      </queuePermission>

    <topicPermission topicSpaceRef="TopicSpace1" topicName="Sports/Cricket">
      <action>ALL</action>
    </topicPermission>

    <user name="user1" />
    <user name="user3" />
    <group name="Developers" />

```

```

    </role>

    <role name="tester">
      <queuePermission queueRef="QUEUE1">
        <action>BROWSE</action>
      </queuePermission>

      <topicPermission topicSpaceRef="TopicSpace1">
        <action>RECEIVE</action>
      </topicPermission>

      <user name="user5" />
      <user name="user6" />
      <group name="Testers" />
    </role>
  </messagingSecurity>
</messagingEngine>

```

In the previous configuration, users *user1* and *user3* and the group *Developers* can perform the SEND and BROWSE actions on *QUEUE1*. They can also perform ALL actions on the topics *Sports/Cricket* in *TopicSpace1*. Similarly, users *user5* and *user6* and the group *Testers* can perform the BROWSE action on queue *QUEUE1* and the RECEIVE action on all the topics in *TopicSpace1*.

3. Optional: When you are connecting to the messaging engine, specify the user name and password in the `createConnection` call.

The following is the syntax:

```
[createConnection(userName, password)]
```

Connect to the messaging engine as an authenticated user and perform the operation that is based on the authorization permissions that are declared by the administrator.

## Enabling interoperability between Liberty and WebSphere Application Server traditional

### 8.5.5.0

The JMS applications that are deployed within Liberty can connect to the messaging engine that runs in the WebSphere Application Server traditional (that is, service integration bus). Similarly, the JMS applications that are deployed within the WebSphere Application Server traditional can connect to the messaging engine that runs in Liberty.

### About this task

The following image depicts the interoperability options for configuring your JMS applications to interact between Liberty messaging and service integration bus in WebSphere Application Server traditional.

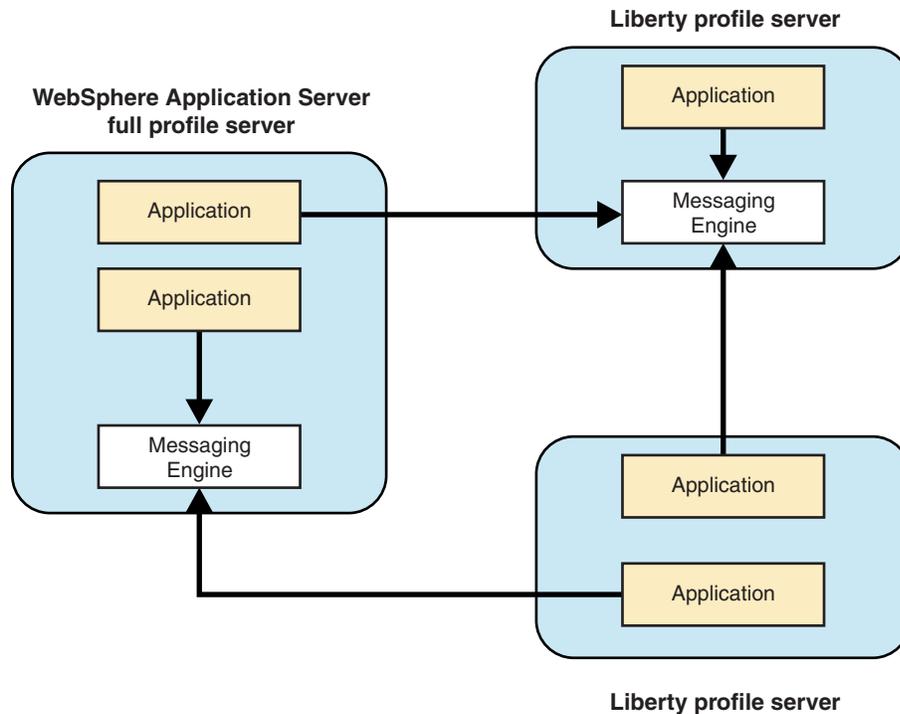

Figure 19. Interoperability between Liberty and WebSphere Application Server traditional

The following tasks provide more information about enabling interoperability between Liberty and WebSphere Application Server traditional.

- “Enabling the JMS application on Liberty to connect to service integration bus”
- “Enabling the JMS application on WebSphere Application Server traditional to connect to Liberty messaging” on page 1132

## Enabling the JMS application on Liberty to connect to service integration bus

8.5.5.6

You can configure the JMS application that is running in Liberty to connect to the service integration bus.

### Procedure

To enable the JMS application to connect to the service integration bus that is running on a WebSphere Application Server traditional server, add the `wasJmsClient-2.0` feature in the `server.xml` file. If you want to perform a JNDI lookup, then you must also add the `jndi-1.0` feature.

```
<featureManager>
  <feature>wasJmsClient-2.0</feature>
  <feature>jndi-1.0</feature>
</featureManager>

<jmsQueueConnectionFactory jndiName="jndi_JMS_BASE_QCF">
  <properties.wasJms
    busName="Bus1"
    remoteServerAddress="localhost:7276:BootStrapBasicMessaging"
    targetTransportChain="InboundBasicMessaging"/>
</jmsQueueConnectionFactory>
```

```
<jmsQueue jndiName="jndi_INPUT_Q">
  <properties.wasJms queueName="Q1" />
</jmsQueue>
```

**Note:** The <remoteServerAddress> must specify the host and port of the server on which the messaging engine is running instead of specifying a bootstrap server.

### Enabling the JMS application on WebSphere Application Server traditional to connect to Liberty messaging:

You can configure JMS applications that are running on the WebSphere Application Server traditional server to connect to Liberty messaging.

#### Procedure

To enable JMS applications that are deployed on the WebSphere Application Server traditional server to connect to Liberty messaging, configure the **Bus name** and the **ProviderEndPoint** in the WebSphere Application Server traditional server to specify the host and port where the Liberty messaging engine is running.

For more information about configuring the bus name in the connection factory in WebSphere Application Server traditional, see Default messaging provider unified connection factory [Settings].

**Note:** The JMS resources that are pointing to the Liberty messaging engine must always specify the **Bus name** as defaultBus (case sensitive).

## Configuring connection pooling for JMS connections

### 8.5.5.1

You can customize the number of concurrent connections (default is 50) that can be created from a JMS connection factory. You can configure connection pooling for a specific JMS connection factory by defining the <connectionManager> element and then associate that element with the JMS connection factory in the server.xml file.

#### Example

The connectionManager element in the server.xml file is used to the connection pool for a JMS connection factory property as given in the following example. The connection pool size is also defined in the connectionManager element.

```
<jmsConnectionFactory id="jmscf1"
  jndiName="jndi/example"
  connectionManagerRef="cm1">
  <properties.wasJms />
</jmsConnectionFactory>
<connectionManager id="cm1" maxPoolSize="10" minPoolSize="2" />
```

The server uses default values for any connection management settings that are not defined on the connectionManager element. If a connection manager is not defined for a connection factory, the server uses the default values for all the settings.

You can define multiple connection factories and associate each with a different connection manager. However, you cannot associate multiple connection factories with a single connection manager.

For more information about the connectionManager element, see .

# Securing JMS communications in Liberty by using SSL

0.5.5.0

You can configure the `ssl-1.0` feature to enable secure communication between the two Liberty servers.

## Before you begin

To secure JMS communications by using SSL, you must configure the SSL feature by providing SSL certificate-related configurations. For more information, see “Enabling SSL communication in Liberty” on page 1834.

## Procedure

### 1. Configure SSL on the server.

- Service integration bus has the following default SSL configuration.

```
<wasJmsEndpoint
  host="*"
  wasJmsSSLPort="7286" >
</wasJmsEndpoint/>
```

Service integration bus inbound uses the `<keyStore>` element as the default SSL configuration. See “Enabling SSL communication in Liberty” on page 1834 for detailed information.

- To modify the configuration to point to a different SSL configuration other than the default, refer to the following example.

```
<keyStore id="customKeyStore" location="key.jks" type="JKS" password="{xor}NDombm1s" />
```

```
<ssl id="CustomSslNewOptions" keyStoreRef="customKeyStore"/>
```

```
<wasJmsEndpoint
  host="*"
  wasJmsSSLPort="7286">
<sslOptions sslRef="CustomSslNewOptions" />
</wasJmsEndpoint>
```

- If the `<wasJmsEndpoint>` configuration is successful, then the service integration bus successfully bounds to port 7286 for secure communications. The JMS client can connect to the messaging engine in a secure way by using SSL.

### 2. Configuring the client

- By default, service integration bus creates an outbound chain that is called `< BootstrapSecureMessaging>`. This chain uses the `<keyStore>` element as a default configuration.

```
<wasJmsOutbound id="BootstrapSecureMessaging"
  useSSL="true">
</wasJmsOutbound>
```

- To change the default SSL configuration to point to some other configuration, refer to the following example:

```
<keyStore id="customKeyStore" location="key.jks" type="JKS" password="{xor}NDombm1s" />
```

```
<ssl id="CustomSslNewOptions" keyStoreRef="customKeyStore"/>
```

```
<wasJmsOutbound id="BootstrapSecureMessaging"
  useSSL="true">
<sslOptions sslRef="CustomSslNewOptions" />
</wasJmsOutbound>
```

- To connect a messaging engine by using the secure communication, specify a secure chain in the `<remoteServerAddress>` element in the connection factory.

```
<jmsQueueConnectionFactory jndiName="jndi_JMS_BASE_QCF">
  <properties.wasJms
    remoteServerAddress="localhost:7286:BootstrapSecureMessaging" />
</jmsQueueConnectionFactory>
```

- You can also create a custom outbound chain and use it to connect to the messaging engine.

```
<keyStore id="customKeyStore" location="key.jks" type="JKS" password="{xor}NDomb1s" />
<ssl id="CustomSslNewOptions" keyStoreRef="customKeyStore"/>

<wasJmsOutbound id="jmsSecureCustomChain"
  useSSL="true">
  <sslOptions sslRef="CustomSslNewOptions" />
</wasJmsOutbound>
```

Now the `<jmsSecureCustomChain>` element is enabled successfully. It uses `<CustomSslNewOptions>` element for SSL keystore configuration.

---

## Setting up the server-management environment for Liberty by using collectives

### 8.5.5.0

To set up the server-management environment for Liberty by using collectives, define the appropriate features in the `server.xml` file and run the corresponding collective command-line tasks to establish the administrative domain security configuration.

### About this task

You can use collectives to manage multiple servers from a single management domain. For high availability, you can configure collective replica sets, clusters, or scaling. For general information about collectives, see “Liberty: Collective architecture” on page 1450.

Liberty provides multiple-server management in the following features:

- **collectiveController-1.0**

The `collectiveController-1.0` feature enables controller functionality for a management collective and includes collective- and cluster-management MBeans that are accessible using the REST JMX connector that is provided by the `restConnector-1.0` feature. The collective controller acts as a storage and collaboration mechanism to which collective members can connect. The administrative domain security configuration for the `collectiveController-1.0` feature is established using the **collective** command-line **create** and **replicate** tasks.

#### Distributed operating systems

IBM i

The `collectiveController-1.0` feature and its capabilities are available only in multiple-server products such as WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in single-server products such as WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a multiple-server product installation, you can use its `collectiveController-1.0` feature to work with collective members from single-server products.

- **collectiveMember-1.0**

The `collectiveMember-1.0` feature enables a server to be a member of a management collective and be managed by the collective controller. The administrative domain security configuration for the `collectiveMember-1.0` feature is established using the **collective** command-line **join** task.

**Tip:** All servers enabled with the `collectiveController-1.0` feature are managed; therefore, you do not need to specify `collectiveMember-1.0` if the server already has the `collectiveController-1.0` feature enabled.

- **clusterMember-1.0**

The cluster member feature enables a collective member to participate in a static cluster.

- **8.5.5.4 dynamicRouting-1.0**

The dynamic routing feature is an Intelligent Management feature of the WebSphere plug-in for Apache and IHS that provides On Demand Router capabilities for the plug-in. The dynamic routing feature enables a server to run a REST service to which the plug-in can connect in order to dynamically route to all servers in a collective.

- **8.5.5.4 scalingController-1.0**

The scaling controller feature enables a collective controller to expand or contract an auto scaling cluster and manage the scaling controller. If an environment has many scaling controllers, only one of the running scaling controllers can make decisions. If that controller is stopped, another running scaling controller takes over for it. The scaling controller can start an auto scaling cluster member in response to increased resource usage, or it might stop an auto scaling cluster member in response to decreased resource usage.

- **8.5.5.4 scalingMember-1.0**

The scaling member feature monitors the workload within a server and its host, then sends this information to the scaling controller. The scaling controller feature is enabled in the collective controllers that are part of the collective. This feature also enables dynamic clustering of the collective members and allows the servers to dynamically start or stop based on criteria that is specified by the scaling policy. If more than one scaling member is on the same host, each scaling member must define a `hostSingleton` element with a port in the `server.xml` file. All scaling members on the same host must use the same port to identify a host leader. The host leader is the only scaling member that communicates with the scaling controller. It communicates metric data from the members to the controller and communicates scaling decisions that are made by the controller to the members in the host.

## Procedure

- Configure a server to act as collective controller.
  - Create a collective controller server using commands and then configure the controller `server.xml` file. See step 1 of “Configuring a Liberty collective” on page 1136.
  - Create a collective controller using developer tools. See step 1 of “Configuring a Liberty collective using the developer tools” on page 1460.
- Join a server to a collective as a member.
  - Join a server to a collective using commands and then configure the member `server.xml` file. See step 2 of “Configuring a Liberty collective” on page 1136.
  - Join a server to a collective using developer tools. See step 2 of “Configuring a Liberty collective using the developer tools” on page 1460.
- Change the collective configuration as needed for your environment.
  - Register host computers with a collective.
  - Override host information by revising parameters in the `hostAuthInfo` element of the member `server.xml` file.
  - Set up Remote Execution and Access (RXA) to enable collective controllers to start and stop servers.
  - Set the `JAVA_HOME` variable for Liberty collective members.
  - Generate collective controller SSL keys.
  - **8.5.5.5** Set administrative metadata for Liberty resources in an `admin-metadata.xml` file.
- Create a replica set, which is a set of collective controllers that are configured to work together, to provide management high availability.
  - **8.5.5.5** Automatically share configurations among replicas.
  - **8.5.5.7** Change the port of a replica.
- Backup, upgrade, or remove a collective controller, replica set, or member.
- Set up static cluster members to provide application high availability and scale.
- **Distributed operating systems** **z/OS** Set up dynamic routing of HTTP requests to collective members.
- **Distributed operating systems** **z/OS** **8.5.5.4** Set up autonomic scaling of collectives.
  - Set up auto scaling for use with Intelligent Management dynamic routing.
  - Configure auto-scalable clusters for JVM elasticity.

- **8.5.5.7** Configure provisionable clusters for Liberty elasticity.
- Define scaling policies.
- **8.5.5.5** Set scaling policies for an auto-scalable cluster in a `scaling-metadata.xml` file.
- **8.5.5.7** Enter maintenance mode before you perform diagnostic tests, maintenance, or tuning on a host or server.
- **8.5.5.7** Configure health management to prevent disruption of service by detecting common problems and generating diagnostic actions based on configured health policies.

## What to do next

You can administer the collective using the following tools:

- Use Jython scripts or a Java client such as JConsole to perform collective controller MBean operations.
- Run collective commands from a command line at the `bin` directory of your Liberty installation. For information about collective commands, run the collective **help** command:

```
wlp/bin/collective help
```

To view details about a specific command, include the command name; for example, to view details about the collective **create** command, run:

```
wlp/bin/collective help create
```

**Tip:** The example commands in this documentation are prefaced with `wlp/bin/`. This means to open a command line at the `bin` directory of your Liberty installation, such as `C:\wlp\bin` on Windows operating systems, and run the command.

- **8.5.5.2** Use WebSphere Liberty Administrative Center ("Admin Center") to administer Liberty servers, applications, and other resources in the collective from a web browser on a smartphone, tablet, or computer.
  1. Add the `adminCenter-1.0` feature to the collective controller `server.xml` file.
  2. To access Admin Center from a smartphone, tablet, or remote computer, ensure that the `server.xml` file sets the `host` attribute of the `httpEndpoint` element to `*` (asterisk) or to a defined host name.
  3. Point a web browser at Admin Center. The URL uses the form:
 

```
https://collective_controller_host_name:collective_controller_port/adminCenter/
```
  4. If your browser prompts you to confirm that the connection is trusted, specify an exception or otherwise enable the connection to continue to Admin Center.
  5. Log in using your collective controller administrative user name and password.
  6. From the Toolbox, open the Server Config tool or Explore tool.
    - **8.5.5.7** Select . Use the Server Config tool to view and edit server configuration files such as `server.xml` files in the collective. For information about the Server Config tool, see "Editing server configuration files in Admin Center" on page 1748.
    - **8.5.5.5** Select . Use the Explore tool to manage applications, clusters, servers, and hosts in the collective. For information about the Explore tool, see "Exploring and managing resources with Admin Center" on page 1749.

For other information about enabling and using Admin Center, see "Administering Liberty using Admin Center" on page 1741.

To ensure that you can remotely start and stop servers, complete the steps for your operating system in "Setting up RXA for Liberty collective operations" on page 1491.

## Configuring a Liberty collective

You can organize Liberty servers into collectives to support clustering, administration, and other operations that act on multiple Liberty servers. By using collectives, you can efficiently and accurately deliver application services to your organization.

## Before you begin

The `collectiveController-1.0` feature and its capabilities are available only in WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a WebSphere Application Server Liberty Network Deployment installation, you can use its `collectiveController-1.0` feature to work with collective members from WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core installations.

## About this task

A Liberty collective is a set of Liberty servers that are configured as part of the same administrative and operational domain.

Configuration and state data about a Liberty collective is housed in an active operational repository.

Membership in a Liberty collective is optional. Liberty servers join a collective by registering with a collective controller to become members. Members share information about themselves through the operational repository of the controller.

The following rules apply:

- A Liberty server can be a member of only one collective.
- Different Liberty servers on the same host can be in different collectives.
- Liberty servers on the same host that are members of a collective can coexist with Liberty servers that are not members of a collective.

 **Watch:** Introduction to creating a collective demonstrates the procedure. This video, and other information about collectives, is available on the WASdev website. [Transcript]

## Procedure

1. Create and configure your controller.
  - a. Create a server to act as the collective controller.

```
wlp/bin/server create myController
```

- b. Create the collective controller configuration.

The collective controller configuration consists primarily of the administrative domain security configuration that is used for secure communication between controllers and members.

```
wlp/bin/collective create myController --keystorePassword=controllerKSPassword
```

**8.5.5.2** By default, this collective command writes all output to a console screen. In the next step, you copy the configuration output into the `server.xml`. To write the configuration to a file instead of to a console screen, specify a `--createConfigFile=outputFilePath` parameter, for example:

```
wlp/bin/collective create myController --keystorePassword=controllerKSPassword --createConfigFile=c:\wlp\usr\servers\myController\
```

After you run the **create** command, the `include` statement to use is displayed. To include the outputted file in the collective configuration, add the `include` statement to the `server.xml` file, for example:

```
<include location="c:\wlp\usr\servers\myController\collective-create-include.xml" />
```

- c. Update the `server.xml` file of the collective controller.

- Copy and paste output.

If the command wrote output to a console screen, proceed with the following steps:

- 1) Copy output from the collective command and paste it into the server.xml file.
- 2) Specify administrative user ID and password values for the collective. For example, change:

```
<quickStartSecurity userName="" userPassword="" />
```

to:

```
<quickStartSecurity userName="adminUser" userPassword="adminPassword" />
```

The default path for the collective controller server.xml file is `${wlp.install.dir}/usr/servers/myController/server.xml` or, if the `$WLP_USER_DIR` variable is set in a server.env file or command window, `$WLP_USER_DIR/servers/myController/server.xml`. After editing, the file will resemble the following example:

```
<server description="controller server">

  <!-- Enable features -->

  <featureManager>
    <feature>jsp-2.2</feature>
  </featureManager>

  <httpEndpoint id="defaultHttpEndpoint"
    host="*"
    httpPort="9080"
    httpsPort="9443" />

  <featureManager>
    <feature>collectiveController-1.0</feature>
  </featureManager>

  <!-- Define the host name for use by the collective.
  If the host name needs to be changed, the server should be
  removed from the collective and re-joined or re-replicated. -->

  <variable name="defaultHostName" value="controllerHostname" />

  <!-- TODO: Set the security configuration for Administrative access -->

  <quickStartSecurity userName="adminUser" userPassword="adminPassword" />

  <!-- clientAuthenticationSupported set to enable bidirectional trust -->

  <ssl id="defaultSSLConfig"
    keyStoreRef="defaultKeyStore"
    trustStoreRef="defaultTrustStore"
    clientAuthenticationSupported="true" />

  <!-- inbound (HTTPS) keystore -->
  <keyStore id="defaultKeyStore" password="yourPassword"
    location="${server.config.dir}/resources/security/key.jks" />

  <!-- inbound (HTTPS) truststore -->
  <keyStore id="defaultTrustStore" password="yourPassword"
    location="${server.config.dir}/resources/security/trust.jks" />

  <!-- server identity keystore -->
  <keyStore id="serverIdentity" password="yourPassword"
    location="${server.config.dir}/resources/collective/serverIdentity.jks" />

  <!-- collective trust keystore -->
  <keyStore id="collectiveTrust" password="yourPassword"
    location="${server.config.dir}/resources/collective/collectiveTrust.jks" />

  <!-- collective root signers keystore -->
  <keyStore id="collectiveRootKeys" password="yourPassword"
    location="${server.config.dir}/resources/collective/rootKeys.jks" />
</server>
```

- **8.5.5.2** Add an include statement.

If you wrote the output to a file by using the `--createConfigFile=outputFilePath` parameter, add an include statement to `$WLP_USER_DIR/servers/myController/server.xml` to include the outputted file in the collective configuration. For example:

```

<server description="controller server">
  <!-- Enable features -->
  <featureManager>
    <feature>jsp-2.2</feature>
  </featureManager>
  <httpEndpoint id="defaultHttpEndpoint"
    host="*"
    httpPort="9080"
    httpsPort="9443" />
  <include location="c:\wlp\usr\servers\myController\collective-create-include.xml" />
</server>

```

Ensure the outputted file sets administrative user ID and password values for the collective, for example:

```
<quickStartSecurity userName="adminUser" userPassword="adminPassword" />
```

- d. Start the collective controller server.

```
wlp/bin/server start myController
```

Figure 20. Collective of one

- e. Verify that the collective controller server started correctly and is ready to receive members.

- 1) Open an editor on the collective controller messages log, \$WLP\_USER\_DIR/servers/myController/logs/messages.log.
- 2) Look for the following message:

```
CWKKX9003I: CollectiveRegistration MBean is available.
```

If you want to enable a collective controller and its members to use the security TLSv1.2 protocol for the Secure Sockets Layer (SSL) context, see “Setting up Liberty to run in SP800-131a” on page 1848. The server.xml files of the controller and members need ssl id elements and each host computer needs a server.env file with the JVM\_ARGS=-Dhttps.protocols=TLSv1.2 statement in its \${wlp.install.dir}/etc directory.

2. Create and configure a member to join the collective.

The controller and members can be on separate hosts. In this example, the controller and member are on the same host.

- a. Create a member server.

```
wlp/bin/server create myMember
```

- b. Join the member.

Run the collective **join** command to join the server to the collective as a member.

The **join** command requires a network connection to the collective controller and an administrative user ID and password for performing MBean operations on the controller. Look at the server.xml file of the collective controller to find the values for the --host, --port, --user, and --password parameters. For --keystorePassword, set a value to use for the member keystore password, such as memberKSPassword. You can specify different --keystorePassword values for each server that is joined to the collective.

```
wlp/bin/collective join myMember --host=controllerHostname --port=9443 --user=adminUser --password=adminPassword --keystorePassword=memberKSPassword
```

The optional parameter --hostname specifies the host name to use for the system. Set --hostname only if the system has multiple host names or does not have its host name configured. If set, the value must match the defaultHostName variable that is defined in the server.xml file.

**8.5.5.2** To write the output of this collective command to a file, instead of to a console screen, specify an optional `--createConfigFile=outputFilePath` parameter. Then, include the outputted file in the collective configuration by adding an `include` statement to the member `server.xml` file:

**8.5.5.2**

```
<include location=outputFilePath />
```

**8.5.5.4** By default, the **join** operation leaves remote procedure call (RPC) credentials undefined. You must specify values for `rpcUser`, `rpcUserPassword`, and the operating system login user and password for the host on which the member server resides. If the member host is registered with the collective controller and the member host is not enabled for SSH, specify an optional `--useHostCredentials` parameter to enable the member to inherit RPC credentials from its host registration on the controller. Typically, Linux hosts are enabled for SSH and Windows hosts are not enabled for SSH; thus, the `--useHostCredentials` parameter is useful for Windows member hosts. Specifying `--useHostCredentials` adds `<hostAuthInfo useHostCredentials="true" />` to the member `server.xml` file. You then can run collective member server commands such as **start** or **stop** without specifying RPC credentials because the member inherits credentials from its host. See “Overriding Liberty server host information” on page 1144 for information about `hostAuthInfo`, the `--useHostCredentials` parameter, and connecting the collective controller to the server.

For information about these required parameters and about optional parameters, run `collective help join` at a command line.

- c. If prompted to accept the certificate chain, enter `y` (yes).
- d. Update the member `server.xml` file.
  - Copy and paste output.

If the command wrote output to a console screen, proceed with the following steps:

- 1) Copy output from the collective command and paste it into the member `server.xml` file.
- 2) Modify the ports so that the server can open its HTTP ports. Ensure the member `server.xml` sets unique HTTP port numbers on its host. For example, if the member is on the same host as the collective controller, change the HTTP port numbers:

```
<httpEndpoint id="defaultHttpEndpoint" httpPort="9081" httpsPort="9444" />
```

Optionally, to access the member server from a remote client, also set `host="*"` in the `httpEndpoint` element.

In `$WLP_USER_DIR/servers/myMember/server.xml`, for example:

```
<server description="member server">
  <!-- Enable features -->

  <featureManager>
    <feature>jsp-2.2</feature>
  </featureManager>

  <httpEndpoint id="defaultHttpEndpoint"
    host="*"
    httpPort="9081"
    httpsPort="9444" />

  <featureManager>
    <feature>collectiveMember-1.0</feature>
  </featureManager>

  <!-- Define the host name for use by the collective.
  If the host name needs to be changed, the server should be
  removed from the collective and re-joined or re-replicated. -->

  <variable name="defaultHostName" value="memberHostname" />
```

**8.5.5.4** `<!-- Remote host authentication configuration --> <hostAuthInfo rpcUser="admin_user_id" rpcUserPassword="admin_user_password" /> <!-- Connection to the`

```

collective controller --> <collectiveMember controllerHost="controllerHostname"
controllerPort="9443" /> <!-- clientAuthenticationSupported set to enable bidirectional trust -->
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore" trustStoreRef="defaultTrustStore"
clientAuthenticationSupported="true" /> <!-- inbound (HTTPS) keystore --> <keyStore
id="defaultKeyStore" password="yourPassword" location="{server.config.dir}/resources/
security/key.jks" /> <!-- inbound (HTTPS) truststore --> <keyStore id="defaultTrustStore"
password="yourPassword" location="{server.config.dir}/resources/security/trust.jks" /> <!--
server identity keystore --> <keyStore id="serverIdentity" password="yourPassword"
location="{server.config.dir}/resources/collective/serverIdentity.jks" /> <!-- collective truststore
--> <keyStore id="collectiveTrust" password="yourPassword" location="{server.config.dir}/
resources/collective/collectiveTrust.jks" /> </server>

```

- **8.5.5.2** Add an include statement.

If you wrote the output to a file by using the `--createConfigFile=outputFilePath` parameter, add an include statement to `$WLP_USER_DIR/servers/myMember/server.xml` to include the outputted file, for example:

```

<server description="member server">
    <!-- Enable features -->

    <featureManager>
        <feature>jsp-2.2</feature>
    </featureManager>

    <httpEndpoint id="defaultHttpEndpoint"
        host="*"
        httpPort="9081"
        httpsPort="9444" />

    <include location="c:\wlp\usr\servers\myMember\collective-join-include.xml" />
</server>

```

- e. **8.5.5.4** If you did not specify `--useHostCredentials` in the `join` command and the member host is not enabled for SSH, set RPC credentials for `hostAuthInfo` in the member `server.xml` file or the outputted file. You can set RPC credentials for the member server in either of two ways:

- Set `hostAuthInfo` RPC user and password values. Set `rpcUser` to an operating system login user ID for the host on which the member server resides, and set `rpcUserPassword` to the operating system login password for the user ID. For example, if you log into the member computer with user `test1` and password `test1pwd`, then change the `hostAuthInfo` element to the following:

```
<hostAuthInfo rpcUser="test1" rpcUserPassword="test1pwd" />
```

- If the member host is registered with the collective controller, set `hostAuthInfo` `useHostCredentials` to `true` for the member server to inherit RPC credentials from its host.

```
<hostAuthInfo useHostCredentials="true" />
```

See “Overriding Liberty server host information” on page 1144 for information about `hostAuthInfo` settings and for an example that shows how to register a member host and run the `join` command with `--useHostCredentials`.

- f. **z/OS** For z/OS only, issue the `updateHost` command to specify the member `JAVA_HOME` directory for the controller.

```

collective updateHost controllerHostname --host=controllerHostname
--port=9443 --user=adminUser --password=adminPassword
--hostWritePath=/dir1 --rpcUser=rpcUser
--rpcUserPassword=rpcUserPassword --hostJavaHome=JAVA_HOME

```

The `hostWritePath` parameter specifies the directories to which the collective controller can write. Paths that are specified by the `hostWritePath` parameter are also readable.

The `hostJavaHome` parameter specifies the absolute path to where the JVM is on the system and where the member server runs, for example `/usr/lpp/java/java_1.7_64`

- g. Start the member server.

```
wlp/bin/server start myMember
```

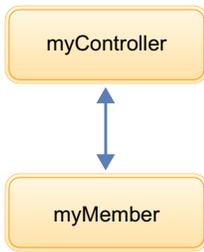

Figure 21. Simple collective

- h. Verify that the member server started correctly and is publishing information to the controller.
  - 1) Open an editor on the member messages log, `$WLP_USER_DIR/servers/myMember/logs/messages.log`.
  - 2) Look for the following messages in any order:
 

```

CWWKX8112I: The server's host information was successfully published to the collective repository.
CWWKX8114I: The server's paths were successfully published to the collective repository.
CWWKX8116I: The server STARTED state was successfully published to the collective repository.
          
```

## Registering host computers with a Liberty collective

### 8.5.5.0

You can register a host computer with a Liberty collective controller, update host information, or unregister a host. Registration enables the collective controller to access applications, command files, and other resources on the host. Registered hosts are members of the collective.

### Before you begin

1. Construct a Liberty collective. See “Configuring a Liberty collective” on page 1136.

#### Distributed operating systems

IBM i

The `collectiveController-1.0` feature and its capabilities are available only in multiple-server products such as WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in single-server products such as WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a multiple-server product installation, you can use its `collectiveController-1.0` feature to work with collective members from single-server products.

2. To enable connections to servers on local and remote hosts, complete the steps for your host operating system in “Setting up RXA for Liberty collective operations” on page 1491. The topic provides information about the Tivoli® Remote Execution and Access (RXA) toolkit and enabling Secure Shell (SSH) protocol. You can use RXA to remotely start and stop servers, including starting and stopping servers on your local computer, and to transfer files to and from registered hosts.

**Note:** **Windows** In Windows, system environment variables are visible only inside the shell that RXA connects to. Setting `PATH` in the command window is not sufficient. You must set `PATH` in the system variable section of the environment variables, or use `-hostJavaHome <PATH TO IBM JAVA>` with the `updateHost` option.

3. If you want to enable a collective controller and its members to use the security TLSv1.2 protocol for the Secure Sockets Layer (SSL) context, see “Setting up Liberty to run in SP800-131a” on page 1848. The `server.xml` files of the controller and members need `ssl id` elements and each host computer needs a `server.env` file with the `JVM_ARGS=-Dhttps.protocols=TLSv1.2` statement in its `${wlp.install.dir}/etc` directory.

## About this task

A host computer is not required to have any WebSphere Application Server products installed. There are no software requirements for a host beyond its operating system. The host can be the same computer on which the product is installed or a different computer.

To register a host with a collective controller, update host information, and unregister a host, use the **registerHost**, **updateHost**, and **unregisterHost** commands. Specify the host computer name in one of the following formats:

- Fully qualified domain name servers (DNS) host name string, such as `xmachine.ibm.com`
- Default short DNS host name string, such as `xmachine`
- Numeric IP address, such as `127.1.255.3`

**Note:** When a Liberty server is joined to a collective, the associated host is automatically registered with the collective controller if it is not already registered.

A host can be registered with the collective under different names. Ensure that the host name specified for **registerHost**, **updateHost**, and **unregisterHost** is consistent with the host name used for the registered collective members. The `defaultHostName` variable in the registered server member's `server.xml` file controls the host name to which the server considers itself to belong.

## Procedure

- Register a host with a collective controller.

To register the current host where both the collective controller host and the remote target host are the same computer, run the **registerHost** command on the collective utility script with no explicit host target. Specify the collective controller's host name, port, and administrative user name and password. For example:

```
wlp/bin/collective registerHost --host=controllerHost --port=controllerHTTPSPort
--user=controllerAdmin --password=controllerAdminPassword
```

This example command generates a unique SSH key pair for authenticating to the SSH server of a specified host computer. If you are registering a remote host for which an SSH key pair is already generated, you can specify the path of the SSH private key file. The following **registerHost** command assumes that the SSH private key is stored on the local controller computer at `/home/user1/.ssh/id_rsa`. The other file in the SSH key pair is the `/home/user1/.ssh/authorized_keys` public key file on the remote target host.

```
wlp/bin/collective registerHost remothost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
--sshPrivateKey=/home/user1/.ssh/id_rsa
```

If the remote target host does not support SSH or you do not want to use SSH keys, you can specify an operating system login user for `rpcUser` and login password for `rpcUserPassword`. If you include `rpcUser` with `rpcUserPassword`, do not include `sshPrivateKey`. The command to specify operating system login user and password resembles:

```
wlp/bin/collective registerHost remothost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
--rpcUser=osUserForRemoteHost --rpcUserPassword=osUserPasswordForRemoteHost
```

### 8.5.5.2

To transfer files to and from a host, you must specify host read and write paths. Unless the **registerHost** command specifies the paths, you cannot deploy a Liberty archive to the host. The `hostReadPath` specifies the directories that the collective controller can read. The `hostWritePath` specifies the directories to which the collective controller can write. Paths that are specified by `hostWritePath` are also readable. For example, to upload an archive to `/opt/wlp`, you must specify `--hostWritePath=/opt`. Specify a parameter multiple times for multiple paths.

```
wlp/bin/collective registerHost myHost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
--rpcUser=osUser --rpcUserPassword=osUserPassword
--hostReadPath=/opt --hostWritePath=/dir1 --hostWritePath=/dir2
```

To use the Deploy tool of the WebSphere Liberty Administrative Center ("Admin Center"), you must set `hostWritePath` to the path to which you want to deploy a server package. To transfer files to multiple directories, include multiple instances of the `hostWritePath` parameter in the command. For example:

```
wlp/bin/collective registerHost myHost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin
--password=controllerAdminPassword --rpcUser=osUser --rpcUserPassword=osUserPassword
--hostWritePath=c:\was\liberty\brokerageAppTest --hostWritePath=c:\wlp_backup
```

**Windows** Before you deploy a server package by using the Deploy tool of Admin Center, complete the steps for your host operating system in "Setting up RXA for Liberty collective operations" on page 1491.

Optionally, specify the path to the Java home directory of the host with the `-hostJavaHome` parameter. For example: `-hostJavaHome=c:\java\jre`

- Update registered host authentication information.

Run the `updateHost` command on the collective utility script to change the authentication information of a registered host. For example, if the user password changes, the following command updates the host password that is used by the collective:

```
wlp/bin/collective updateHost myHost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
--rpcUser=osUser --rpcUserPassword=newOsUserPassword
```

- **8.5.5.2** Update registered host read or write paths.

Run the `updateHost` command on the collective utility script to change the host read and write paths. Paths in this command override the previously set paths for `hostReadPath` and `hostWritePath`, and do not add to the existing paths.

```
wlp/bin/collective updateHost myHost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
--rpcUser=osUser --rpcUserPassword=osUserPassword
--hostReadPath=/optNew --hostWritePath=/opt --hostWritePath=/home/osUser
```

- Unregister a host from a collective controller.

Run the `unregisterHost` command on the collective utility script; for example:

```
wlp/bin/collective unregisterHost myHost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
```

Unregistering a host removes all the registered servers on that host and any other host-based information from the collective controller.

## What to do next

For information about all parameters of the `registerHost`, `updateHost`, and `unregisterHost` commands, see the API documentation for the `CollectiveRegistration` MBean.

## Overriding Liberty server host information

### 8.5.5.0

The `collectiveMember-1.0` feature enables a server to be managed by the collective controller. Most server host information can be automatically detected. In certain scenarios, however, you must provide additional host information so that the collective controller can establish a connection to the server.

**Note:** **Distributed operating systems** **IBM i** The `collectiveController-1.0` feature and its capabilities are available only in WebSphere Application Server Liberty Network Deployment and WebSphere

Application Server Liberty for z/OS. **8.5.5.0** The feature is not available in WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a WebSphere Application Server Liberty Network Deployment installation, you can use

its collectiveController-1.0 feature to work with collective members from WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core installations.

To enable the host information override, add the following element to the server.xml file:

```
<hostAuthInfo rpcPort="ssh_port"
  rpcUser="user_ID"
  rpcUserPassword="password"
  rpcUserHome="user_home"
  rpcHost="host_name"
  sudoUser="sudo_user"
  sudoPassword="sudo_user_password"
  sshPublicKeyPath="public_key_path"
  sshPrivateKeyPath="private_key_path"
  sshPrivateKeyPassword="private_key_password"
```

```
8.5.5.4 useHostCredentials="true_or_false"/>
```

### rpcPort

This parameter specifies the port for the RPC mechanism, which is SSH port 22 by default. If your system uses a nonstandard port, set this value accordingly. If this value is not specified, the default value is 22.

### rpcUser

This parameter specifies the user ID that the collective controller will use to connect to the server. If the host does not support SSH or using SSH keys is not desired, you can use this parameter to specify an operating system login user. For example, if you log in to the host with the myID user, then you specify rpcUser="myID". If this value is not specified, the default value is System.getProperty("user.name").

### rpcUserPassword

This parameter specifies the password for the specified user ID. For example, if you log in to the host with the myID user and the myPwd password, then you specify rpcUser="myID" and rpcUserPassword="myPwd". If this value is not specified, the server will either generate an SSH key pair or use the SSH key pair for the connection that is specified using the **privateKeyPath** and **publicKeyPath** parameters. If SSH is not installed on the server (such as on a Windows or OS/400® operating system), the password is required.

### rpcUserHome

This parameter specifies the home directory of the user. If this value is not specified, the default value is System.getProperty("user.home"). If **rpcUser** is specified, you should specify **rpcUserHome**.

### rpcHost

This parameter specifies the host on which the RPC mechanism is configured to listen. If this value is not specified, the default value is the value of the **defaultHostName** variable. If your system uses a host other than the **defaultHostName**, set this value accordingly.

### sudoUser

If this value is specified, it allows the collective controller to run commands as another, or "sudo", user instead of as the user ID used for the connection. This parameter applies only to servers that have an SSH server installed. This parameter has no default value.

### sudoPassword

This parameter specifies the password for the sudo user specified by the **sudoUser** parameter. This parameter applies only to servers that have an SSH server installed. This parameter has no default value.

### sshPublicKeyPath

This parameter specifies the path and file name of a user-specified public key file. If this value is not

specified, the default is `${server.output.dir}/resources/security/ssh/id_rsa.pub`. If the specified file (or default file) does not exist, a new public key file will be generated.

### **sshPrivateKeyPath**

This parameter specifies the path and file name of a user-specified private key file. If this value is not specified, the default is `${server.output.dir}/resources/security/ssh/id_rsa`. If the specified file (or default file) does not exist, a new private key file will be generated.

### **sshPrivateKeyPassword**

This parameter specifies the password for the private key. This parameter has no default value.

#### **8.5.5.4 useHostCredentials**

This parameter specifies whether collective member server commands inherit RPC credentials from the host. The default is `false`, requiring the user to specify RPC credentials for the controller to remotely start or stop the member. When set to `true`, collective member server commands inherit RPC credentials from the host registration and ignore all other RPC credentials in the `hostAuthInfo` configuration element.

## **Examples**

Scenario 1: Server is on Windows operating system, no SSH is installed

```
<hostAuthInfo rpcUserPassword="myPassword"/>
```

Scenario 2: Server has SSH installed, SSH is running on port 2222

```
<hostAuthInfo rpcPort="2222"/>
```

Scenario 3: Need to run commands as another user

```
<hostAuthInfo sudoUser="anotherUser" sudoPassword="anotherPassword"/>
```

Scenario 4: Server is on a Windows operating system and `ssh` (e.g. `Cygwin`) is installed. With the following server configuration, the controller connects the member server with `ssh`. In this case, the requirement to disable Windows User Account Control (UAC) does not apply. The parameter `<user's home directory>` is the user default home directory, for example: `C:\cygwin\home\bob`

```
<hostAuthInfo rpcUserHome="<user's home directory">"/>
```

**8.5.5.4** Scenario 5: The collective controller and member are on separate hosts, and not on the same host. To specify that the member inherit RPC credentials from the host, set `useHostCredentials` to `true` in the `server.xml` file of the member. Complete the following steps to configure the member to inherit RPC credentials from the host by specifying `--useHostCredentials` in the `join` command that joins a server as a member to the collective.

1. Create, configure, and start a collective controller named `myController` as shown in step 1 of “Configuring a Liberty collective” on page 1136.
2. Register the host for the member with the collective. The member and the collective controller are on different hosts.

In this scenario, the `registerHost` command uses the collective controller host `hostA.ibm.com` with port number 9443, user `admin`, and password `adminpwd`. The command registers the member host `hostB.ibm.com` with the collective, and sets `rpcUser` to an operating system login user ID for the member host `osUser1`, and `rpcUserPassword` to the operating system login password for the user ID for the member host `osUser1Pwd`. Run the `registerHost` command on the collective controller host.

```
wlp/bin/collective registerHost hostB.ibm.com --host=hostA.ibm.com --port=9443 --user=admin --password=adminpwd --rpcUser=osUser1 --
```

Enter `y` (yes) when prompted to accept the certificate chain. After registration, the Host `hostB.ibm.com` successfully registered. message displays. The collective controller host now has the operating system user ID and password of the member host.

3. On the member host, create a server named `myMember` to use as a collective member.

```
wlp/bin/server create myMember
```

4. Add the myMember server to the collective controller, specifying to use host credentials. In the **join** command, which is run on the member host, specify `--useHostCredentials` so that the member inherits RPC credentials from the host registration.

```
wlp/bin/collective join myMember --host=hostA.ibm.com --port=9443 --user=admin --password=adminpwd --keystorePassword=memberKSPas
```

5. Update the member server.xml file as shown in step 2 of “Configuring a Liberty collective” on page 1136.

Because you specified `--useHostCredentials` in the **join** command, the configuration generated for the member server.xml file sets `useHostCredentials` to `true`:

```
<!-- Remote host authentication configuration -->  
<hostAuthInfo useHostCredentials="true" />
```

With the `--useHostCredentials` option, you do not need to specify the operating system user ID and password in the member server.xml file because the member inherits credentials from the host. Later, if the operating system user ID or password of the member server changes, run the **updateHost** command to change the user ID or password. For more information about the **registerHost** and **updateHost** commands, see “Registering host computers with a Liberty collective” on page 1142.

## Setting the JAVA\_HOME variable for Liberty collective members

All Liberty collective members must have a Java Runtime Environment (JRE) installed that meets the minimum requirements of the Liberty server. After a JRE is installed on the host computer, you can set the `JAVA_HOME` variable so that the Liberty operation can locate the JRE.

### About this task

In order for the collective controller to perform remote operations on Windows members such as starting or stopping a member server, the collective controller must run with an IBM JRE. Third-party JREs do not contain the required security classes. You can get a JRE that supports Liberty products and SSL from Installation Manager offerings or developerWorks:

- Using Installation Manager, select the Liberty product first and then select WebSphere SDK for Liberty. Use Installation Manager to install the Liberty product and software development kit (SDK). The WebSphere SDK for Liberty includes the needed support for Liberty products and SSL and offers a Java client, JConsole.
- Go to <http://www.ibm.com/developerworks/java/jdk/index.html> on the developerWorks website and download an IBM Java development kit (JDK) for your operating system. The developerWorks website does not have a JRE for all operating systems. For example, you have to get the JDK from Eclipse for Windows operating systems.

You can set the `JAVA_HOME` variable in operating system settings or at a command line. Setting set the `JAVA_HOME` variable enables remote operations to locate the JRE.

### Procedure

- **Windows** To set `JAVA_HOME` on a Windows system, perform the following actions.

1. On the Control Panel, do the following:
  - Click **System**.
  - Click **Advanced system settings**.

The System Properties window opens.

2. Click the **Environment Variables** button.
3. Click the *New* button in the system-variables section.
4. Add the `JAVA_HOME` variable name and specify a path to the jre directory; for example:  
`C:\wlp_855\IBM\WebSphere\Liberty\java\java_1.7.1_64\jre`

Some collective controller commands require that the path to the Java installation `jre\bin` directory be available in the System path, so also add a path to the `jre\bin` directory.

5. Save the changes. You might need to reboot the computer for the changes to take effect.
6. To verify the changes, at a command line enter `set JAVA_HOME`. The command displays the `JAVA_HOME` settings; for example:

```
JAVA_HOME=C:\wlp_855\IBM\WebSphere\Liberty\java\java_1.7.1_64\jre
```

**Note:** Rather than change operating system settings, you can set `JAVA_HOME` at a command line by entering `set JAVA_HOME=path_to_jre`. A limitation is that the `JAVA_HOME` setting only applies to commands entered in the same command window.

- **AIX** **HP-UX** **Linux** **Solaris** If you are running bash shell, you can add the `JAVA_HOME` environment variable to the `.bashrc` file in the user's home directory.
- One option for setting `JAVA_HOME` is to create a `server.env` file in the `${server.config.dir}` where `server.xml` is residing and add `JAVA_HOME` there.

For example:

```
JAVA_HOME=/java/jre
```

**Linux** Some collective controller commands require that the path to the Java installation `jre/bin` directory be available in the `.bashrc` file, so set a path to `jre/bin` in the `.bashrc` file.

## Configuring Liberty collective replica sets

You can configure collective replica sets. A replica set provides highly available management capabilities for a Liberty administrative domain.

**Distributed operating systems**

**IBM i**

### Before you begin

The `collectiveController-1.0` feature and its capabilities are available only in WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a WebSphere Application Server Liberty Network Deployment installation, you can use its `collectiveController-1.0` feature to work with collective members from WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core installations. A collective member can be from any WebSphere Application Server Liberty release.

### About this task

A *replica set* is a set of collective controllers that are configured to work together. Each replica contains all the repository updates that the other replicas within the set have processed. Therefore, there is no need for a member or client to connect with a particular collective controller each time that it interacts with the collective; any of the collective controllers that are configured in the replica set can provide the same data.

For detailed instructions about creating and configuring a collective controller, see “Configuring a Liberty collective” on page 1136.

You can complete the following procedures to configure a collective replica set:

1. Add a replica to an existing replica set.
2. Modify the default configuration of the initial replica set.

See Example: Create and activate a replica set for an example of creating a replica set consisting of three collective controllers on the same host.

### Procedure

1. Add a replica to an existing replica set.

During the life of a replica set, it might become necessary to add one or more replicas to an existing set, to increase capacity for example.

The existing replicas in the replica set do not require any updates to their configuration. You can update them so that their configurations in the `server.xml` files more accurately reflect the replicas that form the replica set, but this update is unnecessary and does not affect their behaviors.

**Note:** It is not necessary to change the `replicaSet` value in the `server.xml` file of an existing replica in the set. No change to the configuration of an existing replica is required. If you do want to update the `replicaSet` values in the configurations of existing replicas in the set so that the configuration values are consistent across all replicas in the set, you must set the `isInitialReplicaSet` value in the configurations of the existing replicas to `false`. After you alter the `replicaSet` value, it describes a changed replica set rather than the initial replica set.

**Note:** When you refer to a replica, you must be consistent and use the same `host:port` value. If a hostname is used, it must always be used. Or, if an IP address is used, it must always be used.

To add a replica, follow these steps:

- a. Ensure that the existing replica set is running and that most of the replicas are available.
- b. Create a server to be the new collective controller.

```
wlp/bin/server create MyNewController
```

- c. Replicate to transform the new server into a collective controller.

```
wlp/bin/collective replicate MyNewController
--host=host_of_running_controller
--port=https_port_of_running_controller
--user=username_for_running_controller
--password=userPassword_for_running_controller
--keystorePassword=keystore_password_for_new_controller
```

The `replicate` command writes XML output to a console screen. You copy the output into the `server.xml` file.

**8.5.5.2** To write the output of the command to a file, instead of to a console screen, specify the `--createConfigFile=output_file_path` parameter. Then, include the outputted file in the collective configuration by adding an `include` statement to the `server.xml` file:

```
<include location=output_file_path />
```

- d. Configure the new replica's `server.xml` file by using output of the `replicate` command.

Copy the XML output of the `replicate` command into the `server.xml` file. You can modify the replica configuration as follows:

- **Required settings:**

The values must be explicitly set. The XML printed by the `replicate` command contains this configuration and is sufficient for these settings.

**8.5.5.4 hostAuthInfo**

Host authentication information containing properties that a remote client needs to start the server. This setting is only required when the host of the new replica is not enabled for SSH. Typically, Linux hosts are enabled for SSH and Windows hosts are not enabled for SSH. Thus, this setting might only be needed on Windows hosts. Set RPC credentials for the replica in either of two ways:

- Set `rpcUser` to an operating system login user ID for the host on which the replica resides, and set `rpcUserPassword` to the operating system login password for the user ID. For example, if you log into the replica computer with user `test1` and password `test1pwd`, then change the `hostAuthInfo` element to the following:

```
<hostAuthInfo rpcUser="test1" rpcUserPassword="test1pwd" />
```

- If the replica host is registered with the collective controller, set `hostAuthInfo useHostCredentials` to `true` for the replica to inherit RPC credentials from its host.

```
<hostAuthInfo useHostCredentials="true" />
```

See “Overriding Liberty server host information” on page 1144 for information about `hostAuthInfo` settings.

### **replicaSet**

Space-delimited list that contains the `host:port` for each of the `replicaHosts` and `replicaPorts` in the replica set, excluding the values for the collective controller now being added to the set

For example,

```
original.host.com:10001 some.other.host.com:10003
```

At least one of the values in this set must already be a replica of the existing replica set.

- **Optional settings:**

These settings default, but can be altered.

### **isInitialReplicaSet**

False

### **replicaHost**

Hostname for each individual replica

### **replicaPort**

Port for each individual replica

This port is not the `http` or `https` port of the collective controller, but it is a unique port that is used for communication between the replicas of the replica set.

### **repositoryDir**

Directory location that is used to store repository data

Here is an example of what you might add to a new replica `server.xml` file:

```
<collectiveController replicaHost="localhost"
  replicaPort="10012"
  replicaSet="localhost:10010 localhost:10011"
  isInitialReplicaSet="false"/>
```

The XML printed by the **replicate** command requires updating the server's security configuration and specifying the `collectiveRootKeys` keystore password. The server's security configuration should be identical to the original collective controller's configuration, and the `collectiveRootKeys` keystore password should be the password that is used for the original collective controller's `collectiveRootKeys` keystore password. If the replica was created from the controller that is created in “Configuring a Liberty collective” on page 1136, the new controller's configuration should contain the following:

```
<quickStartSecurity userName="adminUser" userPassword="adminPassword" />
<!-- collective root signers keystore -->
<keyStore id="collectiveRootKeys" password="yourPassword"
  location="{server.config.dir}/resources/collective/rootKeys.jks" />
```

- e. Start the new replica by starting the new collective controller.
- f. Confirm that the original collective controller successfully connected to the new replica. Look for message `CWWKX6009I` in the `messages.log` file of the original collective controller and the replica.

**Tip:** For scripts that run the **replicate** and **addReplica** commands, add a 10-second wait after the **replicate** command runs to ensure the original collective controller and replica connect before running the **addReplica** command.

- g. Invoke the `addReplica` operation on the collective utility to activate the new replica. The argument to the `addReplica` set must be the replica endpoint (in the form "`replicaHost:replicaPort`") of the replica to add.

```
wlp/bin/collective addReplica localhost:10012
  --host=host_of_running_controller
  --port=port_of_running_controller
  --user=user_for_running_controller
  --password=user_password
```

- Optional: If necessary, you can modify the default configuration of the initial replica set. This step is recommended but not required.

The configuration of the initial replica set occurs when the initial collective controller is created. If it is necessary to modify the default replica configuration, the following properties can be changed in the `server.xml` file:

**Optional settings:** These values default, but can be altered.

**replicaHost**

Hostname for each individual replica

**replicaPort**

Port for each individual replica

This port is not the http or https port of the collective controller, but it is a unique port that is used for communication between the replicas of the replica set.

**repositoryDir**

Directory location that is used to store the repository data

## Example: Creating and activating a replica set

This example describes how to create a replica set and then activate it. A replica set must have at least three replicas, preferably on different hosts, for high availability. This example has the replicas on the same host, which requires that you assign unique port numbers for the replicas. When replicas are on different hosts, the replicas can use the same port numbers.

1. Create a replica set.

To create a replica set, you increase the number of collective controllers and configure them so that they can communicate with each other. Each new collective controller is called a *replica* because the added collective controllers have the same security configuration as the original controller and because all information written to any one controller is automatically replicated to all other active controllers. Once configured, all collective controllers in the replica set can perform the same operations as the original controller.

- a. If you do not have a collective controller, create one. See step 1 of “Configuring a Liberty collective” on page 1136.
- b. Ensure the existing collective controller is running. For an existing controller named `myController`, run the **status** command:

```
wlp/bin/server status myController
```

If the collective controller is not running, then start it using the **start** or **run** command:

```
wlp/bin/server start myController
```

- c. Create a server to be the new collective controller.

```
wlp/bin/server create myController2
```

- d. Replicate the existing collective controller configuration into the new collective controller. The new collective controller is called a *replica*.

Run a **replicate** command that uses the administrative security domain configuration of the existing collective controller and sets a new keystore password for the replica. Look at the `server.xml` file of the existing collective controller to find the values for the `--host`, `--port`, `--user`, and `--password` parameters. For `--keystorePassword`, set a value to use for the keystore, such as `myController2`. For information about these required parameters and about optional parameters, run `collective help replicate` at a command line.

```
wlp/bin/collective replicate myController2 --host=host_of_existing_controller --port=https_port_of_existing_controller --user=user
```

If prompted to accept the certificate chain, enter `y` (yes).

The **replicate** command writes XML output to a console screen. You copy the output into the `server.xml` file.

**8.5.5.2** To write the output of the command to a file, instead of to a console screen, specify the `--createConfigFile=output_file_path` parameter. Then, include the outputted file in the collective configuration by adding an `include` statement to the `server.xml` file:

```
<include location=output_file_path />
```

- e. Add the XML output of the **replicate** command into the `server.xml` file of the replica and edit the parameter values as needed.
- Ensure that the `httpEndpoint` element sets `replica httpPort` and `httpsPort` values that are unique port numbers on the host. For example, suppose the original controller named `myController` and the replica are both on the same localhost and `myController` has the following the `httpEndpoint` element:

```
<httpEndpoint id="defaultHttpEndpoint"
  host="*"
  httpPort="9080"
  httpsPort="9443" />
```

Change the values for `myController2` to:

```
<httpEndpoint id="defaultHttpEndpoint"
  host="*"
  httpPort="9085"
  httpsPort="9448" />
```

- **8.5.5.4** Set RPC credentials for `hostAuthInfo`. You can set RPC credentials for the replica in either of two ways:

- Set `hostAuthInfo` RPC user and password values. Set `rpcUser` to an operating system login user ID for the host on which the replica resides, and set `rpcUserPassword` to the operating system login password for the user ID. For example, if you log into the replica computer with user `test1` and password `test1pwd`, then change the `hostAuthInfo` element to the following:

```
<hostAuthInfo rpcUser="test1" rpcUserPassword="test1pwd" />
```

- If the replica host is registered with the collective controller, set `hostAuthInfo useHostCredentials` to `true` for the replica to inherit RPC credentials from its host.

```
<hostAuthInfo useHostCredentials="true" />
```

See “Overriding Liberty server host information” on page 1144 for information about `hostAuthInfo` settings.

- Ensure that `replicaPort` sets a port number for the replica that is unique among the replica set and that `replicaSet` sets `host:port` values that identify the replica set. For example, if the original controller named `myController` and the replica are both on the same localhost, change the values for `myController2` from `null`:

```
<collectiveController replicaPort="null"
  replicaSet="localhost:null"
  isInitialReplicaSet="false" />
```

to 10011 for the replica port and 10010 for the replica set port:

```
<collectiveController replicaPort="10011"
  replicaSet="localhost:10010"
  isInitialReplicaSet="false" />
```

- Ensure the security configuration sets the same values as those used by the original controller. For example, both `myController` and the `myController2` replica use:

```
<quickStartSecurity userName="adminUser" userPassword="adminPassword" />
```

- Ensure the collective root signers keystore element sets the same password as that used by the original controller. For example, copy the `collectiveRootKeys` keystore password from the `myController` `server.xml` file and paste it into the `myController2` replica `server.xml` file. This example shows a generated password:

```
<!-- collective root signers keystore -->
<keyStore id="collectiveRootKeys" password="{xor}Lz4sLCgwLTs="
  location="{server.config.dir}/resources/collective/rootKeys.jks"/>
```

- f. Start the new replica by starting the new collective controller.

