifecycle does not work. For more information, see the following table:

Table 171. JAX-RS 2.0 bean and EJB bean lifecycle

Application	JAX-RS 2.0	EJB	Result
Resource	perRequest	Stateless	Stateless
	perRequest	Singleton	Singleton
	Singleton	Stateless	Stateless
	Singleton	Singleton	Singleton
Provider	Singleton	Stateless	Stateless
	Singleton	Singleton	Singleton

## JAX-RS 2.0 scope and CDI scope lifecycle

Beans have a scope that determines the lifecycle of its instances. JAX-RS and CDI have slightly different scopes. If the cope lifecycle of JAX-RS and CDI conflict, see the following table for the result:

Table 172. JAX-RS 2.0 scope and CDI scope lifecycle

Application	JAX-RS 2.0 Scope	CDI Scope annotation	Result
Resource	perRequest	@ApplicationScoped	Singleton
	perRequest	@RequestScoped	perRequest
	perRequest	@Dependent	perRequest
	perRequest	@SessionScoped	Session
	perRequest		perRequest
	Singleton	@ApplicationScoped	Singleton
	Singleton	@RequestScoped	perRequest
	Singleton	@Dependent	Singleton
	Singleton	@SessionScoped	Session
	Singleton		Singleton
Provider	Singleton	@ApplicationScoped	Singleton
	Singleton	@RequestScoped	Singleton
	Singleton	@Dependent	Singleton
	Singleton	@SessionScoped	Singleton
	Singleton		Singleton

## JAX-RS 2.0 scope and CDI scope lifecycle conflict messages

The following warning messages are displayed when the scope lifecycle of JAX-RS 2.0 and CDI conflicts. They are warning messages and no actions are required.

- 

CWWKW1001W: The scope {1} of JAXRS-2.0 Resource {0} does not match the CDI scope {2}. Liberty gets resource instance f

This message is displayed if the JAXRS-2.0 resource scope does not match the CDI scope and the resource instance exists in CDI, so Liberty gets the resource instance from CDI. Instance does not include CDI injection if it is from JAXRS.

- CWWKW1002W: The CDI scope of JAXRS-2.0 Provider {0} is {1}. Liberty gets the provider instance from {2}.

This message is displayed because provider instance is Singleton only. Liberty gets provider instance from CDI if the CDI scope of provider is Dependent or ApplicationScoped. Instance does not include CDI injection if it is from JAXRS.

## JAX-RS 2.0 integration with managed beans

8.5.5.8

JAX-RS 2.0 in Liberty supports the use of managed beans as root resource classes, providers, and application subclasses.

- To integrate JAX-RS 2.0 with managed beans, add the `<feature>managedBeans-1.0</feature>` entry inside the `featureManager` element in the `server.xml` file.
- To use a managed bean as a JAX-RS resource, provider, or application, use the `@ManagedBean` to annotate these classes.

For example, use the Interceptors managed bean feature as follows:

```
@ManagedBean ("JaxrsManagedBean" )
@Path ("/managedbean" )
public class ManagedBeanResource {

    public static class MyInterceptor {
        @AroundInvoke
        public Object around(InvocationContext ctx) throws Exception {
            System. out .println("around() called" );
            return ctx.proceed();
        }
    }

    @GET
    @Produces( "text/plain")
    @Interceptors(MyInterceptor. class )
    public String getIt() {
        return "Hi managed bean!" ;
    }
}
```

## Restrictions on JAX-RS 2.0 with managed beans

Resource injection is only supported by the following JAX-RS component classes that are managed by Contexts and Dependency Injection (CDI):

- Application subclasses
- Providers
- Root resource classes

Specifically, to inject a managed bean instance into a certain JAX-RS component class, you must ensure that this component class can be recognized and managed as a CDI bean.

For example, to inject the `printMyName` managed bean instance into a JAX-RS root resource class as follows, you must add an empty `beans.xml` file in the `.WAR` file/`WEB-INF` repository:

```
@Path ("/managedbean" )
public class ManagedBeanResource {

    @Resource(name = "printMyName" )
    private PrintMyName printMyName ;
}
```

```

@GET
@Produces( "text/plain")
public String getIt() {
    printMyName .print();
    return "Hi managed bean!" ;
}
}

@ManagedBean ("printmyname" )
public class PrintMyName {

    public void print() {
        // TODO Auto-generated method stub
        System. out .println("Injection of ManagedBean is successful" );
    }

}

```

## Sending multiple query parameters from Client - Cascaded or Iterated programming

8.5.5.6

You can see the following sample if you want to send multiple query parameters from the client side to the server.

### About this task

**Note:** Normally, the way to put multiple query parameters in a WebTarget object is by using the following cascaded programming mode:

```
javax.ws.rs.core.Response response = client.target(...).queryParam(key, value).queryParam(key, value).queryParam(key, value);
```

However, in some cases, the cascaded programming mode does not apply because the number of key value pairs is flexible and cannot be predicated. For these cases, you can use the following iteration based programming mode:

```

Map<String, String> queryStrings;
...
javax.ws.rs.client.WebTarget target = client.target(...);
for (String key: queryStrings.keySet()){
    String value = queryStrings.get(key);
    target = target.queryParam(key, value); //It is important to know queryParam method won't update current WebTarget object
}
}
javax.ws.rs.core.Response response = target.request().get();

```

## Using JAX-RS 2.0 context objects to obtain more information about requests

8.5.5.6

Java API for RESTful Web Services (JAX-RS) 2.0 provides different types of context to application subclasses, root resource classes, and providers. You can use the @Context annotation to inject context objects such as HttpHeaders, UriInfo, HttpServletRequest into class field or method parameter in application subclasses, root resource classes, and providers.

### About this task

You can use the following context objects that are available to providers (client and server), resource classes (server only), and Application subclasses (server only):

Context object	Type	Description
Application	Class	The instance of the application-supplied <code>Application</code> subclass can be injected into a class field or method parameter using the <code>@Context</code> annotation. Access to the <code>Application</code> subclass instance allows configuration information to be centralized in that class. <b>Note:</b> This <code>Application</code> subclass cannot be injected into the <code>Application</code> subclass itself since this would create a circular dependency.
UriInfo	Interface	The <code>UriInfo</code> interface provides static and dynamic, per-request information, about the components of a request URI.
HttpHeaders	Interface	The <code>HttpHeaders</code> interface provides access to request header information either in map form or via strongly typed convenience methods.
Request	Interface	The <code>Request</code> interface allows a caller to determine the best matching representation variant and to evaluate whether the current state of the resource matches any preconditions in the request.
SecurityContext	Interface	The <code>SecurityContext</code> interface provides access to information about the security context of the current request.
Providers	Interface	The <code>Providers</code> interface allows for lookup of provider instances based on a set of search criteria.
ResourceContext	Interface	The <code>ResourceContext</code> interface provides access to instantiation and initialization of resource or subresource classes in the default per-request scope.
Configuration	Interface	Both the client and the server runtime configurations are available for injection via <code>@Context</code> . These configurations are available for injection in providers (client or server) and resource classes (server only).

## WADL2JAVA command

8.5.5.6

The **wadl2java** command line tool processes an existing Web Application Description Language (WADL) file and generates the required artifacts for developing Java API for RESTful Web Services (JAX-RS) web service applications. The **wadl2java** command line tool supports the top-down approach to developing JAX-RS web services. When you start with an existing WADL file, use the `wadl2java` command line tool to generate the required JAX-RS artifacts.

## Web Application Description Language (WADL)

WADL is a resource-centric description language that is designed to facilitate the modeling, description, and testing of RESTful web applications. For more information, see Web Application Description Language.

### Syntax

The command syntax is as follows:

```
wadl2java --[options]
```

```
wadl2java -wadlns wadl-namespace -p package-name -sp [schema-namespace =]package-name -tMap schema-type=java-t
```

### Parameters

The following *options* values are available for the **wadl2java** command:

- wadlns** *wadl-namespace*  
Specify the WADL namespace.
- p** *package-name*  
Specifies the Java package name to use for the generated code that represents WADL resource elements.
- sp** [*schema-namespace =*]*package-name*  
Specifies the Java package name to use for the generated code that represents WADL grammar elements. Optionally specify a namespace to Java package name mapping.
- tMap** *schema-type=java-type* \*  
Specifies the optional mapping between WADL parameter or representation schema type and custom Java type.
- repMap** *media-type=class-name* \*  
Specifies the optional mapping between a WADL representation with no **wadl:element** attribute and Java class.
- resource** *resource-name*  
Specify the simple class name to use for the generated code code that represents a WADL resource without the id attribute.
- b** *binding-file-name* \*  
Specify external jaxb binding files. Use one **-b** flag for each binding file.
- catalog** *catalog-file-name*  
Specify catalog file to map the imported wadl or schema.
- d** *output-directory*  
Specify the directory into which the code is placed.
- interface**  
Specifies that interface is generated.
- impl** Specifies that a dummy service implementation is generated.
- async** *methodNames* \*  
Specifies a comma-separated list of method names or identifiers that need to support suspended asynchronous invocations.
- generateEnums**  
Specifies that Enum classes can be generated to represent parameters with multiple options.
- inheritResourceParams**  
Specifies that resource-level (path or matrix) parameters can be inherited by child resources.

**-noTypes**

Turns off generating types

**-noVoidForEmptyResponses**

Use JAX-RS Response return type for methods with no response representation.

**-noAddressBinding**

Specifies that the generator might not use the address jaxb binding file to map `wsa:EndpointReferenceType` or `wsa:EndpointReference` to `javax.xml.ws.wsaddressing.W3CEndpointReference`.

**-supportMultipleXmlReps**

Specifies that if a method contains multiple request XML representations then a separate method per every such representation is generated. Do not enable this option when a server-side JAX-RS code is generated. A single method that contains a `javax.xml.transform`. Source input parameter is generated by default such cases.

**-generateResponseIfHeadersSet**

Use JAX-RS Response return type if WADL Response element has 'header' parameters.

**-generateResponseForMethods *methodNames* \***

Specifies a comma-separated list of method names or identifiers that need to have JAXRS Response return type generated.

**-async *methodNames* \***

Specifies a comma-separated list of method names or identifiers that need to support suspended asynchronous invocations.

**-xjc *xjc-argumentsv* \***

Specifies a comma-separated list of arguments that are passed directly to XJC when the JAXB data binding is used. This option causes XJC to load extra plug-ins that augment code generation. For example, to load the `toString(ts)` plug-in that adds a `toString()` method to all generated types the following *arguments* would be used: `-xjc-Xts` A list of available XJC plug-ins can be obtained by using `-xjc-X`.

**-encoding *encoding***

Specifies the charset encoding to use when Java sources are generated.

**-h|-?|-help**

Display detailed information for options.

**-version|-v**

Display the version of the tool.

**-verbose|-V**

Specifies that the generator runs in verbose mode.

**-quiet|-q|-Q**

`-quiet|-q|-Q`

**wadl** `wadl-url`

## Deploying JAX-WS applications to Liberty

8.5.5.0

You can use Java API for XML-based Web Services (JAX-WS) to develop services and deploy your JAX-WS applications to the Liberty profile. The Liberty feature `jaxws-2.2` supports the JAX-WS programming model.

### Customizing web services endpoints

8.5.5.0

You can use the `ibm-ws-bnd.xml` file to customize web services endpoints for server provider and client within your applications.

## Before you begin

The `ibm-ws-bnd.xml` file must be in the `/WEB-INF` directory of a web-based web services application (WAR file), or in the `/META-INF` directory of a EJB-based web service application (JAR file). If the client is running in `clientContainer`, the `ibm-ws-bnd.xml` file must be in the `/META-INF` directory of the JAR file in the client EAR.

## About this task

By configuring the `ibm-ws-bnd.xml` file, you can override the web services address configurations on both the service provider and consumer, export your web services by using a specific URL in your applications that are deployed on Liberty, and import the web services from JAX-WS client applications.

For all available elements that you can configure within the `ibm-ws-bnd.xml` file, see “Liberty:The `ibm-ws-bnd.xml` file” on page 2186.

## Procedure

### 1. Override web services bindings for service providers.

- a. Override the web services endpoint address. In the `webservice-endpoint` element, you can override the endpoint address of a web service endpoint identified by the **port-component-name** attribute. The **address** attribute specifies the relative path to the context root of your application.

```
<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0_0
  version="1.0">
  <!-- 0 to many endpoint descriptions -->
  <webservice-endpoint port-component-name="Hello" address="/hiService" />
</webservices-bnd>
```

- b. Override the context root for EJB based web services. If the web service is an EJB-based web service and defined in an EJB application (JAR archive), the default context root is the EJB jar name. However, you can override the default value using the **context-root** attribute of the `http-publishing` element.

```
<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0_0
  version="1.0">
  <!-- optional http publishing module overrides -->
  <http-publishing context-root="/HiServer" />
</webservices-bnd>
```

**Note:** The **context-root** attribute takes effective only when the web service is an EJB based web service and defined in an EJB jar archive. If the web service is defined in a web application (WAR archive), no matter if it is an EJB based web service, the **context-root** attribute of the `http-publishing` element is ignored, and the context root will always be the context root of the web application.

### 2. Override web services bindings for client applications.

- a. Override the location of the WSDL document. In the `service-ref` element, you can override the WSDL location of a web service reference within a web service client application.

```
<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
```

```

    xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0.x
    version="1.0">
    <service-ref name="services/hello" wsdl-location="http://localhost:9080/HiServer/hiService?wsdl" />
</webservices-bnd>

```

The **wsdl-location** attribute specifies an absolute URI (either HTTP or file protocol), and it can also be a relative URI to the root of the client application. For example:

```

<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0.x
    version="1.0">
    <service-ref name="services/hello" wsdl-location="WEB-INF/wsdl/hiService.wsdl" />
</webservices-bnd>

```

- b. Override the Port Address. In the port element, you can override the address of a port within web service reference in a web service client.

```

<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0.x
    version="1.0">
    <service-ref name="services/hello" wsdl-location="WEB-INF/wsdl/hiService.wsdl">
        <port name="HelloPort" namespace="http://server.ejb.hello.sample.jaxws.ws.ibm.com/"
            address="http://localhost:9080/HiServer/hiService" />
    </service-ref>
</webservices-bnd>

```

The **address** attribute of the port element specifies the absolute URI of a web service port. If the referenced web service only has one port, you can use the **port-address** attribute of the service-ref element. For example:

```

<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0.x
    version="1.0">
    <service-ref name="services/hello"
        port-address="http://localhost:9080/HiServer/hiService" />
</webservices-bnd>

```

**Note:** If the **port-address** attribute of the service-ref element and the **address** attribute of the port element are both specified, the **address** attribute of the port element takes effect.

## Defining web service policy via policy attachment

In Liberty, you can define your web service policy (WS-Policy) within either policy attachment or Web Services Description Language (WSDL) file of a web service application.

### About this task

When WSDL file is not packaged in your application, you can use the policy attachment to configure the WS-Policy for your web service application. Policy attachment feature is often enabled automatically to your web service application package when you enable Java API for XML Web Services (JAX-WS) 2.2 feature. You only need to configure both web services client and provider sides to define the application's WS-Policy Attachment file.

The WS-Policy support is an implementation of the following specifications on the application server.

- WS-Policy is a specification that web services can use XML to advertise their policies on security, quality of service, and for web service consumers to specify their policy requirements. For more information, see Web Services Policy 1.5 - Framework.

- WS-Policy Attachment defines two general-purpose mechanisms for associating policies, as defined in Web Services Policy Framework, with the subjects to which they apply. For more information, see Web Services Policy 1.2 - Attachment.

## Procedure

1. Create `policy-attachments-client.xml` file or `policy-attachments-server.xml` file.

The following example shows you how to define the attributes in `policy-attachments-client.xml` file or `policy-attachments-server.xml` file:

```
<attachments
xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
xmlns:wsp="http://www.w3.org/ns/ws-policy"
xmlns:wsa="http://www.w3.org/2005/08/addressing"
xmlns:sp13="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200802"
xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702">
<wsp:PolicyAttachment wsdlNamespace="http://tempuri.org/AreaService/">
  <wsp:AppliesTo>
    <wsp:URI>http://tempuri.org/AreaService/#wsdl11.service(AreaService)</wsp:URI>
  </wsp:AppliesTo>
  <wsp:Policy wsu:Id="UsernameTokenwithPasswordHashoverSSL">
    <wsp:ExactlyOne>
      <wsp:All>
        <sp:SupportingTokens>
          <wsp:Policy>
            <sp:UsernameToken sp:IncludeToken="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702/IncludeToken" />
            <wsp:Policy>
              <sp:WssUsernameToken10 />
              <sp:HashPassword />
            </wsp:Policy>
          </sp:UsernameToken>
        </wsp:Policy>
      </sp:SupportingTokens>
    </wsp:All>
  </wsp:ExactlyOne>
</wsp:Policy>
</wsp:PolicyAttachment>
</attachments>
```

There are two ways of binding policy:

- Define web service URL directly by using Endpoint DomainExpression **<wsa:EndpointReference>** as follows.

```
<wsp:AppliesTo>
  <wsa:EndpointReference>
    <wsa:Address>http://localhost:8091/wsatapp/HelloImplService</wsa:Address>
  </wsa:EndpointReference>
</wsp:AppliesTo>
```

- Bind policy by using URI DomainExpression **<wsp:URI>** as follows.

```
<wsp:AppliesTo>
  <wsp:URI>http://server.test.ws.ibm.com/#wsdl11.service(HelloImplService)</wsp:URI>
</wsp:AppliesTo>
```

The following table shows you the WSDL elements and their identifier expressions in the policy attachment file:

Table 173. `<wsp:URI>` Expression list

WSDL Element	Identifier Expression (Omit targetNamespace)
Definitions	<code>wsdl11.definitions()</code>
Message	<code>wsdl11.message(message)</code>
Message/part	<code>wsdl11.messagePart(message / part)</code>
portType	<code>wsdl11.portType(portType)</code>
portType/operation	<code>wsdl11.portTypeOperation(portType/operation)</code>

Table 173. <wsp:URI> Expression list (continued)

WSDL Element	Identifier Expression (Omit targetNamespace)
portType/operation/input	wsdl11.portTypeOperation.input(portType/operation)
portType/operation/output	wsdl11.portTypeOperation.output(portType/operation)
portType/operation/fault	wsdl11.portTypeOperation.fault(portType/operation/fault)
Binding	wsdl11.binding(binding)
Binding/operation	wsdl11.bindingOperation(binding/operation)
Binding/operation/input	wsdl11.bindingOperation.input(binding/operation)
Binding/operation/output	wsdl11.bindingOperation.output(binding/operation)
Binding/operation/fault	wsdl11.bindingOperation.fault(binding/operation/fault)
Service	wsdl11.service(service)
port	wsdl11.port(service/port)

- Put the policy-attachments-client.xml file or policy-attachments-server.xml file into your application's WEB-INF or META-INF folder.
  - Put policy-attachments-client.xml into your application's WEB-INF or META-INF folder for web service client's WS-Policy.
  - Put policy-attachments-server.xml into your application's WEB-INF or META-INF folder for web service provider's WS-Policy.

## Results

You complete to define the WS-Policy via policy attachment without WSDL file packaged in your application.

## Enabling HTTP conduit client properties and user custom properties

8.5.5.0

You can define the HTTP client properties and user custom properties by using the ibm-ws-bnd.xml file for JAX-WS applications on Liberty.

### Before you begin

The ibm-ws-bnd.xml file must be in the /WEB-INF directory of a web-based web services application (WAR file), or in the /META-INF directory of a EJB-based web service application (JAR file). If the client is running in clientContainer, the ibm-ws-bnd.xml file must be in the /META-INF directory of the JAR file in the client EAR.

### About this task

HTTP client properties and user custom properties can be defined by using the service-ref and port elements in the ibm-ws-bnd.xml file for the specific service client or port that is injected by the @WebServiceRef annotation. Properties in the port element override the same properties in the service-ref element.

#### HTTP client properties

The following HTTP client properties are supported in the Liberty profile; these properties must have the prefix **http.conduit.client..** For example: **http.conduit.client.ConnectionTimeout.** These HTTP client properties are valid only when sending or receiving SOAP messages, and they are not applicable when connecting to a WSDL URL.

- ConnectionTimeout**

- **ReceiveTimeout**
- **AsyncExecuteTimeout**
- **AsyncExecuteTimeoutRejection**
- **AutoRedirect**
- **MaxRetransmits**
- **AllowChunking**
- **ChunkingThreshold**
- **Connection**
- **DecoupledEndpoint**
- **ProxyServer**
- **ProxyServerPort**
- **ProxyServerType**
- **NonProxyHosts**

For more information about these properties, see HTTP configuration schema in Apache CXF and Client HTTP Transport (including SSL support) .

### User Custom Properties

Besides the supported HTTP client properties in Liberty, you can define the user custom properties that might be used in your application, and retrieve these properties from the client request context. All attributes defined in the `properties` element will be put into the service client request context.

For all available elements that you can configure within the `ibm-ws-bnd.xml` file, see “Liberty:The `ibm-ws-bnd.xml` file” on page 2186.

### Procedure

1. Configure HTTP conduit properties. The following examples shows how to configure HTTP client properties **ConnectionTimeout** and **ReceiveTimeout** in the `ibm-ws-bnd.xml` file. The following example shows how to apply the HTTP client properties **ConnectionTimeout** and **ReceiveTimeout** for all the ports of the service client injected by using the `@WebServiceRef(name="service/SimpleEchoService")`, and for the port `SimpleEchoPort`, the value of user custom property **vendor** is also applied.

```
<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_1_0
  version="1.0">
  <service-ref name="service/SimpleEchoService">
    <port name="SimpleEchoPort">
      <properties vendor="IBM" />
    </port>
    <properties http.conduit.client.ConnectionTimeout="10000"
      http.conduit.client.ReceiveTimeout="15000" />
  </service-ref>
  ...
</webservices-bnd>
```

2. Then retrieve the properties defined in the `ibm-ws-bnd.xml` file from the request context of the client that is injected by the `@WebServiceRef(name="service/SimpleEchoService")` annotation as follows.

```
@WebServiceRef(name="service/SimpleEchoService")
private EchoService echoService;
...
Echo echo = echoService.getEchoPort();
BindingProvider bp = (BindingProvider)echo;
```

```
String connTimeout = bp.getRequestContext().get("http.conduit.client.ConnectionTimeout").toString();
String recTimeout = bp.getRequestContext().get("http.conduit.client.ReceiveTimeout").toString();
String vendor = bp.getRequestContext().get("vendor").toString();
...
```

## Enforcing adherence to WSDL bindings in JAX-WS web services

### 8.5.5.0

You can add binding extensions in the WSDL document, and then apply the extensions into your applications with JAX-WS support on Liberty.

### About this task

Liberty supports the use of the `wsdl:binding` extension that is required in the JAX-WS 2.2 specification. This topic describes how to define the WSDL extensions, and bind them with the customized extensibility element in Liberty.

### Procedure

1. Define an extensibility element and map it to the user that is defined in the WSDL extension. The following example shows how to bind with the WSDL extension `{http://server.respectbinding.jaxws22/}goodBinding`.

```
@XmlElement(name = "goodBinding", namespace = "http://server.respectbinding.jaxws22/")
public class GoodBindingElement implements ExtensibilityElement, Serializable {
    private String uri;
    private QName elementType = null;
    private Boolean required = null;

    @XmlAttribute(name = "uri")
    public String getUri() {
        return this.uri;
    }

    @Override
    public QName getElementType() {
        return this.elementType;
    }

    @XmlAttribute(name = "required", namespace="http://schemas.xmlsoap.org/wsdl/")
    public Boolean getRequired() {
        return this.required;
    }

    public void setUri(String uri){
        this.uri = uri;
    }

    @Override
    public void setElementType(QName elementType) {
        this.elementType = elementType;
    }

    @Override
    public void setRequired(Boolean required) {
        this.required = required;
    }
}
```

2. Add the `extensions.xml` file into the `/META-INF` directory of your web or EJB application. This file defines where the extensions can be used in the WSDL document. In the following example, an entry to set the `javax.wsdl.Binding` property as the parent type of the `goodBindingElement` class is added in

the extensions.xml file. The entry also means that the extension {http://server.respectbinding.jaxws22/}goodBinding can be only added under the binding element in the WSDL document.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE properties SYSTEM "http://java.sun.com/dtd/properties.dtd">
```

```
<properties>
  <!-- XML Binding -->
  <entry key="org.apache.cxf.bindings.xml-1">javax.wsdl.Binding=jaxws22.respectbinding.server.common.GoodBindingEl
</properties>
```

3. Add the extension {http://server.respectbinding.jaxws22/}goodBinding under the binding element as follows:

```
...
<binding name="EchoPortBinding" type="tns:Echo">
  <soap:binding transport="http://schemas.xmlsoap.org/soap/http" style="document"/>
  <tns:goodBinding wsdl:required="true" uri="http://good/good" xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/" />
  <operation name="echo">
    <soap:operation soapAction="" />
    <input>
      <soap:body use="literal"/>
    </input>
    <output>
      <soap:body use="literal"/>
    </output>
    <fault name="Exception">
      <soap:fault name="Exception" use="literal"/>
    </fault>
  </operation>
</binding>
...
```

## Liberty:Implementation of JAX-WS client applications

### 8.5.5.0

You can use the Java API for XML-Based Web Services (JAX-WS) client-side programming model support in Liberty.

#### Implementing static JAX-WS web services clients

You can develop static web services clients based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification and the Java API for XML-Based Web Services (JAX-WS) programming model.

For more information, see [Implementing static JAX-WS web services clients](#).

#### Implementing dynamic JAX-WS web services clients

You can develop dynamic web services clients based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification and the Java API for XML-Based Web Services (JAX-WS) programming model.

For more information, see [Implementing dynamic JAX-WS web services clients](#).

#### Running an unmanaged web services JAX-WS client

You can use the Thin Client for JAX-WS with WebSphere Application Server as a standalone client run time in a pure Java SE environment, or in an OSGi environment. If you are running the Thin Client with non-IBM JDK for Liberty, add the `-Dcom.ibm.websphere.thinclient=true` property on the Java launch command line.

For more information, see [Running an unmanaged web services JAX-WS client](#).

#### Running a managed web services JAX-WS client

You can use the `@WebServiceRef` or `@Resource` annotation to inject instances of a JAX-WS service or endpoint, or you can use Java Naming and Directory Interface (JNDI) look up to perform service lookup.

For more information, see managed clients on Implementing static JAX-WS web services clients and Implementing dynamic JAX-WS web services clients.

**Note:** The following sections, and any subtopics, are not relevant to Liberty:

- Set up a development environment for web services
- WebSphere Application Server default directories
- Deploying web services applications onto application servers

For more information about the `jaxws-2.2` feature, see Liberty features.

## Liberty:Implementation of JAX-WS web services applications

8.5.5.0

You can use Java API for XML-Based Web Services (JAX-WS) server-side programming model support in Liberty.

### Implementing web services applications with JAX-WS

When starting from existing JavaBeans or enterprise beans, you can use a bottom-up approach to developing Web services based on the Java API for XML-Based Web Services (JAX-WS) programming model.

For more information, see Implementing web services applications with JAX-WS.

### Implementing web services applications from existing WSDL files with JAX-WS

When starting with an existing Web Services Description Language (WSDL) file, you can use a top-down approach to developing web services based on the Java API for XML-Based Web Services (JAX-WS) programming model.

For more information, see Implementing web services applications from existing WSDL files with JAX-WS.

**Note:** The following sections, and any subtopics, are not relevant to Liberty:

- Set up a development environment for web services
- WebSphere Application Server default directories
- Deploying web services applications onto application servers

For more information about the `jaxws-2.2` feature, see Liberty features.

## Liberty:The `ibm-ws-bnd.xml` file

8.5.5.0

You can customize web services endpoints and configure security settings for both web services providers and web service clients by using the `ibm-ws-bnd.xml` file in Liberty. You must store this file in the `/WEB-INF` directory of your web application or in the `/META-INF` directory of your EJB module.

The `ibm-ws-bnd.xml` file provides the following element hierarchy:

- `<webservices-bnd>`
  - `<webservice-endpoint-properties>`
  - `<webservice-endpoint>`
  - `<properties>`

- <http-publishing>
  - <webservice-security>
- <service-ref>
  - <properties>
  - <port>
    - <properties>

The description of each element in the `ibm-ws-bnd.xml` file is as follows:

### <webservice-endpoint-properties>

This element is used to define the default properties for all the web services endpoints in the same module. Only one `webservice-endpoint-properties` element can be specified for one module. You can specify any name and value pairs that are applicable to web services endpoint as attributes of the `webservice-endpoint-properties` element.

### <webservice-endpoint>

This element is used to specify the binding for a specified service instance. It has the following attributes:

- **port-component-name:** This attribute is required. It is used to specify the name of a port component.
- **address:** This attribute is optional. It is used to specify the overridden address of a service endpoint.

### <http-publishing>

This element is used to specify the publishing configurations when using HTTP protocol for all the web services endpoints. Only one `<http-publishing>` element can be specified in each module. It has the following attribute:

- **context-root:** This attribute is optional. It is used to specify the context root of the EJB module in an EJB-based JAX-WS application.

### <webservice-security>

This element is used to configure role-based authorization for POJO web services and EJB-based web services. It has the following attributes:

- **security-constraint:** This attribute is optional. It is used to associate security constraints with one or more web resource collections, and only works as complementary configuration of the deployment descriptors or annotations in web applications.
- **security-role:** This attribute is optional. It contains the definition of a security role, and only works as complementary configuration of the deployment descriptors or annotations in web applications.
- **login-config:** This attribute is optional. It is used to configure the authentication method and realm name, and takes effect only for the EJB-based web services in a JAR file. If the same attribute is specified in the deployment descriptor file, the value from the deployment descriptor is used. The value of this attribute must be *BASIC* or *CLIENT\_CERT*.

### <service-ref>

This element is used to define the web services reference configurations for a web services client. It has the following attributes:

- **name:** This attribute is required. It is used to specify the name of a web services reference.
- **component-name:** This attribute is optional. It is used to specify the EJB bean name if the service reference is used in an EJB module.

- **port-address**: This attribute is optional. It is used to specify the address of the web services port if the referenced web services has only one port.
- **wsdl-location**: This attribute is optional. It is used to specify the URL of a WSDL to be overridden.

## <port>

This element is used to define port configurations that are associated with the web services reference. Multiple port elements can be defined within a `service-ref` element. It has the following attributes:

- **name**: This attribute is required. It is used to specify the name of the web services port.
- **namespace**: This attribute is optional. It is used to specify the namespace of the web services port. If the **namespace** attribute is present, the binding is applied to the port that has the same name and namespace. Otherwise, the binding is applied to the port that has the same name.
- **address**: This attribute is optional. It is used to specify the address for the web services port. If present, it overrides the value of **port-address** attribute that is defined in the `service-ref` element.
- **username**: This attribute is optional. It is used to specify the user name for the basic authentication.
- **password**: This attribute is optional. It is used to specify the password for the basic authentication. The password can be encoded.
- **ssl-ref**: This attribute is optional. It refers to the `ssl` element that is configured in the `server.xml` file by using the **id** attribute. If the attribute is not specified but the server supports the transport level security by enabling the `ssl-1.0` feature, the service client uses the default SSL configuration of Liberty.
- **key-alias**: This attribute is optional. It is used to specify the alias of client certificate. If the attribute is not specified, and the web service provider supports the client certificate, then the first certificate in the keystore is used as the value of this attribute. The attribute can also override the **clientKeyAlias** attribute that is defined in the `ssl` element of the `server.xml` file.

## <properties>

This element is used to define the properties for a web services endpoint or client. The attributes can be any name and any value.

- For web service clients, you can specify **client.ConnectionTimeout**, **authorization.UserName**, **tlsClientParameters.disableCNcheck** and other attributes.
- For web service endpoint, you could specify **publishedEndpointUrl**, **org.apache.cxf.wsdl.create.imports** and other attributes.

The following example shows the typical configuration of a `ibm-ws-bnd.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<webservices-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ws-bnd_
  version="1.0">

  <!-- optional Web service endpoint default properties -->
  <webservice-endpoint-properties org.apache.cxf.wsdl.create.imports="true" ... />

  <!-- 0 to many endpoint descriptions -->
  <webservice-endpoint port-component-name="..." address="optional override address">
    <!-- optional Web service endpoint properties -->
    <properties publishedEndpointUrl="http://www.example.com/services/hello"
      org.apache.cxf.wsdl.create.imports="false" />
  </webservice-endpoint>
  ...

  <!-- optional http publishing module overrides -->
  <http-publishing context-root="optional override of module's context root">
    <!-- optional web.xml fragment for security -->
```

```

<webservice-security>
  <!-- SECURITY CONSTRAINTS -->
  <security-constraint>
    <web-resource-collection>
      <web-resource-name>SayHelloServiceName</web-resource-name>
      <url-pattern>/SayHelloService</url-pattern>
    </web-resource-collection>
    <auth-constraint>
      <description>SayHelloServiceAuth</description>
      <role-name>group123</role-name>
    </auth-constraint>
    <user-data-constraint>
      <transport-guarantee>CONFIDENTIAL</transport-guarantee>
    </user-data-constraint>
  </security-constraint>
  <!-- SECURITY CONSTRAINTS -->
  <security-constraint>
    <web-resource-collection>
      <web-resource-name>SecuredSayHelloServiceName</web-resource-name>
      <url-pattern>/Secured*</url-pattern>
    </web-resource-collection>
    <auth-constraint>
      <description>SecuredSayHelloServiceAuth</description>
      <role-name>group123</role-name>
    </auth-constraint>
    <user-data-constraint>
      <transport-guarantee>CONFIDENTIAL</transport-guarantee>
    </user-data-constraint>
  </security-constraint>
  <!-- SECURITY ROLES -->
  <security-role id="group123_id">
    <role-name>group123</role-name>
  </security-role>
  <!-- AUTHENTICATION METHOD: Client certificate or basic authentication -->
  <login-config>
    <auth-method>BASIC</auth-method>
  </login-config>
</webservice-security>
</http-publishing>

<!-- 0 to many client refs -->
<service-ref name="services/sayHelloService"
port-address="http://productServer:productPort/context-root/SayHelloService"/>
<service-ref name="services/securedSayHelloService"
port-address="http://productServer:productPort/context-root/SecuredSayHelloService"
wsdl-location="optional override of WSDL document" />
</webservices-bnd>

```

## Liberty: The web services commands

### 8.5.5.0

Liberty provides several command utilities to work with Java Architecture for XML Binding (JAXB) and Java API for XML Web Services (JAX-WS) applications.

### schemagen command for JAXB applications

Generate a schema file from Java classes by using the **schemagen** schema generator tool to create the XML schema. After you have created a mapping between XML schema and Java classes, XML instance documents can be converted to and from Java objects by using the JAXB binding runtime API. The resulting Java classes contain all the necessary information that the JAXB run time requires to parse the

XML for marshaling and unmarshaling. You can use the JAXB classes within JAX-WS applications or the JAXB classes in your non-JAX-WS Java applications for processing XML data.

For more information, see `schemagen` command for JAXB applications.

### **xjc command for JAXB applications**

You can generate fully annotated Java classes from an XML schema file by using the **xjc** command-line tool that is provided by the JAXB schema compiler. Use the **xjc** schema compiler tool to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. After you have created a mapping between XML schema and Java classes, you can convert XML instance documents to and from Java objects by using the JAXB binding runtime API. The resulting annotated Java classes contains all the necessary information that the JAXB runtime requires to parse the XML for marshaling and unmarshaling. You can use the resulting JAXB classes within JAX-WS applications or the resulting JAXB classes in your non-JAX-WS Java applications to process XML data.

For more information, see `xjc` command for JAXB applications.

### **wsgen command for JAX-WS applications**

The **wsgen** command-line tool generates the necessary artifacts required by JAX-WS applications when you start with Java code for Web Services programming. When you start with a service endpoint implementation, use the **wsgen** tool to generate the required JAX-WS artifacts.

For more information, see `wsgen` command for JAX-WS applications.

### **wsimport command for JAX-WS applications**

The **wsimport** command-line tool processes an existing Web Services Description Language (WSDL) file and generates the required artifacts for developing JAX-WS web service applications. When you start with an existing WSDL file, use the **wsimport** command-line tool to generate the required JAX-WS artifacts.

**Attention:** If you want to change the package name of the generated classes, include `-p <Expected_Java_Package_Name>` in the **wsimport** command line. After that, do not change Java package name manually.

For more information, see `wsimport` command for JAX-WS applications.

## **Web Services Atomic Transaction in Liberty**

8.5.5.9

Web Services Atomic Transaction (WS-AT) is an OASIS standard. Now it is supported in Liberty. In this section, you can learn how to enable and configure the WS-AT feature in Liberty.

### **Web Services Atomic Transaction overview:**

8.5.5.9

The Web Services Atomic Transaction (WS-AT) support in the application server provides transactional quality of service to the web services environment. Distributed web services applications, and the resources they use, can take part in distributed global transactions. Now WS-AT is also supported in Liberty.

Web services protocols provide standard ways of defining web services applications, and the applications can use it to operate independently of the product, platform, or programming language that is used. The WS-AT support is an implementation of the following specifications on the application server. These

specifications define a set of web services that enable web services applications to participate in global transactions that are distributed across the heterogeneous web services environment.

- WS-AT is a specific coordination type that defines protocols for atomic transactions. Liberty can only use the Web Services Atomic Transaction Version 1.2 specification.
- Web Services Coordination (WS-COOR) specifies a CoordinationContext and a Registration service with which participant web services can enlist to take part in the protocols that are offered by specific coordination types. Liberty can only use the Web Services Coordination Version 1.2 specification.

The WS-AT support is an interoperability protocol that introduces no new programming interfaces for transactional support. Global transaction demarcation is provided by standard enterprise application use of the Java Transaction API (JTA) UserTransaction interface. If an application component that is running under a global transaction makes a web services request, a WS-AT CoordinationContext is implicitly propagated to the target web services, but only if the appropriate application deployment descriptors have been set, as described in the topic about configuring transactional deployment attributes.

If the application server is the system hosting the target endpoint for a web services request that contains a WS-AT Coordination Context, the application server automatically establishes a subordinate JTA transaction in the target run time environment that becomes the transactional context under which the target web services application runs.

The following figure, shows a transaction context shared between two application servers for a web services request that contains a WS-AT CoordinationContext.

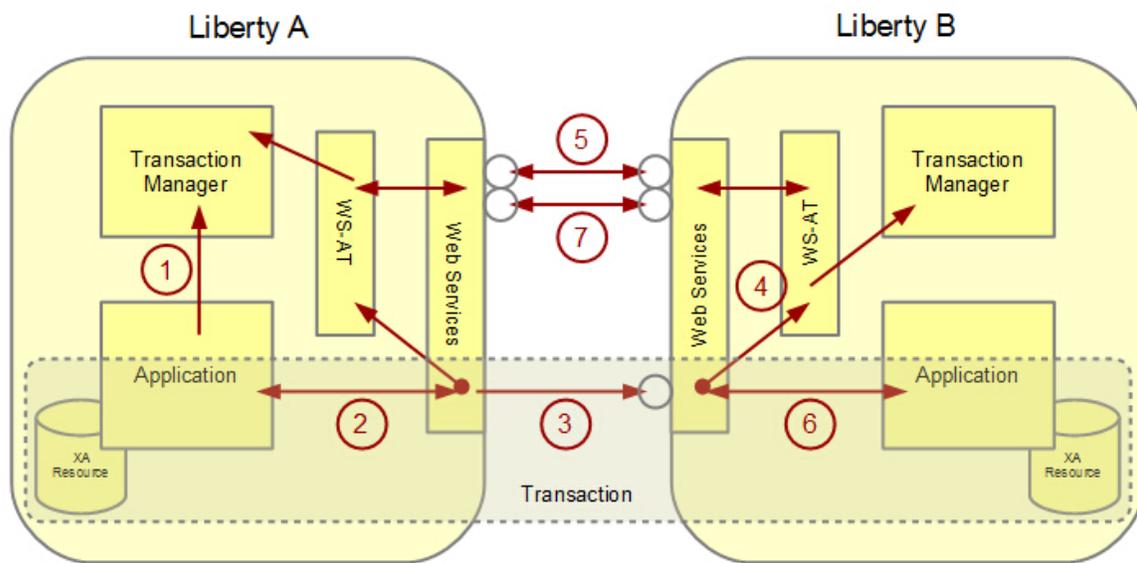

Figure 30. Transaction context shared between two application servers

By default, if you enable WS-AT feature and begin transaction on the client side in Liberty, all the web services operations that are included in client transaction are added to the global transaction. However, if you would run any code outside the scope of the current global transaction, use the UOWManager with type `UOWSynchronizationRegistry.UOW_TYPE_LOCAL_TRANSACTION`. That would have the effect of suspending and resuming the global transaction around that code snippet.

Table 174. Conditions that you can or can not use WS-AT global transaction in Liberty for client outbound

Whether WS-AT feature is enabled	Whether transaction exists	Whether policy assertion exists in WSDL	Whether WS-AT global transaction is enabled
No	No	No	No
No	No	Yes	No with Liberty throwing an exception
No	Yes	No	No
No	Yes	Yes	No with Liberty throwing an exception
Yes	No	No	No
Yes	No	Yes (wsp: Optional="false")	No with Liberty throwing an exception
		Yes (wsp: Optional="true")	No
Yes	Yes	No	Yes
Yes	Yes	Yes	Yes

Table 175. Conditions that you can or can not use WS-AT global transaction in Liberty for server inbound

Whether WS-AT feature is enabled	Whether coordination context exists in SOAP header	Whether policy assertion exists in WSDL	Whether WS-AT global transaction is enabled
No	No	No	No
No	No	Yes	No
No	Yes	No	No with Liberty throwing an exception
No	Yes	Yes	No with Liberty throwing an exception
Yes	No	No	No
Yes	No	Yes (wsp: Optional="false")	No with Liberty throwing an exception
		Yes (wsp: Optional="true")	No
Yes	Yes	No	Yes
Yes	Yes	Yes	Yes

## Application design

WS-AT is a two-phase commit transaction protocol and is suitable for short duration transactions only.

WS-AT is most appropriate for distributing transaction context across web services that are deployed in a single enterprise. Only request-response message exchange patterns carry transaction context because the originator (application or container) of a transaction must be sure that all business tasks that are run under that transaction have finished before requesting the completion of a transaction. Web services called by a one-way request never run under the transaction of the requesting client.

The effect of service faults on WS-AT transactions is similar to the effect of Enterprise JavaBeans (EJB) application exceptions on transactions, as described in the EJB specification. If a service that is running under a requester WS-AT transaction returns a fault, the application server does not automatically mark the transaction rollback-only. The exception handler of the requester chooses whether the transaction can progress and chooses whether to mark the transaction rollback-only. If the requester is running in the application server, the standard JTA or EJB APIs can be used to mark the transaction rollback-only. The

service component that generates the fault might, itself, mark the transaction rollback-only before returning the fault. If the implementation of the service component encounters a system exception, it typically allows its container to handle the exception. Application server containers automatically mark any received transaction context rollback-only when handling a system exception that is generated by a service implementation.

### Configuring Web Services Atomic Transaction: 8.5.5.9

Web Services Atomic Transaction (WS-AT) is an OASIS standard. Now this feature is supported in Liberty.

#### About this task

Before you can configure Web Services Atomic Transaction (WS-AT) in Liberty, you must enable it. This task describes how to enable WS-AT feature in Liberty and also instructs you to add different configurations to WS-AT feature. In addition, you can use the UOWManager with type **UOWSynchronizationRegistry.UOW\_TYPE\_LOCAL\_TRANSACTION** to run any code outside the scope of the current global transaction.

If you do not add the WS-AT feature in Liberty but have any of the following information in your application, an exception message is displayed. The message indicates that the WS-AT feature is not installed in the Liberty log:

- WS-Transaction policy information in WSDL
- Web Services Atomic Transaction Coordination context information in Web Services Soap Header

To enable and configure the WS-AT feature in Liberty, perform the following steps:

#### Procedure

1. To enable the WS-AT feature in Liberty, add the following entry inside the featureManager element in the server.xml file:  

```
<feature>wsAtomicTransaction-1.2</feature>
```
2. Optional: Add some special configurations for the WS-AT feature. You can configure SSL or proxy endpoint for WS-AT internal 2PC protocol communication as follows:  

```
<wsAtomicTransaction SSLEnabled="false" SSLRef="defaultSSLConfig" externalURLPrefix="" clientAuth="false"/>
```

For more information, see Configuring SSL or proxy endpoint parameters in the server.xml file.

3. Optional: To run transactions outside the scope of the current global transaction, add the following code to the client side:

```
UOWManager uowManager = (UOWManager) ctx
    .lookup("java:comp/websphere/UOWManager");
uowManager
    .runUnderUOW(
        UOWSynchronizationRegistry.UOW_TYPE_LOCAL_TRANSACTION,
        false, new UOWAction() {
            public void run() throws Exception {
                ...
                // Example code
                callService1(service1, wsTransactionEnd1);
                ...
            }
        });
```

### Web Services Atomic Transaction security: 8.5.5.9

Web Services Atomic Transaction (WS-AT) defines its own internal web services that are used as part of the protocol. These internal web services are called during the transaction initiation and during the

commitment or rollback processing. Meanwhile WS-AT requires a two-way communication. WS-AT requires a DMZ proxy for Liberty servers to operate in a typical firewall environment and also HTTPS endpoints to get the authorization. The following content describes how to configure proxy and Security Socket Layer (SSL) for WS-AT in Liberty.

## Firewall proxy

When Liberty servers are in a typical firewall environment, the servers cannot communicate with each other through firewalls. In this situation, the servers require a DMZ proxy to operate normally. You can define proxy endpoints by configuring the `server.xml` file.

For example, set IBM HTTP Server (IHS) as the DMZ proxy. In Figure 31, to communicate between two Liberty servers through IHS, perform the following steps:

1. Configure the IHS plug-in to forward requests to Liberty servers. For more information, see [Configuring a web server plug-in for Liberty](#).
  - For IHS 1, configure the IHS 1 plug-in to forward requests to Liberty A and add `<Uri Name="/ibm/wsatservice/*" />` in the `<UriGroup>` item.
  - For IHS 2, configure the IHS 2 plug-in to forward requests to Liberty B and add `<Uri Name="/ibm/wsatservice/*" />` in the `<UriGroup>` item.
2. Add the `externalURLPrefix` parameter to the `server.xml` file in Liberty:
  - In Liberty A, set the `externalURLPrefix` value as `http://proxyserver1:80` for IHS 1 as follows: `<wsAtomicTransaction externalURLPrefix="http://proxyserver1:80"/>`
  - In Liberty B, set the `externalURLPrefix` value as `http://proxyserver2:81` for IHS 2 as follows: `<wsAtomicTransaction externalURLPrefix="http://proxyserver2:81"/>`

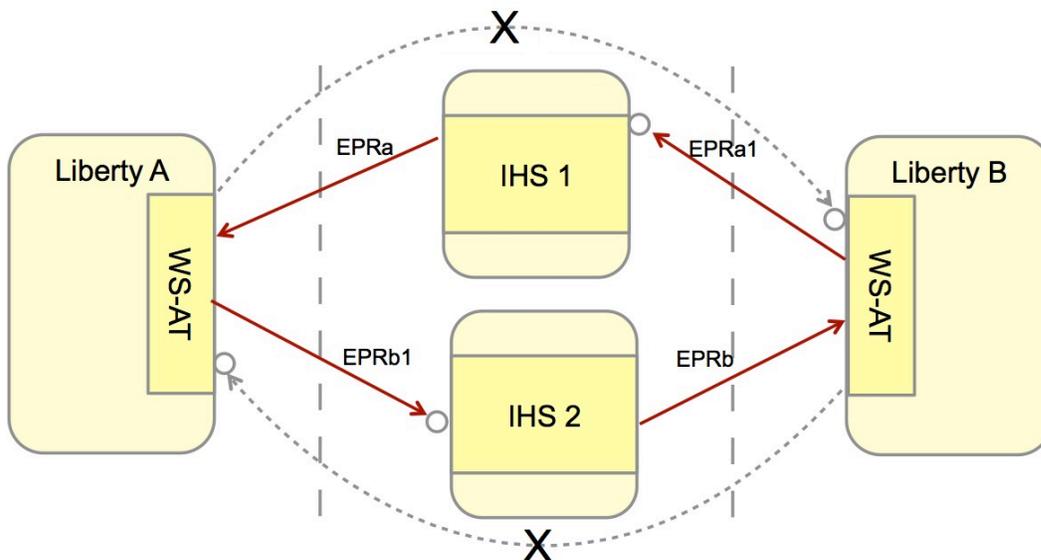

Figure 31. Communication between two Liberty servers through IHS

## Security Socket Layer

By default, Liberty servers communicate without SSL. If you require WS-AT security and security information is redirected to a secure port, you must add the `appSecurity-2.0` Liberty feature to the `server.xml` file. You can also enable SSL in Liberty according to [Securing Liberty and its applications](#).

You can configure SSL for WS-AT security according to the following items:

```
<wsAtomicTransaction SSLEnabled="false" SSLRef="defaultSSLConfig" clientAuth="false"/>
```

Where:

#### **SSLEnabled**

Specifies whether SSL is enabled for WS-AT. Valid values are true and false. The default value is false. Set it to true to enable SSL.

#### **SSLRef**

Defines the SSL configuration in the `server.xml` file. WS-AT requires this SSL configuration to communicate.

#### **clientAuth**

Specifies whether clientAuthentication is enabled for WS-AT. Valid values are true and false. The default value is false. Ensure to set the `clientAuthenticationSupported` value to be true in SSL configuration before you set the `clientAuth` value to be true to enable clientAuthentication.

**Important:** The SSL configuration applies at the Liberty server level only.

**Tip:** In the following code snippet, the default `SSLEnabled` value is false. If you want to enable both SSL and proxy, set the `SSLEnabled` value as true and set the `externalURLPrefix` value as a proxy address that starts with `https://`.

```
<wsAtomicTransaction SSLEnabled="true" SSLRef="defaultSSLConfig" externalURLPrefix="https://proxy" clientAuth="false"/>
```

#### **Web Services Atomic Transaction interoperation:** 8.5.5.9

Liberty supports WS-AT interoperation with WebSphere Application Server classic.

In WebSphere Application Server classic, you can use policy set to control transaction policy. However, if you would run any code outside the scope of the current global transaction in Liberty, use the `UOWManager` with type `UOWSynchronizationRegistry.UOW_TYPE_LOCAL_TRANSACTION`.

If you expect WebSphere Application Server classic to transact with Liberty through proxy, see [Enabling WebSphere Application Server to use an intermediary node for Web services transactions](#).

If you want to use the same Secure Sockets Layer (SSL) to transact between WebSphere Application Server classic and Liberty, see [SSL configurations](#).

---

## Deploying messaging applications to Liberty

8.5.5.6

JMS applications deployed within the Liberty server can make use of the internal embedded messaging provider or the external WebSphere MQ as its JMS messaging provider.

### Deploying JMS applications to connect to the embedded messaging server

8.5.5.6

To deploy messaging applications that use the Java Messaging Service (JMS), you must add the `wasJmsServer-1.0` and `wasJmsClient-2.0` features to the `server.xml` file, and define the connection factory and destination properties. If you want to perform a JNDI lookup, then you must add the `jndi-1.0` feature along with the other two features.

## Before you begin

Ensure that a Liberty server is created on which you want to deploy the messaging application that uses JMS. For more information, see “Creating a Liberty server manually” on page 1423.

**Important:** The `wasJmsClient-2.0` feature supports the features of both JMS 1.1 and JMS 2.0 specifications. However, you can choose to use the `wasJmsClient-1.1` feature if you want to use only the features that are compliant with JMS 1.1 specification.

## About this task

The `wasJmsServer-1.0` feature provides support for applications that use Java Messaging Service 1.1 specifications.

## Procedure

1. Add the `wasJmsServer-1.0`, `wasJmsClient-2.0`, and `jndi-1.0` features to the `server.xml` file.

```
<featureManager>
  <feature>wasJmsServer-1.0</feature>
  <feature>wasJmsClient-2.0</feature>
  <feature>jndi-1.0</feature>
</featureManager>
```

2. Add the destination definitions to the `server.xml` file.

```
<messagingEngine>
  <queue id="QUEUE1"> </queue>
</messagingEngine>
```

3. Optional: Add the `<wasJmsEndpoint>` element to enable the JMS messaging engine to accept the remote incoming messaging connections from TCP/IP (with and without SSL).

```
<wasJmsEndpoint id="InboundJmsEndpoint"
  host="*"
  wasJmsPort="7276"
  wasJmsSSLPort="9100">
</wasJmsEndpoint>
```

**Note:** Adding `<wasJmsEndpoint>` is optional. By default, the Liberty server enables messaging engine to listen on 7276 port (unsecured) and 7286 (secured). If you want to specify a different port, then `<wasJmsEndpoint>` can be configured.

4. Add the connection factory definitions to the `server.xml` file.

- For Point-to-Point domain:

```
<jmsQueueConnectionFactory jndiName="jndi_JMS_BASE_QCF">
  <properties.wasJms
    remoteServerAddress="localhost:7276:BootStrapBasicMessaging" />
</jmsQueueConnectionFactory>
```

```
<jmsQueue jndiName="jndi_INPUT_Q">
  <properties.wasJms queueName="QUEUE1" />
</jmsQueue>
```

- For Publish-Subscribe domain:

```
<jmsTopicConnectionFactory jndiName="eis/tcf">
  <properties.wasJms
    clientID="defaultID" />
</jmsTopicConnectionFactory>
```

```
<jmsTopic jndiName="eis/topic1">
  <properties.wasJms topicName="Football" />
</jmsTopic>
```

The JMS applications are now connected to the embedded messaging server.

# Deploying JMS applications to Liberty to use the IBM MQ messaging provider

8.5.5.6

Through the IBM MQ messaging provider in Liberty, Java Message Service (JMS) messaging applications can use your IBM MQ system as an external provider of JMS messaging resources.

## Before you begin

You must ensure that a Liberty server is created on which you want to deploy the messaging application that uses JMS. For more information, see “Creating a Liberty server manually” on page 1423.

## About this task

The `wmqJmsClient-2.0` feature provides support for applications that use JMS 2.0 specifications.