```
wlp/bin/server start myController2
```

g. Verify that the original collective controller can communicate with the new replica.

- 1) Open an editor on the original controller messages log, `$WLP_USER_DIR/servers/myController/logs/messages.log`.
- 2) Look for the following message, which might have different IP addresses in your environment:

```
CWWKX6009I: The collective controller successfully connected to replica 127.0.0.1:10011. Current active replica set is [127.0.0.1:
```

h. Verify that the new replica can communicate with the original collective controller.

- 1) Open an editor on the replica messages log, `$WLP_USER_DIR/servers/myController2/logs/messages.log`.
- 2) Look for the following message, which might have different IP addresses in your environment:

```
CWWKX6009I: The collective controller successfully connected to replica 127.0.0.1:10010. Current active replica set is []. The con
```

2. Activate the new replica.

Run an **addReplica** command that uses the administrative security domain configuration of the collective controller and specifies the endpoint of the replica that you want to activate in the form `replicaHost:replicaPort`. Look at the `server.xml` file of the collective controller to find the values for the `--host`, `--port`, `--user`, and `--password` parameters. Look at the `server.xml` file of the replica to find the values for `replicaHost:replicaPort`. For information about these parameters, run `collective help addReplica` at a command line.

```
wlp/bin/collective addReplica replicaHost:replicaPort --host=host_of_existing_controller --port=port_of_existing_controller --use
```

For this example, which has the existing collective controller and the replica on the same host, `localhost`, run:

```
wlp/bin/collective addReplica localhost:10011 --host=localhost --port=9443 --user=adminUser --password=adminPassword
```

If prompted to accept the certificate chain, enter `y` (yes).

3. Repeat steps 1 and 2 for additional replicas. For example, add a third replica to the replica set. Name the new replica `myController3` and specify `replicaPort="10012"`. A replica set must have at least three replicas for high availability.

After the third replica is added to the replica set, you can verify that the original collective controller and new replicas synchronized successfully.

- Look for the following messages in the original controller messages log. The messages might have different IP addresses in your environment:

```
CWWKX6015I: A request to change the active collective controller replica set was received and is now processing. The current active
```

```
CWWKX6016I: The active collective controller replica set changed successfully. The current active replica set is {127.0.0.1:10010,
```

```
CWWKX6011I: The collective controller is ready, and can accept requests. The leader is 127.0.0.1:10010. Current active replica set
```

```
CWWKX6014I: This collective controller replica finished synchronizing the data with the other replicas.
```

- Look for the following messages in the messages logs of the added replicas. The messages might have different IP addresses in your environment:

```
CWWKX6016I: The active collective controller replica set changed successfully. The current active replica set is {127.0.0.1:10010,
```

```
CWWKX6011I: The collective controller is ready, and can accept requests. The leader is 127.0.0.1:10010. Current active replica set
```

```
CWWKX8112I: The server's host information was successfully published to the collective repository.
```

```
CWWKX8114I: The server's paths were successfully published to the collective repository.
```

```
CWWKX8116I: The server STARTED state was successfully published to the collective repository.
```

## Setting up Liberty server clusters

8.5.5.0

A Liberty can be configured into a server cluster for application high availability and scale.

The `collectiveController-1.0` feature and its capabilities are available only in multiple-server products such as WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in single-server products such as WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a multiple-server product installation, you can use its `collectiveController-1.0` feature to work with collective members from single-server products.

A Liberty server cluster is comprised of two or more Liberty servers configured into a server cluster within a Liberty collective. A Liberty server cluster has a unique name within the collective. The `collectiveController-1.0` feature supports several operations on Liberty server clusters through the `ClusterManager` MBean:

- List clusters
- Start cluster
- Stop cluster
- List cluster members
- Generate cluster plug-in configuration

To be part of a server cluster, a Liberty must be a member of a Liberty collective and also be configured with the `clusterMember` feature.

A collective member can be a member of only one server cluster. All cluster members must be members of the same collective. Multiple server clusters can be configured within the same collective. The following diagram illustrates these relationships.

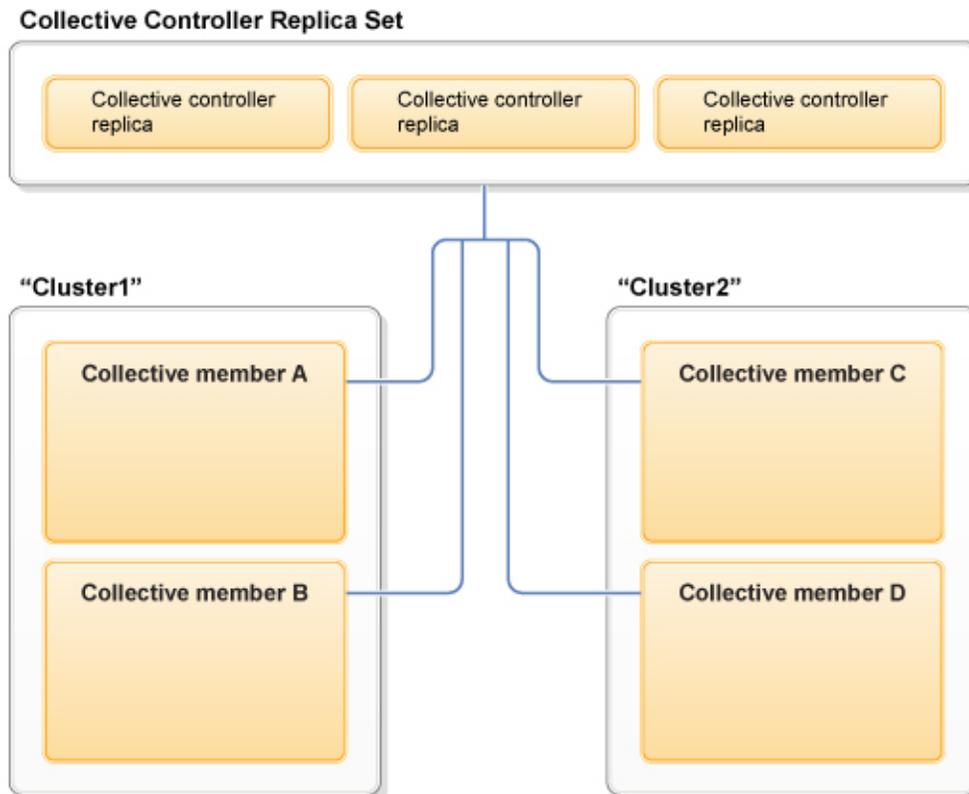

Figure 22. Liberty server clusters

## Configuring a Liberty server cluster

You can configure a collective member to be part of a server cluster by adding the `clusterMember-1.0` feature to the `member server.xml` file. Optionally, you can specify a cluster name to place the member in a particular server cluster. A server cluster has a unique name within a Liberty collective. All Liberty servers that specify the same cluster name within the same collective are members of the same server cluster.

### Before you begin

To be a member of a server cluster, a Liberty server must also be a member of a Liberty collective. If you do not have a Liberty collective and member already, create a collective controller and member server to join the collective. See “Configuring a Liberty collective” on page 1136.

### Procedure

1. Add the `clusterMember-1.0` feature to the feature manager of the `member server.xml` file.

```
<featureManager>
  <feature>collectiveMember-1.0</feature>
  <feature>clusterMember-1.0</feature>
</featureManager>
```

2. Optional: To designate that the member belong to a particular server cluster, add a `clusterMember` element that specifies a cluster name.

For example, place the member in the `myCluster` cluster:

```
<featureManager>
  <feature>collectiveMember-1.0</feature>
  <feature>clusterMember-1.0</feature>
</featureManager>
<clusterMember name="myCluster"/>
```

The default cluster name is `defaultCluster`. If the `member server.xml` does not have a `clusterMember` element that specifies a valid cluster name, then the member is added to `defaultCluster`.

Only specify one cluster name. A single collective can have multiple clusters, but a server can only be part of one cluster at a time.

3. If the collective controller and member server are not running, then start them.

The collective controller and member server must be running for the member to be added to the cluster. For example, use the **start** command to start a collective controller named `myController` and a member named `myMember`:

```
wlp/bin/server start myController

wlp/bin/server start myMember
```

You can configure a collective member to be a cluster member while the member server is running. The new configuration is updated dynamically and published to the collective controller. If you configure a collective member to be a cluster member while the member server is stopped, the member server will not become a member of a cluster until the server starts.

4. Verify that the member is part of the cluster.

- a. Look for a message that indicates the collective member now belongs to the cluster in the collective controller messages log.

The default path for the log is `${wlp.install.dir}/usr/servers/myController/logs/messages.log` or, if the `$WLP_USER_DIR` variable is set in a `server.env` file or command window, `$WLP_USER_DIR/servers/myController/logs/messages.log`.

```
CWWKX9051I: The myMember server has been added to the myCluster cluster.
```

- b. Look for messages that indicate the collective member is now a cluster member in the member messages log, `$WLP_USER_DIR/servers/myMember/logs/messages.log`.

```
CWWKX7400I: The ClusterMember MBean is available.
           myCluster
```

```
CWWKF0012I: The server installed the following features: [clusterMember-1.0].
```

## What to do next

To enable application security for the cluster, copy the LTPA key file from one of the cluster members to all the other members in the cluster. See “Creating a Liberty cluster with security considerations” on page 1488.

To administer the cluster, you can run collective controller `ClusterManager` MBean operations such as start or stop the server cluster, list clusters and cluster members in the collective, or generate a plug-in configuration file. You can run the operations using Jython scripts or a Java client such as JConsole.

**8.5.5.4** Also, you can use WebSphere Liberty Administrative Center (“Admin Center”) to administer the cluster and its servers, applications, and other resources from a web browser. See “Administering Liberty using Admin Center” on page 1741.

**8.5.5.4** After configuring a *static cluster*, which this topic describes, you can route application requests to Liberty servers using IBM HTTP Server (IHS). Static clusters can receive requests through either static or dynamic routing. For information about static routing, see “Generating a Liberty server cluster plug-in configuration” on page 1489. **Distributed operating systems** **z/OS** For information about dynamic routing, see “Setting up dynamic routing for Liberty collectives” on page 1493 and “Generating a plugin-cfg.xml to route to multiple collectives” on page 1499.

**8.5.5.4** To configure an *auto scaling cluster*, which expands and contracts depending on the workload in your environment, see “Setting up auto scaling for Liberty collectives” on page 1503. Auto scaling clusters can receive requests only through dynamic routing.

---

## Chapter 3. Migrating applications to Liberty

You can migrate applications to Liberty.

### Procedure

Migrate data access applications to the Liberty profile.

---

### Migrating data access applications to Liberty

For data access applications, you need to change configurations when you migrate a data source from the WebSphere Application Server traditional to Liberty.

### Procedure

- “Configuration differences between the traditional and Liberty: dataSource and jdbcDriver elements.”
- “Configuration differences between the traditional and Liberty: connectionManager element” on page 1158.
- “Migrating a DB2 data source to Liberty” on page 1159.
- “Migrating a Derby embedded data source to Liberty” on page 1161.

### Configuration differences between the traditional and Liberty: dataSource and jdbcDriver elements

There are some differences in configuration between dataSource in Liberty and data sources in the traditional .

- Data source properties with different names
  - **ifxIFX\_LOCK\_MODE\_WAIT**, which is **informixLockModeWait** in traditional.
  - **supplementalJDBCTrace**, which is **supplementalTrace** in traditional.
  - **transactional**, which is **nonTransactionalDataSource** in traditional.
  - **isolationLevel**, which is **webSphereDefaultIsolationLevel** in traditional.
  - **queryTimeout**, which is **webSphereDefaultQueryTimeout** in traditional.
  - **id**, which is **name** in traditional.
- Data source properties with different values
  - **beginTranForResultSetScrollingAPIs**, which is true by default in Liberty
  - **beginTranForVendorAPIs**, which is true by default in Liberty
  - **connectionSharing**, which is MatchOriginalRequest by default in Liberty
  - **statementCacheSize**, which is is a JDBC provider property in traditional, and a **dataSource** property in Liberty, with a default value of 10.
- Data source properties in traditional that have no Liberty equivalent
  - **category**
  - **supportsDynamicUpdates**
- **connectionSharing** property of data sources
  - Liberty allows **connectionSharing** to be configured to either MatchOriginalRequest or MatchCurrentState. By default, it is **MatchOriginalRequest**.
  - The traditional allows **connectionSharing** to be configured in a finer grained manner, where individual connection properties can be matched based on the original connection request or the current state of the connection. In the traditional, **connectionSharing** is a combination of bits

representing which connection properties to match based on the current state of the connection. In the traditional, a value of 0 means to match all properties based on the original connection request; a value of -1 means to match all properties based on the current state of the connection. The default value for the traditional is 1, which means that the isolation level is matched based on the current state of the connection and all other properties are matched based on the original connection request.

- Time duration properties of data source

Time duration properties can optionally be specified with units in Liberty. For example,

```
<dataSource id="informix" jndiName="jdbc/informix" queryTimeout="5m" ...>
  <properties.informix ifxIFX_LOCK_MODE_WAIT="120s" .../>
</dataSource>
```

See for accepted time units and formats of dataSource element. Omitting the units in Liberty is equivalent to the default units used in the traditional.

- Configuration for JDBC drivers

- In Liberty, you can take the same approach of configuring different jdbcDriver elements for XA capable and non-XA capable data source implementation classes. Alternatively, you can use a single jdbcDriver element for both. Defining multiple jdbcDriver elements does not cause different class loaders to be used. In Liberty, jdbcDriver elements always use the class loader of the shared library with which they are configured.
- In the traditional, a JDBC provider is defined to point to the JDBC driver JARs, compressed files, and native files. You must define separate JDBC providers for XA capable and non-XA capable data source implementation classes.

For some of the commonly used JDBC drivers, Liberty infers the data source implementation class names based on the names the driver JARs. Therefore, you can omit the implementation class names. For example:

```
<jdbcDriver id="Derby" libraryRef="DerbyLib"/>
<library id="DerbyLib">
  <fileset dir="C:/Drivers/derby" includes="derby.jar" />
</library>
```

Use the optional properties of the default implementation classes to override these classes such as javax.sql.DataSource, javax.sql.ConnectionPoolDataSource, and javax.sql.XADataSource.

The following example shows how to override the default javax.sql.XADataSource and javax.sql.ConnectionPoolDataSource implementations that Liberty selects

```
<jdbcDriver id="Derby" libraryRef="DerbyLib"
  javax.sql.XADataSource="org.apache.derby.jdbc.EmbeddedXADataSource"
  javax.sql.ConnectionPoolDataSource="org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource"/>
<library id="DerbyLib">
  <fileset dir="C:/Drivers/derby" includes="derby.jar" />
</library>
```

See for more information about the jdbcDriver element.

## Configuration differences between the traditional and Liberty: connectionManager element

There are some differences in configuration between connectionManager in Liberty and connection pools in the traditional.

- Properties with different names
  - **maxConnectionsPerThread**, which is **maxNumberOfMCSAllowableInThread** in the traditional.
  - **maxIdleTime**, which is **unusedTimeout** in the traditional.
  - **maxPoolSize**, which is **maxConnections** in the traditional.
  - **minPoolSize**, which is **minConnections** in the traditional.

- Time duration properties

You can optionally specify the time duration properties with units in Liberty. For example, `<connectionManager id="pool1" connectionTimeout="30s" reapTime="3m" maxIdleTime="30m"/>`

See for accepted time units and formats for the `connectionManager` element. If you do not specify time units in Liberty, the same default units are used as in the traditional.

- Differences between immediate timeout values and never (disable) timeout

There are differences in the values that represent immediate timeout and never (disabled) timeout.

- Liberty uses a value of 0 to represent immediate, whereas the traditional often uses -1 for immediate.
- Liberty uses a value of -1 to represent never (disabled), whereas the traditional often uses 0 for never (disabled).

Specifically this applies to the following attributes:

- **agedTimeout**
- **connectionTimeout**
- **maxIdleTime**, which is **unusedTimeout** in the traditional
- **reapTime**

- Purge policy changes

In Liberty, there are three purge policy values: **EntirePool**, **FailingConnectionOnly**, and **ValidateAllConnections**.

In the traditional, there are two purge policy values: **EntirePool** and **FailingConnectionOnly**, with a second property, `defaultPretestOptimizationOverride`, determining the behavior of **FailingConnectionOnly**.

Purge policies in Liberty, and their traditional equivalents, are as follows:

- `purgePolicy="EntirePool"`, which is the same for both.
- `purgePolicy="FailingConnectionOnly"`, which is equivalent to `purgePolicy="FailingConnectionOnly"` with `defaultPretestOptimizationOverride="false"` in the traditional.
- `purgePolicy="ValidateAllConnections"`, which is equivalent to `purgePolicy="FailingConnectionOnly"` with `defaultPretestOptimizationOverride="true"` in the traditional.

## Migrating a DB2 data source to Liberty

You can migrate a DB2 data source to Liberty.

### About this task

See the following code examples for the configurations for a DB2 data source in the traditional and Liberty.

### Example

In the traditional:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1321914412932"
    providerType="DB2 Using IBM JCC Driver" isolatedClassLoader="false"
    implementationClassName="com.ibm.db2.jcc.DB2ConnectionPoolDataSource" xa="false">
  <classpath>${DB2_JCC_DRIVER_PATH}/db2jcc4.jar</classpath>
  <classpath>${DB2_JCC_DRIVER_PATH}/db2jcc_license_cu.jar</classpath>
  <classpath>${DB2_JCC_DRIVER_PATH}/db2jcc_license_cisuz.jar</classpath>
  <factories xmi:type="resources.jdbc:DataSource" xmi:id="DataSource_1321914498985"
    name="DefaultDB2Datasource" jndiName="jdbc/DefaultDB2Datasource"
```

```

    providerType="DB2 Using IBM JCC Driver" authMechanismPreference="BASIC_PASSWORD"
    authDataAlias="IBM-9NE5C7ONIG4Node01/dbuser2" relationalResourceAdapter="builtin_rra"
    statementCacheSize="10"
    datasourceHelperClassname="com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper">

    required="false" ignore="false" confidential="false" supportsDynamicUpdates="false"/>
  <resourceProperties xmi:id="J2EEResourceProperty_1321914499063"
    name="syncQueryTimeoutWithTransactionTimeout" type="java.lang.Boolean" value="false"
    required="false" ignore="false" confidential="false" supportsDynamicUpdates="false"/>
  <resourceProperties xmi:id="J2EEResourceProperty_1321914499069"
    name="webSphereDefaultIsolationLevel" type="java.lang.Integer" value="2"
    required="false" ignore="false" confidential="false" supportsDynamicUpdates="false"/>
  <resourceProperties xmi:id="J2EEResourceProperty_1321914499070"
    name="webSphereDefaultQueryTimeout" type="java.lang.Integer" value="10"
    required="false" ignore="false" confidential="false" supportsDynamicUpdates="false"/>

```

```

    </propertySet>
    <connectionPool xmi:id="ConnectionPool_1321914499012" connectionTimeout="180"
        maxConnections="10" minConnections="1" reapTime="180" unusedTimeout="1800"
        agedTimeout="7200" purgePolicy="EntirePool" />
    <mapping xmi:id="MappingModule_1321914681786" mappingConfigAlias=""
        authDataAlias="IBM-9NE5C7ONIG4Node01/dbuser2"/>
</factories>
</resources.jdbc:JDBCProvider>
<systemLoginConfig xmi:id="JAASConfiguration_2">
    <authDataEntries xmi:id="auth1" alias="IBM-9NE5C7ONIG4Node01/dbuser2"
        userId="dbuser2" password="{xor}LDcfLTo70z0=" />
</systemLoginConfig>

```

In Liberty, the equivalent configuration is:

```

<variable name="DB2_JCC_DRIVER_PATH" value="C:/Drivers/DB2" />
<library id="db2Lib">
    <fileset dir="{DB2_JCC_DRIVER_PATH}" includes="db2jcc4.jar
        db2jcc_license_cu.jar db2jcc_license_cisuz.jar" />
</library>
<dataSource id="DefaultDB2Datasource" jndiName="jdbc/DefaultDB2Datasource"
    statementCacheSize="10"
    beginTranForResultSetScrollingAPIs="false"
    beginTranForVendorAPIs="false"
    connectionSharing="MatchCurrentState"
    transactional="false"
    syncQueryTimeoutWithTransactionTimeout="false"
    isolationLevel="TRANSACTION_READ_COMMITTED"
    queryTimeout="10"
    >

        password="{xor}LDcfLTo70z0="
    />
    <connectionManager connectionTimeout="180" maxPoolSize="10" minPoolSize="1" reapTime="180"
        maxIdleTime="1800" agedTimeout="7200" purgePolicy="EntirePool"/>
</dataSource>

```

## Migrating a Derby embedded data source to Liberty

You can migrate a Derby Embedded data source to Liberty.

### About this task

See the following code examples for the configurations for a Derby Embedded data source in the traditional and Liberty.

## Example

In the traditional:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1183122153343"
  providerType="Derby JDBC Provider"
  implementationClassName="org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource"
  xa="false">
  <classpath>${DERBY_JDBC_DRIVER_PATH}/derby.jar</classpath>
  <factories xmi:type="resources.jdbc:DataSource" xmi:id="DataSource_1183122153625"
    name="DefaultDerbyDatasource" jndiName="jdbc/DefaultDatasource"
    providerType="Derby JDBC Provider" authMechanismPreference="BASIC_PASSWORD"
    relationalResourceAdapter="builtin_rra" statementCacheSize="10"
    datasourceHelperClassName="com.ibm.websphere.rsadapter.DerbyDataStoreHelper">
    <propertySet xmi:id="J2EEResourcePropertySet_1183122153625">
      <resourceProperties xmi:id="J2EEResourceProperty_1183122153625" name="databaseName"
        type="java.lang.String" value="C:/myDerby/DefaultDB" required="true"/>
      <resourceProperties xmi:id="J2EEResourceProperty_1183122153626" name="shutdownDatabase"
        type="java.lang.String" value="false" required="false"/>
      <resourceProperties xmi:id="J2EEResourceProperty_1183122153629" name="connectionAttributes"
        type="java.lang.String" value="upgrade=true" required="false"/>
      <resourceProperties xmi:id="J2EEResourceProperty_1183122153630" name="createDatabase"
        type="java.lang.String" value="create" required="false"/>
    </propertySet>
    <connectionPool xmi:id="ConnectionPool_1183122153625" connectionTimeout="180"
      maxConnections="10" minConnections="1" reapTime="180" unusedTimeout="1800"
      agedTimeout="7200" purgePolicy="EntirePool"/>
  </factories>
</resources.jdbc:JDBCProvider>
```

In Liberty, the equivalent configuration is:

```
<variable name="DERBY_JDBC_DRIVER_PATH" value="C:/Drivers/derby" />
<library id="derbyLib">
  <fileset dir="${DERBY_JDBC_DRIVER_PATH}" includes="derby.jar" />
</library>
<dataSource id="DefaultDerbyDatasource" jndiName="jdbc/DefaultDatasource"
  statementCacheSize="10">
  <jdbcDriver libraryRef="derbyLib"
    javax.sql.ConnectionPoolDataSource="org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource"/>
  <properties.derby.embedded
    databaseName="C:/myDerby/DefaultDB"
    shutdownDatabase="false"
    connectionAttributes="upgrade=true"
    createDatabase="create"
  />
  <connectionManager connectionTimeout="180" maxPoolSize="10" minPoolSize="1" reapTime="180"
    maxIdleTime="1800" agedTimeout="7200" purgePolicy="EntirePool" />
</dataSource>
```

---

## Chapter 4. Installing Liberty

There are two methods for installing the WebSphere Application Server Liberty . You can use Installation Manager or use downloaded archive files. With either method, you can also download additional assets from the Liberty Repository.

### About this task

- | **New:** Liberty now follows a continuous delivery process with a new fix pack numbering scheme. Fix pack 16.0.0.2 is the next fix pack after 8.5.5.9. For more information about fix pack 16.0.0.2, see What is new in Liberty in the new location of the latest Liberty documentation.

When choosing installation methods, consider the packaging strategy of each method.

- For Installation Manager, you can download a single package that contains all requested content.
- For downloaded archive files, content is packaged in multiple archives to reduce download size.

The following table compares the available installation methods for WebSphere Application Server Liberty .

Table 90. Comparison of available installation methods

	Installation Manager	Archive
Agent-less installation	No	Yes
Install directly to any fix pack level	Yes	Yes
Apply fix packs in place	Yes	No
Apply interim fixes in place	Yes	Yes
Automated rollback of fix packs and interim fixes	Yes	No
Upgrade product editions	Yes	<b>8.5.5.5</b> Yes
Pluggable Java SDK provided	Yes	No
Integrated with developer tools	No	Yes
Add features in place	Yes	Yes
Liberty Repository integration	Yes	Yes
z/OS packaging provided	Yes	No
Minification supported	Yes, but the output of the minify command is a new image that can only be serviced with archive procedures.	Yes, the output of the minify command is a new image.

**z/OS** On the z/OS platform, installing the profile with downloaded archive files is not supported.

### Procedure

1. Install Liberty using one of the following methods:
  - a. Install Liberty using the Installation Manager.
  - b. Install Liberty using downloaded files and archives. You can install Liberty from a self-extracting Java archive file or a ZIP archive file.
2. Optional: Install assets from the Liberty Repository.

---

## Installing and uninstalling Liberty using Installation Manager

8.5.5.0

You can install WebSphere Application Server Liberty using IBM Installation Manager.

### About this task

**Note:** 8.5.5.11 Support for using Java SE 6 with WebSphere Liberty ends in September 2017. After the end of support, the Liberty kernel will be recompiled and can no longer run with Java SE 6. If you continue to use Java SE 6 on earlier fix packs after the end of support date, you could expose your environment to security risks.

Java SE 8 is the recommended Java SDK because it provides the latest features and security updates. You can install it by installing the IBM SDK, Java Technology Edition, Version 8 package to the package group that contains WebSphere Liberty.

Installation Manager is a general-purpose software installation and update tool that runs on a range of computer systems.

**Note:** Although WebSphere Application Server Liberty can be installed and maintained using Installation Manager Version 1.5.2 and later, this information is optimized for use with Installation Manager Version 1.6.2 and later. To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

**Note:** Starting with Version 1.6.2, Installation Manager supports Mac OS X. Installing and maintaining a Liberty offering using Installation Manager on Mac OS X is supported for the following offerings:

- IBM WebSphere Application Server Liberty
- IBM WebSphere Application Server Liberty Trial
- IBM WebSphere Application Server Liberty Core
- IBM WebSphere Application Server Liberty Core Trial
- IBM WebSphere Application Server Liberty - Express
- IBM WebSphere Application Server Liberty Network Deployment
- IBM WebSphere Application Server Liberty Network Deployment Trial
- IBM WebSphere Application Server Liberty for Developers
- IBM WebSphere Application Server Liberty for Developers (ILAN)

Installation Manager for Mac OS X is not contained in the product image or on the product media. You can obtain Installation Manager Version 1.6.2 and later from the IBM Installation Manager download website. Refer to the System Requirements for IBM Installation Manager website and System Requirements for WebSphere Application Server Version 8.5.5 website for complete details on Mac OS X support.

| **Note:** You can install WebSphere Application Server Liberty using the Installation Manager Graphical User Interface (GUI) or Installation Manager in console mode. Console mode is an interactive text-based user interface to Installation Manager. Use console mode when you do not have a graphics display device available or when you want to run the Installation Manager without the graphical user interface. For example, use console mode for server-side deployments when no graphical user interface is present, or for running the installation from a remote host.

| **New:** Liberty now follows a continuous delivery process with a new fix pack numbering scheme. Fix pack 16.0.0.2 is the next fix pack after 8.5.5.9. You can continue to use the same Version 8.5 Installation

Manager repositories and offering IDs to install or update to 16.0.0.2, or you can use the new versionless repositories and offerings. For more information about fix pack 16.0.0.2, see What is new in Liberty in the new location of the latest Liberty documentation.

Choose from the following options for more information on using Installation Manager for your installation.

## Procedure

- To install Liberty using Installation Manager, choose from the following options:
  - **Distributed operating systems** “Installing and uninstalling Liberty on distributed operating systems”
  - **IBM i** “Installing and uninstalling Liberty on IBM i operating systems” on page 1292
  - **z/OS** “Installing Liberty on z/OS” on page 1343
- **8.5.5.1** If you want to use Installation Manager in console mode, see: Installation Manager Version 1.6 documentation or the Installation Manager Version 1.5 documentation.

## Installing and uninstalling Liberty on distributed operating systems

### 8.5.5.0

IBM Installation Manager is a common installer for many IBM software products. You can use Installation Manager to install and manage the product lifecycle of WebSphere Application Server Liberty Network Deployment.

## Before you begin

Installation Manager is a single installation program that can use remote or local software flat-file repositories to install, modify, or update WebSphere Application Server products. It determines and shows available packages - including products, fix packs, interim fixes, and so on - checks prerequisites and interdependencies, and installs the selected packages. You also use Installation Manager to easily uninstall the packages that it installed.

### Restrictions:

- If you have an earlier Alpha or a Beta version of WebSphere Application Server Liberty Network Deployment installed, uninstall it before installing this version.
- **Windows** If a non-administrator installs WebSphere Application Server Liberty Network Deployment on a Windows Vista, Windows 7, or Windows Server 2008 operating system into the Program Files or Program Files (x86) directory with User Account Control (UAC) enabled, WebSphere Application Server Liberty Network Deployment will not function correctly.

UAC is an access-control mechanism that allows non-administrative users to install a software product into the Program Files or Program Files (x86) directory; but it then prohibits any write access to that directory after the installation has completed.

To resolve this issue, perform one of the following actions:

- Install the offering into a directory other than Program Files or Program Files (x86).

For example:

C:\IBM\WebSphere\Liberty

- Disable UAC.

- When you install an offering using Installation Manager with local repositories, the installation takes a significantly longer amount of time if you use a compressed repository file directly without extracting it.

Before you install an offering using local repositories, extract the compressed repository file to a location on your local system before using Installation Manager to access it.

**Important:** Do not transfer the content of a repository in non-binary mode and do not convert any content on extraction.

**Tip:** Although almost all of the instructions in this section of the documentation work with earlier versions of IBM Installation Manager, this information is optimized for users who installed or upgraded to Installation Manager Version 1.6.2 or later. Version 8.5.5.4 and later of Liberty require Installation Manager Version 1.6.2 or later.

- | **Tip:** Different users can use WebSphere Liberty by using two different methods.
- | 1. Install a new WebSphere Liberty instance for each user. Each WebSphere Liberty install is a new user profile.
- | 2. Create multiple servers with different users. Each user should be part of a group that has access to the wlpdirectory and java\_home used.
- | If you use option two, run the command to create the server as the user who will run the server and create the server in the user's home directory. If you are using Linux, the command is similar to `su user1 export WLP_USER_DIR=/home/user1 server create Server1`.
- | Setting WLP\_USER\_DIR in the user's shell profile makes it easy to ensure that all Liberty commands act on the correct user directory.

**Important:** Installation Manager can install any fix-pack level of the offering directly without installing the intermediate fix packs; in fact, Installation Manager installs the latest level by default. For example, you can skip fix-pack levels and go from Version 8.5.5.1 directly to Version 8.5.5.5. Keep in mind, however, that later you can not roll back to any level that was skipped. If you directly install to Version 8.5.5.5, for example, you cannot roll back to Version 8.5.5.4. If you skip from Version 8.5.5.1 to Version 8.5.5.5, you can only roll back to Version 8.5.5.1. You should plan your installations accordingly.

## About this task

Prepare your system as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.

Perform one of these procedures to install or uninstall WebSphere Application Server Liberty Network Deployment using Installation Manager.

## Procedure

- “Installing Liberty on distributed operating systems using the GUI” on page 1171
- “Installing Liberty on distributed operating systems by using the command line” on page 1174
- “Installing Liberty on distributed operating systems by using response files” on page 1178
- “Uninstalling Liberty from distributed operating systems using the GUI” on page 1188
- “Uninstalling Liberty from distributed operating systems using the command line” on page 1189
- “Uninstalling Liberty from distributed operating systems by using response files” on page 1189

## Results

### Notes on logging and tracing:

- An easy way to view the logs is to open Installation Manager and go to **File > View Log**. An individual log file can be opened by selecting it in the table and then clicking the **Open log file** icon.
- Logs are located in the logs directory of Installation Manager's application data location. For example:

- **Windows** **Administrative installation:**

C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager

- **Windows** **Non-administrative installation:**

C:\Documents and Settings\user\_name\Application Data\IBM\Installation Manager

- **AIX** **HP-UX** **Linux** **Solaris** **Administrative installation:**

/var/IBM/InstallationManager

- **AIX** **HP-UX** **Linux** **Solaris** **Non-administrative installation:**

user\_home/var/ibm/InstallationManager

- The main log files are time-stamped XML files in the logs directory, and they can be viewed using any standard web browser.
- The log.properties file in the logs directory specifies the level of logging or tracing that Installation Manager uses.

### Notes on troubleshooting:

- **HP-UX** When you attempt to launch Installation Manager from a DVD that was mounted using the CD-ROM file system (CDFS) on an HP-UX operating system, it might fail to launch and point to a log file that contains an exceptions similar to one of the following:

java.util.zip.ZipException: Exception in opening zip file:

org.osgi.framework.BundleException: Exception in  
org.eclipse.update.internal.configurator.ConfigurationActivator.start()  
or bundle org.eclipse.update.configurator.

This issue might be caused by Installation Manager reaching the upper limit of number of descriptors that can be opened on a CDFS-mounted device. This upper limit is determined by the value for the tunable kernel parameter ncdnode, which specifies the maximum number of CDFS nodes that can be in memory at any given time. To resolve the problem, change the ncdnode system kernel setting to 250. If the problem persists, increase the setting.

- **HP-UX** By default, some HP-UX systems are configured to not use DNS to resolve host names. This could result in Installation Manager not being able to connect to an external repository.

You can ping the repository, but nslookup does not return anything.

Work with your system administrator to configure your machine to use DNS, or use the IP address of the repository.

- In some cases, you might need to bypass existing checking mechanisms in Installation Manager.
  - On some network file systems, disk space might not be reported correctly at times; and you might need to bypass disk-space checking and proceed with your installation. To bypass disk-space checking, add `cic.override.disk.space=true` to the `config.ini` file in `IM_install_root/eclipse/configuration` and restart Installation Manager.
  - To bypass operating-system prerequisite checking, add `disableOSPrereqChecking=true` to the `config.ini` file in `IM_install_root/eclipse/configuration` and restart Installation Manager.

If you need to use any of these bypass methods, contact IBM Support for assistance in developing a solution that does not involve bypassing the Installation Manager checking mechanisms.

- For more information on using Installation Manager, read the IBM Installation Manager Information Center.

Read the release notes to learn more about the latest version of Installation Manager. To access the release notes, complete the following task:

- **Windows** Click **Start > Programs > IBM Installation Manager > Release Notes**.

- **AIX** **HP-UX** **Linux** **Solaris** Go to the documentation subdirectory in the directory where Installation Manager is installed, and open the `readme.html` file.

- If a fatal error occurs when you try to install the offering, take the following steps:

- Make a backup copy of your current installation directory in case IBM support needs to review it later.
- Use Installation Manager to uninstall everything that you have installed under the installation location (package group). You might run into errors, but they can be safely ignored.
- Delete everything that remains in the installation directory.
- Use Installation Manager to reinstall the offering to the same location or to a new one.
- **8.5.5.1** If you are installing WebSphere Application Server Liberty Version 8.5.5.1 in console mode, you might receive warning messages similar to the following example:

No "conClass" attribute in "commonPanel" element of panel com.ibm.was.liberty.userdata.panel.UserData in com.ibm.was.liberty.userdata.panel.

This problem is caused by an IBM Installation Manager API which is deprecated in Version 1.6.2. These warning messages can be ignored. No action is required.

## Installing Installation Manager and preparing to install Liberty

### 8.5.5.0

Install Installation Manager and obtain the necessary product repositories before installing WebSphere Application Server Liberty Network Deployment.

### About this task

To install Liberty, you must have Installation Manager Version 1.5.2 or later.

**Note:** **8.5.5.4** To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

### Procedure

#### 1. Install Installation Manager.

- a. Obtain the necessary installation files.

There are three basic options for obtaining Installation Manager Version 1.5.2 or later.

- **Access the physical media.**
- **Download the files from the Passport Advantage site.**

Licensed customers with a Passport Advantage ID and password can download Installation Manager from the Passport Advantage site.

**Tip:** See How to download WebSphere Application Server V8.5.5 from Passport Advantage Online.

- **Download the most current version of Installation Manager from the download website.**

You can download the most current version of Installation Manager from the IBM Installation Manager download website.

- b. Change to the location containing the Installation Manager installation files, and run one of the following commands.

#### Administrative installation:

- **Windows** `install.exe`
- **AIX** **HP-UX** **Linux** **Solaris** `./install`

#### Non-administrative installation:

- **Windows** `userinst.exe`
- **AIX** **HP-UX** **Linux** **Solaris** `./userinst`

## Group-mode installation:

**AIX** **HP-UX** **Linux** **Solaris** `./groupinst`

### Notes® on group mode:

- Group mode allows multiple users to use a single instance of IBM Installation Manager to manage software packages.  
This does not mean that two people can use the single instance of IBM Installation Manager at the same time.
- **Windows** Group mode is not available on Windows operating systems.
- If you do not install Installation Manager using group mode, you will not be able to use group mode to manage any of the products that you install later using this Installation Manager.
- Make sure that you change the installation location from the default location in the current user's home directory to a location that is accessible by all users in the group.
- Set up your groups, permissions, and environment variables as described in the Group mode road maps in the IBM Installation Manager documentation before installing in group mode.
- For more information on using group mode, read the Group mode road maps in the IBM Installation Manager documentation.

The installer opens an **Install Packages** window.

c. Make sure that the Installation Manager package is selected, and click **Next**.

d. Accept the terms in the license agreements, and click **Next**.

The program creates the directory for your installation.

e. Click **Next**.

f. Review the summary information, and click **Install**.

- If the installation is successful, the program displays a message indicating that installation is successful.
- If the installation is not successful, click **View Log File** to troubleshoot the problem.

## 2. Update an Installation Manager installation that is already on your system.

For information on updating Installation Manager to Version 1.5.2 or later, see the IBM Installation Manager documentation.

## 3. Obtain the product repositories.

There are three basic options for accessing the product repositories to install the offering.

- **Access the physical media, and use local installation.**

You can access the product repositories on the media.

- **Download the files from the Passport Advantage site, and use local installation.**

Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

**Tip:** See How to download WebSphere Application Server V8.5.5 from Passport Advantage Online for a list of the IBM WebSphere Application Server Liberty Network Deployment installation images downloadable from the IBM Passport Advantage Online website and other information.

- **Access the live repositories, and use web-based installation.**

If you have a Passport Advantage ID and password, you can access the product repositories and install the offering from the web-based repositories. Use Installation Manager to install the offering from the web-based repository located at

<http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85>

**Note:** This location does not contain a web page that you can access using a web browser. This is a remote web-based repository location that you must add to your Installation Manager preferences before the Installation Manager GUI can access the files in this repository to install the offering.

**Tip:** This live repository is accessed by using Passport Advantage authentication. After you have installed Installation Manager, you can set the Passport Advantage preference to connect to the live repositories. To set Passport Advantage preferences, follow this procedure:

- a. Open Installation Manager.
- b. Open the Passport Advantage preferences page by selecting **File > Preferences > Passport Advantage**.
- c. Select **Connect to Passport Advantage** to connect to the Passport Advantage repository.  
The Password Required dialog box opens.
- d. Enter a user name and password for Passport Advantage.
- e. **Optional:** Select **Save password** to save the user name and password credentials.  
If you do not save the user name and password credentials, you are prompted for these credentials each time you access Passport Advantage.
- f. Click **OK** to close the Password Required dialog box.
- g. Click **OK** to close the Preferences window.

For more information on setting your Installation Manager preferences, see the IBM Installation Manager documentation.

Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

**Notes:**

- If you do not have a Passport Advantage ID and password, you must install the offering from the product repositories on the media or local repositories.
- With the Packaging Utility, you can create and manage packages for installation repositories. You can copy multiple packages into one repository or copy multiple disks for one product into a repository. You can copy packages from Passport Advantage or a web-based repository into a local repository for example. For more information on the Packaging Utility, go to the IBM Installation Manager documentation.

4.   Optional: Configure an instance of the Liberty Asset Repository Service or a local directory-based repository.

As part of installing Liberty, you can choose to install assets from the following repositories:

- The IBM WebSphere Liberty Repository, a public IBM-hosted repository that is accessible through the internet. For more information, see “Liberty: Liberty Repository” on page 965.
- The Liberty Asset Repository Service, an open-source service that you can use to create an on-premises repository that is remotely accessible behind the firewall of an enterprise. For more information, see the WASdev/tool.lars project on GitHub.
- Local directory-based repositories that are created by using the **installUtility download** action. For more information, see “Downloading assets using the installUtility command” on page 1400.

Access to the IBM WebSphere Liberty Repository is enabled by default and requires internet access. If your system does not have internet access or you want to install customized Liberty assets, set up an instance of the Liberty Asset Repository Service or a local directory-based repository, and then add the repository in Installation Manager. For more information about the Liberty repositories, see “Installing assets using Installation Manager” on page 1411.

5. **Optional: If you will be using the Installation Manager GUI, add repositories to your Installation Manager preferences.**
- a. Launch Installation Manager.
  - b. Click **File > Preferences**.

- c. Select **Repositories**.
- d. Perform the following actions:
  - 1) Click **Add Repository**.
  - 2) Enter the path to the repository.config file in the location containing the repository files.

For example:

- Windows C:\repositories\offering\_name\local-repositories
- AIX HP-UX Linux Solaris /var/repositories/offering\_name/local-repositories

or

<http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85>

- 3) Click **OK**.
- e. Deselect any locations listed in the Repositories window that you will not be using.
- f. Click **Apply**.
- g. Click **OK**.
- h. Click **File > Exit** to close Installation Manager.

For more information on setting your Installation Manager preferences, see the IBM Installation Manager documentation.

## 6. Optional: If you will be using the Installation Manager GUI, set your Installation Manager rollback preferences.

By default, Installation Manager saves earlier versions of a package to roll back to if you experience issues later. When Installation Manager rolls back a package to a previous version, the current version of the files are uninstalled and the earlier versions are reinstalled. If you choose not to save the files for rollback, you can prevent the files from being saved or delete them after they are saved. To set your rollback preferences, perform the following actions before installing a package:

- a. Launch Installation Manager.
- b. Open the Rollback preferences window by selecting **File > Preferences > Files for Rollback**.
- c. Select or clear the **Save files for rollback** option to save or to stop saving a copy of files that are required to roll back packages on your computer.

You can remove any files that have already been saved by clicking **Delete Saved Files**. If you delete the files and you need to roll back a package later, you must connect to a repository or insert the media to obtain the required files for the previous version of the package.

- d. Click **OK** to save your rollback preferences.

For more information on setting your Installation Manager preferences, see the IBM Installation Manager documentation.

## What to do next

Use Installation Manager to install the offering.

- “Installing Liberty on distributed operating systems using the GUI”
- “Installing Liberty on distributed operating systems by using the command line” on page 1174
- “Installing Liberty on distributed operating systems by using response files” on page 1178

## Installing Liberty on distributed operating systems using the GUI

**8.5.5.0**

You can use the Installation Manager GUI to install WebSphere Application Server Liberty Network Deployment.

## Before you begin

Prepare your system as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.

## About this task

**8.5.5.4** To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

## Procedure

1. Start Installation Manager.

**Tip:** **AIX** **HP-UX** **Linux** **Solaris** You can start Installation Manager in group mode with the `./IBMIM` command.

- Group mode allows multiple users to use a single instance of IBM Installation Manager to manage software packages.
- For more information on using group mode, read the Group mode road maps in the IBM Installation Manager documentation.

2. Click **Install**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

Installation Manager searches its defined repositories for available packages.

3. Perform the following actions.

- a. Select **IBM WebSphere Application Server Liberty Network Deployment** and the appropriate version.

**Note:** If you are installing the trial version of this product, select the appropriate trial edition and the appropriate version.

If you already have the WebSphere Application Server Liberty Network Deployment offering installed on your system in the installation location, a message displays indicating that the product is already installed. To create another installation of the offering in another location, click **Continue**.

**Tip:** If the **Search service repositories during installation and updates** option is selected on the Installation Manager Repository preference page and you are connected to the Internet, you can click **Check for Other Versions and Extensions** to search for updates in the default update repositories for the selected packages. In this case, you do not need to add the specific service-repository URL to the Installation Manager Repository preference page.

- b. Select the fixes to install.

Any recommended fixes are selected by default.

If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.

- c. Click **Next**.

**Note:** Installation Manager might prompt you to update to the latest level of Installation Manager when it connects to the repository. Update to the newer version before you continue if you are prompted to do so. Read the IBM Installation Manager documentation for information about automatic updates.

4. Accept the terms in the license agreements, and click **Next**.

5. Specify the installation root directory for the product binaries, which are also referred to as the core product files or system files.

The panel also displays the shared resources directory and disk-space information.

**Note:** The first time that you install a package using Installation Manager, you can specify the shared resources directory. The shared resources directory is where installation artifacts are located that can be used by one or more package groups. It is also used as a staging area for the product payload during installation operations. By default, this content is cached so that it can be used for rollback. Consider setting your rollback preferences to save these files as described in “Installing Installation Manager and preparing to install Liberty” on page 1168. Use your largest drive for this installation. You cannot change the directory location until after you uninstall all packages.

If you are installing on a 64-bit system, use the bit-selection option to select the bitness of the installed Java libraries. If you are installing on a 32-bit system, this option is not available. When installing on a 64-bit system, you must select either the 32-bit or 64-bit option. This choice will determine the architecture bitness of the installation profile group. All extension offerings to WebSphere Application Server Liberty Network Deployment will be installed under the same profile group and have the same architecture bitness. For example, WebSphere SDK Java Technology Edition Version 7.0 for Liberty is an extension offering to WebSphere Application Server Liberty Network Deployment and its installation will use a 32-bit or 64-bit JDK depending on your choice here.

#### Restrictions:

- Deleting the default target location and leaving an installation-directory field empty prevents you from continuing.
- Do not use symbolic links as the destination directory.  
Symbolic links are not supported.
- Do not use a semicolon in the directory name.

WebSphere Application Server Liberty Network Deployment cannot install properly if the target directory includes a semicolon.

 A semicolon is the character used to construct the class path on Windows systems.

6. Click **Next**.
7. Select the features that you want to install.

Choose from the following features:

- IBM WebSphere Application Server Liberty Network Deployment
  - Embeddable EJB container and JPA client

This option installs the embeddable EJB container and JPA client.

The embeddable EJB container is a Java Archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition (SE) environment. You can run enterprise beans using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.

The JPA client can be used with the embeddable EJB container to provide Java Persistence API capability in a Java SE environment.

**Tip:** You can run Installation Manager later to modify this installation and add or remove this feature.

- Extended Programming Models (Versions 8.5.5.0 to 8.5.5.3)

The Extended Programming Models feature provides a rich set of programming models such as Web Services, JMS (including Message-Driven Beans), and MongoDB 2.0.

8.5.5.4

Beginning with Version 8.5.5.4, the Extended Programming Models are available from the Liberty Repository. This asset provides a rich set of programming models such as Web

Services, JMS (including Message-Driven Beans), and MongoDB 2.0. To install this asset, use the Asset Selection Wizard as described in later steps.

8. Click **Next**.

9.  **8.5.5.2** Optional: Install additional Liberty Repository assets. If you do not want to select any additional assets, you can skip this step. To install Liberty Repository assets, you must have IBM Installation Manager Version 1.6.2 or later. To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.

a. Select whether you want to install assets from the Liberty Repository, and click **Next**. To install assets from the IBM WebSphere Liberty Repository, you must have access to the internet.

**8.5.5.6** If you choose not to connect to the IBM WebSphere Liberty Repository, you can still install assets from configured directory-based repositories or an instance of the Liberty Asset Repository Service. For more information, see “Installing assets using Installation Manager” on page 1411.

b. **8.5.5.4** Click **Launch Asset Selection Wizard**.

c. You can perform a case-insensitive search for assets by display name or description. If you search with the **Keyword** field empty, then the search displays all applicable assets.

**8.5.5.5** With Version 8.5.5.5 and later, you can also search for assets by short name.

d. Select each asset that you want to install, then click **Next**.

e. Accept the license agreement and click **Finish**.

10. Click **Next**.

11. Review the summary information, and click **Install**.

- If the installation is successful, the program displays a message indicating that installation is successful. The program might also display important post-installation instructions.
- If the installation is not successful, click **View Log File** to troubleshoot the problem.

12. Click **Finish**.

13. Click **File > Exit** to close Installation Manager.

## Installing Liberty on distributed operating systems by using the command line

### **8.5.5.0**

You can install WebSphere Application Server Liberty Network Deployment by using the Installation Manager command line.

### Before you begin

**Important:** Before you install WebSphere Application Server Liberty Network Deployment, you must read the license agreement that you can find with the product files. Signify your acceptance of the license agreement by specifying `-acceptLicense` in the command as described in this topic.

Prepare the system onto which you want to install WebSphere Application Server Liberty Network Deployment as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.

### About this task

**8.5.5.4** To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

### Procedure

1. Optional: If the repository requires a user name and password, create credential-storage and master-password files to access this repository.

**Tip:** When you create a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutilsc` command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, use the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the `-keyring` and `-password` options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the `-keyring` and `-password` options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

2. Log on to your system.
3. Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.
4. Verify that the offering repository is available.

Windows

```
imcl.exe listAvailablePackages -repositories source_repository
```

AIX

HP-UX

Linux

Solaris

```
./imcl listAvailablePackages -repositories source_repository
```

You see one or more levels of the offering.

5. Use the `imcl` command to install the offering.

Windows

```
imcl.exe install com.ibm.websphere.liberty.ND.v85_offering_version,optional_feature_ID  
-repositories source_repository  
-installationDirectory installation_directory  
-sharedResourcesDirectory shared_directory  
-preferences preference_key=value  
-properties property_key=value  
-secureStorageFile storage_file -masterPasswordFile master_password_file  
-acceptLicense
```

AIX

HP-UX

Linux

Solaris

```
./imcl install com.ibm.websphere.liberty.ND.v85_offering_version,optional_feature_ID  
-repositories source_repository  
-installationDirectory installation_directory  
-sharedResourcesDirectory shared_directory  
-preferences preference_key=value  
-properties property_key=value  
-secureStorageFile storage_file -masterPasswordFile master_password_file  
-acceptLicense
```

### Tips:

- The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lafiles` or `offering_name/lafiles` subdirectory of the installation image or repository for this offering.
- The first time that you install a package by using the Installation Manager, you can specify the shared resources directory. The shared resources directory is where installation artifacts are located that can be used by one or more package groups. It is also used as a staging area for the product payload during installation operations. By default, this content is cached so that it can be used for rollback. Use your largest drive for this installation. You cannot change the directory location until after you uninstall all packages.
- The `offering_version`, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (8.5.5.20110503\_0200 for example).
  - If `offering_version` is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If `offering_version` is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the `-installFixes` argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the `-installFixes` option defaults to all.
  - If the offering version is specified, the `-installFixes` option defaults to none.
- You can add a list of features that are separated by commas:
  - Embeddable EJB container and JPA client (`embeddablecontainer`)  
This option installs the embeddable EJB container and JPA client.  
The embeddable EJB container is a Java Archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition (SE) environment. You can run enterprise beans by using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.  
The JPA client can be used with the embeddable EJB container to provide Java Persistence API capability in a Java SE environment.
  - Extended Programming Models (`extprogmodels`) - Versions 8.5.5.0 to 8.5.5.3  
The Extended Programming Models feature provides a rich set of programming models such as Web Services, JMS (including Message-Driven Beans), and MongoDB 2.0.

#### Notes:

- If no features are specified, the default features (`embeddablecontainer` and `extprogmodels` Version 8.5.5.3 and previous) are installed. To install only the feature that you want, specify that feature explicitly.

8.5.5.4

Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` addon, or install the individual features that you need from the Liberty Repository. See the following topics for more information:

- Installing Liberty Repository assets
- Liberty features
- To ensure that your installation process completes for systems that do not have internet access specify the `-properties user.feature=""` parameter on the Installation Manager command line. If you do not specify this parameter, the installation process attempts to access the internet and an error occurs.  
ERROR: Unable to connect to the IBM WebSphere Liberty repository or local Installation Manager repository.

Verify that firewalls are configured to allow the Installation Manager to access the internet, or that the local Installation Manager repository can be accessed. If the problem persists, then the repository server might be unavailable. To continue the installation without additional assets, specify the `user.feature=""` and `user.addon=""` parameters.

- 8.5.5.5

You can receive a `NullPointerException` when you apply fix pack V8.5.5.5 for WebSphere Application Server Liberty. The error can occur when you download the WebSphere Application Server Liberty fix pack compressed files and use them, at the downloaded directory location, to install or update Liberty. You can work around this Version 8.5.5.5 error condition by taking the following steps:
- Extract the WebSphere Application Server Liberty fix pack compressed file to a temporary directory.
- Use the temporary directory as the Installation Manager repositories to install or update Liberty.

```

unzip 8.5.5-WS-LIBERTYPROFILE-OS390-FP0000005.zip to /tmp/fp8555
# ./imcl install
com.ibm.websphere.liberty.v85_8.5.5005.20150305_2214
-installationDirectory /SERVICE/usr/lpp/zWebSphere/Liberty/V8R5
-repositories
/tmp/fp8555
-acceptLicense

```

- 
**8.5.5.2** You can specify additional assets to install from the Liberty Repository. For a list of Liberty Repository assets, see the downloads page on WASdev.net. If you want to install additional assets, specify the following properties on the command line. You can specify the short name or symbolic name. Note that the feature short names, such as *FeatureA*, are separated by double commas in the following example:

```
-properties user.feature=FeatureA,,FeatureB,,FeatureC,user.accept.license=true
```

**8.5.5.5** For Version 8.5.5 and later, `user.accept.license=true` is not required.

- 
**8.5.5.4** The following example installs the Extended Programming Models on the `user.addon` parameter, and the Portlet Container feature on the `user.feature` parameter.

```

imcl install com.ibm.websphere.liberty.ND.v85
-properties user.accept.license=true,user.addon=extendedPackage-1.0,user.feature=portlet-2.0
-installationDirectory D:\IBM\Liberty -acceptLicense
-repositories D:\IBM\LibertyRepo
-sharedResourcesDirectory D:\IBM\IMShared
-showProgress

```

- 
**8.5.5.6** You can also install assets from instances of the Liberty Asset Repository Service or local directory-based repositories. For more information about these asset repositories, see “Installing assets using Installation Manager” on page 1411. Add the repository on the `-repositories` parameter. The repositories are accessed in the order that they are specified. By default, the Liberty Repository is the last of the repositories that are accessed during installation. To disable access to the Liberty Repository, on the `-properties` parameter, set the `user.useLibertyRepository` option to `false`.

```

imcl install com.ibm.websphere.liberty.ND.v85
-properties user.useLibertyRepository=false,user.addon=extendedPackage-1.0,user.feature=portlet-2.0
-installationDirectory D:\IBM\Liberty -acceptLicense
-repositories D:\IBM\LibertyProductRepo,https://your_onprem_asset_repo_url,D:\IBM\LocalAssetRepo,D:\IBM\LocalAssetRepo2.zip
-sharedResourcesDirectory D:\IBM\IMShared
-showProgress

```

To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.

- Installation Manager can save earlier versions of a package to roll back to if you experience issues later. When Installation Manager rolls back a package to a previous version, the current versions of the files are uninstalled and the earlier versions are reinstalled. If you choose not to save the files for rollback, you can prevent the files from being saved by using the following preference in your command specification:

```
-preference com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts=False
```

For more information on setting your Installation Manager preferences, see IBM Installation Manager documentation.

**Tip:** Even if you choose not to preserve files locally for rollback, you can still roll back to any previously installed level by accessing the appropriate offering repository.

- You can use the `cic.selector.arch` property key and related value to specify the architecture to install, 32 bit or 64 bit.

Here is an example of specifying a 32-bit architecture:

```
-properties cic.selector.arch=x86
```

If you do not specify anything for this key, you get a correct match for your system. For a 64-bit system, the installation defaults to a 64-bit installation.

Your choice here applies to all packages that are installed in the package group. For information about the supported values for the `cic.selector.key` keys, see the Values for `cic.selector.key` table in the Installation Manager documentation.

- The program might write important post-installation instructions to standard output.

For more information on using the `imcl` command to install the offering, see the IBM Installation Manager documentation.

## Installing Liberty on distributed operating systems by using response files

8.5.5.0

You can install WebSphere Application Server Liberty Network Deployment by using Installation Manager response files.

### Before you begin

Prepare each of the systems onto which you want to install the offering as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.

### About this task

Using Installation Manager, you can work with response files to install the offering in various ways. You can record a response file by using the GUI as described in the following procedure, create a new response file, or copy and modify an existing response file.

8.5.5.4 To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

### Procedure

1. Optional: Record a response file to install the offering.

On one of your systems, perform the following actions to record a response file that can install the offering.

- a. From a command line, change to the `eclipse` subdirectory in the directory where you installed Installation Manager.
- b. Start Installation Manager from the command line by using the `-record` option.

For example:

- **Windows** Administrator or non-administrator:

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"  
-record C:\temp\install_response_file.xml
```

- **AIX** **HP-UX** **Linux** **Solaris** Administrator:

```
./IBMIM -skipInstall /var/temp/imRegistry  
-record /var/temp/install_response_file.xml
```

- **AIX** **HP-UX** **Linux** **Solaris** Non-administrator:

```
./IBMIM -skipInstall user_home/var/temp/imRegistry  
-record user_home/var/temp/install_response_file.xml
```

**Tip:** When you record a new response file, you can specify the `-skipInstall` parameter. Using this parameter has the following benefits:

- No files are installed, which speeds up the recording.
- If you use a temporary data location with the `-skipInstall` parameter, Installation Manager writes the installation registry to the specified data location while recording. When you start Installation Manager again without the `-skipInstall` parameter, you then can use your response file to install against the real installation registry.

Do not use the **-skipInstall** operation on the agent data location that is used by Installation Manager. This operation is unsupported. Use a clean writable location, and reuse that location for future recording sessions.

For more information, read the IBM Installation Manager documentation.

- c. Follow the instructions that are described in “Installing Liberty on distributed operating systems using the GUI” on page 1171.
2. Optional: Create a credential-storage file for installation. If you are using an authenticated remote repository, you can store credentials for URLs that require authentication, such as remote repositories, in a credential-storage file. For IBM Installation Manager Version 1.6.2 and later, use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. For previous versions of Installation Manager, the **-keyring** and **-password** options are used to access credentials in a keyring file. These options are deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures.
  - For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation.
  - For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.
3. Use the response files to install the offering.

Go to a command line on each of the systems on which you want to install the offering, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and install the offering.

For example:

- **Windows** Administrator or non-administrator:

```
imcl.exe -acceptLicense
input C:\temp\install_response_file.xml
-log C:\temp\install_log.xml
-secureStorageFile C:\IM\credential.store -masterPasswordFile C:\IM\master_password_file.txt
```

- **AIX** **HP-UX** **Linux** **Solaris** Administrator:

```
./imcl -acceptLicense
input /var/temp/install_response_file.xml
-log /var/temp/install_log.xml
-secureStorageFile /var/IM/credential.store -masterPasswordFile /var/IM/master_password_file.txt
```

- **AIX** **HP-UX** **Linux** **Solaris** Non-administrator:

```
./imcl -acceptLicense
input user_home/var/temp/install_response_file.xml
-log user_home/var/temp/install_log.xml
-secureStorageFile user_home/var/IM/credential.store -masterPasswordFile user_home/var/IM/master_password_file.txt
```

#### Notes:

- The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lafiles` or `offering_name/lafiles` subdirectory of the installation image or repository for this offering.
- The program might write important post-installation instructions to standard output.

Read the IBM Installation Manager documentation for more information.

## Example

**Windows** The following is an example of a response file for installing the offering.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input clean="true" temporary="true">
<server>
<repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85" />
</server>
<install modify='false'>
<offering id='com.ibm.websphere.liberty.ND.v85'
profile='WebSphere Liberty V8.5'
features='embeddablecontainer' installFixes='none' />
</install>
```

```
<profile id='WebSphere Liberty V8.5'
  installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
</agent-input>
```

**Important:** AIX Linux Solaris Windows If you are installing on a 64-bit system, you must include one of the options for an IBM Software Development Kit.

- You can use the `cic.selector.arch` property key and related value to specify the architecture to install, 32 bit or 64 bit.

Here is an example of specifying a 32-bit architecture:

```
<profile>
...
<data key='cic.selector.arch' value='x86' />
...
</ptofile>
```

If you do not specify anything for this key, you receive a correct match for your system. For a 64-bit system, the installation defaults to a 64-bit installation.

Your choice here applies to all packages that are installed in the package group. For information about the supported values for the `cic.selector.key` keys, see the Values for `cic.selector.key` table in the Installation Manager documentation.

To disable remote searches for updates in the response file, set the following preferences to false:

- **offering.service.repositories.areUsed**  
Used for searching remote repositories for updates to installed offerings
- **com.ibm.cic.common.core.preferences.searchForUpdates**  
Used for searching for updates to Installation Manager

For example:

```
<preference value='false' name='offering.service.repositories.areUsed' />
<preference value='false' name='com.ibm.cic.common.core.preferences.searchForUpdates' />
```

You can find more details on silent preference keys in the IBM Installation Manager documentation.

The following examples show you how to change response file in order to perform alternative actions.

- To install multiple copies of this offering, specify a different installation location and a new package group for each installation. For example, to install a second copy of the offering into the `C:\Program Files\IBM\WebSphere\Liberty_2` directory and create the WebSphere Liberty V8.5\_2 package group, replace:

```
<profile id='WebSphere Liberty V8.5'
  installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
```

with:

```
<profile id='WebSphere Liberty V8.5_2'
  installLocation='C:\Program Files\IBM\WebSphere\Liberty_2'>
```

- To add optional features, add them as an entry in a comma-separated list. For example:

```
<offering id='com.ibm.websphere.liberty.ND.v85'
  profile='WebSphere Liberty V8.5'
  features='embeddablecontainer,extprogmodes' installFixes='none' />
```

- Embeddable EJB container and JPA client (`embeddablecontainer`)

This option installs the embeddable EJB container and JPA client.

The embeddable EJB container is a Java archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition (SE) environment. You can run enterprise beans by using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.

The JPA client can be used with the embeddable EJB container to provide Java Persistence API capability in a Java SE environment.

- Extended Programming Models (extprogmodels) Versions 8.5.5.0 to 8.5.5.3

The Extended Programming Models feature provides a rich set of programming models such as Web Services, JMS (including Message-Driven Beans), and MongoDB 2.0.

 **8.5.5.4** Beginning with Version 8.5.5.4, the Extended Programming Models are available from the Liberty Repository. To install Liberty Repository assets, see the information later in this section.

If no features are specified, the default features (embeddablecontainer and extprogmodels) are installed. To install only the feature that you want, specify that feature explicitly.

-  **8.5.5.2** You can specify additional assets to install from the Liberty Repository. For a list of Liberty Repository assets, see the downloads page on WASdev.net.

To install Liberty Repository assets, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later. Previous versions of Installation Manager do not have the option to install Liberty Repository assets. If you use a response file and did not update Installation Manager to Version 1.6.2 or later, the assets that you specify in the response file are ignored during installation.

If you want to install additional features, specify two extra data key elements in your response file. You can use either the symbolic name or the short name.

The following example installs the Portlet Container and Portlet Serving features using the symbolic name.

```
<data key='user.feature' value='com.ibm.websphere.appserver.portlet-2.0,,com.ibm.websphere.appserver.portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

The following example installs the Portlet Container and Portlet Serving features using the short name:

```
<data key='user.feature' value='portlet-2.0,,portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

 **8.5.5.4** Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` addon, or install the individual features that you need from the Liberty Repository. See the following topics for more information:

- Installing Liberty Repository assets
- Liberty features

The following example installs the Extended Programming Models using the `user.addon` parameter and the Portlet Container and Portlet Serving features using the `user.feature` parameter with short names:

```
<data key='user.addon' value='extendedPackage-1.0' />
<data key='user.feature' value='portlet-2.0,,portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

 **8.5.5.6** You can also install assets from an instance of the Liberty Asset Repository Service or local directory-based repositories. For more information, see “Installing assets using Installation Manager” on page 1411. Add the repository on repository elements. If Installation Manager does not recognize the repository, point directly to the repository.config file. When you install assets, the repositories are accessed in the order that you specify them.

```
<server>
<repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85" />
<repository location="https://your_onprem_asset_repo_url" />
<repository location="D:\IBM\LocalAssetRepo" />
```

**8.5.5.8** `<repository location="D:\IBM\LocalAssetRepo2.zip" /> </server>` By default, the Liberty Repository is the last of the repositories that are accessed during installation. To disable access to the Liberty Repository, set the `user.useLibertyRepository` parameter to false:

```
<data key='user.addon' value='extendedPackage-1.0' />
<data key='user.feature' value='portlet-2.0,,portlet-serving-2.0' />
<data key='user.useLibertyRepository' value='false' />
```

To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.

- Installation Manager can save earlier versions of a package to roll back to if you experience issues later. When Installation Manager rolls back a package to a previous version, the current versions of the files are uninstalled and the earlier versions are reinstalled. If you choose not to save the files for rollback, you can prevent the files from being saved by changing the following preference in your response file:

```
<preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true' />
```

to this:

```
<preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='false' />
```

For more information on setting your Installation Manager preferences, see the IBM Installation Manager documentation.

**Tip:** Even if you choose not to preserve files locally for rollback with this option, you can still roll back to any previously installed level by accessing the appropriate product repository.

## Updating Liberty from Version 8.5.0 to Version 8.5.5

Distributed operating systems

IBM i

8.5.5.0

If you are updating an existing WebSphere Application Server Version 8.5.0.x Liberty feature, you must install WebSphere Application Server Liberty Network Deployment Version 8.5.5.0 or later. You cannot make an in-place update of the Version 8.5.0.x Liberty feature. Afterwards, you can copy your data and server configurations to the new installation or, if your user data are kept in another location, follow typical procedures for managing your data and server configurations.

### About this task

In WebSphere Application Server Version 8.5.5.0, Liberty was promoted from a feature to an independently installable offering. You cannot make an in-place update of the Version 8.5.0.x Liberty feature. The `wlp` folder includes the Liberty runtime and any user data or server configurations that you have saved in the `wlp/usr` folder. If you have a combined full-profile and Liberty-profile Version 8.5.0.x installation, the update program will back up the `wlp` folder for the existing Version 8.5.0.x Liberty feature into the `wlp.bak_<timestamp>` folder and uninstall the feature during an update to Version 8.5.5.0 or higher. You can continue using Liberty from the backed-up location or copy it elsewhere. To update Liberty to Version 8.5.5.0 or higher, you then must install WebSphere Application Server Liberty Network Deployment (with the `com.ibm.websphere.liberty.ND.v85` offering ID). After installing WebSphere Application Server Liberty Network Deployment, you can move any user data and server configurations from the `wlp.bak_<timestamp>` folder to the new Liberty installation.

These instructions describe updating from a combined full-profile and Liberty-profile Version 8.5.0.x installation. If you have only the Version 8.5.0.x Liberty feature installed, you should install WebSphere Application Server Liberty Network Deployment Version 8.5.5.0 or higher in a different location. Then, you can copy the contents of the `wlp/usr` directory from the old installation to the `usr` directory of the new installation. If you are using `WLP_USER_DIR` and `WLP_OUTPUT_DIR` environment variables, make sure that they are pointing to the desired locations. You can continue using Java 6 from the Version 8.5.0.x installation image, use your own Java 6 or Java 7 that meets Liberty minimum requirements, or install one or both of the optional Java 6 or Java 7 Liberty extension offerings (offering ids: `com.ibm.websphere.liberty.IMBJAVA.v60` and `com.ibm.websphere.liberty.IMBJAVA.v70`).

**Note:**  During installation of a Liberty offering on an IBM i system, the `WLP_DEFAULT_USER_DIR` and `WLP_DEFAULT_OUTPUT_DIR` environment variables are set in the `WLP_INSTALL_DIR/etc/default.env` file.

## Procedure

1. Update your existing combined full-profile and Liberty-profile installation to Version 8.5.5 or later following the normal update procedure.

**Note:** If you want to keep using the backed-up Liberty with the current level of Java 6 after the update, you must make a backup of Java 6 before it is updated to the latest level by the fix-pack update. Java 6 can be found in the `<install-root>\java` folder. Set the `JAVA_HOME` environment variable to point to the desired Java. For more information on this environment variable, see “Customizing the Liberty environment” on page 1565.

After updating your WebSphere Application Server Network Deployment installation from Version 8.5.0.x to Version 8.5.5, you can find your Liberty installation in the `<was_home>/wlp.bak_<timestamp>` folder. This backup folder contains the Liberty runtime at the level that it was before you started the update.

2. Use the backed-up Liberty runtime.

A copy of the Installation Manager installation and history information for this snapshot is also stored in the root of the backup in the `installed.xml` and `history.xml` files.

To determine what fixes have been installed in this snapshot, you can use the `bin/productInfo` command in the backed-up Liberty folder. See “Liberty:productInfo command” on page 1415 for more information.

You can continue using the Liberty runtime folder from its backed-up location, or you can copy or move it to a new location. If you have set the `WLP_USER_DIR` or `WLP_OUTPUT_DIR` environment variables, make sure that they point to the location of your user data and the location of output resources generated by your server respectively.

**Note:** Do not move the backed-up `wlp.bak_<timestamp>` folder back to `wlp` in case you decide to roll back to Version 8.5.0.x later.

If `WLP_USER_DIR` has not been set, the server configuration and shared resources are stored in the `usr` directory at the root of the server's runtime environment (`wlp_bak_<timestamp>/usr` for example). In this case, no action is required to use the backed-up runtime because the user data can still be found under the `usr` directory of the new location.

If the `WLP_OUTPUT_DIR` value is not set, the default location is in the server root directory (`wlp_bak_<timestamp>/usr/servers/<server_name>` for example). If this environment variable is not set, no action is required to use the backed up runtime because logs continue to appear under the `usr/servers/<server_name>/logs` directory of the new location.

For more information on these environment variables, see “Customizing the Liberty environment” on page 1565.

**Note:** If the `server.xml` file or any included XML configuration file references another resource outside the server configuration directory, ensure that these resources can be found from the new server location.

Start all Liberty servers with the `--clean` parameter as a launch option. For example:

```
server start --clean
```

You need to use the `--clean` option only once. All subsequent server starts will not require it.

If you need to continue using the backed-up Liberty in the `wlp.bak_<timestamp>` folder, you can apply fixes using the archive interim-fix service procedure documented in “Applying an interim fix to a Liberty archive installation” on page 1388.

3. Install WebSphere Application Server Liberty Network Deployment Version 8.5.5 or later.

See “Installing and uninstalling Liberty using Installation Manager” on page 1164 or “Installing and uninstalling Liberty using downloaded files and archives” on page 1371.

**Tip:** After you install WebSphere Application Server Liberty Network Deployment Version 8.5.5 or later, you can use the `ProductInfo compare` action to compare the old and new installations. This will

show any issues that were resolved in the Version 8.5.0.x level that are not resolved at the Version 8.5.5.x level. See “Liberty:productInfo command” on page 1415 for more information.

4. Start using the WebSphere Application Server Liberty Network Deployment Version 8.5.5 installation. If the WLP\_USER\_DIR and WLP\_OUTPUT\_DIR environment variables are set, then the new Liberty installation will continue using these locations to for user data, including server configurations, and to place server generated output. In this case, it is recommended that you make a backup of the directories referenced by WLP\_USER\_DIR and WLP\_OUTPUT\_DIR before beginning to use the new installation.

If the WLP\_USER\_DIR and WLP\_OUTPUT\_DIR environment variables are not set, Liberty will use folders relative to the installed runtime by default. In this case, you should copy the contents of the backed-up Liberty runtime user folder (`wlp.bak_<timestamp>/usr`) to the `usr` folder of your new installation.

For more information on these environment variables, see “Customizing the Liberty environment” on page 1565.

**Note:** If the `server.xml` file or any included XML configuration file references another resource outside the server configuration directory, ensure that these resources can be found from the new server location.

## Installing the Extended Programming Models

Distributed operating systems

8.5.5.4

Installing and updating Liberty with the Extended Programming Models differs depending on the version of WebSphere Application Server.

### About this task

The Extended Programming Models provide a rich set of programming models such as web services, JMS (including Message-driven beans), and MongoDB 2.0.

How you install the Extended Programming Models depends on your version of WebSphere Application Server:

- Up to Version 8.5.5.3: Extended Programming Models are available as the `extprogmodels` Installation Manager installable feature.
- Version 8.5.5.4 and later: Extended Programming Models are available as the `extendedPackage-1.0` Liberty Repository add-on

You can use the following options to install the Extended Programming Models when you install Liberty or to update an existing copy of Liberty to include the Extended Programming Models:

- Install or update Liberty with the Extended Programming Models using the GUI.
- Install or update Liberty with the Extended Programming Models using the command line.
- Install or update Liberty with the Extended Programming Models using response files.

**Note:** If you are installing or updating to Version 8.5.5.3 or earlier using a remote repository, such as IBM Passport Advantage or a centrally-hosted HTTP server, internet access is required to update the Extended Programming Models.

After you install Liberty Version 8.5.5.4 or later, you can later install the `extendedPackage-1.0` add-on by using the **featureManager** command. For Version 8.5.5.6 and later, you can also use the **installUtility** command to install the add-on from multiple types of repositories. For more information, see “Installing assets using the featureManager command” on page 1403 and “Installing assets using the installUtility command” on page 1393.

## Procedure

Use one of the following options to install the Extended Programming Models:

- Install or update Liberty with the Extended Programming Models using the GUI.
  - For Version 8.5.5.3 and previous versions, in the Features panel, select the **Extended Programming Models** feature.
  - For Version 8.5.5.4 and later, use the Asset Selection Wizard to install the **Extended Programming Models** addon.

For more information, see “Installing Liberty on distributed operating systems using the GUI” on page 1171.

- Install or update Liberty with the Extended Programming Models using the command line.

- V8.5.5.3 and previous versions install the `extprogmodels` feature after the product:

```
imcl install com.ibm.websphere.liberty.ND.v85,extprogmodels
-installationDirectory D:\IBM\Liberty -acceptLicense
-repositories D:\IBM\LibertyRepo
-sharedResourcesDirectory D:\IBM\IMShared
-showProgress
```

- V8.5.5.4 and later versions install the `extendedPackage-1.0` addon on the `-properties user.addon` parameter:

```
imcl install com.ibm.websphere.liberty.ND.v85
-property user.accept.license=true,user.addon=extendedPackage-1.0
-installationDirectory D:\IBM\Liberty -acceptLicense
-repositories D:\IBM\LibertyRepo
-sharedResourcesDirectory D:\IBM\IMShared
-showProgress
```

- Install or update Liberty with the Extended Programming Models using response files.

- V8.5.5.3 and previous versions install the `extprogmodels` feature on the feature attribute of the offering element:

```
<?xml version='1.0' encoding='UTF-8'?>
<agent-input>
  <variables>
    <variable name='sharedLocation' value='/opt/IBM/IMShared'/>
  </variables>
  <server>
    <repository location='http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85'/>
  </server>
  <profile id='WebSphere Liberty V8.5' installLocation='/opt/IBM/WebSphere/Liberty'>
    <data key='eclipseLocation' value='/opt/IBM/WebSphere/Liberty'/>
    <data key='user.import.profile' value='false'/>
    <data key='cic.selector.os' value='linux'/>
    <data key='cic.selector.arch' value='x86_64'/>
    <data key='cic.selector.ws' value='gtk'/>
    <data key='cic.selector.nl' value='en'/>
  </profile>
  <install modify='false'>
    <!-- Install the IBM WebSphere Application Server Network Deployment 8.5.5.0 Liberty with the Extended Programming Models-->
    <offering profile='WebSphere Liberty V8.5' id='com.ibm.websphere.liberty.ND.v85' features='liberty,extprogmodels' installFixes='none'/>
  </install>
  <preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='${sharedLocation}'/>
  <preference name='com.ibm.cic.common.core.preferences.connectTimeout' value='30'/>
  <preference name='com.ibm.cic.common.core.preferences.readTimeout' value='45'/>
  <preference name='com.ibm.cic.common.core.preferences.downloadAutoRetryCount' value='0'/>
  <preference name='offering.service.repositories.areUsed' value='false'/>
  <preference name='com.ibm.cic.common.core.preferences.ssl.nonsecureMode' value='false'/>
  <preference name='com.ibm.cic.common.core.preferences.http.disablePreemptiveAuthentication' value='false'/>
  <preference name='http.ntlm.auth.kind' value='NTLM'/>
  <preference name='http.ntlm.auth.enableIntegrated.win32' value='true'/>
  <preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true'/>
  <preference name='com.ibm.cic.common.core.preferences.keepFetchedFiles' value='false'/>
  <preference name='PassportAdvantageIsEnabled' value='false'/>
  <preference name='com.ibm.cic.common.core.preferences.searchForUpdates' value='false'/>
  <preference name='com.ibm.cic.agent.ui.displayInternalVersion' value='false'/>
  <preference name='com.ibm.cic.common.sharedUI.showErrorLog' value='true'/>
  <preference name='com.ibm.cic.common.sharedUI.showWarningLog' value='true'/>
  <preference name='com.ibm.cic.common.sharedUI.showNoteLog' value='true'/>
</agent-input>
```

- V8.5.5.4 and later versions install the `extendedPackage-1.0` addon on the `user.addon` parameter under the profile element:

```

<?xml version='1.0' encoding='UTF-8'?>
<agent-input>
  <variables>
    <variable name='sharedLocation' value='/opt/IBM/IMShared' />
  </variables>
  <server>
    <repository location='http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85' />
  </server>
  <profile id='WebSphere Liberty V8.5' installLocation='/opt/IBM/WebSphere/Liberty'>
    <data key='eclipseLocation' value='/opt/IBM/WebSphere/Liberty' />
    <data key='user.import.profile' value='false' />
    <data key='cic.selector.os' value='linux' />
    <data key='cic.selector.arch' value='x86_64' />
    <data key='cic.selector.ws' value='gtk' />
    <data key='cic.selector.nl' value='en' />
    <!-- Extended Programming Model add-on -->
    <data key='user.addon' value='com.ibm.websphere.appserver.extendedPackage-1.0' />
    <data key='user.accept.license' value='true' />
  </profile>
  <install modify='false'>
    <!-- IBM WebSphere Application Server Network Deployment 8.5.5.4 Liberty -->
    <offering profile='WebSphere Liberty V8.5' id='com.ibm.websphere.liberty.ND.v85' features='liberty,embeddablecontainer' installFixes='none' />
  </install>
  <preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='${sharedLocation}' />
  <preference name='com.ibm.cic.common.core.preferences.connectTimeout' value='30' />
  <preference name='com.ibm.cic.common.core.preferences.readTimeout' value='45' />
  <preference name='com.ibm.cic.common.core.preferences.downloadAutoRetryCount' value='0' />
  <preference name='offering.service.repositories.areUsed' value='false' />
  <preference name='com.ibm.cic.common.core.preferences.ssl.nonsecureMode' value='false' />
  <preference name='com.ibm.cic.common.core.preferences.http.disablePreemptiveAuthentication' value='false' />
  <preference name='http.ntlm.auth.kind' value='NTLM' />
  <preference name='http.ntlm.auth.enableIntegrated.win32' value='true' />
  <preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true' />
  <preference name='com.ibm.cic.common.core.preferences.keepFetchedFiles' value='false' />
  <preference name='PassportAdvantageIsEnabled' value='false' />
  <preference name='com.ibm.cic.common.core.preferences.searchForUpdates' value='false' />
  <preference name='com.ibm.cic.agent.ui.displayInternalVersion' value='false' />
  <preference name='com.ibm.cic.common.sharedUI.showErrorLog' value='true' />
  <preference name='com.ibm.cic.common.sharedUI.showWarningLog' value='true' />
  <preference name='com.ibm.cic.common.sharedUI.showNoteLog' value='true' />
</agent-input>

```

## Adding and removing features from Liberty on distributed operating systems

**8.5.5.0**

You can use Installation Manager to install and remove WebSphere Application Server LibertyNetwork Deployment features.

### Before you begin

Ensure that your Installation Manager preferences are pointing to the appropriate web-based or local repositories containing WebSphere Application Server Liberty Network Deployment.

### About this task

You can use the Installation Manager to install or remove features using one of the following procedures:

- Using the GUI
- Using a silent response file

You can record this response file using the GUI and Installation Manager's record mode, or you can manually create or modify a response file to suit your needs.

- Using the **imcl** command-line tool

Go to the IBM Installation Manager Information Center for more information.

### Procedure

1. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being modified.
2. Start Installation Manager.
3. Click **Modify**.
4. Select the package group to modify.

5. Click **Next**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

6. Expand IBM WebSphere Application Server Liberty Network Deployment.

7. Select the appropriate checkbox to install a feature, or clear the appropriate checkbox to remove a feature if you already have it installed.

- Embeddable EJB container and JPA client

This option installs the embeddable EJB container and JPA client.

The embeddable EJB container is a Java archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition (SE) environment. You can run enterprise beans using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.

The JPA client can be used with the embeddable EJB container to provide Java Persistence API capability in a Java SE environment.

- Extended Programming Models

The Extended Programming Models feature provides a rich set of programming models such as Web Services, JMS (including Message-Driven Beans), and Mongo 2.0.

8.5.5.4

Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` addon, or install the individual features that you need from the Liberty Repository. See the following topics for more information:

- Installing Liberty Repository assets
- Liberty features

**Note:** To install assets from the IBM WebSphere Liberty Repository, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later.

8. Click **Next**.

9. Review the summary information, and click **Modify**.

- If the modification is successful, the program displays a message indicating that installation is successful.
- If the modification is not successful, click **View Log File** to troubleshoot the problem.

10. Click **Finish**.

11. Click **File > Exit** to close Installation Manager.

## Examples

In the following examples, the optional feature offering names are enclosed in parentheses; for example: Embeddable EJB container and JPA client (`embeddablecontainer`)

- **Windows** Example of a response file that adds a feature to an installation:

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input clean='true' temporary='true'>
<server>
<repository location='http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85' />
</server>
<install modify='true'>
<offering id='com.ibm.websphere.liberty.ND.v85'
  profile='WebSphere Liberty V8.5'
  features='embeddablecontainer' />
</install>
<profile id='WebSphere Liberty V8.5'
  installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
</agent-input>
```

- **Windows** Example of the `imcl` command that is modified to add features to an installation:

```

imcl.exe modify com.ibm.websphere.liberty.ND.v85
-addFeatures embeddablecontainer
-repositories http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85
-installationDirectory C:\Program Files\IBM\WebSphere\Liberty
-secureStorageFile C:\credential.store -masterPasswordFile C:\master_password_file.txt

```

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

- Example of the **imcl** command that is modified to remove a feature from an installation:

```

imcl.exe modify com.ibm.websphere.liberty.ND.v85
-removeFeatures embeddablecontainer
-repositories http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85
-installationDirectory C:\Program Files\IBM\WebSphere\Liberty
-secureStorageFile C:\credential.store -masterPasswordFile C:\master_password_file.txt

```

## Uninstalling Liberty from distributed operating systems using the GUI

**8.5.5.0**

You can use the Installation Manager GUI to uninstall WebSphere Application Server Liberty Network Deployment.

### Procedure

1. Uninstall WebSphere Application Server Liberty Network Deployment.
  - a. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
  - b. Start Installation Manager.
  - c. Click **Uninstall**.
  - d. In the **Uninstall Packages** window, perform the following actions.
    - 1) Select **IBM WebSphere Application Server Liberty Network Deployment** and the appropriate version.

**Note:** If you are uninstalling the trial version of this offering, select **IBM WebSphere Application Server Liberty Network Deployment Trial** and the appropriate version. When you uninstall the IBM WebSphere Application Server Liberty Network Deployment package, you must uninstall all the packages under the same package group that are extensions to the IBM WebSphere Application Server Liberty Network Deployment package. IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty is such an extension.
    - 2) Click **Next**.
  - e. Review the summary information.
  - f. Click **Uninstall**.
    - If the uninstallation is successful, the program displays a message that indicates success.
    - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
  - g. Click **Finish**.
  - h. Click **File > Exit** to close Installation Manager.
2. Optional: Uninstall IBM Installation Manager.

**Important:** Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager.

Read the IBM Installation Manager Information Center for information about performing this procedure.

## Uninstalling Liberty from distributed operating systems using the command line

8.5.5.0

You can uninstall WebSphere Application Server Liberty Network Deployment using the Installation Manager command line.

### Procedure

1. Log on to your system.
2. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
3. Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.
4. Use the `imcl` command to uninstall the offering.

Windows

```
imcl.exe uninstall com.ibm.websphere.liberty.ND.v85 -installationDirectory installation_directory
```

AIX

HP-UX

Linux

Solaris

```
./imcl uninstall com.ibm.websphere.liberty.ND.v85 -installationDirectory installation_directory
```

### Tips:

- Use the `imcl modify` command to add or remove features.
- When you uninstall the IBM WebSphere Application Server Liberty Network Deployment package, you must uninstall all the packages under the same package group that are extensions to the IBM WebSphere Application Server Liberty Network Deployment package. IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty is such an extension.

Go to the IBM Installation Manager Information Center for more information.

5. Optional: Uninstall IBM Installation Manager.

**Important:** Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager.

Read the IBM Installation Manager Information Center for information about using the uninstall script to perform this procedure.

## Uninstalling Liberty from distributed operating systems by using response files

8.5.5.0

You can uninstall WebSphere Application Server Liberty Network Deployment by using Installation Manager response files.

### Before you begin

**Optional:** Perform or record the installation of Installation Manager and installation of the product to a temporary installation registry on one of your systems so that you can use this temporary registry to record the uninstall without using the standard registry where Installation Manager is installed.

### About this task

Using Installation Manager, you can work with response files to uninstall the product in various ways. You can record a response file by using the GUI as described in the following procedure. Or, you can generate a new response file by hand or by taking an example and modifying it.

## Procedure

1. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
2. Optional: **Record a response file to uninstall the product:** On one of your systems, perform the following actions to record a response file that uninstalls the product:
  - a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.
  - b. Start Installation Manager from the command line by using the **-record** option.

For example:

- **Windows Administrator or non-administrator:**

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"  
-record C:\temp\uninstall_response_file.xml
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./IBMIM -skipInstall /var/temp/imRegistry  
-record /var/temp/uninstall_response_file.xml
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./IBMIM -skipInstall user_home/var/temp/imRegistry  
-record user_home/var/temp/uninstall_response_file.xml
```

**Tip:** If you choose to use the **-skipInstall** parameter with a temporary installation registry created as described in *Before you begin*, Installation Manager uses the temporary installation registry while recording the response file. It is important to note that when the **-skipInstall** parameter is specified, no product packages are installed or uninstalled. All of the actions that you perform in Installation Manager update the installation data that is stored in the specified temporary registry. After the response file is generated, it can be used to uninstall the product, removing the product files and updating the standard installation registry.

Do not use the **-skipInstall** operation on the actual agent data location that is used by Installation Manager. This operation is unsupported. Use a clean writable location, and reuse that location for future recording sessions.

For more information, read the IBM Installation Manager Information Center.

- c. Click **Uninstall**.
  - d. In the **Uninstall Packages** window, perform the following actions.
    - 1) Select **IBM WebSphere Application Server Liberty Network Deployment** and the appropriate version.  
  
**Note:** If you are uninstalling the trial version of this offering, select **IBM WebSphere Application Server Liberty Network Deployment Trial** and the appropriate version.
    - 2) Click **Next**.
  - e. Review the summary information.
  - f. Click **Uninstall**.
    - If the uninstallation is successful, the program displays a message that indicates success.
    - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
  - g. Click **Finish**.
  - h. Click **File > Exit** to close Installation Manager.
3. **Use the response file to uninstall the product:** From a command line on each of the systems from which you want to uninstall the product, change to the eclipse/tools sub-directory in the directory where you installed Installation Manager and use the response file that you created to uninstall the product.

For example:

- **Windows Administrator or non-administrator:**

```
imcl.exe
input C:\temp\uninstall_response_file.xml
-log C:\temp\uninstall_log.xml
```

- AIX HP-UX Linux Solaris **Administrator:**

```
./imcl
input /var/temp/uninstall_response_file.xml
-log /var/temp/uninstall_log.xml
```

- AIX HP-UX Linux Solaris **Non-administrator:**

```
./imcl
input user_home/var/temp/uninstall_response_file.xml
-log user_home/var/temp/uninstall_log.xml
```

Go to the IBM Installation Manager Information Center for more information.

#### 4. Optional: List all installed packages to verify the uninstallation.

AIX HP-UX Linux Solaris

```
./imcl listInstalledPackages
```

Windows

```
imcl listInstalledPackages
```

#### 5. Optional: Uninstall IBM Installation Manager.

**Important:** Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager.

Read the IBM Installation Manager Information Center for information about using the uninstall script to perform this procedure.

Windows

### Example

The following is an example of a response file for uninstalling the product.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input clean='true' temporary='true'>
<uninstall modify='false'>
<offering id='com.ibm.websphere.liberty.ND.v85'
  profile='WebSphere Liberty V8.5' />
</uninstall>
<profile id='WebSphere Liberty V8.5'
  installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
</agent-input>
```

**Tip:** When you uninstall the IBM WebSphere Application Server Liberty Network Deployment package, you must uninstall all the packages under the same package group that are extensions to the IBM WebSphere Application Server Liberty Network Deployment package. IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty is such an extension. To uninstall the entire package group, remove the id attribute in the <offering ../> stanza (id='com.ibm.websphere.liberty.ND.v85' in the previous example) from the response file. Installation Manager then uninstalls all of the packages under the package group.

## Installing and uninstalling Liberty interim fixes and fix packs on distributed operating systems

**8.5.5.0**

Interim fixes provide corrective service for specific known problems. Fix packs contain bundled service to bring WebSphere Application Server Liberty Network Deployment up to a new level. You can use IBM Installation Manager to update the offering with the interim fixes and fix packs that are available for your service level of WebSphere Application Server Liberty Network Deployment.

## Before you begin

Contact the IBM Software Support Center for information about updates for WebSphere Application Server Liberty Network Deployment. The most current information is available from the IBM Software Support Center and Fix Central.

IBM Installation Manager is used to apply and remove maintenance.

**Important:** Installation Manager can install any fix-pack level of the product directly without installing the intermediate fix packs; in fact, Installation Manager installs the latest level by default. For example, you can skip fix-pack levels and go from Version 8.5.5.1 directly to Version 8.5.5.5. Keep in mind, however, that later you can not roll back to any level that was skipped. If you directly install to Version 8.5.5.5, for example, you cannot roll back to Version 8.5.5.4. If you skip from Version 8.5.5.1 to Version 8.5.5.5, you can only roll back to Version 8.5.5.1. You should plan your installations accordingly.

- | **New:** Fix pack 16.0.0.2 is the next fix pack after 8.5.5.9. You can continue to use the same Version 8.5
- | Installation Manager repositories and offering IDs to install or update to 16.0.0.2, or you can use the new
- | versionless repositories and offerings. For more information about fix pack 16.0.0.2, see What is new in
- | Liberty in the new location of the latest Liberty documentation.

**Note:** In WebSphere Application Server Version 8.5.5.0, Liberty was promoted from a feature to an independently installable offering. After updating to WebSphere Application Server Liberty Network Deployment Version 8.5.5.x from Version 8.5.0.x, you can roll back to the Version 8.5.0.x Liberty feature level that you were at before updating. If you previously had a combined full-profile and Liberty installation, the Liberty feature will be reinstalled to the wlp folder when you roll back. Any user data and server configurations will not be restored. If necessary, you can copy them from the backed-up location into the new wlp/usr folder after rollback. If any wlp.bak\_<timestamp> directories are present in your installation image, they will not be affected by the rollback. If you update and roll back multiple times between Version 8.5.0.x and Version 8.5.5.x levels, therefore, you will have multiple wlp.bak\_<timestamp> folders in your installation image. These can always be deleted, copied, or moved without negative impact to your installation.

## About this task

**Tip:** You can use the IBM Packaging Utility to generate a new local or web-based repository that contains all of the fixes that you want to install and then use Installation Manager to update WebSphere Application Server Liberty Network Deployment with all of the interim fixes as a group. For information on using the Packaging Utility, see the IBM Installation Manager Information Center.

## Procedure

- “Installing Liberty interim fixes on distributed operating systems using the GUI” on page 1193
- “Installing Liberty interim fixes on distributed operating systems using the command line” on page 1195
- “Uninstalling Liberty interim fixes from distributed operating systems using the GUI” on page 1197
- “Uninstalling Liberty interim fixes from distributed operating systems using the command line” on page 1198
- “Installing Liberty fix packs on distributed operating systems using the GUI” on page 1198
- “Installing Liberty fix packs on distributed operating systems using the command line” on page 1200
- “Installing Liberty fix packs on distributed operating systems using response files” on page 1204
- “Uninstalling Liberty fix packs from distributed operating systems using the GUI” on page 1209
- “Uninstalling Liberty fix packs from distributed operating systems using the command line” on page 1210

- “Uninstalling Liberty fix packs from distributed operating systems by using response files” on page 1212
- AIX HP-UX Linux Solaris Optional: After the fix pack is installed or removed, reapply any ownership and permissions changes that were made after the offering was originally installed.

## Installing Liberty interim fixes on distributed operating systems using the GUI: 8.5.5.0

You can use the IBM Installation Manager graphical user interface (GUI) to update the offering with the interim fixes that are available for your service level of WebSphere Application Server Liberty Network Deployment.

### Before you begin

Contact the IBM Software Support Center for information about updates for WebSphere Application Server Liberty Network Deployment. The most current information is available from the IBM Software Support Center and Fix Central.

Make sure that the web-based or local service repository location is listed and checked or that the **Search service repositories during installation and updates** option is selected on the Repositories panel in your Installation Manager preferences. For more information on using service repositories with Installation Manager, read the IBM Installation Manager Information Center.

### Procedure

1. For a list of fixes that are available for WebSphere Application Server Liberty Network Deployment and specific information about each fix, perform the following actions.
  - a. Go to Fix Central.
  - b. Select **WebSphere** as the product group.
  - c. Select **WebSphere Application Server Liberty Network Deployment** as the product.
  - d. Select the installed version.
  - e. Select your operating system as the platform, and click **Continue**.
  - f. Select **Browse for fixes**, and click **Continue**.
  - g. Click **More Information** under each fix to view information about the fix.
  - h. **Recommendation:** Make a list of the names of the fixes that you would like to install.
2. Update WebSphere Application Server Liberty Network Deployment with the fixes using one of the following procedures.
  - Access the live service repository that contains the fixes, and use web-based updating. Use Installation Manager on your local system to update WebSphere Application Server Liberty Network Deployment with the interim fixes from the live web-based service repositories.
    - For the live service repositories, use the same URLs as those used for the generally available product-offering repositories during installation. These URLs are listed in Online product repositories for WebSphere Application Server offerings.
    - These locations do not contain web pages that you can access using a web browser. They are remote web-based repository locations that you specify for Installation Manager so that it can maintain the offering.

To install a fix from a service repository, perform the following actions:

  - a. Log on to your system.
  - b. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being updated.
  - c. Start Installation Manager.
  - d. Click **Update**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you use to access protected IBM software websites.

- e. Select the package group to update with the fix.

**Tip:** If the **Search service repositories during installation and updates** option is selected on the Installation Manager Repository preference page and you are connected to the Internet, you can click **Check for Other Versions and Extensions** to search for updates in the default update repositories for the selected packages. In this case, you do not need to add the specific service-repository URL to the Installation Manager Repository preference page.

- f. Click **Next**.

- g. Select the fixes to install, and click **Next**.

Any recommended fixes are selected by default.

If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.

- h. Review the summary information, and click **Update**.

- i. Click **Finish**.

- j. Click **File > Exit** to close Installation Manager.

- Download the files that contain the fixes from Fix Central, and use local updating.

You can download compressed files that contain the fixes from Fix Central. Each compressed fix file contains an Installation Manager repository for the fix and usually has a .zip extension. After downloading the fix files, you can use one of the following procedures to update WebSphere Application Server Liberty Network Deployment:

- Use Installation Manager to update WebSphere Application Server Liberty Network Deployment with the fixes.
- Use the IBM Packaging Utility to generate a new repository that contains all of the fix files that you downloaded, then use Installation Manager to update WebSphere Application Server Liberty Network Deployment with all of the fixes as a group. For information on using the Packaging Utility, see the IBM Installation Manager Information Center.

- a. To download the fixes, perform the following actions:

- 1) Go to Fix Central.
- 2) Select **WebSphere** as the product group.
- 3) Select **WebSphere Application Server Liberty Network Deployment** as the product.
- 4) Select the installed version.
- 5) Select your operating system as the platform, and click **Continue**.
- 6) Select **Browse for fixes**, and click **Continue**.
- 7) Select the fixes that you want to download, and click **Continue**.
- 8) Select your download options, and click **Continue**.
- 9) Click **I agree** to agree to the terms and conditions.
- 10) Click **Download now** to download the fixes.

- b. To install a fix from a downloaded compressed file, perform the following actions:

- 1) Log on to your system.
- 2) Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being updated.
- 3) Start Installation Manager.
- 4) Add the location of the fix file that you downloaded to your Installation Manager preferences.
- 5) Click **Update**.
- 6) Select the package group to update with the fix, and click **Next**.

- 7) Select the fixes to install, and click **Next**.  
Any recommended fixes are selected by default.  
If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.
- 8) Review the summary information, and click **Update**.
- 9) Click **Finish**.
- 10) Click **File > Exit** to close Installation Manager.

### Installing Liberty interim fixes on distributed operating systems using the command line:

**8.5.5.0**

You can use the IBM Installation Manager command line to update the offering with the interim fixes that are available for your service level of WebSphere Application Server Liberty Network Deployment.

#### Before you begin

Contact the IBM Software Support Center for information about updates for WebSphere Application Server Liberty Network Deployment. The most current information is available from the IBM Software Support Center and Fix Central.

IBM Installation Manager is used to apply maintenance to WebSphere Application Server Liberty Network Deployment.

#### Procedure

1. For a list of interim fixes and fix packs that are available for WebSphere Application Server LibertyNetwork Deployment and specific information about each fix, perform the following actions.
  - a. Go to Fix Central.
  - b. Select **WebSphere** as the product group.
  - c. Select **WebSphere Application Server Liberty Network Deployment** as the product.
  - d. Select the version of the offering to be updated.
  - e. Select your operating system as the platform, and click **Continue**.
  - f. Select **Browse for fixes**, and click **Continue**.
  - g. Click **More Information** under each fix to view information about the fix.
  - h. **Recommendation:** Make a list of the names of the fixes that you would like to install.
2. Update WebSphere Application Server Liberty Network Deployment with the interim fixes using one of the following procedures.
  - **Access the live service repository that contains the interim fixes, and use web-based updating.**  
Use Installation Manager on your local system to update WebSphere Application Server LibertyNetwork Deployment with the interim fixes from the live web-based service repositories.
    - For the live service repositories, use the same URLs as those used for the generally available product-offering repositories during installation. These URLs are listed in Online product repositories for WebSphere Application Server offerings.
    - These locations do not contain web pages that you can access using a web browser. They are remote web-based repository locations that you specify for Installation Manager so that it can maintain the offering.

To install an interim fix from a service repository, perform the following actions:

    - a. Log on to your system.
    - b. If you do not already have Installation Manager credential-storage and master-password files containing your IBM software user ID and password, create files that will allow you to access the repository.

**Note:** These are the credentials that you use to access protected IBM software websites. For information on creating credential-storage and master-password files for Installation Manager, read the IBM Installation Manager Information Center.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutilsc` command is unable to find the URL that is specified.

- c. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being updated.
- d. Change to the `Installation_Manager_binaries/eclipse/tools` directory, where `Installation_Manager_binaries` is the installation root directory for the Installation Manager.
- e. Install the interim fix.

```
AIX      HP-UX    Linux   Solaris

./imcl install fix_name
  -installationDirectory offering_installation_location
  -repositories repository_URL
  -secureStorageFile storage_file -masterPasswordFile master_password_file
```

```
Windows

imcl.exe install fix_name
  -installationDirectory offering_installation_location
  -repositories repository_URL
  -secureStorageFile storage_file -masterPasswordFile master_password_file
```

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the `-keyring` and `-password` options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the `-keyring` and `-password` options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

- f. **Optional:** List all installed packages to verify the installation:

```
AIX      HP-UX    Linux   Solaris

./imcl listInstalledPackages -long

Windows

imcl.exe listInstalledPackages -long
```

- **Download the files that contain the interim fixes from Fix Central, and use local updating.**

You can download compressed files that contain the interim fixes from Fix Central. Each compressed fix file contains an Installation Manager repository for the interim fix and usually has a `.zip` extension. After downloading the fix files, you can use one of the following procedures to update WebSphere Application Server Liberty Network Deployment:

- Use Installation Manager to update WebSphere Application Server Liberty Network Deployment with the interim fixes.
  - Use the IBM Packaging Utility to generate a new repository that contains all of the fix files that you downloaded, then use Installation Manager to update WebSphere Application Server Liberty Network Deployment with all of the interim fixes as a group. For information on using the Packaging Utility, see the IBM Installation Manager Information Center.
- a. To download the interim fixes, perform the following actions:
    - 1) Go to Fix Central.
    - 2) Select **WebSphere** as the product group.

- 3) Select **WebSphere Application Server Liberty Network Deployment** as the product.
  - 4) Select the version of the offering to be updated.
  - 5) Select your operating system as the platform, and click **Continue**.
  - 6) Select **Browse for fixes**, and click **Continue**.
  - 7) Select the interim fixes that you want to download, and click **Continue**.
  - 8) Select your download options, and click **Continue**.
  - 9) Click **I agree** to agree to the terms and conditions.
  - 10) Click **Download now** to download the interim fixes.
- b. To install an interim fix from a downloaded compressed file, perform the following actions:
- 1) Log on to your system.
  - 2) Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being updated.
  - 3) Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager.
  - 4) Install the interim fix.

AIX

HP-UX

Linux

Solaris

```
./imcl install fix_name
-installationDirectory offering_installation_location
-repositories compressed_file
```

Windows

```
imcl.exe install fix_name
-installationDirectory offering_installation_location
-repositories compressed_file
```

- 5) **Optional:** List all installed packages to verify the installation:

AIX

HP-UX

Linux

Solaris

```
./imcl listInstalledPackages -long
```

Windows

```
imcl.exe listInstalledPackages -long
```

## Uninstalling Liberty interim fixes from distributed operating systems using the GUI: 8.5.5.0

You can use the IBM Installation Manager graphical user interface (GUI) to remove interim fixes from WebSphere Application Server Liberty Network Deployment.

### Procedure

1. Log on to your system.
2. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being updated.
3. Start Installation Manager.
4. Click **Uninstall**.
5. Select the interim fixes to uninstall.
6. Click **Next**.
7. Review the summary information, and click **Uninstall**.
  - If the uninstallation is successful, the program displays a message indicating that the uninstallation is successful.
  - If the uninstallation is not successful, click **View Log File** to troubleshoot the problem.
8. Click **Finish**.

9. Click **File > Exit** to close Installation Manager.

### Uninstalling Liberty interim fixes from distributed operating systems using the command line:

**8.5.5.0**

You can use the IBM Installation Manager command-line function to remove interim fixes from WebSphere Application Server Liberty Network Deployment.

#### Procedure

1. Log on to your system.
2. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being updated.
3. Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager.
4. Uninstall the interim fix:

**AIX**

**HP-UX**

**Linux**

**Solaris**

```
./imcl uninstall interim_fix_name  
-installationDirectory offering_installation_location
```

**Windows**

```
imcl.exe uninstall interim_fix_name  
-installationDirectory offering_installation_location
```

### Installing Liberty fix packs on distributed operating systems using the GUI: **8.5.5.0**

You can update WebSphere Application Server Liberty Network Deployment to a later version using the Installation Manager GUI.

#### Before you begin

Contact the IBM Software Support Center for information about updates for WebSphere Application Server Liberty Network Deployment. The most current information is available from the IBM Software Support Center and Fix Central.

**8.5.5.4**

To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

Make sure that the web-based or local service repository location is listed and checked or that the **Search service repositories during installation and updates** option is selected on the Repositories panel in your Installation Manager preferences. For more information on using service repositories with Installation Manager, read the IBM Installation Manager Information Center.

**8.5.5.6**

If you want to install Liberty assets from local directory-based repositories or an instance of the Liberty Asset Repository Service, configure the repositories. For more information about the Liberty asset repositories, see “Installing assets using Installation Manager” on page 1411.

#### Procedure

1. Log on to your system.
2. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
3. Start Installation Manager.
4. Click **Update**.

**Note:** If prompted to authenticate, specify the IBM ID and password that you use to access protected IBM software websites.

5. Select the package group to update. If you select **Update all**, Installation Manager searches all of the added and predefined repositories for recommended updates to all of the package groups that it has installed.
  - Use this feature only if you have full control over which fixes are contained in the targeted repositories.
    - If you create and point to a set of custom repositories that include only the specific recommended fixes that you want to install, you should be able to use this feature confidently.
    - If you enable searching service repositories or install fixes directly from other live web-based repositories, you might not want to select this option so that you can select only the fixes that you want to install for each offering on subsequent panels.
  - If you select **Update all**, Installation Manager will install only the recommended updates to all of the package groups; it will not allow you to select non-recommended fixes for installation. If you want to install non-recommended fixes, perform the following actions:
    - a. On this panel, clear the **Update all** check box and select an offering to update.
    - b. On the next panel, clear the option to show only recommended fixes and then select the fixes that you want to install.
  - **8.5.5.4** The **Update all** option might generate a warning message if you complete the following steps:
    - a. Install WebSphere Application Server Liberty v8.5.5.3 with the Extended Programming Model.
    - b. Install WebSphere Application Server Network Deployment Liberty v8.5.5.3 with the Extended Programming Model.
    - c. Select **Update all**. Click **Next**.
    - d. You might receive an Update Validation Warning message with multiple messages. Click **OK**. Click **Next**.
    - e. You might receive the Extended Programming Model Warning message panel.
    - f. Click **Back** to the Update Package panel. Click **Next**.
    - g. You might again receive an Update Validation Warning message with multiple messages.
    - h. From the Extended Programming Model Warning message panel, click **Next**. In the Offering License panel, find the following error:

An error has occurred. See error log for more details. Bundle "reference:file:/C:/ProgramData/IBM/InstallationTo fix this problem, complete the following steps:
    - a. Click **Cancel**.
    - b. Select **Update all**.
    - c. Do not click **Back**. This action causes the error that uninstalls the license.
6. Click **Next**.
7. Select the version to which you want to update under **IBM WebSphere Application Server Liberty Network Deployment**.
8. Select any fixes that you want to install. Any recommended fixes are selected by default. If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.
9. Click **Next**.
10. Accept the terms in the license agreements, and click **Next**.
11. Select the optional features that you want in your updated installation.

**8.5.5.4**

Beginning with Version 8.5.5.4, the Extended Programming Model is available from the Liberty Repository. This asset provides a rich set of programming models such as Web Services, JMS (including Message-Driven Beans), and MongoDB 2.0. To install this asset, use the Asset Selection Wizard as described in the next step.

12.  **8.5.5.2** Optional: Install additional Liberty Repository assets. If you do not want to select any additional assets, you can skip this step. To install Liberty Repository assets, you must have IBM Installation Manager Version 1.6.2 or later. To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.
  - a. Select whether you want to install assets from the Liberty Repository, and click **Next**. To install assets from the IBM WebSphere Liberty Repository, you must have access to the internet.
 

**8.5.5.6** If you choose not to connect to the IBM WebSphere Liberty Repository, you can still install assets from configured directory-based repositories or an instance of the Liberty Asset Repository Service. For more information, see “Installing assets using Installation Manager” on page 1411.
  - b. **8.5.5.4** Click **Launch Asset Selection Wizard**.
  - c. You can perform a case-insensitive search for assets by display name or description. If you search with the **Keyword** field empty, then the search displays all applicable assets.
 

**8.5.5.5** With Version 8.5.5.5 and later, you can also search for assets by short name.
  - d. Select each asset that you want to install, then click **Next**.
  - e. Accept the license agreement and click **Finish**.
13. Review the summary information, and click **Update**.
  - If the installation is successful, the program displays a message indicating that installation is successful.
  - If the installation is not successful, click **View Log File** to troubleshoot the problem.
14. Click **Finish**.
15. Click **File > Exit** to close Installation Manager.

### Installing Liberty fix packs on distributed operating systems using the command line: **8.5.5.0**

You can use the IBM Installation Manager command line to update the product with the fix packs that are available for WebSphere Application Server LibertyNetwork Deployment.

#### Before you begin

Contact the IBM Software Support Center for information about updates for WebSphere Application Server Liberty Network Deployment. The most current information is available from the IBM Software Support Center and Fix Central.

**8.5.5.6**

If you want to install Liberty assets from local directory-based repositories or an instance of the Liberty Asset Repository Service, configure the repositories. For more information about the Liberty asset repositories, see “Installing assets using Installation Manager” on page 1411.

**Tip:** As an alternative to the procedure that is described in this article, Installation Manager allows you to use the **updateAll** command in a response file or on the command line to search for and update all installed packages. Use this command only if you have full control over which fixes are contained in the targeted repositories. You can create and point to a set of custom repositories that include only the specific fixes that you want to install. If you enable searching service repositories or install fixes directly from other live web-based repositories, then you might not want to select this option so that you can select only the fixes that you want to install using the **-installFixes** option with the **install** command on the command line or the **installFixes** attribute in a response file.

## About this task

**8.5.5.4** To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

### Procedure

1. For a list of interim fixes and fix packs that are available for WebSphere Application Server LibertyNetwork Deployment and specific information about each fix, perform the following actions.
  - a. Go to Fix Central.
  - b. Select **WebSphere** as the product group.
  - c. Select **WebSphere Application Server** as the product.
  - d. Select the installed version.
  - e. Select your operating system as the platform, and click **Continue**.
  - f. Select **Browse for fixes**, and click **Continue**.
  - g. Click **More Information** under each fix to view information about the fix.
  - h. **Recommendation:** Make a note of the name of the fix pack that you would like to install.
2. Update WebSphere Application Server Liberty Network Deployment with the fix pack using one of the following procedures.
  - Access the live service repository that contains the fix pack, and use web-based updating. Use Installation Manager on your local system to update WebSphere Application Server Liberty Network Deployment with the interim fixes from the live web-based service repositories.
    - For the live service repositories, use the same URLs as those used for the generally available product-offering repositories during installation. These URLs are based on the following pattern:  
`http://www.ibm.com/software/repositorymanager/offering_ID`

where *offering\_ID* is the offering ID that you can find in WebSphere Application Server product offerings for supported operating systems.

- These locations do not contain web pages that you can access using a web browser. They are remote web-based repository locations that you specify for Installation Manager so that it can maintain the product.

To install a fix pack from a service repository, perform the following actions:

- a. Log on to your system.
- b. Create Installation Manager credential-storage and master-password files that contain your IBM software user ID and password. These files enable you to access the repository and protected IBM software websites.

When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutilsc` command is unable to find the URL that is specified.

**Note:** For Installation Manager Version 1.6.2 and later, use the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file. In previous versions, the `-keyring` and `-password` options are used to access credentials in a keyring file. These options are deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures.

- For more information on using the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation.
  - For more information on using the `-keyring` and `-password` options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.
- c. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being updated.

- d. Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager.
- e. Install the fix pack.

**AIX** **HP-UX** **Linux** **Solaris**

```
./imcl install offering_ID_offering_version,optional_feature_ID
-repositories source_repository
-installationDirectory offering_installation_location
-secureStorageFile storage_file -masterPasswordFile master_password_file
-acceptLicense
```

**Windows**

```
imcl.exe install offering_ID_offering_version,optional_feature_ID
-repositories source_repository
-installationDirectory offering_installation_location
-secureStorageFile storage_file -masterPasswordFile master_password_file
-acceptLicense
```

where *offering\_ID* is the offering ID that is listed in WebSphere Application Server product offerings for supported operating systems.

#### Tips:

- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (8.5.5.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the `-installFixes` argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the `-installFixes` option defaults to all.
  - If the offering version is specified, the `-installFixes` option defaults to none.
- You can add a list of features that are separated by commas.
-  **8.5.5.2** You can specify additional features to install from the Liberty Repository. For a list of Liberty Repository assets, see the downloads page on WASdev.net.

**Note:** To install Liberty Repository assets, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later.

If you want to install additional features, specify the following properties in the command line. Note that the feature short names, such as *FeatureA*, are separated by double commas:

```
-properties user.feature=FeatureA,,FeatureB,,FeatureC,user.accept.license=true
```

For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

-  **8.5.5.4** Beginning with Version 8.5.5.4, the Extended Programming Models are available to download from the Liberty Repository as the `extendedPackage-1.0` addon. This addon provides a rich set of programming models such as Web Services, JMS (including Message-Driven Beans), and MongoDB 2.0. To install the addon, specify the `extendedPackage-1.0` addon on the **user.addon** option of the **-properties** parameter:

```

imcl install com.ibm.websphere.liberty.ND.v85
-properties user.acceptLicense=true,user.addon=extendedPackage-1.0
-installationDirectory D:\IBM\Liberty -acceptLicense
-repositories D:\IBM\LibertyRepo
-sharedResourcesDirectory D:\IBM\IMShared
-showProgress

```

8.5.5.6

You can also install assets from instances of the Liberty Asset Repository Service or local directory-based repositories. For more information about these asset repositories, see “Installing assets using Installation Manager” on page 1411. Add the repository on the **-repositories** parameter. The repositories are accessed in the order that they are specified. By default, the Liberty Repository is the last of the repositories that are accessed during installation. To disable access to the Liberty Repository, on the **-properties** parameter, set the **user.useLibertyRepository** option to false.

8.5.5.8

```

imcl install com.ibm.websphere.liberty.ND.v85
-properties user.useLibertyRepository=false,user.addon=extendedPackage-1.0,user.feature=portlet-2.0
-installationDirectory D:\IBM\Liberty -acceptLicense
-repositories D:\IBM\LibertyProductRepo,https://your_onprem_asset_repo_url,D:\IBM\LocalAssetRepo,D:\IBM\LocalAssetRepo2.zip
-sharedResourcesDirectory D:\IBM\IMShared
-showProgress

```

To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.

**Note:** If you do not have the Extended Programming Model installed prior to updating to Version 8.5.5.4, you might encounter the following error during the update:

8.5.5.4

```

java.io.IOException: Too many open files
at java.io.File.createNewFile(File.java:894)

```

To resolve this problem, increase the number of files using the **ulimit** command; for example:

```
ulimit -n 8192
```

- f. List all installed packages to verify the installation:

AIX

HP-UX

Linux

Solaris