**Note:** The `wmqJmsClient-2.0` feature supports the features of both JMS 1.1 and JMS 2.0 specifications. However, you can choose to use the `wmqJmsClient-1.1` feature if you want to use only the features that are compliant with JMS 1.1 specification.

## Procedure

1. Add the `wmqJmsClient-2.0` feature to the `server.xml` file. If you want to perform a JNDI lookup, then you must also add the `jndi-1.0` feature.

```
<featureManager>
  <feature>wmqJmsClient-2.0</feature>
  <feature>jndi-1.0</feature>
</featureManager>
```

Adding the `wmqJmsClient-2.0` feature enables the Liberty server to load the necessary IBM MQ bundles that enable you to define the IBM MQ JMS resources. For example, the connection factory and activation specification properties provide client libraries to connect to the IBM MQ network.

2. Specify the location of the WebSphere MQ Resource Adapter by adding the following entry to the `server.xml` file:

```
<variable name="wmqJmsClient.rar.location" value="/path/to/wmq/rar/wmq.jmsra.rar"/>
```

where the `value` attribute specifies the absolute path to the WebSphere MQ Resource Adapter file, `wmq.jmsra.rar`.

For details of the supported versions and obtaining the `wmq.jmsra.rar` file, refer to the WebSphere MQ technote 1633761. Obtain the `wmq.jmsra.rar` file and install it from Fix central.

3. Add the connection factory definitions to the `server.xml` file.

```
<jmsConnectionFactory jndiName="jms/wmqCF" connectionManagerRef="ConMgr6">
  <properties.wmqJms
    transportType="CLIENT"
    hostName="localhost"
    port="1414"
    channel="SYSTEM.DEF.SVRCONN"
    queueManager="QM1"/>
</jmsConnectionFactory>
<connectionManager id="ConMgr6" maxPoolSize="2"/>

<jmsQueue id="jms/queue1" jndiName="jms/wmqQ1">
  <properties.wmqJms
    baseQueueName="MDBQ"
    baseQueueManagerName="QM1"/>
</jmsQueue>
```

4. Configure JMS applications to connect in the BINDING mode.

To allow the JMS applications to connect by using the shared memories or in BINDING mode to IBM MQ, you must have both Liberty and IBM MQ deployed on the same server. To allow JMS

applications to connect in BINDING mode, use the `nativeLibraryPath` element in the `server.xml` file to specify the location of the IBM MQ native libraries.

```
<wmmqJmsClient nativeLibraryPath="/opt/mqm/java/lib64"/>
```

## Deploying JMS application to connect to the Service Integration Bus running on WebSphere Application Server traditional

8.5.5.6

To deploy the messaging applications that use the Java Messaging Service (JMS) to connect to the messaging engine that is running on WebSphere Application Server traditional, you must add the `wasJmsClient-2.0` and `jndi-1.0` features to the `server.xml` file. If you want to perform a JNDI lookup, then you must add the `jndi-1.0` feature. You must also define the connection factory and destination properties.

### Before you begin

Ensure that you created a Liberty server on which you want to deploy the messaging application that uses JMS. For more information, see “Creating a Liberty server manually” on page 1423.

**Important:** The `wasJmsClient-2.0` feature supports the features of both JMS 1.1 and JMS 2.0 specifications. However, you can choose to use the `wasJmsClient-1.1` feature if you want to use only the features that are compliant with JMS 1.1 specification.

### About this task

The `wasJmsClient-2.0` feature provides support for applications that use Java Messaging Service 1.1 specifications.

### Procedure

- Add the `wasJmsClient-2.0` features to the `server.xml` file.

```
<featureManager>
  <feature>wasJmsClient-2.0</feature>
  <feature>jndi-1.0</feature>
</featureManager>
```

- Add the connection factory definitions to the `server.xml` file.

– For Point-to-Point domain:

```
<jmsQueueConnectionFactory jndiName="jndi_JMS_BASE_QCF">
  <properties.wasJms
    remoteServerAddress="localhost:7276:BootstrapBasicMessaging"
    busName="Bus1"/>
</jmsQueueConnectionFactory>
```

```
<jmsQueue jndiName="jndi_INPUT_Q">
  <properties.wasJms queueName="QUEUE1" />
</jmsQueue>
```

– For Publish-Subscribe domain:

```
<jmsTopicConnectionFactory jndiName="eis/tcf">
  <properties.wasJms
    clientID="defaultID"
    remoteServerAddress="localhost:7276:BootstrapBasicMessaging"
    busName="Bus1"/>
</jmsTopicConnectionFactory>
```

```
<jmsTopic jndiName="eis/topic1">
  <properties.wasJms topicName="Football" />
</jmsTopic>
```

– For message-driven beans

Configure the activation specification property to all message-driven beans deployed in the Liberty server to connect to the messaging engine that is running on WebSphere Application Server traditional.

```
<jmsActivationSpec id="PriceChangeAS">
  <properties.wasJms
    destinationRef="jms/TriggerQ"
    remoteServerAddress="meserver.in.ibm.com:7276:BootstrapBasicMessaging busName="Bus1"/>
</jmsActivationSpec>

<jmsQueue id="jms/TriggerQ" jndiName="jms/TriggerQ">
  <properties.wasJms queueName="Q1"/>
</jmsQueue>
```

**Note:** If an application that is running on the Liberty server needs to connect to a messaging engine that is running on WebSphere Application Server traditional, then ensure that `remoteServerAddress` is configured to point to the server where the messaging engine is locally running instead of pointing to a Bootstrap server.

## Deploying JMS applications on the Liberty application client container

8.5.5.6

You can configure messaging applications that use `wasJmsClient-2.0` feature to run on the Liberty application client container.

### Before you begin

Before you can run an application client, you must create a client and add a configuration for your client application in the `client.xml` file. See the [Creating a Liberty application client manually](#) topic for examples of how you would create the application client.

### Procedure

1. To run the messaging application on the client, add the `javaeeClient-7.0` feature to the `client.xml` file.

```
<featureManager>
  <feature>javaeeClient-7.0</feature>
</featureManager>
```

2. Add the connection factory definitions to the `client.xml` file.

- For Point-to-Point domain:

```
<jmsQueueConnectionFactory jndiName="jndi_JMS_BASE_QCF" connectionManagerRef="ConMgr6">
  <properties.wasJms remoteServerAddress="localhost:7276:BootstrapBasicMessaging" />
</jmsQueueConnectionFactory>
<connectionManager id="ConMgr6" maxPoolSize="10"/>
```

```
<jmsQueue jndiName="jndi_INPUT_Q">
  <properties.wasJms queueName="QUEUE1" />
</jmsQueue>
```

- For Publish-Subscribe domain:

```
<jmsTopicConnectionFactory jndiName="eis/tcf">
  <properties.wasJms
    clientID="defaultID" />
</jmsTopicConnectionFactory>

<jmsTopic jndiName="eis/topic1">
  <properties.wasJms topicName="Football" />
</jmsTopic>
```

The JMS application is ready to run on the Liberty application client container.

# Enabling JMS tracing for the Liberty embedded messaging

8.5.5.6

JMS traces can be used in Liberty for problem determination and troubleshooting.

## Setting JMS traces

The following trace strings can be set in the `server.xml` file to obtain the required information.

### Connection problems

Use the following trace string to gather information about connection issues.

```
SIBTrm=all
```

### Communications and TCP/IP

Use the following trace string to gather information about the application server channel framework and TCP/IP network communications.

```
SIBCommunications=all:SIBJFapChannel=all:TCPChannel=fine:com.ibm.io.async.*=all
```

### JMS client applications

Use the following trace string to gather information about requests from JMS applications.

```
SIBJms*=all:SIBCommunications=all:SIBJFapChannel=all:  
SIBMessageTrace=all:SIBTrm=all:SIBJmsRa=all:SIBRa=all
```

### Locked messages

Use the following trace string if messages that are being delivered to MDBs and applications are locked for longer than you expect.

```
SIBProcessor=all:SIBMessageTrace=all
```

### Message-driven beans

Use the following trace string to gather information about MDBs that are configured by using an Activation Specification against a message destination.

```
SIBMessageTrace=all:SIBJmsRa=all:SIBRa=all
```

### Message format and schema

Use the following trace string if there is a problem in parsing or handling message data.

```
SIBMfp=all:SIBCommunications=all
```

### Message processor

Use the following trace string to gather information about the core functions of the messaging engine. Gathering this data is helpful, but might be potentially large.

```
SIBProcessor=all:SIBMessageTrace=all
```

### Message store

Use the following trace string to gather information about persistent message data, which is written out to storage so that it can be recovered if there is a failure.

```
SIBMessageStore=all
```

### Performance and message tracking

Use the following trace string to determine the delay in passing of messages or if you need to find where the messages are going.

```
SIBMessageTrace=all
```

### Publish/subscribe

Use the following trace string if subscribers are not getting the proper publications for their topic.

```
SIBMatchSpace=all:SIBProcessor=all
```

### Security

Use the following trace string if a user is authenticated incorrectly or is incorrectly allowed or disallowed access to resources.

```
SIBSecurity=all
```

## Deploying message-driven beans within Liberty

8.5.5.0

Liberty supports the configuration and deployment of message-driven beans (MDB) to process the JMS messages asynchronously from various destinations.

### Deploying message-driven beans to connect to WebSphere MQ

8.5.5.6

You can connect to WebSphere MQ by using the message-driven beans (MDB).

#### Procedure

1. Configure the MDB feature:

Enable MDB support in the Liberty server by configuring the `jmsMdb-3.2` and `wmqJmsClient-2.0` features in the `server.xml` file. If you want to perform a JNDI lookup, then you must also add the `jndi-1.0` feature along with the other two features.

```
<featureManager>
  <feature>jmsMdb-3.2</feature>
  <feature>wmqJmsClient-2.0</feature>
  <feature>jndi-1.0</feature>
</featureManager>
```

Configuring the `wmqJmsClient-2.0` feature enables the users to define the required JMS resources and enables MDB to interact with the messaging engine.

**Note:** The `wmqJmsClient-2.0` feature supports the features of both JMS 1.1 and JMS 2.0 specifications. However, you can choose to use the `wmqJmsClient-1.1` feature if you want to use only the features that are compliant with JMS 1.1 specification.

2. Specify the location of the WebSphere MQ Resource Adapter by adding the following entry to the `server.xml` file:

```
<variable name="wmqJmsClient.rar.location" value="/path/to/wmq/rar/wmq.jmsra.rar"/>
```

where the `value` attribute specifies the absolute path to the WebSphere MQ Resource Adapter file, `wmq.jmsra.rar`.

For details of the supported versions and obtaining the `wmq.jmsra.rar` file, refer to the WebSphere MQ technote 1633761. Obtain the `wmq.jmsra.rar` file and install it from Fix central.

3. Configure a JCA activation specification that uses the JMS resource adapter so that the MDB acts as a listener on a specific JMS destination. The following are different ways in which an MDB can be configured to interact with the messaging engine.

- a. Configure MDB by using the activation specification property.

You can define the property in the `server.xml` file so that the MDB can use the property to listen on a specific JMS destination.

```
<jmsActivationSpec id="JMSSample/JMSSampleMDB">
  <properties.wmqJms destinationRef="jndi/MDBQ" transportType="CLIENT" queueManager="myQM" hostName="myHost" port="1414"/>
</jmsActivationSpec>

<jmsQueue id="jndi/MDBQ" jndiName="jndi/MDBQ">
  <properties.wmqJms baseQueueName="MYQ" baseQueueManagerName="myQM"/>
</jmsQueue>
```

The `<destinationRef>` refers to the ID of `<jmsQueue>`. If an ID in `<jmsQueue>` is not mentioned, then `<destinationRef>` must point to the `<jndiName>` of the `<jmsQueue>`.

**Note:** The ID value must be in the format of application name/module name/bean name where

- *application name* is the name of the application that is deployed (for example, JMSSample). The application name applies only if the bean is packaged within an EAR file. The application defaults to the base name of the EAR file with no file name extension unless specified by the application.xml deployment descriptor.
  - *module name* is the name of the module in which the bean is packaged. In a stand-alone ejb-jar file or WAR file, the <module-name> defaults to the base name of the module with any file name extension removed. In an EAR file, the <module-name> defaults to the path name of the module with any file name extension removed, but with any directory names included. The default <module-name> can be overridden by using the module-name element of ejb-jar.xml (for ejb-jar files) or web.xml (for WAR files).
  - *bean name* is the ejb-name of the enterprise bean. For enterprise beans defined through annotation, the bean name defaults to the unqualified name of the session bean class, unless specified in the contents of the name() attribute of the MessageDriven annotation. For enterprise beans defined through ejb-jar.xml, it is specified in the <ejb-name> deployment descriptor element.
- b. Using annotations along with the activation specification property defined in the server.xml file. Liberty supports defining annotations for MDBs that can be used with the activation specification property defined in the server.xml file. In order to use the annotation, first define the activation specification property as mentioned in the previous step. And for each of the MDB, user can define the annotations as shown in the following example:

```
@MessageDriven(
    name = "JMSSampleMDB",
    activationConfig = {
        @ActivationConfigProperty(propertyName = "destinationType",
            propertyValue = "javax.jms.Queue"),
        @ActivationConfigProperty(propertyName = "userName",
            propertyValue = "user1"),
        @ActivationConfigProperty(propertyName = "password",
            propertyValue = "user1pwd"),
        @ActivationConfigProperty(propertyName = "destination",
            propertyValue = "jndi_INPUT_Q")
    }
)
public class JMSSampleMDB implements MessageListener{

    @TransactionAttribute(value = TransactionAttributeType.REQUIRED)
    public void onMessage(Message message) {
    }
}
```

- c. Using the EJB binding file (ibm-ejb-jar-bnd.xml).

You can also use this binding file to define the resource information that is required for the MDB to connect to the messaging engine. When you are using the EJB binding file, the activation specification property ID need not necessarily be in the format of application name/module name/bean name as mentioned in step 1.

Add the activation specification property information in the server.xml.

```
<jmsActivationSpec id="PriceChangeAS">
    <properties.wmqJms destinationRef="jms/TriggerQ" transportType="CLIENT" queueManager="myQM" hostName="myHost" port="1414"/>
</jmsActivationSpec>

<jmsQueue id="jms/TriggerQ" jndiName="jms/TriggerQ">
    <properties.wmqJms baseQueueName="Q1"/>
</jmsQueue>
```

Add the following MDB binding information in the ibm-ejb-jar-bnd.xml file.

```
<ejb-jar-bnd
xmlns="http://websphere.ibm.com/xml/ns/javaee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_1.xsd"
(http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_1.xsd%27) version="1.1">
```

```

<message-driven name="PriceChangeMDBBean">
  <jca-adapter activation-spec-binding-name="PriceChangeAS" destination-binding-name="jms/TriggerQ" />
</message-driven>
</ejb-jar-bnd>

```

**Note:** When using the EJB binding file, the **activation-spec-binding-name** attribute in the `ibm-ejb-jar-bnd.xml` file must point to the activation specification property ID value that is specified in the `server.xml` file.

## Deploying message-driven beans to connect to a JCA resource adapter

### 8.5.5.2

You can connect to a JCA resource adapter by using the message-driven beans (MDB).

### About this task

When you deploy a message-driven bean (MDB) application to Liberty, some configuration is required in the `server.xml` file to enable each MDB to receive messages from a resource adapter. The example configuration described in this topic is for an application that contains only message-driven beans and a JMS resource adapter. If the application will also use session beans, the `ejbLite-3.1` feature must be included.

Configuration properties will vary based on the specific resource adapter that is being used.

### Procedure

1. Configure the MDB feature:

Enable MDB support in Liberty by configuring the `mdb-3.1` and `jca-1.6` features in the `server.xml` file. If you want to perform a JNDI lookup, then you must also add the `jndi-1.0` feature along with the other two features.

```

<featureManager>
  <feature>mdb-3.1</feature>
  <feature>jca-1.6</feature>
  <feature>jndi-1.0</feature>
</featureManager>

```

2. Configure any other features required by your JCA resource adapter.
3. Configure a JCA activation specification that uses the resource adapter so that the MDB acts as a listener. The following examples show different ways that you can configure a MDB to interact with the messaging engine. These examples are specific to JMS resource adapters.
  - a. Configure MDB by using the activation specification property.

You can define the property in the `server.xml` file so that the MDB can use the property to listen on a specific JMS destination.

```

<activationSpec id="JMSSample/JMSSampleMDB">
  <properties.wmqJms destinationRef="jndi/MDBQ" transportType="CLIENT" queueManager="myQM" hostName="myHost" port="1414"/>
</activationSpec>

<jmsQueue id="jndi/MDBQ" jndiName="jndi/MDBQ">
  <properties.wmqJms baseQueueName="MYQ" baseQueueManagerName="myQM"/>
</jmsQueue>

```

The `<destinationRef>` refers to the ID of the `<jmsQueue>`. If an ID in the `<jmsQueue>` is not mentioned, then `<destinationRef>` element must point to the `<jndiName>` of the `<jmsQueue>`.

**Note:** The ID value must be in the format of application name/module name/bean name where

- *application name* is the name of the application that is deployed (for example, `JMSSample`). The application name applies only if the bean is packaged within an EAR file. The application defaults to the base name of the EAR file with no file name extension unless specified by the `application.xml` deployment descriptor.

- *module name* is the name of the module in which the bean is packaged. In a stand-alone ejb-jar file or WAR file, the <module-name> defaults to the base name of the module with any file name extension removed. In an EAR file, the <module-name> defaults to the path name of the module with any file name extension removed, but with any directory names included. The default <module-name> can be overridden by using the module-name element of ejb-jar.xml (for ejb-jar files) or web.xml (for WAR files).
  - *bean name* is the ejb-name of the enterprise bean. For enterprise beans defined through annotation, the bean name defaults to the unqualified name of the session bean class, unless specified in the contents of the name() attribute of the MessageDriven annotation. For enterprise beans defined through ejb-jar.xml, it is specified in the <ejb-name> deployment descriptor element.
- b. Configure the MDB by using annotations along with the activation specification property as defined in the server.xml file.

Liberty profile supports defining annotations for message-driven beans that can be used with the activation specification property defined in the server.xml file. To use the annotation, first define the activation specification property as mentioned in the previous step. And for each of the message-driven beans, you can define the annotations as shown in the following example:

```
@MessageDriven(
    name = "JMSSampleMDB",
    activationConfig = {
        @ActivationConfigProperty(propertyName = "destinationType",
            propertyValue = "javax.jms.Queue"),
        @ActivationConfigProperty(propertyName = "userName",
            propertyValue = "user1"),
        @ActivationConfigProperty(propertyName = "password",
            propertyValue = "user1pwd"),
        @ActivationConfigProperty(propertyName = "destination",
            propertyValue = "jndi_INPUT_Q")
    }
)
public class JMSSampleMDB implements MessageListener{

    @TransactionAttribute(value = TransactionAttributeType.REQUIRED)
    public void onMessage(Message message) {
    }
}
```

- c. Configure the MDB by using the EJB binding file ibm-ejb-jar-bnd.xml.

You can also use this binding file to define the resource information that is required for the MDB to connect to the messaging engine. When you are using the EJB binding file, the activation specification property ID is not required to be in the format of application name/module name/bean name as mentioned in step a.

Add the activation specification property information in the server.xml file.

```
<activationSpec id="PriceChangeAS">
    <properties.wmqJms destinationRef="jms/TriggerQ" transportType="CLIENT" queueManager="myQM" hostName="myHost" port="1414"/>
</activationSpec>

<jmsQueue id="jms/TriggerQ" jndiName="jms/TriggerQ">
    <properties.wmqJms baseQueueName="Q1"/>
</jmsQueue>
```

Add the following MDB binding information in the ibm-ejb-jar-bnd.xml file.

```
<ejb-jar-bnd
    xmlns="http://websphere.ibm.com/xml/ns/javaee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_1.xsd"
    (http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_1.xsd%27) version="1.1">

    <message-driven name="PriceChangeMDBBean">
        <jca-adapter activation-spec-binding-name="PriceChangeAS" destination-binding-name="jms/TriggerQ" />
    </message-driven>
</ejb-jar-bnd>
```

**Note:** When using the EJB binding file, the **activation-spec-binding-name** attribute in the `ibm-ejb-jar-bnd.xml` file must point to the activation specification property ID value that is specified in the `server.xml` file.

## Deploying message-driven beans to connect to the embedded messaging server

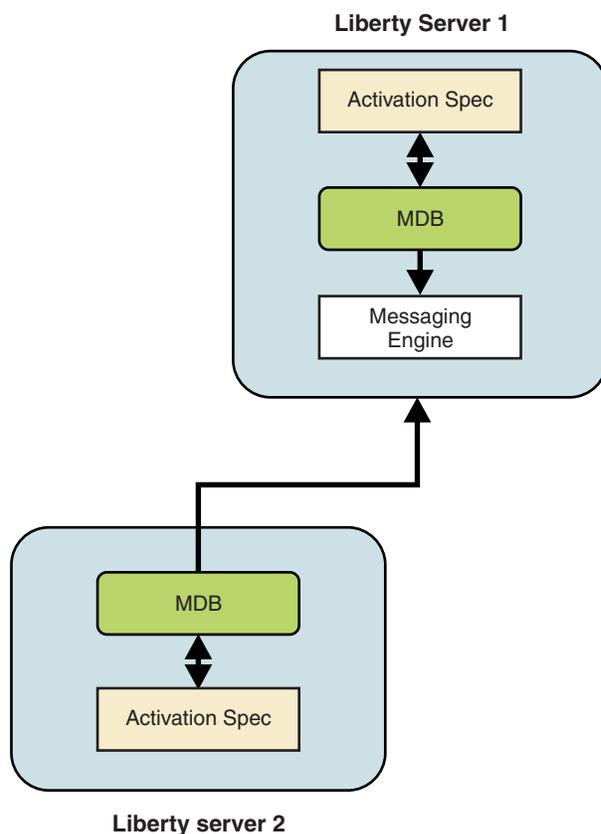

8.5.5.6

Use the message-driven beans (MDB) to connect to the embedded messaging server.

### About this task

MDB can be configured in the Liberty server in the following two scenarios:

- When both MDB and the messaging engine are on the same Liberty server.
- When MDB is connecting to a remote messaging engine that is running on a different Liberty server.

### Procedure

1. Configure the MDB feature:

Enable MDB support in the Liberty server by configuring the `javax.jms.Mdb-3.1` and `wasJmsClient-2.0` features in the `server.xml` file. If you want to perform a JNDI lookup, then you must also add the `javax.naming-1.0` feature along with the other two features.

```
<featureManager>
  <feature>javax.jms.Mdb-3.1</feature>
  <feature>wasJmsClient-2.0</feature>
  <feature>javax.naming-1.0</feature>
</featureManager>
```

Configuring the `wasJmsClient-2.0` feature enables the users to define the required JMS resources and enables MDB to interact with the messaging engine.

**Important:** The `wasJmsClient-2.0` feature supports the features of both JMS 1.1 and JMS 2.0 specifications. However, you can choose to use the `wasJmsClient-1.1` feature if you want to use only the features that are compliant with JMS 1.1 specification.

2. Configure a JCA activation specification that uses the JMS resource adapter so that the MDB acts as a listener on a specific JMS destination. The following are different ways in which an MDB can be configured to interact with the messaging engine.
  - a. Configure MDB by using the activation specification property.

You can define the property in the `server.xml` file so that the MDB can use the property to listen on a specific JMS destination.

```
<jmsActivationSpec id="JMSSample/JMSSampleMDB">
  <properties.wasJms destinationRef="jndi/MDBQ" />
</jmsActivationSpec>

<jmsQueue id="jndi/MDBQ" jndiName="jndi/MDBQ">
  <properties.wasJms queueName="Q1"/>
</jmsQueue>
```

The `<destinationRef>` refers to the ID of `<jmsQueue>`. If an ID in `<jmsQueue>` is not mentioned, then `<destinationRef>` must point to the `<jndiName>` of the `<jmsQueue>`.

**Note:** The ID value must be in the format of application name/module name/bean name where

- *application name* is the name of the application that is deployed (for example, `JMSSample`). The application name applies only if the bean is packaged within an EAR file. The application defaults to the base name of the EAR file with no file name extension unless specified by the `application.xml` deployment descriptor.
  - *module name* is the name of the module in which the bean is packaged. In a stand-alone `ejb-jar` file or `WAR` file, the `<module-name>` defaults to the base name of the module with any file name extension removed. In an EAR file, the `<module-name>` defaults to the path name of the module with any file name extension removed, but with any directory names included. The default `<module-name>` can be overridden by using the `module-name` element of `ejb-jar.xml` (for `ejb-jar` files) or `web.xml` (for `WAR` files).
  - *bean name* is the `ejb-name` of the enterprise bean. For enterprise beans defined through annotation, the bean name defaults to the unqualified name of the session bean class, unless specified in the contents of the `name()` attribute of the `MessageDriven` annotation. For enterprise beans defined through `ejb-jar.xml`, it is specified in the `<ejb-name>` deployment descriptor element.
- b. Using annotations along with the activation specification property defined in the `server.xml` file.

Liberty supports defining annotations for MDBs that can be used with the activation specification property defined in the `server.xml` file. In order to use the annotation, first define the activation specification property as mentioned in the previous step. And for each of the MDB, user can define the annotations as shown in the following example:

```
@MessageDriven(
  name = "JMSSampleMDB",
  activationConfig = {
    @ActivationConfigProperty(propertyName = "destinationType",
      propertyValue = "javax.jms.Queue"),
    @ActivationConfigProperty(propertyName = "userName",
      propertyValue = "user1"),
    @ActivationConfigProperty(propertyName = "password",
      propertyValue = "user1pwd"),
    @ActivationConfigProperty(propertyName = "destination",
      propertyValue = "jndi_INPUT_Q")
  }
)
public class JMSSampleMDB implements MessageListener{
```

```

    @TransactionAttribute(value = TransactionAttributeType.REQUIRED)
    public void onMessage(Message message) {
    }
}

```

c. Using the EJB binding file (ibm-ejb-jar-bnd.xml).

You can also use this binding file to define the resource information that is required for the MDB to connect to the messaging engine. When you are using the EJB binding file, the activation specification property ID need not necessarily be in the format of application name/module name/bean name as mentioned in step 1.

Add the activation specification property information in the server.xml.

```

<jmsActivationSpec id="PriceChangeAS">
  <properties.wasJms destinationRef="jms/TriggerQ" />
</jmsActivationSpec>

```

```

<jmsQueue id="jms/TriggerQ" jndiName="jms/TriggerQ">
  <properties.wasJms queueName="Q1"/>
</jmsQueue>

```

Add the following MDB binding information in the ibm-ejb-jar-bnd.xml file.

```

<ejb-jar-bnd
  xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_1.xsd
  (http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_1.xsd%27) version="1.1">
  <message-driven name="PriceChangeMDBBean">
    <jca-adapter activation-spec-binding-name="PriceChangeAS" destination-binding-name="jms/TriggerQ" />
  </message-driven>
</ejb-jar-bnd>

```

**Note:** When using the EJB binding file, the **activation-spec-binding-name** attribute in the ibm-ejb-jar-bnd.xml file must point to the activation specification property ID value that is specified in the server.xml file.

## Configuring connection pooling for JMS connections

### 8.5.5.1

You can customize the number of concurrent connections (default is 50) that can be created from a JMS connection factory. You can configure connection pooling for a specific JMS connection factory by defining the <connectionManager> element and then associate that element with the JMS connection factory in the server.xml file.

### Example

The connectionManager element in the server.xml file is used to the connection pool for a JMS connection factory property as given in the following example. The connection pool size is also defined in the connectionManager element.

```

<jmsConnectionFactory id="jmscf1"
  jndiName="jndi/example"
  connectionManagerRef="cm1">
  <properties.wasJms />
</jmsConnectionFactory>
<connectionManager id="cm1" maxPoolSize="10" minPoolSize="2" />

```

The server uses default values for any connection management settings that are not defined on the connectionManager element. If a connection manager is not defined for a connection factory, the server uses the default values for all the settings.

You can define multiple connection factories and associate each with a different connection manager. However, you cannot associate multiple connection factories with a single connection manager.

For more information about the `connectionManager` element, see .

---

## Deploying Java batch applications for Liberty

8.5.5.6

You can develop Java batch applications that are based on Java Specification Request (JSR) 352, and then submit Java batch jobs to run on a Liberty server.

### Java batch and managed batch overview

8.5.5.6

The Java batch function extends the application server to accommodate applications that must perform batch work alongside transactional applications. Batch work might take hours or even days to finish and uses large amounts of memory or processing power while it runs.

The Java Platform, Enterprise Edition Version 7 (Java EE 7) applications that are typically hosted by the product perform short, lightweight, transactional units of work. In most cases, an individual request can be completed with seconds of processor time and relatively little memory. Many applications, however, must complete batch work that is computational and resource-intensive.

Liberty supports the following batch features:

- Java batch

The `batch-1.0` feature enables the use of the JSR-352 programming model.

- Managed batch

The `batchManagement-1.0` feature provides the following functions:

- A REST interface for remote job submission
- The `batchManager` command-line utility
- Job logging support
- Multiple server support by using JMS

The `batch-1.0` and the `batchManagement-1.0` features support Java SE 7 and later.

**Note:** The `batchManagement-1.0` feature also enables the `batch-1.0` feature.

### Configuring Liberty for the batch REST API

8.5.5.6

WebSphere Application Server Liberty includes a RESTful management interface to manage your Java batch jobs. Managed batch enables a secure HTTPS REST interface so that you can externally manage your Java batch jobs.

#### Procedure

1. Add the `batchManagement-1.0` feature to your `server.xml` file.

```
<featureManager>
  <feature>batchManagement-1.0</feature>
</featureManager>
```

2. Configure batch persistence by configuring the **databaseStore** used by the Java batch feature. Reference the **databaseStore** in the `server.xml` file by using the **jobStoreRef** element. The following example illustrates what your `server.xml` file should look like.

```
<batchPersistence jobStoreRef="BatchDatabaseStore" />

<databaseStore id="BatchDatabaseStore" dataSourceRef="batchDB" />
```

For more information on database persistence, including auto-creation versus manual creation of tables, see Java batch persistence configuration.

3. Create an SSL certificate and user registry in your `server.xml` file, so that `batchManagement-1.0` automatically enables the SSL feature.

```
<keyStore id="defaultKeyStore" password="Liberty"/>

<basicRegistry id="basic" realm="ibm/api">
  <user name="bob" password="bobpwd" />
  <user name="jane" password="janepwd" />
</basicRegistry>
```

**Important:** The default self-signed SSL certificate in this example is intended only for development use and not for production.

For information on configuring role-based management of the batch environment and assigning users to roles, see [Securing the Liberty batch environment](#).

## Results

The RESTful interface is now configured for the Liberty server.

## Java batch persistence configuration

8.5.5.6

Java batch uses a persistent store to persist status, checkpoints, and application persistent data across multiple runs of a job instance. The persistent store enables a job instance to be restarted if an earlier run fails or must be stopped by supplying the restarted job with the appropriate data.

### Java batch memory-based persistence configuration

The batch persistence allows a job instance to be restarted if the execution ends in a `FAILED` or `STOPPED` state. In the absence of batch persistence configuration, Java batch uses a default capability of memory-based persistence to track status, checkpoints, and application persistent data across multiple runs of a job instance.

The default memory-based persistence implementation for Java batch is used by the underlying batch container when there is no `batchPersistence` and `databaseStore` elements present in the `server.xml` file.

**Note:** As a limitation for Java batch memory-based persistence, by default, persistence in Java batch is based on memory. If the batch container runtime or server JVM crash or are restarted, persistence is lost. This function is intended for development purposes only and is not to be considered for production systems or critical batch processing support.

### Java batch database persistence configuration

By default, the batch run time auto-creates non-existent tables based on the server configuration defined in the `databaseStore` element. The table definitions are customized based on the `schema` and `tablePrefix` attributes of the database store.

Alternatively, the `ddlGen` script can be used to generate a DDL based on the server configuration. If necessary, the DDL can be customized before manually creating the tables. This DDL also incorporates server configuration such as `schema` and `tablePrefix` and contains the appropriate SQL for the database type of the data source referenced by the `databaseStore`.

**Note:** Customized DDL must use positive integer primary key IDs. As a limitation for database persistence, Java Batch does not accept negative or zero integer IDs persisted in the primary key identity columns. The Java Batch container runtime only runs jobs that use positive integer job IDs persisted in the primary key identity columns.

The auto-creation of tables can be disabled by using the `createTables="false"` attribute on the `databaseStore`. This option can be used to ensure that you use manually created tables instead of using auto-created tables if the batch runtime unexpectedly could not find your manually created tables.

The samples shown on this page use the default auto-create behavior. This behavior is equivalent to `createTables="true"`.

**Note:** To avoid data integrity issues that are caused by having an isolation level less than `REPEATABLE_READ`, set the isolation level of the data source to `TRANSACTION_REPEATABLE_READ`. If you do not specify an isolation level, the default depends on the database. In most cases, the default is `TRANSACTION_REPEATABLE_READ`.

## Persistence configuration sample

The following sample configures batch access to the automatically created target database table `RUNTIMEDB` for Derby.

```
<!-- Batch persistence config. References a databaseStore. -->
<batchPersistence jobStoreRef="BatchDatabaseStore" />

<!-- The database store for the batch tables. -->
<!-- Note this database store is referenced by the batchPersistence element. -->
<databaseStore id="BatchDatabaseStore" dataSourceRef="batchDB" schema="JBATCH" tablePrefix="" />

<!-- Derby JDBC driver -->
<!-- Note this library is referenced by the dataSource element -->
<library id="DerbyLib">
  <fileset dir="{server.config.dir}/resources/derby" />
</library>

<!-- Data source for the batch tables. -->
<!-- Note this data source is referenced by databaseStore element -->
<dataSource id="batchDB" isolationLevel="TRANSACTION_REPEATABLE_READ" >
  <jdbcDriver libraryRef="DerbyLib" />
  <properties.derby.embedded
    databaseName="{server.config.dir}/resources/RUNTIMEDB"
    createDatabase="create"
    user="user"
    password="pass" />
</dataSource>
```

## Securing the Liberty batch environment

8.5.5.6

The Liberty batch framework allows you to configure role-based access to all batch management operations and also to view metadata and logs associated with your batch jobs.

### Before you begin

Three batch roles are defined by the batch container. A single user can have more than one batch role.

#### **batchAdmin**

A `batchAdmin` has unrestricted access to all batch operations. This includes permission to submit

new jobs, stop and restart any user's jobs, view any job metadata and job logs that are submitted by any user in the batch domain, and to purge any jobs. A batchAdmin is not necessarily a WebSphere Application Server administrator.

### batchSubmitter

A batchSubmitter has permission to submit new jobs and can only perform batch operations such as stop, restart, or purge on their own jobs. A batchSubmitter cannot view or modify other user's jobs. For example, if user1 and user2 are defined as batchSubmitters, and user1 submits a job, user2 cannot view the job instance data that is associated with user1's job.

### batchMonitor

A batchMonitor has read-only permissions to all jobs. Users in this role can view all job instances and executions and have access to all job logs. A batchMonitor cannot submit their own jobs, or stop, restart, or purge any jobs.

**Note:** Once batch security is enabled, any JobOperator API method or REST operation that returns a list will be filtered based on the batch roles granted to the current user. For example, when a user with only batchSubmitter permissions requests a list of all job instances, only job instances submitted by the current user will be returned.

## About this task

### Procedure

1. By default, the batch-1.0 feature does not enable any security. The JobOperator methods are left open for all users whether they are authenticated or not. The methods are left open for development purposes only and require no security configuration. The batchManagement-1.0 feature enables the batch REST API. The REST API always requires a user to authenticate even when the appSecurity-2.0 feature is not enabled, but all users will be treated as batch administrators and can perform all batch operations on any job instance. Once appSecurity-2.0 is enabled, batch role-based security authorization will be performed and users will be restricted to batch operations defined by their given batch roles.

- a. Enable the batch role-based security through the JobOperator API

```
<featureManager>
  <feature>batch-1.0</feature>
  <feature>appSecurity-2.0</feature>
</featureManager>
```

- b. Enable the batch role-based security through the REST API.

**Note:** The batchManagement-1.0 feature includes the batch-1.0 feature.

```
<featureManager>
  <feature>batchManagement-1.0</feature>
  <feature>appSecurity-2.0</feature>
</featureManager>
```

2. Configure your server.xml file to support role-based security. The following example illustrates a basic user registry that defines a list of users. This registry is used by sample batch role based security configurations.

```
<basicRegistry id="basic" realm="ibm/api">
  <user name="alice" password="alicepwd" />
  <user name="bob" password="bobpwd" />
  <user name="jane" password="janepwd" />
  <user name="joe" password="joepwd" />
  <user name="phyllis" password="phyllispwd" />
  <user name="kai" password="kaipwd" />
</basicRegistry>
```

In this example, one user occupies multiple roles.

```
<authorization-roles id="com.ibm.ws.batch">
  <security-role name="batchAdmin" >
    <user name="alice" />
```

```

</security-role>
<security-role name="batchSubmitter" >
  <user name="jane" />
  <user name="phyllis" />
  <user name="bob" />
</security-role>
<security-role name="batchMonitor" >
  <user name="joe" />
  <user name="bob" />
</security-role>
</authorization-roles>

```

In this example, one user occupies multiple roles. All users have the batchSubmitter role.

```

<authorization-roles id="com.ibm.ws.batch">
  <security-role name="batchAdmin" >
    <user name="alice" />
  </security-role>
  <security-role name="batchSubmitter" >
    <special-subject type="ALL_AUTHENTICATED_USERS"/>
  </security-role>
  <security-role name="batchMonitor" >
    <user name="joe" />
    <user name="bob" />
  </security-role>
</authorization-roles>

```

In this example, one user occupies multiple roles. All users, including those users that are not authenticated, are allowed to have the batchMonitor role.

```

<authorization-roles id="com.ibm.ws.batch">
  <security-role name="batchAdmin" >
    <user name="alice" />
  </security-role>
  <security-role name="batchSubmitter" >
    <user name="joe" />
    <user name="bob" />
  </security-role>
  <security-role name="batchMonitor" >
    <special-subject type="EVERYONE"/>
  </security-role>
</authorization-roles>

```

z/OS

**Note:** If the zosSecurity-1.0 feature is enabled, then batch role-based authorization is handled by the SAF authorization provider.

The SAF authorization provider determines the authorization of the client by checking the client's access level to SAF resource profiles defined in the EJBROLE class. By default, the following resource profiles are associated with the batch roles.

```

batchAdmin:    BBGZDFLT.com.ibm.ws.batch.batchAdmin
batchSubmitter: BBGZDFLT.com.ibm.ws.batch.batchSubmitter
batchMonitor:  BBGZDFLT.com.ibm.ws.batch.batchMonitor

```

The client identity must be granted READ access to the appropriate resource profile to be authorized to the corresponding batch role.

The following example illustrates the RACF commands to grant the client identity, bob, authorization to the batchAdmin role.

```

RDEFINE EJBROLE BBGZDFLT.com.ibm.ws.batch.batchAdmin UACC(NONE)
PERMIT BBGZDFLT.com.ibm.ws.batch.batchAdmin CLASS(EJBROLE) ID(bob) ACCESS(READ)

```

## Java batch shutdown and recovery

8.5.5.6

The Java batch feature behaves differently when the server is shut down while jobs are still running.

### Deactivating Java batch

Java batch is deactivated when the server is stopped or the Java batch feature is removed. It is also deactivated and reactivated to process a dynamic configuration update. Deactivating Java batch causes stop requests to be issued to all active jobs and messages to be logged for each stop. There is a 2-second period for the jobs to stop. If after 2 seconds there are Java batch jobs that are still running, a message is logged that indicates which job execution IDs are still active. Java batch then shuts down. If jobs are still running after Java batch shuts down, they can experience unpredictable behavior.

**Important:** If the server is unexpectedly stopped, Java batch recovers by marking all jobs that were running on the server but not completed as FAILED when the server is restarted.

### Batch REST API

8.5.5.6

The WebSphere Application Server Liberty includes a RESTful management interface to manage your batch jobs.

The basic operations that are associated with a batch job are to submit (start), stop, restart, and view status. You can perform these operations by using any HTTP REST client. Any data that is submitted as part of a request or returned as part of a response is JSON formatted.

The following examples show the functions that you can perform with the REST API.

**Note:** The Batch REST API is versioned on a URL by URL basis. URL's with no version number are considered as version 1 of the API. The web addresses of the batch REST interface all start with the root web address: `https://{host}:{port}/ibm/api/batch/{version}/`.

**Remember:** The web addresses of the batch REST interface all start with the root web address: `https://{host}:{port}/ibm/api/batch`.

- “REST API with a user ID that is only a submitter”
- “Job instances” on page 2214
- “Job executions” on page 2221
- “Step executions” on page 2222
- “Job logs” on page 2225
- “HTTP Return Codes” on page 2226
- “STOP requests in a distributed server batch environment” on page 2226
- “JOBLOGS requests in a distributed server batch environment” on page 2226
- “Purge requests in a distributed server batch environment” on page 2227

### REST API with a user ID that is only a submitter

The results returned by the GET (“read”) URLs will be filtered when the user ID that invokes the REST API over HTTPS has only been granted access to the **batchSubmitter** role. The submitter only sees instance and execution data that is associated with job instances that were submitted by the submitter himself. In contrast, user ids granted access to the **batchAdmin** and **batchMonitor** roles will be able to view all instance and execution data (returned by any given URL with any given set of parameters).

A userid which only has access to the **batchSubmitter** role sees results that are first filtered by the standard parameters as described in the documentation of the given URL, and then further filtered by only returning instance and execution data associated with job instances submitted by the submitter himself.

See *Securing the Liberty batch environment* for more information.

## Job instances

### GET /ibm/api/batch/jobinstances/

This URI returns a list of job instances. Query parameters include:

- `page=[page number]`: Indicates which page (subset of records) to return. The default is 0.
- `pageSize=[number of records per page]`: Indicates the number of records per page. The default is 50.

Sample requests:

```
https://localhost:9443/ibm/api/batch/jobinstances
```

```
https://localhost:9443/ibm/api/batch/jobinstances?page=13&pagesize=20
```

Sample response:

```
[
  {
    "jobName": "test_sleepyBatchlet",
    "instanceId": 7,
    "appName": "SimpleBatchJob#SimpleBatchJob.war",
    "submitter": "bob",
    "batchStatus": "COMPLETED",
    "jobXMLName": "test_sleepyBatchlet",
    "instanceState": "COMPLETED",
    "_links": [
      {
        "rel": "self",
        "href": "https://localhost:9443/ibm/api/batch/jobinstances/7"
      },
      {
        "rel": "job logs",
        "href": "https://localhost:9443/ibm/api/batch/jobinstances/7/joblogs"
      }
    ]
  },
  {
    "jobName": "test_sleepyBatchlet",
    "instanceId": 6,
    "appName": "SimpleBatchJob#SimpleBatchJob.war",
    "submitter": "bob",
    "batchStatus": "COMPLETED",
    "jobXMLName": "test_sleepyBatchlet",
    "instanceState": "COMPLETED",
    "_links": [
      {
        "rel": "self",
        "href": "https://localhost:9443/ibm/api/batch/jobinstances/6"
      },
      {
        "rel": "job logs",
        "href": "https://localhost:9443/ibm/api/batch/jobinstances/6/joblogs"
      }
    ]
  }
]
```

### GET /ibm/api/batch/v2/jobinstances/

This URI returns a list of job instances filtered by the following query parameters:

- `jobInstanceId=[instanceId]:[instanceId]`: Returns job instances equal to and between the `instanceId` range.
- `jobInstanceId=>[instanceId]`: Returns job instances equal to and greater than the provided `instanceId`.
- `jobInstanceId=<[instanceId]`: Returns job instances equal to and less than the provided `instanceId`.
- `jobinstanceId=[instanceId],[instanceId],[instanceId]`: Returns job instances specified.
- `createTime=[yyyy-MM-dd]:[yyy-MM-dd]`: Returns job instances between the date range inclusively. For more information, see note further on in this topic.
- `createTime=[yyyy-MM-dd]`: Returns job instances on the given date. For more information, see note further on in this topic.
- `createTime=>3d`: Returns job instances that were created on or after the day which was three days ago. For example, the `createTime` is greater than or equal to the beginning of the day three days ago. For more information, see note further on in this topic.
- `createTime=<3d`: Returns job instances that were created on or before the day which was three days ago. For example, the `createTime` is less than or equal to the end of the day three days ago. For more information, see note further on in this topic.
- `instanceState=[state],[state]`: Returns job instances with the provided state. Valid Instance States are SUBMITTED, JMS\_QUEUED, JMS\_CONSUMED, DISPATCHED, FAILED, STOPPED, COMPLETED and ABANDONED.
- `exitStatus=[string]`: Returns job instances matching the exit status string. The string criteria may utilize the wildcard(\*) operator on either end.
- `page=[page number]`: Indicates which page (subset of records) to return. The default is 0.
- `pageSize=[number of records per page]`: Indicates the number of records per page. The default is 50.

**Note: The role of the server default timezone in queries involving createTime**

When you submit a job, the `createTime` for the job instance is stored in the job repository and normalized to UTC. When specifying dates via `yyyy-MM-dd`, as in `createTime=[yyyy-MM-dd]` or `createTime=[yyyy-MM-dd]:[yyy-MM-dd]:`, then you must convert the `yyyy-MM-dd` date string into a specific range of UTC times to match against the `createTime` values in the job instance table records. To do this, the application uses the default timezone of the server handling the REST request. It is this server's timezone that is used to convert the date string into a UTC time range that will be matched against.

The following table illustrates data returned by the query parameters **jobInstanceId=10:13**.

JOBINSTANCEID	CREATETIME(* in server1's timezone)	INSTANCESTATE	EXITSTATUS
10	11-05-2015.01:10:00	COMPLETED	SUCCESS
11	11-08-2014.02:20:00	COMPLETED	SUCCESS
12	11-10-2015.03:30:00	FAILED	FAILURE
13	11-11-2015.04:40:00	COMPLETED	SUCCESS

\*Since the job repository stores the `createTime` in a UTC format, it is important to understand that the table data above shows the `createTime` formatted using the server's default timezone of a particular server, for example, "server1". If we had constructed a similar table from the perspective of a second server with a different default timezone (than "server1"), we would show a different set of `CREATETIME` column values which a corresponding timezone-based difference. It is the default timezone of the server handling the REST request which is used to map `yyyy-MM-dd` date string parameters to UTC `createTime` values in the database in the examples below.

The following commands return the same result regardless of which server they are issued against:

- `jobInstanceId=11:13` would return JOBINSTANCEID's 11, 12 and 13.
- `jobInstanceId=>12` would return JOBINSTANCEID's 12 and 13.
- `jobInstanceId=<12` would return JOBINSTANCEID's 11 and 12.
- `jobInstanceId=11,12` would return JOBINSTANCEID's 11 and 12.
- `instanceState=FAILED` would return JOBINSTANCEID 12..
- `exitStatus=SUCCESS` would return JOBINSTANCEID's 10, 11 and 13.

The following commands may return different results against servers with different default timezones. In these examples, they are issued against "server1" (the same server used to populate the table above) at date and time: 11-11-2015:07:00:00 in the server's default timezone.

- `createTime=>2d` would return JOBINSTANCEID's 12 and 13 (on or after 2 days ago, which was 11-09-2015)
- `createTime=<2d` would return JOBINSTANCEID's 10 and 11 (on or before 2 days ago, which was 11-09-2015)
- `createTime=2015-11-08:2015-11-11` would return records with JOBINSTANCEID's 11,12, and 13.
- `createTime=2015-11-10` would return record with JOBINSTANCEID 12.

Sample requests:

```
https://localhost:9443/ibm/api/batch/v2/jobinstances?instanceId=20:50
```

```
https://localhost:9443/ibm/api/batch/jobinstances?createTime=>2d
```

```
https://localhost:9443/ibm/api/batch/v2/jobinstances?instanceId=4,12,17&instanceState=COMPLETED
```

```
https://localhost:9443/ibm/api/batch/v2/jobinstances?instanceId=4500:4600&createTime=2015-11-27&instanceState=COMPLETED
```

#### **GET /ibm/api/batch/jobinstances/job *instance id***

This URI returns detailed information about the specified job instance such as all executions that are associated with a specified job instance. Results are returned in order from most recent to the oldest. The most recent result is displayed first in the list.

Sample response:

```
{
  "jobName": "test_sleepyBatchlet",
  "instanceId": 7,
  "appName": "SimpleBatchJob#SimpleBatchJob.war",
  "submitter": "bob",
  "batchStatus": "COMPLETED",
  "jobXMLName": "test_sleepyBatchlet",
  "instanceState": "COMPLETED",
  "_links": [
    {
      "rel": "self",
      "href": "https://localhost:9443/ibm/api/batch/jobinstances/7"
    },
    {
      "rel": "job logs",
      "href": "https://localhost:9443/ibm/api/batch/jobinstances/7/joblogs"
    },
    {
      "rel": "job execution",
      "href": "https://localhost:9443/ibm/api/batch/jobinstances/7/jobexecutions/7"
    }
  ]
}
```

#### **POST /ibm/api/batch/jobinstances/**

Use this URI to submit (start) a new job.

The following example illustrates the request body for submitting a job that is packaged in a WAR module, in JSON formatting:

```
{
  "applicationName" : "SimpleBatchJob",
  "moduleName" : "SimpleBatchJob.war",
  "jobXMLName" : "test_batchlet_jsl",
  "jobParameters" : { "prop1" : "prop1value", "prop2" : "prop2value"}
}
```

The following example illustrates the request body for submitting a job that is packaged in an EJB module, in JSON formatting:

```
{
  "applicationName" : "SimpleBatchJob",
  "moduleName" : "SimpleBatchJobEJB.jar",
  "componentName" : "MyEJB",
  "jobXMLName" : "test_batchlet_jsl",
  "jobParameters" : { "prop1" : "prop1value", "prop2" : "prop2value"}
}
```

The *applicationName* identifies the batch application. It is required unless *moduleName* is specified, in which case the *applicationName* is derived from the *moduleName* by trimming off the .war or .jar suffix of the *moduleName*. For example, if you provide no *applicationName* and *moduleName*=SimpleBatchJob.war, then *applicationName* defaults to SimpleBatchJob.

The *moduleName* identifies the module within the batch application that contains the job artifacts, such as the JSL. The job is submitted under the module's component context. The *moduleName* is required unless *applicationName* is specified, in which case the *moduleName* is derived from the *applicationName* by appending .war to the *applicationName*. For example, if you provide *applicationName*=SimpleBatchJob and no *moduleName*, then *moduleName* defaults to SimpleBatchJob.war.

The *componentName* identifies the EJB component within the batch application EJB module. If specified, the job is submitted under the EJB's component context.

**Note:** The *componentName* is required only when the module is an EJB module. When the module is a WAR module, the *componentName* is not required.

You must enter a value for *jobXMLName*. The value for *jobParameters* is optional.

**8.5.5.7** As an alternative to using the JSL job definition that is packaged within your batch application under META-INF/batch-jobs, you can pass your JSL inline as part of your REST job submission request. The JSL that is submitted inline always overrides any JSL that is packaged with the batch application. There are two ways to submit your JSL inline as part of your HTTP request.

1. Include your JSL as a JSON property in your job submission request. Add the property **jobXML** to the JSON object and add the entire content of the JSL file as a JSON string as the value of the property.

**Note:** You must properly escape the XML string so it can be parsed by a JSON parser. Most JSON libraries will do this for you.

The following example illustrates the request body for submitting a job that utilizes a single part HTTP request with the JSL being passed in-line by the JSON.

```
{
  "applicationName":"SimpleBatchJob",
  "jobXMLName":"test_multiPartition_3Steps",
  "jobXML":"<?xml version='1.0' encoding='UTF-8'>
standalone='yes'?>
\r\n<job id='test_multiPartition_3Steps'
xmlns='http://xmlns.jcp.org/xml/ns/javaee'\r\n\tversion='1.0'>
\r\n\t<step id='step1' next='step2'>
\r\n\t\t<batchlet ref='simpleBatchlet' />
\r\n\t\t<partition>\r\n\t\t\t<plan partitions='3' />
\r\n\t\t</partition>\r\n\t\t</step>
\r\n\t<step id='step2' next='step3'>
```

```

\r\n\t\t<batchlet ref="simpleBatchlet" />
\r\n\t\t<partition>\r\n\t\t\t<plan partitions="3" />
\r\n\t\t</partition>\r\n\t\t</step>\r\n\t\t<step id="step3">
\r\n\t\t\t<batchlet ref="simpleBatchlet" />\r\n\t\t</partition>
\r\n\t\t\t<plan partitions="3"/>
\r\n\t\t</partition>\r\n\t\t</step>\r\n</job>"
}

```

**Note:** The **jobXML** field must be parsed by a JSON parser and marshalled into a valid JSON object. The **jobXMLName** field is optional, as the job ID information in the inline JSL is used for the job name.

2. Use an HTTP multi-part form. When you use an HTTP multipart form the JSON job submission data and XML job definition need to be submitted as two separate parts of the HTTP body. The JSON part of the multi-part form must be named *jobdata* and the XML part of the form must be named *jsl*. The XML does not need to be marshalled to a JSON string when you use a multi-part form.