```
./imcl listInstalledPackages -long
```

Windows

```
imcl.exe listInstalledPackages -long
```

- Download the file that contains the fix pack from Fix Central, and use local updating. You can download a compressed file that contains the fix pack from Fix Central. Each compressed fix-pack file contains an Installation Manager repository for the fix pack and usually has a .zip extension. After downloading and extracting the fix-pack file, use Installation Manager to update WebSphere Application Server Liberty Network Deployment with the fix pack.
  - a. To download the fix pack, perform the following actions:
    - 1) Go to Fix Central.
    - 2) Select **WebSphere** as the product group.
    - 3) Select **WebSphere Application Server** as the product.
    - 4) Select the installed version.
    - 5) Select your operating system as the platform, and click **Continue**.
    - 6) Select **Browse for fixes**, and click **Continue**.
    - 7) Select the fix pack that you want to download, and click **Continue**.
    - 8) Select your download options, and click **Continue**.
    - 9) Click **I agree** to agree to the terms and conditions.
    - 10) Click **Download now** to download the fix pack.
    - 11) Transfer the compressed file in binary format to the system on which it is installed.
    - 12) Extract the compressed repository files to a directory on your system.
  - b. To install a fix pack from a downloaded file, perform the following actions:
    - 1) Log on to your system.

- 2) Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being updated.
- 3) Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager.
- 4) Install the fix pack.

AIX

HP-UX

Linux

Solaris

```
./imcl install offering_ID offering_version,optional_feature_ID
-installationDirectory offering_installation_location
-repositories location_of_expanded_files
-acceptLicense
```

Windows

```
imcl.exe install offering_ID offering_version,optional_feature_ID
-installationDirectory offering_installation_location
-repositories location_of_expanded_files
-acceptLicense
```

#### Tips:

- The *offering\_ID* is the offering ID that is listed in WebSphere Application Server product offerings for supported operating systems.
- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (8.5.5.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the *-installFixes* argument to indicate which interim fixes you want installed with the offering.
    - If the offering version is **not** specified, the *-installFixes* option defaults to all.
    - If the offering version is specified, the *-installFixes* option defaults to none.
  - You can add a list of features that are separated by commas.
- 5) **Optional:** List all installed packages to verify the installation:

AIX

HP-UX

Linux

Solaris

```
./imcl listInstalledPackages -long
```

Windows

```
imcl.exe listInstalledPackages -long
```

### Installing Liberty fix packs on distributed operating systems using response files: **8.5.5.0**

You can update WebSphere Application Server Liberty Network Deployment to a later version using Installation Manager response files.

#### About this task

**8.5.5.4** To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

If you want to install Liberty assets from local directory-based repositories or an instance of the Liberty Asset Repository Service, configure the repositories. For more information about the Liberty asset repositories, see “Installing assets using Installation Manager” on page 1411.

**Tip:** As an alternative to the procedure that is described in this topic, use the Installation Manager **updateAll** command in a response file or on the command line to search for and update all installed packages. Use this command only if you have full control over which fixes are contained in the targeted repositories. Create and point to a set of custom repositories that include only the specific fixes that you want to install. If you enable searching service repositories or if you install fixes directly from other live web-based repositories, then you might not want to select this option so that you can select only the fixes that you want to install using the **-installFixes** option with the **install** command on the command line or the **installFixes** attribute in a response file.

### Procedure

1. To obtain a list of interim fixes and fix packs that are available for WebSphere Application Server LibertyNetwork Deployment installation and specific information about each fix, perform the following actions.
  - a. Go to Fix Central.
  - b. Select **WebSphere** as the product group.
  - c. Select **WebSphere Application Server** as the product.
  - d. Select the installed version.
  - e. Select your operating system as the platform, and click **Continue**.
  - f. Select **Browse for fixes**, and click **Continue**.
  - g. Click **More Information** under each fix to view information about the fix.
  - h. Note of the name of the fix pack that you would like to install.
2. Update WebSphere Application Server Liberty Network Deployment with the fix pack using one of the following procedures.

- Access the live service repository that contains the fix pack, and use web-based updating.

Use Installation Manager on your local system to update WebSphere Application Server Liberty Network Deployment with the interim fixes from the live web-based service repositories.

- For the live service repositories, use the same URLs as those used for the generally available product-offering repositories during installation. These URLs are based on the following pattern:  
`http://www.ibm.com/software/repositorymanager/offering_ID`

where *offering\_ID* is the offering ID that you can find in WebSphere Application Server product offerings for supported operating systems.

- These locations do not contain web pages that you can access using a web browser. They are remote web-based repository locations that you specify for Installation Manager so that it can maintain the product.

Perform the following actions:

- a. Log on to your system.
- b. Create files that enable you to access the repository. Installation Manager credential-storage and master-password files contain your IBM software user ID and password and enable you to access protected IBM software websites. When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the **imutilsc** command is unable to find the URL that is specified.

**Note:** For Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In previous versions of Installation Manager, the **-keyring** and **-password** options are used to access

credentials in a keyring file. These options are deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures.

- For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation.
- For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.
- c. Stop all servers and applications on the WebSphere Application Server installation that is being updated.
- d. Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager.
- e. Install the fix pack using a response file.

For example:

-  Administrator or non-administrator:

```
imcl.exe -acceptLicense
input C:\temp\update_response_file.xml
-log C:\temp\update_log.xml
-secureStorageFile C:\IM\credential.store -masterPasswordFile C:\IM\master_password_file.txt
```

-     Administrator:

```
./imcl -acceptLicense
input /var/temp/update_response_file.xml
-log /var/temp/update_log.xml
-secureStorageFile /var/IM/credential.store -masterPasswordFile /var/IM/master_password_file.txt
```

-     Non-administrator:

```
./imcl -acceptLicense
input user_home/var/temp/update_response_file.xml
-log user_home/var/temp/update_log.xml
-secureStorageFile user_home/var/IM/credential.store -masterPasswordFile user_home/var/IM/master_password_file.txt
```

- Download the file that contains the fix pack from Fix Central, and use local updating.

You can download a compressed file that contains the fix pack from Fix Central. Each compressed fix-pack file contains an Installation Manager repository for the fix pack and usually has a .zip extension. After downloading and extracting the fix-pack file, use Installation Manager to update WebSphere Application Server Liberty with the fix pack.

- a. To download the fix pack, perform the following actions:

- 1) Go to Fix Central.
- 2) Select **WebSphere** as the product group.
- 3) Select **WebSphere Application Server** as the product.
- 4) Select the installed version.
- 5) Select your operating system as the platform, and click **Continue**.
- 6) Select **Browse for fixes**, and click **Continue**.
- 7) Select the fix pack that you want to download, and click **Continue**.
- 8) Select your download options, and click **Continue**.
- 9) Click **I agree** to agree to the terms and conditions.
- 10) Click **Download now** to download the fix pack.
- 11) Transfer the compressed file in binary format to the system on which it will be installed.
- 12) Extract the compressed repository files to a directory on your system.

- b. Perform the following actions:

- 1) Log on to your system.
- 2) If the repository requires a username and password, create a credential-storage file to access this repository.

For more information on creating a credential-storage file for Installation Manager, read the IBM Installation Manager Information Center.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutils` command is unable to find the URL that is specified.

- 3) Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being updated.
- 4) Change to the `Installation_Manager_binaries/eclipse/tools` directory, where `Installation_Manager_binaries` is the installation root directory for the Installation Manager.
- 5) Install the fix pack using a response file.

For example:

— **Windows Administrator or non-administrator:**

```
imcl.exe -acceptLicense
input C:\temp\update_response_file.xml
-log C:\temp\update_log.xml
-secureStorageFile C:\IM\credential.store -masterPasswordFile C:\IM\master_password_file.txt
```

— **AIX HP-UX Linux Solaris Administrator:**

```
./imcl -acceptLicense
input /var/temp/update_response_file.xml
-log /var/temp/update_log.xml
-secureStorageFile /var/IM/credential.store -masterPasswordFile /var/IM/master_password_file.txt
```

— **AIX HP-UX Linux Solaris Non-administrator:**

```
./imcl -acceptLicense
input user_home/var/temp/update_response_file.xml
-log user_home/var/temp/update_log.xml
-secureStorageFile user_home/var/IM/credential.store -masterPasswordFile user_home/var/IM/master_password_file.txt
```

## Example

**Windows** The following is an example of a response file for updating the product to a later version.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input>
<server>
<repository location='https://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85'/>
</server>
<profile id='WebSphere Liberty V8.5'
installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
<install modify='false'>
<offering profile='WebSphere Liberty V8.5' id='com.ibm.websphere.liberty.ND.v85'
version='8.5.5.20101025_2108'/>
</install>
<preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='C:\Program Files\IBM\IMShared'/>
<preference name='com.ibm.cic.common.core.preferences.connectTimeout' value='30'/>
<preference name='com.ibm.cic.common.core.preferences.readTimeout' value='30'/>
<preference name='com.ibm.cic.common.core.preferences.downloadAutoRetryCount' value='0'/>
<preference name='offering.service.repositories.areUsed' value='true'/>
<preference name='com.ibm.cic.common.core.preferences.ssl.nonsecureMode' value='false'/>
<preference name='com.ibm.cic.common.core.preferences.http.disablePreemptiveAuthentication' value='false'/>
<preference name='http.ntlm.auth.kind' value='NTLM'/>
<preference name='http.ntlm.auth.enableIntegrated.win32' value='true'/>
<preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true'/>
<preference name='com.ibm.cic.common.core.preferences.keepFetchedFiles' value='false'/>
<preference name='PassportAdvantageIsEnabled' value='false'/>
<preference name='com.ibm.cic.common.core.preferences.searchForUpdates' value='false'/>
</agent-input>
```

## Tips:

- The profile ID (`<profile . . . id='profile_ID' . . . .>` and `<offering . . . profile='profile_ID' . . . .>`) can be found when you run the `imcl listInstallationDirectories -verbose` command from the `eclipse/tools` subdirectory in the directory where you installed Installation Manager. It is the same as the package group's name.
- The offering ID (`<offering . . . id='offering_ID' . . . .>`) can be found in WebSphere Application Server product offerings for supported operating systems.
- The *version* is a specific version of the offering to install (8.5.5.20101025\_2108 for example). This specification is optional.

- If *version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
- If *version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
./imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the `installFixes` argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the `installFixes` option defaults to all.
  - If the offering version is specified, the `installFixes` option defaults to none.
-  **8.5.5.2** You can specify additional assets to install from the Liberty Repository. For a list of Liberty Repository assets, see the downloads page on WASdev.net.

To install Liberty Repository assets, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later. Previous versions of Installation Manager do not have the option to install Liberty Repository assets. If you use a response file and did not update Installation Manager to Version 1.6.2 or later, the assets that you specify in the response file are ignored during installation.

If you want to install additional features, specify two extra data key elements in your response file. You can use either the symbolic name or the short name.

The following example installs the Portlet Container and Portlet Serving features using the symbolic name.

```
<data key='user.feature' value='com.ibm.websphere.appserver.portlet-2.0,,com.ibm.websphere.appserver.portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

The following example installs the Portlet Container and Portlet Serving features using the short name:

```
<data key='user.feature' value='portlet-2.0,,portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

**Note:** **8.5.5.3** If you are updating to Version 8.5.5.3 and previously installed Liberty Repository features but do not currently have a connection to the IBM WebSphere Liberty Repository, you cannot update using a response file. Instead, update the product by running the `imcl` command and specifying the `user.feature=""` parameter.

 **8.5.5.4** Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` addon, or install the individual features that you need from the Liberty Repository. See the following topics for more information:

- Installing Liberty Repository assets
- Liberty features

The following example installs the Extended Programming Models using the `user.addon` parameter and the Portlet Container and Portlet Serving features using the `user.feature` parameter with short names:

```
<data key='user.addon' value='extendedPackage-1.0' />
<data key='user.feature' value='portlet-2.0,,portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

 **8.5.5.6** You can also install assets from an instance of the Liberty Asset Repository Service or local directory-based repositories. For more information, see “Installing assets using Installation Manager” on page 1411. Add the repository on `repository` elements. If Installation Manager does not recognize the repository, point directly to the `repository.config` file. When you install assets, the repositories are accessed in the order that you specify them.

```

<server>
<repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85" />
<repository location="https://your_onprem_asset_repo_url" />
<repository location="D:\IBM\LocalAssetRepo" />

```

**8.5.5.8** <repository location="D:\IBM\LocalAssetRepo2.zip" /> </server> By default, the Liberty Repository is the last of the repositories that are accessed during installation. To disable access to the Liberty Repository, set the **user.useLibertyRepository** parameter to false:

```

<data key='user.addon' value='extendedPackage-1.0' />
<data key='user.feature' value='portlet-2.0,,portlet-serving-2.0' />
<data key='user.useLibertyRepository' value='false' />

```

To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.

- When updating a product, your response file must contain the features that were used in the initial install of the product; otherwise, your update will not occur as intended. If you do not add these features to your response file, Installation Manager assumes you are removing them.

## Uninstalling Liberty fix packs from distributed operating systems using the GUI: **8.5.5.0**

You can roll back WebSphere Application Server Liberty Network Deployment to an earlier version using the Installation Manager GUI.

### Before you begin

During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your computer when you install a package. If you change the default setting or delete the saved files, Installation Manager requires access to the repository that was used to install the earlier version.

**Important:** Installation Manager can install any fix-pack level of the product directly without installing the intermediate fix packs; in fact, Installation Manager installs the latest level by default. For example, you can skip fix-pack levels and go from Version 8.5.5.1 directly to Version 8.5.5.5. Keep in mind, however, that later you can not roll back to any level that was skipped. If you directly install to Version 8.5.5.5, for example, you cannot roll back to Version 8.5.5.4. If you skip from Version 8.5.5.1 to Version 8.5.5.5, you can only roll back to Version 8.5.5.1.

**Note:** In WebSphere Application Server Version 8.5.5.0, Liberty was promoted from a feature to an independently installable offering. After updating to WebSphere Application Server Liberty Network Deployment Version 8.5.5.x from Version 8.5.0.x, you can roll back to the Version 8.5.0.x Liberty feature level that you were at before updating. If you previously had a combined full-profile and Liberty-profile installation, the Liberty feature will be reinstalled to the wlp folder when you roll back. Any user data and server configurations will not be restored. If necessary, you can copy them from the backed-up location into the new wlp/usr folder after rollback. If any wlp.bak\_<timestamp> directories are present in your installation image, they will not be affected by the rollback. If you update and roll back multiple times between Version 8.5.0.x and Version 8.5.5.x levels, therefore, you will have multiple wlp.bak\_<timestamp> folders in your installation image. These can always be deleted, copied, or moved without negative impact to your installation.

### Procedure

1. Stop all servers on the WebSphere Application Server Liberty Network Deployment installation that is being modified.
2. Start Installation Manager.
3. Click **Roll Back**.
4. Select the package group to roll back.
5. Click **Next**.

6. Select the version to which you want to roll back under **IBM WebSphere Application Server Liberty Network Deployment**.
7. Click **Next**.
8. Review the summary information, and click **Roll Back**.
  - If the rollback is successful, the program displays a message indicating that the rollback is successful.
  - If the rollback is not successful, click **View Log File** to troubleshoot the problem.
9. Click **Finish**.
10. Click **File > Exit** to close Installation Manager.

### Uninstalling Liberty fix packs from distributed operating systems using the command line:

#### 8.5.5.0

You can roll back WebSphere Application Server Liberty Network Deployment to an earlier version using the Installation Manager command line.

#### Before you begin

**Restriction:** In order to use this procedure, you must have Installation Manager Version 1.6 or later installed on your system.

During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your computer when you install a package. If you change the default setting or delete the saved files, Installation Manager requires access to the repository that was used to install the earlier version.

**Note:** In WebSphere Application Server Version 8.5.5.0, Liberty was promoted from a feature to an independently installable offering. After updating to WebSphere Application Server Liberty Network Deployment Version 8.5.5.x from Version 8.5.0.x, you can roll back to the Version 8.5.0.x Liberty feature level that you were at before updating. If you previously had a combined full-profile and Liberty-profile installation, the Liberty feature will be reinstalled to the wlp folder when you roll back. Any user data and server configurations will not be restored. If necessary, you can copy them from the backed-up location into the new wlp/usr folder after rollback. If any wlp.bak\_<timestamp> directories are present in your installation image, they will not be affected by the rollback. If you update and roll back multiple times between Version 8.5.0.x and Version 8.5.5.x levels, therefore, you will have multiple wlp.bak\_<timestamp> folders in your installation image. These can always be deleted, copied, or moved without negative impact to your installation.

#### Procedure

1. Optional: If the repository requires a username and password, create a credential-storage file to access this repository.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutilsc` command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the `-keyring` and `-password` options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the `-keyring` and `-password` options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

2. Log on to your system.
3. Stop all servers and applications on the installation that is being rolled back.
4. Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.
5. Use the `imcl` command to roll back the product.

AIX

HP-UX

Linux

Solaris

```
./imcl rollback offering_ID_offering_version
-repositories source_repository
-installationDirectory installation_directory
-preferences preference_key=value
-properties property_key=value
-secureStorageFile storage_file -masterPasswordFile master_password_file
-acceptLicense
```

Windows

```
imcl.exe rollback offering_ID_offering_version
-repositories source_repository
-installationDirectory installation_directory
-preferences preference_key=value
-properties property_key=value
-secureStorageFile storage_file -masterPasswordFile master_password_file
-acceptLicense
```

#### Tips:

- The *offering\_ID* is the offering ID that is listed in WebSphere Application Server product offerings for supported operating systems.
- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to which to roll back (8.5.5.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the installation rolls back to the previously installed version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the installation rolls back to the specified earlier version of the offering and **no** interim fixes for that version are installed.
- If you previously installed Liberty Repository features and addons but do not have access to a Liberty repository when you rollback your installation, specify the following properties in the response file:
 

```
-properties user.addon="",user.feature=""
```

Specifying these properties enables the product to rollback and uninstalls all features and addons.

- **8.5.5.4** If you are rolling back from Version 8.5.5.4 to Version 8.5.5.3 and you have the Extended Programming Models installed, you might receive errors. To prevent errors, specify a properties parameter, `addon=""`; for example:

AIX

HP-UX

Linux

Solaris

```
./imcl rollback offering_ID_offering_version
-repositories source_repository
-installationDirectory installation_directory
-preferences preference_key=value
-properties user.accept.license=true,user.addon=""
-secureStorageFile storage_file -masterPasswordFile master_password_file
-acceptLicense
```

Windows

```
imcl.exe rollback offering_ID_offering_version
-repositories source_repository
-installationDirectory installation_directory
-preferences preference_key=value
-properties user.accept.license=true,user.addon=""
-secureStorageFile storage_file -masterPasswordFile master_password_file
-acceptLicense
```

For more information on using Installation Manager, read the IBM Installation Manager documentation.

6. Optional: List all installed packages to verify the roll back.

AIX

HP-UX

Linux

Solaris

```
./imcl listInstalledPackages -long
```

Windows

```
imcl.exe listInstalledPackages -long
```

## Uninstalling Liberty fix packs from distributed operating systems by using response files:

8.5.5.0

You can rollback WebSphere Application Server Liberty Network Deployment to an earlier version by using Installation Manager response files.

### Before you begin

During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your computer when you install a package. If you change the default setting or delete the saved files, Installation Manager requires access to the repository that was used to install the earlier version.

**Note:** In WebSphere Application Server Version 8.5.5.0, Liberty was promoted from a feature to an independently installable offering. After you update to WebSphere Application Server Liberty Network Deployment Version 8.5.5.x from Version 8.5.0.x, you can rollback to the Version 8.5.0.x Liberty feature level that you were at before you updated. If you previously had a combined full-profile and Liberty-profile installation, the Liberty feature is reinstalled to the wlp folder when you rollback. Any user data and server configurations are not restored. If necessary, you can copy them from the backed-up location into the new wlp/usr folder after rollback. If any wlp.bak\_<timestamp> directories are present in your installation image, they are not affected by the rollback. If you update and rollback multiple times between Version 8.5.0.x and Version 8.5.5.x levels, you have multiple wlp.bak\_<timestamp> folders in your installation image. These folders can always be deleted, copied, or moved without negative impact to your installation.

### Procedure

1. Optional: If the repository requires a username and password, create a credential-storage file to access this repository.

**Tip:** When you create a credential-storage file, append /repository.config at the end of the repository URL location if the **imutilsc** command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see Installation Manager Version 1.6 documentation. For more information on **-keyring** and **-password** options to store credentials in a keyring file, see Installation Manager Version 1.5 documentation.

2. Log on to your system.
3. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being rolled back.
4. Use a response file to roll back the product.

Change to the eclipse/tools subdirectory in the directory where you installed Installation Manager, and roll back the product.

For example:

- **Windows Administrator or non-administrator:**

```
imcl.exe
input C:\temp\rollback_response_file.xml
-log C:\temp\rollback_log.xml
-secureStorageFile C:\IM\credential.store -masterPasswordFile C:\IM\master_password_file.txt
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./imcl
input /var/temp/rollback_response_file.xml
-log /var/temp/rollback_log.xml
-secureStorageFile /var/IM/credential.store -masterPasswordFile /var/IM/master_password_file.txt
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./imcl
input user_home/var/temp/rollback_response_file.xml
-log user_home/var/temp/rollback_log.xml
-secureStorageFile user_home/var/IM/credential.store -masterPasswordFile user_home/var/IM/master_password_file.txt
```

**Note:** The program might write important post-installation instructions to standard output.

For more information on using Installation Manager, read the IBM Installation Manager Information Center.

5. Optional: List all installed packages to verify the rollback.

**AIX HP-UX Linux Solaris**

```
./imcl listInstalledPackages -long
```

**Windows**

```
imcl.exe listInstalledPackages -long
```

**Windows**

### Example

The following is an example of a response file for rolling back the product to an earlier version.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input>
<server>
  <repository location='https://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85'/>
</server>
<profile id='WebSphere Liberty V8.5.5' installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
<rollback>
  <offering profile='WebSphere Liberty V8.5.5' id='com.ibm.websphere.liberty.ND.v85' version='8.5.5.20101025_2108' />
</rollback>
</agent-input>
```

### Tips:

- The profile ID (<profile . . . id='profile\_ID' . . . .> and <offering . . . profile='profile\_ID' . . . .>) can be found when you run the imcl listInstallationDirectories -verbose command from the eclipse/tools subdirectory in the directory where you installed Installation Manager. It is the same as the package group's name.
- The offering ID (<offering . . . id='offering\_ID' . . . .>) can be found in WebSphere Application Server product offerings for supported operating systems.
- The *version* is a specific version of the offering to which to roll back (8.5.5.20101025\_2108 for example).

This specification is optional.

- If *version* is **not** specified, the installation rolls back to the previously installed version of the offering and **all** interim fixes for that version are installed.
- If *version* is specified, the installation rolls back to the specified earlier version of the offering and **no** interim fixes for that version are installed.

- If you previously installed Liberty Repository features and add-ons but do not have access to a Liberty repository when you rollback your installation, specify the following properties in the response file:

```
<data key='user.feature' value='' />
<data key='user.addon' value='' />
```

Specifying these properties enables the product to rollback and uninstalls all features and add-ons.

## Upgrading Liberty on distributed operating systems using the GUI

**8.5.5.0**

You can use Installation Manager GUI to upgrade WebSphere Application Server Liberty offerings on distributed operating systems.

### Before you begin

- Make sure that your Installation Manager preferences are pointing to web-based or local repositories that contain the appropriate upgrades for the offering.
- If an interim fix is already installed on the offering that you are trying to upgrade but that specific interim fix is not applicable to the offering to which you want to upgrade, the upgrade will be blocked by Installation Manager. An error message will be generated that indicates that the interim fix is not applicable to the offering. Remove the interim fix before upgrading.

### About this task

You can use Installation Manager to upgrade WebSphere Application Server Liberty offerings in the following paths:

- WebSphere Application Server Liberty Core to WebSphere Application Server Liberty
- WebSphere Application Server Liberty Core to WebSphere Application Server Liberty Network Deployment
- WebSphere Application Server Liberty - Express to WebSphere Application Server Liberty
- WebSphere Application Server Liberty to WebSphere Application Server Liberty Network Deployment
- WebSphere Application Server Liberty Trial to WebSphere Application Server Liberty
- WebSphere Application Server Liberty Core Trial to WebSphere Application Server Liberty Core
- WebSphere Application Server Liberty Network Deployment Trial to WebSphere Application Server Liberty Network Deployment
- WebSphere Application Server Liberty for Developers to WebSphere Application Server Liberty
- WebSphere Application Server Liberty for Developers to WebSphere Application Server Liberty Network Deployment

### Procedure

1. Stop all servers and applications on the WebSphere Application Server Liberty installation that is being upgraded.
2. Start Installation Manager.
3. Click **Install**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

Installation Manager searches its defined repositories for available packages.

4. Select the name of the Liberty offering to which you want to upgrade and the appropriate version, and click **Next**.
5. Accept the terms in the license agreements, and click **Next**.
6. Complete the following actions.

- a. Select **Use the existing package group**.
- b. Select the package group of the product that you want to upgrade.

**Important:** If you select an existing group that cannot be upgraded to the product that you are currently installing, an error will occur.

- c. Click **Next**.
7. Select any features that you want to include in the upgraded installation and click **Next**.
8. Review the summary information, and click **Install**.
  - If the upgrade is successful, the program displays a message indicating that installation is successful.

**Note:** The program might also display important post-installation instructions as well.

  - If the installation is not successful, click **View Log File** to troubleshoot the problem.
9. Click **Finish**.
10. Click **File > Exit** to close Installation Manager.

## Example

Here is an example of how to upgrade a WebSphere Application Server Liberty offering on distributed operating systems using the command line.

- Log on to your system.
- Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.
- List the installed packages.

AIX HP-UX Linux Solaris

```
./imcl listInstalledPackages -long
```

Windows

```
imcl.exe listInstalledPackages -long
```

- Use the **imcl install** command to upgrade the installation to a different edition in the same installation location:

AIX HP-UX Linux Solaris

```
./imcl install com.ibm.websphere.liberty.ND.v85
-repositories source_repository -installationDirectory /opt/IBM/WebSphere/Liberty -acceptLicense -showProgress
```

Windows

```
imcl install com.ibm.websphere.liberty.ND.v85
-repositories source_repository -installationDirectory C:\Program Files\IBM\WebSphere\Liberty -acceptLicense -showProgress
```

## Installing and uninstalling SDK Java Technology Edition Version 6.0 for Liberty on distributed operating systems

8.5.5.0

You can install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using Installation Manager.

### About this task

**Note:** **8.5.5.11** Support for using Java SE 6 with WebSphere Liberty ends in September 2017. After the end of support, the Liberty kernel will be recompiled and can no longer run with Java SE 6. If you continue to use Java SE 6 on earlier fix packs after the end of support date, you could expose your environment to security risks.

Java SE 8 is the recommended Java SDK because it provides the latest features and security updates. You can install it by installing the IBM SDK, Java Technology Edition, Version 8 package to the package group that contains WebSphere Liberty.

Perform one of these procedures to install, update, roll back, or uninstall IBM WebSphere SDK Java Technology Edition Version 6.0 using Installation Manager.

**Note:** For information on installing and removing fix packs for WebSphere Application Server LibertyNetwork Deployment on distributed operating systems using the Installation Manager command line, read the following articles in this information center:

- “Installing Liberty fix packs on distributed operating systems using the command line” on page 1200
- “Uninstalling Liberty fix packs from distributed operating systems using the command line” on page 1210

## Procedure

- “Installing IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the GUI” on page 1217
- “Installing IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using response files” on page 1220
- “Installing IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the command line” on page 1219
- “Installing fix packs on IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the GUI” on page 1224
- “Uninstalling fix packs from IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the GUI” on page 1225
- “Uninstalling IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the GUI” on page 1226
- “Uninstalling IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using response files” on page 1227
- “Uninstalling IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the command line” on page 1227

## Results

### Notes on logging and tracing:

- An easy way to view the logs is to open Installation Manager and go to **File > View Log**. An individual log file can be opened by selecting it in the table and then clicking the **Open log file** icon.
- Logs are located in the logs directory of Installation Manager's application data location. For example:

– **Windows** **Administrative installation:**

C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager\logs

– **Windows** **Non-administrative installation:**

C:\Documents and Settings\user\_name\Application Data\IBM\Installation Manager\logs

– **AIX** **HP-UX** **Linux** **Solaris** **Administrative installation:**

/var/ibm/InstallationManager/logs

– **AIX** **HP-UX** **Linux** **Solaris** **Non-administrative installation:**

user\_home/var/ibm/InstallationManager/logs

- The main log files are time-stamped XML files in the logs directory, and they can be viewed using any standard web browser.
- The log.properties file in the logs directory specifies the level of logging or tracing that Installation Manager uses.

## Notes on troubleshooting:

- **HP-UX** By default, some HP-UX systems are configured to not use DNS to resolve host names. This could result in Installation Manager not being able to connect to an external repository. You can ping the repository, but nslookup does not return anything. Work with your system administrator to configure your machine to use DNS, or use the IP address of the repository.
- For more information on using Installation Manager, read the IBM Installation Manager Information Center. Read the release notes to learn more about the latest version of Installation Manager. To access the release notes, complete the following task:
  - **Windows** Click **Start > Programs > IBM Installation Manager > Release Notes**.
  - **AIX** **HP-UX** **Linux** **Solaris** Go to the documentation subdirectory in the directory where Installation Manager is installed, and open the readme.html file.

## Installing IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the GUI:

**8.5.5.0**

You can install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the Installation Manager GUI.

### Before you begin

**Note:** **8.5.5.11** Support for using Java SE 6 with WebSphere Liberty ends in September 2017. After the end of support, the Liberty kernel will be recompiled and can no longer run with Java SE 6. If you continue to use Java SE 6 on earlier fix packs after the end of support date, you could expose your environment to security risks.

Java SE 8 is the recommended Java SDK because it provides the latest features and security updates. You can install it by installing the IBM SDK, Java Technology Edition, Version 8 package to the package group that contains WebSphere Liberty.

1. Prepare your system as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.
2. Install one the following offerings:
  - IBM WebSphere Application Server Liberty
  - IBM WebSphere Application Server Liberty Trial
  - IBM WebSphere Application Server Liberty - Express
  - IBM WebSphere Application Server Liberty Network Deployment
  - IBM WebSphere Application Server Liberty Network Deployment Trial
  - IBM WebSphere Application Server for Developers
  - IBM WebSphere Application Server for Developers (ILAN)

### Procedure

1. Start Installation Manager.

**Tip:** **AIX** **HP-UX** **Linux** **Solaris** You can start Installation Manager in group mode with the `./IBMIM` command.

- Group mode allows users to share packages in a common location and manage them with the same instance of Installation Manager.
- For more information on using group mode, read the Group mode road maps in the IBM Installation Manager Information Center.

2. Click **Install**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

Installation Manager searches its defined repositories for available packages.

3. Perform the appropriate actions.

a. Select **IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty**.

If you already have IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty installed on a WebSphere Application Server Liberty Network Deployment installation on your system, a message displays indicating that IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty is already installed. To install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty on an installation where it is not yet installed, click **Continue**.

b. Select the fixes to install.

Any recommended fixes are selected by default.

If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.

c. Click **Next**.

**Note:** If you do not have and have not selected an installation of one the following offerings on which to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty, an error dialog displays.

- IBM WebSphere Application Server Liberty
- IBM WebSphere Application Server Liberty Trial
- IBM WebSphere Application Server Liberty - Express
- IBM WebSphere Application Server Liberty Network Deployment
- IBM WebSphere Application Server Liberty Network Deployment Trial
- IBM WebSphere Application Server for Developers
- IBM WebSphere Application Server for Developers (ILAN)

Click **OK**, select an appropriate offering on which to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty, and click **Next**.

4. Select the appropriate WebSphere Application Server Liberty Network Deployment installation on which to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty, and click **Next**.

**Note:** The bit architecture that will be installed, 32 bit or 64 bit, will match the bit selection made during the installation of the Liberty offering. For GUI installations of Liberty offerings, this selection is made on the Location panel. For command-line and response-file installations of Liberty offerings, the default can be overridden using the `cic.selector.arch` property.

5. Click **Next**.

6. Review the summary information, and click **Install**.

- If the installation is successful, the program displays a message indicating that installation is successful.

**Note:** The program might also display important post-installation instructions as well.

- If the installation is not successful, click **View Log File** to troubleshoot the problem.

7. Click **Finish**.

8. Click **File > Exit** to close Installation Manager.

## Installing IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the command line: **8.5.5.0**

You can install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the Installation Manager command line.

### Before you begin

**Note:** **8.5.5.11** Support for using Java SE 6 with WebSphere Liberty ends in September 2017. After the end of support, the Liberty kernel will be recompiled and can no longer run with Java SE 6. If you continue to use Java SE 6 on earlier fix packs after the end of support date, you could expose your environment to security risks.

Java SE 8 is the recommended Java SDK because it provides the latest features and security updates. You can install it by installing the IBM SDK, Java Technology Edition, Version 8 package to the package group that contains WebSphere Liberty.

1. Prepare your system as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.
2. Install one the following offerings:
  - IBM WebSphere Application Server Liberty
  - IBM WebSphere Application Server Liberty Trial
  - IBM WebSphere Application Server Liberty - Express
  - IBM WebSphere Application Server Liberty Network Deployment
  - IBM WebSphere Application Server Liberty Network Deployment Trial
  - IBM WebSphere Application Server for Developers
  - IBM WebSphere Application Server for Developers (ILAN)

### Procedure

1. Optional: If the repository requires a username and password, create a credential-storage file to access this repository.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutilsc` command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the `-keyring` and `-password` options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the `-keyring` and `-password` options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

2. Log on to your system.
3. Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.
4. Verify that the repository is available.

Windows

```
imcl.exe listAvailablePackages -repositories path_to_repository
```

AIX

HP-UX

Linux

Solaris

```
./imcl listAvailablePackages -repositories path_to_repository
```

You should see one or more levels of the offering.

## 5. Use the **imcl** command to install the offering.

Windows

```
imcl.exe install com.ibm.websphere.liberty.IBMJAVA.v60_offering_version
-repositories source_repository
-installationDirectory installation_directory
-secureStorageFile storage_file -masterPasswordFile master_password_file
```

AIX

HP-UX

Linux

Solaris

```
./imcl install com.ibm.websphere.liberty.IBMJAVA.v60_offering_version
-repositories source_repository
-installationDirectory installation_directory
-secureStorageFile storage_file -masterPasswordFile master_password_file
```

**Note:** The bit architecture that will be installed, 32 bit or 64 bit, will match the bit selection made during the installation of the Liberty offering. For GUI installations of Liberty offerings, this selection is made on the Location panel. For command-line and response-file installations of Liberty offerings, the default can be overridden using the `cic.selector.arch` property.

### Tips:

- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (8.5.5.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the `-installFixes` argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the `-installFixes` option defaults to all.
  - If the offering version is specified, the `-installFixes` option defaults to none.
- The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lfiles` or `product_name/lfiles` subdirectory of the installation image or repository for this offering.
- The program might write important post-installation instructions to standard output.

For more information on using the **imcl** command, see the IBM Installation Manager Information Center.

## Installing IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using response files:

8.5.5.0

You can install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using Installation Manager response files.

### Before you begin

**Note:** 8.5.5.11 Support for using Java SE 6 with WebSphere Liberty ends in September 2017. After the end of support, the Liberty kernel will be recompiled and can no longer run with Java SE 6. If you continue to use Java SE 6 on earlier fix packs after the end of support date, you could expose your environment to security risks.

Java SE 8 is the recommended Java SDK because it provides the latest features and security updates. You can install it by installing the IBM SDK, Java Technology Edition, Version 8 package to the package group that contains WebSphere Liberty.

1. Prepare your system as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.
2. Install one the following offerings:
  - IBM WebSphere Application Server Liberty
  - IBM WebSphere Application Server Liberty Trial
  - IBM WebSphere Application Server Liberty - Express
  - IBM WebSphere Application Server Liberty Network Deployment
  - IBM WebSphere Application Server Liberty Network Deployment Trial
  - IBM WebSphere Application Server for Developers
  - IBM WebSphere Application Server for Developers (ILAN)

### About this task

Using Installation Manager, you can work with response files to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty in a variety of ways. You can record a response file using the GUI as described in the following procedure, or you can generate a new response file by hand or by taking an example and modifying it.

### Procedure

1. Optional: **Record a response file to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty:** On one of your systems, perform the following actions to record a response file that will install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty.
  - a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.
  - b. Start Installation Manager from the command line using the `-record` option.

For example:

- **Windows Administrator or non-administrator:**

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"  
-record C:\temp\install_response_file.xml
```
- **AIX HP-UX Linux Solaris Administrator:**

```
./IBMIM -skipInstall /var/temp/imRegistry  
-record /var/temp/install_response_file.xml
```
- **AIX HP-UX Linux Solaris Non-administrator:**

```
./IBMIM -skipInstall user_home/var/temp/imRegistry  
-record user_home/var/temp/install_response_file.xml
```

**Tip:** When you record a new response file, you can specify the `-skipInstall` parameter. Using this parameter has the following benefits:

- No files are actually installed, and this speeds up the recording.
- If you use a temporary data location with the `-skipInstall` parameter, Installation Manager writes the installation registry to the specified data location while recording. When you start Installation Manager again without the `-skipInstall` parameter, you then can use your response file to install against the real installation registry.

The `-skipInstall` operation should not be used on the actual agent data location used by Installation Manager. This is unsupported. Use a clean writable location, and reuse that location for future recording sessions.

For more information, read the IBM Installation Manager Information Center.

- c. Add the appropriate repositories to your Installation Manager preferences.

- 1) Click **File > Preferences**.
- 2) Select **Repositories**.
- 3) Perform the following actions for each repository:
  - a) Click **Add Repository**.
  - b) Enter the path to the repository.config file in the remote web-based repository or the local directory into which you unpacked the repository files.

For example:

- Remote repositories:

`https://downloads.mycorp.com:8080/WAS_85_repository`

or

`http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v60`

- Local repositories:

– **Windows** C:\repositories\jdk6\local-repositories

– **AIX** **HP-UX** **Linux** **Solaris** /var/repositories/jdk6/local-repositories

- c) Click **OK**.
- 4) Click **Apply**.
- 5) Click **OK**.
- d. Click **Install**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

Installation Manager searches its defined repositories for available packages.

- e. Perform the appropriate actions.

- 1) Select **IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty**.

If you already have IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty installed on your system in the targeted location, a message displays indicating that IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty is already installed. To install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty where it is not yet installed, click **Continue**.

- 2) Select the fixes to install.

Any recommended fixes are selected by default.

If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.

- 3) Click **Next**.

**Note:** If you do not have and have not selected an installation of one the following offerings on which to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty, an error dialog displays.

- IBM WebSphere Application Server Liberty
- IBM WebSphere Application Server Liberty Trial
- IBM WebSphere Application Server Liberty - Express
- IBM WebSphere Application Server Liberty Network Deployment
- IBM WebSphere Application Server Liberty Network Deployment Trial
- IBM WebSphere Application Server for Developers
- IBM WebSphere Application Server for Developers (ILAN)

Click **OK**, select an appropriate offering on which to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty, and click **Next**.

- f. Select the appropriate WebSphere Application Server Liberty Network Deployment installation on which to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty, and click **Next**.

**Note:** The bit architecture that will be installed, 32 bit or 64 bit, will match the bit selection made during the installation of the Liberty offering. For GUI installations of Liberty offerings, this selection is made on the Location panel. For command-line and response-file installations of Liberty offerings, the default can be overridden using the `cic.selector.arch` property.

- g. Click **Next**.
- h. Review the summary information, and click **Install**.
  - If the installation is successful, the program displays a message indicating that installation is successful.

**Note:** The program might also display important post-installation instructions as well.

- If the installation is not successful, click **View Log File** to troubleshoot the problem.
- i. Click **Finish**.
  - j. Click **File > Exit** to close Installation Manager.
  - k. Optional: If you are using an authenticated remote repository, create a credential-storage file for silent installation.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

## 2. Use the response files to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty:

- a. Optional: **Use the response file to install the credential-storage file:** Go to a command line on each of the systems on which you want to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and install the credential-storage file.

For example:

-  **Administrator or non-administrator:**

```
imcl.exe
input C:\temp\credentialstorage_response_file.xml
-log C:\temp\credentialstorage_log.xml
```

-     **Administrator:**

```
./imcl
input /var/temp/credentialstorage_response_file.xml
-log /var/temp/credentialstorage_log.xml
```

-     **Non-administrator:**

```
./imcl
input user_home/var/temp/credentialstorage_response_file.xml
-log user_home/var/temp/credentialstorage_log.xml
```

- b. **Use the response file to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty:** Go to a command line on each of the systems on which you want to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty.

For example:

- **Windows Administrator or non-administrator:**

```
imcl.exe
input C:\temp\install_response_file.xml
-log C:\temp\install_log.xml
-secureStorageFile C:\IM\credential.store -masterPasswordFile C:\IM\master_password_file.txt
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./imcl
input /var/temp/install_response_file.xml
-log /var/temp/install_log.xml
-secureStorageFile /var/IM/credential.store -masterPasswordFile /var/IM/master_password_file.txt
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./imcl
input user_home/var/temp/install_response_file.xml
-log user_home/var/temp/install_log.xml
-secureStorageFile user_home/var/IM/credential.store -masterPasswordFile user_home/var/IM/master_password_file.txt
```

### Notes:

- The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lafiles` or `product_name/lafiles` subdirectory of the installation image or repository for this offering.
- The program might write important post-installation instructions to standard output.

Read the IBM Installation Manager Information Center for more information.

### Example

**Windows** The following is an example of a response file for installing IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input clean="true" temporary="true">
<server>
<repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v60" />
</server>
<install modify='false'>
<offering id='com.ibm.websphere.liberty.IBMJAVA.v60'
profile='WebSphere Liberty V8.5' installFixes='none' />
</install>
<profile id='WebSphere Liberty V8.5' installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
</agent-input>
```

### Installing fix packs on IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the GUI: **8.5.5.0**

You can update IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty to a later version using the Installation Manager GUI.

### Before you begin

**Note:** **8.5.5.11** Support for using Java SE 6 with WebSphere Liberty ends in September 2017. After the end of support, the Liberty kernel will be recompiled and can no longer run with Java SE 6. If you continue to use Java SE 6 on earlier fix packs after the end of support date, you could expose your environment to security risks.

Java SE 8 is the recommended Java SDK because it provides the latest features and security updates. You can install it by installing the IBM SDK, Java Technology Edition, Version 8 package to the package group that contains WebSphere Liberty.

Make sure that the web-based or local service repository location is listed and checked or that the **Search service repositories during installation and updates** option is selected on the Repositories panel in your Installation Manager preferences. For more information on using service repositories with Installation Manager, read the IBM Installation Manager Information Center.

## About this task

**Note:** For information on installing and removing fix packs for WebSphere Application Server LibertyNetwork Deployment on distributed operating systems using the Installation Manager command line, read the following articles in this information center:

- “Installing Liberty fix packs on distributed operating systems using the command line” on page 1200
- “Uninstalling Liberty fix packs from distributed operating systems using the command line” on page 1210

## Procedure

1. Start Installation Manager.
2. Click **Update**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you use to access protected IBM software websites.

3. Select the package group to update.

**Tip:** If you select **Update all**, Installation Manager will search all of the added and predefined repositories for recommended updates to all of the package groups that it has installed.

- Use this feature only if you have full control over which fixes are contained in the targeted repositories.
  - If you create and point to a set of custom repositories that include only the specific recommended fixes that you want to install, you should be able to use this feature confidently.
  - If you enable searching service repositories or install fixes directly from other live web-based repositories, you might not want to select this option so that you can select only the fixes that you want to install for each offering on subsequent panels.
- If you select **Update all**, Installation Manager will install only the recommended updates to all of the package groups; it will not allow you to select non-recommended fixes for installation. If you want to install non-recommended fixes, perform the following actions:
  - a. On this panel, clear the **Update all** check box and select an offering to update.
  - b. On the next panel, clear the option to show only recommended fixes and then select the fixes that you want to install.

4. Click **Next**.
5. Select the version to which you want to update under **IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty**.
6. Click **Next**.
7. Accept the terms in the license agreements, and click **Next**.
8. Review the summary information, and click **Update**.
  - If the installation is successful, the program displays a message indicating that installation is successful.
  - If the installation is not successful, click **View Log File** to troubleshoot the problem.
9. Click **Finish**.
10. Click **File > Exit** to close Installation Manager.

**Uninstalling fix packs from IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the GUI:** **8.5.5.0**

You can roll back IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty to an earlier version using the Installation Manager GUI.

## Before you begin

During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your computer when you install a package. If you change the default setting or delete the saved files, Installation Manager requires access to the repository that was used to install the earlier version.

## About this task

**Note:** For information on installing and removing fix packs for WebSphere Application Server Liberty Network Deployment on distributed operating systems using the Installation Manager command line, read the following articles in this information center:

- “Installing Liberty fix packs on distributed operating systems using the command line” on page 1200
- “Uninstalling Liberty fix packs from distributed operating systems using the command line” on page 1210

## Procedure

1. Stop all servers on the installation that is being modified.
2. Start Installation Manager.
3. Click **Roll Back**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you use to access protected IBM software websites.

4. Select the package group to roll back.
5. Click **Next**.
6. Select the version to which you want to roll back under **IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty**.
7. Click **Next**.
8. Review the summary information, and click **Roll Back**.
  - If the rollback is successful, the program displays a message indicating that the rollback is successful.
  - If the rollback is not successful, click **View Log File** to troubleshoot the problem.
9. Click **Finish**.
10. Click **File > Exit** to close Installation Manager.

## Uninstalling IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the GUI:

**8.5.5.0**

Use the Installation Manager GUI to uninstall IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty.

## Before you begin

Make sure that no commands or server profiles are using IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty before uninstalling it. Server profiles using IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty will not function if it is uninstalled.

## Procedure

1. Log on to your system.
2. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.

3. Start Installation Manager.
4. Click **Uninstall**.
5. In the **Uninstall Packages** window, perform the following actions.
  - a. Select **IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty**.
  - b. Click **Next**.
6. Review the summary information.
7. Click **Uninstall**.
  - If the uninstallation is successful, the program displays a message that indicates success.
  - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
8. Click **Finish**.
9. Click **File > Exit** to close Installation Manager.

**Uninstalling IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the command line:** **8.5.5.0**

You can uninstall IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using the Installation Manager command line.

### Before you begin

Make sure that no commands or server profiles are using IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty before uninstalling it. Server profiles using IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty will not function if it is uninstalled.

### Procedure

1. Log on to your system.
2. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
3. Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.
4. Use the `imcl` command to uninstall the offering.

Windows

```
imcl.exe uninstall com.ibm.websphere.liberty.IBMJAVA.v60
-installationDirectory installation_directory
```

AIX

HP-UX

Linux

Solaris

```
./imcl uninstall com.ibm.websphere.liberty.IBMJAVA.v60
-installationDirectory installation_directory
```

Go to the IBM Installation Manager Information Center for more information.

**Uninstalling IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using response files:** **8.5.5.0**

You can uninstall IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty using Installation Manager response files.

### Before you begin

Make sure that no commands or server profiles are using IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty before uninstalling it. Server profiles using IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty will not function if it is uninstalled.

**Optional:** Perform or record the installation of Installation Manager and installation of IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty to a temporary installation registry on one of your systems so that you can use this temporary registry to record the uninstallation without using the standard registry where Installation Manager is installed.

## About this task

Using Installation Manager, you can work with response files to uninstall IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty in a variety of ways. You can record a response file using the GUI as described in the following procedure, or you can generate a new response file by hand or by taking an example and modifying it.

## Procedure

1. **Optional: Record a response file to uninstall IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty:** On one of your systems, perform the following actions to record a response file that will uninstall IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty:
  - a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.
  - b. Start Installation Manager from the command line using the `-record` option.

For example:

- **Windows Administrator or non-administrator:**

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"  
-record C:\temp\uninstall_response_file.xml
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./IBMIM -skipInstall /var/temp/imRegistry  
-record /var/temp/uninstall_response_file.xml
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./IBMIM -skipInstall user_home/var/temp/imRegistry  
-record user_home/var/temp/uninstall_response_file.xml
```

**Tip:** If you choose to use the `-skipInstall` parameter with a temporary installation registry created as described in *Before you begin*, Installation Manager uses the temporary installation registry while recording the response file. It is important to note that when the `-skipInstall` parameter is specified, no packages are installed or uninstalled. All of the actions that you perform in Installation Manager simply update the installation data that is stored in the specified temporary registry. After the response file is generated, it can be used to uninstall IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty, removing the files and updating the standard installation registry.

The `-skipInstall` operation should not be used on the actual agent data location used by Installation Manager. This is unsupported. Use a clean writable location, and reuse that location for future recording sessions.

For more information, read the IBM Installation Manager Information Center.

- c. Click **Uninstall**.
- d. In the **Uninstall Packages** window, perform the following actions.
  - 1) Select **IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty**.
  - 2) Click **Next**.
- e. Review the summary information.
- f. Click **Uninstall**.
  - If the uninstallation is successful, the program displays a message that indicates success.
  - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
- g. Click **Finish**.

h. Click **File > Exit** to close Installation Manager.

2. **Use the response file to uninstall IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty:** From a command line on each of the systems from which you want to uninstall IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager and use the response file that you created to uninstall IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty.

For example:

- **Windows Administrator or non-administrator:**

```
imcl.exe
input C:\temp\uninstall_response_file.xml
-log C:\temp\uninstall_log.xml
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./imcl
input /var/temp/uninstall_response_file.xml
-log /var/temp/uninstall_log.xml
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./imcl
input user_home/var/temp/uninstall_response_file.xml
-log user_home/var/temp/uninstall_log.xml
```

Go to the IBM Installation Manager Information Center for more information.

3. **Optional: List all installed packages to verify the uninstallation.**

**AIX HP-UX Linux Solaris**

```
./imcl listInstalledPackages
```

**Windows**

```
imcl listInstalledPackages
```

**Windows**

## Example

The following is an example of a response file for uninstalling IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input clean='true' temporary='true'>
<uninstall modify='false'>
<offering id='com.ibm.websphere.liberty.IBMJAVA.v60'
  profile='WebSphere Liberty V8.5' />
</uninstall>
<profile id='WebSphere Liberty V8.5'
  installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
</agent-input>
```

## Installing and uninstalling SDK Java Technology Edition Version 7.0 or 7.1 for Liberty on distributed operating systems

**8.5.5.0**

You can install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using Installation Manager.

### About this task

Perform one of these procedures to install, update, roll back, or uninstall IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using Installation Manager.

**8.5.5.2**

You can download and install IBM WebSphere SDK Java Technology Edition Version 7.1. This version is only available from the web. This version is not available on the physical media. You have the following installation options:

- Download the installation files from the IBM Fix Central website and use a local installation.
- Access the live repositories and use your IBM Software ID for a web-based installation.

## Procedure

- “Installing IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the GUI” on page 1231
- “Installing IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using response files” on page 1234
- “Installing IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the command line” on page 1232
- “Installing fix packs on IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the GUI” on page 1239
- “Uninstalling fix packs from IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the GUI” on page 1240
- “Uninstalling IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the GUI” on page 1241
- “Uninstalling IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using response files” on page 1242
- “Uninstalling IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the command line” on page 1241

## Results

### Notes on logging and tracing:

- An easy way to view the logs is to open Installation Manager and go to **File > View Log**. An individual log file can be opened by selecting it in the table and then clicking the **Open log file** icon.
- Logs are located in the logs directory of Installation Manager's application data location. For example:

– **Windows** **Administrative installation:**

C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager\logs

– **Windows** **Non-administrative installation:**

C:\Documents and Settings\user\_name\Application Data\IBM\Installation Manager\logs

– **AIX** **HP-UX** **Linux** **Solaris** **Administrative installation:**

/var/ibm/InstallationManager/logs

– **AIX** **HP-UX** **Linux** **Solaris** **Non-administrative installation:**

user\_home/var/ibm/InstallationManager/logs

- The main log files are time-stamped XML files in the logs directory, and they can be viewed using any standard web browser.
- The log.properties file in the logs directory specifies the level of logging or tracing that Installation Manager uses.

### Notes on troubleshooting:

- **HP-UX** By default, some HP-UX systems are configured to not use DNS to resolve host names. This could result in Installation Manager not being able to connect to an external repository. You can ping the repository, but nslookup does not return anything. Work with your system administrator to configure your machine to use DNS, or use the IP address of the repository.
- For more information on using Installation Manager, read the IBM Installation Manager Information Center.

Read the release notes to learn more about the latest version of Installation Manager. To access the release notes, complete the following task:

- **Windows** Click **Start > Programs > IBM Installation Manager > Release Notes**.
- **AIX** **HP-UX** **Linux** **Solaris** Go to the documentation subdirectory in the directory where Installation Manager is installed, and open the `readme.html` file.

## Installing IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the GUI:

### 8.5.5.0

You can install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the Installation Manager GUI.

### Before you begin

1. Prepare your system as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.
2. Install one the following offerings:
  - IBM WebSphere Application Server Liberty
  - IBM WebSphere Application Server Liberty Trial
  - IBM WebSphere Application Server Liberty Core
  - IBM WebSphere Application Server Liberty Core Trial
  - IBM WebSphere Application Server Liberty - Express
  - IBM WebSphere Application Server Liberty Network Deployment
  - IBM WebSphere Application Server Liberty Network Deployment Trial
  - IBM WebSphere Application Server Liberty for Developers
  - IBM WebSphere Application Server Liberty for Developers (ILAN)

### 8.5.5.2

You can download and install IBM WebSphere SDK Java Technology Edition Version 7.1. This version is only available from the web. You have the following installation options:

- Download the installation files from the IBM Fix Central website and use a local installation.
- Access the live repositories and use your IBM Software ID for a web-based installation.

### Procedure

1. Start Installation Manager.

**Tip:** **AIX** **HP-UX** **Linux** **Solaris** You can start Installation Manager in group mode with the `./IBMIM` command.

- Group mode allows users to share packages in a common location and manage them with the same instance of Installation Manager.
- For more information on using group mode, read the Group mode road maps in the IBM Installation Manager Information Center.

2. Click **Install**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

Installation Manager searches its defined repositories for available packages.

3. Perform the appropriate actions.
  - a. Select **IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty** and the appropriate version.

If you already have IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty installed on a WebSphere Application Server Liberty Network Deployment installation on your system, a message displays indicating that IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty is already installed. To install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty on an installation where it is not yet installed, click **Continue**.

- b. Select the fixes to install.

Any recommended fixes are selected by default.

If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.

- c. Click **Next**.

**Note:** If you do not have and have not selected a Version 8.5 installation of one the following offerings on which to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty, an error dialog displays.

- IBM WebSphere Application Server Liberty
- IBM WebSphere Application Server Liberty Trial
- IBM WebSphere Application Server Liberty Core
- IBM WebSphere Application Server Liberty Core Trial
- IBM WebSphere Application Server Liberty - Express
- IBM WebSphere Application Server Liberty Network Deployment
- IBM WebSphere Application Server Liberty Network Deployment Trial
- IBM WebSphere Application Server Liberty for Developers
- IBM WebSphere Application Server Liberty for Developers (ILAN)

Click **OK**, select an appropriate offering on which to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty, and click **Next**.

4. Select the appropriate installation on which to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty, and click **Next**.

**Note:** The bit architecture that will be installed, 32 bit or 64 bit, will match the bit selection made during the installation of the Liberty offering. For GUI installations of Liberty offerings, this selection is made on the Location panel. For command-line and response-file installations of Liberty offerings, the default can be overridden using the `cic.selector.arch` property.

5. Click **Next**.

6. Review the summary information, and click **Install**.

- If the installation is successful, the program displays a message indicating that installation is successful.

**Note:** The program might also display important post-installation instructions as well.

- If the installation is not successful, click **View Log File** to troubleshoot the problem.

7. Click **Finish**.

8. Click **File > Exit** to close Installation Manager.

**Installing IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the command line:** `8.5.5.0`

You can install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the Installation Manager command line.

## Before you begin

1. Prepare your system as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.
2. Install one the following offerings:
  - IBM WebSphere Application Server Liberty
  - IBM WebSphere Application Server Liberty Trial
  - IBM WebSphere Application Server Liberty Core
  - IBM WebSphere Application Server Liberty Core Trial
  - IBM WebSphere Application Server Liberty - Express
  - IBM WebSphere Application Server Liberty Network Deployment
  - IBM WebSphere Application Server Liberty Network Deployment Trial
  - IBM WebSphere Application Server Liberty for Developers
  - IBM WebSphere Application Server Liberty for Developers (ILAN)

### 8.5.5.2

You can download and install IBM WebSphere SDK Java Technology Edition Version 7.1. This version is only available from the web. You have the following installation options:

- Download the installation files from the IBM Fix Central website and use a local installation.
- Access the live repositories and use your IBM Software ID for a web-based installation.

## Procedure

1. Optional: If the repository requires a username and password, create a credential-storage file to access this repository.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutilsc` command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the `-keyring` and `-password` options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the `-keyring` and `-password` options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

2. Log on to your system.
3. Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.
4. Verify that the repository is available.

Windows

```
imcl.exe listAvailablePackages -repositories path_to_repository
```

AIX

HP-UX

Linux

Solaris

```
./imcl listAvailablePackages -repositories path_to_repository
```

You should see one or more levels of the offering.

5. Use the `imcl` command to install the offering.

Windows

8.5.5.0

```
imcl.exe install com.ibm.websphere.liberty.IBMJAVA.v70_offering_version  
-repositories source_repository  
-installationDirectory installation_directory  
-secureStorageFile storage_file -masterPasswordFile master_password_file
```

## 8.5.5.2

```
imcl.exe install com.ibm.websphere.liberty.IBMJAVA.v71_offering_version
-repositories source_repository
-installationDirectory installation_directory
-secureStorageFile storage_file -masterPasswordFile master_password_file
```

AIX

HP-UX

Linux

Solaris

8.5.5.0

```
./imcl install com.ibm.websphere.liberty.IBMJAVA.v70_offering_version
-repositories source_repository
-installationDirectory installation_directory
-secureStorageFile storage_file -masterPasswordFile master_password_file
```

## 8.5.5.2

```
./imcl install com.ibm.websphere.liberty.IBMJAVA.v71_offering_version
-repositories source_repository
-installationDirectory installation_directory
-secureStorageFile storage_file -masterPasswordFile master_password_file
```

The value of the **-installationDirectory** parameter should be the location of an existing Liberty installation. The SDK offering will be installed into the `<liberty_home>\java\java_1.7_32` or `<liberty_home>\java\java_1.7_64` folder, depending on whether the installation location was configured to be 32-bit or 64-bit when the Liberty offering was initially installed.

**Note:** The bit architecture that will be installed, 32 bit or 64 bit, will match the bit selection made during the installation of the Liberty offering. For GUI installations of Liberty offerings, this selection is made on the Location panel. For command-line and response-file installations of Liberty offerings, the default can be overridden using the `cic.selector.arch` property.

### Tips:

- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (8.5.0.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the `-installFixes` argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the `-installFixes` option defaults to all.
  - If the offering version is specified, the `-installFixes` option defaults to none.
- The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lfiles` or `product_name/lfiles` subdirectory of the installation image or repository for this product.
- The program might write important post-installation instructions to standard output.

For more information on using the **imcl** command, see the IBM Installation Manager Information Center.

## Installing IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using response files: 8.5.5.0

You can install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using Installation Manager response files.

## Before you begin

1. Prepare your system as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.
2. Install one the following offerings:
  - IBM WebSphere Application Server Liberty
  - IBM WebSphere Application Server Liberty Trial
  - IBM WebSphere Application Server Liberty Core
  - IBM WebSphere Application Server Liberty Core Trial
  - IBM WebSphere Application Server Liberty - Express
  - IBM WebSphere Application Server Liberty Network Deployment
  - IBM WebSphere Application Server Liberty Network Deployment Trial
  - IBM WebSphere Application Server Liberty for Developers
  - IBM WebSphere Application Server Liberty for Developers (ILAN)

## About this task

Using Installation Manager, you can work with response files to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty in a variety of ways. You can record a response file using the GUI as described in the following procedure, or you can generate a new response file by hand or by taking an example and modifying it.

### 8.5.5.2

You can download and install IBM WebSphere SDK Java Technology Edition Version 7.1. This version and later versions are only available from the web. You have the following installation options:

- Download the installation files from the IBM Fix Central website and use a local installation.
- Access the live repositories and use your IBM Software ID for a web-based installation.

## Procedure

1. Optional: **Record a response file to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty:** On one of your systems, perform the following actions to record a response file that will install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty.
  - a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.
  - b. Start Installation Manager from the command line using the `-record` option.

For example:

- **Windows Administrator or non-administrator:**

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"  
-record C:\temp\install_response_file.xml
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./IBMIM -skipInstall /var/temp/imRegistry  
-record /var/temp/install_response_file.xml
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./IBMIM -skipInstall user_home/var/temp/imRegistry  
-record user_home/var/temp/install_response_file.xml
```

**Tip:** When you record a new response file, you can specify the `-skipInstall` parameter. Using this parameter has the following benefits:

- No files are actually installed, and this speeds up the recording.
- If you use a temporary data location with the `-skipInstall` parameter, Installation Manager writes the installation registry to the specified data location while recording. When you start

Installation Manager again without the `-skipInstall` parameter, you then can use your response file to install against the real installation registry.

The `-skipInstall` operation should not be used on the actual agent data location used by Installation Manager. This is unsupported. Use a clean writable location, and re-use that location for future recording sessions.

For more information, read the IBM Installation Manager Information Center.

- c. Add the appropriate repositories to your Installation Manager preferences.
  - 1) Click **File > Preferences**.
  - 2) Select **Repositories**.
  - 3) Perform the following actions for each repository:
    - a) Click **Add Repository**.
    - b) Enter the path to the `repository.config` file in the remote web-based repository or the local directory into which you unpacked the repository files.

For example:

- Remote repositories:

[https://downloads.mycorp.com:8080/WAS\\_85\\_repository](https://downloads.mycorp.com:8080/WAS_85_repository)

or **8.5.5.1**

<http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v70>

**8.5.5.2**

<http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v71>

- Local repositories:

– **Windows** C:\repositories\jdk7\local-repositories

– **AIX** **HP-UX** **Linux** **Solaris** /var/repositories/jdk7/local-repositories

- c) Click **OK**.
- 4) Click **Apply**.
- 5) Click **OK**.
- d. Click **Install**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

Installation Manager searches its defined repositories for available packages.

- e. Perform the appropriate actions.
  - 1) Select **IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty**.

If you already have IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty installed on a WebSphere Application Server LibertyNetwork Deployment installation on your system in the targeted location, a message displays indicating that IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty is already installed. To install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 on a WebSphere Application Server Liberty Network Deployment installation where it is not yet installed, click **Continue**.
  - 2) Select the fixes to install.

Any recommended fixes are selected by default.

If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.
  - 3) Click **Next**.

**Note:** If you do not have and have not selected an installation of one the following offerings on which to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty, an error dialog displays.

- IBM WebSphere Application Server Liberty
- IBM WebSphere Application Server Liberty Trial
- IBM WebSphere Application Server Liberty Core
- IBM WebSphere Application Server Liberty Core Trial
- IBM WebSphere Application Server Liberty - Express
- IBM WebSphere Application Server Liberty Network Deployment
- IBM WebSphere Application Server Liberty Network Deployment Trial
- IBM WebSphere Application Server Liberty for Developers
- IBM WebSphere Application Server Liberty for Developers (ILAN)

Click **OK**, select an appropriate offering on which to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty, and click **Next**.

- f. Select the appropriate WebSphere Application Server Liberty Network Deployment installation on which to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty, and click **Next**.

**Note:** The bit architecture that will be installed, 32 bit or 64 bit, will match the bit selection made during the installation of the Liberty offering. For GUI installations of Liberty offerings, this selection is made on the Location panel. For command-line and response-file installations of Liberty offerings, the default can be overridden using the `cic.selector.arch` property.

- g. Click **Next**.
- h. Review the summary information, and click **Install**.
  - If the installation is successful, the program displays a message indicating that installation is successful.

**Note:** The program might also display important post-installation instructions as well.

- If the installation is not successful, click **View Log File** to troubleshoot the problem.
- i. Click **Finish**.
- j. Click **File > Exit** to close Installation Manager.
- k. Optional: If you are using an authenticated remote repository, create a credential-storage file for silent installation.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

## 2. Use the response files to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty:

- a. Optional: **Use the response file to install the credential-storage file:** Go to a command line on each of the systems on which you want to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and install the credential-storage file.

For example:

- **Windows Administrator or non-administrator:**

```
imcl.exe
input C:\temp\credentialstorage_response_file.xml
-log C:\temp\credentialstorage_log.xml
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./imcl
input /var/temp/credentialstorage_response_file.xml
-log /var/temp/credentialstorage_log.xml
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./imcl
input user_home/var/temp/credentialstorage_response_file.xml
-log user_home/var/temp/credentialstorage_log.xml
```

- Use the response file to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty:** Go to a command line on each of the systems on which you want to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty, change to the eclipse/tools subdirectory in the directory where you installed Installation Manager, and install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty.

For example:

- **Windows Administrator or non-administrator:**

```
imcl.exe
input C:\temp\install_response_file.xml
-log C:\temp\install_log.xml
-secureStorageFile C:\IM\credential.store -masterPasswordFile C:\IM\master_password_file.txt
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./imcl
input /var/temp/install_response_file.xml
-log /var/temp/install_log.xml
-secureStorageFile /var/IM/credential.store -masterPasswordFile /var/IM/master_password_file.txt
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./imcl
input user_home/var/temp/install_response_file.xml
-log user_home/var/temp/install_log.xml
-secureStorageFile user_home/var/IM/credential.store -masterPasswordFile user_home/var/IM/master_password_file.txt
```

#### Notes:

- The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the lafiles or *product\_name/lafiles* subdirectory of the installation image or repository for this product.
- The program might write important post-installation instructions to standard output.

Read the IBM Installation Manager Information Center.

#### Example

Windows

**8.5.5.1**

The following is an example of a response file for installing IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input clean="true" temporary="true">
<server>
<repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v70" />
</server>
<install modify='false'>
<offering id='com.ibm.websphere.liberty.IBMJAVA.v70'
profile='WebSphere Liberty V8.5' installFixes='none'/>
</install>
<profile id='WebSphere Liberty V8.5' installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
</agent-input>
```

Windows

**8.5.5.2**

The following is an example of a response file for installing IBM WebSphere SDK Java Technology Edition Version 7.1 for Liberty.

```

<?xml version="1.0" encoding="UTF-8"?>
<agent-input clean="true" temporary="true">
<server>
<repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v71" />
</server>
<install modify='false'>
<offering id='com.ibm.websphere.liberty.IBMJAVA.v71'
profile='WebSphere Liberty V8.5' installFixes='none' />
</install>
<profile id='WebSphere Liberty V8.5' installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
</agent-input>

```

## Installing fix packs on IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the GUI: **8.5.5.0**

You can update IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty to a later version using the Installation Manager GUI.

### Before you begin

Make sure that the web-based or local service repository location is listed and checked or that the **Search service repositories during installation and updates** option is selected on the Repositories panel in your Installation Manager preferences. For more information on using service repositories with Installation Manager, read the IBM Installation Manager Information Center.

### About this task

**Note:** For information on installing and removing fix packs for WebSphere Application Server Liberty Network Deployment on distributed operating systems using the Installation Manager command line, read the following articles in this information center:

- “Installing Liberty fix packs on distributed operating systems using the command line” on page 1200
- “Uninstalling Liberty fix packs from distributed operating systems using the command line” on page 1210

### Procedure

1. Start Installation Manager.
2. Click **Update**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you use to access protected IBM software websites.

3. Select the package group to update.

**Tip:** If you select **Update all**, Installation Manager will search all of the added and predefined repositories for recommended updates to all of the package groups that it has installed.

- Use this feature only if you have full control over which fixes are contained in the targeted repositories.
  - If you create and point to a set of custom repositories that include only the specific recommended fixes that you want to install, you should be able to use this feature confidently.
  - If you enable searching service repositories or install fixes directly from other live web-based repositories, you might not want to select this option so that you can select only the fixes that you want to install for each offering on subsequent panels.
- If you select **Update all**, Installation Manager will install only the recommended updates to all of the package groups; it will not allow you to select non-recommended fixes for installation. If you want to install non-recommended fixes, perform the following actions:
  - a. On this panel, clear the **Update all** check box and select an offering to update.

- b. On the next panel, clear the option to show only recommended fixes and then select the fixes that you want to install.
4. Click **Next**.
5. Select the version to which you want to update under **IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty**.
6. Click **Next**.
7. Accept the terms in the license agreements, and click **Next**.
8. Review the summary information, and click **Update**.
  - If the installation is successful, the program displays a message indicating that installation is successful.
  - If the installation is not successful, click **View Log File** to troubleshoot the problem.
9. Click **Finish**.
10. Click **File > Exit** to close Installation Manager.

### Uninstalling fix packs from IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the GUI: 8.5.5.0

You can roll back IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty to an earlier version using the Installation Manager GUI.

#### Before you begin

During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your computer when you install a package. If you change the default setting or delete the saved files, Installation Manager requires access to the repository that was used to install the earlier version.

#### About this task

**Note:** For information on installing and removing fix packs for WebSphere Application Server Liberty Network Deployment on distributed operating systems using the Installation Manager command line, read the following articles in this information center:

- “Installing Liberty fix packs on distributed operating systems using the command line” on page 1200
- “Uninstalling Liberty fix packs from distributed operating systems using the command line” on page 1210

#### Procedure

1. Stop all servers on the installation that is being modified.
2. Start Installation Manager.
3. Click **Roll Back**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you use to access protected IBM software websites.

4. Select the package group to roll back.
5. Click **Next**.
6. Select the version to which you want to roll back under **IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty**.
7. Click **Next**.
8. Review the summary information, and click **Roll Back**.
  - If the rollback is successful, the program displays a message indicating that the rollback is successful.

- If the rollback is not successful, click **View Log File** to troubleshoot the problem.
9. Click **Finish**.
  10. Click **File > Exit** to close Installation Manager.

### Uninstalling IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the GUI: **8.5.5.0**

Use the Installation Manager GUI to uninstall IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty.

#### Before you begin

Make sure that no commands or server profiles are using IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty before uninstalling it. Server profiles using IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty will not function if it is uninstalled.

#### Procedure

1. Log on to your system.
2. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
3. Start Installation Manager.
4. Click **Uninstall**.
5. In the **Uninstall Packages** window, perform the following actions.
  - a. Select **IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty** and the appropriate version.
  - b. Click **Next**.
6. Review the summary information.
7. Click **Uninstall**.
  - If the uninstallation is successful, the program displays a message that indicates success.
  - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
8. Click **Finish**.
9. Click **File > Exit** to close Installation Manager.

### Uninstalling IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the command line: **8.5.5.0**

You can uninstall IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using the Installation Manager command line.

#### Before you begin

Make sure that no commands or server profiles are using IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty before uninstalling it. Server profiles using IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty will not function if it is uninstalled.

#### Procedure

1. Log on to your system.
2. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
3. Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.
4. Use the `imcl` command to uninstall the offering.

Windows

```
imcl.exe uninstall com.ibm.websphere.liberty.IBMJAVA.v70  
-installationDirectory installation_directory
```

AIX

HP-UX

Linux

Solaris

```
./imcl uninstall com.ibm.websphere.liberty.IBMJAVA.v70  
-installationDirectory installation_directory
```

Go to the IBM Installation Manager Information Center.

## Uninstalling IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using response files: **8.5.5.0**

You can uninstall IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using Installation Manager response files.

### Before you begin

Make sure that no commands or server profiles are using IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty before uninstalling it. Server profiles using IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty will not function if it is uninstalled.

**Optional:** Perform or record the installation of Installation Manager and installation of IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty to a temporary installation registry on one of your systems so that you can use this temporary registry to record the uninstallation without using the standard registry where Installation Manager is installed.

### About this task

Using Installation Manager, you can work with response files to uninstall IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty in a variety of ways. You can record a response file using the GUI as described in the following procedure, or you can generate a new response file by hand or by taking an example and modifying it.

### Procedure

1. **Optional: Record a response file to uninstall IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty:** On one of your systems, perform the following actions to record a response file that will uninstall IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty:
  - a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.
  - b. Start Installation Manager from the command line using the -record option.

For example:

- **Windows Administrator or non-administrator:**

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"  
-record C:\temp\uninstall_response_file.xml
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./IBMIM -skipInstall /var/temp/imRegistry  
-record /var/temp/uninstall_response_file.xml
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./IBMIM -skipInstall user_home/var/temp/imRegistry  
-record user_home/var/temp/uninstall_response_file.xml
```

**Tip:** If you choose to use the -skipInstall parameter with a temporary installation registry created as described in *Before you begin*, Installation Manager uses the temporary installation registry while recording the response file. It is important to note that when the -skipInstall parameter is

specified, no packages are installed or uninstalled. All of the actions that you perform in Installation Manager simply update the installation data that is stored in the specified temporary registry. After the response file is generated, it can be used to uninstall IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty, removing the files and updating the standard installation registry.

The `-skipInstall` operation should not be used on the actual agent data location used by Installation Manager. This is unsupported. Use a clean writable location, and re-use that location for future recording sessions.

For more information, read the IBM Installation Manager Information Center.

- c. Click **Uninstall**.
  - d. In the **Uninstall Packages** window, perform the following actions.
    - 1) Select **IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty** and the appropriate version.
    - 2) Click **Next**.
  - e. Review the summary information.
  - f. Click **Uninstall**.
    - If the uninstallation is successful, the program displays a message that indicates success.
    - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
  - g. Click **Finish**.
  - h. Click **File > Exit** to close Installation Manager.
2. **Use the response file to uninstall IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty:** From a command line on each of the systems from which you want to uninstall IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager and use the response file that you created to uninstall IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty. For example:

- **Windows Administrator or non-administrator:**

```
imcl.exe
input C:\temp\uninstall_response_file.xml
-log C:\temp\uninstall_log.xml
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./imcl
input /var/temp/uninstall_response_file.xml
-log /var/temp/uninstall_log.xml
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./imcl
input user_home/var/temp/uninstall_response_file.xml
-log user_home/var/temp/uninstall_log.xml
```

Go to the IBM Installation Manager Information Center.

3. **Optional: List all installed packages to verify the uninstallation.**

**AIX HP-UX Linux Solaris**

```
./imcl listInstalledPackages
```

**Windows**

```
imcl listInstalledPackages
```

**Windows**

## Example

The following is an example of a response file for uninstalling IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty.

```

<?xml version="1.0" encoding="UTF-8"?>
<agent-input clean='true' temporary='true'>
<uninstall modify='false'>
<offering id='com.ibm.websphere.liberty.IBMJAVA.v70'
  profile='WebSphere Liberty V8.5' />
</uninstall>
<profile id='WebSphere Liberty V8.5'
  installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
</agent-input>

```

## Installing and uninstalling SDK Java Technology Edition Version 8.0 for Liberty on distributed operating systems

8.5.5.5

You can install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using Installation Manager.

### About this task

Perform one of these procedures to install, update, roll back, or uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using Installation Manager.

You can download and install IBM WebSphere SDK Java Technology Edition Version 8.0. This version is only available from the web. This version is not available on the physical media. You have the following installation options:

- Download the installation files from the IBM Fix Central website and use a local installation.
- Access the live repositories and use your IBM Software ID for a web-based installation.

### Procedure

- Install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the GUI.
- Install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using response files.
- Install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the command line.
- Install fix packs on IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the GUI.
- Uninstall fix packs on IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the GUI.
- Uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the GUI.
- Uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using response files.
- Uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the command line.

### Results

#### Notes on logging and tracing:

- An easy way to view the logs is to open Installation Manager and go to **File > View Log**. An individual log file can be opened by selecting it in the table and then clicking the **Open log file** icon.
- Logs are located in the logs directory of Installation Manager's application data location. For example:

— **Windows** **Administrative installation:**

C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager\logs

— **Windows** **Non-administrative installation:**

C:\Documents and Settings\user\_name\Application Data\IBM\Installation Manager\logs

— **AIX** **HP-UX** **Linux** **Solaris** **Administrative installation:**

/var/ibm/InstallationManager/logs

— **AIX** **HP-UX** **Linux** **Solaris** **Non-administrative installation:**

`user_home/var/ibm/InstallationManager/logs`

- The main log files are time-stamped XML files in the logs directory, which you can view using any standard web browser.
- The `log.properties` file in the logs directory specifies the level of logging or tracing that Installation Manager uses.

### Notes on troubleshooting:

- **HP-UX** By default, some HP-UX systems are configured to not use DNS to resolve host names. This can result in Installation Manager not being able to connect to an external repository.  
You can ping the repository, but `nslookup` does not return anything.  
Work with your system administrator to configure your machine to use DNS, or use the IP address of the repository.
- For more information on using Installation Manager, read the IBM Installation Manager Information Center.  
Read the release notes to learn more about the latest version of Installation Manager. To access the release notes, complete the following task:
  - **Windows** Click **Start > Programs > IBM Installation Manager > Release Notes**.
  - **AIX** **HP-UX** **Linux** **Solaris** Go to the documentation subdirectory in the directory where Installation Manager is installed, and open the `readme.html` file.

### Installing IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the GUI:

8.5.5.5

You can install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty by using the Installation Manager GUI.

#### Before you begin

1. Prepare your system as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.
2. Install one the following offerings:
  - IBM WebSphere Application Server Liberty
  - IBM WebSphere Application Server Liberty Trial
  - IBM WebSphere Application Server Liberty Core
  - IBM WebSphere Application Server Liberty Core Trial
  - IBM WebSphere Application Server Liberty - Express
  - IBM WebSphere Application Server Liberty Network Deployment
  - IBM WebSphere Application Server Liberty Network Deployment Trial
  - IBM WebSphere Application Server Liberty for Developers
  - IBM WebSphere Application Server Liberty for Developers (ILAN)

You can download and install IBM WebSphere SDK Java Technology Edition Version 8.0. This version is only available from the web. You have the following installation options:

- Download the installation files from the IBM Fix Central website and use a local installation.
- Access the live repositories and use your IBM Software ID for a web-based installation.

**Note:** You can locate the installation files here IBM Support: Fix central .

#### Procedure

1. Start Installation Manager.

**Tip:** AIX HP-UX Linux Solaris You can start Installation Manager in group mode with the `./IBMIM` command.

- Group mode allows users to share packages in a common location and manage them with the same instance of Installation Manager.
- For more information on using group mode, read the Group mode road maps in the IBM Installation Manager Information Center.

2. Click **Install**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

Installation Manager searches its defined repositories for available packages.

3. Perform the appropriate actions.

- a. Select **IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty** and the appropriate version.

If you already have IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty installed on a WebSphere Application Server Liberty Network Deployment installation on your system, a message displays indicating that IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty is already installed. To install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty on an installation where it is not yet installed, click **Continue**.

- b. Select the fixes to install.

Any recommended fixes are selected by default.

If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.

- c. Click **Next**.

**Note:** If you do not have and have not selected a Version 8.5 installation of one the following offerings on which to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty, an error dialog displays.

- IBM WebSphere Application Server Liberty
- IBM WebSphere Application Server Liberty Trial
- IBM WebSphere Application Server Liberty Core
- IBM WebSphere Application Server Liberty Core Trial
- IBM WebSphere Application Server Liberty - Express
- IBM WebSphere Application Server Liberty Network Deployment
- IBM WebSphere Application Server Liberty Network Deployment Trial
- IBM WebSphere Application Server Liberty for Developers
- IBM WebSphere Application Server Liberty for Developers (ILAN)

Click **OK**, select an appropriate offering on which to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty, and click **Next**.

4. Select the appropriate installation on which to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty, and click **Next**.

**Note:** The bit architecture that is installed, 32 bit or 64 bit, matches the bit selection that is made during the installation of the Liberty offering. For GUI installations of Liberty offerings, this selection is made on the Location panel. For command-line and response-file installations of Liberty offerings, the default can be overridden by using the `cic.selector.arch` property.

5. Click **Next**.

6. Review the summary information, and click **Install**.

- If the installation is successful, the program displays a message that says that installation is successful.

**Note:** The program might also display important post-installation instructions.

- If the installation is not successful, click **View Log File** to troubleshoot the problem.

7. Click **Finish**.

8. Click **File > Exit** to close Installation Manager.

### Installing IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the command line:

8.5.5.5

You can install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the Installation Manager command line.

#### Before you begin

1. Prepare your system as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.
2. Install one the following offerings:
  - IBM WebSphere Application Server Liberty
  - IBM WebSphere Application Server Liberty Trial
  - IBM WebSphere Application Server Liberty Core
  - IBM WebSphere Application Server Liberty Core Trial
  - IBM WebSphere Application Server Liberty - Express
  - IBM WebSphere Application Server Liberty Network Deployment
  - IBM WebSphere Application Server Liberty Network Deployment Trial
  - IBM WebSphere Application Server Liberty for Developers
  - IBM WebSphere Application Server Liberty for Developers (ILAN)

You can download and install IBM WebSphere SDK Java Technology Edition Version 8.0. This version is only available from the web. You have the following installation options:

- Download the installation files from the IBM Fix Central website and use a local installation.
- Access the live repositories and use your IBM Software ID for a web-based installation.

#### Procedure

1. Optional: If the repository requires a username and password, create a credential-storage file to access this repository.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutilsc` command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the `-keyring` and `-password` options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the `-keyring` and `-password` options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

2. Log on to your system.
3. Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.

#### 4. Verify that the repository is available.

Windows

```
imcl.exe listAvailablePackages -repositories path_to_repository
```

AIX

HP-UX

Linux

Solaris

```
./imcl listAvailablePackages -repositories path_to_repository
```

You should see one or more levels of the offering.

#### 5. Use the **imcl** command to install the offering.

Windows

```
imcl.exe install com.ibm.websphere.liberty.IBMJAVA.v80_offering_version  
-repositories source_repository  
-installationDirectory installation_directory  
-secureStorageFile storage_file -masterPasswordFile master_password_file
```

AIX

HP-UX

Linux

Solaris

```
./imcl install com.ibm.websphere.liberty.IBMJAVA.v80_offering_version  
-repositories source_repository  
-installationDirectory installation_directory  
-secureStorageFile storage_file -masterPasswordFile master_password_file
```

The value of the **-installationDirectory** parameter should be the location of an existing Liberty installation. The SDK offering will be installed into the `<liberty_home>\java\java_1.8_32` or `<liberty_home>\java\java_1.8_64` folder, depending on whether the installation location was configured to be 32-bit or 64-bit when the Liberty offering was initially installed.

**Note:** The bit architecture that will be installed, 32 bit or 64 bit, will match the bit selection made during the installation of the Liberty offering. For GUI installations of Liberty offerings, this selection is made on the Location panel. For command-line and response-file installations of Liberty offerings, the default can be overridden using the `cic.selector.arch` property.

#### Tips:

- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (8.5.0.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the **-installFixes** argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the **-installFixes** option defaults to all.
  - If the offering version is specified, the **-installFixes** option defaults to none.
- The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lafiles` or `product_name/lafiles` subdirectory of the installation image or repository for this product.
- The program might write important post-installation instructions to standard output.

For more information on using the **imcl** command, see the IBM Installation Manager Information Center.

## Installing IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using response files:

8.5.5.5

You can install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using Installation Manager response files.

### Before you begin

1. Prepare your system as described in “Installing Installation Manager and preparing to install Liberty” on page 1168.
2. Install one the following offerings:
  - IBM WebSphere Application Server Liberty
  - IBM WebSphere Application Server Liberty Trial
  - IBM WebSphere Application Server Liberty Core
  - IBM WebSphere Application Server Liberty Core Trial
  - IBM WebSphere Application Server Liberty - Express
  - IBM WebSphere Application Server Liberty Network Deployment
  - IBM WebSphere Application Server Liberty Network Deployment Trial
  - IBM WebSphere Application Server Liberty for Developers
  - IBM WebSphere Application Server Liberty for Developers (ILAN)

### About this task

Using Installation Manager, you can work with response files to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty in a variety of ways. You can record a response file using the GUI as described in the following procedure, or you can generate a new response file by hand or by taking an example and modifying it.

You can download and install IBM WebSphere SDK Java Technology Edition Version 8.0. This version and later versions are only available from the web. You have the following installation options:

- Download the installation files from the IBM Fix Central website and use a local installation.
- Access the live repositories and use your IBM Software ID for a web-based installation.

### Procedure

1. Optional: **Record a response file to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty:** On one of your systems, perform the following actions to record a response file that will install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty.
  - a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.
  - b. Start Installation Manager from the command line using the -record option.

For example:

- **Windows Administrator or non-administrator:**

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"  
-record C:\temp\install_response_file.xml
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./IBMIM -skipInstall /var/temp/imRegistry  
-record /var/temp/install_response_file.xml
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./IBMIM -skipInstall user_home/var/temp/imRegistry  
-record user_home/var/temp/install_response_file.xml
```

**Tip:** When you record a new response file, you can specify the `-skipInstall` parameter. Using this parameter has the following benefits:

- No files are actually installed, and this speeds up the recording.
- If you use a temporary data location with the `-skipInstall` parameter, Installation Manager writes the installation registry to the specified data location while recording. When you start Installation Manager again without the `-skipInstall` parameter, you then can use your response file to install against the real installation registry.

The `-skipInstall` operation should not be used on the actual agent data location used by Installation Manager. This is unsupported. Use a clean writable location, and re-use that location for future recording sessions.

For more information, read the IBM Installation Manager Information Center.

c. Add the appropriate repositories to your Installation Manager preferences.

1) Click **File > Preferences**.

2) Select **Repositories**.

3) Perform the following actions for each repository:

a) Click **Add Repository**.

b) Enter the path to the `repository.config` file in the remote web-based repository or the local directory into which you unpacked the repository files.

For example:

- Remote repositories:

`https://downloads.mycorp.com:8080/WAS_85_repository`

or

`http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v80`

- Local repositories:

– **Windows** `C:\repositories\jdk8\local-repositories`

– **AIX** **HP-UX** **Linux** **Solaris** `/var/repositories/jdk8/local-repositories`

c) Click **OK**.

4) Click **Apply**.

5) Click **OK**.

d. Click **Install**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.

Installation Manager searches its defined repositories for available packages.

e. Perform the appropriate actions.

1) Select **IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty**.

If you already have IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty installed on a WebSphere Application Server Liberty Network Deployment installation on your system in the targeted location, a message displays indicating that IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty is already installed. To install IBM WebSphere SDK Java Technology Edition Version 8.0 on a WebSphere Application Server Liberty Network Deployment installation where it is not yet installed, click **Continue**.

2) Select the fixes to install.

Any recommended fixes are selected by default.

If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.

3) Click **Next**.

**Note:** If you do not have and have not selected an installation of one the following offerings on which to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty, an error dialog displays.

- IBM WebSphere Application Server Liberty
- IBM WebSphere Application Server Liberty Trial
- IBM WebSphere Application Server Liberty Core
- IBM WebSphere Application Server Liberty Core Trial
- IBM WebSphere Application Server Liberty - Express
- IBM WebSphere Application Server Liberty Network Deployment
- IBM WebSphere Application Server Liberty Network Deployment Trial
- IBM WebSphere Application Server Liberty for Developers
- IBM WebSphere Application Server Liberty for Developers (ILAN)

Click **OK**, select an appropriate offering on which to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty, and click **Next**.

- f. Select the appropriate WebSphere Application Server Liberty Network Deployment installation on which to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty, and click **Next**.

**Note:** The bit architecture that will be installed, 32 bit or 64 bit, will match the bit selection made during the installation of the Liberty offering. For GUI installations of Liberty offerings, this selection is made on the Location panel. For command-line and response-file installations of Liberty offerings, the default can be overridden using the `cic.selector.arch` property.

- g. Click **Next**.
- h. Review the summary information, and click **Install**.
  - If the installation is successful, the program displays a message indicating that installation is successful.

**Note:** The program might also display important post-installation instructions as well.

- If the installation is not successful, click **View Log File** to troubleshoot the problem.
- i. Click **Finish**.
- j. Click **File > Exit** to close Installation Manager.
- k. Optional: If you are using an authenticated remote repository, create a credential-storage file for silent installation.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

## 2. Use the response files to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty:

- a. Optional: **Use the response file to install the credential-storage file:** Go to a command line on each of the systems on which you want to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and install the credential-storage file.

For example:

- **Windows Administrator or non-administrator:**

```
imcl.exe
input C:\temp\credentialstorage_response_file.xml
-log C:\temp\credentialstorage_log.xml
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./imcl
input /var/temp/credentialstorage_response_file.xml
-log /var/temp/credentialstorage_log.xml
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./imcl
input user_home/var/temp/credentialstorage_response_file.xml
-log user_home/var/temp/credentialstorage_log.xml
```

- Use the response file to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty:** Go to a command line on each of the systems on which you want to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty, change to the eclipse/tools subdirectory in the directory where you installed Installation Manager, and install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty.

For example:

- **Windows Administrator or non-administrator:**

```
imcl.exe
input C:\temp\install_response_file.xml
-log C:\temp\install_log.xml
-secureStorageFile C:\IM\credential.store -masterPasswordFile C:\IM\master_password_file.txt
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./imcl
input /var/temp/install_response_file.xml
-log /var/temp/install_log.xml
-secureStorageFile /var/IM/credential.store -masterPasswordFile /var/IM/master_password_file.txt
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./imcl
input user_home/var/temp/install_response_file.xml
-log user_home/var/temp/install_log.xml
-secureStorageFile user_home/var/IM/credential.store -masterPasswordFile user_home/var/IM/master_password_file.txt
```

### Notes:

- The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the lafiles or *product\_name/lafiles* subdirectory of the installation image or repository for this product.
- The program might write important post-installation instructions to standard output. Read the IBM Installation Manager Information Center.

### Example

**Windows** The following is an example of a response file for installing IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input clean="true" temporary="true">
<server>
<repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v80" />
</server>
<install modify='false'>
<offering id='com.ibm.websphere.liberty.IBMJAVA.v80'
profile='WebSphere Liberty V8.5' installFixes='none' />
</install>
<profile id='WebSphere Liberty V8.5' installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
</agent-input>
```

## Installing fix packs on IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the GUI: 8.5.5.5

You can update IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty to a later version using the Installation Manager GUI.

### Before you begin

Make sure that the web-based or local service repository location is listed and checked or that the **Search service repositories during installation and updates** option is selected on the Repositories panel in your Installation Manager preferences. For more information on using service repositories with Installation Manager, read the IBM Installation Manager Information Center.

### About this task

**Note:** For information on installing and removing fix packs for WebSphere Application Server Liberty Network Deployment on distributed operating systems using the Installation Manager command line, read the following articles in this information center:

- “Installing Liberty fix packs on distributed operating systems using the command line” on page 1200
- “Uninstalling Liberty fix packs from distributed operating systems using the command line” on page 1210

### Procedure

1. Start Installation Manager.
2. Click **Update**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you use to access protected IBM software websites.

3. Select the package group to update.

**Tip:** If you select **Update all**, Installation Manager will search all of the added and predefined repositories for recommended updates to all of the package groups that it has installed.

- Use this feature only if you have full control over which fixes are contained in the targeted repositories.
    - If you create and point to a set of custom repositories that include only the specific recommended fixes that you want to install, you should be able to use this feature confidently.
    - If you enable searching service repositories or install fixes directly from other live web-based repositories, you might not want to select this option so that you can select only the fixes that you want to install for each offering on subsequent panels.
  - If you select **Update all**, Installation Manager will install only the recommended updates to all of the package groups; it will not allow you to select non-recommended fixes for installation. If you want to install non-recommended fixes, perform the following actions:
    - a. On this panel, clear the **Update all** check box and select an offering to update.
    - b. On the next panel, clear the option to show only recommended fixes and then select the fixes that you want to install.
4. Click **Next**.
  5. Select the version to which you want to update under **IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty**.
  6. Click **Next**.
  7. Accept the terms in the license agreements, and click **Next**.
  8. Review the summary information, and click **Update**.

- If the installation is successful, the program displays a message indicating that installation is successful.
- If the installation is not successful, click **View Log File** to troubleshoot the problem.

9. Click **Finish**.

10. Click **File > Exit** to close Installation Manager.

### Uninstalling fix packs from IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the GUI: 8.5.5.5

You can roll back IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty to an earlier version using the Installation Manager GUI.

#### Before you begin

During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your computer when you install a package. If you change the default setting or delete the saved files, Installation Manager requires access to the repository that was used to install the earlier version.

#### About this task

**Note:** For information on installing and removing fix packs for WebSphere Application Server Liberty Network Deployment on distributed operating systems using the Installation Manager command line, read the following articles in this information center:

- “Installing Liberty fix packs on distributed operating systems using the command line” on page 1200
- “Uninstalling Liberty fix packs from distributed operating systems using the command line” on page 1210

#### Procedure

1. Stop all servers on the installation that is being modified.
2. Start Installation Manager.
3. Click **Roll Back**.

**Note:** If you are prompted to authenticate, use the IBM ID and password that you use to access protected IBM software websites.

4. Select the package group to roll back.
5. Click **Next**.
6. Select the version to which you want to roll back under **IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty**.
7. Click **Next**.
8. Review the summary information, and click **Roll Back**.
  - If the rollback is successful, the program displays a message indicating that the rollback is successful.
  - If the rollback is not successful, click **View Log File** to troubleshoot the problem.
9. Click **Finish**.
10. Click **File > Exit** to close Installation Manager.

## Uninstalling IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the GUI:

8.5.5.0

Use the Installation Manager GUI to uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty.

### Before you begin

Make sure that no commands or server profiles are using IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty before uninstalling it. Server profiles using IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty will not function if it is uninstalled.

### Procedure

1. Log on to your system.
2. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
3. Start Installation Manager.
4. Click **Uninstall**.
5. In the **Uninstall Packages** window, perform the following actions.
  - a. Select **IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty** and the appropriate version.
  - b. Click **Next**.
6. Review the summary information.
7. Click **Uninstall**.
  - If the uninstallation is successful, the program displays a message that indicates success.
  - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
8. Click **Finish**.
9. Click **File > Exit** to close Installation Manager.

## Uninstalling IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the command line:

8.5.5.5

You can uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using the Installation Manager command line.

### Before you begin

Make sure that no commands or server profiles are using IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty before uninstalling it. Server profiles using IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty will not function if it is uninstalled.

### Procedure

1. Log on to your system.
2. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
3. Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.
4. Use the `imcl` command to uninstall the offering.

Windows

```
imcl.exe uninstall com.ibm.websphere.liberty.IBMJAVA.v80  
-installationDirectory installation_directory
```

AIX

HP-UX

Linux

Solaris

```
./imcl uninstall com.ibm.websphere.liberty.IBMJAVA.v80
-installationDirectory installation_directory
```

Go to the IBM Installation Manager Information Center.

## Uninstalling IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using response files: 8.5.5.5

You can uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty using Installation Manager response files.

### Before you begin

Make sure that no commands or server profiles are using IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty before uninstalling it. Server profiles using IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty will not function if it is uninstalled.

**Optional:** Perform or record the installation of Installation Manager and installation of IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty to a temporary installation registry on one of your systems so that you can use this temporary registry to record the uninstallation without using the standard registry where Installation Manager is installed.

### About this task

Using Installation Manager, you can work with response files to uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty in a variety of ways. You can record a response file using the GUI as described in the following procedure, or you can generate a new response file by hand or by taking an example and modifying it.

### Procedure

1. **Optional: Record a response file to uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty:** On one of your systems, perform the following actions to record a response file that will uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty:
  - a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.
  - b. Start Installation Manager from the command line using the -record option.

For example:

- Windows **Administrator or non-administrator:**

```
IBMIM.exe -skipInstall "C:\temp\imRegistry"
-record C:\temp\uninstall_response_file.xml
```

- AIX HP-UX Linux Solaris **Administrator:**

```
./IBMIM -skipInstall /var/temp/imRegistry
-record /var/temp/uninstall_response_file.xml
```

- AIX HP-UX Linux Solaris **Non-administrator:**

```
./IBMIM -skipInstall user_home/var/temp/imRegistry
-record user_home/var/temp/uninstall_response_file.xml
```

**Tip:** If you choose to use the -skipInstall parameter with a temporary installation registry created as described in *Before you begin*, Installation Manager uses the temporary installation registry while recording the response file. It is important to note that when the -skipInstall parameter is specified, no packages are installed or uninstalled. All of the actions that you perform in Installation Manager simply update the installation data that is stored in the specified temporary registry. After the response file is generated, it can be used to uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty, removing the files and updating the standard installation registry.

The `-skipInstall` operation should not be used on the actual agent data location used by Installation Manager. This is unsupported. Use a clean writable location, and re-use that location for future recording sessions.

For more information, read the IBM Installation Manager Information Center.

- c. Click **Uninstall**.
  - d. In the **Uninstall Packages** window, perform the following actions.
    - 1) Select **IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty** and the appropriate version.
    - 2) Click **Next**.
  - e. Review the summary information.
  - f. Click **Uninstall**.
    - If the uninstallation is successful, the program displays a message that indicates success.
    - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
  - g. Click **Finish**.
  - h. Click **File > Exit** to close Installation Manager.
2. **Use the response file to uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty:** From a command line on each of the systems from which you want to uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager and use the response file that you created to uninstall IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty. For example:

- **Windows Administrator or non-administrator:**

```
imcl.exe
input C:\temp\uninstall_response_file.xml
-log C:\temp\uninstall_log.xml
```

- **AIX HP-UX Linux Solaris Administrator:**

```
./imcl
input /var/temp/uninstall_response_file.xml
-log /var/temp/uninstall_log.xml
```

- **AIX HP-UX Linux Solaris Non-administrator:**

```
./imcl
input user_home/var/temp/uninstall_response_file.xml
-log user_home/var/temp/uninstall_log.xml
```

Go to the IBM Installation Manager Information Center.

3. **Optional: List all installed packages to verify the uninstallation.**

**AIX HP-UX Linux Solaris**

```
./imcl listInstalledPackages
```

**Windows**

```
imcl listInstalledPackages
```

**Windows**

## Example

The following is an example of a response file for uninstalling IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input clean='true' temporary='true'>
<uninstall modify='false'>
<offering id='com.ibm.websphere.liberty.IBMJAVA.v80'
profile='WebSphere Liberty V8.5' />
</uninstall>
```

```
<profile id='WebSphere Liberty V8.5'
  installLocation='C:\Program Files\IBM\WebSphere\Liberty'>
</profile>
</agent-input>
```

## Using the sample response files

You can edit and use sample response file for installing, modifying, or uninstalling Liberty offerings silently.

### Procedure

- “Sample response file: Installing IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty”
- “Sample response file: Uninstalling IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty” on page 1263
- “Sample response file: Installing IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty” on page 1266
- “Sample response file: Uninstalling IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty” on page 1270
- “Sample response file: Installing IBM WebSphere Application Server Liberty Network Deployment” on page 1273
- “Sample response file: Modifying IBM WebSphere Application Server Liberty Network Deployment” on page 1278
- “Sample response file: Uninstalling IBM WebSphere Application Server Liberty Network Deployment” on page 1283

### Sample response file: Installing IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty:

You can edit and use this example of a response file for installing IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty.

**Note:** 8.5.5.11 Support for using Java SE 6 with WebSphere Liberty ends in September 2017. After the end of support, the Liberty kernel will be recompiled and can no longer run with Java SE 6. If you continue to use Java SE 6 on earlier fix packs after the end of support date, you could expose your environment to security risks.

Java SE 8 is the recommended Java SDK because it provides the latest features and security updates. You can install it by installing the IBM SDK, Java Technology Edition, Version 8 package to the package group that contains WebSphere Liberty.

```

<!-- ##### Frequently Asked Questions #####
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
# Installation Manager Information Center can be found at:
# http://publib.boulder.ibm.com/infocenter/install/v1r6/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
```

```

#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
# Windows = IBMIM.exe -record c:\temp\responsefiles\WASv85.install.Win32.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
# Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv85.install.RHEL64.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse/tools subdirectory in the directory where you installed
# Installation Manager:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
# Windows = imcl.exe -acceptLicense -showProgress
# input c:\temp\responsefile\WASv85.install.Win32.xml
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input /home/user/responsefile/WASv85.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
# license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help: IBMIM -help
#
# Question 3. How do I store and pass credentials to repositories that
# require authentication?
# Answer 3. There are two methods for storing authentication credentials
# for Installation Manager depending on the version being used,
# either key ring files or storage files.
#
# Versions of Installation Manger before 1.6.2 use a key ring file to store
# encrypted credentials for authenticating with repositories. Follow this
# two-step process for creating and using a key ring file with Installation Manager.
#
# First, create a key ring file with your credentials by starting
# Installation Manager from the command line under eclipse subdirectory
# with the keyring parameter.
# Use the optional password parameter to password protect your file.
#
# Windows = IBMIM.exe -keyring <path and file name> -password <password>
# Linux, UNIX, IBM i and z/OS = ./IBMIM -keyring <path and file name>
# -password <password>
#
# Installation Manager will start in graphical mode. Verify that the
# repositories to which you need to authenticate are included in the
# preferences, File / Preferences / Repositories. If they are not
# listed, then click Add Repositories to add the URL or UNC path.
# Installation Manager will prompt for your credentials. If the repository
# is already in the list, then any attempt to access the repository location,
# such as clicking the Test Connections button, will also prompt for your
# credentials. Enter the correct credential and check the Save password
# checkbox. The credentials are saved to the key ring file you specified.
#
# Second, when you start a silent installation, run imcl under eclipse/tools
# subdirectory, and provide Installation Manager with the location of the key
# ring file and the password if the file is protected. For example:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <path and file name of response file>
# -keyring <path and name of key ring file> -password <password>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <path and file name of response file>
# -keyring <path and name of key ring file> -password <password>
#
# Versions of Installation Manager at 1.6.2 or higher use storage files
# to store encrypted credentials. Complete the following steps to create
# master password and storage files to use with Installation Manager.
#
# First, if you do not have a master password file already, create a text file
# that contains a master passphrase. An example of a passphrase is:
# "This text is the passphrase for a master password file."
#
# Next, run imutilsc under the eclipse/tools subdirectory with the following
# options to create and store user credentials in a storage file.
# -secureStorageFile <path and file name of storage file>
# -masterPasswordFile <path and file name of master password file>
# -url <repository address> or -passportAdvantage <PPA repository address>
# -userName <user name>
# -userPassword <password for user>
#
# Example of a command to create a storage file by operating system
# Windows = imutilsc saveCredential -url http://myServer -userName myUserName
# -userPassword myPassword -secureStorageFile C:\IBM\credential.store

```

```

# -masterPasswordFile C:\IBM\master_password_file.txt
# Linux, UNIX, IBM z/OS, and the OS X operating system =
# ./imutilsc saveCredential -url http://myServer -userName myUserName
# -userPassword myPassword -secureStorageFile /home/IBM/credential.store
# -masterPasswordFile /home/user/IBM/master_password_file.txt
#
# Usage hints:
# * Do not use both the -url and -passportAdvantage options in the same command.
# * Enclose file paths that include spaces with double quotation marks.
# * If you use the IBM service repositories, you can specify the value:
#   http://www.ibm.com/software/repositorymanager/entitled/repository.xml
#   for the -url option which is a generic service repository for IBM packages.
# * Repeat steps to store credentials for multiple users in one file.
# * Repeat steps to store credentials for multiple repositories in one file.
#
# Afterwards, when you start a silent installation, run imcl under the eclipse/tools
# subdirectory, and provide Installation Manager with the location of the storage
# file. For example:
#
# Windows = imcl.exe -acceptLicense -showProgress
#   input <path and file name of response file>
#   -secureStorageFile <path and name of storage file>
#   -masterPasswordFile <path and name of master password file>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#   input <path and file name of response file>
#   -secureStorageFile <path and name of storage file>
#   -masterPasswordFile <path and name of master password file>
#

<!-- ##### Agent Input #####
#
# Note that the acceptLicense attribute has been deprecated.
# Use the -acceptLicense command line option to accept license agreements.
#
# The clean and temporary attributes specify the repositories and other
# preferences Installation Manager uses and whether those settings
# should persist after the installation finishes.
#
# Valid values for clean:
#   true = only use the repositories and other preferences that are
#         specified in the response file.
#   false = use the repositories and other preferences that are
#         specified in the response file and Installation Manager.
#
# Valid values for temporary:
#   true = repositories and other preferences specified in the
#         response file do not persist in Installation Manager.
#   false = repositories and other preferences specified in the
#         response file persist in Installation Manager.

<!-- ##### Install Packages #####
#
# Install Command
#
# Use the install command to inform Installation Manager of the
# installation packages to install.
#
# The modify attribute is optional and can be paired with an install
# command to add features or paired with an uninstall command to
# remove commands. If omitted, the default value is set to false.
# false = indicates not to modify an existing install by adding
# or removing features.
# true = indicates to modify an existing install by adding or
# removing features.
#
# The offering ID attribute is required because it specifies the
# offering to be installed. The offering listed must be present in
# at least one of the repositories listed earlier. The example
# command below contains the offering ID for the IBM WebSphere SDK Java
# Technology Edition (Optional) .
#
# The version attribute is optional. If a version number is provided,
# then the offering will be installed at the version level specified
# as long as it is available in the repositories. If the version
# attribute is not provided, then the default behavior is to install
# the latest version available in the repositories. The version number
# can be found in the repository.xml file in the repositories.
# For example, <offering ... version='6.0.5000.20130328_1111'>.
#
# The profile attribute is required and typically is unique to the
# offering. If modifying or updating an existing installation, the
# profile attribute must match the profile ID of the targeted installation
# of IBMJAVA for WebSphere Application Server Liberty.
#
# IBM WebSphere SDK Java Technology Edition (Optional) 6.0.5.0 is an
# extension offering which requires a base WebSphere Application
# Server / Client product to be installed first The profile id for
# IBM WebSphere SDK Java Technology Edition (Optional) 6.0.5.0 must be
# the same as the base product.
#
# The features attribute is optional. Offerings always have at least
# one feature; a required core feature which is installed regardless
# of whether it is explicitly specified. If other feature names
# are provided, then only those features will be installed.
# Features must be comma delimited without spaces.
#
# The installFixes attribute indicates whether fixes available in
# repositories are installed with the product. By default, all
# available fixes will be installed with the offering.
#
# Valid values for installFixes:
# none = do not install available fixes with the offering.
# recommended = installs all available recommended fixes with the offering.
# all = installs all available fixes with the offering.
#
# Interim fixes for offerings also can be installed while they
# are being installed by including the offering ID for the interim
# fix and specifying the profile ID. A commented out example is
# provided in the install command below.
#
# Installation Manager supports installing multiple offerings at once.
# Additional offerings can be included in the install command,
# with each offering requiring its own offering ID, version, profile value,
# and feature values.
#
# Profile Command
#
# A separate profile command must be included for each offering listed
# in the install command. The profile command informs Installation
# Manager about offering specific properties or configuration values.
#
# The installLocation specifies where the offering will be installed.
# If the response file is used to modify or update an existing
# installation, then ensure the installLocation points to the

```

```

# Location where the offering was installed previously.
#
# Include data keys for product specific profile properties.
# For instance, Installing IBMJAVA for Liberty Offerings on
# a 64-bit system will require to include one of the options for an IBM Software
# Development Kit, this can be specified by data key cic.selector.arch, its value
# can be either x86 (for 32-bit), or x86_64 (for 64-bit).
#
# More details for cic.selector.arch can be found in the link below:
#
# https://infocenters.hursley.ibm.com/was/vNext/draft/help/index.jsp?topic=%2Fcom.ibm.websphere.wlp.core.doc%2Fae%2Ftwlp_ins_installation_dist_silent.html
#
##### -->

<install modify="false">

</profile>

<!-- ##### Shared Data Location #####
# Uncomment the preference for eclipseCache to set the shared data
# location the first time you use Installation Manager to do an
# installation.
#
# Eclipse cache location can be obtained from the installed.xml file found in
# Linux/Unix: /var/ibm/InstallationManager
# Windows: C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager
# from the following property:
# <property name='cacheLocation' value='C:\Program Files\IBM\IMShared' />
#
# Open the installed.xml file in a text editor because the style sheet
# might hide this value if opened in a web browser.
# For further information on how to edit preferences, refer to the public library at:
# http://publib.boulder.ibm.com/infocenter/install/v1r5/index.jsp?topic=/com.ibm.silentinstall12.doc/topics/r_silent_prefs.html
#
# After the shared data location is set, it cannot be changed
# using a response file or the graphical wizard.
#
# Ensure that the shared data location is a location that can be written
# to by all user accounts that are expected to use Installation Manager.
#
# By default, Installation Manager saves downloaded artifacts to
# the shared data location. This serves two purposes.
#
# First, if the same product is installed a more than once to the machine,
# then the files in the shared data location will be used rather than
# downloading them again.
#
# Second, during the rollback process, the saved artifacts are used.
# Otherwise, if the artifacts are not saved or are removed, then
# Installation Manager must have to access the repositories used to
# install the previous versions.
#
# Valid values for preserveDownloadedArtifacts:
# true = store downloaded artifacts in the shared data location
# false = remove downloaded artifacts from the shared data location
#
##### -->

<!-- ##### Frequently Asked Questions #####
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
# Installation Manager Information Center can be found at:
# http://publib.boulder.ibm.com/infocenter/install/v1r6/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
# Windows = IBMIM.exe -record c:\temp\responsefiles\WASv85.install.Win32.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
# Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv85.install.RHEL64.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
# Windows = imcl.exe -acceptLicense -showProgress
# input c:\temp\responsefile\WASv85.install.Win32.xml
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input /home/user/responsefile/WASv85.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
# license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help: IBMIM -help
#
##### -->

<!-- ##### Agent Input #####
# The clean and temporary attributes specify the repositories and other
# preferences Installation Manager uses and whether those settings
# should persist after the uninstall finishes.
#

```

```

# Valid values for clean:
#   true = only use the repositories and other preferences that are
#         specified in the response file.
#   false = use the repositories and other preferences that are
#         specified in the response file and Installation Manager.
#
# Valid values for temporary:
#   true = repositories and other preferences specified in the
#         response file do not persist in Installation Manager.
#   false = repositories and other preferences specified in the
#         response file persist in Installation Manager.
#
##### -->
<agent-input clean="true" temporary="true">

<!-- ##### Repositories #####
# Repositories are locations that Installation Manager queries for

<!-- ##### Frequently Asked Questions #####
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
# Installation Manager Information Center can be found at:
# http://publib.boulder.ibm.com/infocenter/install/v1r6/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
# Windows = IBMIM.exe -record c:\temp\responsefiles\WASv85.install.Win32.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
# Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv85.install.RHEL64.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
# Windows = imcl.exe -acceptLicense -showProgress
# input c:\temp\responsefile\WASv85.install.Win32.xml
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input /home/user/responsefile/WASv85.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
# license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help: IBMIM -help
#
# Question 3. How do I store and pass credentials to repositories that
# require authentication?
# Answer 3. There are two methods for storing authentication credentials
# for Installation Manager depending on the version being used,
# either key ring files or storage files.
#
# Versions of Installation Manger before 1.6.2 use a key ring file to store
# encrypted credentials for authenticating with repositories. Follow this
# two-step process for creating and using a key ring file with Installation Manager.
#
# First, create a key ring file with your credentials by starting
# Installation Manager from the command line under eclipse subdirectory
# with the keyring parameter.
# Use the optional password parameter to password protect your file.
#
# Windows = IBMIM.exe -keyring <path and file name> -password <password>
# Linux, UNIX, IBM i and z/OS = ./IBMIM -keyring <path and file name>
# -password <password>
```

```

#
# Installation Manager will start in graphical mode. Verify that the
# repositories to which you need to authenticate are included in the
# preferences, File / Preferences / Repositories. If they are not
# listed, then click Add Repositories to add the URL or UNC path.
# Installation Manager will prompt for your credentials. If the repository
# is already in the list, then any attempt to access the repository location,
# such as clicking the Test Connections button, will also prompt for your
# credentials. Enter the correct credential and check the Save password
# checkbox. The credentials are saved to the key ring file you specified.
#
# Second, when you start a silent installation, run imcl under eclipse/tools
# subdirectory, and provide Installation Manager with the location of the key
# ring file and the password if the file is protected. For example:
#
# Windows = imcl.exe -acceptLicense -showProgress
#   input <path and file name of response file>
#   -keyring <path and name of key ring file> -password <password>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#   input <path and file name of response file>
#   -keyring <path and name of key ring file> -password <password>
#
# Versions of Installation Manager at 1.6.2 or higher use storage files
# to store encrypted credentials. Complete the following steps to create
# master password and storage files to use with Installation Manager.
#
# First, if you do not have a master password file already, create a text file
# that contains a master passphrase. An example of a passphrase is:
# "This text is the passphrase for a master password file."
#
# Next, run imutilsc under the eclipse/tools subdirectory with the following
# options to create and store user credentials in a storage file.
# -secureStorageFile <path and file name of storage file>
# -masterPasswordFile <path and file name of master password file>
# -url <repository address> or -passportAdvantage <PPA repository address>
# -userName <user name>
# -userPassword <password for user>
#
# Example of a command to create a storage file by operating system
# Windows = imutilsc saveCredential -url http://myServer -userName myUserName
#   -userPassword myPassword -secureStorageFile C:\IBM\credential.store
#   -masterPasswordFile C:\IBM\master_password_file.txt
# Linux, UNIX, IBM z/OS, and the OS X operating system =
# ./imutilsc saveCredential -url http://myServer -userName myUserName
#   -userPassword myPassword -secureStorageFile /home/IBM/credential.store
#   -masterPasswordFile /home/user/IBM/master_password_file.txt
#
# Usage hints:
# * Do not use both the -url and -passportAdvantage options in the same command.
# * Enclose file paths that include spaces with double quotation marks.
# * If you use the IBM service repositories, you can specify the value:
#   http://www.ibm.com/software/repositorymanager/entitled/repository.xml
#   for the -url option which is a generic service repository for IBM packages.
# * Repeat steps to store credentials for multiple users in one file.
# * Repeat steps to store credentials for multiple repositories in one file.
#
# Afterwards, when you start a silent installation, run imcl under the eclipse/tools
# subdirectory, and provide Installation Manager with the location of the storage
# file. For example:
#
# Windows = imcl.exe -acceptLicense -showProgress
#   input <path and file name of response file>
#   -secureStorageFile <path and name of storage file>
#   -masterPasswordFile <path and name of master password file>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#   input <path and file name of response file>
#   -secureStorageFile <path and name of storage file>
#   -masterPasswordFile <path and name of master password file>
#

  <!-- <repository location='/home/user/repositories/websphere/' /> -->

  <!-- ##### Local Repositories #####
  # Uncomment and update the following line when using a local
  # repository located on your own machine to install a
  # IBMJAVA for WebSphere Application Server Liberty offering.
  ##### -->
  <!-- <repository location='insert the full directory path inside single quotes' /> -->

</server>

<!-- ##### Install Packages #####
#
# Install Command
#
# Use the install command to inform Installation Manager of the
# installation packages to install.
#
# The modify attribute is optional and can be paired with an install
# command to add features or paired with an uninstall command to
# remove commands. If omitted, the default value is set to false.
# false = indicates not to modify an existing install by adding
#         or removing features.
# true = indicates to modify an existing install by adding or
#        removing features.
#
# The offering ID attribute is required because it specifies the
# offering to be installed. The offering listed must be present in
# at least one of the repositories listed earlier. The example
# command below contains the offering ID for the IBM WebSphere SDK Java
# Technology Edition (Optional) .
#
# The version attribute is optional. If a version number is provided,
# then the offering will be installed at the version level specified
# as long as it is available in the repositories. If the version
# attribute is not provided, then the default behavior is to install
# the latest version available in the repositories. The version number
# can be found in the repository.xml file in the repositories.
# For example, <offering ... version='7.0.4000.20130328_1111'>.
#
# The profile attribute is required and typically is unique to the
# offering. If modifying or updating an existing installation, the
# profile attribute must match the profile ID of the targeted installation
# of IBMJAVA for WebSphere Application Server Liberty.