The following example illustrates the HTTP request for submitting a job that uses a multi-part HTTP request with the JSL being passed inline via the *jsl* message part.

```
Content-Type: multipart/form-data;boundary=-----49424d5f4a4241544348
```

```
-----49424d5f4a4241544348
```

```
Content-Disposition: form-data; name="jobdata"
```

```
Content-Type: application/json; charset=UTF-8
```

```
{
  "applicationName" : "SimpleBatchJob",
  "moduleName" : "SimpleBatchJob.war",
  "jobXMLName" : "test_multiPartition"
}
```

```
-----49424d5f4a4241544348
```

```
Content-Disposition: form-data; name="jsl"
```

```
Content-Type: application/xml; charset=UTF-8
```

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<job id="test_multiPartition" xmlns="http://xmlns.jcp.org/xml/ns/javaee"
version="1.0">
<step id="step1">
<batchlet ref="simpleBatchlet" />
<partition>
  <plan partitions="3" />
</partition>
</step>
</job>
```

```
-----49424d5f4a4241544348--
```

**Note:** The **jobXMLName** field is optional, as the job ID information in the inline JSL is used for the job name.

The following sample response illustrates a successful job submission:

```
{
  "jobName": "test_sleepyBatchlet",
  "instanceId": 10,
  "appName": "SimpleBatchJob#SimpleBatchJob.war",
  "submitter": "bob",
  "batchStatus": "STARTING",
  "jobXMLName": "test_sleepyBatchlet",
  "instanceState": "SUBMITTED",
  "_links": [
    {
      "rel": "self",
      "href": "https://localhost:9443/ibm/api/batch/jobinstances/10"
    }
  ],
}
```

```

    {
      "rel": "job logs",
      "href": "https://localhost:9443/ibm/api/batch/jobinstances/10/joblogs"
    }
  ]
}

```

**PUT /ibm/api/batch/jobinstances/job *instance id*?action=stop**

Use this URI to stop the most recent job execution that is associated with this job instance if it is running. If it is not, the API returns an error.

**PUT /ibm/api/batch/jobinstances/job *instance id*?action=restart**

Use this URI to restart the most recent job execution that is associated with this job instance only if it is in STOPPED or FAILED state. If no job execution is associated with this instance, or the latest job execution is in COMPLETED state, the API returns an error.

**PUT /ibm/api/batch/jobinstances/job *instance id*?action=restart&reusePreviousParams=true**

Use this URI to restart the most recent job execution and reuse the job parameters from the previous execution that is associated with this job instance. The previous execution must be in STOPPED or FAILED state. If no job execution is associated with this instance, or the latest job execution is in COMPLETED state, then the API returns an error. Note that **reusePreviousParams** is an optional setting. The default setting is **reusePreviousParams=false**.

**Note:** When **reusePreviousParams=true**, any job parameters that are submitted as part of the current restart request take precedence over any previous job parameters. Current parameters override previous parameters with the same job parameter key name.

**DELETE /ibm/api/batch/jobinstances/job *instance id***

This URI purges all database entries and job logs that are associated with this job instance. This API returns an error if the job instance has active job executions. If there is an error when you delete the job logs, then no attempt is made to delete the job instance data from the job store database. Query parameters include:

- `purgeJobStoreOnly=true|false`: When `purgeJobStoreOnly=true`, no attempt is made to purge the job logs associated with this job instance. The default setting is `purgeJobStoreOnly=false`. This API returns an error if the job instance has active job executions.

**Note:** No purge response message is returned when you utilize the single purge API.

**DELETE /ibm/api/batch/v2/jobinstances/**

This URI purges all database entries and job logs associated with the job instances returned by the following purge filter parameters:

**Note:** It is recommended that you utilize the GET interface to list out the jobs and verify they are the correct jobs to purge before performing the DELETE interface to purge them.

- `page=[page number]`: Indicates which page (subset of records) to return. The default is 0
- `pageSize=[number of records per page]`: Indicates the number of records per page. The default is 50.
- `purgeJobStoreOnly=true|false`: When `purgeJobStoreOnly=true`, no attempt is made to purge the job logs associated with this job instance. The default setting is `purgeJobStoreOnly=false`. This API returns an error if the job instance has active job executions.
- `jobInstanceId=[instanceId]:[instanceId]`: Purges job instances equal to and between the `instanceId` range.
- `jobInstanceId=>[instanceId]`: Purges job instances equal to and greater than the provided `instanceId`.
- `jobInstanceId=<[instanceId]`: Purges job instances equal to and less than the provided `instanceId`.
- `jobinstanceId=[instanceId],[instanceId],[instanceId]`: Purges job instances specified.

- createTime=[yyyy-MM-dd]:[yyy-MM-dd]: Returns job instances between the date range inclusively. For more information, see note further on in this topic.
- createTime=[yyyy-MM-dd]: Returns job instances on the given date. For more information, see note further on in this topic.
- createTime=>3d: Returns job instances that were created on or after the day which was three days ago. For example, the createTime is greater than or equal to the beginning of the day three days ago. For more information, see note further on in this topic.
- createTime=<3d: Returns job instances that were created on or before the day which was three days ago. For example, the createTime is less than or equal to the end of the day three days ago. For more information, see note further on in this topic.
- instanceState=[state],[state]: Purges job instances with the provided state. Valid Instance States are SUBMITTED, JMS\_QUEUED, JMS\_CONSUMED, DISPATCHED, FAILED, STOPPED, COMPLETED, and ABANDONED.
- exitStatus=[string]: Returns job instances matching the exit status string. The string criteria may utilize the wildcard(\*) operator on either end.

**Note:** By default, unless the page and pageSize parameters are specified, a maximum of 50 records are purged.

**Note: The role of the server default timezone in queries involving createTime**

When you submit a job, the createTime for the job instance is stored in the job repository and normalized to UTC. When specifying dates via yyyy-MM-dd, as in createTime=[yyyy-MM-dd] or createTime=[yyyy-MM-dd]:[yyy-MM-dd]:, then you must convert the yyyy-MM-dd date string into a specific range of UTC times to match against the createTime values in the job instance table records. To do this, the application uses the default timezone of the server handling the REST request. It is this server's timezone that is used to convert the date string into a UTC time range that will be matched against.

The following table illustrates data returned by the query parameters **jobInstanceId=10:13**.

JOBINSTANCEID	CREATETIME(* in server1's timezone)	INSTANCESTATE	EXITSTATUS
10	11-05-2015.01:10:00	COMPLETED	SUCCESS
11	11-08-2014.02:20:00	COMPLETED	SUCCESS
12	11-10-2015.03:30:00	FAILED	FAILURE
13	11-11-2015.04:40:00	COMPLETED	SUCCESS

\*Since the job repository stores the createTime in a UTC format, it is important to understand that the table data above shows the createTime formatted using the server's default timezone of a particular server, for example, "server1". If we had constructed a similar table from the perspective of a second server with a different default timezone (than "server1"), we would show a different set of CREATETIME column values which a corresponding timezone-based difference. It is the default timezone of the server handling the REST request which is used to map yyyy-MM-dd date string parameters to UTC createTime values in the database in the examples below.

The following commands return the same result regardless of which server they are issued against:

- jobInstanceId=11:13 would return JOBINSTANCEID's 11, 12 and 13.
- jobInstanceId=>12 would return JOBINSTANCEID's 12 and 13.
- jobInstanceId=<12 would return JOBINSTANCEID's 11 and 12.
- jobInstanceId=11,12 would return JOBINSTANCEID's 11 and 12.
- instanceState=FAILED would return JOBINSTANCEID 12..

- `exitStatus=SUCCESS` would return `JOBINSTANCEID`'s 10, 11 and 13.

The following commands may return different results against servers with different default timezones. In these examples, they are issued against "server1" (the same server used to populate the table above) at date and time: 11-11-2015:07:00:00 in the server's default timezone.

- `createTime=>2d` would return `JOBINSTANCEID`'s 12 and 13 (on or after 2 days ago, which was 11-09-2015)
- `createTime=<2d` would return `JOBINSTANCEID`'s 10 and 11 (on or before 2 days ago, which was 11-09-2015)
- `createTime=2015-11-08:2015-11-11` would return records with `JOBINSTANCEID`'s 11,12, and 13.
- `createTime=2015-11-10` would return record with `JOBINSTANCEID` 12.

Sample response:

```
[{"instanceId":394,"purgeStatus":"COMPLETED","message":"Successful purge.,"redirectUrl":""},
{"instanceId":395,"purgeStatus":"COMPLETED","message":"Successful purge.,"redirectUrl":""},
{"instanceId":396,"purgeStatus":"COMPLETED","message":"Successful purge.,"redirectUrl":""},
{"instanceId":397,"purgeStatus":"COMPLETED","message":"Successful purge.,"redirectUrl":""},
{"instanceId":398,"purgeStatus":"COMPLETED","message":"Successful purge.,"redirectUrl":""}]
```

The following `purgeStatus` values can be returned:

#### **COMPLETED**

Indicates that the job purge completed successfully.

#### **FAILED**

Indicates that the job purge failed.

#### **STILL\_ACTIVE**

Indicates that the job purge failed because it was still active.

#### **JOBLOGS\_ONLY**

Indicates that the database purge failed, but that the job logs were successfully purged.

#### **NOT\_LOCAL**

Indicates that the job purge failed because the job is not local.

## **Job executions**

### **GET /ibm/api/batch/jobexecutions/*job execution id***

This URI returns detailed information about a specified job execution and includes links to associated step executions and job logs.

Sample request:

```
https://localhost:9443/ibm/api/batch/jobexecutions/9
```

Sample response:

```
{
  "jobName":"test_sleepyBatchlet",
  "executionId":9,
  "instanceId":9,
  "batchStatus":"COMPLETED",
  "exitStatus":"COMPLETED",
  "createTime":"2015/05/07 16:09:41.025 -0400",
  "endTime":"2015/05/07 16:09:52.127 -0400",
  "lastUpdatedTime":"2015/05/07 16:09:52.127 -0400",
  "startTime":"2015/05/07 16:09:41.327 -0400",
  "jobParameters":{
  },
  "restUrl":"https://localhost:9443/ibm/api/batch",
  "serverId":"localhost/C:/ibm/RAD_workspaces/Liberty7/build.image/wlp/usr/server1",
  "logpath":"C:\\ibm\\Liberty\\wlp\\usr\\servers\\server1\\logs\\joblogs\\test_sleepyBatchlet\\2015-05-07\\ins",
  "stepExecutions":[
  ]
}
```

```

        "stepExecutionId":9,
        "stepName":"step1",
        "batchStatus":"COMPLETED",
        "exitStatus":"SleepyBatchlet:i=10;stopRequested=false",
        "stepExecution":"https://localhost:9443/ibm/api/batch/jobexecutions/9/stepexecutions/step1"
    },
    "_links":[
        {
            "rel":"self",
            "href":"https://localhost:9443/ibm/api/batch/jobexecutions/9"
        },
        {
            "rel":"job instance",
            "href":"https://localhost:9443/ibm/api/batch/jobinstances/9"
        },
        {
            "rel":"step executions",
            "href":"https://localhost:9443/ibm/api/batch/jobexecutions/9/stepexecutions"
        },
        {
            "rel":"job logs",
            "href":"https://localhost:9443/ibm/api/batch/jobexecutions/9/joblogs"
        },
        {
            "rel":"stop url",
            "href":"https://localhost:9443/ibm/api/batch/jobexecutions/9?action=stop"
        }
    ]
}

```

#### **GET /ibm/api/batch/jobexecutions/job execution id/jobinstance**

This URI returns detailed information about the job instance related to the specified job execution.

#### **GET /ibm/api/batch/jobinstances/job instance id/jobexecutions**

This URI returns detailed information about the job execution(s) for a specified job instance. This includes links to associated step executions and job logs.

#### **GET /ibm/api/batch/jobinstances/job instance id/jobexecutions/job execution sequence number**

This URI returns detailed information about the specified job execution in relation to the specified job instance ID. This includes links to associated step executions and job logs.

**Note:** The job execution sequence number means the 0th, 1st, 2nd, etc. job execution related to the specified job instance.

#### **PUT /ibm/api/batch/jobexecutions/job execution id?action=stop**

Use this URI to stop the specified running job execution. Required parameters include action = *stop*, *restart*.

#### **PUT /ibm/api/batch/jobexecutions/job execution id?action=restart**

Use this URI to restart the specified job execution. Required parameters include action = *stop*, *restart*.

## **Step executions**

#### **GET /ibm/api/batch/jobexecutions/job execution id/stepexecutions**

This URI returns a JSON array of all the step execution details for the specified job execution. If your job contains a partitioned step, the partition information will be returned listed within each step.

Sample request:

`https://localhost:8020/ibm/api/batch/jobexecutions/40/stepexecutions`

The following sample illustrates a response for a partitioned step.

```

[
  {
    "stepExecutionId":47,
    "executionId":39,
    "instanceId":35,
    "stepName":"step1",
    "batchStatus":"COMPLETED",
    "startTime":"2015/03/30 11:10:08.652 -0400",
    "endTime":"2015/03/30 11:10:09.817 -0400",
    "exitStatus":"COMPLETED",
    "metrics":{
      "READ_COUNT":"0",
      "WRITE_COUNT":"0",
      "COMMIT_COUNT":"0",
      "ROLLBACK_COUNT":"0",
      "READ_SKIP_COUNT":"0",
      "PROCESS_SKIP_COUNT":"0",
      "FILTER_COUNT":"0",
      "WRITE_SKIP_COUNT":"0"
    },
    "partitions":[
      {
        "partitionNumber":0,
        "batchStatus":"COMPLETED",

      "WRITE_SKIP_COUNT":"0"
    }
  },
  {
    "_links":[
      {
        "rel":"job execution",
        "href":"https://localhost:9443/ibm/api/batch/jobexecutions/9"
      },
      {
        "rel":"job instance",
        "href":"https://localhost:9443/ibm/api/batch/jobinstances/9"
      }
    ]
  }
]

```

**GET /ibm/api/batch/jobexecutions/job execution id/stepexecutions/step name**

This URI returns a JSON array containing the step execution details for the specified job execution and step name.

**GET /ibm/api/batch/jobinstances/job instance id/jobexecutions/job execution sequence number/stepexecutions/step name**

This URI returns a JSON array containing the step execution details for the specified job instance, job execution, and step name.

**GET /ibm/api/batch/stepexecutions/step execution id**

This URI returns a JSON array containing the step execution details for the specified step execution.

## Job logs

**GET /ibm/api/batch/jobinstances/job instance id/joblogs**

This URI returns a JSON array with REST links to all job log parts for the specified job instance.

**GET /ibm/api/batch/jobexecutions/job execution id/joblogs**

This URI returns a JSON array with REST links to all job log parts for the specified job execution.

**Important:** The following example shows the format of the REST links.

If your job execution has the following job log parts,

```

joblogs/instance.inst-id/execution.exec-id/part.1.log
joblogs/instance.inst-id/execution.exec-id/part.2.log
joblogs/instance.inst-id/execution.exec-id/step.step-name/partition.0/part.1.log
joblogs/instance.inst-id/execution.exec-id/step.step-name/partition.1/part.1.log

```

then the corresponding REST links are:

```

/ibm/api/batch/jobexecutionsexec-id/joblogs?part=part.1.log
/ibm/api/batch/jobexecutionsexec-id/joblogs?part=part.2.log
/ibm/api/batch/jobexecutionsexec-id/joblogs?part=step.step-name/partition.0/part.1.log
/ibm/api/batch/jobexecutionsexec-id/joblogs?part=step.step-name/partition.1/part.1.log

```

Optional parameters include:

**type = text**

Text returns all job logs as plain text. All job log parts are aggregated together. Part delimiting header and footer records are inserted into the stream to delimit the different parts as they are aggregated together.

**type = zip**

Zip returns all job logs for the specified job instance or job execution as a compressed file. The directory structure of the job logs is preserved in the compressed file.

**GET /ibm/api/batch/jobinstances/job instance id/joblogs?type=text | zip**

**GET /ibm/api/batch/jobexecutions/job execution id/joblogs?type=text | zip**

The behavior of these two URIs with the **type** parameter specified varies by value.

**type = text**

Text returns all job logs as plain text. All job log parts are aggregated together. Part delimiting header and footer records are inserted into the stream to delimit the different parts as they are aggregated together.

**type = zip**

Zip returns all job logs for the specified job instance or job execution as a compressed file. The directory structure of the job logs is preserved in the compressed file.

**GET /ibm/api/batch/jobexecutions/job execution id/joblogs?part=path to part&type=text | zip**

With the **part** parameter specified, this URI returns job log parts as either plain text (type=text) or in a compressed file (type=zip). The default setting is type=text.

## HTTP Return Codes

The following HTTP return codes for the REST API.

- HTTP 200 OK
- HTTP 201 Successfully created a new resource.
- HTTP 202 Accepted request, but processing is not complete.
- HTTP 400 Bad Request with invalid parameters. See returned message for details.
- HTTP 401 Unauthorized to access this resource.
- HTTP 403 Authentication failed.
- HTTP 404 The requested resource cannot be found or does not exist.
- HTTP 409 The request conflicts with the current state of the resource. See returned message for details.
- HTTP 500 Internal Server Error.

## STOP requests in a distributed server batch environment

Stop requests sent to the batch REST API must be sent directly to the executor where the job is running. If a stop request is sent to a dispatcher or executor where the job is not running, the request is redirected to the correct executor by an HTTP 302 redirection response message. The **location** field in the HTTP 302 redirection response indicates the correct URL to use for the stop request.

## JOBLOGS requests in a distributed server batch environment

Job logs requests sent to the batch REST API must be sent directly to the executor where the job is running. If a job logs request is sent to a dispatcher or executor where the job is not running, the request is redirected to the correct executor by an HTTP 302 redirection response message. The **location** field in the HTTP 302 redirection response indicates the correct URL to use for the job logs request.

**Note:** Job logs requests that are sent to the batch REST API for an entire job instance work only if all job executions for that instance ran on the same executor. If the executions ran on different executors, then the job logs requests for the instance fails. In this case, you must fetch the job logs for each execution separately.

## Purge requests in a distributed server batch environment

Purge requests sent to the batch REST API must be sent directly to the executor where the job is running. If a purge request is sent to a dispatcher or executor where the job is not running, the request is redirected to the correct executor by an HTTP 302 redirection response message. The **location** field in the HTTP 302 redirection response indicates the correct URL to use for the purge request.

**Note:** Purge requests that are sent to the batch REST API for an entire job instance work only if all job executions for that instance ran on the same executor. If the executions ran on different executors, then the purge requests for the instance fails.

## Enabling multiple server support by using the Liberty embedded messaging provider

8.5.5.6

The batch environment can be set up to have servers function as batch dispatchers while other servers function as batch executors. Batch dispatchers accept requests from external clients and make them available to the batch executors. The batch executors receive requests that match its defined capabilities and execute those requests. Batch dispatchers and batch executors communicate by using Java Messaging Service (JMS).

### Before you begin

Determine where the embedded message engine is hosted. It can be hosted on the batch dispatch server, the batch executor server, or on a separate server. This server must be configured before you complete this task. The JMS connection factory and activation specification references the message engine server in its configuration. To configure the message engine:

1. Add the **wasJmsServer-1.0** feature to the `server.xml`.
2. Define the message engine by adding the **messageEngine** element. Define the queue that is used for the batch dispatcher and batch executor. The following example illustrates the message engine configuration in your `server.xml`.

```
<!--specify the ports for the message engine.
The ports in this example are the default ports.
This element is not needed when the default ports are used. -->
<wasJmsEndpoint host="*"
  wasJmsPort="7280"
  wasJmsSSLPort="7290"
  enabled="true">
</wasJmsEndpoint>

<messagingEngine>
  <!-- queue for batch jms message. -->
  <queue id="batchLibertyQueue"
    forceReliability="ReliablePersistent"
    receiveAllowed="true"/>
</messagingEngine>
```

### About this task

This task helps you configure the batch dispatch server and the batch executor by using the Liberty embedded messaging provider.

## Procedure

To configure batch dispatcher and executor that uses Liberty embedded messaging provider:

1. Configure the batch JMS dispatcher.
  - a. Enable JMS support by adding the **wasJmsClient-2.0** feature to the feature manager in your `server.xml`.
  - b. Add the **batchJmsDispatcher** element to your `server.xml` on the server that hosts the batch dispatcher.

```
<batchJmsDispatcher connectionFactoryRef={reference to a configured JMS connection factory}
queueRef={reference to a configured JMS queue} />
```

**Note:** If you do not specify the `connectionFactoryRef` and `queueRef` attributes, the default value for `connectionFactoryRef` is **batchConnectionFactory** and the default value for `queueRef` is **batchJobSubmissionQueue**. You can specify the `batchJmsDispatcher` element as `<batchJmsDispatcher />`. You still must configure the **batchConnectionFactory** JMS connection factory and the JMS **batchJobSubmissionQueue** queue in the `server.xml` file.

- c. Add the corresponding JMS connection factory and JMS queue to the server configuration. This is not specific to batch configuration. The following example illustrates the batch JMS dispatcher configuration and its JMS configuration.

**Note:** The **remoteServerAddress** attribute points to the `host:port` of the server that is hosting the Liberty message engine.

```
<batchJmsDispatcher connectionFactoryRef="batchConnectionFactory"
queueRef="batchJobSubmissionQueue" />

<jmsConnectionFactory id="batchConnectionFactory"
jndiName="jms/batch/connectionFactory">
  <properties.wasJms remoteServerAddress="host:7280:BootstrapBasicMessaging">
  </properties.wasJms>
</jmsConnectionFactory>

<jmsQueue id="batchJobSubmissionQueue"
jndiName="jms/batch/jobSubmissionQueue">
  <properties.wasJms deliveryMode="Persistent"
queueName="batchLibertyQueue">
  </properties.wasJms>
</jmsQueue>
```

2. Configure the batch JMS executor.
  - a. Enable JMS support by adding the **wasJmsClient-2.0** feature to the feature manager in your `server.xml`.
  - b. Add the **batchJmsExecutor** element to your `server.xml` file on the server that hosts the batch executor.

```
<batchJmsExecutor activationSpecRef={configured activation specification or batch executor}
queueRef={reference to the configured JMS queue} />
```

**Note:** If you do not specify the `activationSpecRef` and `queueRef` attributes, the default value for `activationSpecRef` is **batchActivationSpec** and the default value for `queueRef` is **batchJobSubmissionQueue**. You can specify the `batchJmsExecutor` element as `<batchJmsExecutor />`. You still must configure the JMS activation specification for `batchActivationSpec` and the `batchJobSubmissionQueue` JMS queue in the `server.xml` file.

- c. Add the corresponding JMS activation specification and JMS queue to the server configuration. This is not specific to batch configuration.
  - d. Define batch executor server capabilities by including a JMS message selector in the activation specification.
    - Filtering based on system defined properties:  
There is a set of batch dispatcher properties available on the batch JMS message that the batch executor can use to filter for inbound messages.

- **com\_ibm\_ws\_batch\_applicationName**: the name of the batch application for the job request
- **com\_ibm\_ws\_batch\_moduleName**: the module name of the batch application for the job request
- **com\_ibm\_ws\_batch\_componentName**: the component name of the batch application for the job request

**Note:** It is recommended that a message selector is specified with at least the **com\_ibm\_ws\_batch\_applicationName** property to ensure that the executor only receives jobs that it can process.

The following example indicates the **messageSelector** attribute for the executor to accept a job for the application SimpleBatchJob and BonusPayout.

```
messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob' OR com_ibm_ws_batch_applicationName = 'BonusPayout'>
```

The following example indicates the **messageSelector** attribute for the executor to accept a job for the application SimpleBatchJob.

```
messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob'>
```

- Filtering based on user-defined properties:

The batch dispatcher sets all job parameters that conform to the proper JMS message property on the batch dispatcher request message. These properties can also be used by the message selector to add extra filtering to the message selector. The property name, or identifier, must conform to JMS message property constraints. For example, the property is an unlimited length sequence of letters and digits, the first of which must be a letter. A letter is any character for which the method **Character.isJavaLetter** returns true, and includes '\_' and '\$'. A letter or digit is any character for which the method **Character.isJavaLetterOrDigit** returns true. Check JMS Javadoc for more information on JMS message selectory.

The following example illustrates a possible message selector using the **com\_ibm\_ws\_batch\_applicationName** property and a job parameter **specialCapability**.

```
messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob' AND specialCapability = 'superCapability'>
```

The following example illustrates the batch JMS executor configuration and its JMS configuration.

```
<batchJmsExecutor activationSpecRef="batchActivationSpec"
  queueRef="batchJobSubmissionQueue"/>

<jmsActivationSpec id="batchActivationSpec" >
  <properties.wasJms destinationRef="batchJobSubmissionQueue"
    messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob' OR com_ibm_ws_batch_applicationName = 'BonusPayoutCDI'"
    destinationType="javax.jms.Queue"
    remoteServerAddress="host:7280:BootstrapBasicMessaging">
  </properties.wasJms>
</jmsActivationSpec>

<jmsQueue id="batchJobSubmissionQueue"
  jndiName="jms/batch/jobSubmissionQueue">
  <properties.wasJms deliveryMode="Persistent"
    queueName="batchLibertyQueue">
  </properties.wasJms>
</jmsQueue>
```

3. Install your batch application on the server. For more information, see Chapter 10, “Deploying applications in Liberty,” on page 2139.

## Enabling multiple server support by using the WebSphere MQ messaging provider

8.5.5.6

The batch environment can be set up to have servers function as batch dispatchers while other servers function as batch executors. Batch dispatchers accept requests from external clients and make them available to the batch executors. The batch executors receive requests that match its defined capabilities and execute those requests. Batch dispatchers and batch executors communicate by using Java Messaging Service (JMS).

## About this task

This task helps you configure the batch dispatch server and the batch executor by using the WebSphere MQ messaging provider.

### Procedure

1. Configure the batch JMS dispatcher.
  - a. Enable JMS support by adding the `wmqJmsClient-2.0` feature to the feature manager in your `server.xml` file.
  - b. Add the `batchJmsDispatcher` element to your `server.xml` file on the server that hosts the batch dispatcher.

```
<batchJmsDispatcher connectionFactoryRef={reference to a configured JMS connection factory}  
queueRef={reference to a configured JMS queue} />
```

**Note:** If you do not specify the `connectionFactoryRef` and `queueRef` attributes, the default value for `connectionFactoryRef` is `batchConnectionFactory` and the default value for `queueRef` is `batchJobSubmissionQueue`. You can specify the `batchJmsDispatcher` element as `<batchJmsDispatcher />`. You still must configure the `batchConnectionFactory` JMS connection factory and the JMS `batchJobSubmissionQueue` queue in the `server.xml` file.

- c. Add the corresponding JMS connection factory and JMS queue to the server configuration. This is not specific to batch configuration.

The following example illustrates the batch JMS dispatcher configuration and its JMS configuration using WMQ binding mode.

```
<batchJmsDispatcher connectionFactoryRef="batchConnectionFactory"  
queueRef="batchJobSubmissionQueue" />
```

```
<!-- wmq resource adapter -->  
<variable name="wmqJmsClient.rar.location"  
value="{server.config.dir}/wmq.wlp.rar"/>  
  
<!-- nativeLibraryPath is required for BINDING mode -->  
<!-- the startup retry and reconnect retry properties are  
recommended to ensure robustness of the system.-->  
<wmqJmsClient nativeLibraryPath="/mqm/jms/java/lib"  
startupRetryCount=999  
startupRetryInterval="1000ms"  
reconnectionRetryCount=10  
reconnectionRetryInterval="5m">  
</wmqJmsClient>  
  
<authData password="pwd" user="user">  
</authData>  
  
<jmsConnectionFactory id="batchConnectionFactory"  
jndiName="jms/batch/connectionFactory">  
<properties.wmqJms transportType="BINDINGS"  
queueManager="WMQX">  
</properties.wmqJms>  
</jmsConnectionFactory>  
  
<!-- baseQueueName is the queue defined on WMQ system -->  
<jmsQueue id="batchJobSubmissionQueue"  
jndiName="jms/batch/jobSubmissionQueue">  
<properties.wmqJms baseQueueName="BATCHQ"  
priority="QDEF"  
baseQueueManagerName="WMQX">  
</properties.wmqJms>  
</jmsQueue>
```

The following example illustrates the batch JMS dispatcher configuration and its JMS configuration using WMQ in client mode.

```
<batchJmsDispatcher connectionFactoryRef="batchConnectionFactory"  
queueRef="batchJobSubmissionQueue" />
```

```
<!-- wmq resource adapter -->  
<variable name="wmqJmsClient.rar.location"  
value="{server.config.dir}/wmq.wlp.rar"/>
```

```

<!-- the startup retry and reconnect retry properties are
      recommended to ensure robustness of the system.-->
<wmqJmsClient startupRetryCount=999
  startupRetryInterval="1000ms"
  reconnectionRetryCount=10
  reconnectionRetryInterval="5m">
</wmqJmsClient>

<authData password="pwd" user="user">
</authData>

<jmsConnectionFactory id="batchConnectionFactory"
  jndiName="jms/batch/connectionFactory">
  <properties.wmqJms
    hostname="webs24.pok.stglabs.ibm.com"
    transportType="CLIENT"
    channel="WAS.JMS.SVRCONN"
    port="1414"
    queueManager="WMQX"/>>
</properties.wmqJms>
</jmsConnectionFactory>

<!-- baseQueueName is the queue defined on WMQ system -->
<jmsQueue id="batchJobSubmissionQueue"
  jndiName="jms/batch/jobSubmissionQueue">
  <properties.wmqJms baseQueueName="BATCHQ"
    priority="QDEF"
    baseQueueManagerName="WMQX">
  </properties.wmqJms>
</jmsQueue>

```

## 2. Configure the batch JMS executor.

- a. Enable JMS support by adding the **wmqJmsClient-2.0** feature to the feature manager in your `server.xml` file.
- b. Add the **batchJmsExecutor** element to your `server.xml` file on the server that hosts the batch executor.

```

<batchJmsExecutor activationSpecRef={configured activation specification or batch executor}
  queueRef={reference to the configured JMS queue} />

```

**Note:** If you do not specify the `activationSpecRef` and `queueRef` attributes, the default value for `activationSpecRef` is **batchActivationSpec** and the default value for `queueRef` is **batchJobSubmissionQueue**. You can specify the `batchJmsExecutor` element as `<batchJmsExecutor />`. You still must configure the JMS activation specification for `batchActivationSpec` and the `batchJobSubmissionQueue` JMS queue in the `server.xml` file.

- c. Add the corresponding JMS activation specification and JMS queue to the server configuration. This is not specific to batch configuration.
- d. Define batch executor server capabilities by including a JMS message selector in the activation specification.

- Filtering based on system defined properties:

There is a set of batch dispatcher properties available on the batch JMS message that the batch executor can use to filter for inbound messages.

- **com\_ibm\_ws\_batch\_applicationName:** the name of the batch application for the job request
- **com\_ibm\_ws\_batch\_moduleName:** the module name of the batch application for the job request
- **com\_ibm\_ws\_batch\_componentName:** the component name of the batch application for the job request

**Note:** It is recommended that a message selector is specified with at least the **com\_ibm\_ws\_batch\_applicationName** property to ensure that the executor only receives jobs that it can process.

The following example indicates the **messageSelector** attribute for the executor to accept a job for the application `SimpleBatchJob` and `BonusPayout`.

```

messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob' OR com_ibm_ws_batch_applicationName = 'BonusPayout'">

```

The following example indicates the **messageSelector** attribute for the executor to accept a job for the application SimpleBatchJob.

```
messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob'">
```

- Filtering based on user-defined properties:

The batch dispatcher sets all job parameters that conform to the proper JMS message property on the batch dispatcher request message. These properties can also be used by the message selector to add extra filtering to the message selector. The property name, or identifier, must conform to JMS message property constraints. For example, the property is an unlimited length sequence of letters and digits, the first of which must be a letter. A letter is any character for which the method **Character.isJavaLetter** returns true, and includes '\_' and '\$'. A letter or digit is any character for which the method **Character.isJavaLetterOrDigit** returns true. Check JMS Javadoc for more information on JMS message selectory.

The following example illustrates a possible message selector by using the **com\_ibm\_ws\_batch\_applicationName** property and a job parameter **specialCapability**.

```
messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob' AND specialCapability = 'superCapability'">
```

The following example illustrates the batch JMS executor configuration and its JMS configuration using WMQ binding mode.

```
<batchJmsExecutor activationSpecRef="batchActivationSpec"
  queueRef="batchJobSubmissionQueue"/>

<!-- wmq resource adapter -->
<variable name="wmqJmsClient.rar.location"
  value="${server.config.dir}/wmq.wlp.rar"/>

<!-- nativeLibraryPath is required for BINDING mode -->
<!-- the startup retry and reconnect retry properties are
  recommended to ensure robustness of the system.-->
<wmqJmsClient nativeLibraryPath="/mqm/jms/java/lib"
  startupRetryCount=999
  startupRetryInterval="1000ms"
  reconnectionRetryCount=10
  reconnectionRetryInterval="5m">
</wmqJmsClient>

<authData password="pwd" user="user">
</authData>

<JmsActivationSpec id="batchActivationSpec" >
  <properties.wmqJms destinationRef="batchJobSubmissionQueue"
    destinationType="javax.jms.Queue"
    messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob' OR com_ibm_ws_batch_applicationName = 'BonusPayout'"
    transportType="BINDINGS"
    queueManager="WMQX">
  </properties.wmqJms>
</JmsActivationSpec>

<!-- baseQueueName is the queue defined on WMQ system -->
<jmsQueue id="batchJobSubmissionQueue"
  jndiName="jms/batch/jobSubmissionQueue">
  <properties.wmqJms baseQueueName="BATCHQ"
    priority="QDEF"
    baseQueueManagerName="WMQX">
  </properties.wmqJms>
</jmsQueue>
```

The following example illustrates the batch JMS executor configuration and its JMS configurations using WMQ client mode.

```
<batchJmsExecutor activationSpecRef="batchActivationSpec"
  queueRef="batchJobSubmissionQueue"/>

<!-- wmq resource adapter -->
<variable name="wmqJmsClient.rar.location"
  value="${server.config.dir}/wmq.wlp.rar"/>

<!-- the startup retry and reconnect retry properties are
  recommended to ensure robustness of the system.-->
<wmqJmsClient startupRetryCount=999
  startupRetryInterval="1000ms"
```

```

    reconnectionRetryCount=10
    reconnectionRetryInterval="5m">
</wmqJmsClient>

<authData password="pwd" user="user">
</authData>

<JmsActivationSpec id="batchActivationSpec" >
  <properties.wmqJms destinationRef="batchJobSubmissionQueue"
    messageSelector="com_ibm_ws_batch_applicationName = SimpleBatchJob' OR com_ibm_ws_batch_applicationName = 'BonusPayout'"
    transportType="CLIENT"
    channel="WAS.JMS.SVRCONN"
    destinationType="javax.jms.Queue"
    queueManager="WMQX"
    hostName="webs24.pok.stglabs.ibm.com"
    port="1414">
  </properties.wmqJms>
</jmsActivationSpec>

<!-- baseQueueName is the queue defined on WMQ system -->
<jmsQueue id="batchJobSubmissionQueue"
  jndiName="jms/batch/jobSubmissionQueue">
  <properties.wmqJms baseQueueName="BATCHQ"
    baseQueueManagerName="WMQX">
  </properties.wmqJms>
</jmsQueue>

```

3. Install your batch application on the server. For more information, see Chapter 10, “Deploying applications in Liberty,” on page 2139.

## Enabling multiple server partitions support by using the WebSphere MQ messaging provider

8.5.5.8

You can set up the batch environment to have servers function as batch dispatchers, while other servers function as batch executors.

### About this task

Batch dispatchers accept requests from external clients and make them available to the batch executors. The batch executors receive requests that match its defined capabilities and execute those requests. If the job is configured to run partitions, the batch executors make them available to the other executors to run. The batch executors communicate by using Java Messaging Service (JMS). This task helps you configure the batch dispatch server and the batch executor by using the WebSphere MQ messaging provider.

### Procedure

1. Configure the batch JMS dispatcher.
  - a. Enable JMS support by adding the **wmqJmsClient-2.0** feature to the feature manager in your `server.xml` file.
  - b. Add the **batchJmsDispatcher** element to your `server.xml` file on the server that hosts the batch dispatcher; for example:

```

<batchJmsDispatcher connectionFactoryRef={reference to a configured JMS connection factory}
  queueRef={reference to a configured JMS queue} />

```

**Note:** If you do not specify the `connectionFactoryRef` and `queueRef` attributes, the default value for `connectionFactoryRef` is **batchConnectionFactory** and the default value for `queueRef` is **batchJobSubmissionQueue**. You can specify the `batchJmsDispatcher` element as `<batchJmsDispatcher/>`. You still must configure the **batchConnectionFactory** JMS connection factory and the JMS **batchJobSubmissionQueue** queue in the `server.xml` file.

- c. Add the corresponding JMS connection factory and JMS queue to the server configuration. This is not specific to batch configuration.

The following example illustrates the batch JMS dispatcher configuration and its JMS configuration using WebSphere MQ binding mode:

```
<batchJmsDispatcher connectionFactoryRef="batchConnectionFactory"
  queueRef="batchJobSubmissionQueue" />

<!-- wmq resource adapter -->
<variable name="wmqJmsClient.rar.location"
  value="{server.config.dir}/wmq.wlp.rar"/>

<!-- nativeLibraryPath is required for BINDING mode -->
<!-- the startup retry and reconnect retry properties are
  recommended to ensure robustness of the system.-->
<wmqJmsClient nativeLibraryPath="/mqm/jms/java/lib"
  startupRetryCount=999
  startupRetryInterval="1000ms"
  reconnectionRetryCount=10
  reconnectionRetryInterval="5m">
</wmqJmsClient>

<authData password="pwd" user="user">
</authData>

<jmsConnectionFactory id="batchConnectionFactory"
  jndiName="jms/batch/connectionFactory">
  <properties.wmqJms transportType="BINDINGS"
    queueManager="WMQX">
  </properties.wmqJms>
</jmsConnectionFactory>

<!-- baseQueueName is the queue defined on WMQ system -->
<jmsQueue id="batchJobSubmissionQueue"
  jndiName="jms/batch/jobSubmissionQueue">
  <properties.wmqJms baseQueueName="BATCHQ"
    priority="QDEF"
    baseQueueManagerName="WMQX">
  </properties.wmqJms>
</jmsQueue>
```

The following example illustrates the batch JMS dispatcher configuration and its JMS configuration using WebSphere MQ in client mode:

```
<batchJmsDispatcher connectionFactoryRef="batchConnectionFactory"
  queueRef="batchJobSubmissionQueue" />

<!-- wmq resource adapter -->
<variable name="wmqJmsClient.rar.location"
  value="{server.config.dir}/wmq.wlp.rar"/>

<!-- the startup retry and reconnect retry properties are
  recommended to ensure robustness of the system.-->
<wmqJmsClient startupRetryCount=999
  startupRetryInterval="1000ms"
  reconnectionRetryCount=10
  reconnectionRetryInterval="5m">
</wmqJmsClient>

<authData password="pwd" user="user">
</authData>

<jmsConnectionFactory id="batchConnectionFactory"
  jndiName="jms/batch/connectionFactory">
  <properties.wmqJms
    hostName="webs24.pok.stglabs.ibm.com"
    transportType="CLIENT"
    channel="WAS.JMS.SVRCONN"
    port="1414"
    queueManager="WMQX"/>>
  </properties.wmqJms>
</jmsConnectionFactory>

<!-- baseQueueName is the queue defined on WMQ system -->
<jmsQueue id="batchJobSubmissionQueue"
  jndiName="jms/batch/jobSubmissionQueue">
  <properties.wmqJms baseQueueName="BATCHQ"
    priority="QDEF"
    baseQueueManagerName="WMQX">
  </properties.wmqJms>
</jmsQueue>
```

## 2. Configure the batch JMS executor for executing jobs

- a. Enable JMS support by adding the **wmqJmsClient-2.0** feature to the feature manager in your `server.xml` file.
- b. Add the **batchJmsDispatcher** element to your `server.xml` file on the server that hosts the batch executor.

**Note:** If you do not add the **batchJmsDispatcher** element to your `server.xml` file, the server will not dispatch partitions to run on multiple servers and will run the partitions locally.

- c. Add the **batchJmsExecutor** element and a `connectionFactory` to your `server.xml` file on the server that hosts the batch executor. For more information, see step 1b and 1c.

```
<batchJmsExecutor activationSpecRef={configured activation specification or batch executor}  
queueRef={reference to the configured JMS queue} />
```

**Note:** If you do not specify the `activationSpecRef` and `queueRef` attributes, the default value for `activationSpecRef` is **batchActivationSpec** and the default value for `queueRef` is **batchJobSubmissionQueue**. You can specify the `batchJmsExecutor` element as `<batchJmsExecutor/>`. You still must configure the JMS activation specification for `batchActivationSpec` and the `batchJobSubmissionQueue` JMS queue in the `server.xml` file.

- d. Add the corresponding JMS activation specification and JMS queue to the server configuration. This is not specific to batch configuration.
- e. Define batch executor server capabilities by including a JMS message selector in the activation specification.

- Filter based on system-defined properties:

The following batch dispatcher properties are available on the batch JMS message that the batch executor can use to filter for inbound messages.

- **com\_ibm\_ws\_batch\_applicationName**: the name of the batch application for the job request
- **com\_ibm\_ws\_batch\_moduleName**: the module name of the batch application for the job request
- **com\_ibm\_ws\_batch\_componentName**: the component name of the batch application for the job request
- **com\_ibm\_ws\_batch\_work\_type**: the work type : "Job"

**Note:** Specify a message selector with at least the **com\_ibm\_ws\_batch\_applicationName** property to ensure that the executor only receives jobs that it can process.

The following example indicates the **messageSelector** attribute for the executor to accept a job for the application `SimpleBatchJob` and `BonusPayout`:

```
messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob' OR com_ibm_ws_batch_applicationName = 'BonusPayout'>
```

- Filter based on user-defined properties:

The batch dispatcher sets all job parameters that conform to the proper JMS message property on the batch dispatcher request message. These properties can also be used by the message selector to add extra filtering to the message selector. The property name, or identifier, must conform to JMS message property constraints. For example, the property is an unlimited length sequence of letters and digits, the first of which must be a letter. A letter is any character for which the method **Character.isJavaLetter** returns true, and includes '\_' and '\$'. A letter or digit is any character for which the method **Character.isJavaLetterOrDigit** returns true. Check the JMS API documentation for more information on JMS message selectory.

The following example illustrates a possible message selector by using the **com\_ibm\_ws\_batch\_applicationName** property and a job parameter **specialCapability**:

```
messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob' AND specialCapability = 'superCapability'>
```

The following example illustrates the batch JMS executor configuration and its JMS configuration using WebSphere MQ binding mode:

```

<batchJmsExecutor activationSpecRef="batchActivationSpec"
  queueRef="batchJobSubmissionQueue" />

<!-- wmq resource adapter -->
<variable name="wmqJmsClient.rar.location"
  value="{server.config.dir}/wmq.wlp.rar"/>

<!-- nativeLibraryPath is required for BINDING mode -->
<!-- the startup retry and reconnect retry properties are
  recommended to ensure robustness of the system.-->
<wmqJmsClient nativeLibraryPath="/mqm/jms/java/lib"
  startupRetryCount=999
  startupRetryInterval="1000ms"
  reconnectionRetryCount=10
  reconnectionRetryInterval="5m">
</wmqJmsClient>

<authData password="pwd" user="user">
</authData>

<JmsActivationSpec id="batchActivationSpec" >
  <properties.wmqJms destinationRef="batchJobSubmissionQueue"
    destinationType="javax.jms.Queue"
    messageSelector="(com_ibm_ws_batch_applicationName = 'SimpleBatchJob' OR com_ibm_ws_batch_applicationName = 'BonusPayout') AND com_ibm_ws_batch_applicationName = 'BINDINGS'"
    transportType="BINDINGS"
    queueManager="WMQX">
  </properties.wmqJms>
</JmsActivationSpec>

<!-- baseQueueName is the queue defined on WMQ system -->
<jmsQueue id="batchJobSubmissionQueue"
  jndiName="jms/batch/jobSubmissionQueue">
  <properties.wmqJms baseQueueName="BATCHQ"
    priority="QDEF"
    baseQueueManagerName="WMQX">
  </properties.wmqJms>
</jmsQueue>

```

The following example illustrates the batch JMS executor configuration and its JMS configurations using Websphere MQ client mode:

```

<batchJmsExecutor activationSpecRef="batchActivationSpec"
  queueRef="batchJobSubmissionQueue" />

<!-- wmq resource adapter -->
<variable name="wmqJmsClient.rar.location"
  value="{server.config.dir}/wmq.wlp.rar"/>

<!-- the startup retry and reconnect retry properties are
  recommended to ensure robustness of the system.-->
<wmqJmsClient startupRetryCount=999
  startupRetryInterval="1000ms"
  reconnectionRetryCount=10
  reconnectionRetryInterval="5m">
</wmqJmsClient>

<authData password="pwd" user="user">
</authData>

<JmsActivationSpec id="batchActivationSpec" >
  <properties.wmqJms destinationRef="batchJobSubmissionQueue"
    messageSelector="com_ibm_ws_batch_applicationName = SimpleBatchJob' OR com_ibm_ws_batch_applicationName = 'BonusPayout'"
    transportType="CLIENT"
    channel="WAS.JMS.SVRCONN"
    destinationType="javax.jms.Queue"
    queueManager="WMQX"
    hostName="webs24.pok.stglabs.ibm.com"
    port="1414">
  </properties.wmqJms>
</JmsActivationSpec>

<!-- baseQueueName is the queue defined on WMQ system -->
<jmsQueue id="batchJobSubmissionQueue"
  jndiName="jms/batch/jobSubmissionQueue">
  <properties.wmqJms baseQueueName="BATCHQ"
    baseQueueManagerName="WMQX">
  </properties.wmqJms>
</jmsQueue>

```

3. Configure the batch JMS executor for executing only partitions.
  - a. Enable JMS support by adding the **wmqJmsClient-2.0** feature to the feature manager in your `server.xml` file.
  - b. Add the **batchJmsExecutor** element and a `connectionFactory` to your `server.xml` file on the server that hosts the batch executor. For more information, see step 1b and 1c.

```
<batchJmsExecutor activationSpecRef={configured activation specification or batch executor}
  queueRef={reference to the configured JMS queue}
  replyConnectionFactoryRef={reference to the configured JMS connection factory} />
```

**Note:** If you do not specify the `activationSpecRef` and `queueRef` attributes, the default value for `activationSpecRef` is **batchActivationSpec** and the default value for `queueRef` is **batchJobSubmissionQueue**. You can specify the `batchJmsExecutor` element as `<batchJmsExecutor/>`. You still must configure the JMS activation specification for `batchActivationSpec` and the `batchJobSubmissionQueue` JMS queue in the `server.xml` file.

- c. Add the corresponding JMS activation specification and JMS queue to the server configuration. This is not specific to batch configuration.
- d. Define batch executor server capabilities by including a JMS message selector in the activation specification.

- Filter based on system-defined properties:

The following batch dispatcher properties are available on the batch JMS message that the batch executor can use to filter for inbound messages.

- **com.ibm.ws.batch.applicationName:** the name of the batch application for the job request
- **com.ibm.ws.batch.moduleName:** the module name of the batch application for the job request
- **com.ibm.ws.batch.componentName:** the component name of the batch application for the job request
- **com.ibm.ws.batch.work.type:** the work type : "Partition"
- **com.ibm.ws.batch.partitionNum**(Type=Integer): the partition number of the partition that is being dispatched
- **com.ibm.ws.batch.stepName:** the name of the step as defined in the JSL

**Note:** Specify a message selector with at least the **com.ibm.ws.batch.applicationName** property to ensure that the executor only receives jobs that it can process.

The following example indicates the **messageSelector** attribute for the executor to accept a job for the application `SimpleBatchJob` and `BonusPayout`:

```
messageSelector="com.ibm.ws.batch.applicationName = 'SimpleBatchJob' OR com.ibm.ws.batch.applicationName = 'BonusPayout'>
```

- Filter based on user-defined properties:

The batch dispatcher sets all job parameters that conform to the proper JMS message property on the batch dispatcher request message. These properties can also be used by the message selector to add extra filtering to the message selector. The property name, or identifier, must conform to JMS message property constraints. For example, the property is an unlimited length sequence of letters and digits, the first of which must be a letter. A letter is any character for which the method **Character.isJavaLetter** returns true, and includes '\_' and '\$'. A letter or digit is any character for which the method **Character.isJavaLetterOrDigit** returns true. Check the JMS API documentation for more information on JMS message selector.

The following example illustrates a possible message selector by using the **com.ibm.ws.batch.applicationName** property and a job parameter **specialCapability**:

```
messageSelector="com.ibm.ws.batch.applicationName = 'SimpleBatchJob' AND specialCapability = 'superCapability'>
```

The following example illustrates the batch JMS executor configuration and its JMS configuration using WebSphere MQ binding mode:

```
<jmsConnectionFactory id="batchConnectionFactory"
  jndiName="jms/batch/connectionFactory"/>
```

```
<batchJmsExecutor activationSpecRef="batchActivationSpec"
```

```

        queueRef="batchJobSubmissionQueue"
        replyConnectionFactoryRef="batchConnectionFactory"/>

<!-- wmq resource adapter -->
<variable name="wmqJmsClient.rar.location"
    value="{server.config.dir}/wmq.wlp.rar"/>

<!-- nativeLibraryPath is required for BINDING mode -->
<!-- the startup retry and reconnect retry properties are
    recommended to ensure robustness of the system.-->
<wmqJmsClient nativeLibraryPath="/mqm/jms/java/lib"
    startupRetryCount=999
    startupRetryInterval="1000ms"
    reconnectionRetryCount=10
    reconnectionRetryInterval="5m">
</wmqJmsClient>

<authData password="pwd" user="user">
</authData>

<JmsActivationSpec id="batchActivationSpec" >
    <properties.wmqJms destinationRef="batchJobSubmissionQueue"
        destinationType="javax.jms.Queue"
        messageSelector="(com_ibm_ws_batch_applicationName = 'SimpleBatchJob' OR com_ibm_ws_batch_applicationName = 'BonusPayout') AND com_ibm_ws_batch_applicationName = 'BonusPayout'"
        transportType="BINDINGS"
        queueManager="WMQX">
    </properties.wmqJms>
</jmsActivationSpec>

<!-- baseQueueName is the queue defined on WMQ system -->
<jmsQueue id="batchJobSubmissionQueue"
    jndiName="jms/batch/jobSubmissionQueue">
    <properties.wmqJms baseQueueName="BATCHQ"
        priority="QDEF"
        baseQueueManagerName="WMQX">
    </properties.wmqJms>
</jmsQueue>

```

The following example illustrates the batch JMS executor configuration and its JMS configurations using Websphere MQ client mode:

```

<jmsConnectionFactory id="batchConnectionFactory"
    jndiName="jms/batch/connectionFactory"/>

<batchJmsExecutor activationSpecRef="batchActivationSpec"
    queueRef="batchJobSubmissionQueue"
    replyConnectionFactoryRef="batchConnectionFactory"/>

<!-- wmq resource adapter -->
<variable name="wmqJmsClient.rar.location"
    value="{server.config.dir}/wmq.wlp.rar"/>

<!-- the startup retry and reconnect retry properties are
    recommended to ensure robustness of the system.-->
<wmqJmsClient startupRetryCount=999
    startupRetryInterval="1000ms"
    reconnectionRetryCount=10
    reconnectionRetryInterval="5m">
</wmqJmsClient>

<authData password="pwd" user="user">
</authData>

<JmsActivationSpec id="batchActivationSpec" >
    <properties.wmqJms destinationRef="batchJobSubmissionQueue"
        messageSelector="(com_ibm_ws_batch_applicationName = SimpleBatchJob' OR com_ibm_ws_batch_applicationName = 'BonusPayout') AND com_ibm_ws_batch_applicationName = 'BonusPayout'"
        transportType="CLIENT"
        channel="WAS.JMS.SVRCONN"
        destinationType="javax.jms.Queue"
        queueManager="WMQX"
        hostName="webs24.pok.stglabs.ibm.com"
        port="1414">
    </properties.wmqJms>
</jmsActivationSpec>

<!-- baseQueueName is the queue defined on WMQ system -->
<jmsQueue id="batchJobSubmissionQueue"
    jndiName="jms/batch/jobSubmissionQueue">

```

```

    <properties.wmqJms baseQueueName="BATCHQ"
    baseQueueManagerName="WMQX">
  </properties.wmqJms>
</jmsQueue>

```

4. Install your batch application on the server. For more information, see Chapter 10, “Deploying applications in Liberty,” on page 2139. To disable multiple server partition execution: If you want to have multiple server support but do not want multiple server partition executions, you can set job property `com.ibm.websphere.batch.partition.multiJVM` to `false` in your `jsl` job XML file. The following example illustrates a JSL job to disable multiple server partitions:

```
<property name="com.ibm.websphere.batch.partition.multiJVM" value="false"/>
```

**Note:** If you are running a partition on a remote executor, there are no job logs created for that partition.

## Enabling multiple server partitions support by using the Liberty embedded messaging provider

8.5.5.8

You can set up the batch environment to have servers function as batch dispatchers, while other servers function as batch executors.

### Before you begin

1. Determine where the embedded message engine is hosted. It can be hosted on the batch dispatch server, the batch executor server, or on a separate server. This server must be configured before you complete this task. The JMS connection factory and activation specification references the message engine server in its configuration.
2. To configure the message engine:
  - a. Add the **wasJmsServer-1.0** feature to the `server.xml`.
  - b. Define the message engine by adding the **messageEngine** element. Define the queue that is used for the batch dispatcher and batch executor. The following example illustrates the message engine configuration in your `server.xml` file:

```

<!--specify the ports for the message engine.
The ports in this example are the default ports.
This element is not needed when the default ports are used. -->
<wasJmsEndpoint host="*"
  wasJmsPort="7280"
  wasJmsSSLPort="7290"
  enabled="true">
</wasJmsEndpoint>

<messagingEngine>
  <!-- queue for batch jms message. -->
  <queue id="batchLibertyQueue"
    forceReliability="ReliablePersistent"
    receiveAllowed="true"/>
</messagingEngine>

```

### About this task

Batch dispatchers accept requests from external clients and make them available to the batch executors. The batch executors receive requests that match its defined capabilities and execute those requests. If the job is configured to run partitions, the batch executors make them available to the other executors to run. The batch executors communicate with each other by using Java Messaging Service (JMS). This task helps you configure the batch dispatch server and the batch executor by using the Liberty profile embedded messaging provider.

### Procedure

1. Configure the batch JMS dispatcher.

- a. Enable JMS support by adding the **wasJmsClient-2.0** feature to the feature manager in your `server.xml` file.
- b. Add the **batchJmsDispatcher** element to your `server.xml` file on the server that hosts the batch dispatcher; for example:

```
<batchJmsDispatcher connectionFactoryRef={reference to a configured JMS connection factory}
queueRef={reference to a configured JMS queue} />
```

**Note:** If you do not specify the `connectionFactoryRef` and `queueRef` attributes, the default value for `connectionFactoryRef` is **batchConnectionFactory** and the default value for `queueRef` is **batchJobSubmissionQueue**. You can specify the `batchJmsDispatcher` element as `<batchJmsDispatcher/>`. You still must configure the **batchConnectionFactory** JMS connection factory and the JMS **batchJobSubmissionQueue** queue in the `server.xml` file.

- c. Add the corresponding JMS connection factory and JMS queue to the server configuration. This is not specific to batch configuration. The following example illustrates the batch JMS dispatcher configuration and its JMS configuration:

**Note:** The `remoteServerAddress` attribute points to the `host:port` of the server that is hosting the Liberty profile message engine.