```

```

#
# IBM WebSphere SDK Java Technology Edition (Optional) 7.0.4.0 is an
# extension offering which requires a base WebSphere Application
# Server / Client product to be installed first The profile id for
# IBM WebSphere SDK Java Technology Edition (Optional) 7.0.4.0 must be
# the same as the base product.
#
# The features attribute is optional. Offerings always have at least
# one feature; a required core feature which is installed regardless
# of whether it is explicitly specified. If other feature names
# are provided, then only those features will be installed.
# Features must be comma delimited without spaces.
#
# The installFixes attribute indicates whether fixes available in
# repositories are installed with the product. By default, all
# available fixes will be installed with the offering.
#
# Valid values for installFixes:
#   none = do not install available fixes with the offering.
#   recommended = installs all available recommended fixes with the offering.
#   all = installs all available fixes with the offering.
#
# Interim fixes for offerings also can be installed while they
# are being installed by including the offering ID for the interim
# fix and specifying the profile ID. A commented out example is
# provided in the install command below.
#
# Installation Manager supports installing multiple offerings at once.
# Additional offerings can be included in the install command,
# with each offering requiring its own offering ID, version, profile value,
# and feature values.
#
# Profile Command
#
# A separate profile command must be included for each offering listed
# in the install command. The profile command informs Installation
# Manager about offering specific properties or configuration values.
#
# The installLocation specifies where the offering will be installed.
# If the response file is used to modify or update an existing
# installation, then ensure the installLocation points to the
# location where the offering was installed previously.
#
# Include data keys for product specific profile properties.
# For instance, Installing IBMJAVA for Liberty Offerings on
# a 64-bit system will require to include one of the options for an IBM Software
# Development Kit, this can be specified by data key cic.selector.arch, its value
# can be either x86 (for 32-bit), or x86_64 (for 64-bit).
#
# More details for cic.selector.arch can be found in the link below:
#
# https://infocenters.hursley.ibm.com/was/vNext/draft/help/index.jsp?topic=%2Fcom.ibm.websphere.wlp.core.doc%2Fae%2Ftwlp_ins_installation_dist_silent.html

<!-- ##### Shared Data Location #####
# Uncomment the preference for eclipseCache to set the shared data
# location the first time you use Installation Manager to do an
# installation.
#
# Eclipse cache location can be obtained from the installed.xml file found in
# Linux/Unix: /var/ibm/InstallationManager
# Windows: C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager
# from the following property:
# <property name='cacheLocation' value='C:\Program Files\IBM\IMShared' />
#
# Open the installed.xml file in a text editor because the style sheet
# might hide this value if opened in a web browser.
# For further information on how to edit preferences, refer to the public library at:
# http://publib.boulder.ibm.com/infocenter/install/v1r5/index.jsp?topic=/com.ibm.silentinstall12.doc/topics/r_silent_prefs.html
#
# After the shared data location is set, it cannot be changed
# using a response file or the graphical wizard.
#
# Ensure that the shared data location is a location that can be written
# to by all user accounts that are expected to use Installation Manager.
#
# By default, Installation Manager saves downloaded artifacts to
# the shared data location. This serves two purposes.
#
# First, if the same product is installed a more than once to the machine,
# then the files in the shared data location will be used rather than

```

```

# downloading them again.
#
# Second, during the rollback process, the saved artifacts are used.
# Otherwise, if the artifacts are not saved or are removed, then
# Installation Manager must have to access the repositories used to
# install the previous versions.
#
# Valid values for preserveDownloadedArtifacts:
#   true = store downloaded artifacts in the shared data location
#   false = remove downloaded artifacts from the shared data location
#
##### -->

<!-- ##### Frequently Asked Questions #####
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
# Installation Manager Information Center can be found at:
# http://publib.boulder.ibm.com/infocenter/install/v1r6/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do

```

```

# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
# Windows = IBMIM.exe -record c:\temp\responsefiles\WASv85.install.Win32.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
# Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv85.install.RHEL64.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
# Windows = imcl.exe -acceptLicense -showProgress
# input c:\temp\responsefile\WASv85.install.Win32.xml
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input /home/user/responsefile/WASv85.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
# license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help: IBMIM -help
#

#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
# Windows = IBMIM.exe -record c:\temp\responsefiles\WASv85.install.Win32.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry

```

```

# Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv85.install.RHEL64.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
# Windows = imcl.exe -acceptLicense -showProgress
# input c:\temp\responsefile\WASv85.install.Win32.xml
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input /home/user/responsefile/WASv85.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
# license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help: IBMIM -help
#
# Question 3. How do I store and pass credentials to repositories that
# require authentication?
# Answer 3. There are two methods for storing authentication credentials
# for Installation Manager depending on the version being used,
# either key ring files or storage files.
#
# Versions of Installation Manager before 1.6.2 use a key ring file to store
# encrypted credentials for authenticating with repositories. Follow this
# two-step process for creating and using a key ring file with Installation Manager.
#
# First, create a key ring file with your credentials by starting
# Installation Manager from the command line under eclipse subdirectory
# with the keyring parameter.
# Use the optional password parameter to password protect your file.
#
# Windows = IBMIM.exe -keyring <path and file name> -password <password>
# Linux, UNIX, IBM i and z/OS = ./IBMIM -keyring <path and file name>
# -password <password>
#
# Installation Manager will start in graphical mode. Verify that the
# repositories to which you need to authenticate are included in the
# preferences, File / Preferences / Repositories. If they are not
# listed, then click Add Repositories to add the URL or UNC path.
# Installation Manager will prompt for your credentials. If the repository
# is already in the list, then any attempt to access the repository location,
# such as clicking the Test Connections button, will also prompt for your
# credentials. Enter the correct credential and check the Save password
# checkbox. The credentials are saved to the key ring file you specified.
#
# Second, when you start a silent installation, run imcl under eclipse/tools
# subdirectory, and provide Installation Manager with the location of the key
# ring file and the password if the file is protected. For example:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <path and file name of response file>
# -keyring <path and name of key ring file> -password <password>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <path and file name of response file>
# -keyring <path and name of key ring file> -password <password>
#
# Versions of Installation Manager at 1.6.2 or higher use storage files
# to store encrypted credentials. Complete the following steps to create
# master password and storage files to use with Installation Manager.
#
# First, if you do not have a master password file already, create a text file
# that contains a master passphrase. An example of a passphrase is:
# "This text is the passphrase for a master password file."
#
# Next, run imutilsc under the eclipse/tools subdirectory with the following
# options to create and store user credentials in a storage file.
# -secureStorageFile <path and file name of storage file>
# -masterPasswordFile <path and file name of master password file>
# -url <repository address> or -passportAdvantage <PPA repository address>
# -userName <user name>
# -userPassword <password for user>
#
# Example of a command to create a storage file by operating system
# Windows = imutilsc saveCredential -url http://myServer -userName myUserName
# -userPassword myPassword -secureStorageFile C:\IBM\credential.store
# -masterPasswordFile C:\IBM\master_password_file.txt
# Linux, UNIX, IBM z/OS, and the OS X operating system =
# ./imutilsc saveCredential -url http://myServer -userName myUserName
# -userPassword myPassword -secureStorageFile /home/IBM/credential.store
# -masterPasswordFile /home/user/IBM/master_password_file.txt
#
# Usage hints:

```

```

# * Do not use both the -url and -passportAdvantage options in the same command.
# * Enclose file paths that include spaces with double quotation marks.
# * If you use the IBM service repositories, you can specify the value:
#   http://www.ibm.com/software/repositorymanager/entitled/repository.xml
#   for the -url option which is a generic service repository for IBM packages.
# * Repeat steps to store credentials for multiple users in one file.
# * Repeat steps to store credentials for multiple repositories in one file.
#
# Afterwards, when you start a silent installation, run imcl under the eclipse/tools
# subdirectory, and provide Installation Manager with the location of the storage
# file. For example:
#
# Windows = imcl.exe -acceptLicense -showProgress
#   input <path and file name of response file>
#   -secureStorageFile <path and name of storage file>
#   -masterPasswordFile <path and name of master password file>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#   input <path and file name of response file>
#   -secureStorageFile <path and name of storage file>
#   -masterPasswordFile <path and name of master password file>
#
##### -->

<!-- ##### Agent Input #####
#
# Note that the acceptLicense attribute has been deprecated.
# Use the -acceptLicense command line option to accept license agreements.
#
# The clean and temporary attributes specify the repositories and other
# preferences Installation Manager uses and whether those settings
# should persist after the installation finishes.
#
# Valid values for clean:
#   true = only use the repositories and other preferences that are
#         specified in the response file.
#   false = use the repositories and other preferences that are
#          specified in the response file and Installation Manager.
#
# Valid values for temporary:
#   true = repositories and other preferences specified in the
#         response file do not persist in Installation Manager.
#   false = repositories and other preferences specified in the
#         response file persist in Installation Manager.
#

<agent-input clean="true" temporary="true">

<!-- ##### Repositories #####
# Repositories are locations that Installation Manager queries for
# installable packages. Repositories can be local (on the machine
# with Installation Manager) or remote (on a corporate intranet or
# hosted elsewhere on the internet).
#
# If the machine using this response file has access to the internet,
# then include the IBM WebSphere Live Update Repositories in the list
# of repository locations.
#
# If the machine using this response file cannot access the internet,
# then comment out the IBM WebSphere Live Update Repositories and
# specify the URL or UNC path to custom intranet repositories and
# directory paths to local repositories to use.
#
##### -->

<server>
  <!-- ##### IBM WebSphere Live Update Repositories #####
  # These repositories contain WebSphere Application Server Liberty offerings,
  # and updates for those offerings
  #
  # To use the secure repository (https), you must have an IBM ID,
  # which can be obtained by registering at: http://www.ibm.com/account
  # or your Passport Advantage account.
  #
  # And, you must use a key ring file with your response file.
  ##### -->
  <repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85"/>
  <!-- <repository location="https://www.ibm.com/software/rational/repositorymanager/repositories/websphere" /> -->

  <!-- ##### Custom Repositories #####
  # Uncomment and update the repository location key below
  # to specify URLs or UNC paths to any intranet repositories
  # and directory paths to local repositories to use.
  ##### -->
  <!-- <repository location='https:\\w3.mycompany.com\repositories\' /> -->
  <!-- <repository location='/home/user/repositories/websphere/' /> -->

  <!-- ##### Local Repositories #####
  # Uncomment and update the following line when using a local
  # repository located on your own machine to install a

```

```

# WebSphere Application Server Liberty offering.
##### -->
<!-- <repository location='insert the full directory path inside single quotes' /> -->
</server>

<!-- ##### Install Packages #####
#
# Install Command
#
# Use the install command to inform Installation Manager of the
# installation packages to install.
#
# The modify attribute is optional and can be paired with an install
# command to add features or paired with an uninstall command to
# remove commands. If omitted, the default value is set to false.
# false = indicates not to modify an existing install by adding
# or removing features.
# true = indicates to modify an existing install by adding or
# removing features.
#
# The offering ID attribute is required because it specifies the
# offering to be installed. The offering listed must be present in
# at least one of the repositories listed earlier. The example
# command below contains the offering ID for the Network Deployment
# edition of WebSphere Application Server Liberty.
#
# The version attribute is optional. If a version number is provided,
# then the offering will be installed at the version level specified
# as long as it is available in the repositories. If the version
# attribute is not provided, then the default behavior is to install
# the latest version available in the repositories. The version number
# can be found in the repository.xml file in the repositories.
# For example, <offering ... version='8.5.5000.20130326_0211'>.
#
# The profile attribute is required and typically is unique to the
# offering. If modifying or updating an existing installation, the
# profile attribute must match the profile ID of the targeted installation
# of WebSphere Application Server Liberty.
#
# The features attribute is optional. Offerings always have at least
# one feature; a required core feature which is installed regardless
# of whether it is explicitly specified. If other feature names
# are provided, then only those features will be installed.
# Features must be comma delimited without spaces.
#
# The feature values for WebSphere Application Server Liberty include:
# liberty,embeddablecontainer,extprogmodels
#
# The features embeddablecontainer,extprogmodels
# are subfeatures of liberty.
#
# You can use these functions to add or remove feature embeddablecontainer or extprogmodels later.
#
# The installFixes attribute indicates whether fixes available in
# repositories are installed with the product. By default, all
# available fixes will be installed with the offering.
#
# Valid values for installFixes:
# none = do not install available fixes with the offering.
# recommended = installs all available recommended fixes with the offering.
# all = installs all available fixes with the offering.
#
# Interim fixes for offerings also can be installed while they
# are being installed by including the offering ID for the interim
# fix and specifying the profile ID.
#
# Installation Manager supports installing multiple offerings at once.
# Additional offerings can be included in the install command,
# with each offering requiring its own offering ID, version, profile value,
# and feature values.
#
# Profile Command
#
# A separate profile command must be included for each offering listed
# in the install command. The profile command informs Installation
# Manager about offering specific properties or configuration values.
#
# The installLocation specifies where the offering will be installed.
# If the response file is used to modify or update an existing
# installation, then ensure the installLocation points to the
# location where the offering was installed previously.
#
# The eclipseLocation data key should use the same directory path to
# WebSphere Application Server Liberty as the installationLocation attribute.
#
# Include data keys for product specific profile properties.
# For instance, installing a WebSphere Application Server Liberty offering
# on a 64-bit system requires including the data key cic.selector.arch
# with either the value x86 (for 32-bit) or x86_64 (for 64-bit) for
# the IBM WebSphere Software Development Kit Java Technology Edition.

```

```

#
# More details for cic.selector.arch can be found in the link below:
# http://www14.software.ibm.com/webapp/wsbroker/redirect?version=phil&product=was-nd-mp&topic=twlp_ins_installation_dist_silent
#
# Two optional data keys were introduced for WebSphere Application Server Liberty
# offerings in version 8.5.5.2 that enable installing additional product assets
# during an installation or update.
#
# <data key='user.feature' value='FeatureA,FeatureB' />
# <data key='user.accept.license' value='true' />
#
# Use the user.feature data key to specify the names of one or more assets to install.
# Separate multiple assets names with a comma.
#
# For Liberty version 8.5.5.2, the available assets are:
# com.ibm.websphere.appserver.adminCenter-1.0 - The adminCenter-1.0 feature is a web-based
# graphical interface for managing Liberty servers and applications and other
# resources from a web browser on a cell phone, tablet, or computer.
#
# com.ibm.websphere.appserver.jca-1.6 - This feature enables the configuration of resource
# adapters to access Enterprise Information Systems (EIS) from applications. The
# configuration of a resource adapter also includes the configuration of connection
# factories, administered objects and activation specifications. Any resource adapter
# that complies with the JCA 1.0 specification can be used. High performance connection
# pooling is also provided.
#
# com.ibm.websphere.appserver.jcaInboundSecurity-1.0 - This feature enables security inflow for resource adapters.
#
# com.ibm.websphere.appserver.jms-1.1 - This feature enables the configuration of resource
# adapters to access messaging systems using the Java Message Service API. This also
# includes the configuration JMS connection factories, queues, topics and activation
# specifications. Any JMS resource adapter that complies with the JCA 1.6 specification
# can be used.
#
# com.ibm.websphere.appserver.mdb-3.1 - This feature enables the use of Message-Driven Enterprise
# JavaBeans. MDBs allow asynchronous processing of messages within a Java EE component.
#
# A current list of the assets available for installation is maintained in the following article.
# http://www14.software.ibm.com/webapp/wsbroker/redirect?version=phil&product=was-nd-mp&topic=twlp_ins_installation_dist_silent
#
# The user.accept.license data key is required and its value must be true,
# to indicate acceptance of the licenses for the assets or acknowledge they
# are governed by the terms of the license agreement of the product offering,
# if any additional assets are being installed.
##### -->

<install modify="false">
<offering id="com.ibm.websphere.liberty.ND.v85" profile="WebSphere Liberty V8.5" features="liberty,embeddablecontainer,extprogmodels" installFixes="none" />
</install>
<profile id="WebSphere Liberty V8.5" installLocation="C:\Program Files\IBM\WebSphere\Liberty">

</profile>

<!-- ##### Shared Data Location #####
# Uncomment the preference for eclipseCache to set the shared data
# location the first time you use Installation Manager to do an
# installation.
#
# Eclipse cache location can be obtained from the installed.xml file found in
# Linux/Unix: /var/ibm/InstallationManager
# Windows: C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager
# from the following property:
# <property name='cacheLocation' value='C:\Program Files\IBM\IMShared' />
#
# Open the installed.xml file in a text editor because the style sheet
# might hide this value if opened in a web browser.
# For further information on how to edit preferences, refer to the public library at:
# http://publib.boulder.ibm.com/infocenter/install/v1r5/index.jsp?topic=/com.ibm.silentinstall112.doc/topics/r_silent_prefs.html
#
# After the shared data location is set, it cannot be changed
# using a response file or the graphical wizard.
#
# Ensure that the shared data location is a location that can be written
# to by all user accounts that are expected to use Installation Manager.
#
# By default, Installation Manager saves downloaded artifacts to
# the shared data location. This serves two purposes.
#
# First, if the same product is installed a more than once to the machine,
# then the files in the shared data location will be used rather than
# downloading them again.
#
# Second, during the rollback process, the saved artifacts are used.
# Otherwise, if the artifacts are not saved or are removed, then
# Installation Manager must have to access the repositories used to
# install the previous versions.
#
# Valid values for preserveDownloadedArtifacts:
# true = store downloaded artifacts in the shared data location

```

```

# false = remove downloaded artifacts from the shared data location
#
##### -->

<!--
<preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='C:\Program Files\IBM\IMShared' />

<!-- ##### Frequently Asked Questions #####
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
# Installation Manager Information Center can be found at:
# http://publib.boulder.ibm.com/infocenter/install/v1r6/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
# Windows = IBMIM.exe -record c:\temp\responsefiles\WASv85.install.Win32.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
# Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv85.install.RHEL64.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?

```

```

# Answer 2. Create a silent installation response file and run the following command
# from the eclipse/tools subdirectory in the directory where you installed
# Installation Manager:
#
#   Windows = imcl.exe -acceptLicense -showProgress
#   input <response_file_path_and_name> -log <log_file_path_and_name>
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#   input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
#   Windows = imcl.exe -acceptLicense -showProgress
#   input c:\temp\responsefile\WASv85.install.Win32.xml
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#   input /home/user/responsefile/WASv85.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
# license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help: IBMIM -help
#
# Question 3. How do I store and pass credentials to repositories that
# require authentication?
# Answer 3. There are two methods for storing authentication credentials
# for Installation Manager depending on the version being used,
# either key ring files or storage files.
#
# Versions of Installation Manger before 1.6.2 use a key ring file to store
# encrypted credentials for authenticating with repositories. Follow this
# two-step process for creating and using a key ring file with Installation Manager.
#
# First, create a key ring file with your credentials by starting
# Installation Manager from the command line under eclipse subdirectory
# with the keyring parameter.
# Use the optional password parameter to password protect your file.
#
#   Windows = IBMIM.exe -keyring <path and file name> -password <password>
#   Linux, UNIX, IBM i and z/OS = ./IBMIM -keyring <path and file name>
#   -password <password>
#
# Installation Manager will start in graphical mode. Verify that the
# repositories to which you need to authenticate are included in the
# preferences, File / Preferences / Repositories. If they are not
# listed, then click Add Repositories to add the URL or UNC path.
# Installation Manager will prompt for your credentials. If the repository
# is already in the list, then any attempt to access the repository location,
# such as clicking the Test Connections button, will also prompt for your
# credentials. Enter the correct credential and check the Save password
# checkbox. The credentials are saved to the key ring file you specified.
#
# Second, when you start a silent installation, run imcl under eclipse/tools
# subdirectory, and provide Installation Manager with the location of the key
# ring file and the password if the file is protected. For example:
#
#   Windows = imcl.exe -acceptLicense -showProgress
#   input <path and file name of response file>
#   -keyring <path and name of key ring file> -password <password>
#   Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
#   input <path and file name of response file>
#   -keyring <path and name of key ring file> -password <password>
#
# Versions of Installation Manager at 1.6.2 or higher use storage files
# to store encrypted credentials. Complete the following steps to create
# master password and storage files to use with Installation Manager.
#
# First, if you do not have a master password file already, create a text file
# that contains a master passphrase. An example of a passphrase is:
# "This text is the passphrase for a master password file."
#
# Next, run imutilsc under the eclipse/tools subdirectory with the following
# options to create and store user credentials in a storage file.
# -secureStorageFile <path and file name of storage file>
# -masterPasswordFile <path and file name of master password file>
# -url <repository address> or -passportAdvantage <PPA repository address>
# -userName <user name>
# -userPassword <password for user>
#
# Example of a command to create a storage file by operating system
# Windows = imutilsc saveCredential -url http://myServer -userName myUserName
# -userPassword myPassword -secureStorageFile C:\IBM\credential.store
# -masterPasswordFile C:\IBM\master_password_file.txt
# Linux, UNIX, IBM z/OS, and the OS X operating system =
# ./imutilsc saveCredential -url http://myServer -userName myUserName
# -userPassword myPassword -secureStorageFile /home/IBM/credential.store
# -masterPasswordFile /home/user/IBM/master_password_file.txt
#
# Usage hints:
# * Do not use both the -url and -passportAdvantage options in the same command.
# * Enclose file paths that include spaces with double quotation marks.
# * If you use the IBM service repositories, you can specify the value:
#   http://www.ibm.com/software/repositorymanager/entitled/repository.xml

```

```

# for the -url option which is a generic service repository for IBM packages.
# * Repeat steps to store credentials for multiple users in one file.
# * Repeat steps to store credentials for multiple repositories in one file.
#
# Afterwards, when you start a silent installation, run imcl under the eclipse/tools
# subdirectory, and provide Installation Manager with the location of the storage
# file. For example:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <path and file name of response file>
# -secureStorageFile <path and name of storage file>
# -masterPasswordFile <path and name of master password file>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <path and file name of response file>
# -secureStorageFile <path and name of storage file>
# -masterPasswordFile <path and name of master password file>

  # Uncomment and update the repository location key below
  # to specify URLs or UNC paths to any intranet repositories
  # and directory paths to local repositories to use.
  ##### -->
  <!-- <repository location='https://w3.mycompany.com/repositories/' /> -->
  <!-- <repository location='/home/user/repositories/websphere/' /> -->

  <!-- ##### Local Repositories #####
  # Uncomment and update the following line when using a local
  # repository located on your own machine to install a
  # WebSphere Application Server Liberty offering.
  ##### -->
  <!-- <repository location='insert the full directory path inside single quotes' /> -->
</server>

<!-- ##### Modify Packages #####
#

```

```

# Install and Uninstall Commands
#
# Use the install and uninstall commands to inform Installation Manager
# of the installation packages to install or uninstall.
#
# The modify attribute is optional and can be paired with an install
# command to add features or paired with an uninstall command to
# remove commands. If omitted, the default value is set to false.
#   false = indicates not to modify an existing install by adding
#           or removing features.
#   true  = indicates to modify an existing install by adding or
#           removing features.
#
# The offering ID attribute is required because it specifies the
# offering to be installed. The offering listed must be present in
# at least one of the repositories listed earlier. The example
# command below contains the offering ID for the Network Deployment
# edition of WebSphere Application Server Liberty.
#
# The version attribute is optional. If a version number is provided,
# then the offering will be installed or uninstalled at the version level
# specified as long as it is available in the repositories. If the version
# attribute is not provided, then the default behavior is to install or
# uninstall the latest version available in the repositories. The version
# number can be found in the repository.xml file in the repositories.
# For example, <offering ... version='8.5.5000.20130328_1111'>.
#
# The profile attribute is required and typically is unique to the
# offering. If modifying or updating an existing installation, the
# profile attribute must match the profile ID of the targeted installation
# of WebSphere Application Server Liberty.
#
# The features attribute is optional. Offerings always have at least
# one feature; a required core feature which is installed regardless
# of whether it is explicitly specified. If other feature names
# are provided, then only those features will be installed.
# Features must be comma delimited without spaces.
#
# The feature values for WebSphere Application Server Liberty include:
# liberty,embeddablecontainer,extprogmodels
#
# The features embeddablecontainer,extprogmodels
# are subfeatures of liberty.
#
# You can use these functions to add or remove feature embeddablecontainer
# or extprogmodels later.
#
# In the example that follows, the feature embeddablecontainer and extprogmodels
# are being added and no feature are being removed from the specified offering.
#
# The installFixes attribute indicates whether fixes available in
# repositories are installed with the product. By default, all
# available fixes will be installed with the offering.
#
# Valid values for installFixes:
#   none = do not install available fixes with the offering.
#   recommended = installs all available recommended fixes with the offering.
#   all = installs all available fixes with the offering.
#
# Installation Manager supports modifying multiple offerings at once.
# Additional offerings can be included in the install and uninstall commands,
# with each offering requiring its own offering ID, version, profile value,
# and feature values.
#
# Profile Command
#
# A separate profile command must be included for each offering listed
# in the install command. The profile command informs Installation
# Manager about offering specific properties or configuration values.
#
# The installLocation specifies where the offering will be installed.
# If the response file is used to modify or update an existing
# installation, then ensure the installLocation points to the
# location where the offering was installed previously.
#
# The eclipseLocation data key should use the same directory path to
# WebSphere Application Server Liberty as the installationLocation attribute.
#
# Include data keys for product specific profile properties.
# For instance, Installing WebSphere Application Server Liberty Offerings on
# a 64-bit system will require to include one of the options for an IBM Software
# Development Kit, this can be specified by data key cic.selector.arch, its value
# can be either x86 (for 32-bit), or x86_64 (for 64-bit).
#
# More details for cic.selector.arch can be found in the link below:
#
# https://infocenters.hursley.ibm.com/was/vNext/draft/help/index.jsp?topic=%2Fcom.ibm.websphere.wlp.core.doc%2Fae%2Ftwlp_ins_installation_dist_silent.html
#

</profile>

<!-- ##### Shared Data Location #####
# Uncomment the preference for eclipseCache to set the shared data
# location the first time you use Installation Manager to do an
# installation.
#
# Eclipse cache location can be obtained from the installed.xml file found in
# Linux/Unix: /var/ibm/InstallationManager
# Windows: C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager
# from the following property:
# <property name='cacheLocation' value='C:\Program Files\IBM\IMShared' />
#
# Open the installed.xml file in a text editor because the style sheet
# might hide this value if opened in a web browser.
# For further information on how to edit preferences, refer to the public library at:
# http://publib.boulder.ibm.com/infocenter/install/v1r5/index.jsp?topic=/com.ibm.silentinstall12.doc/topics/r_silent_prefs.html
#
# After the shared data location is set, it cannot be changed
# using a response file or the graphical wizard.
#
# Ensure that the shared data location is a location that can be written
# to by all user accounts that are expected to use Installation Manager.
#
# By default, Installation Manager saves downloaded artifacts to
# the shared data location. This serves two purposes.
#
# First, if the same product is installed a more than once to the machine,
# then the files in the shared data location will be used rather than
# downloading them again.
#
# Second, during the rollback process, the saved artifacts are used.
# Otherwise, if the artifacts are not saved or are removed, then
# Installation Manager must have to access the repositories used to
# install the previous versions.
#
# Valid values for preserveDownloadedArtifacts:
# true = store downloaded artifacts in the shared data location
# false = remove downloaded artifacts from the shared data location
#
##### -->

<!-- ##### Frequently Asked Questions #####
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
# Installation Manager Information Center can be found at:
# http://publib.boulder.ibm.com/infocenter/install/v1r6/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
# Windows = IBMIM.exe -record c:\temp\responsefiles\WASv85.install.Win32.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
# Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv85.install.RHEL64.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
# Windows = imcl.exe -acceptLicense -showProgress
# input c:\temp\responsefile\WASv85.install.Win32.xml
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input /home/user/responsefile/WASv85.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
# license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help: IBMIM -help
#

## Creating custom installation repositories with IBM Packaging Utility

**8.5.5.0**

IBM WebSphere Application Server Liberty uses IBM Installation Manager for installation and lifecycle management. Installation Manager accesses source repositories that contain the content for a software product installation. Repositories are available on product media, in IBM-hosted web-based repositories, and from Passport Advantage. IBM Packaging Utility can help you create and customize enterprise repositories that contain the correct combination of products and maintenance levels needed for all aspects of your business.

### About this task

You use Installation Manager to connect to an Installation Manager repository (or set of repositories) to find products and service updates that are available to you for installation. An Installation Manager repository is simply a tree-structured file folder that includes product payload and metadata. You can install the software products that you need directly from an IBM web-based service repository or download and unpack compressed files from Passport Advantage and install the products from the resulting unpacked file folders. The result of unpacking the files is also considered to be an Installation Manager repository. Like any Installation Manager repository, these unpacked files can be hosted on an internal HTTP server, FTP server, or network mount in order to make them available to the organization.

Packaging Utility is a companion tool for Installation Manager with which you can create and manage custom Installation Manager repositories for your organization. You can copy multiple packages, maintenance levels, and fixes into a single repository. Packaging Utility copies from source repositories to your target custom repositories. Source repositories can include any accessible Installation Manager repository, including IBM web-hosted product repositories and unzipped Passport Advantage downloads.

For more information on Packaging Utility, go to the IBM Packaging Utility Information Center.

### Procedure

Use Packaging Utility to create custom or "enterprise" Installation Manager repositories that contain specific products and maintenance levels that fit the needs of your business.

As an administrator, you can control the content of your enterprise repository, which then can serve as the central repository to which your organization connects in order to perform product installations and updates.

Packaging Utility essentially copies from a set of source Installation Manager repositories to a target repository and eliminates duplicate artifacts, helping to keep the repository size as small as possible. You can also delete (or "prune") a repository, removing maintenance levels or products that are not needed. You can download the latest version of Packaging Utility from the IBM Support Portal.

Like Installation Manager, Packaging Utility has GUI and command-line interfaces. You must specify repository URLs for Installation Manager repositories that contain the offerings that you wish to copy. Installation Manager repository URLs follow this pattern:

`http://www.ibm.com/software/repositorymanager/offering_name`

**Note:** This location does not contain a web page that you can access using a web browser. For example, WebSphere Application Server Liberty product repositories are located at the following URLs:

- WebSphere Application Server Liberty Network Deployment Version 8.5  
`http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85`
- WebSphere Application Server Liberty Network Deployment Trial Version 8.5  
`http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.NDTRIAL.v85`

See Online product repositories for WebSphere Application Server offerings for additional product repositories.

The target repository that you create with Packaging Utility will always support a full installation; therefore, you cannot use Packaging Utility to create a repository that is only a copy of a fix pack. You can, however, create a repository that contains the minimum content to support direct installation to a fix-pack level. Consider the following two examples that use the Packaging Utility command-line interface (**PUCL.exe**) that is available in the Packaging Utility installation folder.

- **Example 1**

**Note:** Note that you must read the license agreement that you can find with the product files and then signify your acceptance of the license agreement by specifying **-acceptLicense** in the command as shown in the following example.

```
PUCL copy com.ibm.websphere.liberty.ND.v85
-repositories
  http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85
-target D:\LIB_ND_version
-prompt
-showProgress
-acceptLicense
```

Since no version number is specified with the offering name, this command will create a new repository that supports direct installation to the latest fix-pack level for WebSphere Application Server Liberty Version 8.5. This new repository does not support the installation of Version 8.5.5.0, but it does support the update from an existing Version 8.5.5.0 installation to the latest version.

- **Example 2**

```
PUCL copy com.ibm.websphere.liberty.ND.v85_8.5.5.0.20110503_0200
-repositories
  http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85
-target D:\LIB_ND
-prompt
-showProgress
-acceptLicense
```

```
PUCL copy com.ibm.websphere.liberty.ND.v85_8.5.5.1.20110829_1838
-repositories
  http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85
-target D:\LIB_ND
-prompt
-showProgress
-acceptLicense
```

The first command creates a target repository with WebSphere Application Server Liberty Version 8.5.5.0. The second command adds the Version 8.5.5.1 fix pack to the same repository. You can now use this resulting repository to install Version 8.5.5.0, install Version 8.5.5.1, or update from Version 8.5.5.0 to Version 8.5.5.1.

**Tip:** With some offerings, such as WebSphere SDK Java Technology Edition Version 7.0 for Liberty, you can use Packaging Utility with the **-platform** option (sometimes called "platform slicing") to create a repository that is scoped to the platforms and architectures that are used by your organization. This feature is available in command-line mode by specifying the **-platform** option with the `os` and `arch` arguments as shown in the following example:

```
PUCL copy com.ibm.websphere.liberty.IBMJAVA.v70
-repositories http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v70
-platform os=linux,arch=ppc64
-target D:\LIB_ND
-prompt
-showProgress
-acceptLicense</p>
```

Your repository can be scoped for platforms other than the one on which it is created or stored. For example, you can run Packaging Utility on a Windows system to create a repository with the content needed to install on a Linux system. During installation on Linux, you point Installation Manager to your custom repository.

The following table lists valid combinations for creating a local WebSphere SDK Java Technology Edition Version 7.0 for Liberty offering repository that is sliced by operating system and architecture.

*Table 91. Valid combinations for creating a local WebSphere SDK Java Technology Edition Version 7.0 for Liberty offering repository using the Packaging Utility*

Platform	Options	Resulting Repository
Windows	os=win32,arch=x86	32-bit repository for 32-bit Windows OS and 64-bit Windows
	os=win32.arch=x86_64	64-bit repository for 64-bit Windows
Linux Intel	os=linux,arch=x86	32-bit repository for 32-bit Linux Intel and 64-bit Linux Intel
	os=linux.arch=x86_64	64-bit repository for 64-bit Linux Intel
Linux Power®	os=linux,arch=ppc	32-bit repository for 32-bit Linux Power and 64-bit Linux Power
	os=linux.arch=ppc64	64-bit repository for 64-bit Linux Power
zLinux	os=linux,arch=s390	32-bit repository for 32-bit zLinux and 64-bit zLinux
	os=linux.arch=s390x	64-bit repository for 64-bit zLinux
AIX®	os=aix,arch=ppc	32-bit repository for 32-bit AIX and 64-bit AIX
	os=aix.arch=ppc64	64-bit repository for 64-bit AIX
Solaris Sparc	os=solaris,arch=sparc	32-bit repository for 32-bit Solaris Sparc and 64-bit Solaris Sparc
	os=solaris,arch=sparc64	64-bit repository for 64-bit Solaris Sparc
Solaris Intel	os=solaris,arch=x86_64	64-bit repository for 64-bit Solaris Intel
HP-UX Itanium	os=hpux,arch=ia64	64-bit repository for 64-bit HP-UX Itanium
z/OS	os=zos,arch=s390x	64-bit repository for z/OS

The following table lists valid combinations for creating a local WebSphere SDK Java Technology Edition Version 6.0 for Liberty offering repository that is sliced by operating system and architecture.

Table 92. Valid combinations for creating a local WebSphere SDK Java Technology Edition Version 6.0 for Liberty offering repository using the Packaging Utility

Platform	Options	Resulting Repository
Windows	os=win32,arch=x86	32-bit repository for 32-bit Windows OS and 64-bit Windows
	os=win32.arch=x86_64	64-bit repository for 64-bit Windows
Linux Intel	os=linux,arch=x86	32-bit repository for 32-bit Linux Intel and 64-bit Linux Intel
	os=linux.arch=x86_64	64-bit repository for 64-bit Linux Intel
Linux Power	os=linux,arch=ppc	32-bit repository for 32-bit Linux Power and 64-bit Linux Power
	os=linux.arch=ppc64	64-bit repository for 64-bit Linux Power
zLinux	os=linux,arch=s390	32-bit repository for 32-bit zLinux and 64-bit zLinux
	os=linux.arch=s390x	64-bit repository for 64-bit zLinux
AIX	os=aix,arch=ppc	32-bit repository for 32-bit AIX and 64-bit AIX
	os=aix.arch=ppc64	64-bit repository for 64-bit AIX
Solaris Sparc	os=solaris,arch=sparc	32-bit repository for 32-bit Solaris Sparc and 64-bit Solaris Sparc
	os=solaris,arch=sparc64	64-bit repository for 64-bit Solaris Sparc
Solaris Intel	os=solaris,arch=x86_64	64-bit repository for 64-bit Solaris Intel
HP-UX Itanium	os=hpx,arch=ia64	64-bit repository for 64-bit HP-UX Itanium

For more information on platform slicing, go to the IBM Packaging Utility Information Center.

## Using the launchpad to start Liberty installations

**8.5.5.0**

The launchpad console is the starting point for installing IBM WebSphere Application Server Liberty Network Deployment.

### Before you begin

- The launchpad is a web application. Before using the launchpad, you must have a supported web browser. The launchpad supports the following browsers:
  - **AIX** **HP-UX** **Linux** **Solaris** Mozilla Firefox Version 3.5 or later
  - **Windows** Internet Explorer Version 6.0 Service Pack 2 or later
- Install a supported web browser if one is not installed.
  - **AIX** **HP-UX** **Linux** **Solaris** Install a browser such as Mozilla Firefox. Download Firefox from the following location: <http://www.mozilla.org/products/firefox/>.
  - **Windows** Install a browser for the Windows operating system.
    - Download Internet Explorer from the following location: <http://www.microsoft.com/windows/ie/default.msp>

- Download Mozilla Firefox from the following location: <http://www.mozilla.org/products/firefox/>.

- **AIX** **HP-UX** **Linux** **Solaris** You must install the Bash shell package to use the launchpad application. Although the Bash shell must be installed, the Bash shell does not need to be used to run the **launchpad.sh** command. If you attempt to run the launchpad application from a DVD on the HP-UX, Linux, or Solaris operating systems without the Bash shell installed, the launchpad fails with an error message indicating that the Bash interpreter is not found. If you attempt to run the launchpad from any image on AIX, the launchpad fails with an error message indicating that the current browser is not supported. The Bash package for the AIX operating system is included in the IBM AIX Toolbox.

#### Examples of what the launchpad can do:

- The launchpad does support installing Installation Manager in admin or non-admin (user) mode.
- The launchpad does support updating Installation Manager from an earlier version in admin or non-admin (user) mode.

#### Examples of what the launchpad cannot do:

- The launchpad does not support installing in group mode.
- The launchpad does not support installing or updating with a custom application data location.

**Restriction:** You cannot run the launchpad remotely to install a product. Only local use of the launchpad is supported.

#### About this task

The launchpad identifies components on the product disk or image that you can install (launch).

The launchpad is a single point of reference for installing the application server environment. If you click a link that points to a product repository on another disk or image, you are prompted to insert that disk or browse to that image.

#### Procedure

1. Start the launchpad.

The launchpad program is available in the root directory of the product disk. You can start the launchpad manually using a fully qualified command instead of changing directories to the disk and running the command locally from the root directory:

- **AIX** **HP-UX** **Linux** **Solaris** Mount the disk drive if necessary.
- Open a shell window and issue a fully qualified **launchpad** command to start the launchpad.

**Tip:** **Windows** If you need to navigate using the keyboard, use Mozilla Firefox as your web browser and start the launchpad with the following command:

```
launchpad_all.y.exe
```

**Note:** **Windows** Some Windows operating systems such as Windows 2003, Windows Vista, Windows Server 2008, and Windows 7 have implemented a more restrictive security policy that denies access to trusted files by non-trusted files or applications. When the launchpad application is run as a non-trusted program, you will receive JavaScript "Access is denied" errors that subsequently cause the application to hang. Because downloaded images are automatically blocked, unblock the files so that the launchpad can successfully access the files. Before you extract the image, right-click the image file and select **Properties** to open the Properties panel and locate the security section and click the **Unblock** button. You can now extract the image and run the launchpad application. The launchpad opens in the language of the locale setting of the machine.

2. Use the launchpad to perform the following Liberty related tasks.

- View the Welcome page, and access links to the IBM WebSphere Application Server Information Center and the IBM Education Assistant.
- Launch IBM Installation Manager installation, and access the IBM Installation Manager Information Center.
- Launch IBM Packaging Utility installation, and access the Packaging Utility information in the IBM Installation Manager Information Center.
- Launch Installation Manager to install WebSphere Application Server Liberty Network Deployment, and access the installation instructions in the information center.
- Launch Installation Manager to install IBM HTTP Server, and access the installation instructions in the information center.
- Launch Installation Manager to install Web Server Plug-ins for IBM WebSphere Application Server, and access the installation instructions in the information center.
- Access the latest version of IBM Support Assistant.
- Launch Installation Manager to install IBM WebSphere SDK Java Technology Edition Version 6.0 for Liberty, and access the installation instructions in the information center.
- Launch Installation Manager to install IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty, and access the installation instructions in the information center.
- Launch Installation Manager to install the IBM WebSphere Application Server Web 2.0 and Mobile Toolkit, and access the installation instructions in the information center.
- Launch Installation Manager to install IBM WebSphere Adapters.

## Results

This procedure results in using the launchpad to start the installation and to access information through a browser.

### Troubleshooting

If you can start the launchpad but clicking a link does not resolve to a page in the launchpad, you might have the wrong media in the disk drive. Check the validity of the media.

Use the following procedure to correct any error that is preventing the launchpad from displaying. Then, try to start the launchpad again:

1. If the product disk is no longer accessible, insert the disk.
2. **AIX** **HP-UX** **Linux** **Solaris** Mount the drive as necessary on platforms such as AIX or Linux.
3. Enable the JavaScript function in your browser.
 

Mozilla Firefox: Click **Tools** > **Options** > **Content**:

  - Select **Enable Java**.
  - Select **Enable JavaScript**.
  - Click **Advanced** and allow scripts to ... (Select all boxes.)

**Windows** Internet Explorer: Click **Tools** > **Internet Options** > **Security** > **Custom Level for Internet > Scripting** > **Active scripting** > **Enable**.
4. Restart the launchpad by issuing the **launchpad** command.

If the launchpad links still do not work after following this procedure, launch Installation Manager and point it at the appropriate repositories to install the offerings.

## What to do next

Go to “Installing and uninstalling Liberty on distributed operating systems” on page 1165 to continue installing your application serving environment.

## Installing and uninstalling Liberty on IBM i operating systems

8.5.5.0

IBM Installation Manager is a common installer for many IBM software products. You can use Installation Manager to install and manage the product lifecycle of WebSphere Application Server Liberty Network Deployment.

### Before you begin

**Note:** 8.5.5.11 Support for using Java SE 6 with WebSphere Liberty ends in September 2017. After the end of support, the Liberty kernel will be recompiled and can no longer run with Java SE 6. If you continue to use Java SE 6 on earlier fix packs after the end of support date, you could expose your environment to security risks.

Java SE 8 is the recommended Java SDK because it provides the latest features and security updates.

Installation Manager is a single installation program that can use remote or local software repositories to install, modify, or update WebSphere Application Server Liberty Network Deployment. It determines available packages - including products, fix packs, interim fixes, and so on - checks prerequisites and interdependencies, and installs the selected packages. You also use Installation Manager to uninstall the packages that it installed.

**Restriction:** The Installation Manager GUI is not available on IBM i; all interaction with Installation Manager on IBM i is done through the command line or response files.

**Overview of IBM Installation Manager:** IBM Installation Manager is a general-purpose software installation and update tool that runs on a range of computer systems. Installation Manager can be invoked through a command-line interface. You can also create response files in XML and use them to direct the performance of Installation Manager tasks in silent mode.

For more information on using Installation Manager, read the IBM Installation Manager Information Center.

**Packages and package groups:** Each software product that can be installed with Installation Manager is referred to as a package. An installed package has a product level and an installation location. A package group consists of all of the products that are installed at a single location.

**How many Installation Managers do you need:** You only need to run Installation Manager on those systems on which you install or update product code. You normally need only one Installation Manager on a system because one Installation Manager can keep track of any number of product installations.

**Creating an Installation Manager:** When the installation kit is available on your system, you can create an Installation Manager. An Installation Manager consists of a set of binaries that are copied from the installation kit and a set of runtime data that describe the products that have been installed by this particular Installation Manager. Before creating an Installation Manager, you must decide in which mode the Installation Manager will run as well as where the binaries and runtime data - called agent data or appdata - will reside. Then, you issue the Installation Manager installation command from the appropriate user ID to create the Installation Manager.

**Accessing product repositories:** All software materials that will be installed with IBM Installation Manager are stored in repositories. Each repository contains program objects and metadata for one or more packages - that is, software products at a particular level. Repositories can also contain product maintenance, such as fix packs and interim fixes. Whenever you install a new product, you can choose from any of the available product levels in any accessible repository.

**Installing the product:** After you have created an Installation Manager and have access to all necessary product repositories, you can use Installation Manager command-line commands or response files to perform the actual product installations. When you install a product, you provide the package name, optionally the product level to be installed, the product location, and any other optional properties. For example, some products have optional features that you can select at installation time or a list of optional supported language packs from which you can select.

**Working with installed products:** You can use Installation Manager commands to list installed products and product levels. You can also obtain this information for installed copies of WebSphere Application Server Liberty Network Deployment by issuing the **versionInfo** command from the product file system. You can use Installation Manager commands or response files to install a new product level, roll back to a previous level, or modify the product by adding or removing optional features or language packs.

#### Notes:

- You must have Java SE 6 32 bit (option 11 of the IBM Developer Kit for Java) installed on your IBM i system before installing WebSphere Application Server Liberty Network Deployment. For more information, read IBM i prerequisites.
- Do not transfer the content of a repository in non-binary mode and do not convert any content on extraction.
- When you try to install IBM Installation Manager locally from the WebSphere Application Server Liberty Network Deployment media on an IBM i operating system, the following error message might be displayed:

The Installc executable launcher was unable to locate its companion shared library.

This error occurs because all directory and files names contained by the media are displayed in uppercase. To resolve this issue, enable the handling of mixed case on your IBM i operating system using the following command:

```
CHGOPTA EXTMEDFMT(*YES)
```

- **8.5.5.1** If you are installing WebSphere Application Server Liberty Version 8.5.5.1 in console mode, you might receive warning messages similar to the following example:

```
No "conClass" attribute in "commonPanel" element of panel com.ibm.was.liberty.userdata.panel.UserData in com.ibm.was.liberty.userdata.panel.
```

This problem is caused by an IBM Installation Manager API which is deprecated in Version 1.6.2. These warning messages can be ignored. No action is required.

## About this task

For more information on using Installation Manager, read the IBM Installation Manager Information Center.

Perform one of these procedures to install, update, rollback, or uninstall the offering using Installation Manager.

**Note:** Before using Installation Manager to install a offering, you might want to back up your Installation Manager configuration using the instructions in the IBM Installation Manager Information Center if the possibility of corruption is a concern.

## Procedure

- “Installing Liberty on IBM i operating systems using response files” on page 1299
- “Installing Liberty on IBM i operating systems using the command line”
- “Installing Liberty remotely on IBM i operating systems using the **iRemoteInstall** command” on page 1304
- “Adding and removing features from Liberty on IBM i operating systems using response files” on page 1312
- “Installing Liberty interim fixes on IBM i operating systems using the command line” on page 1315
- “Uninstalling Liberty interim fixes from IBM i operating systems using the command line” on page 1326
- “Installing Liberty fix packs on IBM i operating systems using response files” on page 1323
- “Installing Liberty fix packs on IBM i operating systems using the command line” on page 1318
- “Uninstalling Liberty fix packs from IBM i operating systems by using response files” on page 1329
- “Uninstalling Liberty fix packs from IBM i operating systems using the command line” on page 1327
- “Uninstalling Liberty from IBM i operating systems using response files” on page 1315
- “Uninstalling Liberty from IBM i operating systems using the command line” on page 1314

## Results

- The following locations are the defaults for Installation Manager files on IBM i systems:
  - **Installation location:** /QIBM/ProdData/InstallationManager
  - **Agent data location:** /QIBM/UserData/InstallationManager
  - **Registry:** /QIBM/InstallationManager/.ibm/registry/InstallationManager.dat
- Logs are located in the logs directory of Installation Manager's agent data location. For example:

/QIBM/UserData/InstallationManager/logs

The main log files are time-stamped XML files in the logs directory, and they can be viewed using any standard web browser.

## Installing Liberty on IBM i operating systems using the command line

**8.5.5.0**

You can install WebSphere Application Server Liberty Network Deployment on IBM i operating systems using the Installation Manager command line.

### Before you begin

Prepare for the installation before using this procedure. See [Preparing the operating system for installation on IBM i](#) for more information.

**8.5.5.6**

If you want to install Liberty assets from local directory-based repositories or an instance of the Liberty Asset Repository Service, configure the repositories. For more information about the Liberty asset repositories, see [“Installing assets using Installation Manager”](#) on page 1411.

**Important:** Before installing WebSphere Application Server Liberty Network Deployment, you must read the license agreement that you can find with the product files. Signify your acceptance of the license agreement by specifying **-acceptLicense** in the command as described in this topic.

**Install Installation Manager** on the system onto which you want to install the product.

- If you want to use the Installation Manager that comes with this product, perform the following actions:

1. Obtain the necessary files.

There are three basic options for obtaining and installing Installation Manager and the product.

– **Access the physical media, and use local installation**

You can access the product repositories on the media.

a. Install Installation Manager on your system.

You can install Installation Manager using the media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager download website.

b. Use Installation Manager to install the product from the product repositories on the media.

– **Download the files from the Passport Advantage site, and use local installation**

Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

a. Download the files from the Passport Advantage site.

b. Install Installation Manager on your system.

You can install Installation Manager using the media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager download website.

c. Use Installation Manager to install the product from the downloaded repositories.

– **Access the live repositories, and use web-based installation**

If you have a Passport Advantage ID and password, you can install the product from the web-based repositories.

a. Install Installation Manager on your system.

You can install Installation Manager using the media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager download website.

b. Use Installation Manager to install the product from the web-based repository located at

<http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85>

**Note:** This location does not contain a web page that you can access using a web browser. This is a remote web-based repository location that you must specify for the value of the `-repositories` parameter so that the `imcl` command can access the files in this repository to install the product.

Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

**Note:** If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.

2. Choose three separate locations for Installation Manager's binaries, runtime data (agent data), and shared data locations.

3. Install Installation Manager using the Installation Manager command line.

a. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.

b. On a CL command line, run the **STRQSH** command to start the Qshell command shell.

c. Make sure that the umask is set to 022.

To verify the umask setting, issue the following command:

```
umask
```

To set the umask setting to 022, issue the following command:

```
umask 022
```

- d. Change to the location containing the Installation Manager installation files, and run the following command:

```
installc -acceptLicense -log log_file_path_and_name
```

**Notes:**

- For more information on installing Installation Manager, see the IBM Installation Manager Information Center.
- Use only the **installc** command to install Installation Manager.
- If you already have a version of Installation Manager installed on your system and you want to use it to install and maintain the product, obtain the necessary product files.

There are three basic options for installing the product.

- **Access the physical media, and use local installation**

You can access the product repositories on the media. Use Installation Manager to install the product from the product repositories on the media.

- **Download the files from the Passport Advantage site, and use local installation**

Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

1. Download the product repositories from the Passport Advantage site.
2. Use Installation Manager to install the product from the downloaded repositories.

- **Access the live repositories, and use web-based installation**

If you have a Passport Advantage ID and password, you can use Installation Manager to install the product from the web-based repositories. Use Installation Manager to install the product from the web-based repository located at

<http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85>

**Note:** This location does not contain a web page that you can access using a web browser. This is a remote web-based repository location that you must specify for the value of the **-repositories** parameter so that the **imcl** command can access the files in this repository to install the product.

Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

**Note:** If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.

## About this task

**8.5.5.4** To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

## Procedure

1. Optional: If the repository requires a username and password, create a credential-storage file to access this repository.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the **imutilsc** command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store

credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

2. Choose three separate locations for the product's binaries, runtime data (agent data), and shared data locations.
3. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
4. On a CL command line, run the **STRQSH** command to start the Qshell command shell.
5. Make sure that the umask is set to 022.

To verify the umask setting, issue the following command:

```
umask
```

To set the umask setting to 022, issue the following command:

```
umask 022
```

6. Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.
7. Use the **imcl** command to install the product.

```
./imcl install com.ibm.websphere.liberty.ND.v85_offering_version,optional_feature_ID  
-repositories source_repository  
-installationDirectory installation_directory  
-sharedResourcesDirectory shared_directory  
-preferences preference_key=value  
-properties property_key=value  
-secureStorageFile storage_file -masterPasswordFile master_password_file  
-acceptLicense
```

### Tips:

- The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lafiles` or `product_name/lafiles` subdirectory of the installation image or repository for this offering.
- You can install a list of features that are separated by commas.
  - Embeddable EJB container and JPA client (`embeddablecontainer`)

This option installs the embeddable EJB container and JPA client.

The embeddable EJB container is a Java Archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition (SE) environment. You can run enterprise beans using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.

The JPA client can be used with the embeddable EJB container to provide Java Persistence API capability in a Java SE environment.

- Extended Programming Models - `extprogmodels` (for fix pack 8.5.5.3 and earlier versions)

The Extended Programming Models feature provides a rich set of programming models such as Web Services, JMS (including Message-Driven Beans), and Mongo 2.0.

### Notes:

- If no features are specified, the default features (`embeddablecontainer` and `extprogmodels`) are installed. To install only the feature that you want, specify that feature explicitly.

-  **8.5.5.2** You can specify additional assets to install from the Liberty Repository. For a list of Liberty Repository assets, see the downloads page on WASdev.net.

To install assets from the IBM WebSphere Liberty Repository, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later.

If you want to install Liberty Repository features, specify the short names or symbolic names on the **user.feature** option of the **-properties** parameter. Multiple feature names are separated with double commas. The following example installs the Portlet Container and Portlet Serving features:

```
-properties user.feature=portlet-2.0,,portletserving-2.0,user.accept.license=true
```

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

**8.5.5.4**

Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` addon, or install the individual features that you need from the Liberty Repository. See the following topics for more information:

- Installing Liberty Repository assets
- Liberty features

You can install the complete set of Extended Programming Model features by specifying the `user.addon` option:

```
-properties user.addon=extendedPackage-1.0,user.accept.license=true
```

If you upgrade WebSphere Application Server Liberty Version 8.5.5.3 or previous versions that contain the `extprogmodels` feature, Installation Manager automatically installs the `extendedPackage-1.0` add-on. You must specify the `user.accept.license` option:

```
-properties user.accept.license=true
```

**8.5.5.6**

You can also install assets from instances of the Liberty Asset Repository Service or local directory-based repositories. For more information about these asset repositories, see “Installing assets using Installation Manager” on page 1411. Add the repository on the `-repositories` parameter. The repositories are accessed in the order that they are specified. By default, the Liberty Repository is the last of the repositories that are accessed during installation. To disable access to the Liberty Repository, on the `-properties` parameter, set the `user.useLibertyRepository` option to `false`.

**8.5.5.8**

```
./imcl install com.ibm.websphere.liberty.nd.v85
-properties user.useLibertyRepository=false,user.addon=extendedPackage-1.0,user.feature=portlet-2.0
-installationDirectory /QIBM/ProdData/Liberty -acceptLicense
-repositories /QIBM/LibertyProductRepo,https://your_onprem_asset_repo_url,/QIBM/LocalAssetRepo,/QIBM/LocalAssetRepo2.zip
-sharedResourcesDirectory /QIBM/UserData/InstallationManager/IMShared
-showProgress
```

To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.

- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (8.5.5.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
./imcl listAvailablePackages -repositories source_repository
```

- You can also specify `none`, `recommended` or `all` with the `-installFixes` argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the `-installFixes` option defaults to `all`.
  - If the offering version is specified, the `-installFixes` option defaults to `none`.
- For initial installations, it is a good practice to specify the *user\_data\_root*; otherwise, the default value for the *user\_data\_root*, `/QIBM/UserData/WebSphere/AppServer/V85/ND`, is used. Use the `was.install.os400.profile.location` property to specify the *user\_data\_root*. If the *user\_data\_root* is to be `/QIBM/UserData/WebSphere/AppServer/V85/ND_1`, for example, specify `-properties was.install.os400.profile.location=/QIBM/UserData/WebSphere/AppServer/V85/ND_1` on the `imcl` installation command.
- The program might write important post-installation instructions to standard output.

For more information on using the `imcl` command to install the product, see the IBM Installation Manager Information Center.

## Example

The following example uses the **imcl** command to install WebSphere Application Server Liberty Network Deployment:

```
./imcl install com.ibm.websphere.liberty.ND.v85
-repositories https://downloads.mycorp.com:8080/WAS_85_repository
-installationDirectory /QIBM/ProdData/WebSphere/AppServer/V85/ND
-properties was.install.os400.profile.location=/QIBM/UserData/WebSphere/AppServer/V85/ND
-sharedResourcesDirectory /QIBM/UserData/InstallationManager/IMShared
-secureStorageFile $HOME/WASFiles/temp/credential.store -masterPasswordFile $HOME/WASFiles/IM/master_password_file.txt
-acceptLicense
```

## Installing Liberty on IBM i operating systems using response files

**8.5.5.0**

You can install WebSphere Application Server Liberty on IBM i operating systems using Installation Manager response files.

### Before you begin

Prepare for the installation before using this procedure. See *Preparing the operating system for installation on IBM i* for more information.

**8.5.5.6**

If you want to install Liberty assets from local directory-based repositories or an instance of the Liberty Asset Repository Service, configure the repositories. For more information about the Liberty asset repositories, see “Installing assets using Installation Manager” on page 1411.

Before you install WebSphere Application Server, ensure that your user profile has \*ALLOBJ and \*SECADM special authorities.

**Install Installation Manager** on the system onto which you want to install the product.

**8.5.5.4**

To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

- If you want to use the Installation Manager that comes with this product, perform the following actions:

1. Obtain the necessary files.

There are three basic options for obtaining and installing Installation Manager and the product.

– **Access the physical media, and use local installation**

You can access the product repositories on the media.

- a. Install Installation Manager on your system.

You can install Installation Manager using the media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager download website.

- b. Use Installation Manager to install the product from the product repositories on the media.

– **Download the files from the Passport Advantage site, and use local installation**

Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

- a. Download the files from the Passport Advantage site.

- b. Install Installation Manager on your system.

You can install Installation Manager using the media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager download website.

- c. Use Installation Manager to install the product from the downloaded repositories.