```
<batchJmsDispatcher connectionFactoryRef="batchConnectionFactory"
queueRef="batchJobSubmissionQueue" />

<jmsConnectionFactory id="batchConnectionFactory"
jndiName="jms/batch/connectionFactory">
  <properties.wasJms remoteServerAddress="host:7280:BootstrapBasicMessaging">
  </properties.wasJms>
</jmsConnectionFactory>

<jmsQueue id="batchJobSubmissionQueue"
jndiName="jms/batch/jobSubmissionQueue">
  <properties.wasJms deliveryMode="Persistent"
queuename="batchLibertyQueue">
  </properties.wasJms>
</jmsQueue>
```

## 2. Configure the batch JMS executor for executing batch jobs.

- a. Enable JMS support by adding the **wasJmsClient-2.0** feature to the feature manager in your `server.xml` file.
- b. Add the **batchJmsDispatcher** element to your `server.xml` file on the server that hosts the batch executor.

```
<batchJmsExecutor activationSpecRef={configured activation specification or batch executor}
queueRef={reference to the configured JMS queue} />
```

**Note:** If you do not add the **batchJmsDispatcher** element to your `server.xml` file, the server will not dispatch partitions to run on multiple servers and will run the partitions locally.

**Note:** If you do not specify the `connectionFactoryRef` and `queueRef` attributes, the default value for `connectionFactoryRef` is **batchConnectionFactory** and the default value for `queueRef` is **batchJobSubmissionQueue**. You can specify the `batchJmsDispatcher` element as `<batchJmsDispatcher/>`. You still must configure the **batchConnectionFactory** JMS connections factory and the `batchJobSubmissionQueue` in the `server.xml` file.

- c. Add the corresponding JMS connection factory and JMS queue to the server configuration. This is not specific to batch configuration. The following example illustrates the batch JMS dispatcher configuration and its JMS configuration:

**Note:** The `remoteServerAddress` attribute points to the `host:port` of the server that is hosting the Liberty profile message engine.

```
<batchJmsDispatcher connectionFactoryRef="batchConnectionFactory"
queueRef="batchJobSubmissionQueue" />

<jmsConnectionFactory id="batchConnectionFactory"
jndiName="jms/batch/connectionFactory">
```

```

<properties.wasJms remoteServerAddress="host:7280:BootstrapBasicMessaging">
</properties.wasJms>
</jmsConnectionFactory>

<jmsQueue id='batchJobSubmissionQueue'
  jndiName="jms/batch/jobSubmissionQueue">
  <properties.wasJms deliveryMode="Persistent"
    queueName="batchLibertyQueue">
  </properties.wasJms>
</jmsQueue>

```

- d. Add the **batchJmsExecutor** element to your **server.xml** on the server that hosts the batch executor; for example:

```

<batchJmsExecutor activationSpecRef={configured activation specification or batch executor}
  queueRef={reference to the configured JMS queue} />

```

**Note:** If you do not specify the `activationSpecRef` and `queueRef` attributes, the default value for `activationSpecRef` is **batchConnectionFactory** and the default value for `queueRef` is **batchJobSubmissionQueue**. You can specify the `batchJmsExecutor` element as `<batchJmsExecutor/>`. You still must configure the JMS activation specification for **batchActivationSpec** and the **batchJobSubmissionQueue** queue in the `server.xml` file.

- e. Add the corresponding JMS activation specification and JMS queue to the server configuration. This is not specific to batch configuration.
- f. Define batch executor server capabilities by including a JMS message selector in the activation specification.

- Filter based on system-defined properties:

The following batch dispatcher properties are available on the batch JMS message that the batch executor can use to filter for inbound messages.

- **com\_ibm\_ws\_batch\_applicationName:** the name of the batch application for the job request
- **com\_ibm\_ws\_batch\_moduleName:** the module name of the batch application for the job request
- **com\_ibm\_ws\_batch\_componentName:** the component name of the batch application for the job request
- **com\_ibm\_ws\_batch\_work\_type:** the work type : "Job"

**Note:** Specify a message selector with at least the **com\_ibm\_ws\_batch\_applicationName** property to ensure that the executor only receives jobs that it can process.

The following example indicates the **messageSelector** attribute for the executor to accept only batch jobs for the application `SimpleBatchJob`:

```
messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob' AND com_ibm_ws_batch_work_type = 'Job'">
```

- Filtering based on user-defined properties:

The batch dispatcher sets all job parameters that conform to the proper JMS message property on the batch dispatcher request message. These properties can also be used by the message selector to add extra filtering to the message selector. The property name, or identifier, must conform to JMS message property constraints. For example, the property is an unlimited length sequence of letters and digits, the first of which must be a letter. A letter is any character for which the method `Character.isJavaLetter` returns true, and includes '\_' and '\$'. A letter or digit is any character for which the method `Character.isJavaLetterOrDigit` returns true. Check the JMS API documentation for more information on JMS message selector.

The following example illustrates a possible message selector by using the **com\_ibm\_ws\_batch\_applicationName** property and a job parameter **specialCapability**:

```
messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob' AND specialCapability = 'superCapability'">
```

The following example illustrates the batch JMS executor configuration and its JMS configuration:

```

<batchJmsExecutor activationSpecRef="batchActivationSpec"
  queueRef="batchJobSubmissionQueue"/>

<jmsActivationSpec id="batchActivationSpec" >
  <properties.wasJms destinationRef="batchJobSubmissionQueue"

```

sequence of letters and digits, the first of which must be a letter. A letter is any character for which the method `Character.isJavaLetter` returns true, and includes '\_' and '\$'. A letter or digit is any character for which the method `Character.isJavaLetterOrDigit` returns true. Check the JMS API documentation for more information on JMS message selectory.

The following example illustrates a possible message selector by using the `com_ibm_ws_batch_applicationName` property and a job parameter `specialCapability`:

```
messageSelector="com_ibm_ws_batch_applicationName = 'SimpleBatchJob' AND specialCapability = 'superCapability'">
```

The following example illustrates the batch JMS executor configuration and its JMS configuration:

```
<jmsConnectionFactory id="batchConnectionFactory"
    jndiName="jms/batch/connectionFactory"/>

<batchJmsExecutor activationSpecRef="batchActivationSpec"
    queueRef="batchJobSubmissionQueue"
    replyConnectionFactoryRef="batchConnectionFactory"/>

<jmsActivationSpec id="batchActivationSpec" >
  <properties.wasJms destinationRef="batchJobSubmissionQueue"
    messageSelector="(com_ibm_ws_batch_applicationName = 'SimpleBatchJob' OR com_ibm_ws_batch_applicationName = 'BonusPayoutCDI') AND com_ibm_ws_batch_applicationName = 'SimpleBatchJob'"
    destinationRef="batchJobSubmissionQueue"
    destinationType="javax.jms.Queue"
    remoteServerAddress="host:7280:BootstrapBasicMessaging">
  </properties.wasJms>
</jmsActivationSpec>

<jmsQueue id="batchJobSubmissionQueue"
    jndiName="jms/batch/jobSubmissionQueue">
  <properties.wasJms deliveryMode="Persistent"
    queueName="batchLibertyQueue">
  </properties.wasJms>
</jmsQueue>
```

4. Install your batch application on the server. For more information, see Chapter 10, “Deploying applications in Liberty,” on page 2139. To disable multiple server partition execution: If you want to have multiple server support but do not want multiple server partition executions, you can set job property `com.ibm.websphere.batch.partition.multiJVM` to false in your jsl job XML file. The following example illustrates a JSL job to disable multiple server partitions:

```
<property name="com.ibm.websphere.batch.partition.multiJVM" value="false"/>
```

**Note:** If you are running a partition on a remote executor, there are no job logs created for that partition.

## Enabling batch job events publishing

8.5.5.7

By using Java Messaging System (JMS), the batch server can publish job-related events to external clients.

### About this task

The ability of the batch server to publish job-related events to external clients enables a monitor to see job-related events and report on failures. The batch dispatcher server can publish events for a job in the dispatching phase. The batch executor server can publish events for jobs when it moves through different phases of execution. These events are published in a topic tree in the following structures:

Table 176. File structures of topic trees for event publishing

Structure	Description
batch	The root of the topic tree.
batch/jobs	The topic tree for all job-related events.
batch/jobs/instance	The topic tree for all events that are related to a job instance.

Table 176. File structures of topic trees for event publishing (continued)

Structure	Description
batch/jobs/instance/submitted	A topic tree node. A message is published when the batch server creates a job instance for a new job submission.
batch/jobs/instance/jms_queued	A topic tree node. A message is published when job submission is placed on the job submission queue by the batch JMS dispatcher.
batch/jobs/instance/jms_consumed	A topic tree node. A message is published when the batch executor receives the job submission from the job submission queue.
batch/jobs/instance/dispatched	A topic tree node. A message is published when the batch executor accepts a job instance for execution.
batch/jobs/instance/completed	A topic tree node. A message is published when the job instance is completed.
batch/jobs/instance/stopped	A topic tree node. A message is published when the job instance is stopped.
batch/jobs/instance/stopping	A topic tree node. A message is published when the job instance is stopping.
batch/jobs/instance/failed	A topic tree node. A message is published when the job instance failed.
batch/jobs/instance/purged	A topic tree node. A message is published when a job instance is purged successfully.
batch/jobs/execution	The topic tree for all events that are related to a job execution.
batch/jobs/execution/restarting	A topic tree node. A message is published when the batch executor is restarting an execution.
batch/jobs/execution/starting	A topic tree node. A message is published when a job execution is starting.
batch/jobs/execution/completed	A topic tree node. A message is published when a job execution ends successfully.
batch/jobs/execution/failed	A topic tree node. A message is published when a job execution ends because of failure.
batch/jobs/execution/stopped	A topic tree node. A message is published when a job execution is stopped.
batch/jobs/execution/jobLogPart	A topic tree node. A message is published when a new job log part is created, a job stops, or a job ends.
batch/jobs/execution/step/started	A topic tree node. A message is published when a step execution is started.
batch/jobs/execution/step/completed	A topic tree node. A message is published when a step execution is completed successfully.
batch/jobs/execution/step/failed	A topic tree node. A message is published when a step execution fails.
batch/jobs/execution/step/stopped	A topic tree node. A message is published when a step execution is stopped.

Table 176. File structures of topic trees for event publishing (continued)

Structure	Description
batch/jobs/execution/step/checkpoint	A topic tree node. A message is published when a checkpoint is taken.
batch/jobs/execution/partition/started	A topic tree node. A message is published when a partition is started.
batch/jobs/execution/partition/completed	A topic tree node. A message is published when a partition is completed successfully.
batch/jobs/execution/partition/failed	A topic tree node. A message is published when a partition fails.
batch/jobs/execution/partition/stopped	A topic tree node. A message is published when a partition is stopped.
batch/jobs/execution/split-flow/started	A topic tree node. A message is published when a split-flow is started.
batch/jobs/execution/split-flow/ended	A topic tree node. A message is published when a split-flow is completed.

The published message for each topic is a JMS TextMessage. The contents of this message is a JSON formatted string that represents the object of the topic, such as job instance, job execution, step execution, or partition. In addition, this message also includes the following JMS message properties set:

- com\_ibm\_ws\_batch\_internal\_jobInstanceId: The job instance ID, if available.
- com\_ibm\_ws\_batch\_internal\_jobExecutionId: The job execution ID, if available.
- com\_ibm\_ws\_batch\_internal\_stepExecutionId: The job step execution ID, if available.

The batch server must be configured to enable the publishing of job-related events. The batch dispatcher and batch executor have the same configuration. The following steps enable the publication of job-related events for a batch server.

## Procedure

1. Enable JMS support by adding the appropriate JMS feature to the feature manager in the server.xml file. If you are using the WebSphere Application Server Liberty default messaging provider, add the **wasJmsClient-2.0** feature and related JMS configurations for the message engine. If you are using WebSphere MQ Messaging provider, add the **wmqJmsClient-2.0** feature.

2. Add the **batchJmsEvents** element to the server.xml file.

```
<batchJmsEvents connectionFactoryRef="batchConnectionFactory" />
```

**Note:** If you do not specify the **connectionFactoryRef** attribute, the default value for **connectionFactoryRef** is **batchConnectionFactory**. You must still configure the **batchConnectionFactory** JMS connection factory in the server.xml file.

3. Add the corresponding JMS connection factory to the server configuration. This is not specific to batch configuration.

The following example illustrates the batch events configuration and its JMS configuration by using the WebSphere MQ messaging provider.

```
<!-- wmq resource adapter -->
<variable name="wmqJmsClient.rar.location" value="{server.config.dir}/wmq.wlp.rar"/>
<!-- require for BINDING mode -->
<wmqJmsClient nativeLibraryPath="/mqm/jms/java/lib"/>

<batchJmsEvents connectionFactoryRef="batchConnectionFactory" />
```

```
<jmsConnectionFactory id="batchConnectionFactory" jndiName="jms/batch/connectionFactory">
  <properties.wmq.Jms
    transportType="BINDINGS"
    queueManager="WMQX" />
</jmsConnectionFactory>
```

The following example illustrates the batch events configuration and its JMS configuration by using the WebSphere Liberty default messaging provider.

```
<batchJmsEvents connectionFactoryRef="batchConnectionFactory" />
<jmsConnectionFactory id="batchConnectionFactory" jndiName="jms/batch/connectionFactory">
  <properties.wasJms></properties.wasJms>
</jmsConnectionFactory>
```

## Example

The following examples illustrate sequence of events for basic execution flows.

- Submit and run a single-step job with checkpoints.

```
batch/jobs/instance/submitted
batch/jobs/instance/jms_queued
batch/jobs/instance/jms_consumed
batch/jobs/execution/starting
batch/jobs/instance/dispatched
batch/jobs/execution/started
batch/jobs/execution/step/started
batch/jobs/execution/step/checkpoint
batch/jobs/execution/step/checkpoint
...
batch/jobs/execution/step/checkpoint
batch/jobs/execution/step/completed
batch/jobs/execution/completed
batch/jobs/instance/completed
```

- Submit and run a single-step job with partition.

```
batch/jobs/instance/submitted
batch/jobs/instance/jms_queued
batch/jobs/instance/jms_consumed
batch/jobs/execution/starting
batch/jobs/instance/dispatched
batch/jobs/execution/started
batch/jobs/execution/step/started
batch/jobs/execution/partition/started
batch/jobs/execution/partition/started
batch/jobs/execution/partition/started
batch/jobs/execution/partition/completed
batch/jobs/execution/partition/completed
batch/jobs/execution/partition/completed
batch/jobs/execution/step/completed
batch/jobs/execution/completed
batch/jobs/instance/completed
```

## batchManager command-line client utility

8.5.5.6

The batchManager command-line client utility provides a command-line interface for managing your batch jobs that run on Liberty.

The batchManager command-line client utility interacts with the batch manager over the batch manager's REST API. To use the batchManager command-line client utility, the batch manager must be running on your Liberty server. Use the batch management feature to install and enable the Liberty batch manager.

## SSL configuration

The batchManager command-line client utility communicates with the batch manager over an SSL connection. To facilitate SSL communication with a batch manager that is running on a Liberty server, the utility must be able to verify the SSL certificate of the Liberty server.

If the SSL certificate is signed by a well-known certificate authority (CA), the utility can verify the certificate by the CA. No further configuration is necessary.

If the SSL certificate is not signed by a CA, then you must configure the utility to trust the SSL certificate of the server by doing one of the following actions.

- Specify the option `--trustSslCertificates`, which configures the utility to trust all SSL certificates.
- Include the server's SSL certificate in the utility's truststore.

If you choose to specify the option `--trustSslCertificates`, the utility trusts all SSL certificates that it receives and no further configuration is necessary.

If you choose the option to include the server's SSL certificate in the utility's truststore, then you must also configure the utility so that it can find its truststore. The utility is a stand-alone Java main. You configure SSL by using system properties such as `javax.net.ssl.truststore`.

If the batch manager is running on the same machine as the utility, then you can point the utility directly at the server keystore:

```
$ export JVM_ARGS="-Djavax.net.ssl.trustStore=/path/to/server/keystore.jks"
$ batchManager submit ...
```

**Attention:** JVM arguments, such as `-D` properties, are passed to the batchManager command-line client utility by the `JVM-ARGS` environment variable.

If you cannot use the server keystore directly, you must export the server certificate from the server keystore and import it into the client truststore. Use the JDK keytool utility for exporting and importing certificates. In the following example, the server certificate is stored in the `[server-dir]/resources/security/key.jks` keystore file under the `default` alias, and the password is `Liberty`.

```
$ keytool -export -alias default -file server.crt -keystore [server-dir]/resources/security/key.jks -storepass Liberty
$ keytool -import -alias server_cert -file server.crt -keystore /path/to/truststore.jks -storepass password
```

**Attention:** The `import` command creates the `truststore.jks` file if the file does not exist.

```
$ export JVM_ARGS="-Djavax.net.ssl.trustStore=/path/to/truststore.jks"
$ batchManager submit ...
```

## Commands and usage

The batchManager command-line client utility provides commands for submitting, stopping, restarting, and checking the status of jobs.

To generally use the utility:

```
$ batchManager [command] [options]
```

To see a list of available commands:

```
$ batchManager help
```

To see the description and options for a specific command:

```
$ batchManager help [command]
```

The following example illustrates how to submit a job and wait for its completion:

```
$ batchManager submit \  
  --batchManager=<host>:<port>  
  --user=[credentials for logging into the batch manager]  
  --password=[credentials for logging into the batch manager]  
  --applicationName=[application name used when packaging the batch app]  
  --jobXMLName=[job XML file basename in the app's batch-jobs dir]  
  --wait
```

## jobParametersFile and jobPropertiesFile

When submitting a batch job by using the batchManagerZos client utility, the jobParametersFile and jobPropertiesFiles supports the use of multiple files separated by commas. Files later in the comma separated list take precedence over files that appear first in the list. The following example illustrates correct usage of the comma separated list.

```
jobParametersFile=filePath1,filePath2,filePath3  
jobPropertiesFile=filePath1,filePath2,filePath3
```

As an example, `--jobParametersFile=<filepath1>` would override `--jobParametersFile=<filepath1>,<filepath2>` in the control properties file. The resulting parameter is `--jobParametersFile=<filepath1>`.

z/OS

## batchManager command-line client utility on z/OS with an SAF key ring

To use the System Authorization Facility (SAF) key ring of your WebSphere Application Server Liberty server with the batchManager command-line client utility, you must set the java.environment settings and a user ID specified on the batchManager command-line client utility call that is authorized to read the SAF key ring.

The following commands authorize the user to read the SAF key ring.

**Important:** The *ringOwnerId* is normally the same ID as the user ID of the WebSphere Application Server Liberty server.

```
PermitRingOwnerId.RingName.LST CLASS(RDATALIB) ID(userId) ACCESS(UPDATE)
```

```
SETROPTS RACLIST(RDATALIB) GENERIC(RDATALIB) REFRESH
```

For more information, see the WebSphere Application Server z/OS Security Server RACF command language reference.

The following example defines the environment variable JVM\_ARGS.

```
export JVM_ARGS="-Djavax.net.ssl.trustStore=safkeyring://ringOwnerId/ringName  
-Djavax.net.ssl.trustStoreType=JCERACFKS -Djavax.net.ssl.keyStore=safkeyring://ringOwnerId/ringName  
-Djavax.net.ssl.keyStoreType=JCERACFKS -Dcom.ibm.ssl.keyStoreFileBased=false -Dcom.ibm.ssl.trustStoreFileBased=false  
-Djava.protocol.handler.pkgs=com.ibm.crypto.provider -Djavax.net.ssl.keyStorePassword=password"
```

**Attention:** The `javax.net.ssl.keyStorePassword` property is required and its value must be password and is used for decoding the copy of the key information in the Java virtual machine (JVM) while it exists in storage.

## Return codes

The batchManager command-line client utility outputs the following return codes:

Code	Description
0	The task completed normally.
20	A required argument was not specified.
21	An unrecognized argument was specified.
22	An invalid argument value was specified.
255	An unknown error occurred.

**Note:** If you specify the `--wait` argument, the utility outputs the following return codes about the status of the job that you are waiting for.

Code	Description
33	The job stopped.
34	The job did not complete successfully.
35	The job completed successfully.
36	The job was abandoned.

## Configuring the batchManagerZos client utility

You can manage batch jobs that are running on Liberty on z/OS by using the batchManagerZos client utility.

### About this task

The batchManagerZos client utility is a natively compiled version of the batchManager command-line utility for managing batch jobs that are running on Liberty for z/OS. It is a native program and does not require a JVM. The utility is included with the batchManagement-1.0 feature.

The batchManagerZos client utility supports a subset of the commands and options that are supported by the batchManager command-line utility. Use the `$ batchManagerZos help` command to view the list of commands and options.

The batchManagerZos client utility uses optimized local adapters to connect to a Liberty server that is running in a local environment. The batchManagerZos client utility cannot connect to remote servers.

### Security Considerations

The security behavior of the batchManagerZos client utility depends on whether the Liberty server uses a SAF registry.

- If the server is using a SAF user registry, then the batchManagerZos client utility identity is set as the requestor's identity (the JEE RunAs Subject) for the batch request.
- If the server is not using a SAF user registry, then the batchManagerZos client utility identity is ignored. In this case, the EVERYONE special subject is set as the requestor's identity for the batch request.

### Batch role-based authorization

If appSecurity is enabled in the server, you must assign the requestor's identity to the appropriate batch security role required by the request. Valid batch security roles are batchAdmin, batchSubmitter and batchMonitor. If the identity is not assigned to the role that is required, the request fails with a security exception.

Authorization is managed by the security authorization provider. If the server using SAF authorization, the SAF authorization provider determines the authorization of the requestor's identity by checking the identity's access to SAF resource profiles defined the EJBROLE class. By default, the following resource profiles are associated with the batch roles.

```
batchAdmin:      BBGZDFLT.com.ibm.ws.batch.batchAdmin
batchSubmitter: BBGZDFLT.com.ibm.ws.batch.batchSubmitter
batchMonitor:   BBGZDFLT.com.ibm.ws.batch.batchMonitor
```

The requestor's identity must be granted READ access to the appropriate resource profile to be authorized to the corresponding batch role.

The following example illustrates the RACF commands to grant the client identity, bob, authorization to the batchAdmin role.

```
RDEFINE EJBROLE BBGZDFLT.com.ibm.ws.batch.batchAdmin UACC(NONE)
PERMIT BBGZDFLT.com.ibm.ws.batch.batchAdmin CLASS(EJBROLE) ID(bob) ACCESS(READ)
```

### | jobParametersFile and jobPropertiesFile

| When submitting a batch job by using the batchManagerZos client utility, the jobParametersFile and jobPropertiesFiles supports the use of multiple files separated by commas. Files later in the comma separated list take precedence over files that appear first in the list. The following example illustrates correct usage of the comma separated list.

```
| jobParametersFile=filePath1,filePath2,filePath3
| jobPropertiesFile=filePath1,filePath2,filePath3
```

| As an example, `--jobParametersFile=<filepath1>` would override `--jobParametersFile=<filepath1>,<filepath2>` in the control properties file. The resulting parameter is `--jobParametersFile=<filepath1>`.

### Job Log streaming

The client subscribes to job log events and prints the received message to the **STDOUT** if the `--getJobLog`, `--queueManagerName`, and `--wait` command options are specified on the **submit** or **restart** command. To receive job log events, batch job events publishing must be enabled. For more information about configuring batch job events publishing, see *Enabling batch job events publishing*.

### Return codes

The batchManagerZos client utility outputs the following return codes:

Code	Description
0	The task completed normally.
20	A required argument was not specified.
21	An unrecognized argument was specified.
22	An invalid argument value was specified.
255	An unknown error occurred.

**Note:** If you specify the `--wait` argument, the utility outputs the following return codes about the status of the job that you are waiting for.

Code	Description
33	The job stopped.
34	The job did not complete successfully.
35	The job completed successfully.
36	The job was abandoned.

**Note:** If you run `batchManagerZos` by running `BPXBATCH`, the return code from `BPXBATCH` will not match the return code from `batchManagerZos`. `BPXBATCH` takes the `batchManagerZos` return code and shifts it up by one byte. For example, if `batchManagerZos` returns 1, then `BPXBATCH` returns 256, which is the hex value `0x01`, shifted up one byte to `0x100`.

If you call `BPXBATCH` from a JCL STEP, the STEP return code is truncated to the lower three hex characters of the return code from `BPXBATCH`. For example, if `batchManagerZos` returns 35, which is `0x23` hex, the `BPXBATCH` will return `0x2300`. The JCL STEP truncates the return code to `0x0300`, or 768.

### Limitations

The `batchManagerZos` client utility **stop** commands must be directed at the batch executor where the job is running. **Stop** commands in a multi-server environment might fail with a `BatchJobNotLocalException` if the `batchManagerZos` client utility connects to a designated batch dispatcher rather than the batch executor where the job is running. Batch dispatchers typically receive submission requests and distribute them to downstream batch executors.

### Procedure

1. Enable the `batchManagement-1.0` and `zosLocalAdapters-1.0` features in your `server.xml` file.

```
<featureManager>
  <feature>batchManagement-1.0</feature>
  <feature>zosLocalAdapters-1.0</feature>
</featureManager>
```

2. Configure a `zosLocalAdapters-1.0` endpoint. The following example illustrates a `zosLocalAdapters-1.0` endpoint configuration.

```
<zosLocalAdapters wolaGroup="LIBERTY" wolaName2="BATCH" wolaName3="MANAGER"/>
```

3. Permit the `batchManagerZos` client utility to connect to the `zosLocalAdapters` endpoint. For the `batchManagerZos` client to connect to the server over optimized local adapters, the `userId` of the client must be authorized to the CBIND SAF resource associated with the `zosLocalAdapters` endpoint. The resource that is associated with the endpoint is named `BBG.WOLA.{wolaGroup}.{wolaName2}.{wolaName3}` in the CBIND class. To bind the `zosLocalAdapters` endpoint that is named `LIBERTY BATCH MANAGER`, you must grant read access to resource `BBG.WOLA.LIBERTY.BATCH.MANAGER` in class `CBIND` for the `batchManagerZos` `userId`. The following example illustrates the RACF commands that you must use to grant read access to the resource.

```
RDEFINE CBIND BBG.WOLA.LIBERTY.BATCH.MANAGER UACC(NONE)
PERMIT BBG.WOLA.LIBERTY.BATCH.MANAGER CLASS(CBIND) ACCESS(READ) ID(bob)
```

**Note:** In this example, `bob` is the user that is running `batchManagerZos`.

4. If you want `batchManagerZos` requests to run on the server under the client's identity, you must authorize the server to use SAFCREDS z/OS authorized resources. The following example illustrates the RACF commands that you must use to enable the server to use SAFCREDS z/OS authorized resources.

```
RDEFINE SERVER BBG.AUTHMOD.BBGZSAFM.SAFCREDS UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.SAFCREDS CLASS(SERVER) ACCESS(READ) ID(wluser1)
```

5. Start the Angel address space.
6. Start the Liberty server.

7. Use the **ping** command to test connectivity between the batchManagerZos client and the Liberty server.

```
$ batchManagerZos ping '--batchManager=LIBERTY BATCH MANAGER'
```

If the ping was successful, the client exits with a return code of 0. If the ping was not successful, an error message is issued.

8. To troubleshoot, you can enable extra tracing in the client by setting the `$ export batchManagerZosTrace=1` environment variable.
9. Optional: Configure the batchManagerZos client utility to wait for a batch job event to exit, instead of waiting by using polling.

You must configure the batch server to enable the publishing of job-related events that use WebSphere MQ messaging provider. See the documentation for Enabling batch job events publishing

The following example shows how to submit a job and wait for its completion by a job end event:

```
$ batchManagerZos submit
--batchManager=LIBERTY+BATCH+MANAGER
--applicationName=[application name used when
    packaging the batch app]
--jobXMLName=[job XML file basename in the app's batch-jobs dir]
--wait
--queueManagerName=[name of MQ queue manager]
```

The batchManagerZos client waits to receive 1 of 3 events that represents a job instance ended state:

```
batch/jobs/instance/stopped
batch/jobs/instance/failed
batch/jobs/instance/completed
```

## Viewing Java batch job logs

8.5.5.6

When you are running Java batch jobs in the WebSphere Application Server Liberty, a log is written for each job.

The logs are created in the following directory structure:

```
log directory/joblogs/job name/date/instance.job instance ID/execution.execution ID
```

**Attention:** The variable *job name* is the *id* attribute of the job element within the JSL (XML) document. It is not necessarily related to the file name of the JSL file.

The naming of logs begins at `part.1.log` and rotates to new log parts as needed. By default, the job log contains all messages and trace information that is logged in the server by the thread that performs the job execution. Output that is not logged within the `java.util.logging` framework is not collected.

**Important:** If a new log part cannot be created, batch attempts to continue processing without a log, or with the current log part.

For more information about retrieving or deleting job logs by using the REST API, see the *REST API administration* documentation.

**Important:** If you use the `log4j` API, applications that use the `log4j` framework can participate in batch job logging by using `org.apache.log4j.jul.JULAppender`. The `JULAppender` forwards `log4j` log records to the `java.util.logging` framework, where they are collected for job logging.

## Configuring job logging

Batch job logging can be configured by using the `<batchJobLogging>` configuration element `<batchJobLogging enabled="true" maxRecords="1000" />`.

The attribute `maxRecords` indicates the number of records that are written to a job log part before the records roll over to the next part.

The batch feature uses a logger that is named `com.ibm.ws.batch.JobLogger` to log certain batch messages to the job log only. Examples include job lifecycle messages and checkpoint messages. The logger does not write to the server log. By default, the logger is enabled for Level `.FINE` messages. You can configure the level of the logger by specifying it in the trace specification of the server. For example, `<logging traceSpecification="*=info:com.ibm.ws.batch.JobLogger=all" />`.

Any log messages that are written by the job thread, including messages that are written by the run time and by application code, are written to both the job log and the server log.

The `System.out` and `System.err` files are only written to the server log and are not written to the job log.

## Partitioned steps

Partitioned steps have more subdirectories for each partition. The log files in the *execution ID* directory contain entries from the thread that is running the top-level job. The job logs for the partitions are stored with the following structure:

```
log directory/joblogs/job name/date/instance.job instance ID/execution.execution ID/name of
partitioned step/partition number
```

**Important:** A directory is created in the *name of partitioned step* directory for each partition.

## Split flows

If a split flow occurs in the job, more subdirectories are created to capture the output from the thread of each flow. The log files that are located directly under the *execution ID* directory contains entries from the thread that is running the top-level job. The job logs for individual flow threads are stored with the following structure:

```
log directory/joblogs/job name/date/instance.job instance ID/execution.execution ID/split
ID/flow ID
```

**Important:** A directory is created in the *split ID* directory for each flow.

## Job log events

| If batch job events are enabled, then job log events are published when a job log part is completed and  
| when a job goes to an ended state, such as stopped, failed, or completed. The job log event messages  
| contain multiple JSON properties to help with identifying the message along with the actual job log file  
| content.

| **Important:** The JSON properties are part of the JMS message body and can be retrieved by converting  
| the body text to a `JsonObject` and pulling the specific JSON property from that object.

| The following example illustrates how to retrieve the job log content property.

```
| //The retrieved job log event message  
| Message msg  
| //Convert the Message to a TextMessage
```

```
| TextMessage txtMsg = (TextMessage) msg;
| //Convert the text in the message to a JsonObject
| JsonObject jobLogEventObject = Json.createReader(new StringReader(txtMsg.getText())).readObject();
| //Pull the job log text content from the JsonObject as an example
| JSONArray logContentArray = jobLogEventObject.getJSONArray("contents");
```

| For more information about enabling batch job events, see *Enabling batch job events publishing*.

---

## Liberty: Shared libraries

**8.5.5.0**

Shared libraries are files used by multiple applications. **8.5.5.0** You can use shared libraries and global libraries to reduce the number of duplicate library files on your system.

### Library elements

Liberty libraries have three elements; <folder>, <file>, and <fileset>. For example:

```
<library>
  <folder dir="..." />
  <file name="..." />
  <fileset dir="..." includes="*.jar" scanInterval="5s" />
</library>
```

A specified file must be a container for the resource (for example a JAR file) rather than the resource itself.

If an element in the list is a file, the contents of that JAR or compressed .zip file are searched. If a folder is specified then resources are loaded from that directory.

### Global libraries

Global libraries can be used by any application. JAR files are placed in a global library directory, and then are specified in the class loader configuration for each application.

You can place global libraries in two locations:

- \${shared.config.dir}/lib/global
- \${server.config.dir}/lib/global

If there are files present in these locations at the time an application is started, and that application does not have a <classloader> element configured, the application uses these libraries. If a class loader configuration is present, these libraries are not used unless the global library is explicitly referenced.

For more information, see “Providing global libraries for all Java EE applications” on page 1598.

### Resource files

Within Liberty libraries, you can have resource files defined in the library element. For example,

```
<library>
  <folder dir="..." />
  <file name="..." />
  <fileset dir="..." includes="*.jar" scanInterval="5s" />
  <folder dir="${server.config.dir}/mylibs" />
  <file name="${server.config.dir}/otherlibs/my.jar" />
</library>
```

The folder setting in the previous example, allows all files under the `mylibs` directory to be available on the classpath. You can use this style of entry to have your `.xml` and `.properties` available.

## Library elements

Liberty libraries have three child elements, `<folder>`, `<file>` and `<fileset>`. For example,

```
<library>
  <folder dir="..." />
  <file name="..." />
  <fileset dir="..." includes="*.jar" scanInterval="5s" />
</library>
```

- `<folder>`: All resources under each configured folder will be loadable
- `<file>`: Each configured file should be either a native library or a container for resources (such as a JAR or a ZIP file). All resources within a container are loadable and any other filetype that is specified will have no effect.
- `<fileset>`: Each configured fileset is effectively a collection of files. Each file in the fileset should be a native library or a container for resources (such as a JAR or a ZIP file). All resources within a container are loadable and any other filetype that is specified will have no effect.

For example,

```
<library id="someLibrary">
  <!-- Location of XML and .properties files in the file system for easy editing -->
  <folder dir="${server.config.dir}/editableConfig" />

  <!-- Location of some classes and resources in the file system -->
  <folder dir="${server.config.dir}/extraStuff" />

  <!-- A zip file containing some resources -->
  <file name="${server.config.dir}/lib/someResources.zip" />

  <!-- All the jar files in ther servers lib folder -->
  <fileset dir="${server.config.dir}/lib" includes="*.jar" scanInterval="5s" />
</library>

<application location ="webStore.war">
  <classloader commonLibraryRef="someLibrary" />
</application>
```

The configuration snippet in the previous example, allows all resources under the `editableConfig` directory to be loaded by the `webStore` application.

---

## Loose applications

8.5.5.4

Loose applications are applications that are composed from multiple physical locations, which are provided to the run time via an XML file. Loose applications are supported for Java EE and OSGi applications and are particularly beneficial in a development environment.

### Normal application

Normally an application is contained under one directory (or in one archive), with its content, modules, resources, classdata, and metadata at known locations within that directory. For example: the location of resources for a web application is as follows:

- Library Java archive (JAR) files are stored in `WEB-INF/lib`
- Classes are either in library JAR files or in `WEB-INF/classes`
- The deployment descriptor is in `WEB-INF/web.xml`

- Content to be served is located from the root of the directory

## Loose application

A loose application is described as “a virtual directory that represents the application, where information might be in any location”. It enables development tools, such as WebSphere Application Server Developer Tools, to run applications where the associated files are loaded directly from the workspace, rather than being exported. Examples of associated files are Java classes, JavaServer Pages, or images. If you load the associated files directly from the workspace, it results in a faster build-run-debugging cycle. The content is not present under one directory, but can come from other locations. These locations are specified in an XML configuration file.

There are two ways you can provide the XML file to the run time:

1. By placing the XML file in the `location` attribute in an application configuration element with an appended `.xml` suffix
2. By placing the XML file directly into the `dropins` folder

For example, if you specify `<application location="myapp.war" />`, the run time looks for a file called `myapp.war.xml`. The search rules are the same as for an application directory or archive. If the application files and the `.xml` loose application configuration files are both found, then the loose application configuration file is ignored. For example, if you have `myapp.war` and `myapp.war.xml`, the Liberty server uses `myapp.war` to run the application. You can also deploy loose applications directly into the `dropins` folder. To use the `dropins` folder, follow the naming conventions that are defined for the folder and append `.xml` to the end of the file name.

## Loose application configuration file

The Liberty server uses the loose application configuration file to obtain the application content, rather than locating it from a root directory or single archive. Using the appropriate XML, you can take the following actions:

- Map any physical directory to any location within the application
- Map any physical file to any location within the application
- Map any physical JAR file or directory to any location as a nested archive
- Map multiple physical sources to a single target location (merging)

For example:

1. Map the root of the archive to one location on disk, such as a folder in an Eclipse project.
2. Map a Java `bin/output` folder that is not in the “usual” location into the `WEB-INF/classes` folder. This location might be in a different folder due to your workspace preferences, corporate guidelines, source control project layout guidelines, and so on. You might have multiple Java source and output locations in the same project, and want to map them both to `WEB-INF/classes`.
3. Map an “external” JAR file into the application. This “external” JAR file might be one of the following:
  - A separate Java project that you want to treat like a JAR file in `WEB-INF/lib`
  - A utility JAR file somewhere else on your hard disk drive that you built the `.war` file against, and need to include in `WEB-INF/lib` at run time

## Loose application configuration file examples

You can configure three different elements in the loose application configuration file:

- `<archive>` for archives
- `<file>` for files
- `<dir>` for directories

## Archives

The `<archive>` element is always used as the root of the loose application configuration file. It is also the root of the virtual file system that is represented in the XML. You can nest any of the three elements under the root `<archive>` element. The root `<archive>` element does not have any attributes.

Archive elements can be nested recursively. For `<archive>` elements nested under the root `<archive>` element, you can set the `targetInArchive` attribute. The `targetInArchive` attribute defines the path where the archive appears within the loose defined enclosing archive. You cannot map an archive on the file system as an archive in the application with an `<archive>` element. To use loose application configuration to map an archive on disk, use a `<file>` element instead.

**Note:** The `targetInArchive` attribute value is an absolute path with a leading forward slash (/).

The following code is an example of the root `<archive>` element with another `<archive>` element nested under it:

```
<archive>
  <archive targetInArchive="/jarName.jar">
    <!-- more objects can be embedded here-->
  </archive>
</archive>
```

**Files** You can use the `<file>` element to map a file on your hard disk to a file in your loose application configuration. You can set the following attributes on the `<file>` element:

- `targetInArchive` defines the path where the archive appears within the loose defined enclosing archive.
- `sourceOnDisk` defines the actual location of your file on your file system.

**Note:** The `sourceOnDisk` attribute value is an absolute location. You can use Liberty variables such as `${was.server.dir}`, which are resolved correctly.

The following code is an example of a file in `C:/devFolder/myApplication.zip` that is represented as `/apps/webApplication.war` by the loose application configuration:

```
<file targetInArchive="/apps/webApplication.war"
      sourceOnDisk="C:/devFolder/myApplication.zip" />
```

The following code is an example of an enclosing archive that defines an archive at path `/apps/webApplication.war`. Within the archive, `webApplication.war` defines a file, `jarName.jar` at path `/applications/myApplications`. The actual file location is `c:\devFolder\myApplication.zip`:

```
<archive targetInArchive="/apps/webApplication.war">
  <file targetInArchive="/applications/myApplications/jarName.jar"
        sourceOnDisk="C:/devFolder/myApplication.zip" />
</archive>
```

## Directories

You can use the `<dir>` element to map a directory, and all of its contents on disk, to a directory location in the loose application configuration. The element has the same attributes as the `<file>` element and you use it in a similar way.

The following code is an example of a directory that the loose application configuration shows as being in `/META-INF` and on your file system in `${was.server.dir}/applicationData/myApplication`:

```
<dir targetInArchive="/META-INF"
     sourceOnDisk="${was.server.dir}/applicationData/myApplication" />
```

To add the directory to an archive so it appears to be in `/apps/jarName.jar/META-INF`, embed the `<dir>` element as follows:

```

<archive targetInArchive="/apps/jarName.jar">
  <dir targetInArchive="/META-INF"
        sourceOnDisk="${was.server.dir}/applicationData/myApplication" />
</archive>

```

In both of the previous examples, all files that are in `${was.server.dir}/applicationData/myApplication` are mapped and visible in the loose application configuration under the directory that is mapped by the `targetInArchive` attribute.

## Virtual paths and file names

If you add `<file>` or `<dir>` elements to an archive, the name of the file or directory in the loose archive does not need to be the same as the actual name on disk.

The following code is an example of how you can configure `${was.server.dir}/applicationFiles/newfile.txt` to appear in the archive as `/application.txt`:

```

<archive>
  <file targetInArchive="/application.txt"
        sourceOnDisk="${was.server.dir}/applicationFiles/newfile.txt"/>
</archive>

```

The same concept also holds true for the path of any added file or directory. The physical resource on disk does not need to be in a directory hierarchy that corresponds to the one being declared.

The following code is an example of how you can make `${was.server.dir}/applicationFiles/newfile.txt` appear in the archive as `/only/available/in/application.txt`:

```

<archive>
  <file targetInArchive="/only/available/in/application.txt"
        sourceOnDisk="`${was.server.dir}/applicationFiles/newfile.txt"/>
</archive>

```

In each case, the Liberty server sees the resource by the name and path declared by the `targetInArchive` attribute. The Liberty server can navigate the directory hierarchy declared, even if the hierarchy contains only virtual elements, as in the previous example.

```

<archive>
  <file targetInArchive="/only/available/in/red.txt"
        sourceOnDisk="${was.server.dir}/applicationFiles/newfile.txt" />
<archive targetInArchive="/apps/jarName.jar">
  <dir targetInArchive="/META-INF"
        sourceOnDisk="${was.server.dir}/applicationData/myApplication" />
</archive>

```

## Folders and files with the same name

If you have two folders with the same name in the same virtual location in the loose application configuration, the folders are merged, and the contents of both folders are available. If you have two files with the same target location in the loose archive, the first occurrence of the file is used. The first occurrence is based on a top-down approach to reading the elements of the loose application configuration file.

If the first file found is the wrong file, reorder the XML so that the element that contains the version of the file you want is processed first. The first occurrence applies to files defined in `<dir>` elements and files that are defined in `<file>` elements. The first occurrence of a file with the same name and virtual location is the one returned from the virtual file system.

## Considerations for loose applications

For all loose configured applications, the files are not on disk in the hierarchy that they are declared to be. If your applications directly access their own resources, and expect them to be arranged on disk as they would be with an expanded war or ear layout, they might exhibit unexpected behavior.

You can use `ServletContext.getRealPath` in your applications to discover physical resource paths. `ServletContext.getRealPath` can discover file paths to open to read or write data, and obtain directories. However, if you use `ServletContext.getRealPath` in web applications to obtain a path for `"/"`, you cannot use this path to navigate the application on disk.

`ServletContext.getRealPath` allows only a single physical path to be returned, and the loose application might have merged multiple directories to form one path visible to the application.

Consider the following configuration:

```
<archive>
  <dir targetInArchive="/"
        sourceOnDisk="c:\myapplication" />
  <dir targetInArchive="/web/pages"
        sourceOnDisk="c:\webpagesforapplication" />
</archive>
```

An application that directly accesses `/web/pages` and then navigates up the directory hierarchy, finds that the parent of the physical path of `/web/pages` is `c:\` and not `/web`. `c:\` has no `pages` directory and no parent directory.

These considerations apply only if your applications attempt to directly access the content on disk, and perform their own path navigation based on an assumption of a corresponding hierarchical layout on disk. The same applications also encounter issues if they are deployed as an archive. These applications generally experience issues with portability.

## Complex example

The following code is a more complex example of loose application configuration. This example uses all of the elements and creates a complex mapping of files and directories:

```
<archive>
  <dir targetInArchive="/appResources"
        sourceOnDisk="{was.server.dir}/applicationFiles" />
  <archive targetInArchive="application.jar">
    <dir targetInArchive="/src"
          sourceOnDisk="{was.server.dir}/applicationCode/src" />
  </archive>
  <archive targetInArchive="webApp.war">
    <dir targetInArchive="/META-INF"
          sourceOnDisk="{was.server.dir}/manifestFiles/" />
    <dir targetInArchive="/WEB-INF"
          sourceOnDisk="c:/myWorkspace/webAppProject/web-inf" />
    <archive targetInArchive="/WEB-INF/lib/myUtility.jar">
      <dir targetInArchive="/"
            sourceOnDisk="c:/myWorkspace/myUtilityProject/src" />
      <file targetInArchive="/someJar.jar"
            sourceOnDisk="c:/myWorkspace/myUtilityProject/aJar.jar" />
    </archive>
  </archive>
  <file targetInArchive="/myjar.jar"
        sourceOnDisk="{was.server.dir}/apps/application.zip" />
</archive>
```

---

## Discovering REST API documentation on a Liberty server

8.5.5.8

You can discover your REST API documentation. Use the API Discovery feature to find what REST APIs are available on a Liberty server and then use the Swagger user interface to invoke the found REST endpoints.

### Procedure

1. Add the `apiDiscovery-1.0` feature to a feature manager in the `server.xml` file of the Liberty server whose available REST APIs you want to find.

The `apiDiscovery-1.0` feature enables the REST API discovery bundles in the product. The feature also exposes documentation from Liberty REST endpoints such as JMX, if the server configuration uses the `restConnector-1.0` feature, and collectives, if the server configuration uses the `collectiveController-1.0` feature.

**8.5.5.9** The `apiDiscovery-1.0` feature enabled on a Liberty collective controller server finds the REST APIs available on the controller and on its member servers with the `apiDiscovery-1.0` feature enabled.

Ensure the server configuration has all features needed for your deployed application, such as `servlet-3.0`, `jsp-2.2`, and so on. Also ensure the ports and user registry settings are correct for the deployed application.

The following `server.xml` file has the `apiDiscovery-1.0` feature:

```
<server>
  <featureManager>
    <feature>apiDiscovery-1.0</feature>
  </featureManager>

  <httpEndpoint id="defaultHttpEndpoint"
    host="*"
    httpPort="8010"
    httpsPort="8020"/>

  <keyStore id="defaultKeyStore" password="Liberty"/>

  <basicRegistry id="basic" realm="ibm/api">
    <user name="bob" password="bobpwd" />
  </basicRegistry>
</server>
```

2. Expose the Swagger 2.0 documentation in Liberty REST endpoints.

You can configure the location of your API documentation in either of two ways:

- Use the `getDocument` method of the SPI `com.ibm.wsspi.rest.api.discovery.APIProvider` interface.

The `getDocument` method enables OSGi bundles from extension features to contribute REST API documents to the overall “master” documentation. For this release, the only supported `DocType` are `DocType.Swagger_20_JSON` and `DocType.Swagger_20_YAML`. Implementers of this interface can return the serialized JSON or YAML document as a `java.lang.String` value, or they can pass in a file reference (prefixed with `file:///`) to the JSON or YAML file location.

- Use a deployed web application.

Each web module can contribute its own REST API document. Multiple WAR files inside an enterprise application (EAR) file can have different Swagger 2.0 documents.

The easiest way to expose the documentation of web modules is to include a `swagger.json` or `swagger.yaml` file inside the corresponding `META-INF` folder. During application deployment, the API Discovery feature looks for a `META-INF/swagger.json` value for each of the web modules. If a `META-INF/swagger.json` value is not found then the API Discovery feature looks for a `META-INF/swagger.yaml` value.

Another way to expose the REST API documentation for a web module is in a `server.xml` configuration file. Put a `webModuleDoc` element for each web module in a parent `apiDiscovery` element; for example:

```
<apiDiscovery>
  <webModuleDoc contextRoot="/30ExampleServletInEar" enabled="true" docURL="/swagger.json" />
  <webModuleDoc contextRoot="/22ExampleServlet" enabled="false" />
  <webModuleDoc contextRoot="/custom" enabled="true" docURL="http://petstore.swagger.io/v2/swagger.json" />
</apiDiscovery>
```

The `webModuleDoc` element must have a `contextRoot` attribute to uniquely identify the web module whose documentation you want to expose.

An optional attribute, `enabled`, toggles the API discovery for a web module. The default of this attribute is `true`.

The `docURL` attribute specifies where to find the documentation for the web module. The `docURL` value can start with a forward slash (`/`) so that the URL is relative to the context root; for example, `/30ExampleServletInEar/swagger.json`. Or the `docURL` value can start with `http` or `https` for an absolute URL that identifies the complete location of the documentation.

**8.5.5.9** If the web application does not provide a `swagger.json` or `swagger.yaml` file and the application contains JAX-RS annotated resources, you can automatically generate the Swagger document. The server configuration must have the `apiDiscovery-1.0` feature and the `jaxrs-1.1` or `jaxrs-2.0` feature; for example:

```
<featureManager>
  <feature>apiDiscovery-1.0</feature>
  <feature>jaxrs-1.0</feature>
</featureManager>
```

The product scans all classes in the web application for JAX-RS and Swagger annotations, searching for classes with `@Path`, `@Api`, and `@SwaggerDefinition` annotations. The product also automatically generates a corresponding Swagger document during the web application deployment or startup.

**8.5.5.9** You can also use the `apiDiscovery-1.0` feature to merge previously generated documentation with the documentation that it finds during annotation scanning. The product searches for a `META-INF/stub/swagger.json` or `META-INF/stub/swagger.yaml` file in the web module. If the feature finds either of these files, the feature generates a Swagger document that contains both the content of the file and any JAX-RS and Swagger annotations that are in the web module. You can use this feature to document non-JAX-RS servlets because the documentation is automatically merged with the JAX-RS portions.

**8.5.5.9** Another way to expose the REST API documentation for a web module is to add `swagger.json` or `swagger.yaml` to the context root of the web application; for example:

```
http://host:http_port/context_root/swagger.json
```

or

```
http://host:http_port/context_root/swagger.yaml
```

A call to `context_root/swagger.json` or `context_root/swagger.yaml` returns the documentation for the context root in the requested JSON or YAML format. During web module startup, the API Discovery feature pulls any available `context_root/swagger.json` into the aggregated document from `/ibm/api/docs` and `/ibm/api/explorer`. If `context_root/swagger.json` is not available, then the API Discovery feature pulls any available `context_root/swagger.yaml` into the aggregated document from `/ibm/api/docs` and `/ibm/api/explorer`. The `apiDiscovery-1.0` feature can handle `swagger.json` or `swagger.yaml` virtually, which means that if the web application has a `server.xml` file that configures a `docURL` attribute, a `swagger.json` or `swagger.yaml` file in the `META-INF` folder, or JAX-RS and Swagger annotations, then the call to `context_root/swagger.json` or `context_root/swagger.yaml` returns the documentation for this other configuration in the requested JSON or YAML format.

### 3. Discover your API documentation.

After you configure the location of your API documentation, you can discover it in the following ways:

- Use the GET `https://host:https_port/ibm/api/docs` endpoint.  
This endpoint provides a valid Swagger 2.0 document with all available Liberty REST APIs merged into a single document. This is useful for consumer applications that want to programmatically navigate the set of available APIs, such as an API Management solution. Including an optional Accept header with an `application/yaml` value provides the Swagger 2.0 document in YAML format. This endpoint has a multiple-cardinality, optional query parameter called `root` that can filter the found context roots. For example, a call to GET `https://host:https_port/ibm/api/docs?root=/myApp` retrieves a Swagger 2.0 document that only has the documentation for the `myApp` context root.

- Use the GET `https://host:https_port/ibm/api/explorer` endpoint.  
This endpoint provides an attractive, rendered HTML page that displays the content from the `/ibm/api/docs` URL. This page follows the same pattern as the standard online sample (<http://petstore.swagger.io/>), so that users can invoke the REST API. This endpoint helps you explore the available REST APIs on a Liberty server, and perhaps invoke them from the page. A filter input box enables a comma-separated list of context roots to filter the content. This filtering works like the `root` query parameter. You can test drive the APIs by providing the required input values and click the "Try it out" button.

- **8.5.5.9** If a collective controller, use the GET `https://host:https_port/ibm/api/collective/docs` endpoint.

This endpoint on the collective controller provides a valid Swagger 2.0 document with REST APIs available from the collective controller and its members with the `apiDiscovery-1.0` feature enabled merged into a single document. This is useful for consumer applications that want to programmatically navigate the set of available APIs, such as an API Management solution. Including an optional Accept header with an `application/yaml` value provides the Swagger 2.0 document in YAML format. This endpoint has two multiple-cardinality, optional query parameters called `root` and `serverID`.

Query parameter `root` can filter the found context roots. For example, a call to GET `https://host:https_port/ibm/api/collective/docs?root=/myApp` retrieves a Swagger 2.0 document that only has the documentation for the `myApp` context root.

Query parameter `serverID` can filter the REST APIs available from a Liberty server. The format of `serverID` is `hostName,userDir,serverName`. The format provides the name of the host followed by a comma (,) followed by the installation directory followed by a comma (,) followed by the name of the server. For example, a call to GET `https://host:https_port/ibm/api/collective/docs?serverID=samplehost.com:8020,/users/admin/wlp/usr,server1` retrieves a Swagger 2.0 document that only has the documentation for REST APIs available from the Liberty server with the specified `serverID`.

- **8.5.5.9** If a collective controller, use the GET `https://host:https_port/ibm/api/collective/explorer` endpoint.

This endpoint on the collective controller provides an attractive, rendered HTML page that displays the content from the `/ibm/api/collective/docs` URL. This endpoint helps you explore the available REST APIs on the entire collective, and perhaps invoke them from the page. A filter input box at a top corner of the page enables a comma-separated list of context roots and server ID to filter the content. The format of the server ID is `"hostName,userDir,serverName"`. Quotation marks (") must surround the server ID. If you would like to test drive the APIs using the "Try it out" button, you will need to setup Cross Origin Request Sharing (CORS) in the `server.xml` of the member server.

For example, the following snippet is required in the `server.xml` of the member server which provide the API `/IBMJMXConnectorREST/mbeanCount`.

```
<cors domain="/IBMJMXConnectorREST/mbeanCount"
      allowedOrigins="https://<controller_hostname>:<https_port>"
      allowedMethods="GET,POST,DELETE,PUT,PATCH,OPTIONS"
      allowedHeaders="Content-Type,api_key,Authorization"
      allowCredentials="true"
/>
```

For further information on setting up CORS, see [Configuring Cross Origin Request Sharing on a Liberty server](#).

**Note:** The CORS requirement is only applicable to the collective version of the Swagger UI ([https://host:https\\_port/ibm/api/collective/explorer](https://host:https_port/ibm/api/collective/explorer)).

**8.5.5.9** After you enable the `apiDiscovery-1.0` feature, the management bean (MBean) that has the `ObjectName` value `WebSphere:feature=apiDiscovery,name=APIDiscovery` is registered in the Liberty MBeanServer. This MBean provides the following attributes:

- The `DocumentationURL` attribute is the full URL of the `/ibm/api/docs` endpoint, and it displays the raw JSON or YAML documentation.
- The `ExplorerURL` attribute is the full URL of the `/ibm/api/explorer` endpoint, and it displays the rendered UI of the documentation.

You can use this MBean to learn whether REST API Discovery is enabled and where a client can reach it.

## Subscribe to Liberty REST API updates

**8.5.5.9**

The Liberty REST API discovery feature now exposes a new REST API, `/ibm/api/docs/subscription`, which allows users to subscribe to any REST API update, such as new APIs being available or old APIs being removed. This is useful when a user wants to be notified immediately of any changes in the endpoints that are provided by a particular Liberty instance.

- Enable subscriptions
- Example request and response

### Enable subscriptions

In addition to the base `apiDiscovery-1.0` configuration, it is required to also configure either `websocket-1.0` or `websocket-1.1` in your `server.xml`.

```
<server>
  <featureManager>
    <feature>apiDiscovery-1.0</feature>
    <feature>websocket-1.1</feature>
  </featureManager>

  <httpEndpoint id="defaultHttpEndpoint"
    host="*"
    httpPort="8010"
    httpsPort="8020"/>

  <keyStore id="defaultKeyStore" password="Liberty"/>

  <basicRegistry id="basic" realm="ibm/api">
    <user name="bob" password="bobpwd" />
  </basicRegistry>
</server>
```

The `/ibm/api/docs/subscription` endpoint allows for POST requests with a JSON payload in the format:

```
{ "docType" : String }
```

Where the `String` can be one of `Swagger_20_JSON` or `Swagger_20_YAML`. The returning JSON payload outlines the type of subscription feed and its URL.

### Example request and corresponding response

Request:

```
{"docType":"Swagger_20_JSON"}
```

Response:

```
{
  "feedType": "websocket",
  "feedURL": "wss://myserver.com:8020/ibm/api/docs/subscription/websocket/60db0d79-1863-48f5-a0f9-4fe22a27b82d"
}
```

You can now use a websocket client to connect to the feed URL. Once connected, any further updates to REST APIs in the Liberty server is pushed through the websocket. The update is either in JSON or YAML format, depending on the subscription.

## Subscribing to Liberty REST API updates in a collective

8.5.5.9

Use the subscription API in the collective controller to immediately learn about new REST APIs, removed APIs, or changes to APIs such as changes in the endpoints from a specific collective member server.

### Before you begin

The `/ibm/api/collective/docs/subscription` API is in the Liberty REST API discovery feature. To subscribe to updates to REST APIs from collective member servers, you must first complete the procedure in "Discovering REST API documentation on a Liberty server" on page 2260 for a collective controller.

### Procedure

#### 1. Enable subscriptions.

Add the `websocket-1.0` or `websocket-1.1` feature to the collective controller `server.xml` file; for example:

```
<server>
  <featureManager>
    <feature>collectiveController-1.0</feature>
    <feature>apiDiscovery-1.0</feature>
    <feature>websocket-1.1</feature>
  </featureManager>

  <!-- some collective controller configurations are omitted -->

  <httpEndpoint id="defaultHttpEndpoint"
    host="*"
    httpPort="8010"
    httpsPort="8020"/>

  <keyStore id="defaultKeyStore" password="Liberty"/>

  <basicRegistry id="basic" realm="ibm/api">
    <user name="bob" password="bobpwd" />
  </basicRegistry>
</server>
```

The `/ibm/api/collective/docs/subscription` endpoint enables POST requests with a JSON payload in the following format:

```
{ "docType" : String }
```

*String* is either `Swagger_20_JSON` or `Swagger_20_YAML`. The returning JSON payload outlines the type of subscription feed and its URL.

For example, the following request:

```
{"docType": "Swagger_20_JSON"}
```

returns a response such as:

```
{
  "feedType": "websocket",
  "feedURL": "wss://myserver.com:8020/ibm/api/collective/docs/subscription/websocket/60db0d79-1863-48f5-a0f9-4fe22a27b82d"
}
```

#### 2. Use a websocket client to connect to the feed URL.

You can write code or use a third-party websocket client to connect to the feed URL. Once connected, any further updates to REST APIs in the Liberty server are pushed through the websocket. The update is either in JSON or YAML format, depending on the subscription.

## REST endpoints for pushing APIs into IBM API Connect

8.5.5.9

Use the REST endpoint, which is a central location for both on-premises and cloud Liberty users, to visualize, call, and push APIs into IBM API Connect.

### Pushing deployed REST endpoints into IBM API Connect

To push deployed REST endpoints into IBM API Connect, you must call a new REST endpoint, `/ibm/api/docs/apiconnect`, which is exposed by the `apiDiscovery-1.0` feature in the server configuration. Administrators and developers can use the REST endpoints to expose assets from a Liberty instance to any enterprise developer who is searching the IBM API Connect framework catalogs.

### Providing a product definition

All APIs are referenced by a product and exposed from a catalog. Therefore, the caller provides a product definition that Liberty uses to refer to its RESTful APIs and push the resulting product into IBM API Connect. A sample product is provided in this topic.

### Exposing assets of a Liberty collective into IBM API Connect

Using a corresponding Liberty collective endpoint, `/ibm/api/collective/docs/apiconnect`, you can expose all assets of a Liberty Collective into IBM API Connect with a single RESTful trigger. The Liberty collective endpoint can expose thousands of APIs to any cloud developer connected to API Connect. See the Liberty RESTful API registry, `/ibm/api/explorer`, for the full Swagger definition of this endpoint.

### Endpoint summary

HTTP Request method: POST

URL: `https://server:https_port/ibm/api/docs/apiconnect`

### Required headers

#### X-APIM-Authorization

Credentials to connect to API Connect display in the two following forms:

- username and password
- xyz where xyz is the base64 encoded version of username: password.

### Required query parameters

**Server** The name of the IBM API Connect server, starting with `https://`.

#### Catalog

The name of the catalog that hosts the resulting product.

#### Organization

The name of the organization of the caller.

### Optional query parameters

#### apiRoot

A multi-cardinality parameter that specifies exactly which context roots, such as, `apiRoot=/myApp`,

the caller wants to push into API Connect. By default, Liberty includes any deployed application except known Liberty runtime Web Application Bundles. This parameter is useful when you want to filter which applications get exposed.

#### **member ID (only available for the Collective variant)**

A multi-cardinality parameter that specifies the ID of the exact Collective Members from which the caller wants to expose assets. This ID is composed of a string with the host name, the URLEncoded user dir, and the server name, all separated by a comma, for example: myHost.com,%2Ftmp%2Fwlp%2Fusr, server1.

#### **Input body**

Product definition in either in YAML or JSON code. See the following YAML example:

```
product: "1.0.0"
  info:
    name: "pushed-product"
    title: "A Product that encapsulates Liberty APIs"

## Chapter 11. Monitoring the Liberty server runtime environment

You can use the `monitor-1.0` feature to monitor the server runtime environment.

### About this task

To enable monitoring for your Liberty server, you add `monitor-1.0` Liberty feature in the `server.xml` file.

The `monitor-1.0` feature provides monitoring support for user runtime components.

- JVM
- Web applications
- Thread pool
- **8.5.5.0** JAX-WS endpoints
- **8.5.5.0** Session management
- **8.5.5.0** ConnectionPool

For more details, see “Liberty features” on page 826.

### Procedure

1. Add the `monitor-1.0` feature and the monitoring starts.

**Note:** **8.5.5.3** If you launch the server by not using the server script (`server.sh` or `server.bat`) on a Java Virtual Machine (JVM), ensure that the JavaAgent is configured for JVM as given in the following example: `agentlib=-javaagent:<path to liberty install>/bin/tools/ws-javaagent.jar`.

2. Monitoring data is reported as standard MBeans.
3. You can use JConsole to connect to JVM and look at the performance data by clicking each attribute of the MBean.

The MBeans for monitoring are as following:

- `WebSphere:type=JvmStats`
  - `WebSphere:type=ServletStats,name=*`
  - `WebSphere:type=ThreadPoolStats,name=Default Executor`
  - **8.5.5.0** `org.apache.cxf:type=WebServiceStats,service=*,port=*`
  - **8.5.5.0** `WebSphere:type=SessionStats,name=*`
  - **8.5.5.0** `WebSphere:type=ConnectionPool,name=*`
4. Optional: The same data is available with traditional PMI MBean (Perf MBean). Note that the Perf MBean is stabilized.

---

### Liberty:JVM monitoring

You can use the `JvmStats` MBean for JVM monitoring in Liberty.

Each Liberty instance has one `JvmStats` MBean.

The `ObjectName` for identifying JVM MBean is:

```
WebSphere:type=JvmStats
```

Available Instances = 1

This MBean is responsible for reporting performance of JVM. Following attributes are available for JVM.

#### Heap Information

- Amount of free heap available (in Bytes)
- Total used memory by JVM for from heap (in Bytes)
- Heap size (in Bytes)

#### CPU Information

- Percentage of CPU consumed by this JVM

#### Garbage Collection (GC) Information

- Number of times that GC happened since JVM started
- Total time taken by GC activity

#### General Information

- Time in milliseconds since JVM has started.

#### Counter definitions (Attributes to MBean)

- Heap: Heap size used for current JVM.
- FreeMemory: Free heap available for current JVM.
- UsedMemory: Used heap for current JVM.
- ProcessCPU: Percentage of CPU used by JVM process.
- GcCount: Number of times GC has happened since JVM starts.
- GcTime: Total accumulated value of GC time.
- UpTime: Time in milliseconds, since JVM has started.

#### 8.5.0.1 Management Interface

The management interface of JVM monitoring is `com.ibm.websphere.monitor.jmx.JvmMBean`.

**8.5.0.1** You can use the management interface to obtain a proxy object. See “Liberty:Examples of accessing MBean attributes and operations” on page 1654.

For more information about the management interface, see the Java API document for Liberty. The Java API documentation for each Liberty API is available in a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

---

## Liberty:Web application monitoring

You can use a servlet MBean for web application monitoring of Liberty.

Performance data is available for each Servlet in the Web Application. Each servlet has its own MBean.

The ObjectName for identifying each servlet MBean is:

```
WebSphere:type=ServletStats,name=<AppName>.<ServletName>
```

For example:

```
WebSphere:type=ServletStats,name=snoop.Alpine Snoop Servlet
WebSphere:type=ServletStats,name=MyApp.MyServlet
```

This MBean is responsible for reporting ServletStats for each servlet. Following key data is available for ServletStats MBean:

- Request Count
- Response Time
- Servlet Name
- Application Name

#### Counter definitions (Attributes to MBean)

- `AppName`: Name of the application.
- `ServletName`: Name of the servlet.
- `RequestCount`: Number of hits to this servlet.
- `ResponseTime`: Average response time (nano-seconds).
- `Description`: Description of counter.
- `RequestCountDetails`: RequestCount details including last time stamp.
- `ResponseTimeDetails`: ResponseTime details including number of snapshot taken, min, and max values.

#### 8.5.0.1 Management Interface

The management interface of web application monitoring is

`com.ibm.websphere.webcontainer.ServletStatsMBean`. 8.5.0.1 You can use the management interface to obtain a proxy object. See “Liberty:Examples of accessing MBean attributes and operations” on page 1654.

For more information about the management interface, see the Java API document for Liberty. The Java API documentation for each Liberty API is available in a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

---

## Liberty:ThreadPool monitoring

You can use a ThreadPool MBean for thread pool monitoring in Liberty.

All Web Requests executes in the thread pool, named **Default Executor** thread pool. You can monitor the usage of **Default Executor** thread pool using ThreadPoolMBean.

The ObjectName for identifying MBean for thread pool is :

```
WebSphere:type=ThreadPoolStats,name=Default Executor
```

Key Performance data available for ThreadPool are:

- Threads in the pool which represents the pool size.
- Active threads which are serving requests.

#### Attributes for ThreadPool

- `ActiveThreads`
- `PoolSize`
- `PoolName` (Only supports Default Executor thread pool)

### 8.5.0.1 Management Interface

The management interface of ThreadPool monitoring is

`com.ibm.websphere.monitor.jmx.ThreadPoolMBean`. **8.5.0.1** You can use the management interface to obtain a proxy object. See “Liberty:Examples of accessing MBean attributes and operations” on page 1654.

For more information about the management interface, see the Java API document for Liberty. The Java API documentation for each Liberty API is available in a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

---

## Liberty:JAX-WS monitoring

### 8.5.5.0

You can use the endpoint MBean for JAX-WS monitoring of Liberty.

Performance data is available for each endpoint and operation in the JAX-WS application. Each web service endpoint has its own MBean.

The ObjectName for identifying each endpoint MBean might be in one of the following formats:

```
org.apache.cxf:bus.id=<bus.name>,type=Performance.Counter.Server,service="<NameSpace><ServiceName>",port="<PortName>"
org.apache.cxf:bus.id=<bus.name>,type=Performance.Counter.Client,service="<NameSpace><ServiceName>",port="<PortName>"
```

For example:

```
org.apache.cxf:bus.id=JaxWsLibertyDemo-Server-Bus,type=Performance.Counter.Server,
service="{http://jaxws.samples/}SimpleEchoService",port="SimpleEchoPort"
org.apache.cxf:bus.id=JaxWsLibertyDemo-Server-Bus,type=Performance.Counter.Client,
service="{http://jaxws.samples/}SimpleEchoService",port="SimpleEchoPort"
```

This MBean is responsible for reporting the web service status of each endpoint and operation.

#### Counter definitions (Attributes to MBean)

- AvgResponseTime: Average response time (millisecond).
- MaxResponseTime: Maximum response time (millisecond).
- MinResponseTime: Minimum response time (millisecond).
- NumInvocations: Number of invocations to this endpoint or operation.
- NumCheckedApplicationFaults: Number of checked application faults.
- NumLogicalRuntimeFaults: Number of logical runtime faults.
- NumRuntimeFaults: Number of runtime faults.
- NumUncheckedApplicationFaults: Number of unchecked application faults.
- TotalHandlingTime: Total response handling time (millisecond)..

#### Management Interface

The management interface for web service application monitoring is

`org.apache.cxf.management.counters.ResponseTimeCounterMBean`. **8.5.0.1** You can use the management interface to obtain a proxy object. See “Liberty:Examples of accessing MBean attributes and operations” on page 1654.

For more information about the `org.apache.cxf.management.counters.ResponseTimeCounterMBean`, see the Apache CXF Javadoc.

## SIP application monitoring

8.5.5.9

Session Initiation Protocol (SIP) Performance Monitoring Infrastructure (PMI) is a component that collects SIP performance metrics of a running application server. To monitor the SIP metrics, you must enable PMI on your server. To enable monitoring for SIP, add `monitor-1.0` and `sipServlet-1.1` Liberty features to the `server.xml` file.

All Liberty SIP PMI counters are shown by standard MBeans.

The SIP container provides the following MBean interfaces for the SIP counters:

- `WebSphere:type=SipContainerBasicCounters,name=SipContainer.Basic`
- `WebSphere:type=TaskDurationCounters,name=SipContainer.TaskDuration`
- `WebSphere:type=InboundRequestCounters,name=SipContainer.InboundRequest`
- `WebSphere:type=OutboundRequestCounters,name=SipContainer.OutboundRequest`
- `WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse`
- `WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse`
- `WebSphere:type=QueueMonitoringModule,name=SipContainer.QueueMonitor`

Each interface shows a different set of SIP PMI metrics. Refer to the tables for module details. You can view the SIP PMI counters in multiple ways:

- Use JConsole to connect to JVM and look at the SIP PMI counters by clicking each attribute of the MBean.
- Create your own JMX client application to inspect the counters by starting the MBean operations.

For more information about how to create a JMX client to start the MBean operations, see [Connecting to Liberty by using JMX and Liberty: Examples of accessing MBean attributes and operations](#). SIP provides the following counters in PMI to monitor SIP performance.

*Table 177. SIP container basic counters.* The object name of the MBean from which the counters can be retrieved is: `"WebSphere:type=SipContainerBasicCounters,name=SipContainer.Basic"`. To retrieve the attributes, use the `JMXConnection.getAttribute` method. For example:  
`_connection.getAttribute("WebSphere:type=SipContainerBasicCounters,name=SipContainer.Basic", "SipAppSessions")`.

This table lists the SIP container basic counters.

Name	Attribute	Description	Granularity
Incoming traffic	<code>ReceivedSipMsgs</code>	The average number of messages that are handled by the container and calculated over a configurable period	Server
New SIP application sessions	<code>NewSipApplications</code>	The average number of new SIP application sessions created in the container and calculated over a configurable period	Server
Response time	<code>SipRequestProcessing</code>	The average amount of time that it takes between when a message gets into the container and when a response is sent from the container	Server

*Table 177. SIP container basic counters (continued).* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=SipContainerBasicCounters,name=SipContainer.Basic". To retrieve the attributes, use the JMXConnection.getAttribute method. For example: `_connection.getAttribute("WebSphere:type=SipContainerBasicCounters,name=SipContainer.Basic", "SipAppSessions")`.

This table lists the SIP container basic counters.

Name	Attribute	Description	Granularity
Queue size	InvokerSize	The size of the invoke queue in the product	Server
Rejected SIP messages	RejectedMessages	The number of rejected SIP messages	Server
SIP timer invocations	SipTimersInvocations	The number of invocations of the SIP timers (Timer A, Timer B, Timer C, Timer D, Timer E, Timer F, Timer G, Timer H)	Server
Number of active SIP sessions	SipSessions	The number of SIP sessions that belong to each application	Server
Number of active SIP application sessions	SipAppSessions	The number of SIP application sessions that belong to each application	Server

*Table 178. SIP container inbound requests.* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=InboundRequestCounters,name=SipContainer.InboundRequest". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=InboundRequestCounters,name=SipContainer.InboundRequest", "getTotalInboundRequests", _appName, "INVITE")`.

This table lists the inbound request counters.

Name	Method	Description	Granularity
Number of inbound NOT SIP STANDARD requests	<code>getTotalInboundRequests(appName, "NOTSIPSTANDARD");</code>	Number of inbound NOT SIP STANDARD requests that belong to each application	Application
Number of inbound REGISTER requests	<code>getTotalInboundRequests(appName, "REGISTER");</code>	Number of inbound REGISTER requests that belong to each application	Application
Number of inbound INVITE requests	<code>getTotalInboundRequests(appName, "INVITE");</code>	Number of inbound INVITE requests that belong to each application	Application
Number of inbound ACK requests	<code>getTotalInboundRequests(appName, "ACK");</code>	Number of inbound ACK requests that belong to each application	Application
Number of inbound OPTIONS requests	<code>getTotalInboundRequests(appName, "OPTIONS");</code>	Number of inbound OPTIONS requests that belong to each application	Application
Number of inbound BYE requests	<code>getTotalInboundRequests(appName, "BYE");</code>	Number of inbound BYE requests that belong to each application	Application

*Table 178. SIP container inbound requests (continued).* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=InboundRequestCounters,name=SipContainer.InboundRequest". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=InboundRequestCounters,name=SipContainer.InboundRequest", "getTotalInboundRequests", _appName, "INVITE")`.

This table lists the inbound request counters.

Name	Method	Description	Granularity
Number of inbound CANCEL requests	<code>getTotalInboundRequests(applicationName, "CANCEL");</code>	Number of inbound CANCEL requests that belong to each application	Application
Number of inbound PRACK requests	<code>getTotalInboundRequests(applicationName, "PRACK");</code>	Number of inbound PRACK requests that belong to each application	Application
Number of inbound INFO requests	<code>getTotalInboundRequests(applicationName, "INFO");</code>	Number of inbound INFO requests that belong to each application	Application
Number of inbound SUBSCRIBE requests	<code>getTotalInboundRequests(applicationName, "SUBSCRIBE");</code>	Number of inbound SUBSCRIBE requests that belong to each application	Application
Number of inbound NOTIFY requests	<code>getTotalInboundRequests(applicationName, "NOTIFY");</code>	Number of inbound NOTIFY requests that belong to each application	Application
Number of inbound MESSAGE requests	<code>getTotalInboundRequests(applicationName, "MESSAGE");</code>	Number of inbound MESSAGE requests that belong to each application	Application
Number of inbound PUBLISH requests	<code>getTotalInboundRequests(applicationName, "PUBLISH");</code>	Number of inbound PUBLISH requests that belong to each application	Application
Number of inbound REFER requests	<code>getTotalInboundRequests(applicationName, "REFER");</code>	Number of inbound REFER requests that belong to each application	Application
Number of inbound UPDATE requests	<code>getTotalInboundRequests(applicationName, "UPDATE");</code>	Number of inbound UPDATE requests that belong to each application	Application

*Table 179. SIP container inbound responses.* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse", "getTotalInboundResponses", _appName, "100")`.

This table lists the inbound response counters.

Name	Method	Description	Granularity
Number of inbound 100 responses	<code>getTotalInboundResponses(applicationName, "100");</code>	Number of inbound 100 (Trying) responses that belong to each application	Application
Number of inbound 180 responses	<code>getTotalInboundResponses(applicationName, "180");</code>	Number of inbound 180 (Ringing) responses that belong to each application	Application

Table 179. SIP container inbound responses (continued). The object name of the MXBean from which the counters can be retrieved is: "WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse", "getTotalInboundResponses", _appName, "100")`.

This table lists the inbound response counters.

Name	Method	Description	Granularity
Number of inbound 181 responses	<code>getTotalInboundResponses(applicationName, "181");</code>	Number of inbound 181 (Call being forwarded) responses that belong to each application	Application
Number of inbound 182 responses	<code>getTotalInboundResponses(applicationName, "182");</code>	Number of inbound 182 (Call Queued) responses that belong to each application	Application
Number of inbound 183 responses	<code>getTotalInboundResponses(applicationName, "183");</code>	Number of inbound 183 (Session Progress) responses that belong to each application	Application
Number of inbound 200 responses	<code>getTotalInboundResponses(applicationName, "200");</code>	Number of inbound 200 (OK) responses that belong to each application	Application
Number of inbound 202 responses	<code>getTotalInboundResponses(applicationName, "202");</code>	Number of inbound 202 (Accepted) responses that belong to each application	Application
Number of inbound 300 responses	<code>getTotalInboundResponses(applicationName, "300");</code>	Number of inbound 300 (Multiple choices) responses that belong to each application	Application
Number of inbound 301 responses	<code>getTotalInboundResponses(applicationName, "301");</code>	Number of inbound 301 (Moved Permanently) responses that belong to each application	Application
Number of inbound 302 responses	<code>getTotalInboundResponses(applicationName, "302");</code>	Number of inbound 302 (Moved Temporarily) responses that belong to each application	Application
Number of inbound 305 responses	<code>getTotalInboundResponses(applicationName, "305");</code>	Number of inbound 305 (Use Proxy) responses that belong to each application	Application
Number of inbound 380 responses	<code>getTotalInboundResponses(applicationName, "380");</code>	Number of inbound 380 (Alternative Service) responses that belong to each application	Application
Number of inbound 400 responses	<code>getTotalInboundResponses(applicationName, "400");</code>	Number of inbound 400 (Bad Request) responses that belong to each application	Application
Number of inbound 401 responses	<code>getTotalInboundResponses(applicationName, "401");</code>	Number of inbound 401 (Unauthorized) responses that belong to each application	Application

Table 179. SIP container inbound responses (continued). The object name of the MXBean from which the counters can be retrieved is: "WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse", "getTotalInboundResponses", _appName, "100").`

This table lists the inbound response counters.

Name	Method	Description	Granularity
Number of inbound 402 responses	<code>getTotalInboundResponses(applicationName, "402");</code>	Number of inbound 402 (Payment Required) responses that belong to each application	Application
Number of inbound 403 responses	<code>getTotalInboundResponses(applicationName, "403");</code>	Number of inbound 403 (Forbidden) responses that belong to each application	Application
Number of inbound 404 responses	<code>getTotalInboundResponses(applicationName, "404");</code>	Number of inbound 404 (Not Found) responses that belong to each application	Application
Number of inbound 405 responses	<code>getTotalInboundResponses(applicationName, "405");</code>	Number of inbound 405 (Method Not Allowed) responses that belong to each application	Application
Number of inbound 406 responses	<code>getTotalInboundResponses(applicationName, "406");</code>	Number of inbound 406 (Not Acceptable) responses that belong to each application	Application
Number of inbound 407 responses	<code>getTotalInboundResponses(applicationName, "407");</code>	Number of inbound 407 (Proxy Authentication Required) responses that belong to each application	Application
Number of inbound 408 responses	<code>getTotalInboundResponses(applicationName, "408");</code>	Number of inbound 408 (Request Timeout) responses that belong to each application	Application
Number of inbound 410 responses	<code>getTotalInboundResponses(applicationName, "410");</code>	Number of inbound 410 (Gone) responses that belong to each application	Application
Number of inbound 413 responses	<code>getTotalInboundResponses(applicationName, "413");</code>	Number of inbound 413 (Request Entity Too Large) responses that belong to each application	Application
Number of inbound 414 responses	<code>getTotalInboundResponses(applicationName, "414");</code>	Number of inbound 414 (Request URI Too Long) responses that belong to each application	Application
Number of inbound 415 responses	<code>getTotalInboundResponses(applicationName, "415");</code>	Number of inbound 415 (Unsupported Media Type) responses that belong to each application	Application
Number of inbound 416 responses	<code>getTotalInboundResponses(applicationName, "416");</code>	Number of inbound 416 (Unsupported URI Scheme) responses that belong to each application	Application

Table 179. SIP container inbound responses (continued). The object name of the MXBean from which the counters can be retrieved is: "WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse", "getTotalInboundResponses", _appName, "100")`.

This table lists the inbound response counters.

Name	Method	Description	Granularity
Number of inbound 420 responses	<code>getTotalInboundResponses(applicationName, "420");</code>	The number of inbound 420 (Bad Extension) responses that belong to each application	Application
Number of inbound 421 responses	<code>getTotalInboundResponses(applicationName, "421");</code>	The number of inbound 421 (Extension Required) responses that belong to each application	Application
Number of inbound 423 responses	<code>getTotalInboundResponses(applicationName, "423");</code>	The number of inbound 423 (Interval Too Brief) responses that belong to each application	Application
Number of inbound 480 responses	<code>getTotalInboundResponses(applicationName, "480");</code>	The number of inbound 480 (Temporarily Unavailable) responses that belong to each application	Application
Number of inbound 481 responses	<code>getTotalInboundResponses(applicationName, "481");</code>	The number of inbound 481 (Call Leg Done) responses that belong to each application	Application
Number of inbound 482 responses	<code>getTotalInboundResponses(applicationName, "482");</code>	The number of inbound 482 (Loop Detected) responses that belong to each application	Application
Number of inbound 483 responses	<code>getTotalInboundResponses(applicationName, "483");</code>	The number of inbound 483 (Too Many Hops) responses that belong to each application	Application
Number of inbound 484 responses	<code>getTotalInboundResponses(applicationName, "484");</code>	The number of inbound 484 (Address Incomplete) responses that belong to each application	Application
Number of inbound 485 responses	<code>getTotalInboundResponses(applicationName, "485");</code>	The number of inbound 485 (Ambiguous) responses that belong to each application	Application
Number of inbound 486 responses	<code>getTotalInboundResponses(applicationName, "486");</code>	The number of inbound 486 (Busy Here) responses that belong to each application	Application
Number of inbound 487 responses	<code>getTotalInboundResponses(applicationName, "487");</code>	The number of inbound 487 (Request Terminated) responses that belong to each application	Application
Number of inbound 488 responses	<code>getTotalInboundResponses(applicationName, "488");</code>	The number of inbound 488 (Not Acceptable Here) responses that belong to each application	Application

Table 179. SIP container inbound responses (continued). The object name of the MXBean from which the counters can be retrieved is: "WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse", "getTotalInboundResponses", _appName, "100")`.

This table lists the inbound response counters.

Name	Method	Description	Granularity
Number of inbound 491 responses	<code>getTotalInboundResponses(applicationName, "491");</code>	Number of inbound 491 (Request Pending) responses that belong to each application	Application
Number of inbound 493 responses	<code>getTotalInboundResponses(applicationName, "493");</code>	Number of inbound 493 (Undecipherable) responses that belong to each application	Application
Number of inbound 500 responses	<code>getTotalInboundResponses(applicationName, "500");</code>	Number of inbound 500 (Server Internal Error) responses that belong to each application	Application
Number of inbound 501 responses	<code>getTotalInboundResponses(applicationName, "501");</code>	Number of inbound 501 (Not Implemented) responses that belong to each application	Application
Number of inbound 502 responses	<code>getTotalInboundResponses(applicationName, "502");</code>	Number of inbound 502 (Bad Gateway) responses that belong to each application	Application
Number of inbound 503 responses	<code>getTotalInboundResponses(applicationName, "503");</code>	Number of inbound 503 (Service Unavailable) responses that belong to each application	Application
Number of inbound 504 responses	<code>getTotalInboundResponses(applicationName, "504");</code>	Number of inbound 504 (Server Timeout) responses that belong to each application	Application
Number of inbound 505 responses	<code>getTotalInboundResponses(applicationName, "505");</code>	Number of inbound 505 (Version Not Supported) responses that belong to each application	Application
Number of inbound 513 responses	<code>getTotalInboundResponses(applicationName, "513");</code>	Number of inbound 513 (Message Too Large) responses that belong to each application	Application
Number of inbound 600 responses	<code>getTotalInboundResponses(applicationName, "600");</code>	Number of inbound 600 (Busy Everywhere) responses that belong to each application	Application
Number of inbound 603 responses	<code>getTotalInboundResponses(applicationName, "603");</code>	Number of inbound 603 (Decline) responses that belong to each application	Application

*Table 179. SIP container inbound responses (continued).* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=InboundResponseCounters,name=SipContainer.InboundResponse", "getTotalInboundResponses", _appName, "100")`.

This table lists the inbound response counters.

Name	Method	Description	Granularity
Number of inbound 604 responses	<code>getTotalInboundResponses(applicationName, "604");</code>	The number of inbound 604 (Does Not Exit Anywhere) responses that belong to each application	Application
Number of inbound 606 responses	<code>getTotalInboundResponses(applicationName, "606");</code>	The number of inbound 606 (Not Acceptable Anywhere) responses that belong to each application	Application

*Table 180. SIP container outbound requests.* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=OutboundRequestCounters,name=SipContainer.OutboundRequest". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=OutboundRequestCounters,name=SipContainer.OutboundRequest", "getTotalOutboundRequests", _appName, "INVITE")`.

This table lists the outbound request counters.

Name	Method	Description	Granularity
Number of outbound NOT SIP STANDARD requests	<code>getTotalOutboundRequests(applicationName, "NOTSIPSTANDARD");</code>	The number of outbound NOT SIP STANDARD requests that belong to each application	Application
Number of outbound REGISTER requests	<code>getTotalOutboundRequests(applicationName, "REGISTER");</code>	The number of outbound REGISTER requests that belong to each application	Application
Number of outbound INVITE requests	<code>getTotalOutboundRequests(applicationName, "INVITE");</code>	The number of outbound INVITE requests that belong to each application	Application
Number of outbound ACK requests	<code>getTotalOutboundRequests(applicationName, "ACK");</code>	The number of outbound ACK requests that belong to each application	Application
Number of outbound OPTIONS requests	<code>getTotalOutboundRequests(applicationName, "OPTIONS");</code>	The number of outbound OPTIONS requests that belong to each application	Application
Number of outbound BYE requests	<code>getTotalOutboundRequests(applicationName, "BYE");</code>	The number of outbound BYE requests that belong to each application	Application
Number of outbound CANCEL requests	<code>getTotalOutboundRequests(applicationName, "CANCEL");</code>	The number of outbound CANCEL requests that belong to each application	Application
Number of outbound PRACK requests	<code>getTotalOutboundRequests(applicationName, "PRACK");</code>	The number of outbound PRACK requests that belong to each application	Application
Number of outbound INFO requests	<code>getTotalOutboundRequests(applicationName, "INFO");</code>	The number of outbound INFO requests that belong to each application	Application

*Table 180. SIP container outbound requests (continued).* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=OutboundRequestCounters,name=SipContainer.OutboundRequest". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=OutboundRequestCounters,name=SipContainer.OutboundRequest", "getTotalOutboundRequests", _appName, "INVITE").`

This table lists the outbound request counters.

Name	Method	Description	Granularity
Number of outbound SUBSCRIBE requests	<code>getTotalOutboundRequests(applicationName, "SUBSCRIBE");</code>	The number of outbound SUBSCRIBE requests that belong to each application	Application
Number of outbound NOTIFY requests	<code>getTotalOutboundRequests(applicationName, "NOTIFY");</code>	The number of outbound NOTIFY requests that belong to each application	Application
Number of outbound MESSAGE requests	<code>getTotalOutboundRequests(applicationName, "MESSAGE");</code>	The number of outbound MESSAGE requests that belong to each application	Application
Number of outbound PUBLISH requests	<code>getTotalOutboundRequests(applicationName, "PUBLISH");</code>	The number of outbound PUBLISH requests that belong to each application	Application
Number of outbound REFER requests	<code>getTotalOutboundRequests(applicationName, "REFER");</code>	The number of outbound REFER requests that belong to each application	Application
Number of outbound UPDATE requests	<code>getTotalOutboundRequests(applicationName, "UPDATE");</code>	The number of outbound UPDATE requests that belong to each application	Application

*Table 181. SIP container outbound responses.* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse", "getTotalOutboundResponses", _appName, "100").`

This table lists the outbound response counters.

Name	Method	Description	Granularity
Number of outbound 100 responses	<code>getTotalOutboundResponses(applicationName, "100");</code>	The number of outbound 100 (Trying) responses that belong to each application	Application
Number of outbound 180 responses	<code>getTotalOutboundResponses(applicationName, "180");</code>	The number of outbound 180 (Ringing) responses that belong to each application	Application
Number of outbound 181 responses	<code>getTotalOutboundResponses(applicationName, "181");</code>	The number of outbound 181 (Call being forwarded) responses that belong to each application	Application
Number of outbound 182 responses	<code>getTotalOutboundResponses(applicationName, "182");</code>	The number of outbound 182 (Call Queued) responses that belong to each application	Application

*Table 181. SIP container outbound responses (continued).* The object name of the MXBean from which the counters can be retrieved is: "WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse", "getTotalOutboundResponses", _appName, "100")`.

This table lists the outbound response counters.

Name	Method	Description	Granularity
Number of outbound 183 responses	<code>getTotalOutboundResponses("183");</code>	The number of outbound 183 (Session Progress) responses that belong to each application	Application
Number of outbound 200 responses	<code>getTotalOutboundResponses("200");</code>	The number of outbound 200 (OK) responses that belong to each application	Application
Number of outbound 202 responses	<code>getTotalOutboundResponses("202");</code>	The number of outbound 202 (Accepted) responses that belong to each application	Application
Number of outbound 300 responses	<code>getTotalOutboundResponses("300");</code>	The number of outbound 300 (Multiple choices) responses that belong to each application	Application
Number of outbound 301 responses	<code>getTotalOutboundResponses("301");</code>	The number of outbound 301 (Moved Permanently) responses that belong to each application	Application
Number of outbound 302 responses	<code>getTotalOutboundResponses("302");</code>	The number of outbound 302 (Moved Temporarily) responses that belong to each application	Application
Number of outbound 305 responses	<code>getTotalOutboundResponses("305");</code>	The number of outbound 305 (Use Proxy) responses that belong to each application	Application
Number of outbound 380 responses	<code>getTotalOutboundResponses("380");</code>	The number of outbound 380 (Alternative Service) responses that belong to each application	Application
Number of outbound 400 responses	<code>getTotalOutboundResponses("400");</code>	The number of outbound 400 (Bad Request) responses that belong to each application	Application
Number of outbound 401 responses	<code>getTotalOutboundResponses("401");</code>	The number of outbound 401 (Unauthorized) responses that belong to each application	Application
Number of outbound 402 responses	<code>getTotalOutboundResponses("402");</code>	The number of outbound 402 (Payment Required) responses that belong to each application	Application

*Table 181. SIP container outbound responses (continued).* The object name of the MXBean from which the counters can be retrieved is: "WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse", "getTotalOutboundResponses", _appName, "100")`.

This table lists the outbound response counters.

Name	Method	Description	Granularity
Number of outbound 403 responses	<code>getTotalOutboundResponses("403");</code>	Number of outbound 403 (Forbidden) responses that belong to each application	Application
Number of outbound 404 responses	<code>getTotalOutboundResponses("404");</code>	Number of outbound 404 (Not Found) responses that belong to each application	Application
Number of outbound 405 responses	<code>getTotalOutboundResponses("405");</code>	Number of outbound 405 (Method Not Allowed) responses that belong to each application	Application
Number of outbound 406 responses	<code>getTotalOutboundResponses("406");</code>	Number of outbound 406 (Not Acceptable) responses that belong to each application	Application
Number of outbound 407 responses	<code>getTotalOutboundResponses("407");</code>	Number of outbound 407 (Proxy Authentication Required) responses that belong to each application	Application
Number of outbound 408 responses	<code>getTotalOutboundResponses("408");</code>	Number of outbound 408 (Request Timeout) responses that belong to each application	Application
Number of outbound 410 responses	<code>getTotalOutboundResponses("410");</code>	Number of outbound 410 (Gone) responses that belong to each application	Application
Number of outbound 413 responses	<code>getTotalOutboundResponses("413");</code>	Number of outbound 413 (Request Entity Too Large) responses that belong to each application	Application
Number of outbound 414 responses	<code>getTotalOutboundResponses("414");</code>	Number of outbound 414 (Request URI Too Long) responses that belong to each application	Application
Number of outbound 415 responses	<code>getTotalOutboundResponses("415");</code>	Number of outbound 415 (Unsupported Media Type) responses that belong to each application	Application
Number of outbound 416 responses	<code>getTotalOutboundResponses("416");</code>	Number of outbound 416 (Unsupported URI Scheme) responses that belong to each application	Application

Table 181. SIP container outbound responses (continued). The object name of the MXBean from which the counters can be retrieved is: "WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse", "getTotalOutboundResponses", _appName, "100")`.

This table lists the outbound response counters.

Name	Method	Description	Granularity
Number of outbound 420 responses	<code>getTotalOutboundResponses("420");</code>	Number of outbound 420 (Bad Extension) responses that belong to each application	Application
Number of outbound 421 responses	<code>getTotalOutboundResponses("421");</code>	Number of outbound 421 (Extension Required) responses that belong to each application	Application
Number of outbound 423 responses	<code>getTotalOutboundResponses("423");</code>	Number of outbound 423 (Interval Too Brief) responses that belong to each application	Application
Number of outbound 480 responses	<code>getTotalOutboundResponses("480");</code>	Number of outbound 480 (Temporarily Unavailable) responses that belong to each application	Application
Number of outbound 481 responses	<code>getTotalOutboundResponses("481");</code>	Number of outbound 481 (Call Leg Done) responses that belong to each application	Application
Number of outbound 482 responses	<code>getTotalOutboundResponses("482");</code>	Number of outbound 482 (Loop Detected) responses that belong to each application	Application
Number of outbound 483 responses	<code>getTotalOutboundResponses("483");</code>	Number of outbound 483 (Too Many Hops) responses that belong to each application	Application
Number of outbound 484 responses	<code>getTotalOutboundResponses("484");</code>	Number of outbound 484 (Address Incomplete) responses that belong to each application	Application
Number of outbound 485 responses	<code>getTotalOutboundResponses("485");</code>	Number of outbound 485 (Ambiguous) responses that belong to each application	Application
Number of outbound 486 responses	<code>getTotalOutboundResponses("486");</code>	Number of outbound 486 (Busy Here) responses that belong to each application	Application
Number of outbound 487 responses	<code>getTotalOutboundResponses("487");</code>	Number of outbound 487 (Request Terminated) responses that belong to each application	Application

Table 181. SIP container outbound responses (continued). The object name of the MXBean from which the counters can be retrieved is: "WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse", "getTotalOutboundResponses", _appName, "100")`.

This table lists the outbound response counters.

Name	Method	Description	Granularity
Number of outbound 488 responses	<code>getTotalOutboundResponses("488");</code>	Number of outbound 488 (Not Acceptable Here) responses that belong to each application	Application
Number of outbound 491 responses	<code>getTotalOutboundResponses("491");</code>	Number of outbound 491 (Request Pending) responses that belong to each application	Application
Number of outbound 493 responses	<code>getTotalOutboundResponses("493");</code>	Number of outbound 493 (Undecipherable) responses that belong to each application	Application
Number of outbound 500 responses	<code>getTotalOutboundResponses("500");</code>	Number of outbound 500 (Server Internal Error) responses that belong to each application	Application
Number of outbound 501 responses	<code>getTotalOutboundResponses("501");</code>	Number of outbound 501 (Not Implemented) responses that belong to each application	Application
Number of outbound 502 responses	<code>getTotalOutboundResponses("502");</code>	Number of outbound 502 (Bad Gateway) responses that belong to each application	Application
Number of outbound 503 responses	<code>getTotalOutboundResponses("503");</code>	Number of outbound 503 (Service Unavailable) responses that belong to each application	Application
Number of outbound 504 responses	<code>getTotalOutboundResponses("504");</code>	Number of outbound 504 (Server Timeout) responses that belong to each application	Application
Number of outbound 505 responses	<code>getTotalOutboundResponses("505");</code>	Number of outbound 505 (Version Not Supported) responses that belong to each application	Application
Number of outbound 513 responses	<code>getTotalOutboundResponses("513");</code>	Number of outbound 513 (Message Too Large) responses that belong to each application	Application
Number of outbound 600 responses	<code>getTotalOutboundResponses("600");</code>	Number of outbound 600 (Busy Everywhere) responses that belong to each application	Application

*Table 181. SIP container outbound responses (continued).* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse". To retrieve the counters, use the JMXConnection.invoke method. For example, `_connection.invoke("WebSphere:type=OutboundResponseCounters,name=SipContainer.OutboundResponse", "getTotalOutboundResponses", _appName, "100")`.

This table lists the outbound response counters.

Name	Method	Description	Granularity
Number of outbound 603 responses	<code>getTotalOutboundResponses(applicationName, "603");</code>	The number of outbound 603 (Decline) responses that belong to each application	Application
Number of outbound 604 responses	<code>getTotalOutboundResponses(applicationName, "604");</code>	The number of outbound 604 (Does Not Exit Anywhere) responses that belong to each application	Application
Number of outbound 606 responses	<code>getTotalOutboundResponses(applicationName, "606");</code>	The number of outbound 606 (Not Acceptable Anywhere) responses that belong to each application	Application

*Table 182. SIP container task duration counters.* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=TaskDurationCounters,name=SipContainer.TaskDuration". To retrieve the attributes, use the JMXConnection.getAttribute method. For example: `_connection.getAttribute("WebSphere:type=TaskDurationCounters,name=SipContainer.TaskDuration", "AvgTaskDurationOutBoundQueue")`

This table lists the task duration module counters.

Name	Attribute/Method	Description	Granularity
Average Task Duration in outbound queue	<code>AvgTaskDurationOutBoundQueue</code>	The average task duration in the SIP stack outbound queue over a configured window of time	Server
Maximum Task Duration in outbound queue	<code>MaxTaskDurationOutBoundQueue</code>	The maximum task duration in the SIP stack outbound queue over a configured window of time	Server
Minimum Task Duration in outbound queue	<code>MinTaskDurationOutBoundQueue</code>	The minimum task duration in the SIP stack outbound queue over a configured window of time	Server
Average Task Duration in processing queue	<code>AvgTaskDurationInProcessingQueue</code>	The average task duration in the SIP container processing queue over a configured window of time	Server
Maximum Task Duration in processing queue	<code>MaxTaskDurationInProcessingQueue</code>	The maximum task duration in the SIP container processing queue over a configured window of time	Server
Minimum Task Duration in processing queue	<code>MinTaskDurationInProcessingQueue</code>	The minimum task duration in the SIP container processing queue over a configured window of time	Server

*Table 182. SIP container task duration counters (continued).* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=TaskDurationCounters,name=SipContainer.TaskDuration". To retrieve the attributes, use the JMXConnection.getAttribute method. For example:

```
_connection.getAttribute("WebSphere:type=TaskDurationCounters,name=SipContainer.TaskDuration", "AvgTaskDurationOutBoundQueue")
```

This table lists the task duration module counters.

Name	Attribute/Method	Description	Granularity
Average Task Duration in application code	getAvgTaskDurationInApplication(appName)	The average task duration in the SIP application code over a configured period	Application
Maximum Task Duration in application code	getMaxTaskDurationInApplication(appName)	The maximum task duration in the SIP application code over a configured period	Application
Minimum Task Duration in application code	getMinTaskDurationInApplication(appName)	The minimum task duration in the SIP application code over a configured period	Application

*Table 183. SIP container queue monitoring counters.* The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=QueueMonitoringModule,name=SipContainer.QueueMonitor". To retrieve the attributes, use the JMXConnection.getAttribute method. For example:

```
_connection.getAttribute("WebSphere:type=QueueMonitoringModule,name=SipContainer.QueueMonitor", "TotalTasksCountInProcessingQueue").
```

This table lists the queue monitoring counters.

Name	Attribute	Description	Granularity
Total number of tasks that have flowed through the processing SIP container queue	TotalTasksCountInProcessingQueue	The total number of tasks, such as messages or SIP timer events, that have flowed through the processing SIP container queue over a configured window of time	Server
Maximum number of tasks in the processing SIP container queue	PeakTasksCountInProcessingQueue	The maximum number of tasks in the processing SIP container queue over a configured window of time	Server
Minimum number of tasks in the processing SIP container queue	MinTasksCountInProcessingQueue	The minimum number of tasks in the processing SIP container queue over a configured window of time	Server
Maximum percent full of the processing SIP container queue	PercentageFullTasksCountInProcessingQueue	The maximum processing SIP container queue usage percentage over a configured window of time	Server
Total number of tasks that have flowed through the outbound SIP stack queue	TotalTasksCountInOutboundQueue	The total number of tasks that have flowed through the outbound SIP stack queue over a configured window of time	Server

Table 183. SIP container queue monitoring counters (continued). The object name of the MBean from which the counters can be retrieved is: "WebSphere:type=QueueMonitoringModule,name=SipContainer.QueueMonitor". To retrieve the attributes, use the JMXConnection.getAttribute method. For example:  
`_connection.getAttribute("WebSphere:type=QueueMonitoringModule,name=SipContainer.QueueMonitor", "TotalTasksCountInProcessingQueue").`

This table lists the queue monitoring counters.

Name	Attribute	Description	Granularity
Maximum number of tasks in the outbound SIP stack queue	PeakTasksCountInOutboundQueue	The maximum number of tasks in the outbound SIP stack queue over a configured window of time	Server
Minimum number of tasks in the outbound SIP stack queue	MinTasksCountInOutboundQueue	The minimum number of tasks in the outbound SIP stack queue over a configured window of time	Server
Maximum percent full of the outbound SIP stack queue	PercentageFullTasksCountInOutboundQueue	The maximum outbound SIP stack queue usage percentage over a configured window of time	Server

---

## Liberty:Sessions monitoring

### 8.5.5.0

You can use the SessionStats MBean to monitor the performance data of sessions in Liberty.

The performance data of sessions for each application is available as an MBean, which can be accessed through JMX.

The sessions that are associated with a single web application have their own SessionStats MBean (that is, one SessionStats MBean for each web application).

The ObjectName for identifying each Session MBean is:

`WebSphere:type=SessionStats,name=*`

For example:

`WebSphere:type=SessionStats,name=default_host/trade_lite`

`WebSphere:type=SessionStats,name=default_host/moneybank`

The MBean is responsible for reporting SessionStats for a single web application. The following key data is available for the SessionStats MBean after monitoring is enabled:

#### CreateCount

The total number of sessions created.

#### LiveCount

The total number of sessions that are currently cached in memory.

#### ActiveCount

The total number of concurrently active sessions. A session is active if Liberty is processing a request that uses that session.

#### InvalidatedCount

The total number of sessions that are invalidated.

## InvalidatedCountbyTimeout

The total number of sessions invalidated by a timeout.

---

## Liberty:ConnectionPool monitoring

### 8.5.5.0

You can use the ConnectionPool MBean for ConnectionPool monitoring of Liberty.

Performance data is made available for each ConnectionPool. Connection pools manage connections from data sources and connection factories.

Each connection manager has a ConnectionPool MBean associated with it, and there is one MBean for every connection manager.

The ObjectName for identifying each ConnectionPool MBean is:

```
WebSphere:type=ConnectionPoolStats,name=<IDENTIFIER_OF_CONNECTION_MANAGER>
```

The following example shows a connection pool (for a data source or connection factory) that does not have a JNDI name. The data source [default-x] name is considered as the data source object when JNDI is not specified.

```
WebSphere:type=ConnectionPoolStats,name=transaction/dataSource[default-0]/connectionManager
```

```
<transaction enableLoggingForHeuristicReporting="true" transactionLogSize="2048">
  <dataSource transactional="false">
    <jdbcDriver libraryRef="DerbyLib"/>
    <properties.derby.embedded databaseName="<DIR Path>/<DatabaseName>" createDatabase="create"/>
  </dataSource>
</transaction>
```

Example configurations when connection manager is provided

- When an explicit ID is not specified, an ID is generated based on its parent

```
WebSphere:type=ConnectionPoolStats,name=dataSource[MyDataSource]/connectionManager[default-0]
```

```
<dataSource id="MyDataSource">
  <connectionManager maxPoolSize="10"/>
  <jdbcDriver libraryRef="DB2JCC4LIB"/>
  <properties.db2.jcc .../>
</dataSource>
```

- When an ID is specified, that becomes the identifier

```
WebSphere:type=ConnectionPoolStats,name=connectionManager[Pool2]
```

```
<dataSource id="DataSource2" jdbcDriverRef="DB2JCCDriver" connectionManagerRef="Pool2">
  <properties.db2.jcc .../>
</dataSource>
<connectionManager id="Pool2" maxPoolSize="20"/>
```

- Obtaining the correct identifier for a type 2 driver connection pool.
  - Ensure that the application that is using the pool makes a call to DB2 so that the pool is initialized.
  - Navigate to the REST interface to determine the proper identifier to use in the configuration. For example:

```
host:443/IBMJMXConnectorREST/mbeans
```

Specifying the correct identifier for a connection pool for a type 2 driver

```
{ "objectName": "WebSphere:type=ConnectionPoolStats,name=jdbc/acp01", "
  className": "com.ibm.ws.connectionpool.monitor.ConnectionPoolStats", "
  URL": "/IBMJMXConnectorREST/mbeans/WebSphere%3Aname%3Djdbc%2Facp01%
  2Ctype%3DConnectionPoolStats" }
```

The ConnectionPool MBean is responsible for reporting ConnectionPool Stats for a single connection manager. The following counter attributes are available for the ConnectionPool MBean after monitoring is enabled:

#### CreateCount

The total number of connections created.

#### DestroyCount

The total number of connections destroyed.

#### ManagedConnectionCount

The number of ManagedConnection objects that are in use.

#### WaitTime

The average waiting time in milliseconds until a connection is granted.

#### ConnectionHandleCount

The number of Connection objects that are in use.

#### FreeConnectionCount

The number of free connections in the pool.

---

## Liberty:Multiple components monitoring

### 8.5.5.0

You can filter the components that you want to monitor by using the monitor-1.0 feature in Liberty. The components to be filtered must be configured in the server.xml file.

1. To specify the components that you want to filter, add the following code to the server.xml file.

```
<server description="new server">
    <featureManager>
        <feature>jsp-2.2</feature>
        <feature>jdbc-4.0</feature>
        <feature>monitor-1.0</feature>
    </featureManager>
    <monitor filter="JVM,ThreadPool,WebContainer,Session,ConnectionPool"/>
</server>
```

By default, if the filters are not provided in the <monitor> tag, all the components that are currently monitored as part of the monitor-1.0 feature are monitored. You can specify the components that you want to monitor by providing the group name as part of the filter.

For example: If you want to monitor only the *JVM* and *WebContainer* components, specify the components in the server.xml file as follows:

```
<monitor filter="JVM,WebContainer"/>
```

2. To remove components from monitoring.

To stop monitoring a component, you must remove the component from the filter group at run time.

For example: The following filter configuration monitors the *JVM*, *ThreadPool*, *WebContainer*, *Session* and *ConnectionPool* components:

```
<monitor filter="JVM,ThreadPool,WebContainer,Session,ConnectionPool"/>
```

To stop monitoring the components *WebContainer* and *Session*, remove those components from the filter configuration:

```
<monitor filter="JVM,ThreadPool,ConnectionPool" />
```

3. To enable monitoring of components at run time.

If you want to enable monitoring for specific components at run time, you can specify the components in the monitor tag at run time.

The data that is collected by the filtering components is available as MXBeans. For more information about the various MXBeans, see Chapter 11, "Monitoring the Liberty server runtime environment," on page 2267.

**Note:** **8.5.5.0** Currently, fine-grained monitoring is supported only at the component level (such as *WebContainer*, *ThreadPool*, *JVM*) and not at the counter level.