– **Access the live repositories, and use web-based installation**

If you have a Passport Advantage ID and password, you can install the product from the web-based repositories.

a. Install Installation Manager on your system.

You can install Installation Manager using the media, using a file obtained from the Passport Advantage site, or using a file containing the most current version of Installation Manager from the IBM Installation Manager download website.

b. Use Installation Manager to install the product from the web-based repository located at

`http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85`

**Note:** This location does not contain a web page that you can access using a web browser. This is a remote web-based repository location that you must specify in the response file so that the installation can access the files in this repository.

Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

**Note:** If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.

2. Install Installation Manager.

a. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.

b. On a CL command line, run the **STRQSH** command to start the Qshell command shell.

c. Make sure that the umask is set to 022.

To verify the umask setting, issue the following command:

```
umask
```

To set the umask setting to 022, issue the following command:

```
umask 022
```

d. Change to the temporary directory where you unpacked the Installation Manager files.

e. Run the following command in the temporary folder:

```
installc -acceptLicense -log log_file_path_and_name
```

**Notes:**

– For more information on installing Installation Manager, see the IBM Installation Manager Information Center.

– Use only the **installc** command to install Installation Manager.

- If you already have a version of Installation Manager installed on your system and you want to use it to install and maintain the product, obtain the necessary product files.

There are three basic options for installing the product.

– **Access the physical media, and use local installation**

You can access the product repositories on the media. Use Installation Manager to install the product from the product repositories on the media.

– **Download the files from the Passport Advantage site, and use local installation**

Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.

1. Download the product repositories from the Passport Advantage site.

2. Use Installation Manager to install the product from the downloaded repositories.

– **Access the live repositories, and use web-based installation**

If you have a Passport Advantage ID and password, you can use Installation Manager to install the product from the web-based repositories. Use Installation Manager to install the product from the web-based repository located at

<http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85>

**Note:** This location does not contain a web page that you can access using a web browser. This is a remote web-based repository location that you must specify in the response file so that the installation can access the files in this repository.

Whenever possible, you should use the remote web-based repositories so that you are accessing the most up-to-date installation files.

**Note:** If you do not have a Passport Advantage ID and password, you must install the product from the product repositories on the media or local repositories.

## Procedure

1. Optional: If the repository requires a username and password, create a credential-storage file to access this repository.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutils` command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the `-keyring` and `-password` options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the `-keyring` and `-password` options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

2. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
3. On a CL command line, run the `STRQSH` command to start the Qshell command shell.
4. Make sure that the `umask` is set to 022.

To verify the `umask` setting, issue the following command:

```
umask
```

To set the `umask` setting to 022, issue the following command:

```
umask 022
```

5. Use a response file to install the product.

Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and install the product. For example:

```
./imcl -acceptLicense  
input $HOME/WASFiles/temp/install_response_file.xml  
-log $HOME/WASFiles/temp/install_log.xml  
-secureStorageFile $HOME/WASFiles/temp/credential.store -masterPasswordFile $HOME/WASFiles/master_password_file.txt
```

### Notes:

- The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lafiles` or `product_name/lafiles` subdirectory of the installation image or repository for this offering.
- `/QIBM/ProdData/InstallationManager` is the default installation location for Installation Manager files on IBM i systems.
- The program might write important post-installation instructions to standard output.

Read the IBM Installation Manager Information Center for more information.

## Example

The following is an example of a response file for installing the product with no optional features into the /QIBM/ProdData/WebSphere/AppServer/V85/ND directory using a web-based repository located at <http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85>.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input>
<server>
  <repository location='http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85' />
</server>
<profile id='WebSphere Liberty V8.5' installLocation='/QIBM/ProdData/WebSphere/AppServer/V85/ND'>
  <data key='was.install.os400.profile.location' value='/QIBM/UserData/WebSphere/AppServer/V85/ND' />
  <data key='user.import.profile' value='false' />
</profile>
<install modify='false'>
  <offering profile='WebSphere Liberty V8.5'
    features='' id='com.ibm.websphere.liberty.ND.v85' />
</install>
<preference name='com.ibm.cic.common.core.preferences.eclipseCache'
  value='/QIBM/UserData/InstallationManager/IMShared' />
<preference name='com.ibm.cic.common.core.preferences.connectTimeout' value='30' />
<preference name='com.ibm.cic.common.core.preferences.readTimeout' value='30' />
<preference name='com.ibm.cic.common.core.preferences.downloadAutoRetryCount' value='0' />
<preference name='offering.service.repositories.areUsed' value='true' />
<preference name='com.ibm.cic.common.core.preferences.ssl.nonsecureMode' value='false' />
<preference name='com.ibm.cic.common.core.preferences.http.disablePreemptiveAuthentication' value='false' />
<preference name='http.ntlm.auth.kind' value='NTLM' />
<preference name='http.ntlm.auth.enableIntegrated.win32' value='true' />
<preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true' />
<preference name='com.ibm.cic.common.core.preferences.keepFetchedFiles' value='false' />
<preference name='PassportAdvantageIsEnabled' value='false' />
<preference name='com.ibm.cic.common.core.preferences.searchForUpdates' value='false' />
</agent-input>
```

### Tips:

- Make sure that the repository location points to the web-based or local product repository. For example:

```
<repository location='https://downloads.mycorp.com:8080/WAS_85_repository' />
```

- The following line from the example specifies the default value of the profile location for IBM i:

```
<data key='was.install.os400.profile.location' value='/QIBM/UserData/WebSphere/AppServer/V85/ND' />
```

To override this default location, specify a different location

- The following line from the example specifies the default value of the shared resources directory for IBM i:

```
<preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='/QIBM/UserData/InstallationManager/IMShared' />
```

To override this default location, specify a different location

**Note:** There is only one shared resources directory for Installation Manager. If there has been an installation on the system in the past, it will use that shared resources directory and not the one specified in the response file.

- To disable remote searches for updates in the response file, set the following preferences to false:

- offering.service.repositories.areUsed

Used for searching remote repositories for updates to installed offerings

- com.ibm.cic.common.core.preferences.searchForUpdates

Used for searching for updates to Installation Manager

For example:

```
<preference value='false' name='offering.service.repositories.areUsed' />
<preference value='false' name='com.ibm.cic.common.core.preferences.searchForUpdates' />
```

You can find more details on silent preference keys in the IBM Installation Manager Information Center.

- To install more than one instance of an offering, you must make the profile ID of each additional instance unique. For example:

```
<offering profile='WebSphere Liberty V8.5 - Another User's WAS Liberty ND'  
  features='' id='com.ibm.websphere.liberty.ND.v85' />
```

This must be changed in both places that specify the profile ID in the response file.

Here are some examples of changes that you could make to manipulate this response file to perform alternative actions.

- To alter the location of the installation, simply change the installation location. For example:

Replace

```
<profile id='WebSphere Liberty V8.5' installLocation='/QIBM/ProdData/WebSphere/AppServer/V85/ND'>
```

with

```
<profile id='WebSphere Liberty V8.5' installLocation='/home/user/IBM/WebSphere/AppServer/V85/Server'>
```

- To install from a local repository instead of the live remote repository, replace the repository location. For example:

Replace

```
<repository location='http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85' />
```

with

```
<repository location='/home/user/repositories/WAS85/local-repositories' />
```

- To add the optional features, add each desired feature in the offering as an entry in a comma-separated list.

In the following list, the offering IDs to be used in the response files are enclosed in parentheses:

- Embeddable EJB container and JPA client (embeddablecontainer)

This option installs the embeddable EJB container and JPA client.

The embeddable EJB container is a Java Archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition (SE) environment. You can run enterprise beans using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.

The JPA client can be used with the embeddable EJB container to provide Java Persistence API capability in a Java SE environment.

- Extended Programming Models (extprogmodels) - Versions 8.5.5.0 to 8.5.5.3

The Extended Programming Models feature provides a rich set of programming models such as Web Services, JMS (including Message-Driven Beans), and MongoDB 2.0.

#### Notes:

- If no features are specified, the default features (embeddablecontainer and extprogmodels) are installed. To install only the feature that you want, specify that feature explicitly.

For example, to install the Embeddable EJB container:

Replace

```
<offering profile='WebSphere Liberty V8.5'  
  features='' id='com.ibm.websphere.liberty.ND.v85' />
```

with

```
<offering profile='WebSphere Liberty V8.5'  
  features='embeddablecontainer' id='com.ibm.websphere.liberty.ND.v85' />
```

-  **8.5.5.2** You can specify additional assets to install from the Liberty Repository. For a list of Liberty Repository assets, see the downloads page on WASdev.net.

To install Liberty Repository assets, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later. Previous versions of Installation Manager do not have the

option to install Liberty Repository assets. If you use a response file and did not update Installation Manager to Version 1.6.2 or later, the assets that you specify in the response file are ignored during installation.

If you want to install additional features, specify two extra data key elements in your response file. You can use either the symbolic name or the short name.

The following example installs the Portlet Container and Portlet Serving features using the symbolic name.

```
<data key='user.feature' value='com.ibm.websphere.appserver.portlet-2.0,,com.ibm.websphere.appserver.portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

The following example installs the Portlet Container and Portlet Serving features using the short name:

```
<data key='user.feature' value='portlet-2.0,,portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

**8.5.5.4**

Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` addon, or install the individual features that you need from the Liberty Repository. See the following topics for more information:

- Installing Liberty Repository assets
- Liberty features

The following example installs the Extended Programming Models using the `user.addon` parameter and the Portlet Container and Portlet Serving features using the `user.feature` parameter with short names:

```
<data key='user.addon' value='extendedPackage-1.0' />
<data key='user.feature' value='portlet-2.0,,portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

**8.5.5.6**

You can also install assets from an instance of the Liberty Asset Repository Service or local directory-based repositories. For more information, see “Installing assets using Installation Manager” on page 1411. Add the repository on `repository` elements. If Installation Manager does not recognize the repository, point directly to the `repository.config` file. When you install assets, the repositories are accessed in the order that you specify them.

```
<server>
<repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85" />
<repository location="https://your_onprem_asset_repo_url" />
<repository location="/QIBM/LocalAssetRepo" />
```

**8.5.5.8**

`<repository location="/QIBM/LocalAssetRepo2.zip" />` By default, the Liberty Repository is the last of the repositories that are accessed during installation. To disable access to the Liberty Repository, set the `user.useLibertyRepository` parameter to `false`:

```
<data key='user.addon' value='extendedPackage-1.0' />
<data key='user.feature' value='portlet-2.0,,portletserving-2.0' />
<data key='user.useLibertyRepository' value='false' />
```

To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.

## Installing Liberty remotely on IBM i operating systems using the `iRemoteInstall` command

**8.5.5.0**

You can use the `iRemoteInstall` command to install IBM Installation Manager or WebSphere Application Server Liberty Network Deployment from a Windows workstation to a remote target IBM i system.

### Before you begin

Prepare for the installation before using this procedure. See Preparing the operating system for installation on IBM i for more information.

The product offering repository files or the IBM Installation Manager for IBM i installation kit compressed file must be available on the Windows system.

**Important:** You must set your JAVA\_HOME environment variable to your IBM Installation Manager JRE home before running the command directly from the media.

#### Restrictions:

- The **iRemoteInstall** command does not support credential-storage files used to pass confidential information. You must use the physical media or download the installation files to your local system.
- The **iRemoteInstall** command does not support the use of response files.

#### About this task

**Note:** By running this script, you accept the terms of the product license. The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lafiles` or `offering_name/lafiles` subdirectory of the installation image or repository for this offering.

#### Location of the iRemoteInstall command:

The **iRemoteInstall** command is located in the following directory when it has been installed as part of the WebSphere Customization Toolbox:

```
wct_root/Remote_Installation_Tool_for_IBM_i
```

**Tip:** A version of this utility that is current when the product is released is also available on the media or installation image. You can run the command directly from the media connected to a Windows system to install the offering on a remote target IBM i system. This version of the utility is located at the following location:

```
media_root\Remote_Installation_Tool_for_IBM_i\iRemoteInstall.bat
```

where *media\_root* is the root directory of the media or installation image containing the product or supplements.

#### Syntax of the iRemoteInstall command:

```
iRemoteInstall.bat
-hostname i5_hostname
-username user_login_name
-password user_login_password
-iminstit im_install_kit_file_path_and_name | -wasoid was_offering_id
-wasrepoloc was_install_file_location
-appdataloc im_agent_data_location
-wasinstloc was_install_location
-wassharedloc was_shared_location
-features feature_ID_1,feature_ID_2, . . .
-properties key=value,key=value, . . .
-log log_file_path_and_name
-trace
-version
-help
```

#### Parameters of the iRemoteInstall command:

##### **-hostname *i5\_hostname***

Specifies the host name of the target IBM i machine to which Installation Manager or WebSphere Application Server Liberty Network Deployment is going to be installed.

This parameter is required.

##### **-username *user\_login\_name***

Specifies the login name of the user who is performing the Installation Manager or WebSphere Application Server Liberty Network Deployment remote installation.

This user must be a valid user for the target IBM i system with \*ALLOBJ and \*SECADM special authorization.

##### **-password *user\_login\_password***

Specifies the login password of the user specified in **-username**.

- iminstkit *im\_install\_kit\_file\_name***  
 Specifies the location of the Installation Manager for IBM i installation kit  
 You must include the path if it is not in the same directory as the command.  
 This parameter is required.
- wasoid *was\_offering\_id***  
 Specifies the ID of the WebSphere Application Server Liberty offering being installed  
 Example values are base, nd, express, etc. This parameter is not case sensitive.  
 The value to use can be found in the product offering ID. If the offering ID is com.ibm.websphere.liberty.XXX.v85, for example, the **-wasoid** value should be liberty.XXX.
- wasrepoloc *was\_install\_file\_location***  
 Specifies the location of the WebSphere Application Server Liberty Network Deployment installation repository  
 This option must be specified if the **-wasoid** parameter is specified.
- appdataloc *im\_agent\_data\_location***  
 Specifies the location of the Installation Manager agent data  
 If no value is specified for this parameter, it is set to the default value of /QIBM/UserData/InstallationManager.
- wasinstloc *was\_install\_location***  
 Specifies the location of the WebSphere Application Server Liberty Network Deployment installation  
 If no value is specified for this parameter, it is set to the default value of /QIBM/WAS85/Liberty.
- wassharedloc *was\_shared\_location***  
 Specifies the location of the WebSphere Application Server Liberty Network Deployment shared location  
 If no value is specified for this parameter, it is set to the default value of /QIBM/WAS85/Liberty\_Shared.
- features *feature\_ID\_1,feature\_ID\_2, . . .***  
 Specifies the features to be installed  
 The feature IDs must be separated by commas (,).
- Tip:** If no features are specified, the default features (embeddablecontainer and extprogmodels) are installed. To install only the feature that you want, specify that feature explicitly.
- properties *key=value,key=value, . . .***  
 Specifies package-group (profile) properties
- log *log\_file\_path\_and\_name***  
 Turns on the log, and sends all messages to the specified file and location  
 The path can be absolute (c:\temp\mylog.log for example) or relative (..\mylog.log for example).  
 Because you can append multiple installation actions into the same log, the actual name of a log file that is generated is *log\_file\_path\_and\_name.x.log*, where *x* is the number of the log file from 0 to 29. The maximum log file size is approximately 10 MB; and the maximum number of log files generated is 30.
- trace**  
 Provides trace output of what the command checks and what the command discovers

**-version**

Displays the version information for the command

**-help**

Displays usage information for the command

**Procedure**

1. Log in to the IBM i machine using the IBM Personal Communications tool, or telnet with TN5250 to the IBM i machine.
2. If TCP/IP is not started or if you do not know if TCP/IP is started, enter the following command on the Control Language (CL) command line:

```
STRTCP
```

3. Verify that the host server jobs are started on your IBM i server.

The host server jobs allow the installation code to run on IBM i.

Enter the following command on the CL command line:

```
STRHOSTSVR SERVER(*ALL)
```

4. Verify that your user profile has \*ALLOBJ and \*SECADM special authorities.
5. Run the **iRemoteInstall** command in the temporary directory to install Installation Manager or Websphere Application Server Liberty Network Deployment.  
In order to install Websphere Application Server Liberty Network Deployment, Installation Manager must already be installed on the target system.
6. Verify the installation.
  - Check for error messages in the output from the **iRemoteInstall** command.
  - Look for errors in the installation log.

**Example**

Here is an example of installing IBM Installation Manager with the **iRemoteInstall** command:

```
./iRemoteInstall
-hostname iserver1.somedomain.com
-username wasadmin -password mypwd
-iminstit E:\agent.installer.os400.motif.ppc_1.6.2000.20101206_0100.zip
```

Here is an example of installing WebSphere Application Server Liberty Network Deployment with the **iRemoteInstall** command:

```
./iRemoteInstall
-hostname iserver1.somedomain.com
-username wasadmin -password mypwd
-wasoid liberty.ND
-wasrepoloc E:\repository
```

**Verifying the installation**

**8.5.5.0**

You can verify successful installation of the offering using the capabilities of IBM Installation Manager.

**Procedure**

- To verify installation of the offering, you can use Installation Manager to find the offering in the list of installed packages.

Change the directory to the `eclipse/tools` subdirectory of the Installation Manager binaries location, and run this command:

```
./imcl listInstalledPackages
```

This will display a list indicating which packages this Installation Manager has installed. For example:

```
com.ibm.websphere.liberty.ND.v85_8.5.5.20110203_0234
```

- If an installation was successful, the `installed.xml` file should contain a location element for the installed offering.

For example, the following file:

```
installation_manager_root/properties/version/installed.xml
```

should contain something like this:

```
<location id="IBM WebSphere Application Server Liberty Network Deployment V8.5" kind="product" path="/QIBM/ProdData/WebSphere/AppServer/V85/ND"> ..... </location>
```

- If you used the Installation Manager **-log** option during installation, you can verify that the resulting log file does not contain any errors.

If you used the following command to install the offering silently for example:

```
./imcl -acceptLicense
input $HOME/WASFiles/liberty/temp/install_response_file.xml
-log $HOME/WASFiles/liberty/temp/install_log.xml
-secureStorageFile $HOME/WASFiles/liberty/temp/credential.store -masterPasswordFile $HOME/WASFiles/liberty/master_password_file.txt
```

and the installation was successful, the `install_log.xml` file should contain something like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<result>
</result>
```

## Updating Liberty from Version 8.5.0 to Version 8.5.5

Distributed operating systems

IBM i

8.5.5.0

If you are updating an existing WebSphere Application Server Version 8.5.0.x Liberty feature, you must install WebSphere Application Server Liberty Network Deployment Version 8.5.5.0 or later. You cannot make an in-place update of the Version 8.5.0.x Liberty feature. Afterwards, you can copy your data and server configurations to the new installation or, if your user data are kept in another location, follow typical procedures for managing your data and server configurations.

### About this task

In WebSphere Application Server Version 8.5.5.0, Liberty was promoted from a feature to an independently installable offering. You cannot make an in-place update of the Version 8.5.0.x Liberty feature. The `wlp` folder includes the Liberty runtime and any user data or server configurations that you have saved in the `wlp/usr` folder. If you have a combined full-profile and Liberty-profile Version 8.5.0.x installation, the update program will back up the `wlp` folder for the existing Version 8.5.0.x Liberty feature into the `wlp.bak_<timestamp>` folder and uninstall the feature during an update to Version 8.5.5.0 or higher. You can continue using Liberty from the backed-up location or copy it elsewhere. To update Liberty to Version 8.5.5.0 or higher, you then must install WebSphere Application Server Liberty Network Deployment (with the `com.ibm.websphere.liberty.ND.v85` offering ID). After installing WebSphere Application Server Liberty Network Deployment, you can move any user data and server configurations from the `wlp.bak_<timestamp>` folder to the new Liberty installation.

These instructions describe updating from a combined full-profile and Liberty-profile Version 8.5.0.x installation. If you have only the Version 8.5.0.x Liberty feature installed, you should install WebSphere Application Server Liberty Network Deployment Version 8.5.5.0 or higher in a different location. Then, you can copy the contents of the `wlp/usr` directory from the old installation to the `usr` directory of the new installation. If you are using `WLP_USER_DIR` and `WLP_OUTPUT_DIR` environment variables, make sure that they are pointing to the desired locations. You can continue using Java 6 from the Version 8.5.0.x installation image, use your own Java 6 or Java 7 that meets Liberty minimum requirements, or install one or both of the optional Java 6 or Java 7 Liberty extension offerings (offering ids: `com.ibm.websphere.liberty.IMBJAVA.v60` and `com.ibm.websphere.liberty.IMBJAVA.v70`).

**Note:**  During installation of a Liberty offering on an IBM i system, the `WLP_DEFAULT_USER_DIR` and `WLP_DEFAULT_OUTPUT_DIR` environment variables are set in the `WLP_INSTALL_DIR/etc/default.env` file.

## Procedure

1. Update your existing combined full-profile and Liberty-profile installation to Version 8.5.5 or later following the normal update procedure.

**Note:** If you want to keep using the backed-up Liberty with the current level of Java 6 after the update, you must make a backup of Java 6 before it is updated to the latest level by the fix-pack update. Java 6 can be found in the `<install-root>\java` folder. Set the `JAVA_HOME` environment variable to point to the desired Java. For more information on this environment variable, see “Customizing the Liberty environment” on page 1565.

After updating your WebSphere Application Server Network Deployment installation from Version 8.5.0.x to Version 8.5.5, you can find your Liberty installation in the `<was_home>/wlp.bak_<timestamp>` folder. This backup folder contains the Liberty runtime at the level that it was before you started the update.

2. Use the backed-up Liberty runtime.

A copy of the Installation Manager installation and history information for this snapshot is also stored in the root of the backup in the `installed.xml` and `history.xml` files.

To determine what fixes have been installed in this snapshot, you can use the `bin/productInfo` command in the backed-up Liberty folder. See “Liberty:productInfo command” on page 1415 for more information.

You can continue using the Liberty runtime folder from its backed-up location, or you can copy or move it to a new location. If you have set the `WLP_USER_DIR` or `WLP_OUTPUT_DIR` environment variables, make sure that they point to the location of your user data and the location of output resources generated by your server respectively.

**Note:** Do not move the backed-up `wlp.bak_<timestamp>` folder back to `wlp` in case you decide to roll back to Version 8.5.0.x later.

If `WLP_USER_DIR` has not been set, the server configuration and shared resources are stored in the `usr` directory at the root of the server's runtime environment (`wlp_bak_<timestamp>/usr` for example). In this case, no action is required to use the backed-up runtime because the user data can still be found under the `usr` directory of the new location.

If the `WLP_OUTPUT_DIR` value is not set, the default location is in the server root directory (`wlp_bak_<timestamp>/usr/servers/<server_name>` for example). If this environment variable is not set, no action is required to use the backed up runtime because logs continue to appear under the `usr/servers/<server_name>/logs` directory of the new location.

For more information on these environment variables, see “Customizing the Liberty environment” on page 1565.

**Note:** If the `server.xml` file or any included XML configuration file references another resource outside the server configuration directory, ensure that these resources can be found from the new server location.

Start all Liberty servers with the `--clean` parameter as a launch option. For example:

```
server start --clean
```

You need to use the `--clean` option only once. All subsequent server starts will not require it.

If you need to continue using the backed-up Liberty in the `wlp.bak_<timestamp>` folder, you can apply fixes using the archive interim-fix service procedure documented in “Applying an interim fix to a Liberty archive installation” on page 1388.

3. Install WebSphere Application Server Liberty Network Deployment Version 8.5.5 or later.

See “Installing and uninstalling Liberty using Installation Manager” on page 1164 or “Installing and uninstalling Liberty using downloaded files and archives” on page 1371.

**Tip:** After you install WebSphere Application Server Liberty Network Deployment Version 8.5.5 or later, you can use the `ProductInfo compare` action to compare the old and new installations. This will

show any issues that were resolved in the Version 8.5.0.x level that are not resolved at the Version 8.5.5.x level. See “Liberty:productInfo command” on page 1415 for more information.

4. Start using the WebSphere Application Server Liberty Network Deployment Version 8.5.5 installation. If the WLP\_USER\_DIR and WLP\_OUTPUT\_DIR environment variables are set, then the new Liberty installation will continue using these locations to for user data, including server configurations, and to place server generated output. In this case, it is recommended that you make a backup of the directories referenced by WLP\_USER\_DIR and WLP\_OUTPUT\_DIR before beginning to use the new installation.

If the WLP\_USER\_DIR and WLP\_OUTPUT\_DIR environment variables are not set, Liberty will use folders relative to the installed runtime by default. In this case, you should copy the contents of the backed-up Liberty runtime user folder (`wlp.bak_<timestamp>/usr`) to the `usr` folder of your new installation.

For more information on these environment variables, see “Customizing the Liberty environment” on page 1565.

**Note:** If the `server.xml` file or any included XML configuration file references another resource outside the server configuration directory, ensure that these resources can be found from the new server location.

## Installing the Extended Programming Models on IBM i

IBM i

8.5.5.4

Installing and updating Liberty with the Extended Programming Models differs depending on the version of WebSphere Application Server.

### About this task

The Extended Programming Models provide a rich set of programming models such as web services, JMS (including Message-driven beans), and MongoDB 2.0.

How you install the Extended Programming Models depends on your version of WebSphere Application Server:

- Up to Version 8.5.5.3: Extended Programming Models are available as the `extprogmodels` Installation Manager installable feature.
- Version 8.5.5.4 and later: Extended Programming Models are available as the `extendedPackage-1.0` Liberty Repository add-on

You can use the following options to install the Extended Programming Models when you install Liberty or to update an existing copy of Liberty to include the Extended Programming Models:

- Install or update Liberty with the Extended Programming Models using the command line.
- Install or update Liberty with the Extended Programming Models using response files.

**Note:** If you are installing or updating to Version 8.5.5.3 or earlier using a remote repository, such as IBM Passport Advantage or a centrally-hosted HTTP server, internet access is required to update the Extended Programming Models.

After you install Liberty Version 8.5.5.4 or later, you can later install the `extendedPackage-1.0` add-on by using the **featureManager** command. For Version 8.5.5.6 and later, you can also use the **installUtility** command to install the add-on from multiple types of repositories. For more information, see “Installing assets using the featureManager command” on page 1403 and “Installing assets using the installUtility command” on page 1393.

## Procedure

Use one of the following options to install the Extended Programming Models:

- Install or update Liberty with the Extended Programming Models using the command line.
  - V8.5.5.3 and previous versions install the `extprogmodels` feature after the product:

```
imcl install com.ibm.websphere.liberty.ND.v85,extprogmodels
-installationDirectory /QIBM/ProdData/WebSphere/AppServer/V85/ND -acceptLicense
-repositories https://downloads.mycorp.com:8080/WAS_85_repository
-sharedResourcesDirectory /QIBM/UserData/InstallationManager/IMShared
-showProgress
```
  - V8.5.5.4 and later versions install the `extendedPackage-1.0` addon on the `-properties user.addon` parameter:

```
imcl install com.ibm.websphere.liberty.ND.v85
-properties user.accept.license=true,user.addon=extendedPackage-1.0
-installationDirectory /QIBM/ProdData/WebSphere/AppServer/V85/ND -acceptLicense
-repositories https://downloads.mycorp.com:8080/WAS_85_repository
-sharedResourcesDirectory /QIBM/UserData/InstallationManager/IMShared
-showProgress
```
- Install or update Liberty with the Extended Programming Models using response files.
  - V8.5.5.3 and previous versions install the `extprogmodels` feature on the feature attribute of the offering element:

```
<?xml version='1.0' encoding='UTF-8'?>
<agent-input>
  <variables>
    <variable name='sharedLocation' value='/QIBM/UserData/InstallationManager/IMShared' />
  </variables>
  <server>
    <repository location='http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85' />
  </server>
  <profile id='WebSphere Liberty V8.5' installLocation='/QIBM/ProdData/WebSphere/AppServer/V85/ND'>
    <data key='eclipseLocation' value='/QIBM/ProdData/WebSphere/AppServer/V85/ND' />
    <data key='user.import.profile' value='false' />
  </profile>
  <install modify='false'>
    <!-- Install the IBM WebSphere Application Server Network Deployment 8.5.5.0 Liberty with the Extended Programming Models-->
    <offering profile='WebSphere Liberty V8.5' id='com.ibm.websphere.liberty.ND.v85' features='liberty,extprogmodels' installFixes='none' />
  </install>
  <preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='${sharedLocation}' />
  <preference name='com.ibm.cic.common.core.preferences.connectTimeout' value='30' />
  <preference name='com.ibm.cic.common.core.preferences.readTimeout' value='45' />
  <preference name='com.ibm.cic.common.core.preferences.downloadAutoRetryCount' value='0' />
  <preference name='offering.service.repositories.areUsed' value='false' />
  <preference name='com.ibm.cic.common.core.preferences.ssl.nonsecureMode' value='false' />
  <preference name='com.ibm.cic.common.core.preferences.http.disablePreemptiveAuthentication' value='false' />
  <preference name='http.ntlm.auth.kind' value='NTLM' />
  <preference name='http.ntlm.auth.enableIntegrated.win32' value='true' />
  <preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true' />
  <preference name='com.ibm.cic.common.core.preferences.keepFetchedFiles' value='false' />
  <preference name='PassportAdvantageIsEnabled' value='false' />
  <preference name='com.ibm.cic.common.core.preferences.searchForUpdates' value='false' />
  <preference name='com.ibm.cic.agent.ui.displayInternalVersion' value='false' />
  <preference name='com.ibm.cic.common.sharedUI.showErrorLog' value='true' />
  <preference name='com.ibm.cic.common.sharedUI.showWarningLog' value='true' />
  <preference name='com.ibm.cic.common.sharedUI.showNoteLog' value='true' />
</agent-input>
```

- V8.5.5.4 and later versions install the `extendedPackage-1.0` addon on the `user.addon` parameter under the profile element:

```
<?xml version='1.0' encoding='UTF-8'?>
<agent-input>
  <variables>
    <variable name='sharedLocation' value='/QIBM/UserData/InstallationManager/IMShared' />
  </variables>
  <server>
    <repository location='http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85' />
  </server>
  <profile id='WebSphere Liberty V8.5' installLocation='/QIBM/ProdData/WebSphere/AppServer/V85/ND'>
    <data key='eclipseLocation' value='/QIBM/ProdData/WebSphere/AppServer/V85/ND' />
    <data key='user.import.profile' value='false' />
    <!-- Extended Programming Model addon -->
    <data key='user.addon' value='com.ibm.websphere.appserver.extendedPackage-1.0' />
    <data key='user.accept.license' value='true' />
  </profile>
  <install modify='false'>
    <!-- IBM WebSphere Application Server Network Deployment 8.5.5.4 Liberty -->
```

```

    <offering profile='WebSphere Liberty V8.5' id='com.ibm.websphere.liberty.ND.v85' features='liberty' installFixes='none' />
  </install>
  <preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='${sharedLocation}' />
  <preference name='com.ibm.cic.common.core.preferences.connectTimeout' value='30' />
  <preference name='com.ibm.cic.common.core.preferences.readTimeout' value='45' />
  <preference name='com.ibm.cic.common.core.preferences.downloadAutoRetryCount' value='0' />
  <preference name='offering.service.repositories.areUsed' value='false' />
  <preference name='com.ibm.cic.common.core.preferences.ssl.nonsecureMode' value='false' />
  <preference name='com.ibm.cic.common.core.preferences.http.disablePreemptiveAuthentication' value='false' />
  <preference name='http.ntlm.auth.kind' value='NTLM' />
  <preference name='http.ntlm.auth.enableIntegrated.win32' value='true' />
  <preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true' />
  <preference name='com.ibm.cic.common.core.preferences.keepFetchedFiles' value='false' />
  <preference name='PassportAdvantageIsEnabled' value='false' />
  <preference name='com.ibm.cic.common.core.preferences.searchForUpdates' value='false' />
  <preference name='com.ibm.cic.agent.ui.displayInternalVersion' value='false' />
  <preference name='com.ibm.cic.common.sharedUI.showErrorLog' value='true' />
  <preference name='com.ibm.cic.common.sharedUI.showWarningLog' value='true' />
  <preference name='com.ibm.cic.common.sharedUI.showNoteLog' value='true' />
</agent-input>

```

## Adding and removing features from Liberty on IBM i operating systems using response files

### 8.5.5.0

You can install and remove WebSphere Application Server Liberty Network Deployment features using Installation Manager response files.

### About this task

Perform this procedure to use Installation Manager to install or remove a feature silently using a response file.

Like other Installation Manager operations, you can invoke a modification using the **imcl** command-line tool. Go to the IBM Installation Manager Information Center for more information.

#### 8.5.5.4

To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

**Optional features:** In the following list of optional features, the names to be used in the response files are enclosed in parentheses:

- Embeddable EJB container and JPA client (`embeddablecontainer`)

This option installs the embeddable EJB container and JPA client.

The embeddable EJB container is a Java Archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition (SE) environment. You can run enterprise beans using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.

The JPA client can be used with the embeddable EJB container to provide Java Persistence API capability in a Java SE environment.

- Extended Programming Models (`extprogmodels`) - Versions 8.5.5.0 to 8.5.5.3

The Extended Programming Models feature provides a rich set of programming models such as Web Services, JMS (including Message-Driven Beans), and MongoDB 2.0.

#### 8.5.5.4

Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` addon, or install the individual features that you need from the Liberty Repository. See the following topics for more information:

- Installing Liberty Repository assets
- Liberty features

**Note:** To install assets from the IBM WebSphere Liberty Repository, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later.

## Procedure

1. Optional: If the repository requires a username and password, create a credential-storage file to access this repository.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutilsc` command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the `-keyring` and `-password` options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the `-secureStorageFile` and `-masterPasswordFile` options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the `-keyring` and `-password` options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

2. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
3. On a CL command line, run the `STRQSH` command to start the Qshell command shell.
4. Use a response file to install or remove a feature.

Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and modify the product. For example:

```
./imcl
input $HOME/WASFiles/temp/modify_response_file.xml
-log $HOME/WASFiles/temp/modify_log.xml
-secureStorageFile $HOME/WASFiles/temp/credential.store -masterPasswordFile $HOME/WASFiles/master_password_file.txt
```

**Note:** The program might write important post-installation instructions to standard output.

For more information on using Installation Manager, read the IBM Installation Manager Information Center.

## Example

- Here are examples of response files for modifying the features in an installation:
  - Here is a response file that adds the Embeddable EJB container and JPA client to an existing product that is installed in the `/QIBM/ProdData/WebSphere/AppServer/V85/ND` directory:

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input>
<server>
  <repository location='https://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85' />
</server>
<profile id='WebSphere Liberty V8.5' installLocation='/QIBM/ProdData/WebSphere/AppServer/V85/ND'>
  <data key='was.install.os400.profile.location' value='/QIBM/UserData/WebSphere/AppServer/V85/ND' />
</profile>
<install modify='true'>
  <offering profile='WebSphere Liberty V8.5' features='embeddablecontainer' id='com.ibm.websphere.liberty.ND.v85' />
</install>
<preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='/QIBM/UserData/InstallationManager/IMShared' />
<preference name='com.ibm.cic.common.core.preferences.connectTimeout' value='30' />
<preference name='com.ibm.cic.common.core.preferences.readTimeout' value='30' />
<preference name='com.ibm.cic.common.core.preferences.downloadAutoRetryCount' value='0' />
<preference name='offering.service.repositories.areUsed' value='true' />
<preference name='com.ibm.cic.common.core.preferences.ssl.nonsecureMode' value='false' />
<preference name='com.ibm.cic.common.core.preferences.http.disablePreemptiveAuthentication' value='false' />
<preference name='http.ntlm.auth.kind' value='NTLM' />
<preference name='http.ntlm.auth.enableIntegrated.win32' value='true' />
<preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true' />
<preference name='com.ibm.cic.common.core.preferences.keepFetchedFiles' value='false' />
<preference name='PassportAdvantageIsEnabled' value='false' />
<preference name='com.ibm.cic.common.core.preferences.searchForUpdates' value='false' />
</agent-input>
```

- To alter this response file to remove a feature, simply change the `install` tags to `uninstall`. Here is the same response file modified to remove the Embeddable EJB container and JPA client:

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input>
<server>
  <repository location='https://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85' />
```

```

</server>
<profile id='WebSphere Liberty V8.5' installLocation='/QIBM/ProdData/WebSphere/AppServer/V85/ND'>
  <data key='was.install.os400.profile.location' value='/QIBM/UserData/WebSphere/AppServer/V85/ND' />
</profile>
<uninstall modify='true'>
  <offering profile='WebSphere Liberty V8.5' features='embeddablecontainer' id='com.ibm.websphere.liberty.ND.v85' />
</uninstall>
<preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='/QIBM/UserData/InstallationManager/IMShared' />
<preference name='com.ibm.cic.common.core.preferences.connectTimeout' value='30' />
<preference name='com.ibm.cic.common.core.preferences.readTimeout' value='30' />
<preference name='com.ibm.cic.common.core.preferences.downloadAutoRetryCount' value='0' />
<preference name='offering.service.repositories.areUsed' value='true' />
<preference name='com.ibm.cic.common.core.preferences.ssl.nonsecureMode' value='false' />
<preference name='com.ibm.cic.common.core.preferences.http.disablePreemptiveAuthentication' value='false' />
<preference name='http.ntlm.auth.kind' value='NTLM' />
<preference name='http.ntlm.auth.enableIntegrated.win32' value='true' />
<preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true' />
<preference name='com.ibm.cic.common.core.preferences.keepFetchedFiles' value='false' />
<preference name='PassportAdvantageIsEnabled' value='false' />
<preference name='com.ibm.cic.common.core.preferences.searchForUpdates' value='false' />
</agent-input>

```

- To combine adding and removing features using a single response file, add both an install action and an uninstall action.

- Here is an example of the **imcl** command for modifying the features in an installation:

```

./imcl modify com.ibm.websphere.liberty.ND.v85
-addFeatures embeddablecontainer
-repositories http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85
-installationDirectory /QIBM/ProdData/WebSphere/AppServer/V85/ND
-secureStorageFile /var/credential.store -masterPasswordFile /var/master_password_file.txt

```

## Uninstalling Liberty from IBM i operating systems using the command line

**8.5.5.0**

You can use Installation Manager to uninstall WebSphere Application Server Liberty Network Deployment using the Installation Manager command line (**imcl**).

### Procedure

1. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
2. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
3. On a CL command line, run the **STRQSH** command to start the Qshell command shell.
4. Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager.
5. Use the **imcl** command to uninstall the product.

For example:

```

./imcl uninstall com.ibm.websphere.liberty.ND.v85,optional_feature_ID
-installationDirectory installation_directory

```

You can remove a list of features that are separated by commas. If a list of features is not specified, the entire product is uninstalled.

For more information on using the **imcl** command to uninstall the product, see the IBM Installation Manager Information Center.

6. Optional: Uninstall IBM Installation Manager.

**Important:** Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager.

For more information on uninstalling Installation Manager, see the IBM Installation Manager Information Center.

### Example

Here is an example of using the **imcl** command to uninstall Websphere Application Server:

```

./imcl uninstall com.ibm.websphere.liberty.ND.v85
-installationDirectory /QIBM/ProdData/WebSphere/AppServer/V85/ND

```

## Uninstalling Liberty from IBM i operating systems using response files

8.5.5.0

You can uninstall WebSphere Application Server Liberty Network Deployment using Installation Manager response files.

### About this task

Using Installation Manager, you can work with response files to uninstall the product.

### Procedure

1. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
2. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
3. On a CL command line, run the **STRQSH** command to start the Qshell command shell.
4. Use a response file to uninstall the product.

From a command line on each of the systems from which you want to uninstall the product, change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager and use a response file that you created to uninstall the product. For example:

```
./imcl  
input $HOME/WASFiles/temp/uninstall_response_file.xml  
-log $HOME/WASFiles/temp/uninstall_Tog.xml
```

Here is an example of what the response file might contain:

```
<agent-input>  
<uninstall>  
<offering profile="WebSphere Liberty V8.5"/>  
</uninstall>  
</agent-input>
```

Go to the IBM Installation Manager Information Center for more information.

5. Optional: Uninstall IBM Installation Manager.

**Important:** Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager.

Read the IBM Installation Manager Information Center for information about using the uninstall script to perform this procedure.

## Installing Liberty interim fixes on IBM i operating systems using the command line

8.5.5.0

Fix packs contain bundled service to bring WebSphere Application Server Liberty for IBM i up to a new level. Interim fixes provide corrective service for specific known problems. You can use the IBM Installation Manager command-line function to update the offering with the fixes that are available for your service level of WebSphere Application Server Liberty for IBM i.

### Before you begin

Contact the IBM Software Support Center for information about updates for WebSphere Application Server Liberty for IBM i. The most current information is available from the IBM Software Support Center and Fix Central.

IBM Installation Manager is used to apply maintenance to WebSphere Application Server Liberty for IBM i.

## About this task

Use this procedure whenever you want to apply a new interim fix to your system.

**Tip:** You can also install interim fixes using silent response files with Installation Manager. For information on creating and using response files, read the IBM Installation Manager Information Center.

**Restriction:** You cannot use the `iRemoteInstall` command to install an interim fix.

## Procedure

1. For a list of interim fixes that are available for WebSphere Application Server Liberty for IBM i and specific information about each interim fix, perform the following actions.
  - a. Go to Fix Central.
  - b. Select **WebSphere** as the product group.
  - c. Select **WebSphere Application Server Liberty for IBM i** as the product.
  - d. Select the version of the offering to be updated.
  - e. Select your operating system as the platform, and click **Continue**.
  - f. Select **Browse for fixes**, and click **Continue**.
  - g. Click **More Information** under each fix to view information about the fix.
  - h. **Recommendation:** Make a list of the names of the interim fixes that you would like to install.

2. Update WebSphere Application Server Liberty for IBM i with the interim fixes using one of the following procedures.

- **Access the live service repository that contains the fixes, and use web-based updating.**

Use Installation Manager on your local system to update WebSphere Application Server Liberty for IBM i with the interim fixes from the live web-based service repositories.

- For the live service repositories, use the same URLs as those used for the generally available product-offering repositories during installation. These URLs are listed in Online product repositories for WebSphere Application Server offerings.
- These locations do not contain web pages that you can access using a web browser. They are remote web-based repository locations that you specify for Installation Manager so that it can maintain the offering.

To install an interim fix from a service repository, perform the following actions:

- a. If you do not already have Installation Manager credential-storage and master-password files containing your IBM software user ID and password, create files that will allow you to access the repository.

**Note:** These are the credentials that you use to access protected IBM software websites.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutilsc` command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

- b. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
- c. Stop all servers and applications on the WebSphere Application Server Liberty for IBM i installation that is being updated.
- d. On a CL command line, run the STRQSH command to start the Qshell command shell.
- e. Make sure that the umask is set to 022.

To verify the umask setting, issue the following command:

```
umask
```

To set the umask setting to 022, issue the following command:

```
umask 022
```

- f. Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager. On IBM i systems, the root directory for the Installation Manager is */QIBM/ProdData/InstallationManager*.

- g. Install the interim fix.

```
./imcl install interim_fix_name
  -installationDirectory offering_installation_location
  -repositories repository_URL
  -secureStorageFile storage_file -masterPasswordFile master_password_file
```

- h. **Optional:** List all installed packages to verify the installation:

```
./imcl listInstalledPackages -long
```

- **Download the files that contain the fixes from Fix Central, and use local updating.**

You can download compressed files that contain the fixes from Fix Central. Each compressed fix file contains an Installation Manager repository for the fix and usually has a .zip extension. After downloading the fix files, you can use Installation Manager to update WebSphere Application Server Liberty for IBM i with the interim fixes.

- a. To download the interim fixes, perform the following actions:

- 1) Go to Fix Central.
- 2) Select **WebSphere** as the product group.
- 3) Select **WebSphere Application Server Liberty for IBM i** as the product.
- 4) Select the version of the offering to be updated.
- 5) Select your operating system as the platform, and click **Continue**.
- 6) Select **Browse for fixes**, and click **Continue**.
- 7) Select the interim fixes that you want to download, and click **Continue**.
- 8) Select your download options, and click **Continue**.
- 9) Click **I agree** to agree to the terms and conditions.
- 10) Click **Download now** to download the interim fixes.
- 11) Transfer the compressed fix files in binary format to the IBM i system on which they will be installed.

- b. To install an interim fix from a downloaded file, perform the following actions:

- 1) Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
- 2) Stop all servers and applications on the WebSphere Application Server Liberty for IBM i installation that is being updated.
- 3) On a CL command line, run the STRQSH command to start the Qshell command shell.
- 4) Make sure that the umask is set to 022.

To verify the umask setting, issue the following command:

```
umask
```

To set the umask setting to 022, issue the following command:

```
umask 022
```

- 5) Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager.

On IBM i systems, the root directory for the Installation Manager is */QIBM/ProdData/InstallationManager*.

- 6) Install the interim fix.

```
./imcl install interim_fix_name  
-installationDirectory offering_installation_location  
-repositories compressed_file
```

- 7) **Optional:** List all installed packages to verify the installation:

```
./imcl listInstalledPackages -long
```

## Installing Liberty fix packs on IBM i operating systems using the command line

8.5.5.0

Product fix packs contain bundled service to bring WebSphere Application Server Liberty Network Deployment up to a new product level. Interim fixes provide corrective service for specific known problems. You can use the IBM Installation Manager command-line function to update the product with the fixes that are available for your service level of WebSphere Application Server Liberty Network Deployment installation.

### Before you begin

Contact the IBM Software Support Center for information about updates for WebSphere Application Server for IBM i. The most current information is available from the IBM Software Support Center and Fix Central.

8.5.5.6

If you want to install Liberty assets from local directory-based repositories or an instance of the Liberty Asset Repository Service, configure the repositories. For more information about the Liberty asset repositories, see “Installing assets using Installation Manager” on page 1411.

**Tip:** As an alternative to the procedure that is described in this article, Installation Manager allows you to use the **updateAll** command in a response file or on the command line to search for and update all installed packages. Use this command only if you have full control over which fixes are contained in the targeted repositories. If you create and point to a set of custom repositories that include only the specific fixes that you want to install, you should be able to use this command confidently. If you enable searching service repositories or install fixes directly from other live web-based repositories, then you might not want to select this option so that you can select only the fixes that you want to install using the **-installFixes** option with the **install** command on the command line or the **installFixes** attribute in a response file.

### About this task

**New:** Fix pack 16.0.0.2 is the next fix pack after 8.5.5.9. You can continue to use the same Version 8.5 Installation Manager repositories and offering IDs to install or update to 16.0.0.2, or you can use the new versionless repositories and offerings. For more information about fix pack 16.0.0.2, see What is new in Liberty in the new location of the latest Liberty documentation.

- You can also install fix packs using response files with Installation Manager. For information on creating and using response files, read “Installing Liberty fix packs on IBM i operating systems using response files” on page 1323 and the IBM Installation Manager Information Center.
- You cannot use the `iRemoteInstall` command to install a fix pack.

- **8.5.5.4** To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

## Procedure

1. For a list of fixes that are available for WebSphere Application Server Liberty Network Deployment installation and specific information about each fix, perform the following actions.
  - a. Go to Fix Central.
  - b. Select **WebSphere** as the product group.
  - c. Select **WebSphere Application Server** as the product.
  - d. Select the installed version.
  - e. Select your operating system as the platform, and click **Continue**.
  - f. Select **Browse for fixes**, and click **Continue**.
  - g. Click **More Information** under each fix to view information about the fix.
  - h. **Recommendation:** Make a list of the names of the fixes that you would like to install.
2. Update WebSphere Application Server Liberty Network Deployment installation with the fix pack using one of the following procedures.

- Access the live service repository that contains the fix pack, and use web-based updating.

Use Installation Manager on your local system to update WebSphere Application Server Liberty Network Deployment with the interim fixes from the live web-based service repositories.

- For the live service repositories, use the same URLs as those used for the generally available product-offering repositories during installation. These URLs are based on the following pattern:  
`http://www.ibm.com/software/repositorymanager/offering_ID`

where *offering\_ID* is the offering ID that you can find in WebSphere Application Server product offerings for supported operating systems.

- These locations do not contain web pages that you can access using a web browser. They are remote web-based repository locations that you specify for Installation Manager so that it can maintain the product.

To install a fix from a service repository, perform the following actions:

- a. If you do not already have Installation Manager credential-storage and master-password files containing your IBM software user ID and password, create files that will allow you to access the repository.

**Note:** These are the credentials that you use to access protected IBM software websites. For information on creating credential-storage and master-password files for Installation Manager, read the IBM Installation Manager Information Center.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the `imutilsc` command is unable to find the URL that is specified.

- b. Sign on to the IBM i system with a user profile that has `*ALLOBJ` and `*SECADM` special authorities.
- c. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being updated.
- d. On a CL command line, run the STRQSH command to start the Qshell command shell.
- e. Make sure that the umask is set to 022.

To verify the umask setting, issue the following command:

```
umask
```

To set the umask setting to 022, issue the following command:

```
umask 022
```

- f. Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager. On IBM i systems, the root directory for the Installation Manager is */QIBM/ProdData/InstallationManager*.
- g. Install the fix pack.

```
./imcl install offering_ID_offering_version,optional_feature_ID
-repositories source_repository
-installationDirectory offering_installation_location
-secureStorageFile storage_file -masterPasswordFile master_password_file
-acceptLicense
```

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

#### Tips:

- The *offering\_ID* is the offering ID that is listed in WebSphere Application Server product offerings for supported operating systems.
- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (8.5.5.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
./imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the **-installFixes** argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the **-installFixes** option defaults to all.
  - If the offering version is specified, the **-installFixes** option defaults to none.
- You can add a list of features that are separated by commas.

-  **8.5.5.2** You can specify additional assets to install from the Liberty Repository. For a list of Liberty Repository assets, see the downloads page on WASdev.net.

To install assets from the IBM WebSphere Liberty Repository, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later.

If you want to install Liberty Repository features, specify the short names or symbolic names on the **user.feature** option of the **-properties** parameter. Multiple feature names are separated with double commas. The following example installs the Portlet Container and Portlet Serving features:

```
-properties user.feature=portlet-2.0,,portletserving-2.0,user.accept.license=true
```

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

**8.5.5.4**

Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` addon, or install the individual features that you need from the Liberty Repository. See the following topics for more information:

- Installing Liberty Repository assets
- Liberty features

You can install the complete set of Extended Programming Model features by specifying the `user.addon` option:

```
-properties user.addon=extendedPackage-1.0,user.acceptLicense=true
```

If you upgrade WebSphere Application Server Liberty Version 8.5.5.3 or previous versions that contain the `extprogmodels` feature, Installation Manager automatically installs the `extendedPackage-1.0` add-on. You must specify the `user.acceptLicense` option:

```
-properties user.acceptLicense=true
```

**8.5.5.6**

You can also install assets from instances of the Liberty Asset Repository Service or local directory-based repositories. For more information about these asset repositories, see “Installing assets using Installation Manager” on page 1411. Add the repository on the `-repositories` parameter. The repositories are accessed in the order that they are specified. By default, the Liberty Repository is the last of the repositories that are accessed during installation. To disable access to the Liberty Repository, on the `-properties` parameter, set the `user.useLibertyRepository` option to `false`.

**8.5.5.8**

```
./imcl install com.ibm.websphere.liberty.ND.v85
-properties user.useLibertyRepository=false,user.addon=extendedPackage-1.0,user.feature=portlet-2.0
-installationDirectory /QIBM/ProdData/Liberty -acceptLicense
-repositories /QIBM/LibertyProductRepo,https://your_onprem_asset_repo_url,/QIBM/LocalAssetRepo,/QIBM/LocalAssetRepo2.zip
-sharedResourcesDirectory /QIBM/UserData/InstallationManager/IMShared
-showProgress
```

To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.

- If you obtained the fix pack by installing the WebSphere Application Server group PTF, you can use the local fix-pack repositories to install the fix pack.

For information about the local fix-pack repositories, see file `/QIBM/WAS/WASFixpacks/ReadmeV85.html` or `/QIBM/WAS/WASFixpacks/ReadmeV85.txt`.

h. **Optional:** List all installed packages to verify the installation:

```
./imcl listInstalledPackages -long
```

- Download a file that contains the fix pack from Fix Central, and use local updating.

You can download a compressed file that contains the fix pack from Fix Central. Each compressed fix file contains an Installation Manager repository for the fix pack and usually has a `.zip` extension. After downloading the fix file, you can use Installation Manager to update WebSphere Application Server LibertyNetwork Deployment with the fix pack.

a. To download the fix pack, perform the following actions:

- 1) Go to Fix Central.
- 2) Select **WebSphere** as the product group.
- 3) Select **WebSphere Application Server** as the product.
- 4) Select the installed version.
- 5) Select your operating system as the platform, and click **Continue**.
- 6) Select **Browse for fixes**, and click **Continue**.
- 7) Select the fix pack that you want to download, and click **Continue**.
- 8) Select your download options, and click **Continue**.
- 9) Click **I agree** to agree to the terms and conditions.
- 10) Click **Download now** to download the fix pack.

- 11) Transfer the compressed fix file in binary format to the IBM i systems on which it will be installed.
  - 12) Extract the compressed repository file to a directory on your system.
- b. To install a fix pack from a downloaded file, perform the following actions:
- 1) Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
  - 2) Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation that is being updated.
  - 3) On a CL command line, run the STRQSH command to start the Qshell command shell.
  - 4) Make sure that the umask is set to 022.

To verify the umask setting, issue the following command:

```
umask
```

To set the umask setting to 022, issue the following command:

```
umask 022
```

- 5) Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager.

On IBM i systems, the root directory for the Installation Manager is /QIBM/ProdData/InstallationManager.

- 6) Install the fix pack.

```
./imcl install offering_ID_offering_version,optional_feature_ID
-repositories location_of_expanded_files
-installationDirectory offering_installation_location
-acceptLicense
```

#### Tips:

- The *offering\_ID* is the offering ID that is listed in WebSphere Application Server product offerings for supported operating systems.
- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (8.5.5.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
./imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the *-installFixes* argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the *-installFixes* option defaults to all.
  - If the offering version is specified, the *-installFixes* option defaults to none.
- You can add a list of features that are separated by commas.
- You can specify additional assets to install from the Liberty Repository. For a list of Liberty Repository assets, see the downloads page on WASdev.net.

To install assets from the IBM WebSphere Liberty Repository, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later.

If you want to install Liberty Repository features, specify the short names or symbolic names on the **user.feature** option of the **-properties** parameter. Multiple feature names are separated with double commas. The following example installs the Portlet Container and Portlet Serving features:

```
-properties user.feature=portlet-2.0,,portletserving-2.0,user.accept.license=true
```

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

**8.5.5.4** Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` addon, or install the individual features that you need from the Liberty Repository. See the following topics for more information:

- Installing Liberty Repository assets
- Liberty features

You can install the complete set of Extended Programming Model features by specifying the **user.addon** option:

```
-properties user.addon=extendedPackage-1.0,user.accept.license=true
```

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

If you upgrade WebSphere Application Server Liberty Version 8.5.5.3 or previous versions that contain the `extprogmodels` feature, Installation Manager automatically installs the `extendedPackage-1.0` add-on. You must specify the **user.accept.license** option:

```
-properties user.accept.license=true
```

**8.5.5.6** You can also install assets from instances of the Liberty Asset Repository Service or local directory-based repositories. For more information about these asset repositories, see “Installing assets using Installation Manager” on page 1411. Add the repository on the **-repositories** parameter. The repositories are accessed in the order that they are specified. By default, the Liberty Repository is the last of the repositories that are accessed during installation. To disable access to the Liberty Repository, on the **-properties** parameter, set the **user.useLibertyRepository** option to `false`. **8.5.5.8**

```
imcl install com.ibm.websphere.liberty.nd.v85
-properties user.useLibertyRepository=false,user.addon=extendedPackage-1.0,user.feature=portlet-2.0
-installationDirectory D:\IBM\Liberty -acceptLicense
-repositories D:\IBM\LibertyProductRepo,https://your_onprem_asset_repo_url,D:\IBM\LocalAssetRepo,D:\IBM\LocalAssetRepo2.zip
-sharedResourcesDirectory D:\IBM\IMShared
-showProgress
```

To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.

- If you obtained the fix pack by installing the WebSphere Application Server group PTF, you can use the local fix-pack repositories to install the fix pack.

For information about the local fix-pack repositories, see file `/QIBM/WAS/WASFixpacks/ReadmeV85.html` or `/QIBM/WAS/WASFixpacks/ReadmeV85.txt`.

- 7) **Optional:** List all installed packages to verify the installation:

```
./imcl listInstalledPackages -long
```

## Installing Liberty fix packs on IBM i operating systems using response files

**8.5.5.0**

You can update WebSphere Application Server Liberty Network Deployment to a later version using Installation Manager response files.

## Before you begin

8.5.5.6

If you want to install Liberty assets from local directory-based repositories or an instance of the Liberty Asset Repository Service, configure the repositories. For more information about the Liberty asset repositories, see “Installing assets using Installation Manager” on page 1411.

**Tip:** As an alternative to the procedure that is described in this article, Installation Manager allows you to use the **updateAll** command in a response file or on the command line to search for and update all installed packages. Use this command only if you have full control over which fixes are contained in the targeted repositories. If you create and point to a set of custom repositories that include only the specific fixes that you want to install, you should be able to use this command confidently. If you enable searching service repositories or install fixes directly from other live web-based repositories, then you might not want to select this option so that you can select only the fixes that you want to install using the **-installFixes** option with the **install** command on the command line or the **installFixes** attribute in a response file.

## About this task

- | **New:** Fix pack 16.0.0.2 is the next fix pack after 8.5.5.9. You can continue to use the same Version 8.5
- | Installation Manager repositories and offering IDs to install or update to 16.0.0.2, or you can use the new
- | versionless repositories and offerings. For more information about fix pack 16.0.0.2, see What is new in
- | Liberty in the new location of the latest Liberty documentation.

8.5.5.4

To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

## Procedure

1. Optional: If the repository requires a username and password, create a credential-storage file to access this repository.

**Tip:** When creating a credential-storage file, append `/repository.config` at the end of the repository URL location if the **imutilsc** command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

2. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
3. On a CL command line, run the **STRQSH** command to start the Qshell command shell.
4. Use a response file to update the product.

Change to the `eclipse/tools` subdirectory in the directory where you installed Installation Manager, and update the product. For example:

```
./imcl -acceptLicense  
input $HOME/WASFiles/temp/update_response_file.xml  
-log $HOME/WASFiles/temp/update_log.xml  
-secureStorageFile $HOME/WASFiles/temp/credential.store -masterPasswordFile $HOME/WASFiles/master_password_file.txt
```

**Note:** The program might write important post-installation instructions to standard output.

For more information on using Installation Manager, read the IBM Installation Manager Information Center.

## Example

The following is an example of a response file for updating WebSphere Application Server LibertyNetwork Deployment to a later version.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input>
<server>
  <repository location='https://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85' />
</server>
<profile id='WebSphere Liberty V8.5' installLocation='/QIBM/ProdData/WebSphere/AppServer/V85/ND'>
  <data key='was.install.os400.profile.location' value='/QIBM/UserData/WebSphere/AppServer/V85/ND' />
</profile>
<install modify='false'>
  <offering profile='WebSphere Liberty V8.5' id='com.ibm.websphere.liberty.ND.v85'
    version='8.5.5.20101025_2108' />
</install>
<preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='/QIBM/UserData/InstallationManager/IMShared' />
<preference name='com.ibm.cic.common.core.preferences.connectTimeout' value='30' />
<preference name='com.ibm.cic.common.core.preferences.readTimeout' value='30' />
<preference name='com.ibm.cic.common.core.preferences.downloadAutoRetryCount' value='0' />
<preference name='offering.service.repositories.areUsed' value='true' />
<preference name='com.ibm.cic.common.core.preferences.ssl.nonsecureMode' value='false' />
<preference name='com.ibm.cic.common.core.preferences.http.disablePreemptiveAuthentication' value='false' />
<preference name='http.ntlm.auth.kind' value='NTLM' />
<preference name='http.ntlm.auth.enableIntegrated.win32' value='true' />
<preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true' />
<preference name='com.ibm.cic.common.core.preferences.keepFetchedFiles' value='false' />
<preference name='PassportAdvantageIsEnabled' value='false' />
<preference name='com.ibm.cic.common.core.preferences.searchForUpdates' value='false' />
</agent-input>
```

### Tips:

- The profile ID (`<profile . . . id='profile_ID' . . . >` and `<offering . . . profile='profile_ID' . . . >`) can be found when you run the `imcl listInstallationDirectories -verbose` command from the `eclipse/tools` subdirectory in the directory where you installed Installation Manager. It is the same as the package group's name.
- The *version* is a specific version of the offering to install (8.5.5.20101025\_2108 for example). This specification is optional.
  - If *version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
./imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the `-installFixes` argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the `-installFixes` option defaults to all.
  - If the offering version is specified, the `-installFixes` option defaults to none.
- If you obtained the fix pack by installing the WebSphere Application Server group PTF, you can use the local fix-pack repositories to install the fix pack.