---

## Liberty:HTTP access logging

You can configure access log settings for HTTP endpoints.

### HTTP access log settings

An HTTP access log contains a record of all inbound client requests handled by HTTP endpoints. You can enable access logging in the HTTP server, or you can enable it in the Liberty server in two modes: one log common to multiple endpoints, or one log for each endpoint.

**Note:** If you do not specify attributes, the defaults are used. To see a list of the default attributes, see `httpAccessLogging` in the list of liberty configuration elements: .

- Using a common log

To enable logging for multiple endpoints using common settings, include *httpAccessLogging* as a top-level element in your `server.xml` file, and then reference it from multiple `httpEndpoint` elements:

```
<httpAccessLogging id="accessLogging"/>
<httpEndpoint id="defaultHttpEndpoint" accessLoggingRef="accessLogging"/>
<httpEndpoint id="otherHttpEndpoint" accessLoggingRef="accessLogging" httpPort="9081" httpsPort="9444"/>
```

- Using distinct logs for each endpoint

To enable logging for individual endpoints, use an *accessLogging* child element and specify a file path that does not conflict with other logs:

```
<httpEndpoint id="defaultHttpEndpoint">
  <accessLogging filepath="${server.output.dir}/logs/http_defaultEndpoint_access.log"/>
</httpEndpoint>
```

- Using logs for the HTTP server

For a list of the available HTTP server side properties and their descriptions, see Apache Module `mod_log_config`.

### HTTP access log format

For a list of the available log format properties and their descriptions, see the *accessLogFormat* configuration for WebSphere Application Server traditional in HTTP transport channel custom properties. This log format string is specified using the *logFormat* attribute of `httpAccessLogging` or `accessLogging` elements in `server.xml`:

```
<httpAccessLogging logFormat='%h %u %{t}W "%r" %s %b' />
```

or

```
<httpEndpoint id="defaultHttpEndpoint">
  <accessLogging filepath="${server.output.dir}/logs/http_defaultEndpoint_access.log"
    logFormat='%h %i %u %t "%r" %s %b' />
</httpEndpoint>
```

---

## Chapter 12. Tuning Liberty

You can tune parameters and attributes of Liberty.

### About this task

Liberty supports different attributes in the `server.xml` file to influence application performance. You can use these parameters and attributes to achieve better performance. To tune Liberty for secure applications, see [Tuning Liberty for secure applications](#).

### Procedure

- Tune the JVM.

Tuning the JVM is a most important tuning step whether you configure a development or production environment. When you tune the JVM for Liberty, use the `jvm.options` file in the `${server.config.dir}` directory. You can specify each of the JVM arguments that you want to use, one option per line. For more information, see “Customizing the Liberty environment” on page 1565. An example of the `jvm.options` file is as follows:

```
-Xms50m  
-Xmx256m
```

For a development environment, you might be interested in faster server startup, so consider setting the minimum heap size to a small value, and the maximum heap size to whatever value is needed for your application. For a production environment, setting the minimum heap size and maximum heap size to the same value can provide the best performance by avoiding heap expansion and contraction.

- Tune transport channel services.

The transport channel services manage client connections, I/O processing for HTTP, thread pools, and connection pools. For applications on Liberty, the following attributes are available for different elements that can be used to improve runtime performance, scalability, or both. For each of these attributes, see .

#### **maxKeepAliveRequests of httpOptions**

This option specifies the maximum number of persistent requests that are allowed on a single HTTP connection if persistent connections are enabled. A value of `-1` means unlimited. This option supports low latency or high throughput applications, and SSL connections for use in situations where building up a new connection can be costly. Here is an example of how you code this option in the `server.xml` file:

```
<httpOptions maxKeepAliveRequests="-1" />
```

#### **maxPoolSize of connectionManager**

This option specifies the maximum number of physical connections for the connection pool. The default value is 50. The optimal setting here depends on the application characteristics. For an application in which every thread obtains a connection to the database, you might start with a 1:1 mapping to the `coreThreads` attribute. Here is an example of how you code this option in the `server.xml` file:

```
<connectionManager ... maxPoolSize="40" />
```

#### **purgePolicy of connectionManager**

This option specifies which connections to destroy when a stale connection is detected in a pool. The default value is the entire pool. It might be better to purge only the failing connection. Here is an example of how you code this option in the `server.xml` file:

```
<connectionManager ... purgePolicy="FailingConnectionOnly" />
```

#### **numConnectionsPerThreadLocal of connectionManager**

This option specifies the number of database connections to cache for each executor thread.

This setting can provide a major improvement on large multi-core (8+) machines by reserving the specified number of database connections for each thread.

Using thread local storage for connections can increase performance for applications on multi-threaded systems. When you set **numConnectionsPerThreadLocal** to 1 or more, these connections per thread are stored in thread local storage. When you use **numConnectionsPerThreadLocal**, consider two other values:

- The number of application threads
- The connection pool maximum connections

For best performance, if you have *n* applications threads, you must set the maximum pool connections to at least *n* times the value of the **numConnectionsPerThreadLocal** attribute and you must use the same credentials for all connection requests. For example, if you use 20 application threads, set the maximum pool connections to 20 or more; If you set the value of **numConnectionsPerThreadLocal** attribute as 2 and there are 20 application threads, set the maximum pool connection to 40 or more. Here is an example of how you code this option in the `server.xml` file:

```
<connectionManager ... numConnectionsPerThreadLocal="1" />
```

#### **statementCacheSize of dataSource**

This option specifies the maximum number of cached prepared statements per connection. To set this option, complete the following prerequisite:

- Review the application code (or an SQL trace that you gather from the database or database driver) for all unique prepared statements.
- Ensure that the cache size is larger than the number of statements.

Here is an example of how you code this option in the `server.xml` file:

```
<dataSource ... statementCacheSize="60" >
```

#### **isolationLevel of dataSource**

The data source isolation level specifies the degree of data integrity and concurrency, which in turns controls the level of database locking. Four different options are available as following in order of best performing (least integrity) to worst performing (best integrity).

##### **TRANSACTION\_READ\_UNCOMMITTED**

Dirty reads, non-repeatable reads, and phantom reads can occur.

##### **TRANSACTION\_READ\_COMMITTED**

Dirty reads are prevented; non-repeatable reads and phantom reads can occur.

##### **TRANSACTION\_REPEATABLE\_READ**

Dirty reads and non-repeatable reads are prevented; phantom reads can occur.

##### **TRANSACTION\_SERIALIZABLE**

Dirty reads, non-repeatable reads, and phantom reads are prevented.

Here is an example of how you code this option in the `server.xml` file:

```
<dataSource ... isolationLevel="TRANSACTION_READ_COMMITTED">
```

- **8.5.5.6** Tune the default executor.

The Liberty default executor is self-tuning and adapts to the current workload by dynamically adding or removing threads. For most workloads, the executor does not require any tuning, and you are advised not to change any settings of the executor unless you encounter specific problems with thread creation.

If necessary, you can configure the **coreThreads** and **maxThreads** parameters of the executor element in the `server.xml` file to set lower and upper bounds for the Liberty auto-tuning code. The **coreThreads** setting is not usually needed because the executor contains aggressive anti-deadlocking code that adds threads to break the executor out of deadlock scenarios. Rarely, the anti-deadlocking code adds more

threads than are required. In this situation, you can use the **maxThreads** parameter of the executor element to cap the number of threads the executor is allowed to create.

- Decrease response time of servlets.

To decrease response time of servlets, add the following attribute to the `server.xml` file:

```
<webContainer skipMetaInfResourcesProcessing="true"/>
```

- Reduce idle server CPU time.

To reduce idle server CPU time, add the following attributes to the `server.xml` file:

```
<applicationMonitor dropinsEnabled="false" updateTrigger="disabled"/>
<config updateTrigger="disabled"/>
```

When the attributes are added, your server no longer monitors for configuration or application updates.

For more information about the configuration element descriptions, see .

- **8.5.5.7** Tuning startup time.

### CDI 1.2

By default, the CDI 1.2 feature scans all application archives. The CDI 1.2 feature can increase startup time substantially and have the most effect on larger applications. Implicit archive scanning for annotations can be disabled by setting **enableImplicitBeanArchives** value to `false`. This setting skips the scanning of archives unless they contain a `beans.xml` file.

```
<cdi12 enableImplicitBeanArchives="false"/>
```

**Note:** The `cdi-1.2` feature may be included even if its not in the `<features>` section of your `server.xml` file because other features, such as `webProfile-7.0` and `javaee-7.0`, include the `cdi-1.2` feature. Look in the `messages.log` file for "The server installed the following features:" to see if `cdi-1.2` was installed.

---

## Tuning Liberty for secure applications

You can tune Liberty to maximize the performance for secure applications.

### About this task

When you are securing your WebSphere application environment, it is important to understand the impact security can have on performance. Within an application server environment, running applications with security settings can often decrease performance because of increased processor usage from security tasks such as encryption, authentication, and authorization. These services can often increase the path length of application server requests, requiring more resources for each request and slowing down application throughput.

In most cases, you can reduce or eliminate some of this security-related performance loss through performance tuning. You can adjust the resources that are used by security services and choose to use only the security services that are required by a particular application or environment. Achieving the best possible performance, without sacrificing any necessary security, requires an understanding of your network topology and the security needs of your applications.

### Procedure

- Choose the connections that you want to encrypt.

In a WebSphere Application Server environment, you can encrypt the following transports:

- HTTP traffic that is to the web server
- HTTP traffic that is from the web server to the application server
- SOAP/JMX traffic
- File transfer service

– Web services over HTTP

When you are determining which traffic to transport over encrypted connections, consider whether the network that is connecting the communicating machines is private or public. There is a significant amount of resources that are associated with setting up a secured connection and encrypting and decrypting the traffic over that connection. You can make significant performance improvements by not requiring encryption over a secured network, for instance. If your application does not require that traffic is encrypted from the client to the HTTP server and from the HTTP server to the application Server, you might be able to use SSL only from the client to the HTTP server and therefore reduce resources that are required by security.

- Enable on-chip Advanced Encryption Standard (AES) Encryption.

If you are using IBM® SDK Java Technology Edition Version 7, Service Refresh 3 or later, and you are running on an Intel processor that supports the Advanced Encryption Standard (AES) New Instructions (AES-NI) instruction set, you can achieve performance improvement by taking advantage of on-chip AES encryption. Using these features, you can run AES encryption and decryption using hardware instructions without extra software.

To enable AES-NI usage, add the following property to the JVM command line or `jvm.options` file:

```
com.ibm.crypto.provider.doAESInHardware=true
```

Add the following property to the JVM command line or the `jvm.options` file to verify that the processor supports AES-NI instruction set:

```
com.ibm.crypto.provider.AESNITrace=true
```

For more information, see Intel Advanced Encryption Standard New Instructions.

- Choose your cipher key length.

In some cases, the bit length of a cipher key is governed by regulations that are put on the transfer of certain types of data. In these cases, the cipher and key length that you choose for a particular SSL connection can be predetermined. For situations where the key length is not regulated, you must choose the appropriate resources to allocate to security so that performance is not decreased more than is necessary. For example, a 256-bit cipher offers stronger encryption than a corresponding 128-bit cipher. However, decrypting messages with a stronger cipher requires more processing time.

When you are making your decision about the encryption strength to choose, consider the type of data that is traveling across a network. For example, sensitive information, such as financial or medical records, needs the maximum amount of security. Also, consider who has access to the network. If the network is protected by a firewall, consider decreasing the strength of the cipher, or possibly transmitting the data over an decrypted connection.

For more information about configuring SSL settings on Liberty, see “Liberty:SSL configuration attributes” on page 1835

- Set connection keep-alive requests.

In the Secure Socket Layer (SSL) protocol, the initial handshake uses a public-key cipher to exchange a private key for a faster private-key cipher. This faster cipher is used to encrypt and decrypt communication beyond the initial handshake. Because the cipher used for subsequent communication is faster than the one used for the initial handshake, it is important from a performance perspective to limit the number of SSL handshakes that are performed within the application server. You can achieve this result by increasing the length of an SSL connection by increasing session affinity.

One way to increase the duration of a single SSL connection is to enable persistent HTTP keep-alive connections. Increasing the duration prevents SSL handshakes from taking place on consecutive requests. You can make sure that persistent connections are enabled by verifying that the `keepAliveEnabled` attribute in the `httpOptions` element is set to `true` in the `server.xml` file. The default value is `true`.

Another way to tune persistent connections is by setting the maximum number of consecutive requests on a single HTTP connection. If your clients are making more than 100 requests consecutively, consider increasing the value of the `maxKeepAliveRequests` attribute in the `httpOptions` element in the `server.xml` file. The default value is 100.

For more information, see .

- Set the authentication cache settings.

Because the creation of an authentication subject can increase processor usage, Liberty provides an authentication cache to store a subject after the authentication of a user is successful. To fully take advantage of this service to increase performance, you must make sure that it is turned on and tuned according to your users and applications.

- Make sure that you do not disable the authentication cache. By default, the authentication cache is enabled to help improve performance.
- Consider changing the authentication cache timeout value. Increasing the timeout value enables subjects to remain in the authentication cache longer and reduces the number of reauthentications needed. However, increasing the timeout value increases the risk of user permissions becoming stale compared to a modified external repository, such as LDAP. Set your authentication cache timeout to reflect the estimated length of client sessions. You can specify the cache timeout by setting the value of the timeout attribute to whichever time you choose in the authCache element in the server.xml file. The default value is 600 seconds.
- Finally, if you are experiencing authentication times longer than expected, or you are noticing more traffic to an external authentication repository than expected, the authentication cache might be full. When the authentication cache is full, subjects are evicted. There is not a one-to-one mapping of authenticated users to authentication cache entries. The number of entries in the cache per user depends on other security configurations. It is a best practice for the maximum size of the authentication cache to be larger than the number of distinct authenticated users that are accessing the server at one time. Setting the maximum size of the authentication cache this way helps prevent subjects from being evicted from the cache before timing out. You can change the maximum size of the authentication cache by setting the value of the maxSize attribute in the authCache element in the server.xml file. The default size is 25000.

For more information, see “Configuring the authentication cache in Liberty” on page 1867.

- Configure the HTTP session affinity settings.

One of the operations in a secure application environment that drains performance the most is the initial setup, including the SSL handshake and authentication. In clustered environments, performance decreases might occur when a web client accesses different application servers. To prevent the increased processor usage of the SSL handshake and reauthentication, it is important to make sure that HTTP session affinity is configured.

HTTP session affinity ensures that consecutive client requests are routed to the same application server. HTTP session affinity aids performance in various ways, but specifically, it prevents the increased processor usage of reauthentication and SSL handshaking. Consult the documentation of your HTTP Server or Load Balancer for instructions on setting up HTTP session affinity.

For more information, see “Configuring session persistence for Liberty” on page 1610.

---

## Tuning federated LDAP repositories in Liberty

### 8.5.5.1

You can improve the performance of the federated LDAP repositories by monitoring and adjusting the cache and the context pool elements in the server.xml file.

#### About this task

The cached query results of the LDAP repositories save time, because the data need not be retrieved from the back-end server every time an LDAP operation is performed. The LDAP cache attributes are stored in the <ldapCache> element for quicker access. You must monitor the status of the cache and adjust the cache control parameters to improve the performance of the cache. The context pooling parameters can be adjusted to improve the performance of concurrent accesses to the LDAP servers.

## Procedure

- Configure the <ldapCache> element in the server.xml file.

Specify the LDAP cache control parameters to improve the performance:

### attributesCache

<size>: Specifies the number of entities that are stored in the cache. You can increase the size of the cache based on your business requirement, for example, increase the cache size if more number of entities are required in a business scenario.

<timeout>: Specifies how long the results can be cached before they are invalidated. If the back-end LDAP data is refreshed frequently to maintain an up-to-date cache, set a lesser timeout duration value.

<sizeLimit>: Specifies the maximum number of LDAP attributes per entity that can be stored in the cache. If an entity is associated with many attributes, increase the <sizeLimit> value.

### searchResultSizeLimit

Specifies the maximum number of search results that can be stored in the cache. Use the parameters in the <searchResultSizeLimit> element to tune the search results that are returned as part of the query.

- Configure the <contextPool> element parameters in the server.xml file to improve the performance of concurrent access to an LDAP server.

You can adjust the following parameters in the <contextPool> element to control the cache:

### contextPool

<initialSize>: Specifies the initial size of the context pool. The value must be set based on the load on the repository. If the initial number of requests to the LDAP server is expected to be high, increase the value of the initial size.

<maxSize>: Specifies the maximum context pool size. The value must be set based on the load on the repository. If you want to restrict the number of connections to the LDAP server, then set the value of the <maxSize> element to less than half of the maximum number of connections that the LDAP server can handle.

<timeout>: Specifies the duration after which the context pool times out. Specify a shorter timeout value so that fresh connections can be made to the LDAP server after the specified duration is timed out. For example, if the established connection is timed out after the configured interval, then set a shorter duration than the firewall timeout duration so that the connection is re-established.

<waitTime>: Specifies the waiting time before the context pool times out. If the value specified is high, then the time that is taken to establish a connection to the LDAP server is increased accordingly.

For more information about the <ldapCache> and <contextPool> elements, see

---

## Chapter 13. Liberty: Troubleshooting tips

Tips for troubleshooting Liberty.

To help you identify and resolve problems, the product has a unified logging component. See “Liberty: Logging and Trace” on page 2313. You can also use the IBM Support Assistant Data Collector (ISADC) command tool in the `${wlp.install.dir}/bin` directory to quickly collect diagnostic files, such as log files, configuration files or to run traces.

If you receive an exception message, information about the message is available in “Liberty: Messages” on page 2344.

The Java API documentation for each Liberty API is available in a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

**Distributed operating systems** Details of the main known restrictions that apply when you use Liberty are provided in the following two topics:

- “Liberty: Runtime environment known issues and restrictions” on page 2333.
- **Distributed operating systems** “Liberty: Developer Tools known issues and restrictions” on page 2342.

**z/OS** **IBM i** For details of the main known restrictions that apply when using Liberty, see “Liberty: Runtime environment known issues and restrictions” on page 2333.

Here is a set of tips to help you troubleshoot commonly experienced problems:

- Troubleshooting JDKs
- “Troubleshooting security” on page 2298
- “Troubleshooting LDAP” on page 2300
- “Troubleshooting SSL” on page 2300
- “Troubleshooting CORBA/IIOP” on page 2301
- “Troubleshooting logging and tracing” on page 2302
- “Troubleshooting JAX-WS” on page 2302
- “Troubleshooting WS-Security” on page 2306
- **Distributed operating systems** **IBM i** “Applying fix packs and interim fixes to an archive install” on page 2308
- “Troubleshooting performance” on page 2308
- **8.5.5.7** Troubleshooting SAML

### Check that your JDKs are at a supported level

If you experience problems that are not readily explained, check that the JDKs you are using are compliant with Java Version 6 or later, and are at a current service level. See “Minimum supported Java levels” on page 2333.

**Note:** A deadlock can occur when using Oracle based JVMs using Java Version 6. If you are using an affected JVM or JDK, the following settings can help prevent the deadlock from occurring:

- Enable the following VM option: `-XX:+UnlockDiagnosticVMOptions -XX:+UnsyncloadClass`
- Set the Equinox framework option to use classname locking for classloading by setting the following Equinox configuration option: `-Dosgi.classloader.lock=classname`

These can be set in a Java properties file, for example `jvm.options`, when starting the Liberty server.

## Troubleshooting security

This section describes some common security problems and solutions you can choose.

### **SESN0008E: A user authenticated as anonymous has attempted to access a session owned by user:LdapRegistry/cn=steven,o=myCompany,c=US.**

This error happens when an unauthenticated user tries to access a session created by an authenticated user. Session security that is enabled by default prevents unauthorized access of the sessions. Only the user who created a session can access it. See session security for more information.

This error can happen when you use a JSP (login.jsp for example) for your form-login and the SSO token sent by the browser is expired. Because the SSO token is expired, the user is prompted to log in again using the login.jsp page configured for the form-login. The jsp page, by default, tries to get a session. This session was originally created by the user whose token is expired. However, the token is expired and the user is not authenticated, no credentials are established when accessing this session that results in this error.

To avoid this error, restart the browser that starts a new session, or configure the login.jsp file to not create the session by default. If you choose to update the login.jsp file, set `<%@ page session="false" %>`.

### **CWWKS9104A: Authorization failed for user {0} while invoking {1} on {2}. The user is not granted access to any of the required roles: {3}.**

This error occurs when you do not have authorization to the roles required by the application. Make sure that the user or the group it belongs to is mapped to at least one of the roles that are mentioned in the error message. A user-to-role mapping defined in the `ibm-application-bnd.xml` file takes precedence over a mapping defined in the `server.xml` file. Check both resources to ensure that the correct mapping is defined. See “Configuring authorization for applications in Liberty” on page 1939.

### **CWWKS9104A: Authorization failed for user {0}.**

This error can occur if you specify both an application and webApplication for the same context root. If a conflict happens the latest configuration that is defined is ignored and causes an unexpected error, such as CWWKS9104A.

### **CWWKZ0013E: It is not possible to start two applications called {0} followed by unexpected security behavior and error messages such as CWWKS9104A.**

This error occurs when you specify your application in both the `server.xml` by using the application element and in the `dropins` folder. As a result, the application is attempted to be installed twice and the security configuration in the `server.xml` file might or might not take effect. To fix this, you must remove your application from the `dropins` folder and copy it to another directory. If you have to leave it in the `dropins` folder, you must disable the application monitoring by using the following code in your `server.xml` file:

```
<applicationMonitor dropinsEnabled="false"/>
```

### **An unauthenticated user was able to access my servlet or JSP.**

A user with a principal of **UNAUTHENTICATED** (or the unauthenticated SAF user on z/OS) is created when authentication fails or when your servlet or JSP is unprotected. An unauthenticated user can access your servlet or JSP if you do not define any security constraints or if you map the **EVERYONE** special subject to the role required by your application. Review the user-to-role mappings in the `ibm-application-bnd.xml/xml` and `server.xml` files. Take one of the following options:

- If your servlet or JSP is unprotected, add security constraints to the deployment descriptor of your application. See “Liberty:Authentication” on page 976.
- If you do not want any unauthenticated user to access your application, remove the **EVERYONE** special subject from the mapping for that role. See “Configuring authorization for applications in Liberty” on page 1939.

- If a certain user cannot be authorized to your servlet or JSP, review who is mapped to that role by examining the `ibm-application-bnd.xml/xml` and `server.xml` files. You can map a role to a user, group, or special subject. If your role is mapped to the **EVERYONE** special subject, any user is granted access. If your role is mapped to the **ALL\_AUTHENTICATED** special subject, any authenticated user is granted access. Remove these special subjects if you want to further limit who can access your servlet or JSP. Finally, check what group the user belongs to. Although the user might not have explicit access, the group might be mapped to the role. In this case, remove the user from the authorized group or remove the group from role mapping. See “Configuring authorization for applications in Liberty” on page 1939.

### Single sign-on (SSO) does not work.

If SSO does not work, make sure that the different Liberty servers that use the same LTPA keys, password, and `ssoCookieName` attribute of `webAppSecurity` element have the same Universal Time (UTC) and share the same user registry. Also, if the token expires or if the cookie is sent from a web browser after changing the user registry in a manner that is inconsistent, such as modifying the realm or removing the user the cookie represents, the SSO fails and the user is prompted to enter the credential information again. See “Customizing SSO configuration using LTPA cookies in Liberty” on page 1887.

### Debugging security public APIs.

`WSSecurityHelper` and `RegistryHelper` are loaded even if security is not enabled, for example, if a security feature - `appSecurity-1.0,appSecurity-2.0` or `zosSecurity-1.0` - is not specified. If security is not enabled, then `WSSecurityHelper.isServerSecurityEnabled()` and `WSSecurityHelper.isGlobalSecurityEnabled()` methods both return false, and `RegistryHelper.getUserRegistry()` method returns null.

Other security public API classes might not be loaded if security is not enabled. If you try to access these classes and call a method on one of these classes, you might get a `java.lang.NoClassDefFoundError` exception.

To avoid getting `java.lang.NoClassDefFoundError` exceptions, you must first test to see whether security is enabled by calling the `WSSecurityHelper.isServerSecurityEnabled()` or `WSSecurityHelper.isGlobalSecurityEnabled()` class, and then call other security public API classes only when security is enabled. See “Liberty:Security public APIs” on page 1004 for examples of this coding technique.

**Note:** This behavior is different from the traditional. In traditional, all classes are always loaded regardless of whether security is enabled or not.

### Cannot authenticate users with Unicode characters

In order to authenticate users whose names contain Unicode characters, you must set the character encoding type used by the Liberty server to UTF-8 by adding the following `jvm` option to the server start command:

```
-Dclient.encoding.override=UTF-8
```

You must also specify the `charset` and `pageEncoding` in your login page. Here is an example for specifying these parameters on a login JSP page:

```
<%@page contentType="text/html"; charset=UTF-8" pageEncoding="UTF-8"%>
```

### 8.5.5.4 `java.lang.annotation.AnnotationFormatError: java.lang.IllegalArgumentException:Wrong type at constant pool index at sun.reflect.annotation.AnnotationParser.parseAnnotations(AnnotationParser.java:87)`

This error can occur when an OpenID Connect or OAuth provider uses a Database Store for client registration with some JDK 7 versions.

To avoid this problem, upgrade to JDK version 7.1.

## Troubleshooting LDAP

This section describes some common LDAP problems and solutions you can choose.

**FFDC1015I: An FFDC Incident has been created: javax.naming.ServiceUnavailableException: myldapserver.mycompany.com:636; socket closed  
com.ibm.ws.security.registry.ldap.internal.LdapRegistry 298**

This message in messages.log indicates that the configured LDAP server cannot be reached. Check your LDAP server to verify that it is running and that its IP address can be accessed from Liberty server.

**The javax.naming.CommunicationException: simple bind failed: myldapserver.mycompany.com:636 [Root exception is javax.net.ssl.SSLHandshakeException: com.ibm.jsse2.util.g: PKIX path building failed: java.security.cert.CertPathBuilderException: unable to find valid certification path to requested target]**

If you enable SSL on your LDAP server without copying the signer of the LDAP server into the truststore referenced in the LDAPSSLSettings element, a connection with the LDAP server fails with an SSL handshake error. Make sure that you copy the signer of the LDAP server into your truststore.

**The javax.naming.CommunicationException: myldapserver.mycompany.com:389 [Root exception is java.net.BindException: Address already in use: connect]**

This message might appear in the FFDC logs and indicates that the usable sockets on the local server are exhausted, which can result in a failure when connecting to your LDAP server. Make sure that the socket is not used and try again.

**CWWKS1100A: Authentication did not succeed for user ID xxxxx. An invalid user ID or password was specified**

This FFDC exception might happen on the server even though the user mentioned in the message is a valid user on the LDAP server under heavy load. With the LDAP configuration, you can add the reuseConnection=false property or disable it by using the developer tools. To fix the problem, set this property to the default value of true.

## Troubleshooting SSL

This section describes some common SSL problems and solutions you can choose.

**CWWKS9105E: Could not determine the SSL port for automatic redirection.**

This error occurs when you try to access an application that redirects to an SSL port and the SSL port is not available. The port might not be available because of a missing SSL configuration or some error in the SSL configuration definition. Check the SSL configuration in the server.xml file to make sure that it exists and is correct. See "Securing communications in Liberty" on page 1833.

**FFDC1015I: An FFDC Incident has been created: "java.lang.IllegalArgumentException: Unknown, incomplete configuration: missing id field  
com.ibm.ws.config.internal.cm.ManagedServiceFactoryTracker aSyncReadNupdate. Exception thrown while trying to read configuration and update ManagedServiceFactory. Exception = java.lang.IllegalArgumentException: Unknown, incomplete configuration: missing id field" at  
ffdc\_12.04.18\_16.09.42.0.log**

This error occurs when a keystore element exists in the configuration without an ID field. If you use a minimal SSL configuration, set the ID field to defaultKeyStore.

**You might get an exception if using a LDAP user registry with sslEnabled and a sslRef value is not specified.**

For example, a configuration has sslEnabled set to true but there is not a sslRef value, as shown in the following example:

```
<ldapRegistry id="ldap" realm="SampleLdapIDSRealm"  
host="ccwin12.austin.ibm.com" port="636" ignoreCase="true"  
baseDN="o=ibm,c=us"  
bindDN="cn=root"
```

```
bindPassword="rootpwd"
ldapType="IBM Tivoli Directory Server"
idsFilters="ibm_dir_server"
sslEnabled="true"
searchTimeout="8m" />
```

You must enter a `sslRef` value. If you are using a minimal SSL configuration that is similar to the following:

```
<ltkeyStore id="defaultKeyStore" location="key.jks"
password="mypassword" />
```

the `sslRef` field should be set to `defaultSSLConfig`.

If a custom SSL configuration is configured, the name of that configuration should be placed in the `sslRef` field.

### If you use a JDK from the WebSphere Application Server, you might see the following error if SSL is enabled on your Liberty Server.

```
java.net.SocketException: java.lang.ClassNotFoundException: Cannot find the specified class com.ibm.websphere.ssl.protocol.SSLSocketFactory
    at javax.net.ssl.DefaultSSLContextImpl.createSocket(SSLContextImpl.java:11)
    at javax.net.ssl.DefaultSSLContextImpl.createSocket(SSLContextImpl.java:6)
    at com.ibm.net.ssl.www2.protocol.https.c.afterConnect(c.java:161)
    at com.ibm.net.ssl.www2.protocol.https.d.connect(d.java:36)
    at sun.net.www.protocol.http.HttpURLConnection.getInputStream(HttpURLConnection.java:1184)
    at java.net.HttpURLConnection.getResponseCode(HttpURLConnection.java:390)
    at com.ibm.net.ssl.www2.protocol.https.b.getResponseCode(b.java:75)
    at com.ibm.ws.jmx.connector.client.rest.internal.RESTBeanServerConnection.loadJMXServerInfo(RESTBeanServerConnection.java:114)
    at com.ibm.ws.jmx.connector.client.rest.internal.RESTBeanServerConnection.<init>(RESTBeanServerConnection.java:114)
    at com.ibm.ws.jmx.connector.client.rest.internal.Connector.connect(Connector.java:315)
    at com.ibm.ws.jmx.connector.client.rest.internal.Connector.connect(Connector.java:103)
```

This error occurs because the WebSphere Application Server SSL socket factories are not supported by Liberty. You can get past this problem by taking the following steps:

- Create a text file, such as `my.java.security` with the following two empty entries
 

```
ssl.SocketFactory.provider=
ssl.ServerSocketFactory.provider=
```
- Create a `jvm.options` file for your Liberty server
- Add the following property to your `jvm.options` file, that includes the full path to your text file that you just created
 

```
-Djava.security.properties=fullPathTo/my.java.security
```
- If you want to make this more reusable, you can put the `my.java.security` file in your server directory, and then you will be able to use a relative path like this:
 

```
-Djava.security.properties=./my.java.security
```

For more information, see “Customizing the Liberty environment” on page 1565.

## Troubleshooting CORBA/IIOP

This section describes some common CORBA problems and solutions you can choose.

### If you use a JDK from the WebSphere Application Server, you might see the following error if your application uses CORBA/IIOP communications.

```
15:21:58.096 com.ibm.rmi.pi.InterceptorManager runPreInit:178 Init Process ORBRas [default] java.lang.ClassNotFoundException: com.ibm.ISecurityLocalObjectBaseL13Impl.CSIClientRI
    at com.ibm.CORBA.iiop.UtilDelegateImpl.loadClass(UtilDelegateImpl.java:685)
    at javax.rmi.CORBA.Util.loadClass(Util.java:246)
    at com.ibm.rmi.pi.InterceptorManager.runPreInit(InterceptorManager.java:172)
    at com.ibm.rmi.corba.ORB.initializeInterceptors(ORB.java:664)
    at com.ibm.CORBA.iiop.ORB.initializeInterceptors(ORB.java:1084)
    at com.ibm.rmi.corba.ORB.orbParameters(ORB.java:1359)
```

```

at com.ibm.rmi.corba.ORB.set_parameters(ORB.java:1271)
at com.ibm.CORBA.iiop.ORB.set_parameters(ORB.java:1694)
at org.omg.CORBA.ORB.init(ORB.java:371)
...

```

This error occurs because the WebSphere Application Server Object Request Broker (ORB) interceptors are not supported by Liberty. You can resolve this problem by editing the orb.properties file from the JDK to not use these interceptors. This file is usually found in the WebSphere <JAVA\_HOME>/jre/lib directory directory, though you might have overridden it with a copy in the user's <USER\_HOME> directory. The following example shows the lines in the orb.properties file that must be commented out:

```

# WS Interceptors
#org.omg.PortableInterceptor.ORBInitializerClass.com.ibm.ws.Transaction.JTS.TxInterceptorInitializer
#org.omg.PortableInterceptor.ORBInitializerClass.com.ibm.ejs.ras.RasContextSupport
#org.omg.PortableInterceptor.ORBInitializerClass.com.ibm.ISecurityLocalObjectBaseL13Impl.ClientRIWrapper
#org.omg.PortableInterceptor.ORBInitializerClass.com.ibm.ws.activity.remote.cos.ActivityServiceClientInterceptor
#org.omg.PortableInterceptor.ORBInitializerClass.com.ibm.ISecurityLocalObjectBaseL13Impl.CSIClientRI
#org.omg.PortableInterceptor.ORBInitializerClass.com.ibm.debug.olt.ivbtrjrt.OLT_RI
#org.omg.PortableInterceptor.ORBInitializerClass.com.ibm.ws.wlm.client.WLMClientInitializer

# WS ORB & Plugins properties
#com.ibm.ws.orb.transport.ConnectionInterceptorName=com.ibm.ISecurityLocalObjectBaseL13Impl.SecurityConnectionInter

```

## Troubleshooting logging and tracing

This section describes some common problems with logging and tracing.

### The java.util.logging -- Java logging programming interface.

Liberty does not support using the logging.properties file to configure java.util.logging. Use java code, for example in a deployed application or user feature, to create and add java.util.logging handlers, filters, or formatters.

Since the Liberty server manages the java.util.logging logger levels in accordance with the traceSpecification attribute of the logging configuration element, you should avoid using the Logger.setLevel method.

## Troubleshooting JAX-WS

This section describes some common JAX-WS problems and solutions you can choose.

### The org.apache.cxf.bus.extension.ExtensionException occurred when deploying web services application on Liberty.

If your application has CXF libraries and configurations embedded already and you want to deploy the application to Liberty, you must make sure that the jaxws-2.2 server feature is disabled by removing the feature from the server.xml file.

### The java.lang.NoClassDefFoundError exception occurred when running IBM fastpath with the Oracle JVM.

To use IBM fastpath Java Architecture for XML Binding (JAXB), you can configure the com.ibm.xml.xlsp.jaxb.opti.level custom property to control whether optimization methods are enabled for JAXB unmarshalling (deserialization) and marshalling (serialization). If you are experiencing the java.lang.NoClassDefFoundError exception when running IBM fastpath JAXB with the Oracle JVM, you can change the value of com.ibm.xml.xlsp.jaxb.opti.level property to 0 to turn off the optimization. For example, you can use the -Dcom.ibm.xml.xlsp.jaxb.opti.level=0 property in the command line, or add the following line to the jvm.options file:

```

# Turn off the JAXB optimization
-Dcom.ibm.xml.xlsp.jaxb.opti.level=0

```

See more information of the com.ibm.xml.xlsp.jaxb.opti.level property on the Java virtual machine custom properties page.

**The java.lang.NoClassDefFoundError : com.ibm.CORBA.iiop.ORB exception occurred when running the WebSphere Application Server traditional thin client with the Oracle JVM.**

This error occurs when you try to run the WebSphere Application Server traditional thin client with the Oracle JVM and the jaxws-2.2 feature is already enabled on Liberty. To resolve this problem, you can use the `-Dcom.ibm.websphere.thinclient=true` property when running the WebSphere Application Server traditional thin client as follows:

```
java -Dcom.ibm.websphere.thinclient=true
-cp <classpath_entries_including_classic_thinclient_jar> <WebServicesClientEntryClass> <any_more_parameters>
```

See the similar information of the `com.ibm.websphere.thinclient` property on the PM39777: ADMINISTRATIVE THIN CLIENT USING SOAP CONNECTOR AND SUN JDK DOES NOT WORK page.

**An Empty file returned when retrieving binary files from an MTOM service to a MTOM client.**

This scenario happens when a MTOM client sent binary files successfully to an MTOM service, but an empty file is returned when retrieving the same binary files back from the MTOM service.

As a workaround, you can create a new `DataHandler` and initialize the `DataHandler` by filling the content of the binary file. For example, use a `FileDataSource` object to read from I/O and return the newly created `DataHandler` back , and then pass the `DataHandler` to other web services.

```
...
File f = new File("received_image");
if (f.exists()) {
    f.delete();
}

FileOutputStream fos = new FileOutputStream(f);
img_in.writeTo(fos);

FileDataSource fos_out = new FileDataSource(f);
DataHandler img_out = new DataHandler(fos_out);
return img_out;
...
```

**The javax.xml.ws.soap.SOAPFaultException: Unmarshalling Error occurred when using XMLGregorianCalendar in xsd:gMonth format with the Oracle JVM.**

This error occurs when you use the `XMLGregorianCalendar` class to store `gMonth` format constants as part of your SOAP request on client side and the jaxws-2.2 feature is enabled on Liberty with the Oracle JVM. The root cause is that the Oracle JVM supports the new standard format `--MM` for the `xsd:gMonth` type while the latest JAXB RI (Reference Implementation) only supports the format of `--MM--`.

To resolve this problem, you can change the Oracle JVM to the IBM JVM for both the client side and the server side applications.

**The java.io.FileNotFoundException occurred when resolving WSDL files specified by the wsdlLocation attribute.**

This error occurs when you specify the WSDL file as in the code `wsdlLocation = "file:/WEB-INF/wsdl/a.wsdl"` and the WSDL file is packaged within your application. If you want to refer to the WSDL file that is packaged in your application, you must use relative URIs for the `wsdlLocation` attribute defined in the `@WebService`, `@WebServiceProvider`, `@WebServiceClient` or `@WebServiceRef` annotation.

The relative URI for the `wsdlLocation` attribute must be one of the following values:

- `wsdlLocation = "/WEB-INF/wsdl/a.wsdl"`
- `wsdlLocation = "WEB-INF/wsdl/a.wsdl"`

**A large number of "Creating service" messages occur in the messages.log file.**

This scenario happens when you call the `getPort` or related methods in the generated client stub

classes. Liberty is configured with the default logging configuration, and all the information messages are written into the messages.log file. There are lots of occurrences of messages that might be similar to the following one:

```
00000037 org.apache.cxf.service.factory.ReflectionServiceFactoryBean I Creating Service {http://www.echo.org/}EchoService from WSDL:
wsjar:file:/wlp/usr/servers/default/workarea/org.eclipse.osgi/bundles/100/data/cache/
com.ibm.ws.app.manager_gen_15a42559-f979-4ee6-b488-9fa1fb212c96/.cache/Echo.war!/WEB-INF/wsdl/Echo.wsdl
```

To suppress these information messages, you can change the logging configuration in the server.xml file as follows:

```
<logging traceSpecification="org.apache.cxf.*=warning=enabled"/>
```

**The SOAPFaultException: The given SOAPAction *test* does not match an operation occurred when a client application sent a SOAP Action.**

**Note:** *test* is the value of the soapAction attribute in the request HTTP header.

Each operation in a SOAP web service can be associated with a SOAP Action String, such as in the WSDL binding or via an annotation. The web service client sends the SOAP Action string as a header with the request to match the operation of the web service provider. The error message is displayed in either of the following scenarios:

- When the SOAP action sent by the client does not match the SOAP action of the operation.
- When using the WebSphere Application Server traditional as the JAX-WS client and Liberty as the JAX-WS service and the soapAction defined in the WSDL file equals empty value "".

To resolve this problem:

- Make sure that you specify the same SOAP action for both the web service client and service provider.
- Provide a valid value to the soapAction attribute that is defined in the WSDL file or do not use soapAction in the WSDL file.

**The javax.xml.ws.WebServiceException occurred when using the Service.create() method to create service.**

This error occurs when you use the Service.create() method to create a service while the WSDL document is not provided. If you want to use the Service.create() to create a service and getPort() method to get the port number, you must use the addPort() method to provide the binding information.

A sample example code is provided as follows on how to use the addPort() method:

```
QName serviceName = new QName("http://test.com/wssvt/acme/InsBusiness/", "MTOM11Service");
QName portName = new QName("http://test.com/wssvt/acme/InsBusiness/", "MTOM11Port");

// Setup the necessary JAX-WS artifacts
Service svc = Service.create(serviceName);
// Add the port in the service instance
svc.addPort(portName, SOAPBinding.SOAP11HTTP_MTOM_BINDING, mtom11URL);

port = svc.getPort(portName, MTOMInterface.class);
```

**The Null Response returned when the name attribute in @WebResult annotation is different from the name element in the WSDL document.**

This problem occurs when you use a SEI class to define the **name** attribute for @WebResult annotation, and the SEI class has supplied WSDL location as follows:

```
@WebService(wsdlLocation="WEB-INF/wsdl/WebServiceIfc.wsdl")
public interface WebServiceRuntimeIfc {
    @WebMethod
    @WebResult(name="nononoreturn")
    public String echo (String parm);
}
```

But the XML element declaration in the supplied WSDL document is as follows:

```

<xs:element name="echoResponse">
  <xs:complexType>
    <xs:sequence>
      <xs:element name="return" type="xs:string" minOccurs="0"/>
    </xs:sequence>
  </xs:complexType>
</xs:element>

```

Then the web service client will get a NULL response when the echo() method is called.

To resolve this problem, you must make sure that the **name** attribute of @WebResult annotation match the value of name element in the WSDL document.

### The JAX-WS client application failed to get the WSDL document changes from the server side.

The problem occurs when the web service client and service provider are in two different applications on Liberty, and the client needs to retrieve the WSDL document from the service provider dynamically. Because Liberty caches the WSDL definition when the WSDL document is accessed for the first time, which is different from the behavior in the WebSphere Application Server traditional. By caching the WSDL definition in Liberty, applications can avoid connecting and parsing the WSDL document frequently.

To solve this problem, you have to restart the client application so that the updated wsdl definitions can be reloaded.

### WebApp in Liberty hangs if a web service refers to itself.

If you use annotation @WebService for a web service and the annotation @WebServiceRef to refer to itself, the service endpoint publishing fails. For example,

```

@WebService
public class Test {
    @WebServiceRef
    private Test selfservice;

    public String echo(String msg) {
        return selfservice.invoke();
    }

    public String invoke() {
        return "hello world";
    }
}

```

To avoid this issue, use the service-stub (TestService as is shown in the following example) to get the service instance instead of using the @WebServiceRef to refer to self-service. For example,

```

@WebService
public class Test {

    private Test selfservice;

    public String echo(String msg) {
        TestService ts=new TestService();
        selfservice=ts.getTestPort();
        return selfservice.invoke();
    }

    public String invoke() {
        return "hello world";
    }
}

```

### Different behavior of the WebSphere Application Server traditional and Liberty when policies are attached to both of the service level and the operation level

The behaviors of the WebSphere Application Server traditional and Liberty are different when

policies are attached to both of the service level and the operation level. When both policies of service and operation level are applied, as is shown in the following example,

```
<wsdl:binding name="UrnMustUnderstandBinding2" type="tns:MustUnderstand">
  <wsp:PolicyReference URI="#UserNameToken1" />
  <soap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>
  <wsdl:operation name="invoke">
    <soap:operation soapAction="" style="document"/>
    <wsdl:input name="getVerRequest">
      <soap:body use="literal"/>
      <wsp:PolicyReference URI="#UserNameToken2" />
    </wsdl:input>
    <wsdl:output name="getVerResponse">
      <soap:body use="literal"/>
    </wsdl:output>
  </wsdl:operation>
</wsdl:binding>
```

- For the WebSphere Application Server traditional, the expected behavior is that if the operation name in SOAP request matches the operation name of <wsdl:input> like "getVerRequest", the policy of operation level "#UserNameToken2" is applied only.
- For Liberty,
  - If some SOAP requests match the expectation of "#UserNameToken2", the "#UserNameToken2" policy is applied.
  - If some SOAP requests do not match the expectation of "#UserNameToken2", the "#UserNameToken1" policy is applied.

If you want the behavior in the Liberty level to be the same as in the WebSphere Application Server traditional, declare the policies that have the same or similar function at one level only, either at the service level or at the operation level.

## Troubleshooting WS-Security

This section describes some common solutions that you can use to solve WS-Security problems.

1. Check the server.xml file to make sure that the required JAX-WS (jaxws-2.2) and security (appSecurity-2.0) features are configured correctly.
2. To protect your web service application with WS-Security, your JAX-WS application must contain a WSDL file that has an embedded WS-Security policy. There must be a PolicyReference to the embedded WS-Security policy in either the wsdl:binding or wsdl:operation sections or both.
3. If you use a callback handler for retrieving passwords to generate UsernameTokens or for retrieving passwords for private keys from keystore files, the password callback handler must be packaged and deployed as a user feature in Liberty.

### Enabling WS-Security trace

If the cause of the problem cannot be determined by the information in the error message, you can use the Liberty trace and logging facility to collect trace for the WS-Security component. See Liberty: Trace and logging.

You can use the following trace string to collect trace to debug WS-Security failures:

```
org.apache.ws.security.*=all=enabled:
org.apache.cxf.ws.security.*=all=enabled:
org.apache.cxf.ws.policy.*=all=enabled
org.apache.xml.security.*=all=enabled:
com.ibm.ws.wssecurity.*=all=enabled
```

This section described some common WS-Security problems and solutions you can choose.

**org.apache.cxf.ws.policy.PolicyException: None of the policy alternatives can be satisfied.**

This error usually occurs when the WS-Security feature wsSecurity-1.1 is not defined in the server.xml file. To avoid this error, you must define the wsSecurity-1.1 feature in the server.xml file as follows:

```
<featureManager>
  <feature>usr:wssecbh-1.0</feature>
  <feature>servlet-3.0</feature>
  <feature>appSecurity-2.0</feature>
  <feature>jaxws-2.2</feature>
  <feature>wsSecurity-1.1</feature>
</featureManager>
```

**org.apache.cxf.ws.policy.PolicyException: No callback handler and no password available.**

This error occurs when the WS-Security run time cannot retrieve a password that is required to generate a UsernameToken or to access a private key from the keystore. To avoid this error, check the following configuration:

1. Ensure that the password callback handler feature wssecbh-1.0 is defined as a user feature in the server.xml file:

```
<featureManager>
  <feature>usr:wssecbh-1.0</feature>
  <feature>servlet-3.0</feature>
  <feature>appSecurity-2.0</feature>
  <feature>jaxws-2.2</feature>
  <feature>wsSecurity-1.1</feature>
</featureManager>
```

2. Ensure that the callback handler property ws-security.callback-handler is defined in the <wsSecurityClient> or <wsSecurityProvider> elements of the server.xml file:

```
ws-security.callback-handler="<full class name of the callback handler>"
```

example:

```
ws-security.callback-handler="com.ibm.ws.wssecurity.example.cbh.CommonPasswordCallback"
```

3. Ensure that the password callback handler returns the correct password for the user name or the key alias that is specified in the server.xml file. The password must be clear text and not encoded or encrypted.

**org.apache.ws.security.WSSecurityException: The signature does not cover the required elements (soap:Body).**

This error occurs when a web service provider application expects the SOAP body in the request message to be signed, but the received SOAP message does not have the SOAP body signed. To avoid this error, ensure that your web service client is configured with the correct WS-Security policy that matches the web service provider policy.

**org.apache.ws.security.WSSecurityException: The signature or decryption was invalid.**

This error occurs when the WS-Security run time fails to validate the signature or decrypt an encrypted message part in the received SOAP message. To avoid this error, verify that the correct keys are used when you configure WS-Security in the <wsSecurityClient> and <wsSecurityProvider> elements of the server.xml file. If a web service client uses Bob's public key to encrypt a message part, then the web service provider must have access to Bob's private key to decrypt the message. Similarly, if a web service client signs a message part by using Alice's private key, then the web service provider must use Alice's public key to validate the signature.

**org.apache.cxf.ws.policy.PolicyException: These policy alternatives can not be satisfied.**

This error occurs when the WS-Security run time cannot process the incoming SOAP message successfully by using the WS-Security policy that is configured to process this request. To avoid this error, look at the messages that follow this exception to determine the specific WS-Security policy assertions that are causing this exception. For example, the log file might contain the following messages:

```
Caused by: org.apache.cxf.ws.policy.PolicyException: These policy alternatives can not be satisfied:
{http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702}AsymmetricBinding: The encryption algorithm does not match the requirement
{http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702}InitiatorEncryptionToken
```

```
{http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200702}RecipientEncryptionToken
at org.apache.cxf.ws.policy.AssertionInfoMap.checkEffectivePolicy(AssertionInfoMap.java:167)
at org.apache.cxf.ws.policy.PolicyVerificationInInterceptor.handle(PolicyVerificationInInterceptor.java:101)
```

In this case, the error occurred because the encryption algorithm that is used by the web service client does not match the encryption algorithm that is specified by the AlgorithmSuite assertion. The algorithm suites that are specified in the WS-Security policy of both the web service client and the web service provider must specify the same encryption algorithm.

### **javax.xml.ws.soap.SOAPFaultException: The message has expired (WSSecurityEngine: Invalid timestamp The security semantics of the message have expired).**

This message occurs when the message timestamp is expired or the message was created with a timestamp in the future.

Distributed operating systems

IBM i

## **Applying fix packs and interim fixes to an archive install**

If you installed your Liberty runtime environment from an archive file, rather than by using Installation Manager, you must take special measures when you apply service updates. For more information, see “Applying a fix pack to a Liberty Java archive installation” on page 1380 and “Applying an interim fix to a Liberty archive installation” on page 1388.

## **Troubleshooting performance**

This section describes some common performance problems and solutions you can choose.

### **High CPU usage by your application monitor.**

This error can occur if your application monitor has many files under the apps/ directory and is polling too frequently.

To avoid this problem there are a number of things you can change.

1. Increase the value of the pollingRate attribute.
2. Update the server.xml to include an applicationMonitor element with an updateTrigger that is not polled.

```
server.xml
<applicationMonitor updateTrigger="mbean" />
```

3. Reduce the number of files under the apps/ directory.

For more information about the applicationMonitor element, see “Controlling dynamic updates” on page 1594.

8.5.5.7

## **Troubleshooting SAML**

This section describes some common problems with SAML and the solutions you must apply.

### **java.lang.ArrayIndexOutOfBoundsException: Array index out of range: 0**

This exception can occur when attempting multiple logins through an unsolicited Service Provider (SP) initiated request without removing the Identity Provider token (IdP).

To avoid this, add `<httpSession invalidateOnUnauthorizedSessionRequestException="true" />` in the relevant unsolicited server.xml file.

### **java.lang.IllegalStateException: CWWKS0010E: While getting the caller principal, the caller subject was found to have more than one principal of type WSPincipal. Only one WSPincipal can exist in the subject. The names of the WSPincipals are: {0}**

This exception can occur if a SAML user has previously logged directly into an on-premises user registry. To avoid this problem, a SAML user must not directly login to an on-premises user registry.

---

## Security bulletins for the Liberty profile

To avoid preventable security issues, stay up to date on the most current maintenance options for the product.

### Subscription to security bulletins

Subscribe to My Notifications to receive notifications of security bulletins for WebSphere Application Server. These notifications include important product support alerts.

### Update Strategy

Refer to the Update Strategy for fix packs. Take special note of the recommended update path.

### Security fixes

Refer to the security fixes for WebSphere Application Server traditional, WebSphere Application Server Liberty, IBM HTTP Server, and Java.

---

## Logstash collector

8.5.5.9

Liberty generates various events at runtime, such as log events, trace events, first failure data capture (ffdc) events, access log events, and garbage collection events. It is helpful to consolidate events from all servers so the events can be searched, filtered, and analyzed, particularly when you are managing many servers, or when you are running servers on different platforms (for example on dedicated hardware and in the cloud). It can also be helpful to store events on a separate server in cases where you use Liberty in environments that lack persistent file storage for problem determination data. Liberty now provides the Logstash collector feature to help you remotely consolidate events. You can avoid running the agents on your Liberty server machine to collect your events using this feature. The collector captures in-flight events, breaks them into fields, and securely forwards the events to the configured Logstash server.

### Logstash collector

The Logstash collector feature (logstashCollector-1.0) sends events to a Logstash server that you provide.

The logstash collector feature offers a flexible way to choose one or more of the following supported sources of data that needs to be sent to logstash:

- message - messages log events
- trace - traces log events
- accesslog - Http access log events
- ffdc - FFDC log events
- garbageCollection - GarbageCollection events

Logstash can be used with the Elasticsearch search server and Kibana dashboard, all of which you provide, set up, and manage, to give a consolidated view of logs or other events from across your enterprise. Note that there are no separate processes or agents to be set up on the Liberty server machine when using the Logstash collector to forward events.

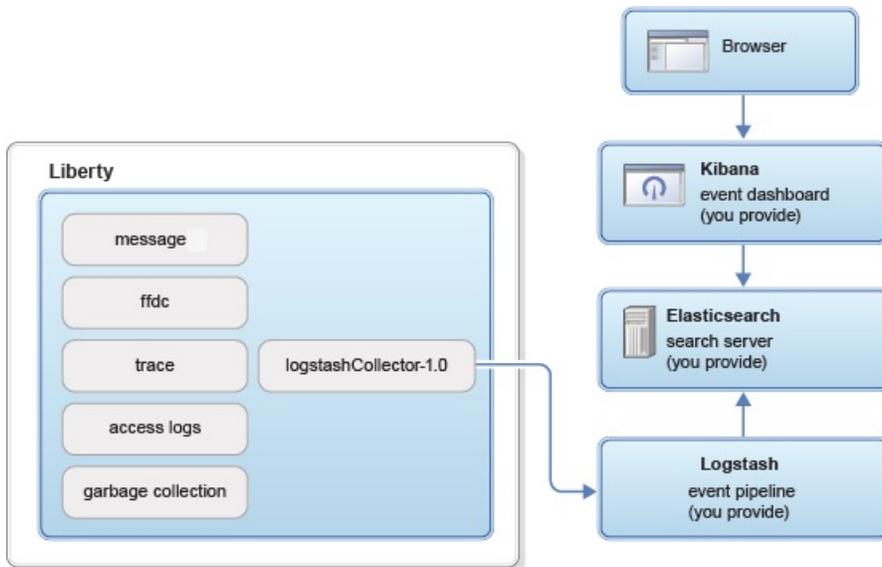

Figure 32. Logstash collector

## Event structure

The collectors send each event as a set of field name-value pairs. Each different type of event has its own set of fields. Knowing which fields each event has is useful when creating your own Kibana dashboards.

The following fields are common and present in all events:

- type – a string that identifies the type of event
- datetime – time at which the event occurred
- hostName – host name of the server that was the source of the event
- wlpUserDir – user directory of the server that was the source of the event, for example, D:\wlp\usr
- serverName – server name of the server that was the source of the event
- sequence – sequence number of event (useful for sorting records with the same time stamp)

Besides the common fields, each of the event types also has its own unique fields:

### Message events (type:"liberty\_message")

- severity – 1 letter severity indicator (F = Fatal, E = Error, W = Warning, A = Audit, I = Info, O = SystemOut, R = SystemErr)
- messageId – message ID in the log line, which can be used to find out specific types of errors, for example, SRVE0250I
- methodName – method name from log record
- className – class name from log record
- loggerName – logger name from log record
- threadId – thread ID in the log line, for example, 00000015. Note that the thread ID is a string and not a number
- message – the message, starting with the message ID

### Trace events (type:"liberty\_trace")

- severity – 1 letter severity indicator (1 = Fine, 2 = Finer, 3 = Finest, > = Entry, < = Exit)

methodName – method name from log record  
className – class name from log record  
loggerName – logger name from log record  
threadId – thread ID in the log line, for example, 00000015. Note that the thread ID is a string and not a number  
message – the message

#### **HTTP access log events (type:"liberty\_accesslog")**

uriPath – Path information for the requested URL. This does NOT contain the query parameters, for example, /pushworksserver/ push/apps/tags  
requestMethod – HTTP verb used, for example, GET  
remoteHost – remote host IP address in the log line, for example, 127.0.0.1  
userAgent – userAgent value in the request.  
requestProtocol – Protocol information in the log line, for example, HTTP/1.1  
queryString – string representing query string from the HTTP request, for example, color=blue&size=large  
bytesReceived – bytes received in the URL, for example, 94 in the sample 1  
responseCode – HTTP response code, for example, 200  
elapsedTime – time that is taken to serve the request  
requestHost – request host IP address in the log line, for example, 127.0.0.1  
requestPort – port number of the request

#### **FFDC events (type:"liberty\_ffdc")**

className – the class that emitted the FFDC entry  
exceptionName – the exception that was reported in the FFDC entry  
probeID – the unique identifier of the FFDC point within the class  
stackTrace – the stack trace of the FFDC incident  
objectDetails – the incident details for the FFDC incident  
threadId – the thread ID of the ffdc incident

#### **Garbage Collection events (type:"liberty\_gc")**

heap – the total heap available  
usedHeap – the amount of heap used  
duration – the duration for which GarbageCollection was run  
gcType – the type of garbage collection event (for example: Nursery, Global, etc.)  
reason – the reason for garbage collection

## **Using the Logstash collector**

8.5.5.9

Use the Logstash collector feature in Liberty to collect log and other events from your Liberty servers and send them to a remote Logstash server. The collected events can be used for log analysis and troubleshooting purposes.

## Before you begin

The logstashCollector-1.0 feature was tested with Logstash V2.x, Elasticsearch V2.x, and Kibana V4.x. You can use the logstashCollector-1.0 feature with a Logstash server that runs with any of the available output plug-ins from Logstash. However, many users choose to use Logstash V2.x with Elasticsearch V2.x and Kibana V4.x to provide a complete log consolidation and analysis facility. For more information, see Elasticsearch.

## Procedure

1. Set up Logstash V2.x by following the instructions from Elasticsearch.
2. Create or acquire certificate and key pair files for SSL for Logstash. The following example is the command for openssl that can be used for generating a certificate and key pair. Customize the number of days the keys are valid as required.

```
openssl req -x509 -newkey rsa:2048 -keyout logstash.key -out logstash.crt -days 365 -nodes
```

3. For Logstash V2.x and Elasticsearch users, copy the sample into a `liberty_logstash_template.json` file. See the repository for a sample Logstash index template. Customize the `_ttl` defaults as required to indicate the number of milliseconds to keep records of each event type.
4. For Logstash V2.x and Elasticsearch users, copy the sample into a `liberty_logstash.conf` file. See the repository for sample Logstash filters. Customize lumberjack `ssl_certificate` path, `ssl_key` path, and port number as required. Customize Elasticsearch hosts and template path as required.
5. Complete the following steps for each of the Liberty servers that you want to collect events from:

- a. Acquire or create a keystore for the Liberty server. To create a self-signed certificate use the following command. Customize the server name, password, and subject as required.

```
d:\wlp\bin\securityUtility createSSLCertificate --server=myServerName --password="Liberty" --subject=CN=myHostname,OU=defaultServer,C
```

- b. Import the `logstash.crt` file from step 2 into your server's `key.jks` file. Customize the `wlp_install_dir` and server name as required. When prompted for a password, use the certificate password from step 5a.

```
d:\java\bin\keytool -import -noprompt -alias logstash -file logstash.crt -keystore wlp_install_dir\usr\servers\myServerName\resources
```

- c. Run the following command to install the logstashcollector-1.0 feature:

```
d:\wlp\bin\installUtility install logstashcollector-1.0
```

- d. Configure Logstash collector in the `server.xml` file in Liberty by adding the following content. Customize the logstashCollector list of sources, host name, and port as required.

```
<featureManager>
  <feature>logstashCollector-1.0</feature>
</featureManager>

<keyStore id="defaultKeyStore" password="Liberty" />

<ssl id="mySSLConfig" trustStoreRef="defaultKeyStore" keyStoreRef="defaultKeyStore" />

<logstashCollector
  source="message,trace,garbageCollection,ffdc,accessLog"
  hostName="localhost"
  port="5043"
  sslRef="mySSLConfig"
/>
```

**Note:** Trace and access logs are usually high volume logs and require more network, CPU, and storage resources to collect.

6. For users of Elasticsearch and Kibana V4.x, import the Kibana dashboard as follows:
  - a. Save the Kibana dashboard JSON to a file on your local file system. For Elasticsearch and Kibana V4.x users, see the repository for a sample Kibana dashboard.
  - b. Import the dashboard into Kibana by clicking **Settings > Objects > Import..** When prompted provide the path to the file you saved in the previous step.

7. Save the dashboard using the save (disk) icon. Enter "Liberty" in the text box that is provided and click the save icon near the text box. The next time that you visit Kibana from any browser you can reload this dashboard using the load icon and clicking **Liberty**.

## Results

Your Liberty servers are configured to send events to your Logstash server, and you can now view your events in the Liberty dashboard using Kibana.

---

## Liberty:Logging and Trace

The product has a unified logging component that handles messages that are written by the product and provides First Failure Data Capture (FFDC) services.

Additionally, the logging component captures messages that are written to `System.out`, `System.err`, `java.util.logging`, and OSGi logging. The logging component unifies the handling of these messages with other messages written by the product. The logging component is not capable of capturing messages that are written directly by the JVM process, such as `-verbose:gc` output.

There are three primary log files for a server:

1. `console.log` - containing the redirected standard output and standard error from the JVM process. This console output is intended for direct human consumption. The console output contains major events and errors if you use the default `consoleLogLevel` configuration. The console output also contains any messages that are written to the `System.out` and `System.err` streams if you use the default `copySystemStreams` configuration. The console output always contains messages that are written directly by the JVM process, such as `-verbose:gc` output. This file is created only if the **server start** command is used, and its location can be altered only by using the `LOG_DIR` environment variable. For more information, see "Administering Liberty from the command line" on page 1567.
2. `messages.log` - containing all messages except trace messages that are written or captured by the logging component. All messages that are written to this file contain additional information such as the message time stamp and the ID of the thread that wrote the message. This file does not contain messages that are written directly by the JVM process.
3. `trace.log` - containing all messages that are written or captured by the product. This file is created only if you enable additional trace. This file does not contain messages that are written directly by the JVM process.

## Logging configuration

The logging component can be controlled through the server configuration. The primary location for the logging configuration is in the `server.xml` file. Occasionally, you might need to configure trace to diagnose a problem that occurs before the `server.xml` file is processed. In this case, the equivalent configuration properties can be specified in the `bootstrap.properties` file. If a configuration property is specified in both the `bootstrap.properties` file and the `server.xml` file, the value in `bootstrap.properties` is used until the `server.xml` file is processed. Then, the value in the `server.xml` file is used. Avoid specifying different values for the same configuration property in both the `bootstrap.properties` and the `server.xml` file.

Table 184. Logging properties for Liberty. Column 1 contains attributes that can be set in the server.xml file. Column 2 contains equivalent properties that can be used in the bootstrap.properties file. Column 3 provides a description of each logging property.

Attribute	Equivalent property	Description
<b>logDirectory</b>	com.ibm.ws.logging.log.directory	This attribute sets the directory for all log files, excluding the console.log file, but including FFDC. By default, <b>logDirectory</b> is set to the LOG_DIR environment variable. The default LOG_DIR environment variable path is <i>WLP_OUTPUT_DIR/serverName/logs</i> . <b>Avoid trouble:</b> Use the LOG_DIR environment variable or com.ibm.ws.logging.log.directory property rather than the <b>logDirectory</b> attribute to configure the directory in which you want all the messages to be written. Otherwise, a few messages are written initially in the logs directory by default, and then the remaining messages are written to the specified directory based on your configuration. The <b>logDirectory</b> attribute might be used to dynamically update the logs to the specified directory while the server is running.
<b>maxFileSize</b>	com.ibm.ws.logging.max.file.size	The maximum size (in MB) that a log file can reach before it is rolled. The Liberty runtime does only size-based log rolling. To disable this attribute, set the value to 0. The maximum file size is approximate. By default, the value is 20. <b>Note:</b> <b>maxFileSize</b> does not apply to the console.log file.
<b>maxFiles</b>	com.ibm.ws.logging.max.files	If an enforced maximum file size exists, this setting is used to determine how many of each of the log files are kept. This setting also applies to the number of exception logs that summarize exceptions that occurred on any particular day. So if this number is 10, you might have 10 message logs, 10 trace logs, and 10 exception summaries in the ffdc/ directory. By default, the value is 2. <b>Note:</b> <b>maxFiles</b> does not apply to the console.log file.
<b>consoleLogLevel</b>	com.ibm.ws.logging.console.log.level	This filter controls the granularity of messages that go to the console.log file. The valid values are INFO, AUDIT, WARNING, ERROR, and OFF. By default, the level is AUDIT. <b>Note:</b> <b>Distributed operating systems</b> Before you change this value, consider the information in section “Unable to interact with the Liberty server after modifying the console log level settings” in the topic “Liberty: Developer Tools known issues and restrictions” on page 2342.
<b>copySystemStreams</b>	com.ibm.ws.logging.copy.system.streams	If true, messages that are written to the System.out and System.err streams are copied to console.log. If false, those messages are written to configured logs such as messages.log or trace.log, but they are not copied to console.log. The default value is true.

Table 184. Logging properties for Liberty (continued). Column 1 contains attributes that can be set in the server.xml file. Column 2 contains equivalent properties that can be used in the bootstrap.properties file. Column 3 provides a description of each logging property.

Attribute	Equivalent property	Description
<b>messageFileName</b>	com.ibm.ws.logging.message.fileName	The message log has a default name of messages.log. This file always exists, and contains INFO and other (AUDIT, WARNING, ERROR, FAILURE) messages in addition to System.out and System.err. This log also contains time stamps and the issuing thread ID. If the log file is rolled over, the names of earlier log files have the format messages_timestamp.log
<b>suppressSensitiveTrace</b>		The server trace can expose sensitive data when it traces untyped data, such as bytes received over a network connection. This attribute, when set to true, prevents potentially sensitive information from being exposed in log and trace files. The default value is false.
<b>traceFileName</b>	com.ibm.ws.logging.trace.fileName	The trace.log file is only created if additional or detailed trace is enabled. <b>stdout</b> is recognized as a special value, and causes trace to be directed to the original standard out stream.
<b>traceSpecification</b>	com.ibm.ws.logging.trace.specification	The trace string is used to selectively enable trace. The default is *=info.
<b>traceFormat</b>	com.ibm.ws.logging.trace.format	This attribute controls the format of the trace log. The default format for Liberty is ENHANCED. You can also use BASIC and ADVANCED formats as in the traditional.
<b>8.5.5.4 hideMessage</b>	com.ibm.ws.logging.hideMessage	You can use the <b>hideMessage</b> attribute to configure the messages that you want to hide from the console.log and message.log files. If the messages are configured to be hidden, then they are redirected to the trace.log file.  <b>Note:</b> <b>Distributed operating systems</b> Before you use this attribute, consider the information that is given under the <i>Unable to recognize the start of the server when the hideMessage attribute is used to suppress the messages</i> section in the “Liberty: Developer Tools known issues and restrictions” on page 2342 topic.

You can set logging properties in the server configuration file by selecting **Logging and Tracing** in the **Server Configuration** view in the developer tools, or by adding a logging element to the server configuration file as follows:

```
<logging traceSpecification="*=audit:com.myco.mypackage.*=finest"/>
```

The format of the log detail level specification is:

```
<component> = <level>
```

where *<component>* is the component for which to set a log detail level, and *<level>* is one of the valid logger levels (off, fatal, severe, warning, audit, info, config, detail, fine, finer, finest, all). Separate multiple log detail level specifications with colons (:).

**Attention:** For a given logger, the level is determined by the most specific trace specification that applies to that logger.

Components correspond to Java packages and classes, or to collections of Java packages. Use an asterisk (\*) as a wildcard to indicate components that include all the classes in all the packages that are contained by the specified component. For example:

- \* Specifies all traceable code that is running in the application server, including the product system code and customer code.

**com.ibm.ws.\***

Specifies all classes with the package name beginning with com.ibm.ws.

**com.ibm.ws.classloader.JarClassLoader**

Specifies the JarClassLoader class only.

Table 185. Valid logging levels. The following table lists the valid levels for application servers at WebSphere Application Server Version 6 and later.

Version 6 and later logging level	Content / Significance
off	Logging is turned off.
fatal	Task cannot continue and component, application, and server cannot function.
severe	Task cannot continue but component, application, and server can still function. This level can also indicate an impending unrecoverable error.
warning	Potential error or impending error. This level can also indicate a progressive failure (for example, the potential leaking of resources).
audit	Significant event that affects server state or resources
info	General information that outlines overall task progress
config	Configuration change or status
detail	General information that details subtask progress
fine	Trace information - General trace + method entry, exit, and return values
finer	Trace information - Detailed trace
finest	Trace information - A more detailed trace that includes all the detail that is needed to debug problems
all	All events are logged. If you create custom levels, <i>all</i> includes those levels, and can provide a more detailed trace than finest.

The console.log file does not have the same level of management as other log files. The only property that you can change is **consoleLogLevel**. If you are concerned about the increasing size of the console.log file, you can disable the console.log file and use the message log file instead. The same data, in a different format, is written to the message log file, and you can control the size and number of message log files by using the **maxFileSize** and **maxFiles** attributes. For example, the following bootstrap.properties file results in an empty console.log file and a maximum of three rolling 1 MB loggingMessages.log files. However, messages from the underlying JVM can still be written to the console.log. Settings in the bootstrap.properties file take effect before the message log file is created, so the message log file is initially created as loggingMessages.log and not the default messages.log.

```
com.ibm.ws.logging.max.file.size=1
com.ibm.ws.logging.max.files=3
com.ibm.ws.logging.console.log.level=OFF
com.ibm.ws.logging.message.file.name=loggingMessages.log
```

The console.log file is reset when the server is restarted.

**Note:** On all platforms, logs are written in the default system encoding.

- **z/OS** On z/OS systems, the console.log file uses the default code page, and all other log files uses IS08859-1 encoding and are tagged as text files with that encoding. If the z/OS UNIX System Services (USS) automatic code page conversion feature is active, you can use standard editors and text utilities to view the log files that are encoded with IS08859-1.
- **Windows** On Windows systems, there are two types of encoding: OEM code page, which is used for console output, and ANSI code page, which is used to read and write files. The console.log file uses the OEM code page, and all other logs use the ANSI code page.
- **Distributed operating systems** On all other platforms, all log files use the default encoding.

**Note:** For general help on understanding message formats, see Message log interpretation.

---

## Viewing trace and message log files by using developer tools

Linux

Windows

8.5.5.7

You can view trace and message log files for either local or remote servers by using WebSphere Developer Tools.

### Before you begin

- To view the trace file, you must enable tracing by specifying the traceformat and tracespecification settings in the server.xml file or the bootstrap.properties file. For more information about enabling tracing, see Liberty: Logging and Trace.
- You can change the default log file names from messages.log and trace.log, and the default directory name from WLP\_OUTPUT\_DIR/serverName/logs by changing any of the configuration files.
  - Configuration files include server.xml, bootstrap.properties, and server.properties.
- Actions for local servers:
  - Ensure that the log file is in the log directory that you specified. Otherwise, the menu actions for the local server are disabled.
  - If you change the bootstrap.properties file or the server.env file, you must restart the server for changes to take effect. Menu actions are temporarily disabled until the server is restarted.
  - If the same configuration setting is specified in more than one configuration file, the setting in the server.xml file overrides the other values.
- Actions for remote servers:
  - Ensure that the server is running. If it is not running, menu actions are not displayed.
  - If you change the default location of a log file, include remote access by adding either a ReadDir or a WriteDir configuration to your server.xml file to indicate the log location. The following example shows how to add remote access.

```
<logging logDirectory="${server.output.dir}/log_a" maxFiles="10" traceFormat="BASIC" traceSpecification="com.i
<remoteFileAccess>
  <writeDir >${wlp.user.dir}</writeDir>
  <writeDir>${server.config.dir}</writeDir>
  <writeDir>${server.output.dir}</writeDir>
  <writeDir>${server.output.dir}/log_a</writeDir>
</remoteFileAccess>
```

### Procedure

1. To view a list of servers, select **Window > Show View > Servers**.
2. Right-click a server.

- To view the trace log file, select **Open Log Files > Trace File** from the menu.
- To view the messages log file, select **Open Log Files > Message Log File** from the menu.

For remote servers, downloading log files can take several seconds depending on the size of the log file.

## Results

The log file that you selected is displayed in the default editor. The following example shows records in a message log file.

```
[3/3/11 23:01:30:147 EST] 0000000f ApplicationMg Z WSVR0221I: Application started: DefaultApplication
```

In this example, *[3/3/11 23:01:30:147 EST]* is the time stamp, *0000000f* is the thread ID, *ApplicationMg* is the logger, *Z* is the level, *WSVR0221I* is the message ID, and *Application started: DefaultApplication* is the message.

---

## Liberty: Timed operations and JDBC calls

### 8.5.5.0

Timed operations generate a logged warning when JDBC calls in the application server are operating more slowly or quickly than expected.

## Overview

When enabled, the timed operation feature tracks the duration of JDBC operations running in the application server. In cases where operations take more or less time to execute than expected, the timed operation feature logs a warning. Periodically, the timed operation feature will create a report, in the application server log, detailing which operations took longest to execute. If you run the server dump command, the timed operation feature will generate a report containing information about all operations it has tracked. You can use the information listed in these reports to decide if anything is running slower or faster than you expect.

Periodically, the system generates a report to the logs that contains the ten longest JDBC timed operations. The frequency and enablement of this report is configurable in the `server.xml` file, with a default of once per day (24 hours).

To enable timed operations, add the `timedOperations-1.0` feature to the `server.xml` file.

You can disable the generation of the report to the logs, or change the frequency of the report, for example to once every 12 hours, using the `timedOperation` element as shown in the following example:

```
<timedOperation enableReport="false" reportFrequency="12" />
```

You can also use the `maxNumberTimedOperations` attribute to log a warning when the total number of timed operations reaches the value specified by this attribute. The number of timed operations is monitored and useful to know since each timed operation is allocated memory from the heap, and if you find that the number of timed operations is excessive, you can disable the timed operations feature. You can use the following example to configure the `maxNumberTimedOperations` attribute:

```
<timedOperation enableReport="false" reportFrequency="12" maxNumberTimedOperations="10000"/>
```

This example results in a warning message in the log as follows when the number of timed operations exceeds 10000:

[4/18/13 23:01:37:316 EDT] 0000002c com.ibm.wsspi.timedoperations.TimedOperationService W TRAS0094I: The total number of timed operations is 10000, which exceeds the configured maximum number of 10000. You can also find the number of timed operations in the report that is periodically generated to the logs. If you find that the number of timed operations is excessive, you can disable the timed operations feature.

### 8.5.5.2

If you set the value of the *com.ibm.timedOperations.autoCleanup* WebSphere environment variable to true, the server automatically limits the number of tracked timed operations to the value specified in the <maxNumberTimedOperations> attribute. A warning is logged when the total number of timed operations reaches the maximum value specified. To limit the number of tracked timed operations, when a new timed operation is required to be tracked, the least recently used timed operation record is deleted. When the number of timed operations that are tracked reaches the specified maximum value, a warning message is displayed as follows:

TRAS0095I: The total number of timed operations has reached the configured maximum of 10000. As new timed operations are

You can also use the **server dump** command to get a full report of all timed operations in the `messages.log` file, grouped by type, and sorted within each group by average of actual duration.

The following example shows a sample logged message:

```
[3/14/13 14:01:25:960 CDT] 00000025 TimedOperatio W TRAS0080W: Operation websphere.datasourc.execute:
jdbc/exampleDS:insert into cities values ('myHomeCity', 106769, 'myHomeCountry') took 1.541 ms to complete,
which was longer than the expected duration of 0.213 ms based on past observations.
```

The following example shows a sample automatically generated report in the log:

```
[12/13/12 7:42:29:509 CST] 0000001d com.ibm.wsspi.timedoperations.TimedOperationService I TRAS0092I:
The following operations took the longest time to run since the last report has been generated:
Operation websphere.datasourc.execute:jdbc/exampleDS:insert into cities values ('myHomeCity',
106769, 'myHomeCountry') took 194ms to complete
Operation websphere.datasourc.execute:jdbc/exampleDS:select county from cities where name=
'myHomeCity' took 187ms to complete
Operation websphere.datasourc.execute:jdbc/exampleDS:drop table cities took 182ms to
complete\Operation websphere.datasourc.execute:jdbc/exampleDS:insert into cities values
('myHomeCity', 106769, 'myHomeCountry') took 151ms to complete
```

For the full timed operation configuration reference, see the `timedOperation` element in the following topic:

---

## Event Logging

### 8.5.5.6

As part of the monitoring and diagnostic capabilities, the WebSphere Application Server Liberty generates events at various components of Java Platform, Enterprise Edition to track the requests. The `eventLogging-1.0` feature logs such events when the application requests are running. Using this feature, the user can track the requests that are running in the WebSphere Application Server Liberty. Each request is associated with a unique correlator called the request ID and the context information that helps the user to understand the request-specific data.

The event logging feature is controlled through the server configuration. The feature is configured in the `server.xml` file.

The following sample log shows the end-to-end event logs for the `AAY6Ta1VDTO_AAAAAAAAAAAK` request ID and `TradeWeb` context:

```
[12/15/14 18:24:29:528 IST] 0000002e EventLogging I BEGIN requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=webspher
[12/15/14 18:24:29:531 IST] 0000002e EventLogging I BEGIN requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=webspher
[12/15/14 18:24:29:532 IST] 0000002e EventLogging I BEGIN requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=webspher
[12/15/14 18:24:29:533 IST] 0000002e EventLogging I BEGIN requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=webspher
[12/15/14 18:24:29:534 IST] 0000002e EventLogging I BEGIN requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=webspher
[12/15/14 18:24:29:547 IST] 0000002e EventLogging I END requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=websphere.
[12/15/14 18:24:29:556 IST] 0000002e EventLogging I END requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=websphere.
```

```

[12/15/14 18:24:29:671 IST] 0000002e EventLogging I BEGIN requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=websphere.
[12/15/14 18:24:29:672 IST] 0000002e EventLogging I BEGIN requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=websphere.
[12/15/14 18:24:29:677 IST] 0000002e EventLogging I END requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=websphere.da
[12/15/14 18:24:29:684 IST] 0000002e EventLogging I END requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=websphere.se
[12/15/14 18:24:29:685 IST] 0000002e EventLogging I END requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=websphere.se
[12/15/14 18:24:29:686 IST] 0000002e EventLogging I END requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=websphere.se
[12/15/14 18:24:29:687 IST] 0000002e EventLogging I END requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=websphere.se

```

The request begins at the BEGIN websphere.servlet.service "contextInfo=TradeWeb | TradeScenarioServlet" event (refer to the first line in the sample code) and ends at END websphere.servlet.service "contextInfo=TradeWeb | TradeScenarioServlet" (refer to the last line in the sample code). The total time that is taken by this request is also displayed at the end (which is 158.283 ms in the sample code).

You can look at the child requests by looking at the BEGIN and END of the main request. You can also find the time that is taken by each of the child request.

For best performance, you might use binary logging when event logging is enabled. The eventType, contextInfo, and requestID attributes from the event log entries are stored as log record extensions. You can use those log record extensions to filter the logs with the **binaryLog** command.

## Parsing the event log entries in the messages.log file

The event logs capture the information of the events in the following format:

```
[Log mode] [Request Identifier] # [Event Type] # [Context Information] # [Duration] (optional)
```

where

- Log mode indicates whether the log was recorded at the entry to the event or the exit from the event. BEGIN refers to the entry and END refers to the exit.
- Request identifier is a unique string that is assigned to each request. This can be used for filtering events that belong to a specific request.
- Event type provides information about the event source and can be any of the supported event types as given in Table 186.
- Context information of the event provides details relevant to the event type. The information varies depending on the event type.
- Duration indicates the time that is taken by the event. The duration appears only in the exit event entries. Example: 158.283 ms.

Except the log mode, which is separated by a space, all other log attributes are separated by #(space#space). For example,

```
[12/15/14 18:24:29:687 IST] 0000002e EventLogging I END requestID=AAY6Ta1VDTO_AAAAAAAAAAAK # eventType=websphere.servlet.service
```

The following table lists the event types that are supported by event logging:

Table 186. Supported event types along with the relevant context information

Component	Event types	Context information	Example
Servlet	websphere.servlet.destroy websphere.servlet.service	[Application Name]   [Servlet Name]	contextInfo=TradeWeb   display=0   queryString=
Session	websphere.session.dbSessionDestroyed websphere.session.dbSessionDestroyed websphere.session.sessionAccessed websphere.session.sessionCreated websphere.session.sessionDestroyedByTimeout websphere.session.sessionDestroyed websphere.session.sessionLiveCountDec websphere.session.sessionLiveCountInc websphere.session.sessionReleased  websphere.session.getAttribute websphere.session.setAttribute	[Session ID]   [Session Attribute Name]   [Session Attribute Value]	contextInfo=EuitabHZU0D7J2u01HDdAG0   user=

Table 186. Supported event types along with the relevant context information (continued)

Component	Event types	Context information	Example
JDBC	websphere.datasources.execute websphere.datasources.executeQuery websphere.datasources.executeUpdate websphere.datasources.psExecute websphere.datasources.psExecuteQuery websphere.datasources.psExecuteUpdate websphere.datasources.rsCancelRowUpdates websphere.datasources.rsDeleteRow websphere.datasources.rsInsertRow websphere.datasources.rsUpdateRow	Indi Name Of Data Source   conf {SQL in jdbc/TradeDataSource   sele	

## Slow and hung request detection

8.5.5.6

The requestTiming-1.0 feature provides diagnostic information when the duration of any request exceeds the configured threshold.

The request timing feature can track the duration of every request that is coming into the system. You can configure the feature to watch for slow and hung requests.

- “Slow request detection”
- “Hung request detection” on page 2322

### Slow request detection

When a request has been running for longer than configured, a warning message is written in the messages log file. Details about the request and events that made up the request are captured.

The following sample shows the log message for a request that crossed the slow request threshold (default is 10 seconds):

```
[12/1/14 11:58:09:629 IST] 0000001d com.ibm.ws.request.timing.SlowRequestTimer W TRAS0112W: Req

    at java.util.HashMap.getEntry(HashMap.java:516)
    at java.util.HashMap.get(HashMap.java:504)

    at javax.servlet.http.HttpServlet.service(HttpServlet.java:668)
    at com.ibm.ws.webcontainer.servlet.ServletWrapper.service(ServletWrapper.java:1275)
    ....
    at java.util.concurrent.ThreadPoolExecutor.runWorker(ThreadPoolExecutor.java:1121)
```

```

at java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:614)
at java.lang.Thread.run(Thread.java:769)

```

Duration	Operation
10007.571ms +	websphere.servlet.service   TradeWeb   TradeConfigServlet?action=resetTrade
3.923ms	websphere.datasource.psExecuteUpdate   jdbc/TradeDataSource   delete from holdingejb where holding_
0.853ms	websphere.datasource.psExecuteUpdate   jdbc/TradeDataSource   delete from accountprofileejb where
5271.341ms +	websphere.datasource.psExecuteUpdate   jdbc/TradeDataSource   delete from orderejb where account_

The request continues to be monitored, and a further warning is logged if the request is running beyond another 10 seconds. The log messages are in the following format:

```

TRAS0112W: Request <(Request ID)> has been running on thread <THREADID> for at least <DURATION>. The following stack
<STACK TRACE>
<DURATION AND OPERATIONS Table>

```

### REQUEST ID

This same ID can be used to search for log and trace messages corresponding to the request. In particular, if you use binary logging, you can search for log and trace entries with the same requestID extension by using the binary log command.

### STACK TRACE

Indicates the method that is running. In the previous sample, you can see a stack trace of the current request after TRAS0112W line.

### DURATION AND OPERATIONS Table

After the stack trace, you can find the tabular format of the request that shows the duration and operation (also referred to as the event). The Duration column indicates the time that is taken by the corresponding operation of the request. The plus sign (+) indicates events within the request that are still running. The next line shows the duration without +, which indicates that the corresponding operation has completed in the specified duration. Operation shows the EVENT TYPE and CONTEXT INFO (which is optional) for that operation. For more information about event types and context information, see “Event Logging” on page 2319.

By analyzing the messages, you can figure out why the request is slow. However, it might be difficult to determine whether the request is stuck at that point or is still running slowly. Hence you can see three messages that are logged for any slow request at the interval of specified *<slowRequestThreshold>*. Using the three different stack trace and request data, you get a better insight into the issue. After the third warning, no further warnings are logged about the request unless the duration of the request crosses the hung request detection threshold.

## Hung request detection

If the request exceeds the default hungRequestThreshold or the configured threshold value, a warning message is written in the messages log file along with the details about the request. Details about the request and events that made up the request are captured. In case of hung request detection, a series of three thread dumps (javacores) is taken, with 1 minute delay between them. The following log message sample shows the log messages for a request that crossed the hung request detection threshold. The default duration value is 10 min. The value that is configured in the following example is 4 min.

```

[WARNING ] TRAS0114W: Request AAA7WlpP7I7_AAAAAAAAAAAAA has been running on thread
00000021 for at least 240001.015ms. The following table shows the events that have run during this
request.

```

Duration	Operation
240001.754ms +	websphere.servlet.service   TestWebApp   TestServlet?sleepTime=480000
0.095ms	websphere.session.setAttribute   mCzBMyzMvAEnjMJjx9zQYIw   userID
0.007ms	websphere.session.setAttribute   mCzBMyzMvAEnjMJjx9zQYIw   visitCount

If a request gets completed later, which was detected to be hanging initially, a message similar to the following example is logged: TRAS0115W: Request AAA7WlpP7I7\_AAAAAAAAAAAAA, which was previously detected to be hung, has completed after 479999.681 s.

**Note:** When a request is detected to be hanging, a series of three thread dumps is initiated. After the completion of the three thread dumps, further thread dumps are created only if the new requests are detected to be hanging.

---

## Liberty:Binary logging

8.5.5.0

Binary logging is a high performance log and trace facility based on the High Performance Extensible Logging (HPEL) technology in WebSphere Application Server traditional.

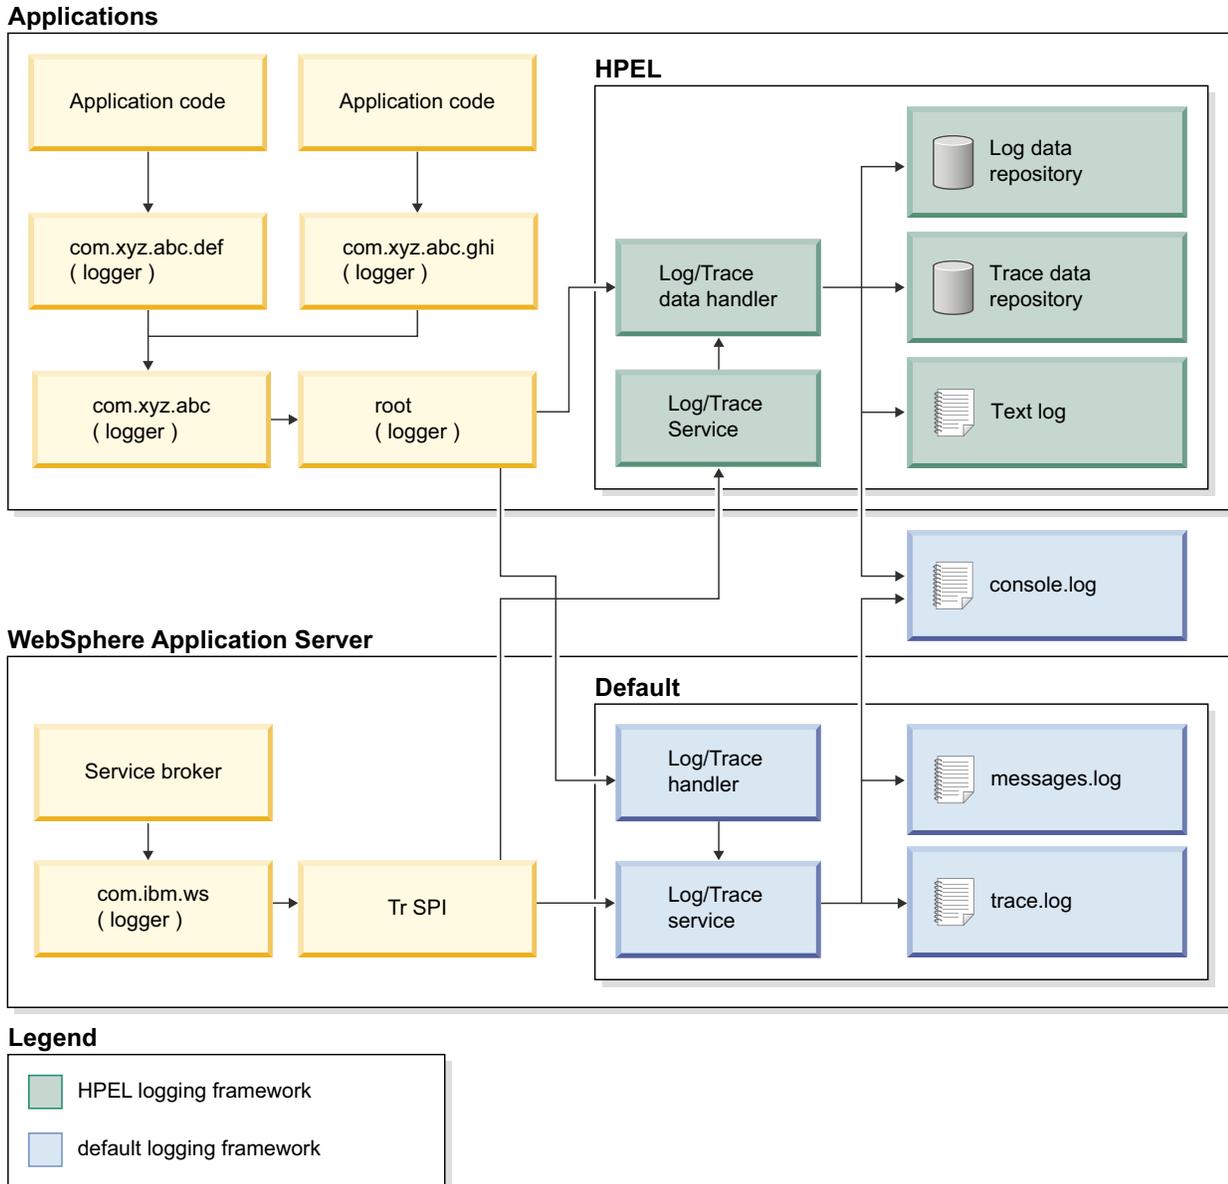

### Overview

**Note:** You must enable the binary logging facility to use it.

Binary logging provides a convenient mechanism for storing and accessing log, trace, System.err, and System.out information produced by the application JVM server or your applications. It is an alternative to the default log and trace facility, which provides the JVM logs and diagnostic trace files commonly named messages.log and trace.log.

### Log and trace storage

Binary logging provides a log data repository and a trace data repository. See the following figure to understand how applications and the application server store log and trace information.

### Log data repository

The log data repository is a storage facility for log records. Log data is typically intended to be reviewed by administrators. This includes any information applications or the server write to System.out, System.err, OSGi logging service at level LOG\_INFO or higher (including LOG\_INFO, LOG\_WARNING, and LOG\_ERROR), or java.util.logging at level Detail or higher (including Detail, Config, Info, Audit, Warning, Severe, Fatal, and any custom levels at level Detail or higher).

### Trace data repository

The trace data repository is a storage facility for trace records. Trace data is typically intended for use by application programmers or by the WebSphere Application Server support team. This includes any information applications or the server write to the OSGi logging service at level LOG\_DEBUG or java.util.logging at levels below level Detail (including Fine, Finer, Finest, and any custom levels below level Detail).

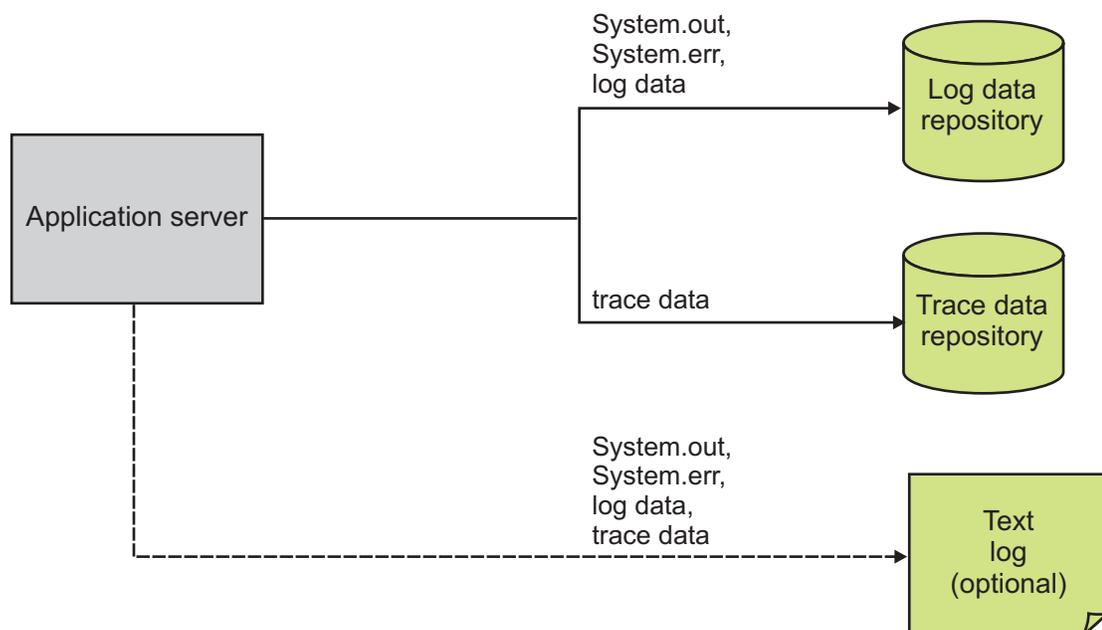

## Log and trace performance

Binary logging has been designed and tested to significantly outperform the default log and trace facility. One result is that the application server can run with trace enabled while causing less impact to performance than tracing the same components using the default log and trace framework. Another result is that applications that frequently write to the logs can run faster when using binary logging.

### Log and trace events are each stored in only one place

Log events, System.out, and System.err are stored in the log data repository. Trace events are stored in the trace data repository. Storing each type of event in only one place ensures that performance is not wasted on redundant data storage.

**Note:** The console log should be disabled in cases where logging performance is important. Any content written to the console log will already be stored in the log data repository.

### Data is not formatted unless it is needed

Formatting data for a user to read uses processor time. Rather than format log event and trace event data at run time, log and trace data are stored more rapidly in a proprietary binary representation. This improves the performance of the log and trace facility. By deferring log and trace formatting until the binaryLog command is run, sections of the log or trace that are never viewed are never formatted.

### Log and trace data are buffered before being written to disk

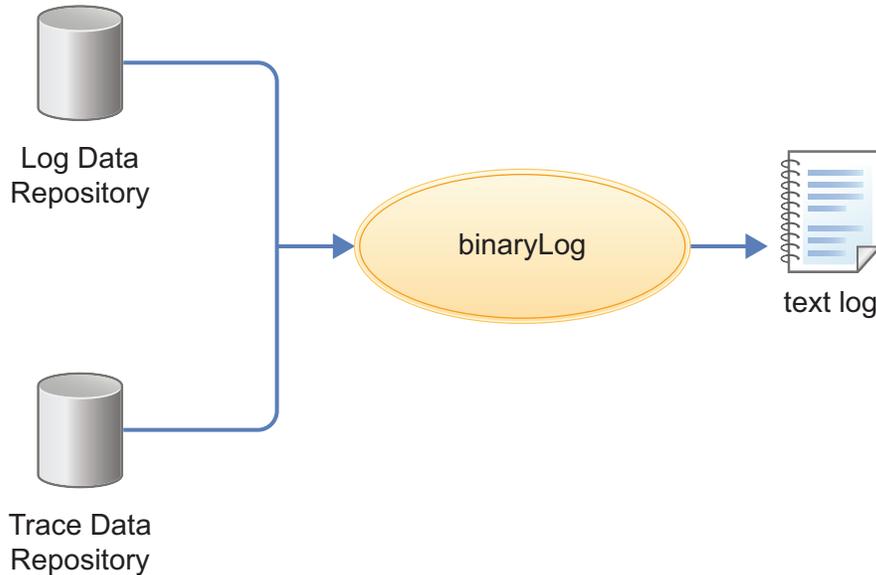

Writing large blocks of data to a disk is more efficient than writing the same amount of data in small blocks. The binary logging facility provides the capability to buffer log and trace data before writing it to disk. By default, log and trace data are stored in an 8 KB buffer before being written to disk. If the buffer is filled within 10 seconds, the buffer is written to disk. If the buffer is not filled within that time it is automatically written to disk to ensure that the logs have the most current information.

## Administration of log and trace

Binary logging has been designed to be easy to configure and understand. For example, administrators can easily configure how much disk space to dedicate to logs or trace, or how long to retain log and trace records, and leave the management of log and trace content up to the server. As another example all log, trace, System.out, and System.err content can be accessed using one easy-to-use command (`binaryLog`), avoiding any possible confusion over which file to access for certain content.

### Reading from the log data and trace data repositories

The log data and trace data repositories are stored in a WebSphere Application Server proprietary format and cannot be read using text file editors such as Notepad or VI. You can copy the log data and trace data repositories in to a plain text format using the `binaryLog` command.

### binaryLog command

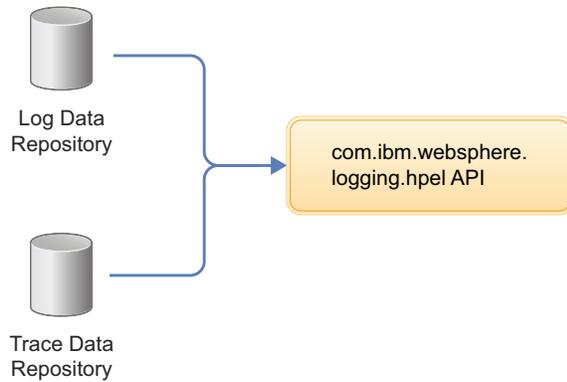

`binaryLog` is an easy-to-use command-line tool provided for users to work with the log data and trace data repositories. `binaryLog` provides filtering and formatting options that make finding important content in the log data and trace data repositories easy. For example, a user might filter any errors or warnings, then filter all log and trace entries that occurred within 10 seconds of a key error message on the same thread.

### Filtering using log and trace record extension content

The binary logging facility provides the capability for developers to add custom extensions to log and trace records using a log record context API (`com.ibm.websphere.logging.hpel.LogRecordContext`). You can use the `binaryLog` command-line tool to filter records based on the content of log and trace record extensions.

## Development resources

Binary logging has been designed to make working with log and trace content more flexible and effective than the default logging facility. Log and trace content can be easily filtered to show only the records that are of interest. You can use the command line (see the description of the `binaryLog` command), or developers can create powerful log handling programs using the HPEL API.

### Reading the log data and trace data

An API has been provided to make it easy for developers to develop tools to consume content from the binary log and trace repositories. For example, a developer might write a Java program to search the log and trace content to find any messages with message IDs that match a known list of important message IDs. This API is in the `com.ibm.websphere.logging.hpel` package. Refer to the API documentation for details on the HPEL log reading API.

### Log and trace record extensibility

Developers can add custom extensions to log and trace records through a log record context API (`com.ibm.websphere.logging.hpel.LogRecordContext`). When binary logging stores log and trace records, it includes any extensions present in the log record context on the same thread. For example, a developer might write a servlet filter to add important HTTP request parameters to the log record context. While that servlet runs, HPEL API adds those extensions to any log and trace records created on the same thread.

As with other log and trace record fields, developers can access the record extensions using the HPEL API. This is useful when writing tools to read from log and trace repositories. Developers can also make use of the log record context API to access extensions in custom log handlers, filters, and formatters at run time.

## BinaryLog command options

8.5.5.0

Use the **binaryLog** command to view or copy the contents of a binary logging repository, or list the available server process instances in the repository. The **binaryLog** command is equivalent to the **logViewer** command in the profile bin directory of the traditional application server.

The binary log and trace facility writes to a repository in a binary format. You can view, query and filter the repository using the **binaryLog** command. The **binaryLog** command provides options for quickly converting repository contents into a text file in various formats, such as basic and advanced formats. The command also provides options to make getting the data you need from the logs easier; for example, allowing you to filter what log records you want by level, logger name, or date and time.

### Syntax

The command syntax is as follows:

```
binaryLog action {serverName | repositoryPath} [options]
```

The value of **options** is different based on the value of **action**.

## Parameters

The following actions are available for the binaryLog command:

### view

Read a repository, optionally filter it, and create a version that users can read.

The command syntax is as follows:

```
binaryLog view {serverName | repositoryPath} [options]
```

*serverName*

Specify the name of a Liberty server with a repository to read from.

*repositoryPath*

Specify the path to a repository to read from. This is typically the directory that contains both the logdata and tracedata directories.

**Note:** If neither a *serverName* nor a *repositoryPath* is specified on the command line, the task is performed against the default server instance, `defaultServer`, if it exists.

Filter options:

All filters are optional. When multiple filters are used, they are logically ANDed together.

- `--minDate=value`  
Filter based on minimum record creation date. Value must be specified as either a date (for example `--minDate="2/20/13"`) or a date and time (for example `--minDate="2/20/13 16:47:21:445 EST"`).
- `--maxDate=value`  
Filter based on maximum record creation date. Value must be specified as either a date (for example `--maxDate="2/20/13"`) or a date and time (for example `--maxDate="2/20/13 16:47:21:445 EST"`).
- `--minLevel=value`  
Filter based on minimum level. Value must be one of FINEST | FINER | FINE | DETAIL | CONFIG | INFO | AUDIT | WARNING | SEVERE | FATAL.
- `--maxLevel=value`  
Filter based on maximum level. Value must be one of the following: FINEST | FINER | FINE | DETAIL | CONFIG | INFO | AUDIT | WARNING | SEVERE | FATAL.
- `--includeLogger=value[,value]*`  
Include records with specified logger name. Value may include \* or ? as a wildcard.
- `--includeMessage=value`  
Filter based on message name. Value may include \* or ? as a wildcard.
- `--includeThread=value`  
Include records with specified thread id. Values must be in hexadecimal (for example, `--includeThread=2a`).
- `--includeExtension=name=value[,name=value]*`  
Include records with specified extension name and value. Value may include \* or ? as a wildcard. To include a comma in the value, you must use "\",
- `--includeInstance=value`  
Include records from the specified server instance. Value must either be "latest" or be a valid instance ID. Run this command using the `listInstances` action to see a list of valid instance IDs.

Monitor option:

`--monitor`

Continuously monitor the repository and output new content as it is generated.

Output options:

- `--format={basic | advanced | CBE-1.0.1}`  
Specify the output format to use. "basic" is the default format.
- `--encoding=value`  
Specify the character encoding to use for output.

## copy

Read a repository, optionally filter it, and write the contents to a new repository.

The command syntax is as follows:

```
binaryLog copy {serverName | repositoryPath} targetPath [options]
```

*serverName*

Specify the name of a Liberty server with a repository to read from.

*repositoryPath*

Specify the path to a repository to read from. This is typically the directory that contains the logdata and tracedata directories.

*targetPath*

Specify the path at which to create a new repository. The *targetPath* must be specified.

**Note:** Either *serverName* or *repositoryPath* must be specified, as well as the *targetPath*.

Filter options:

All filters are optional. When multiple filters are used, they are logically ANDed together.

- `--minDate=value`  
Filter based on minimum record creation date. Value must be specified as either a date (for example `--minDate="2/20/13"`) or a date and time (for example `--minDate="2/20/13 16:52:32:808 EST"`).
- `--maxDate=value`  
Filter based on maximum record creation date. Value must be specified as either a date (for example `--maxDate="2/20/13"`) or a date and time (for example `--maxDate="2/20/13 16:52:32:808 EST"`).
- `--minLevel=value`  
Filter based on minimum level. Value must be one of the following: FINEST | FINER | FINE | DETAIL | CONFIG | INFO | AUDIT | WARNING | SEVERE | FATAL.
- `--maxLevel=value`  
Filter based on maximum level. Value must be one of the following: FINEST | FINER | FINE | DETAIL | CONFIG | INFO | AUDIT | WARNING | SEVERE | FATAL.
- `--includeLogger=value[,value]*`  
Include records with specified logger name. Value may include \* or ? as a wildcard.
- `--excludeLogger=value[,value]*`  
Exclude records with specified logger name. Value may include \* or ? as a wildcard.
- `--includeMessage=value`  
Filter based on message name. Value may include \* or ? as a wildcard.
- `--includeThread=value`  
Include records with specified thread id. Values must be in hexadecimal (for example, `--includeThread=2a`).
- `--includeExtension=name=value[,name=value]*`

Include records with specified extension name and value. Value may include \* or ? as a wildcard. To include a comma in the value, you must use "\",

- `--includeInstance=value`

Include records from the specified server instance. Value must either be "latest" or be a valid instance ID. Run this command using the listInstances action to see a list of valid instance IDs.

## listInstances

List the IDs of server instances in the repository. A server instance is the collection of all log/trace records written from the time a server is started until it is stopped. Server instance IDs can be used with the `--includeInstance` option of the binaryLog view action.

The command syntax is as follows:

```
binaryLog listInstances {serverName | repositoryPath}
```

*serverName*

Specify the name of a Liberty server with a repository to read from.

*repositoryPath*

Specify the path to a repository to read from. This is typically the directory that contains the logdata and tracedata directories.

**Note:** If *serverName* or *repositoryPath* are not specified on the command line, the task is performed against the default server instance, `defaultServer`, if it exists.

Be aware of binaryLog filtering optimizations. The binaryLog tool is able to filter log and trace data most efficiently when used with the following filter options:

- `--minDate`
- `--maxDate`
- `--includeThread`
- `--minLevel`
- `--maxLevel`

## Example usage

See the following examples of binaryLog commands.

- Display all events in the `defaultServer` repository between July 19th, 2013 and August 2nd, 2013.  

```
binaryLog view --minDate=07/19/13 --maxDate=08/02/13
```
- Display new events from server `myServer`, whose specified level is `WARNING` or higher, using the advanced format as the server writes them to the log repository.  

```
binaryLog view myServer --monitor --minLevel=WARNING --format=advanced
```
- Write log messages from a repository at `/apps/server1/logs`; include only those that were written to the error stream of a specific repository.  

```
binaryLog view /apps/server1/logs --includeLogger=SystemErr
```
- View events from the `defaultServer` repository that occurred before September 14th, 2012 4:28 PM eastern daylight time.  

```
binaryLog view --maxDate="09/14/12 16:28:00:000 EDT"
```
- Write events from the `defaultServer` repository that contain a 'thread' extension with value 'Default Executor-thread-4'  

```
binaryLog view --includeExtension=thread="Default Executor-thread-4" --format=advanced
```
- View the list of server instances in the `defaultServer` repository:  

```
binaryLog listInstances
```

Using `D:\wlp\usr\servers\defaultServer\logs` as repository directory.

Instance ID	Start Date
1358809441761	1/21/13 18:04:01:761 EST
1358864476191	1/22/13 9:21:16:191 EST

1358869523192	1/22/13 10:45:23:192 EST
1358871281166	1/22/13 11:14:41:166 EST
1358879829000	1/22/13 13:37:09:000 EST
1358892222067	1/22/13 17:03:42:067 EST

- View events from the defaultServer using one of the instance IDs from the previous example:

```
binaryLog view --includeInstance=1358871281166
```

- Copy events from the defaultServer, whose specified level is WARNING or higher, from the latest server instance to a new repository at d:\toSupport directory.

```
binaryLog copy defaultServer d:\toSupport --minLevel=warning --includeInstance=latest
```

## Configuring binary logging in Liberty

8.5.5.0

Use this information as a guide for configuring binary logging in your Liberty.

### About this task

Binary logging provides faster log and trace handling capabilities and more flexible ways to use log and trace content than the default Liberty log and trace framework.

A server configuration consists of a bootstrap.properties file, a server.xml file, and any (optional) files that are included with those files. The bootstrap.properties file specifies properties that need to be available before the main configuration is processed, and are kept to a minimum. The server.xml file is the primary configuration file for the server.

The server.xml file and its associated files use a simple xml format that is suitable for most text editors.

**Distributed operating systems** A richer editing experience is provided by the eclipse server adapter for Liberty (WAS4D+ adapter), which uses a generated schema to provide drop-down lists of available choices, auto-completion, and other editing tools. For a description of the eclipse server adapter for Liberty, see “Editing the Liberty configuration by using developer tools” on page 1556.

The bootstrap.properties file specifies whether the server uses binary logging as the log and trace framework, or the default log and trace framework. A server restart is required to switch between binary logging and the default log and trace framework.

You can modify the configuration of binary logging through the server configuration or the bootstrap.properties file.

- Server configuration: To get logging from your own code, which is loaded after server configuration processing, use the server configuration to configure binary logging.
- bootstrap.properties file: You might need to set logging properties to take effect before the server configuration files are processed. For example, if you need to analyze problems that occur early in server start or configuration processing. In this case, you can configure binary logging in the bootstrap.properties file.

You can set Logging properties in either the bootstrap.properties or the server.xml file. Use attributes in the server.xml file, or use equivalent properties in the bootstrap.properties file. Any settings in the bootstrap.properties file are used from the time the server reads the bootstrap.properties file until the time the server.xml file is processed. If the logging properties in the bootstrap.properties file are not replaced or reset in the server.xml file, the property values in the bootstrap.properties file continue to be used.

When binary logging is enabled, the **maxFileSize**, **maxFiles**, **messageFileName**, **traceFileName**, and **traceFormat** logging element attributes are ignored (since binary logging runs without trace.log and

messages.log files). The **traceSpecification**, **consoleLogLevel**, and **logDirectory** attributes continue to be used to set the trace specification, the level for the console log, and the placement of the log and trace files.

If you set logging or binary logging attributes in the server.xml file, you can avoid changes in configuration between startup time and runtime by setting the corresponding properties in the bootstrap.properties file to the same value. If no logging or binary logging properties are set in the bootstrap.properties file, the server uses the default logging settings.

## Procedure

- Enable binary logging for the server by updating the bootstrap.properties file. In the bootstrap.properties file, add the following text on a line by itself:  
websphere.log.provider=binaryLogging-1.0
- Use the following parameters to configure binary logging. All subelements that are listed are subelements of the logging element in the server.xml file. The following table lists the attributes that are configurable in the server.xml file and the equivalent properties that can be set in the bootstrap.properties file:

*Table 187. Binary logging attributes that are configurable in server.xml and the equivalent properties that can be set in bootstrap.properties*

Logging subelement	Attribute	Equivalent bootstrap.properties property
binaryLog	purgeMaxSize	com.ibm.hpel.log.purgeMaxSize
	purgeMinTime	com.ibm.hpel.log.purgeMinTime
	fileSwitchTime	com.ibm.hpel.log.fileSwitchTime
	bufferingEnabled	com.ibm.hpel.log.bufferingEnabled
	outOfSpaceAction	com.ibm.hpel.log.outOfSpaceAction
binaryTrace	purgeMaxSize	com.ibm.hpel.trace.purgeMaxSize
	purgeMinTime	com.ibm.hpel.trace.purgeMinTime
	fileSwitchTime	com.ibm.hpel.trace.fileSwitchTime
	bufferingEnabled	com.ibm.hpel.trace.bufferingEnabled
	outOfSpaceAction	com.ibm.hpel.trace.outOfSpaceAction

The following example shows a bootstrap.properties file that is configured to enable binary logging:  
websphere.log.provider=binaryLogging-1.0

The following example shows a server.xml file with the binary logging subelements. The log content is set to expire after 96 hours and the trace content is set to retain a maximum of 1024MB:

```
<server description="new server">
  <logging>
    <binaryLog purgeMinTime="96"/>
    <binaryTrace purgeMaxSize="1024"/>
  </logging>
</server>
```

For the full logging configuration reference, see the logging, binaryLog, and binaryTrace elements in the .

## Results

After you restart the server, binary logging is enabled and configured.

---

## Liberty:Runtime environment known issues and restrictions

There are some known issues and restrictions that apply when working with the Liberty runtime environment.

### Distributed operating systems

See also “Liberty: Developer Tools known issues and restrictions” on page 2342.

## Minimum supported Java levels

Liberty is supported with any compliant Java SE 6, Java SE 7, or Java SE 8 runtime environment (JRE) or Java SDK, subject to the minimum supported levels shown for the following specific implementations.

### Java SE 6 runtime environment

For the Java SDK from IBM, the minimum supported level is 6.0 (J9 2.6) SR 1. For the JDK from Oracle, the minimum supported level is Java 6 update 26.

### Java SE 7 runtime environment

For the Java SDK from IBM, the minimum supported level is IBM Runtime Environment, Java Technology Edition 7.0.4.1. For the JDK from Oracle on Windows and Linux, the minimum supported level is Java SDK/JRE/JDK 7.0.17. For the JDK from Oracle on Mac OS X, the minimum supported level is Java SDK/JRE/JDK 7.0 Update 15.

### 8.5.5.5 Java SE 8 runtime environment

For the Java SDK from IBM, the minimum supported level is IBM SDK, Java Technology Edition, Version 8. For the JDK from Oracle, the minimum supported level is Java 8 update 25.

### Distributed operating systems

On distributed platforms, 32-bit or 64-bit Java is supported. **z/OS** On the z/OS platform, only 64-bit Java is supported.

### Distributed operating systems

For Windows and Linux systems, you can use either the JDK from Oracle or the JDK from IBM. If you are developing applications on Windows or Linux, and you plan to deploy those applications to a server running on WebSphere Application Server classic, you should use the JDK from IBM. For HP systems and Mac OS, use the JDK from Oracle. **z/OS** For z/OS systems, use the JDK from IBM.

**Note:** **IBM i** To obtain the minimum supported Java level for IBM iSeries, install IBM J2SE 6.0 32-bit JVM (5761-JV1 option 11 **8.5.5.2** or 5770-JV1 option 11) or IBM SE 6.0 64 bit (5761-JV1 option 12 **8.5.5.2** or 5770-JV1 option 12), and also install Java PTF group SF99572 level 8 (or later) for IBM i 7.1.

## The installation directory name and path cannot include non-ASCII characters

Recent JVMs do not fully support use of non-ASCII characters with the **-jar** and **-javaagent** commands. You should use only ASCII characters in your installation directory names and paths.

## Changing the JDBC data source at run time might result in JPA failures

If the database dictionary type is not specified through properties, it is detected and calculated by OpenJPA when the first entity manager is created and the database connection is made. This database dictionary type is used for all entity managers that are subsequently created. If the JDBC data source is changed while an application is running, the entity manager factory does not detect this change and continues to use the old dictionary for operations against the new data source. This can result in failures if the database is changed to a different vendor.

When you change a database to a different vendor, restart the application.

## Modifying the dataSource, jdbcDriver, connectionManager, and JDBC vendor properties at run time might result in JPA failures

If you update the configuration of dataSource, jdbcDriver, connectionManager or any of the JDBC vendor properties lists (for example, properties.db2.jcc or properties.oracle) while the server is running, you might see J2CA8040E failures. These failures state that multiple dataSource elements cannot be associated with a single connectionManager. These failures are generated even if your configuration associates only one connectionManager with the dataSource element.

When you make updates to the configuration of any of these JDBC resources, restart the server.

## An application that relies on a result being returned by getRealPath must be deployed as an expanded application, not as a WAR file

The Java EE specification states that the getRealPath() method returns a null value if the content is being made available from a web archive (WAR) file. When you deploy a WAR file to Liberty, Liberty does not automatically extract the archive file into a directory structure. Therefore the application might fail to start. If your application relies on a result being returned by getRealPath(), you must deploy the application as an expanded web application, not as a WAR file. For example, you can manually extract the WAR file and copy the expanded application to the dropins directory.

## WebSphere Application Server traditional scripts do not work with Liberty

You cannot use any of the scripts under the bin directory of the WebSphere Application Server traditional to administer Liberty.

## Fileset restrictions

The following restriction applies to Filesets:

- Filesets do not recursively explore subdirectories of the base directory. For example, the following instructions are not supported:

```
<fileset id="testFileset" dir="\temp" includes="**\a.jar"/>
<fileset id="testFileset" dir="\temp" includes="a\a.jar"/>
<fileset id="testFileset" dir="\temp" includes="*\a.jar"/>
<fileset id="testFileset" dir="\temp" includes="a\b\a.jar"/>
```

## Overriding classes from the Java SDK

Some Java EE 6 technologies supported by Liberty require newer versions of APIs that are provided by Java SE 6. JAX-WS, JAXB and the javax.annotation.Resource annotation are all examples where a Java 6 SDK contains older classes than those required by Java EE 6. When compiling your application code against these APIs using Java SDK version 6, you need to use classes that are provided by Liberty rather than the Java SDK. You must take one of the following actions:

- If you are using javac to build from the command line, compile your code by using the javac -endorseddirs option and the JAR files in the \${wlp.install.dir}/dev/specs directory.
- If you are using Apache Ant to build, compile your code by using the <compilerarg> child element of the javac task and the JAR files in the \${wlp.install.dir}/dev/specs directory. In the build script, specify the -endorseddirs option and the \${wlp.install.dir}/dev/specs directory as separate <compilerarg> elements. For example:

```
<javac srcdir="src" destdir="classes"/>
  <compilerarg value="-endorseddirs"/>
  <compilerarg value="${wlp.install.dir}/dev/specs"/>
</javac>
```

- If you are using Apache Maven to build, compile your code by using the `endorseddirs` element of the Maven compiler plug-in and the JAR files in the `${wlp.install.dir}/dev/specs` directory. For example:

```
<plugin>
  <groupId>org.apache.maven.plugins</groupId>
  <artifactId>maven-compiler-plugin</artifactId>
  <configuration>
    <source>1.6</source>
    <target>1.6</target>
    <compilerArguments>
      <endorseddirs>${wlp.install.dir}/dev/specs</endorseddirs>
    </compilerArguments>
  </configuration>
</plugin>
```

Windows

## When you unpublish a shared library, it cannot be deleted until the server is stopped

When you unpublish a shared library from a server, the library JAR file is not immediately released from the server. Therefore the operating system does not know that the file is no longer in use, and does not let you delete the file. When you next stop the server, the library JAR file is released and you can delete the file.

z/OS

## Version 1.11 or later is required for Liberty on z/OS

To use the native z/OS capabilities of Liberty, you must use z/OS Version 1.11 or later.

z/OS

## z/OS APAR OA37620 is required to enable server tracing for a specific trace group

If you want to trace individual trace groups, apply z/OS APAR OA37620. When enabling tracing for Liberty on the z/OS platform, use the package/class syntax (that is, `com.ibm.ws.*=all`) unless directed otherwise by IBM support.

## java:global lookups restrictions

Resources defined in applications with `java:global` lookups can only be used to access names declared by applications deployed in the current server.

## appSecurity-2.0 feature restrictions

8.5.5.0

For the `appSecurity-2.0` feature, the following restrictions apply:

- For EJB applications, the **run-as-mode** of `SYSTEM_IDENTITY` is not supported in the extension settings of the `ibm-ejb-jar-ext.xml` file.
- The `getCallerIdentity` API is not supported for Singleton session beans.
- Role names can be referenced by the `HttpServletRequest.isUserInRole` and `EJBContext.isCallerInRole` APIs or by elements in the deployment descriptor without first declaring the role names using the `@DeclareRoles` annotation or the `<security-role/>` element in the deployment descriptor. However, roles must be declared before being used in WebSphere Application Server traditional.

## Applications not starting in an embedded Liberty server

Ensure that the Java process that starts the embedded Liberty server was started with the `-javaagent` JVM argument that pointed to the `libertyInstallDir/bin/tools/ws-javaagent.jar`. If the `-javaagent` JVM argument is not used the server runtime starts, but applications fail to start with no obvious exceptions.

8.5.5.6

## WebSphere MQ resource adapter and generic JCA support related restrictions

The WebSphere® MQ resource adapter can be used within the WebSphere Application Server Liberty by using either the `wmqJmsClient-1.1` or `wmqJmsClient-2.0` feature or by using generic JCA support.

You can use the WebSphere MQ resource adapter version 7.5 with Liberty version 8.5.5 and later. If you want to use WebSphere MQ resource adapter version 8.0, which is based on JMS 2.0 resource adapter, you must ensure that you are using the latest Liberty version that is compatible with the JMS 2.0 resource adapter.

### Notes:

- With Liberty version 8.5.5.2, the `wmqJmsClient-1.1` feature must be used with a IBM MQ resource adapter version 7.5.0.5 or later.
- With Liberty version 8.5.5.6, the `wmqJmsClient-2.0` feature must be used with a IBM MQ resource adapter version 8.0.0.3 or later

To know more about the version compatibility information between WebSphere MQ resource adapter and Liberty, see the Reference to obtain the WebSphere MQ resource adapter.

If you are using generic JCA support, the following restrictions apply:

- To run the IBM® WebSphere MQ resource adapter on z/OS, you must use the `wmqJmsClient-1.1` or `wmqJmsClient-2.0` feature.
- Tracing and logging are not integrated within the Liberty trace system using generic JCA. Trace is written to a separate file, and it must be enabled by setting the system properties. The procedure to enable tracing is the same as configuring the WebSphere MQ classes for JMS trace facility for a Java Standard Environment. See Java Standard Environment Trace stanza.
- The IBM MQ classes for Java are not supported in Liberty. They must not be used with either the IBM MQ Liberty messaging feature or with the generic JCA support. For more information, see Using WebSphere MQ Java Interfaces in J2EE/JEE Environments.

## Versioning is not possible for applications in the “dropins” directory

For applications in the “dropins” directory, the file name and file extension are used by the application monitor to determine the type of application, and to generate the application id and application name. It is therefore not possible to specify the version number for the application by using the file name or file extension. In a production environment, you are not recommended to use the “dropins” directory.

## Shared session applications must store session objects in shared libraries

When you are using the `shared-session-context` application extension, or `<shared-session-context value="true"/>` in `ibm-application-ext.xml`, all objects that are stored in the session must be available in the shared libraries that are associated with the application so that the session can be invalidated.

## Configuring session persistence

There is only one `server.xml` file for each server, not a `server.xml` file for each EAR or WAR file. You set session persistence in a database by adding:

```
<httpSessionDatabase id="SessionDB" dataSourceRef="SessionDS" ... />
```

In Liberty, this setting for the database applies to all EAR and WAR files. It is not possible to set up some databases with session persistence and others without.

## Ported locally transacted JMS sessions do not work in Liberty

In WebSphere Application Server traditional, you can develop applications to take advantage of locally transacted JMS sessions. When you port these applications to Liberty, these applications behave differently or do not work at all.

Even though WebSphere Application Server traditional allows locally transacted JMS sessions, porting a WebSphere Application Server traditional locally transacted JMS session to Liberty is not allowed.

## Admin Center feature restrictions

For the adminCenter-1.0 feature, the following restriction applies:

- **8.5.5.2** Using an IBM Java virtual machine (JVM) available with a WebSphere Application Server traditional product, such as Network Deployment, can cause WebSphere Liberty Administrative Center ("Admin Center") to not display in a browser. By default, the IBM JVM available with the WebSphere Application Server traditional product points to security classes that are available only with the WebSphere Application Server traditional product, and not to security classes needed by Admin Center, which requires Secure Sockets Layer (SSL). Use a JVM that supports Liberty products and SSL.
  - **8.5.5.4** You can get a JVM that supports Liberty products and SSL from Installation Manager offerings or developerWorks:
    - Using Installation Manager, select the Liberty product first and then select WebSphere SDK for Liberty. Use Installation Manager to install the Liberty product and software development kit (SDK). The WebSphere SDK for Liberty includes the needed support for Liberty products and SSL and offers a Java client, JConsole.
    - Go to <http://www.ibm.com/developerworks/java/jdk/index.html> on the developerWorks website and download an IBM Java development kit (JDK) for your operating system. The developerWorks website does not have a JVM for all operating systems. For example, you have to get the JDK from Eclipse for Windows operating systems.
- **8.5.5.4** From the Admin Center Deploy tool, you cannot use the **Use the connection method and credentials configured for each target host** option of **Remote Management Credentials** to deploy Liberty 8.5.5.3 or earlier server package to a registered host. The server package must support Liberty 8.5.5.4 or later.
- **8.5.5.5** The CPU Usage chart of the Admin Center Monitor view shows either **0%** or **null%** CPU usage for JVMs that do not supply process CPU statistics. For information about the chart, see "Monitoring metrics in Admin Center" on page 1754.

## Bean validation feature restrictions

For the beanvalidation-1.0 feature, the following restriction applies:

- There is no support for bean validation inside OSGi applications.

**8.5.5.6** For the beanValidation-1.1 feature, the following restrictions apply:

- There is no support for bean validation inside OSGi applications.
- Applications that provide a custom ConstraintValidatorFactory implementation in a validation.xml file with the beanValidation-1.0 feature do not compile against the Bean Validation 1.1 API.
- If a validation.xml file is not located in the module it is associated with, then there can be only one validation.xml file and the com.ibm.ws.beanvalidation.allowMultipleConfigsPerApp property must be set to false in either of the following files:

```
| - jvm.options
|   -Dcom.ibm.ws.beanvalidation.allowMultipleConfigsPerApp=false
| - bootstrap.properties
|   com.ibm.ws.beanvalidation.allowMultipleConfigsPerApp=false
```

## Dynamic cache feature restrictions

### 8.5.5.0

The following dynamic cache features are not available or have limited availability:

- Cache replication is not supported.
- Only high performance disk caching mode is supported with random and size based eviction techniques.
- There is no support for Web Services client and server side caching as well as portlet cache in the `cachespec.xml` file.
- There is no support for servlet caching of `SingleThreadModel` servlets.
- Defining cache configuration by using properties files is not supported for JAR files that contain only Enterprise JavaBeans (EJBs).
- Limiting a heap cache size works only for 32-bit Java virtual machines (JVM).

## ejbLite-3.1 feature restrictions

### 8.5.5.0

For the `ejbLite-3.1` feature, the following restrictions apply:

- EJB modules prior to version 3.0 are not supported. This restriction also means that bindings and extensions using the `.xmi` file format rather than the `.xml` file format are not supported.
- Session beans are not bound to the `ejblocal` namespace, which means JNDI lookups and `ejb-ref` binding names must use `java:global`, `java:app`, or `java:module` names. The `simple-binding-name` and `interface-binding-name` elements are ignored in `ibm-ejb-jar-bnd.xml` files.
- The stateful bean passivation directory is not configurable. Files are passivated to the server work area.

### 8.5.5.6

## j2eeManagement-1.1 feature restrictions

For the `j2eeManagement-1.1` feature, the following restriction applies:

- The Management EJB `getListenerRegistry()` method is not supported. You cannot register an event notification listener in a Management EJB component.

### 8.5.5.0

## jaxb-2.2 feature restriction

For the `jaxb-2.2` feature, the following restrictions apply:

- If your application requires JAXB API classes and has already been started, and the `jaxb-2.2` server feature is to be enabled, you must restart the server with the `--clean` option so that your application can call the JAXB 2.2 API and implementation classes that are provided by the `jaxb-2.2` feature. Otherwise, your application might still bind to the JAXB API and implementation classes that are provided in the Java SDK.
- If the `jaxb-2.2` server feature is enabled, and you want to use your own JAXB API and implementation classes in your application, you must place your own JAXB API and implementation JAR files into the `/WEB-INF/lib` directory of your application, and configure the class loader of your application to use *parentLast* delegation behavior. Other wise, the JAXB API and implementation classes that are provided by the `jaxb-2.2` feature always take effect. For more information of configuring class loader behavior for you applications on Liberty, see “Overriding a provided API with an alternative version” on page 1600.

## 8.5.5.0

### jaxws-2.2 feature restrictions

For the jaxws-2.2 feature, the following restrictions apply:

- If your application provides its own copy of CXF JAR files as the application libraries, for example, in the WEB-INF/lib directory of a web application, you cannot enable the jaxws-2.2 feature in the server.xml file.
- Because the jaxws-2.2 feature depends on the jaxb-2.2 feature, the jaxb-2.2 feature restrictions also apply to the jaxws-2.2 feature.
- If your application requires JAX-WS API classes and has already been started, and the jaxws-2.2 server feature is to be enabled, you must restart the server with the --clean option so that your application can call the JAX-WS 2.2 API and implementation classes that are provided by the jaxws-2.2 feature. Otherwise, your application might still bind to the JAX-WS API and implementation classes that are provided in the Java SDK
- The web services binding file for Liberty is the ibm-ws-bnd.xml file. The following web services binding files for WebSphere Application Server traditional are not supported:
  - ibm-webservices-ext.xml
  - ibm-webservices-bnd.xml
  - ibm-webservicesclient-ext.xml
  - ibm-webservicesclient-bnd.xml
  - ws-security.xml
- The Apache Axis2 configurations or classes are not supported.
- The web service providers that implement javax.xml.ws.Provider<OMElement> or javax.xml.ws.Provider<String> interface are not supported.
- The **content-id** attribute of MIME attachments must be enclosed with angle brackets for Liberty. For example, <testID>.
- The **-inlineSchemas** option is not supported by the **wsgen** tool that is provided by Liberty.
- Enable MTOM if you want to transfer big binary data using JAX-WS web services to avoid the Out of Memory (OOM) error.
- For web service applications, if the service client and service provider are not in the same application and the WSDL file in the service provider application is changed, you need to restart the web service client application manually to avoid the WSDL definition cache issue.

## 8.5.5.6

### jpa-2.1 feature restrictions

For the jpa-2.1 feature, JPA entity exchange over CORBA/RMI-IIOP requires that both participants in the communication must enable identical JPA feature levels.

### jsp-2.2 feature restrictions

For the jsp-2.2 feature, the following restriction applies:

- There is no support for the useInMemory configuration option to only store the translated JSP file in memory.

## 8.5.5.9

### logstashCollector-1.0 feature restrictions

The following limitations apply to the logstashCollector-1.0 feature:

- Data Loss – Some events that are generated in Liberty might not be forwarded to Logstash as expected. Data loss might occur under the following scenarios:

1. Starting the Liberty server before the Logstash server is started. It is recommended that you start the Logstash server before starting the Liberty server.
  2. Heavy load conditions. Events might be dropped in cases where events are created in Liberty faster than they can be processed by Liberty's event pipeline, Logstash, and any other downstream consumers. Liberty uses buffers to avoid data loss when event creation is briefly faster than event consumption.
- The `logstashCollector-1.0` feature is tested and is compatible with Logstash V2.x.

#### 8.5.5.0

### **monitor-1.0 feature restriction**

For the `monitor-1.0` feature, the following restriction applies:

- When the feature is removed from the `server.xml` file, you must restart the server to make the JAX-WS applications work.

#### 8.5.5.6

### **requestTiming-1.0 feature restrictions**

For the `requestTiming-1.0` feature, the following restriction applies:

- The `requestTiming-1.0` feature, when activated, has been shown to have an 4% impact on maximum possible application throughput when measured with the DayTrader application. While the impact on your application might be more or less than that, you should be aware that some performance degradation might be noticeable.

#### 8.5.5.6

### **restConnector-1.0 feature restriction**

For the `restConnector-1.0` feature, the following restriction applies:

- Users of the `restConnector-1.0` feature or any feature that includes `restConnector-1.0`, such as `collectiveMember-1.0` and `collectiveController-1.0`, who want to run applications containing a custom JAXRS 2.0 runtime must add the `jaxrs-2.0` feature to that server.

#### 8.5.5.8

### **scim-1.0 feature restrictions**

The following restrictions apply for the `scim-1.0` feature:

- The `members` attributes are not retrieved while searching for groups.
- The `groups` attributes of users are not retrieved while searching for users.
- The Canonical type of `direct/indirect` cannot be set for groups attribute of users.
- Only one `email` attribute of user of Canonical type, `work`, can be defined.
- Only one `ims` attribute of user of Canonical type, `work`, can be defined.
- Extended schema attributes of SCIM such as `entitlements`, `roles` and `x509Certificates` cannot be set or returned.
- The `userName` attribute cannot be used with some other attributes in a filter.
- For users in Basic and SAF registries, only `userName`, `displayName`, `id`, `schema`, `meta.location` and `groups` can be set. The `userName` and `displayName` will have the same value.
- List/query with Basic and SAF registries does not work the same as the `ldapRegistry` registry.
- Operators like `pr`, `gt`, `ge`, `lt`, `le`, `and`, `or`, and `()` will not work with Basic and SAF registries. Also, only one operator must be used in the filter for Basic and SAF registries.
- Basic and SAF are read only registries.
- While creating user, `groups` attribute cannot be set.

## wmqJmsClient-1.1 feature restrictions

8.5.5.0

For the wmqJmsClient-1.1 feature, the following restrictions apply:

8.5.5.0

- You must manually set the PATH variable in the Windows environment variables to point to the IBM MQ installation bin directory. You must set this path variable when the application uses the BINDING connection mode.
- The IBM MQ classes for Java (generally called the Base Java) are not included in the wmqJmsClient-1.1 feature. This is included in the Resource Adapter for other application servers but is not recommended for the Base Java APIs in the Java Enterprise Edition environments. For more information, see Using IBM MQ Java Interfaces in J2EE/JEE Environments.
- The BINDINGS\_THEN\_CLIENT transport type of IBM MQ resource adapter is not supported for the wmqJmsClient-1.1 feature.
- The Advanced Messaging Security (AMS) feature is not included for the wmqJmsClient-1.1 feature.

8.5.5.6

## wmqJmsClient-2.0 feature restrictions

For the wmqJmsClient-2.0 feature, the following restrictions apply:

- You must manually set the PATH variable in the Windows environment variables to point to the IBM MQ installation bin directory. You must set this path variable when the application uses the BINDING connection mode.
- The IBM MQ classes for Java (generally called the Base Java) are not included in the wmqJmsClient-2.0 feature. This is included in the Resource Adapter for other application servers but is not recommended for the Base Java APIs in the Java Enterprise Edition environments. For more information, see Using IBM MQ Java Interfaces in J2EE/JEE Environments.
- The BINDINGS\_THEN\_CLIENT transport type of IBM MQ resource adapter is not supported for the wmqJmsClient-2.0 feature.

## collectiveController-1.0 feature restriction

8.5.5.0

If you start a collective controller server and then change your IP configuration, the controller no longer functions correctly.

## concurrent-1.0 feature restrictions

8.5.5.4

For the concurrent-1.0 feature, the following restrictions apply:

For the thread context of type securityContext, any custom information in the subject that was not added by using a JAAS login module will not be propagated. For example, if the submitter's subject contains a custom Principal that was added by a TAI, the propagated subject will not contain this custom Principal.

8.5.5.6

## jacc-1.5 feature restrictions

For the jacc-1.5 feature, the following configurations are ignored:

- Authorization information (the users and groups attributes of the authorizations attribute) in an ibm-application-bnd.xml file or an ibm-application-bnd.xmi file of the application's ear file.
- Authorization information (the user, group and special-subject attributes of the security-role attribute in the application-bnd element) in the server.xml file.

---

## Liberty: Developer Tools known issues and restrictions

### Distributed operating systems

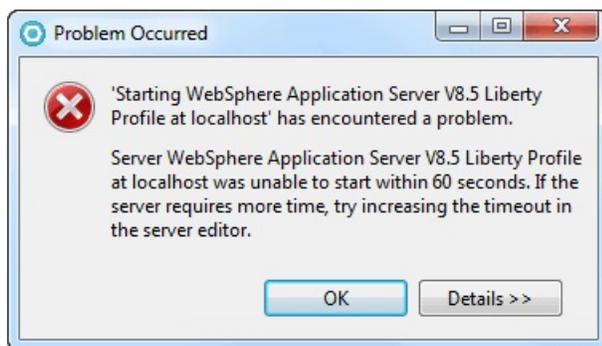

Several known issues and restrictions apply when you are working with WebSphere Application Server Developer Tools for Eclipse.

See also “Liberty:Runtime environment known issues and restrictions” on page 2333.

### 8.5.5.0

## Unable to interact with the Liberty server after you modify the console log level settings

There is a known limitation when the console log level is set to WARNING, ERROR, or OFF. The workbench has problems when it interacts with the Liberty server, such as cannot start, stop, or publish to the server. For example, the workbench is unable to start the Liberty server and the following timeout error message displays:

The console log level (`consoleLogLevel`) is an attribute of the logging configuration element in the server configuration (`server.xml`) file with the following range options: INFO, AUDIT, WARNING, ERROR, and OFF. AUDIT is the default value for the console log level settings. For more details, search for the `consoleLogLevel` attribute in the topic.

To work around this known limitation, specify INFO or use the default AUDIT setting for the console log level:

1. In the Servers view, expand your Liberty server.
2. Right-click the **Server Configuration[server.xml]** node and select **Open**.
3. In the Server Configuration editor and under the **Configuration Structure** section, expand **Server Configuration** node. The next step depends if the **Logging** element is available:
  - If the **Logging** element is available, select it and under the **Logging** section of the server configuration editor, use the drop-down menu for the **Console log level** field, and select either the AUDIT or INFO option. Type `Ctrl + s` to save your changes in the editor.
  - If the **Logging** element is not available, the workbench is already using the default AUDIT setting. As a result, you might be experiencing a different problem that is causing interaction failures between the workbench and the Liberty server.

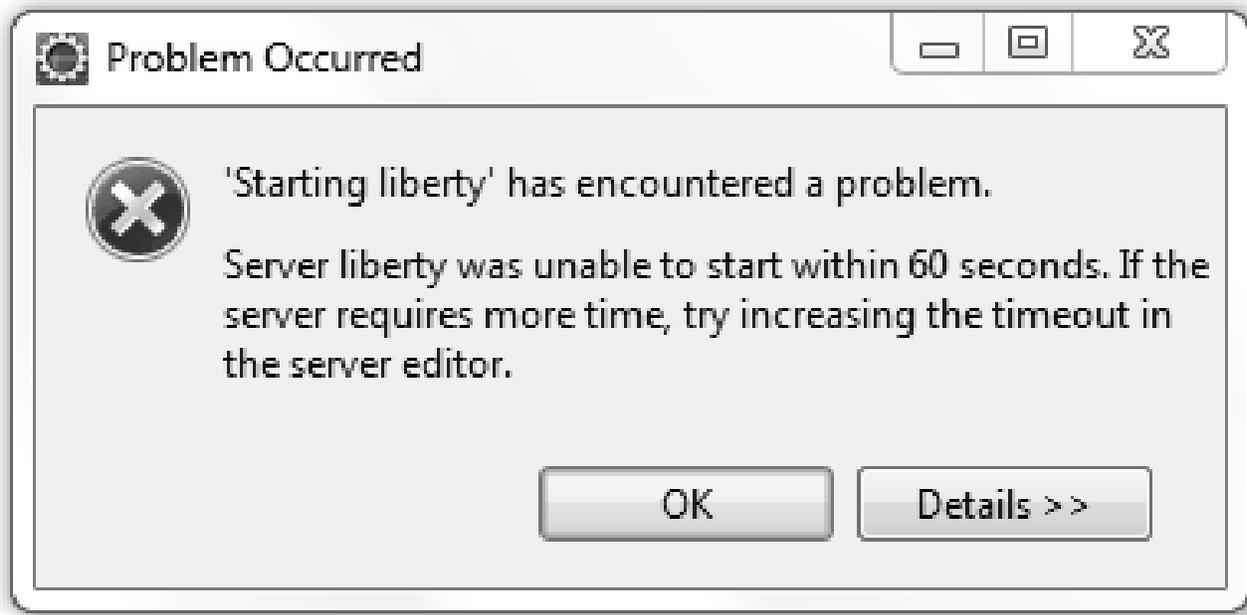

## Copying and pasting servers might cause the publishing state to become out of synchronization

Try to avoid copying and pasting servers because they point to the same configuration file. Copying and pasting servers might cause the publishing state to become out of synchronization. For example, when you remove an application from one server, the application still appears to be deployed to the other server even though it is not. Server state will not synchronize up again until the next publish operation.

8.5.5.4

### Unable to recognize the start of the server when the hideMessage attribute is used to suppress the messages

You can configure the <hideMessage> attribute in the Logging element of **Server Configuration** [server.xml] to suppress messages. If you configure to hide the server start message, for example <logging hideMessage="CWWKF0011I"/>, then the tool fails to recognize the state of the server when it is started. In such a situation, the state of the server in the **Server** view remains as *starting* until timeout and finally displays the following message:

8.5.5.4

### Remote servers cannot run projects that were created with a newer version of Java

If you compile a project with a higher version of Java than your remote server is running, you can receive the following error messages:

```
Error 404: javax.servlet.UnavailableException:  
SRVE0202E: Servlet [s1]: s1 was found, but is corrupted:  
SRVE0227E: Check that the class resides in the proper package directory.  
SRVE0228E: Check that the classname has been defined in the server using the proper case and fully qualified package.  
SRVE0229E: Check that the class was transferred to the filesystem using a binary transfer mode.  
SRVE0230E: Check that the class was compiled using the proper case (as defined in the class definition).  
SRVE0231E: Check that the class file was not renamed after it was compiled.
```

If you create a project in a package with a higher version of Java than your remote server is running, you can receive the following error messages:

```

Error 404: java.io.FileNotFoundException: SRVE0190E: File not found: /s2
Console output: [ERROR ] SRVE0266E: Error occurred while initializing servlets: java.lang.UnsupportedClassVersionError:
at java.lang.ClassLoader.defineClassImpl(Native Method)
at java.lang.ClassLoader.defineClass(ClassLoader.java:383)
at com.ibm.ws.classloading.internal.AppClassLoader.definePackageAndClass(AppClassLoader.java:318)
at [internal classes]

```

To avoid these errors, compile your project with the same version of Java that your remote server is running, or with an earlier version. You can also create your project in a package with the same version of Java that your remote server is running, or with an earlier one. To find the Java version of the remote server, check the `messages.log` file. For more information about viewing the `messages.log` file, see “Viewing trace and message log files by using developer tools” on page 2317.

8.5.5.10

## Some utilities are unavailable when you use a remote Liberty server or a Liberty server in a Docker container

WebSphere Developer Tools do not support some of the utilities when you use a remote Liberty server or Liberty server in a Docker container.

The tools do not support the following utilities when you use a remote Liberty server:

- **Generate Web Server Plug-in...**
- **Add Config Snippets...**

The tools do not support the following utilities when you use a Liberty server in a Docker container:

- **Generate Web Server Plug-in...**
- **Package Server...**
- **Create Collective...**
- **Add Config Snippets...**

---

## Liberty:Messages

When you use Liberty, you might encounter system messages. Each message has a unique message identifier, and includes an explanation of the problem, and details of any action that you can take to resolve the problem.

Liberty system messages are logged from various sources, including application server components and applications. For Liberty, the message identifier is 10 characters in length and has the following form:

CWXXX9999X

where:

**CWXXX**

Is a five-character alphabetic message prefix that identifies the Liberty component.

**9999** Is a four-character numeric identifier used to identify the specific message for that component.

**X** Is an optional alphabetic indicator that identifies the message type: I=Informational, W=Warning, E=Error.

*Table 188. Alphabetic message prefixes for Liberty messages*

Liberty message prefix	Range	Liberty component
CWIMK	0001-0500	LDAP registry federation (configuration messages)
CWIML	0001-5000	LDAP registry federation (runtime messages)

Table 188. Alphabetic message prefixes for Liberty messages (continued)

Liberty message prefix	Range	Liberty component
CWLIB	0001-0100	Transactions
	0101-0200	z/OS Transaction Extensions
CWWKB		<i>z/OS Native integration</i>
	0001-0050	z/OS Command Processing
	0051-0100	z/OS Native code only
	0101-0150	z/OS Core
	0151-0200	z/OS WLM services
	0201-0250	z/OS Native code non-console
CWWKC	0000-0250	Annotation scanning
CWWKE		<i>Core kernel and kernel services</i>
	0001-0099	Boot/Launcher
	0100-0199	Service utilities
	0200-0299	Location service
	0300-0399	File installation service
	0400-0499	FileMonitor service
	0500-0599	Extensible Class Scanner
CWWKF		Feature manager
CWWKG		Configuration manager
CWWKJ		Light touch administration
CWWKL	0001-0100	Class loading service
CWWKM	0001-0050	Artifact API messages (container factory)
	0051-0100	Overlay Messages (all implementations)
	0101-0150	Artifact API Zip implementation
	0151-0200	Artifact API File implementation
	0401-0450	Adaptable API Implementation messages (adaptable module factory / adapter service)
	1001-1100	Loose archive API (used by the Eclipse-based tools option that runs an application directly from the Eclipse workspace(The Eclipse platform supports a "virtual" application archive, where a set of files that appear to be in the same archive file are actually spread out across the Eclipse workspace. Liberty calls this a "loose archive", and the tools option that uses the loose archive API is called <b>Run this application directly from the workspace</b> )).
	2000-2999	Ant and Maven plug-in
CWWKN	0001-0100	JNDI default namespace

Table 188. Alphabetic message prefixes for Liberty messages (continued)

Liberty message prefix	Range	Liberty component	
CWWKO		CFW components	
	0000-0199	CFW	
	0200-0399	TCP	
	0400-0599	UDP	
	0600-0799	bytebuffer	
	0800-0899	SSL channel	
	0900-0999	SSL

## Liberty: Abend reason codes

z/OS

When you use Liberty, you might encounter abend reason codes. Each message has a unique message identifier, and includes an explanation, and details of any action that you can take.

**Note:** Abend reason codes that are not listed in this chapter must be reported to the IBM Support Center.

Table 189. Liberty for z/OS abend codes

Abend code	Abend reason	Explanation	Suggested action
EC3 hex	20000005	The BBGZSAFM module cannot be loaded from the file system.	Make sure that Liberty is installed without errors, and that the user ID running Liberty server has permission to read the files in Liberty installation. If the problem persists, contact your next level of support.
EC3 hex	20000006	The BBGZSAFM module is not APF-authorized.	Make sure that Liberty is installed without errors. The BBGZSAFM module must have been installed with the APF authorization bit set. If the problem persists, contact your next level of support.

Table 189. Liberty for z/OS abend codes (continued)

Abend code	Abend reason	Explanation	Suggested action
EC3 hex	20000007	A call to UNIX System Services stat function to the BBGZSAFM load module failed.	Make sure that Liberty is installed without errors, and that the user ID running Liberty server has permission to read the files in Liberty installation. If the problem persists, contact your next level of support.
EC3 hex	20000008	The path name to the BBGZSAFM module in the file system is too long. The path cannot be more than 4096 characters.	Install Liberty to the file system that can be accessed with a shorter PATH.
EC3 hex	20000009	The size of the BBGZSAFM module is smaller than the minimum size for this load module.	Make sure that Liberty is installed without errors. If the problem persists, contact your next level of support.
EC3 hex	2000000A	The size of the BBGZSAFM module is smaller than the minimum size for this load module based on the number of functions it contains.	Make sure that Liberty is installed without errors. If the problem persists, contact your next level of support.

## Troubleshooting OSGi applications by using developer tools

### 8.5.5.9

You can configure the `osgiAppConsole-1.0` feature with WebSphere Developer Tools and then use it to determine and analyze the OSGi applications-related issues.

### Before you begin

- Install WebSphere Developer Tools for Eclipse and WebSphere Application Server Liberty. You can install the tools by using downloaded installation files. For more information about installing WebSphere Developer Tools and Liberty, see “Installing Liberty developer tools and (optionally) Liberty” on page 1374.
- Deploy an OSGi application to a running Liberty server.
- The `osgiAppConsole-1.0` feature is available as part of the downloaded compressed files. If the feature is not already installed, then install the feature from the Liberty Repository by using the following command:

```
bin\installUtility install osgiAppConsole-1.0
```

### Procedure

1. Configure the `osgiAppConsole-1.0` feature in the `server.xml` file.

```
<featureManager>
  <feature>osgiAppConsole-1.0</feature>
</featureManager>
```

2. Add the security configurations.

The following example shows a sample security configuration with an admin role that uses basic authorization and HTTPS security.

```
<httpEndpoint httpPort="9080" httpsPort="9443" id="defaultHttpEndpoint"/>
<keyStore id="defaultKeyStore" password="Liberty"/>
<quickStartSecurity userName="admin" userPassword="password"/>
```

3. Start the OSGi Application Console or the OSGi Shared Bundle Console by completing one of the following tasks.
  - Start the OSGi Application Console:
    - a. In the Servers view, right-click the OSGi module.
    - b. Select **Launch OSGi Application Console**.The tools open a browser that displays the OSGi Application Console page.
  - Start the OSGi Shared Bundle Console:
    - a. Right-click your server.
    - b. Select **Utilities > Launch OSGi Shared Bundle Console**.The tools open a browser that displays the OSGi Shared Bundle Console page.

---

## Troubleshooting Session Initiation Protocol (SIP) on Liberty

Troubleshoot SIP by using the available log and trace facilities. You can use the default log and trace facility, or you can enable binary logging for high-performance, extensible logging and tracing.

### Troubleshooting the SIP container session repository on Liberty

8.5.5.7

When you troubleshoot the SIP container session repository, you might need the SIP session details to dump to a specified trace file.

#### About this task

You can use the SIP session memory dump utility to help debug problems that are related to SIP container sessions. The SIP container provides the `SipContainerMBean` method to perform several serviceability type operations on the SIP container, including the initiation of a server quiesce through the command line. This task describes how you can use the `SipContainerMBean` method to dump SIP application session and SIP session information that is contained in the in-memory session repository for SIP containers. By configuring the `SIPContainerMBean` method to use various trace methods, you can specify the SIP session details to dump to the specified trace file.

When the session dump methods are started, the requested information about the sessions prints by default into the `console.log` file. You can also send the information to a predefined source specified on the `setDumpMethod` method.

You can run the dumping utility in two modes, *succinct* and *verbose*. When you use the succinct session dump methods, only the session IDs are printed for every dump method execution. If you want to use the verbose session dump methods, the following actions occur:

- Transaction user details, along with the SIP session details, if they exist, print for every dump method execution.
- The only attributes that dump to the trace file are those attributes that the JSR 289 specification permits for exposure.
- The verbose methods print the following information in the trace file: `appName`, `callID`, `dialog state`, `creation time`, `attribute names`.

The trace printouts occur per SIP application; therefore, the sorting of all the SIP session data structures occurs before printing. The `SIPContainerMBean` dump facility runs in a low-priority thread so that the tracing does not affect the call processing latency of the overall system for a production server.

The dump distinguishes between a transaction user that has a SIP session versus a transaction user that has no SipSession object. Also included in the dump, in a delineated fashion, are SIP sessions that no longer exist, that are no longer valid, or that exist at the time of the trace snapshot.

On Liberty, you can invoke the SipContainerMBean dumping methods in two ways:

- By running the **server dump** command
- By implementing a Java Management Extensions (JMX) client that establishes a connection to the JMX connector to invoke the methods

The following succinct SipContainerMBean methods are used to dump SIP session IDs.

*Table 190. Succinct SipContainerMBean methods used to dump SIP session information.*

Method	Description
dumpAllSASIDs()	Prints a number of all SIP application sessions and the SIP application session IDs.
dumpAllTUSipSessionIds()	Prints a number of transaction users and the SIP session IDs within the transaction user (TU), if one exists.

The following verbose SipContainerMBean methods are used to dump SIP session details.

*Table 191. Verbose SipContainerMBean methods used to dump SIP session information.*

Method	Description
dumpAllSASDetails()	Prints a number of all SIP application sessions and the SIP application session ID details.
dumpAllTUSipSessionDetails()	Prints a number of transaction users and details of the SIP session IDs within the transaction user (TU), if one exists.
dumpSASDetails(String sasId)	Prints the details of the SIP application session that is specified by the sasId parameter.
dumpSipSessionDetails(String sessionId)	Prints the details of the SIP session that is specified by the sessionId parameter.

**Note:** Use the following information to help parse print output:

- For all print output, the first line provides an application name and a number of records.
- The delimiter between the output is a TAB.
- The delimiter between session attributes is a ; (semi-colon).

## Procedure

- Invoke the SipContainerMBean methods with the **server dump** command. For more information about the **server dump** command, see “Generating a Liberty server dump from the command line” on page 1579.

1. In the server.xml file, specify the dumping utility mode on a sipIntrospect element.

- For succinct mode, specify the following code:

```
<sipContainer>
  <sipIntrospect method="SUCCINCT"/>
</sipContainer>
```

- For verbose mode, specify the following code:

```
<sipContainer>
  <sipIntrospect method="VERBOSE"/>
</sipContainer>
```

2. Open a command line and change to the wlp/bin directory.

- To generate the SIP sessions and SIP application sessions dump, run the following command, where *server\_name* is the Liberty server:

```
server dump server_name
```

If you do not specify a server name, defaultServer is used.

You can optionally specify the name of the server dump package file on the **archive** parameter:

```
server dump server_name --archive=package_file_name.dump.zip
```

After you run the command, the server dump package file is generated and contains the following files:

- SipContainerIntrospector.txt, which includes the requested level of trace information about the SIP application sessions and SIP sessions
- Other *artifact*Introspector.txt files, which provide the server status information

SipContainerIntrospector.txt includes the following information, where dump.ids.test.appl is the application name, 2 is the number of sessions, and the local.##### lines are the SAS\_ids:

The description of this introspector:  
SIP state details

Succinct dumping

```
dump.ids.test.appl 2
local.1347524282775_8
local.1347524282775_7
```

--- End of Dump ---

- Invoke a specific dumping utility method through JMX connectors. For more information, see “Connecting to Liberty by using JMX” on page 1641 and “Developing a JMX Java client for Liberty” on page 1645.

The following Java code example invokes the dumpAllSASIDs method:

```
System.setProperty("javax.net.ssl.trustStore", "..\\wlp\\usr\\servers\\SIPServer\\resources\\security\\key.jks");
System.setProperty("javax.net.ssl.trustStorePassword", "Liberty");
```

```
//If the type of the trustStore is not jks, which is default,
//set the type by using the following line.
System.setProperty("javax.net.ssl.trustStoreType", "jks");
```

```
try {
    HashMap<String, Object> environment = new HashMap<String, Object>();
    environment.put("jmx.remote.protocol.provider.pkgs", "com.ibm.ws.jmx.connector.client");
    environment.put("com.ibm.ws.jmx.connector.client.disableURLHostnameVerification", Boolean.TRUE);
    environment.put(JMXConnector.CREDENTIALS, new String[] { "theUser", "thePassword" });
    environment.put(ConnectorSettings.DISABLE_HOSTNAME_VERIFICATION, true);

    JMXServiceURL url = new JMXServiceURL("service:jmx:rest://localhost:9443/IBMJMXConnectorREST");
    JMXConnector connector = JMXConnectorFactory.newJMXConnector(url, environment);
    connector.connect();
    MBeanServerConnection connection = connector.getMBeanServerConnection();

    // test dumping utility
    connection.invoke(new ObjectName("WebSphere:name=com.ibm.ws.sip.container.SipContainerMBean"), "dumpAllSASIDs",
```

Succinct SipContainerMBean methods have the following print formats.

Table 192. Succinct SipContainerMBean method print formats.

Method	Print format
dumpAllSASIDs()	Each line represents a SIP application session ID, in the format [SAS_ID].  For example: local.1347524282775_8

Table 192. Succinct SipContainerMBean method print formats (continued).

Method	Print format
dumpAllTUSipSessionIds()	Each line represents the transaction ID, whether the transaction has a SIP session, and the session ID if it exists, in the format [TU_ID] [hasSIPSession] [SipSessionId]  For example: local.1349965420866_1_0 true local.1349965420866_1_0_1

Verbose SipContainerMBean methods have the following print formats.

Table 193. Verbose SipContainerMBean method print formats.

Method	Description
dumpAllSASDetails()	Each line represents the SIP application session ID, the creation time, and the SIP session attributes, in the format [SAS_ID] [CreationTime] [attributes]  For example: local.1348147884986_2 Sep 20,2012 16:31 DumpSasDetailsAttr;
dumpAllTUSipSessionDetails()	Each line represents the transaction ID, whether the transaction has a SIP session, and the session details if it exists, in the format [TU_ID] [hasSIPSession] [SipSessionId] [Call-Id] [DialogState] [hasOutgoingTransaction] [initialMethod] [SAS_ID] [CreationTime] [attributes]  For example: local.1349965420866_1_0 true local.1349965420866_1_0_1 8-8548@9.148.57.128 2 false INVITE local.1349965420866_1 Jan 24,2013 14:41 TestSSAttr1; TestSSAttr2;
dumpSASDetails(String sasId)	Only one line is printed, in the format [TU_ID] [hasSIPSession] [SipSessionId]  For example: local.1349965420866_1_0 true local.1349965420866_1_0_1  If the requested session does not exist, the following error message is printed: ERROR: Requested session <local.1349965420866_1_0_1> does not exist.
dumpSipSessionDetails(String sessionId)	Only one line is printed, in the format [SipSessionId] [Call-Id] [DialogState] [hasOutgoingTransaction] [initialMethod] [SAS_ID] [CreationTime] [attributes]  For example: local.1349965420866_1_0_1 8-8548@9.148.57.128 2 false INVITE local.1349965420866_1 Jan 24,2013 14:41 TestSSAttr1; TestSSAttr2;  If the requested session does not exist, the following error message is printed: ERROR: Requested session <local.1349965420866_1_0_1> does not exist.

## Tracing a Session Initiation Protocol (SIP) container on Liberty

8.5.5.7

You can trace a Session Initiation Protocol (SIP) container, starting either immediately or after the next server start. This tracing writes a record of SIP events to a log file.

## Procedure

In the `server.xml` file, add a logging element and specify tracing for the SIP container by setting `traceSpecification="*=info:com.ibm.ws.sip=all"`.

```
<logging logDirectory="${server.config.dir}/logs" traceFileName="trace.log" traceSpecification="*=info:com.ibm.ws.sip=all"/>
```

## Results

SIP-level tracing messages appear in `serverName/logs/trace.log`, where `serverName` is the name of the specific instance of the application server that is running the SIP container to be traced. These messages include application load events as well as SIP request and response parsing and SIP servlet invocation.

## Session Initiation Protocol (SIP) binary log and trace extensions on Liberty

8.5.5.7

Binary logging provides a way for developers to add extension fields to log and trace records, and a corresponding way for you to filter log and trace records by extension value.

Log and trace records contain fields for information such as the time the record was created and the content of the message that is logged. These fields are core fields that are present in every log and trace record. In contrast, extension fields are fields which application developers can add to log and trace records, which you can use as filter criteria when you search for specific log and trace content. These log and trace extensions are visible in the binary log when you configure the text output format to use the advanced format, or they are visible when you use the `binaryLog` command in the advanced format.

### Administrators

The application server automatically creates a number of extensions that you can use to filter log and trace records. You can also filter log and trace records by using any extensions that are added by your application developers. You can use the `binaryLog` command-line tool to filter records based on the content of log and trace record extensions. For more information, see “BinaryLog command options” on page 1027.

For example, to see all SIP application sessions that the SIP container processed, you can use the following `binaryLog` command:

```
binaryLog view binaryFile --includeExtension=SIPASId=* --format=advanced
```

### Developers

Developers can use binary logging to add custom extensions to log and trace records through the log record context API, `com.ibm.websphere.logging.hpel.LogRecordContext`. When binary logging stores log and trace records, it includes any extensions that are present in the log record context on the same thread. For example, you can write a servlet filter to add important HTTP request parameters to the log record context. While that servlet runs, the HPEL API adds those extensions to any log and trace records that are created on the same thread.

As with other log and trace record fields, developers can access the record extensions by using the HPEL API. This API is useful when you write tools to read from log and trace repositories. Developers can also use the log record context API to access extensions in custom log handlers, filters, and formatters at run time.

The following table describes the log and trace extensions, including the identifier that you can use to filter various aspects of the trace.

Table 194. Log and trace extensions.

Extension	Description
appName	Specifies the name of the Java Platform, Enterprise Edition (Java EE) application that the log or trace record relates to, if any.
requestID	Specifies the unique ID of the request that each log or trace record relates to, if any. For the application server to add the requestID extension to log and trace records, you must enable Cross Component Trace (XCT), also referred to in the administrative console as log and trace correlation. Request IDs are only added for certain types of requests, such as HTTP or JMS requests.
SIPCallId	Specifies the SIP call identifier that is being processed by the SIP proxy server or SIP container. This information is common across SIP proxy servers and SIP containers. You can use this extension to track the SIP call flow across the various components. The SIP proxy server and SIP container automatically adds this identifier to each log and trace record when HPEL logging is enabled.
SIPASId	Specifies the SIP application session ID that is being processed by the SIP container. This information is common across SIP containers. You can use this extension to track the SIP call flow. The SIP container automatically adds this identifier to each log and trace record when HPEL logging is enabled.
SIPSessionId	Specifies the SIP session ID that is being processed by the SIP container. This information is common across SIP containers. You can use this extension to track the SIP call flow. The SIP container automatically adds this identifier to each log and trace record when HPEL logging is enabled.
SIPCallId2	<p>Specifies the second SIP call ID that is associated with the same SIP application session and is being processed by the SIP container. This information is common across SIP containers. You can use this extension to track the SIP call flow. The SIP container automatically adds this identifier to each log and trace record when HPEL logging is enabled.</p> <p>If more than two SIP call IDs are associated with a single SIP application session, only the first two IDs are recorded. The additional IDs are not recorded.</p>
SIPSessionId2	<p>Specifies the second SIP session ID that is associated with the same SIP application session and is being processed by the SIP container. This information is common across SIP containers. You can use this extension to track the SIP call flow. The SIP container automatically adds this identifier to each log and trace record when HPEL logging is enabled.</p> <p>If more than two SIP session IDs are associated with a single SIP application session, only the first two IDs are recorded. The additional IDs are not recorded.</p>
thread	Specifies the thread name of the request that each log or trace record relates to.