For information about the local fix-pack repositories, see file `/QIBM/WAS/WASFixpacks/ReadmeV8.html` or `/QIBM/WAS/WASFixpacks/ReadmeV8.txt`.

-  **8.5.5.2** You can specify additional assets to install from the Liberty Repository. For a list of Liberty Repository assets, see the downloads page on WASdev.net.

To install Liberty Repository assets, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later. Previous versions of Installation Manager do not have the option to install Liberty Repository assets. If you use a response file and did not update Installation Manager to Version 1.6.2 or later, the assets that you specify in the response file are ignored during installation.

If you want to install additional features, specify two extra data key elements in your response file. You can use either the symbolic name or the short name.

The following example installs the Portlet Container and Portlet Serving features using the symbolic name.

```
<data key='user.feature' value='com.ibm.websphere.appserver.portlet-2.0,,com.ibm.websphere.appserver.portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

The following example installs the Portlet Container and Portlet Serving features using the short name:

```
<data key='user.feature' value='portlet-2.0,,portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

**8.5.5.4**

Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` addon, or install the individual features that you need from the Liberty Repository. See the following topics for more information:

- Installing Liberty Repository assets
- Liberty features

The following example installs the Extended Programming Models using the `user.addon` parameter and the Portlet Container and Portlet Serving features using the `user.feature` parameter with short names:

```
<data key='user.addon' value='extendedPackage-1.0' />
<data key='user.feature' value='portlet-2.0,,portletserving-2.0' />
<data key='user.accept.license' value='true' />
```

**8.5.5.6**

You can also install assets from an instance of the Liberty Asset Repository Service or local directory-based repositories. For more information, see “Installing assets using Installation Manager” on page 1411. Add the repository on `repository` elements. If Installation Manager does not recognize the repository, point directly to the `repository.config` file. When you install assets, the repositories are accessed in the order that you specify them.

```
<server>
<repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85" />
<repository location="https://your_onprem_asset_repo_url" />
<repository location="/QIBM/LocalAssetRepo" />
```

**8.5.5.8**

`<repository location="/QIBM/LocalAssetRepo2.zip" /> </server>` By default, the Liberty Repository is the last of the repositories that are accessed during installation. To disable access to the Liberty Repository, set the `user.useLibertyRepository` parameter to `false`:

```
<data key='user.addon' value='extendedPackage-1.0' />
<data key='user.feature' value='portlet-2.0,,portletserving-2.0' />
<data key='user.useLibertyRepository' value='false' />
```

To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.

•

**Note:** **8.5.5.3** If you are updating to Version 8.5.5.3 and previously installed Liberty Repository features but do not currently have a connection to the IBM WebSphere Liberty Repository, you cannot update using a response file. Instead, update the product by running the `imcl` command and specifying the `user.feature=""` parameter.

## Uninstalling Liberty interim fixes from IBM i operating systems using the command line

**8.5.5.0**

You can use the IBM Installation Manager command-line function to remove interim fixes from WebSphere Application Server Liberty Network Deployment.

## About this task

Use this procedure whenever you want to remove an interim fix from your system using the command line.

**Tip:** You can also uninstall interim fixes using silent response files with Installation Manager. For information on creating and using response files, read “Installing Liberty fix packs on IBM i operating systems using response files” on page 1323 and the IBM Installation Manager Information Center.

## Procedure

1. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
2. Stop all servers and applications on the WebSphere Application Server Liberty Network Deployment installation.
3. On a CL command line, run the STRQSH command to start the Qshell command shell.
4. Make sure that the umask is set to 022.

To verify the umask setting, issue the following command:

```
umask
```

To set the umask setting to 022, issue the following command:

```
umask 022
```

5. Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager. On IBM i systems, the root directory for the Installation Manager is */QIBM/ProdData/InstallationManager*.

6. Uninstall the interim fix:

```
./imcl uninstall interim_fix_name  
-installationDirectory offering_installation_location
```

7. Optional: List all installed packages to verify the uninstallation.

```
./imcl listInstalledPackages -long
```

## Uninstalling Liberty fix packs from IBM i operating systems using the command line

8.5.5.0

You can roll back WebSphere Application Server Liberty Network Deployment to an earlier version using the Installation Manager command line.

### Before you begin

**Restriction:** In order to use this procedure, you must have Installation Manager Version 1.6 or later installed on your system.

During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your computer when you install a package. If you change the default setting or delete the saved files, Installation Manager requires access to the repository that was used to install the earlier version.

**Note:** In WebSphere Application Server Version 8.5.5.0, Liberty was promoted from a feature to an independently installable offering. After updating to WebSphere Application Server Liberty Network Deployment Version 8.5.5.x from Version 8.5.0.x, you can roll back to the Version 8.5.0.x Liberty feature level that you were at before updating. If you previously had a combined full-profile and Liberty-profile installation, the Liberty feature will be reinstalled to the wlp folder when you roll back. Any user data and server configurations will not be restored. If necessary, you can copy them from the backed-up

location into the new wlp/usr folder after rollback. If any wlp.bak\_<timestamp> directories are present in your installation image, they will not be affected by the rollback. If you update and roll back multiple times between Version 8.5.0.x and Version 8.5.5.x levels, therefore, you will have multiple wlp.bak\_<timestamp> folders in your installation image. These can always be deleted, copied, or moved without negative impact to your installation.

## Procedure

1. Optional: If the repository requires a username and password, create a credential-storage file to access this repository.

**Tip:** When creating a credential-storage file, append /repository.config at the end of the repository URL location if the **imutilsc** command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

2. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
3. Stop all servers and applications on the installation that is being rolled back.
4. On a CL command line, run the **STRQSH** command to start the Qshell command shell.
5. Change to the eclipse/tools subdirectory in the directory where you installed Installation Manager.
6. Use the **imcl** command to roll back the product.

```
./imcl rollback offering_ID offering_version
  -repositories source_repository
  -installationDirectory installation_directory
  -preferences preference_key=value
  -properties property_key=value
  -secureStorageFile storage_file -masterPasswordFile master_password_file
  -acceptLicense
```

### Tips:

- The *offering\_ID* is the offering ID that is listed in WebSphere Application Server product offerings for supported operating systems.
- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to which to roll back (8.5.5.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the installation rolls back to the previously installed version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the installation rolls back to the specified earlier version of the offering and **no** interim fixes for that version are installed.
- If you previously installed Liberty Repository features and addons but do not have access to a Liberty repository when you rollback your installation, specify the following properties in the response file:

```
-properties user.addon="",user.feature=""
```

Specifying these properties enables the product to rollback and uninstalls all features and addons.

For more information on using the **imcl** command, read the IBM Installation Manager Information Center.

7. Optional: List all installed packages to verify the roll back.

```
./imcl listInstalledPackages -long
```

## Uninstalling Liberty fix packs from IBM i operating systems by using response files

8.5.5.0

You can rollback WebSphere Application Server Liberty Network Deployment to an earlier version by using Installation Manager response files.

### Before you begin

During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your computer when you install a package. If you change the default setting or delete the saved files, Installation Manager requires access to the repository that was used to install the earlier version.

**Note:** In WebSphere Application Server Version 8.5.5.0, Liberty was promoted from a feature to an independently installable offering. After updating to WebSphere Application Server Liberty Network Deployment Version 8.5.5.x from Version 8.5.0.x, you can rollback to the Version 8.5.0.x Liberty feature level that you were at before updating. If you previously had a combined full-profile and Liberty-profile installation, the Liberty feature will be reinstalled to the wlp folder when you rollback. Any user data and server configurations will not be restored. If necessary, you can copy them from the backed-up location into the new wlp/usr folder after rollback. If any wlp.bak\_<timestamp> directories are present in your installation image, they will not be affected by the rollback. If you update and rollback multiple times between Version 8.5.0.x and Version 8.5.5.x levels, therefore, you will have multiple wlp.bak\_<timestamp> folders in your installation image. These can always be deleted, copied, or moved without negative impact to your installation.

### Procedure

1. Optional: If the repository requires a username and password, create a credential-storage file to access this repository.

**Tip:** When creating a credential-storage file, append /repository.config at the end of the repository URL location if the **imutilsc** command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

2. Sign on to the IBM i system with a user profile that has \*ALLOBJ and \*SECADM special authorities.
3. Stop all servers and applications on the installation that is being rolled back.
4. On a CL command line, run the **STRQSH** command to start the Qshell command shell.
5. Use a response file to rollback the product.

Change to the eclipse/tools subdirectory in the directory where you installed Installation Manager, and rollback the product. For example:

```
./imcl
input $HOME/WASFiles/temp/rollback_response_file.xml
-log $HOME/WASFiles/temp/rollback_log.xml
-secureStorageFile $HOME/WASFiles/temp/credential.store -masterPasswordFile $HOME/WASFiles/master_password_file.txt
```

**Note:** The program might write important post-installation instructions to standard output.  
For more information on using Installation Manager, read the IBM Installation Manager Information Center.

6. Optional: List all installed packages to verify the rollback.

```
./imcl listInstalledPackages -long
```

## Example

The following is an example of a response file for rolling back the product to an earlier version.

```
<?xml version="1.0" encoding="UTF-8"?>
<agent-input>
<server>
  <repository location='https://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85' />
</server>
<profile id='WebSphere Liberty V8.5' installLocation='/QIBM/ProdData/WebSphere/AppServer/V85/ND'>
</profile>
<rollback>
  <offering profile='WebSphere Liberty V8.5' id='com.ibm.websphere.liberty.ND.v85' version='8.5.5.20101025_2108' />
</rollback>
</agent-input>
```

## Tips:

- The profile ID (<profile . . . id='profile\_ID' . . . .> and <offering . . . profile='profile\_ID' . . . .>) can be found when you run the `imcl listInstallationDirectories -verbose` command from the `eclipse/tools` subdirectory in the directory where you installed Installation Manager. It is the same as the package group's name.
- The offering ID (<offering . . . id='offering\_ID' . . . .>) can be found in WebSphere Application Server product offerings for supported operating systems.
- The *version* is a specific version of the offering to which to rollback (8.5.5.20101025\_2108 for example). This specification is optional.
  - If *version* is **not** specified, the installation rolls back to the previously installed version of the offering and **all** interim fixes for that version are installed.
  - If *version* is specified, the installation rolls back to the specified earlier version of the offering and **no** interim fixes for that version are installed.
- If you previously installed Liberty Repository features and addons but do not have access to a Liberty repository when you rollback your installation, specify the following properties in the response file:

```
<data key='user.feature' value='' />
<data key='user.addon' value='' />
```

Specifying these properties enables the product to rollback and uninstalls all features and addons.

## Using the sample response files

You can edit and use sample response files for installing, modifying, or uninstalling IBM Web Enablement Liberty for IBM i silently.

## Procedure

- “Sample response file: Installing IBM Web Enablement Liberty for IBM i”
- “Sample response file: Modifying IBM Web Enablement Liberty for IBM i” on page 1335
- “Sample response file: Uninstalling IBM Web Enablement Liberty for IBM i” on page 1339

## Sample response file: Installing IBM Web Enablement Liberty for IBM i:

You can edit and use this example of a response file for installing IBM Web Enablement Liberty for IBM i.

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- ##### Copyright #####
# Licensed Materials - Property of IBM (c) Copyright IBM Corp. 2013.
# All Rights Reserved. US Government Users Restricted Rights-Use, duplication
# or disclosure restricted by GSA ADP Schedule Contract with IBM Corp.
```

```

##### -->

<!-- ##### Frequently Asked Questions #####
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
# Installation Manager Information Center can be found at:
# http://publib.boulder.ibm.com/infocenter/install/v1r6/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
# Windows = IBMIM.exe -record c:\temp\responsefiles\WASv85.install.Win32.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
# Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv85.install.RHEL64.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse/tools subdirectory in the directory where you installed
# Installation Manager:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
# Windows = imcl.exe -acceptLicense -showProgress
# input c:\temp\responsefile\WASv85.install.Win32.xml
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input /home/user/responsefile/WASv85.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
# license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help: IBMIM -help
#
# Question 3. How do I store and pass credentials to repositories that
# require authentication?
# Answer 3. There are two methods for storing authentication credentials
# for Installation Manager depending on the version being used,
# either key ring files or storage files.
#
# Versions of Installation Manger before 1.6.2 use a key ring file to store
# encrypted credentials for authenticating with repositories. Follow this
# two-step process for creating and using a key ring file with Installation Manager.
#
# First, create a key ring file with your credentials by starting
# Installation Manager from the command line under eclipse subdirectory
# with the keyring parameter.
# Use the optional password parameter to password protect your file.
#
# Windows = IBMIM.exe -keyring <path and file name> -password <password>
# Linux, UNIX, IBM i and z/OS = ./IBMIM -keyring <path and file name>
# -password <password>
#
# Installation Manager will start in graphical mode. Verify that the
# repositories to which you need to authenticate are included in the
# preferences, File / Preferences / Repositories. If they are not
# listed, then click Add Repositories to add the URL or UNC path.
# Installation Manager will prompt for your credentials. If the repository
# is already in the list, then any attempt to access the repository location,
# such as clicking the Test Connections button, will also prompt for your
# credentials. Enter the correct credential and check the Save password
# checkbox. The credentials are saved to the key ring file you specified.
#
# Second, when you start a silent installation, run imcl under eclipse/tools
# subdirectory, and provide Installation Manager with the location of the key
# ring file and the password if the file is protected. For example:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <path and file name of response file>
# -keyring <path and name of key ring file> -password <password>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <path and file name of response file>

```

```

# -keyring <path and name of key ring file> -password <password>
#
# Versions of Installation Manager at 1.6.2 or higher use storage files
# to store encrypted credentials. Complete the following steps to create
# master password and storage files to use with Installation Manager.
#
# First, if you do not have a master password file already, create a text file
# that contains a master passphrase. An example of a passphrase is:
# "This text is the passphrase for a master password file."
#
# Next, run imutilsc under the eclipse/tools subdirectory with the following
# options to create and store user credentials in a storage file.
# -secureStorageFile <path and file name of storage file>
# -masterPasswordFile <path and file name of master password file>
# -url <repository address> or -passportAdvantage <PPA repository address>
# -userName <user name>
# -userPassword <password for user>
#
# Example of a command to create a storage file by operating system
# Windows = imutilsc saveCredential -url http://myServer -userName myUserName
# -userPassword myPassword -secureStorageFile C:\IBM\credential.store
# -masterPasswordFile C:\IBM\master_password_file.txt
# Linux, UNIX, IBM z/OS, and the OS X operating system =
# ./imutilsc saveCredential -url http://myServer -userName myUserName
# -userPassword myPassword -secureStorageFile /home/IBM/credential.store
# -masterPasswordFile /home/user/IBM/master_password_file.txt
#
# Usage hints:
# * Do not use both the -url and -passportAdvantage options in the same command.
# * Enclose file paths that include spaces with double quotation marks.
# * If you use the IBM service repositories, you can specify the value:
# http://www.ibm.com/software/repositorymanager/entitled/repository.xml
# for the -url option which is a generic service repository for IBM packages.
# * Repeat steps to store credentials for multiple users in one file.
# * Repeat steps to store credentials for multiple repositories in one file.
#
# Afterwards, when you start a silent installation, run imcl under the eclipse/tools
# subdirectory, and provide Installation Manager with the location of the storage
# file. For example:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <path and file name of response file>
# -secureStorageFile <path and name of storage file>
# -masterPasswordFile <path and name of master password file>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <path and file name of response file>
# -secureStorageFile <path and name of storage file>
# -masterPasswordFile <path and name of master password file>
#
##### -->

<!-- ##### Agent Input #####
#
# Note that the acceptLicense attribute has been deprecated.
# Use the -acceptLicense command line option to accept license agreements.
#
# The clean and temporary attributes specify the repositories and other
# preferences Installation Manager uses and whether those settings
# should persist after the installation finishes.
#
# Valid values for clean:
# true = only use the repositories and other preferences that are
# specified in the response file.
# false = use the repositories and other preferences that are
# specified in the response file and Installation Manager.
#
# Valid values for temporary:
# true = repositories and other preferences specified in the
# response file do not persist in Installation Manager.
# false = repositories and other preferences specified in the
# response file persist in Installation Manager.
#
##### -->

<agent-input clean="true" temporary="true">

<!-- ##### Repositories #####
# Repositories are locations that Installation Manager queries for
# installable packages. Repositories can be local (on the machine
# with Installation Manager) or remote (on a corporate intranet or
# hosted elsewhere on the internet).
#
# If the machine using this response file has access to the internet,
# then include the IBM WebSphere Live Update Repositories in the list
# of repository locations.
#
# If the machine using this response file cannot access the internet,
# then comment out the IBM WebSphere Live Update Repositories and
# specify the URL or UNC path to custom intranet repositories and
# directory paths to local repositories to use.

```

```

#
##### -->

<server>
<!-- ##### IBM WebSphere Live Update Repositories #####
# These repositories contain WebSphere Application Server Liberty offerings,
# and updates for those offerings
#
# To use the secure repository (https), you must have an IBM ID,
# which can be obtained by registering at: http://www.ibm.com/account
# or your Passport Advantage account.
#
# And, you must use a key ring file with your response file.
##### -->
<repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.WEBENAB.v85"/>
<!-- <repository location="https://www.ibm.com/software/rational/repositorymanager/repositories/websphere" /> -->

<!-- ##### Custom Repositories #####
# Uncomment and update the repository location key below
# to specify URLs or UNC paths to any intranet repositories
# and directory paths to local repositories to use.
##### -->
<!-- <repository location="https://w3.mycompany.com/repositories"/> -->
<!-- <repository location="/home/user/repositories/websphere"/> -->

<!-- ##### Local Repositories #####
# Uncomment and update the following line when using a local
# repository located on your own machine to install a
# WebSphere Application Server Liberty offering.
##### -->
<!-- <repository location='insert the full directory path inside single quotes' /> -->
</server>

<!-- ##### Install Packages #####
#
# Install Command
#
# Use the install command to inform Installation Manager of the
# installation packages to install.
#
# The modify attribute is optional and can be paired with an install
# command to add features or paired with an uninstall command to
# remove commands. If omitted, the default value is set to false.
# false = indicates not to modify an existing install by adding
# or removing features.
# true = indicates to modify an existing install by adding or
# removing features.
#
# The offering ID attribute is required because it specifies the
# offering to be installed. The offering listed must be present in
# at least one of the repositories listed earlier. The example
# command below contains the offering ID for the WEBENAB
# edition of WebSphere Application Server Liberty.
#
# The version attribute is optional. If a version number is provided,
# then the offering will be installed at the version level specified
# as long as it is available in the repositories. If the version
# attribute is not provided, then the default behavior is to install
# the latest version available in the repositories. The version number
# can be found in the repository.xml file in the repositories.
# For example, <offering ... version='8.5.5000.20130326_0211'>.
#
# The profile attribute is required and typically is unique to the
# offering. If modifying or updating an existing installation, the
# profile attribute must match the profile ID of the targeted installation
# of WebSphere Application Server Liberty.
#
# The features attribute is optional. Offerings always have at least
# one feature; a required core feature which is installed regardless
# of whether it is explicitly specified. If other feature names
# are provided, then only those features will be installed.
# Features must be comma delimited without spaces.
#
# The feature values for WebSphere Application Server Liberty include:
# liberty,embeddablecontainer,extprogmodels
#
# The features embeddablecontainer,extprogmodels
# are subfeatures of liberty.
#
# You can use these functions to add or remove feature embeddablecontainer or extprogmodels later.
#
# The installFixes attribute indicates whether fixes available in
# repositories are installed with the product. By default, all
# available fixes will be installed with the offering.
#
# Valid values for installFixes:
# none = do not install available fixes with the offering.
# recommended = installs all available recommended fixes with the offering.
# all = installs all available fixes with the offering.
#

```

```

# Interim fixes for offerings also can be installed while they
# are being installed by including the offering ID for the interim
# fix and specifying the profile ID.
#
# Installation Manager supports installing multiple offerings at once.
# Additional offerings can be included in the install command,
# with each offering requiring its own offering ID, version, profile value,
# and feature values.
#
# Profile Command
#
# A separate profile command must be included for each offering listed
# in the install command. The profile command informs Installation
# Manager about offering specific properties or configuration values.
#
# The installLocation specifies where the offering will be installed.
# If the response file is used to modify or update an existing
# installation, then ensure the installLocation points to the
# location where the offering was installed previously.
#
# The eclipseLocation data key should use the same directory path to
# WebSphere Application Server Liberty as the installationLocation attribute.
#
# Include data keys for product specific profile properties.
# For instance, installing WebSphere Application Server Liberty Offerings on
# a 64-bit system will require to include one of the options for an IBM Software
# Development Kit, this can be specified by data key cic.selector.arch, its value
# can be either x86 (for 32-bit), or x86_64 (for 64-bit).
#
# More details for cic.selector.arch can be found in the link below:
#
# https://infocenters.hursley.ibm.com/was/vNext/draft/help/index.jsp?topic=%2Fcom.ibm.websphere.wlp.core.doc%2Fae%2Ftwlp_ins_installation_dist_silent.html
#
##### -->

<install modify="false">
<offering id="com.ibm.websphere.liberty.WEBENAB.v85" profile="WebSphere Liberty V8.5" features="liberty,embeddablecontainer,extprogmodels" installFixes="none" />
</install>
<profile id="WebSphere Liberty V8.5" installLocation="/QIBM/ProdData/WebSphere/Liberty/V85/Express">
<data key="eclipseLocation" value="/QIBM/ProdData/WebSphere/Liberty/V85/Express" />
<data key="cic.selector.arch" value="x86_64" />
</profile>

<!-- ##### Shared Data Location #####
# Uncomment the preference for eclipseCache to set the shared data
# location the first time you use Installation Manager to do an
# installation.
#
# Eclipse cache location can be obtained from the installed.xml file found in
# Linux/Unix: /var/ibm/InstallationManager
# Windows: C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager
# from the following property:
# <property name='cacheLocation' value='C:\Program Files\IBM\IMShared' />
#
# Open the installed.xml file in a text editor because the style sheet
# might hide this value if opened in a web browser.
# For further information on how to edit preferences, refer to the public library at:
# http://publib.boulder.ibm.com/infocenter/install/v1r5/index.jsp?topic=/com.ibm.silentinstall12.doc/topics/r_silent_prefs.html
#
# After the shared data location is set, it cannot be changed
# using a response file or the graphical wizard.
#
# Ensure that the shared data location is a location that can be written
# to by all user accounts that are expected to use Installation Manager.
#
# By default, Installation Manager saves downloaded artifacts to
# the shared data location. This serves two purposes.
#
# First, if the same product is installed a more than once to the machine,
# then the files in the shared data location will be used rather than
# downloading them again.
#
# Second, during the rollback process, the saved artifacts are used.
# Otherwise, if the artifacts are not saved or are removed, then
# Installation Manager must have to access the repositories used to
# install the previous versions.
#
# Valid values for preserveDownloadedArtifacts:
# true = store downloaded artifacts in the shared data location
# false = remove downloaded artifacts from the shared data location
#
##### -->

<!--
<preference name='com.ibm.cic.common.core.preferences.eclipseCache' value='C:\Program Files\IBM\IMShared' />
<preference name='com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts' value='true' />
-->

<!-- ##### Preferences Settings #####

```

```

# Additional preferences for Installation Manager can be specified.
# These preference correspond to those that are located in the graphical
# interface under File / Preferences.
#
# If a preference command is omitted from or commented out of the response
# file, then Installation Manager uses the preference value that was
# previously set or the default value for the preference.
#
# Preference settings might be added or deprecated in new versions of
# Installation Manager. Consult the online Installation Manager
# Information Center for the latest set of preferences and
# descriptions about how to use them.
#
# http://publib.boulder.ibm.com/infocenter/install/v1r6/index.jsp

<!-- ##### Frequently Asked Questions #####
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
# Installation Manager Information Center can be found at:
# http://publib.boulder.ibm.com/infocenter/install/v1r6/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
# Windows = IBMIM.exe -record c:\temp\responsefiles\WASv85.install.Win32.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
# Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv85.install.RHEL64.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
# Windows = imcl.exe -acceptLicense -showProgress

```

```

# input c:\temp\responsefile\WASv85.install.Win32.xml
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input /home/user/responsefile/WASv85.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
# license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help: IBMIM -help
#
# Question 3. How do I store and pass credentials to repositories that
# require authentication?
# Answer 3. There are two methods for storing authentication credentials
# for Installation Manager depending on the version being used,
# either key ring files or storage files.
#
# Versions of Installation Manager before 1.6.2 use a key ring file to store
# encrypted credentials for authenticating with repositories. Follow this
# two-step process for creating and using a key ring file with Installation Manager.
#
# First, create a key ring file with your credentials by starting
# Installation Manager from the command line under eclipse subdirectory
# with the keyring parameter.
# Use the optional password parameter to password protect your file.
#
# Windows = IBMIM.exe -keyring <path and file name> -password <password>
# Linux, UNIX, IBM i and z/OS = ./IBMIM -keyring <path and file name>
# -password <password>
#
# Installation Manager will start in graphical mode. Verify that the
# repositories to which you need to authenticate are included in the
# preferences, File / Preferences / Repositories. If they are not
# listed, then click Add Repositories to add the URL or UNC path.
# Installation Manager will prompt for your credentials. If the repository
# is already in the list, then any attempt to access the repository location,
# such as clicking the Test Connections button, will also prompt for your
# credentials. Enter the correct credential and check the Save password
# checkbox. The credentials are saved to the key ring file you specified.
#
# Second, when you start a silent installation, run imcl under eclipse/tools
# subdirectory, and provide Installation Manager with the location of the key
# ring file and the password if the file is protected. For example:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <path and file name of response file>
# -keyring <path and name of key ring file> -password <password>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <path and file name of response file>
# -keyring <path and name of key ring file> -password <password>
#
# Versions of Installation Manager at 1.6.2 or higher use storage files
# to store encrypted credentials. Complete the following steps to create
# master password and storage files to use with Installation Manager.
#
# First, if you do not have a master password file already, create a text file
# that contains a master passphrase. An example of a passphrase is:
# "This text is the passphrase for a master password file."
#
# Next, run imutilsc under the eclipse/tools subdirectory with the following
# options to create and store user credentials in a storage file.
# -secureStorageFile <path and file name of storage file>
# -masterPasswordFile <path and file name of master password file>
# -url <repository address> or -passportAdvantage <PPA repository address>
# -userName <user name>
# -userPassword <password for user>
#
# Example of a command to create a storage file by operating system
# Windows = imutilsc saveCredential -url http://myServer -userName myUserName
# -userPassword myPassword -secureStorageFile C:\IBM\credential.store
# -masterPasswordFile C:\IBM\master_password_file.txt
# Linux, UNIX, IBM z/OS, and the OS X operating system =
# ./imutilsc saveCredential -url http://myServer -userName myUserName
# -userPassword myPassword -secureStorageFile /home/IBM/credential.store
# -masterPasswordFile /home/user/IBM/master_password_file.txt
#
# Usage hints:
# * Do not use both the -url and -passportAdvantage options in the same command.
# * Enclose file paths that include spaces with double quotation marks.
# * If you use the IBM service repositories, you can specify the value:
# http://www.ibm.com/software/repositorymanager/entitled/repository.xml
# for the -url option which is a generic service repository for IBM packages.
# * Repeat steps to store credentials for multiple users in one file.
# * Repeat steps to store credentials for multiple repositories in one file.
#
# Afterwards, when you start a silent installation, run imcl under the eclipse/tools
# subdirectory, and provide Installation Manager with the location of the storage
# file. For example:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <path and file name of response file>
# -secureStorageFile <path and name of storage file>

```

```

# -masterPasswordFile <path and name of master password file>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <path and file name of response file>
# -secureStorageFile <path and name of storage file>
# -masterPasswordFile <path and name of master password file>
#

<!-- ##### Agent Input #####
#
# The clean and temporary attributes specify the repositories and other
# preferences Installation Manager uses and whether those settings
# should persist after the installation finishes.
#
# Valid values for clean:
# true = only use the repositories and other preferences that are
# specified in the response file.
# false = use the repositories and other preferences that are
# specified in the response file and Installation Manager.
#
# Valid values for temporary:
# true = repositories and other preferences specified in the
# response file do not persist in Installation Manager.
# false = repositories and other preferences specified in the
# response file persist in Installation Manager.
#
##### -->

<agent-input clean="true" temporary="true">

<!-- ##### Repositories #####
# Repositories are locations that Installation Manager queries for
# installable packages. Repositories can be local (on the machine
# with Installation Manager) or remote (on a corporate intranet or
# hosted elsewhere on the internet).
#
# If the machine using this response file has access to the internet,
# then include the IBM WebSphere Live Update Repositories in the list
# of repository locations.
#
# If the machine using this response file cannot access the internet,
# then comment out the IBM WebSphere Live Update Repositories and
# specify the URL or UNC path to custom intranet repositories and
# directory paths to local repositories to use.
#
##### -->

<server>
  <!-- ##### IBM WebSphere Live Update Repositories #####
  # These repositories contain WebSphere Application Server Liberty offerings,
  # and updates for those offerings
  #
  # To use the secure repository (https), you must have an IBM ID,
  # which can be obtained by registering at: http://www.ibm.com/account
  # or your Passport Advantage account.
  #
  # And, you must use a key ring file with your response file.
  ##### -->
  <repository location="http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.WEBENAB.v85"/>
  <!-- <repository location="https://www.ibm.com/software/rational/repositorymanager/repositories/websphere" /> -->

  <!-- ##### Custom Repositories #####
  # Uncomment and update the repository location key below
  # to specify URLs or UNC paths to any intranet repositories
  # and directory paths to local repositories to use.
  ##### -->
  <!-- <repository location="https://w3.mycompany.com/repositories"/> -->
  <!-- <repository location="/home/user/repositories/websphere/" /> -->

  <!-- ##### Local Repositories #####
  # Uncomment and update the following line when using a local
  # repository located on your own machine to install a
  # WebSphere Application Server Liberty offering.
  ##### -->
  <!-- <repository location="insert the full directory path inside single quotes"/> -->
</server>

<!-- ##### Modify Packages #####
#
# Install and Uninstall Commands
#
# Use the install and uninstall commands to inform Installation Manager
# of the installation packages to install or uninstall.
#
# The modify attribute is optional and can be paired with an install
# command to add features or paired with an uninstall command to
# remove commands. If omitted, the default value is set to false.
# false = indicates not to modify an existing install by adding
# or removing features.
# true = indicates to modify an existing install by adding or

```

```

#         removing features.
#
# The offering ID attribute is required because it specifies the
# offering to be installed. The offering listed must be present in
# at least one of the repositories listed earlier. The example
# command below contains the offering ID for the WEBENAB
# edition of WebSphere Application Server Liberty.
#
# The version attribute is optional. If a version number is provided,
# then the offering will be installed or uninstalled at the version level
# specified as long as it is available in the repositories. If the version
# attribute is not provided, then the default behavior is to install or
# uninstall the latest version available in the repositories. The version
# number can be found in the repository.xml file in the repositories.
# For example, <offering ... version='8.5.5000.20130328_1111'>.
#
# The profile attribute is required and typically is unique to the
# offering. If modifying or updating an existing installation, the
# profile attribute must match the profile ID of the targeted installation
# of WebSphere Application Server Liberty.
#
# The features attribute is optional. Offerings always have at least
# one feature; a required core feature which is installed regardless
# of whether it is explicitly specified. If other feature names
# are provided, then only those features will be installed.
# Features must be comma delimited without spaces.
#
# The feature values for WebSphere Application Server Liberty include:
# liberty,embeddablecontainer,extprogmodels
#
# The features embeddablecontainer,extprogmodels
# are subfeatures of liberty.
#
# You can use these functions to add or remove feature embeddablecontainer
# or extprogmodels later.
#
# In the example that follows, the feature embeddablecontainer and extprogmodels
# are being added and no feature are being removed from the specified offering.
#
# The installFixes attribute indicates whether fixes available in
# repositories are installed with the product. By default, all
# available fixes will be installed with the offering.
#
# Valid values for installFixes:
#     none = do not install available fixes with the offering.
#     recommended = installs all available recommended fixes with the offering.
#     all = installs all available fixes with the offering.
#
# Installation Manager supports modifying multiple offerings at once.
# Additional offerings can be included in the install and uninstall commands,
# with each offering requiring its own offering ID, version, profile value,
# and feature values.
#
# Profile Command
#
# A separate profile command must be included for each offering listed
# in the install command. The profile command informs Installation
# Manager about offering specific properties or configuration values.
#
# The installLocation specifies where the offering will be installed.
# If the response file is used to modify or update an existing
# installation, then ensure the installLocation points to the
# location where the offering was installed previously.
#
# The eclipseLocation data key should use the same directory path to
# WebSphere Application Server Liberty as the installationLocation attribute.
#
# Include data keys for product specific profile properties.
# For instance, Installing WebSphere Application Server Liberty Offerings on
# a 64-bit system will require to include one of the options for an IBM Software
# Development Kit, this can be specified by data key cic.selector.arch, its value
# can be either x86 (for 32-bit), or x86_64 (for 64-bit).
#
# More details for cic.selector.arch can be found in the link below:
#
# https://infocenters.hursley.ibm.com/was/vNext/draft/help/index.jsp?topic=%2Fcom.ibm.websphere.wlp.core.doc%2Fae%2Fwlp_ins_installation_dist_silent.html
#

<!-- ##### Shared Data Location #####
# Uncomment the preference for eclipseCache to set the shared data
# location the first time you use Installation Manager to do an

```

```

# installation.
#
# Eclipse cache location can be obtained from the installed.xml file found in
# Linux/Unix: /var/ibm/InstallationManager
# Windows: C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager
# from the following property:
# <property name='cacheLocation' value='C:\Program Files\IBM\IMShared' />
#
# Open the installed.xml file in a text editor because the style sheet
# might hide this value if opened in a web browser.
# For further information on how to edit preferences, refer to the public library at:
# http://publib.boulder.ibm.com/infocenter/install/v1r5/index.jsp?topic=/com.ibm.silentinstall12.doc/topics/r_silent_prefs.html
#
# After the shared data location is set, it cannot be changed
# using a response file or the graphical wizard.
#
# Ensure that the shared data location is a location that can be written
# to by all user accounts that are expected to use Installation Manager.
#
# By default, Installation Manager saves downloaded artifacts to
# the shared data location. This serves two purposes.
#
# First, if the same product is installed a more than once to the machine,
# then the files in the shared data location will be used rather than
# downloading them again.
#
# Second, during the rollback process, the saved artifacts are used.
# Otherwise, if the artifacts are not saved or are removed, then
# Installation Manager must have to access the repositories used to
# install the previous versions.
#
# Valid values for preserveDownloadedArtifacts:
#   true = store downloaded artifacts in the shared data location
#   false = remove downloaded artifacts from the shared data location
#
##### -->

<!-- ##### Frequently Asked Questions #####
# The latest information about using Installation Manager is
# located in the online Information Center. There you can find
# information about the commands and attributes used in
# silent installation response files.
#
# Installation Manager Information Center can be found at:
# http://publib.boulder.ibm.com/infocenter/install/v1r6/index.jsp
#
# Question 1. How do I record a response file using Installation Manager?
# Answer 1. Start Installation Manager from the command line under the
# eclipse subdirectory with the record parameter and it will generate a
# response file containing actions it performed, repositories it used, and
# its preferences settings. Optionally use the -skipInstall parameter if
# you do not want the product to be installed to the machine. Specify a
# new agentDataLocation location value when doing a new installation. Do
# not use an existing agentDataLocation for an installation because it might
# damage the installation data and prevent you from modifying, updating,
# rolling back, or uninstalling the installed packages.
#
# Windows: IBMIM -record <responseFile> -skipInstall <agentDataLocation>
# Linux or UNIX: ./IBMIM -record <responseFile> -skipInstall <agentDataLocation>
#
# For example:
# Windows = IBMIM.exe -record c:\temp\responsefiles\WASv85.install.Win32.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
# Linux or UNIX = ./IBMIM -record /home/user/responsefiles/WASv85.install.RHEL64.xml
# -skipInstall c:\temp\skipInstall\WebSphere_Temp_Registry
#
# Question 2. How do I run Installation Manager silently using response file?
# Answer 2. Create a silent installation response file and run the following command
# from the eclipse\tools subdirectory in the directory where you installed
# Installation Manager:
#
# Windows = imcl.exe -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input <response_file_path_and_name> -log <log_file_path_and_name>
#
# For example:
# Windows = imcl.exe -acceptLicense -showProgress
# input c:\temp\responsefile\WASv85.install.Win32.xml
# Linux, UNIX, IBM i and z/OS = ./imcl -acceptLicense -showProgress
# input /home/user/responsefile/WASv85.install.RHEL64.xml
#
# The -acceptLicense command must be included to indicate acceptance of all
# license agreements of all offerings being installed, updated or modified.
# The -showProgress command shows progress when running in silent mode.
# Additional commands can be displayed by requesting help: IBMIM -help
#

<!-- ##### Uninstall Packages #####
#
# Uninstall Command
#
# Use the uninstall command to inform Installation Manager of the
# installation packages to uninstall.
#
# The modify attribute is optional and can be paired with an install
# command to add features or paired with an uninstall command to
# remove commands. If omitted, the default value is set to false.
# false = indicates not to modify an existing install by adding
# or removing features.
# true = indicates to modify an existing install by adding or
# removing features.
#
# The offering ID attribute is required because it specifies the
# offering to be uninstalled. The example command below contains the
# offering ID for WebSphere Application Server Liberty WEBENAB edition.
#
# The version attribute is optional. If a version number is provided,
# then the offering will be uninstalled at the version level specified
# If the version attribute is not provided, then the default behavior is
# to uninstall the latest version. The version number can be found in
# the repository.xml file in the repositories.
# For example, <offering ... version='8.5.5000.20130326_0211'>.
#
# The profile attribute is required and must match the package group
# name for the offering to be uninstalled.
#
# The features attribute is optional. Offerings always have at least
# one feature; a required core feature which is installed regardless
# of whether it is explicitly specified. If other feature names
# are provided, then only those features will be installed.
# Features must be comma delimited without spaces.
#
# The feature values for WebSphere Application Server Liberty include:

## Installing Liberty on z/OS

### 8.5.5.0

You install the offering by using IBM Installation Manager. Installation Manager installs offerings from one or more product repositories.

### About this task

**Note:** 8.5.5.11 Support for using Java SE 6 with WebSphere Liberty ends in September 2017. After the end of support, the Liberty kernel will be recompiled and can no longer run with Java SE 6. If you continue to use Java SE 6 on earlier fix packs after the end of support date, you could expose your environment to security risks.

Java SE 8 is the recommended Java SDK because it provides the latest features and security updates.

To install WebSphere Application Server Liberty for z/OS, you need both of the following:

- Installation Manager Version 1.5.2 or later running on a z/OS system
  - To create an Installation Manager on z/OS, use one of the following procedures:
    - Install the Installation Manager installation kit (FMID HGIN140) by using SMP/E, and run batch jobs to create the Installation Manager.
    - Download the Installation Manager installation kit as a compressed file, extract it to your z/OS system, and invoke shell commands to create the Installation Manager.

**Tip:** To extract the file, you can use the unzip utility from the z/OS Unix System Services ported tools page.

**Note:** 8.5.5.4 To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

- Access to a copy of the product repository at Fix Pack 8.5.5.0 or later.
  - Perform one of the following procedures:
    - Install the WebSphere Application Server Liberty for z/OS repository (FMID HBBO850) by using SMP/E, and apply the PTFs for Fix Pack 8.5.5.0 or later.
    - Copy the compressed product repositories from the WebSphere Application Server Version 8.5.5 media to your z/OS system, and uncompress them.

### 8.5.5.1

If you are installing WebSphere Application Server Liberty Version 8.5.5.1 in console mode, you might receive warning messages similar to the following example:

```
No "conClass" attribute in "commonPanel" element of panel com.ibm.was.liberty.userdata.panel.UserData in com.ibm.was.liberty.userdata.panel.
```

This problem is caused by an IBM Installation Manager API which is deprecated in Version 1.6.2. These warning messages can be ignored. No action is required.

## Procedure

1. Create an Installation Manager.  
Perform the following procedures:
  - “Obtaining an Installation Manager installation kit for installing Liberty on z/OS”
  - “Creating an Installation Manager for installing Liberty on z/OS” on page 1345
2. Obtain the product repositories.  
Perform the following procedure: “Obtaining repositories for installing Liberty on z/OS” on page 1348.

3.  **8.5.5.6** Optional: Configure an instance of the Liberty Asset Repository Service or a local directory-based repository.  
As part of installing Liberty, you can choose to install assets from the following repositories:
  - The IBM WebSphere Liberty Repository, a public IBM-hosted repository that is accessible through the internet. For more information, see “Liberty: Liberty Repository” on page 965.
  - The Liberty Asset Repository Service, an open-source service that you can use to create an on-premises repository that is remotely accessible behind the firewall of an enterprise. For more information, see the WASdev/tool.lars project on GitHub.
  - Local directory-based repositories that are created by using the **installUtility download** action. For more information, see “Downloading assets using the installUtility command” on page 1400.

Access to the IBM WebSphere Liberty Repository is enabled by default and requires internet access. If your system does not have internet access or you want to install customized Liberty assets, set up an instance of the Liberty Asset Repository Service or a local directory-based repository, and then add the repository in Installation Manager. For more information about the Liberty repositories, see “Installing assets using Installation Manager” on page 1411.

4. Install WebSphere Application Server Liberty for z/OS.  
Perform the following procedure: “Installing WebSphere Application Server Liberty for z/OS” on page 1353.

## What to do next

You can use Installation Manager to install the Web Server Plug-ins for WebSphere Application Server on z/OS, IBM WebSphere SDK Java Technology Edition Version 7.0, and the IBM HTTP Server for WebSphere Application Server for z/OS.

## Obtaining an Installation Manager installation kit for installing Liberty on z/OS

### 8.5.5.0

The installation kit for the IBM Installation Manager is provided with the WebSphere Application Server Liberty for z/OS offering as FMID HGIN140. You can also download the IBM Installation Manager Version 1.5.2 installation kit to your z/OS system.

## Procedure

- To install the IBM Installation Manager installation kit with SMP/E:
  - If you ordered the WebSphere Application Server Liberty for z/OS offering as part of a ServerPac or SystemPac, the IBM Installation Manager installation kit will already be installed. PTFs must be installed to bring the installation kit up to Installation Manager Version 1.5.2, the minimum Installation Manager level for WebSphere Application Server Liberty for z/OS.  
Mount the installation kit file system at a location of your choice.
  - If you ordered the WebSphere Application Server Liberty for z/OS offering as part of a Custom-Built Product Delivery Offering (CBPDO), the IBM Installation Manager installation kit will be included in the CBPDO as FMID HGIN140. Install this offering following the instructions in the

Installation Manager program directory. PTFs must be installed to bring the installation kit up to Installation Manager Version 1.5.2, the minimum Installation Manager level for WebSphere Application Server Liberty for z/OS.

Mount the installation kit file system at a location of your choice.

- To install the IBM Installation Manager installation kit from a downloaded compressed file:
  1. Download a current Installation Manager kit for z/OS from Installation Manager and Packaging Utility download links.
  2. Copy the Installation Manager kit in binary to your z/OS system; for example, using FTP.
  3. Extract the installation files to a directory, such as `/usr/lpp/InstallationManager/V1R4`, using an `unzip` or `jar` command. You can obtain an `unzip` command for z/OS from IBM z/OS Unix System Services Ported Tools. If you use the `jar` command to extract the installation files, you must restore the file permissions and the execute permissions for the extracted files:

```
chmod -R 755 /usr/lpp/InstallationManager/V1R4
```

4. To set extended attributes for the installation files, run the `./set-ext-attr.sh` command. After the command completes, you can remount the installation files as read-only.

## What to do next

When the Installation Manager installation kit is available on your z/OS system, you can use it to create an Installation Manager. See “Creating an Installation Manager for installing Liberty on z/OS.”

## Creating an Installation Manager for installing Liberty on z/OS

**8.5.5.0**

You can create one or more Installation Managers on your z/OS system to install and maintain software products.

### Before you begin

In order to install WebSphere Application Server Liberty for z/OS, your Installation Manager must be at Version 1.5.2 or later.

Install the fix for z/OS APAR OA34228 on each z/OS system that will run IBM Installation Manager to allow the copying of files with extended attributes.

Decide in which of the following modes you want to run the Installation Manager:

#### admin mode

In admin mode, the Installation Manager is installed from a superuser ID (`uid=0`) and can be invoked from any superuser ID. There can only be one admin-mode Installation Manager on a system.

#### user mode

In user mode (also called nonAdmin mode), the Installation Manager can be invoked only by the user that installed it. There can only be one user-mode Installation Manager for a user.

#### group mode

In group mode, the Installation Manager can be invoked by any user ID that is connected to the owning group for the Installation Manager (the default group of the user ID that creates it). There is no limit to the number of group-mode Installation Managers that you can have on a system.

The Installation Manager will consist of two sets of files - a set of executable files that are copied or updated from the installation kit, and a set of runtime data files that describe the products installed by this Installation Manager. Both sets of files must be writeable by the Installation Manager. You must select locations for both the executable and runtime data for each Installation Manager.

Table 93. Default locations for Installation Manager files. The following table shows the default locations for the Installation Manager executable files (binaries) and runtime data on z/OS.

Files	Admin or group mode	User mode
Binaries	/InstallationManager/bin	\$HOME/InstallationManager/bin
Runtime data (also called agent data)	/InstallationManager/appdata	\$HOME/InstallationManager/appdata

These locations are assumed in the Installation Manager documentation and sample jobs. If these names are not appropriate for your system or if you choose to have several Installation Managers, you can choose different names and specify them when you create the Installation Manager.

## Procedure

1. Make sure that the fix for z/OS APAR OA34228 is installed on your z/OS system.
2. Create a user ID and group to own the Installation Manager.

This user ID must have the following attributes:

- Read/write home directory
- Read access to FACILITY profile BPX.FILEATTR.APF
- Read access to FACILITY profile BPX.FILEATTR.PROGCTL
- Read access to FACILITY profile BPX.FILEATTR.SHARELIB
- Read access to UNIXPRIV profile SUPERUSER.FILESYS.CHOWN
- Read access to UNIXPRIV profile SUPERUSER.FILESYS.CHANGEPERMS

The user ID that creates the Installation Manager will become the initial (possibly only) user ID that can invoke that particular Installation Manager. If you create an Installation Manager in group mode, the default group for this user will become the owning group for the Installation Manager. This user ID must have a read/write home directory.

You can use an existing user ID if it meets these requirements.

If you installed the Installation Manager installation kit with SMP/E, you can use the Installation Manager sample job GIN2ADMN in SGINJCL to create this user ID and group as well as to assign appropriate permissions.

When you invoke a group mode Installation Manager, your effective group must be the same as the group that created the Installation Manager.

It is no longer necessary to set your umask to allow group-write when invoking a group-mode Installation Manager. Instead, an Installation Manager running in group mode will turn on group-write by default then reset the umask to its previous value when Installation Manager processing is complete.

3. If the Installation Manager binaries and runtime data will not reside in existing read/write file systems, create file systems for the data and mount the file systems read/write.

The file systems should be owned by the user ID and group that will create the Installation Manager and have permissions 755 for an admin or user-mode Installation Manager or 775 for a group-mode Installation Manager.

If you installed the Installation Manager installation kit with SMP/E, you can use the Installation Manager sample job GIN2CFS in SGINJCL to allocate and mount a file system to hold the binaries and runtime data.

The Installation Manager creation process described in this topic will create the binaries and runtime data directories if they do not already exist.

4. Log in to the Unix system services shell under the owning user ID for the Installation Manager, and change the directory to the location of the Installation Manager installation kit.

```
cd /usr/lpp/InstallationManager/V1R5
```

The installation kit must be at Version 1.5.2 or later.

5. Run the **installc**, **userinstc**, or **groupinstc** command from the installation kit to create the Installation Manager.

- To create an Installation Manager in admin mode, issue the following command from the shell:

```
installc -acceptLicense  
-installationDirectory binaries_location  
-dataLocation appdata_location
```

- To create an Installation Manager in user mode, issue the following command from the shell:

```
userinstc -acceptLicense  
-installationDirectory binaries_location  
-dataLocation appdata_location
```

- To create an Installation Manager in group mode, issue the following command from the shell:

```
groupinstc -acceptLicense  
-installationDirectory binaries_location  
-dataLocation appdata_location
```

You can omit the **-installationDirectory** and **-dataLocation** parameters if you use the default locations.

If you used SMP/E to install the Installation Manager installation kit, you can use sample job GIN2INST in SGINJCL to create an Installation Manager.

6. You can now unmount the Installation Manager installation kit.

## What to do next

You can verify that the Installation Manager is correctly installed by logging in to the Unix System Services shell under the user ID that created the Installation Manager and running the Installation Manager `imcl` command from the `eclipse/tools` subdirectory of the Installation Manager's binaries location. For example:

```
cd /InstallationManager/bin/eclipse/tools  
imcl -version
```

You are now ready to install products using IBM Installation Manager.

**Authorizing additional users to a group-mode Installation Manager:** To allow additional users to access a group-mode Installation Manager, make sure that they meet the requirements listed in the first step of the procedure described previously and then connect them to the owning group for the Installation Manager using the TSO CONNECT command:

```
CONNECT user2 GROUP(IMGROUP)
```

To create an additional Installation Manager, follow the steps in the procedure described previously, selecting a new user ID and group (if appropriate) and new binaries and runtime data locations. Do not share binaries or runtime data locations between separate Installation Managers.

**Correcting file ownership or permission problems:** If you accidentally invoke an Installation Manager from the wrong user ID, some files might end up with ownerships that prevent normal use of the Installation Manager. To correct this problem, log on to a super user or other privileged user ID and reset the file ownership and permissions for the Installation Manager binaries and runtime data. For example:

```
chown IMADMIN:IMGROUP /InstallationManager/bin  
chmod 775 /InstallationManager/bin  
  
chown IMADMIN:IMGROUP /InstallationManager/appdata  
chmod 775 /InstallationManager/appdata
```

If the users of a group-mode Installation Manager do not have `umask` set to allow group-write permission on created files, you might also have to perform this step when switching from one user ID to another. You might also need to set permissions and owners for the product files that you install with the Installation Manager to ensure that maintenance can be performed from other user IDs in the group.

**Upgrading the Installation Manager:** To upgrade an Installation Manager to a new level of the Installation Manager product, download or install the new level of the IBM Installation Manager

installation kit and mount it on your system. Then, change directory to the new level of the installation kit and reissue the same **installc**, **userinstc**, or **groupinstc** command that you used to create the Installation Manager. This will update the Installation Manager's binaries from the new installation kit.

## Obtaining repositories for installing Liberty on z/OS

8.5.5.0

WebSphere Application Server Liberty for z/OS offerings are distributed as IBM Installation Manager repositories. These repositories contain the metadata and files that are required to create one or more levels of a particular product.

### About this task

The initial repository for the WebSphere Application Server Liberty for z/OS offering can be obtained by one of the following methods:

- Installing with SMP/E by using a ServerPac, SystemPac, or Customer-Build Product Delivery Offering (CBPDO)

This results in a repository file system that contains the initial repositories for WebSphere Application Server for z/OS (including the WebSphere Application Liberty Server Liberty for z/OS offering), IBM HTTP Server for z/OS, and Web Server Plug-ins for WebSphere Application Server for z/OS. An optional second repository contains the code for IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty.

- Copying the initial (compressed) product repositories from the product physical media or ShopzSeries to your z/OS system, and uncompressing them

When you place an order for the product (CBPDO or ServerPac) on ShopzSeries, you can select whether you want to receive either a physical tape delivery or an internet/electronic delivery.

- If you select physical tape delivery, you receive a CD or DVD that includes the IBM WebSphere Application Server Liberty for z/OS compressed repositories in a compressed file in the Additional Material directory of the CD or DVD.
- If you select internet/electronic delivery, the WebSphere Application Server Liberty for z/OS compressed repositories are shipped to you as an ISO file. You can then burn the ISO file to a CD or DVD, or you can use virtualcd software to mount and process the ISO file on your workstation.

New service levels can be installed from the web-based service repositories or downloaded as service repositories that contain extra product code. Each service repository contains all the necessary materials to upgrade any previous service level of WebSphere Application Server Liberty for z/OS to the level of the service repository.

- Applying PTFs to an SMP/E-based repository adds a single level of the service repository for each component to the SMP/E-managed repository.
- Downloading service repositories from Fix Central allows you to upgrade WebSphere Application Server components to new service levels.

Perform this procedure to obtain the repositories for WebSphere Application Server Liberty for z/OS.

### Procedure

- To install initial repositories by using SMP/E, perform the following procedure.
  1. Order an IBM ServerPac, SystemPac, or CBPDO for the WebSphere Application Server Liberty for z/OS offering.

It contains the following FMIDs:

#### HBBO850

Product repository for WebSphere Application Server for z/OS (including the WebSphere

Application Liberty Server Liberty for z/OS offering), IBM HTTP Server for z/OS, and Web Server Plug-ins for WebSphere Application Server for z/OS

### **HBJA700**

Product repository for IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty

This FMID is only needed if you plan to use IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty with WebSphere Application Server Liberty for z/OS Version 8.5.5.

2. Verify that the PTFs for Fix Pack 8.5.5.0 or later, are available and are installed.
3. Install the product repositories according to the instructions in your order.

Mount the base repository (FMID HBBO850) at a location of your choice. In the examples in this documentation, this repository is mounted at:

```
/usr/lpp/InstallationManagerRepository/HBBO850
```

If you plan to use IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty with WebSphere Application Server Liberty for z/OS Version 8.5.5, mount the repository at a location of your choice. In the examples in this documentation, these repositories are mounted at:

```
/usr/lpp/InstallationManagerRepository/HBJA700
```

- To install initial repositories without SMP/E, perform the following procedure.
  1. Obtain product media at Fix Pack 8.5.5.0 or later.
  2. Copy the following files from the media to your z/OS system. If you use FTP, be sure to transfer the files in binary format.

#### **was.repo.8550.liberty.zOS.zip**

Initial repository for WebSphere Application Server Liberty for z/OS

#### **was.repo.8550.plg.zip**

Initial repository for Web Server Plug-ins for WebSphere Application Server for z/OS

#### **was.repo.8550.ihs.zip**

Initial repository for IBM HTTP Server for z/OS

3. If you plan to use IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty with WebSphere Application Server Liberty for z/OS Version 8.5.5, copy the following file from the product media to your z/OS system. If you use FTP, be sure to transfer the file in binary format.

#### **was.repo.8550.java7.zip**

Initial repository for IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty

Uncompress each file into an empty directory. You can download an extract utility from z/OS Unix System Services ported tools.

## **Results**

If you installed the initial repository with SMP/E, you now have a single repository file system that contains materials for WebSphere Application Server Liberty for z/OS, IBM HTTP Server for z/OS, and Web Server Plug-ins for WebSphere Application Server for z/OS and a second (optional) file system that contains the IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty repository. Each repository file system contains the initial product level. If PTFs are installed, each repository file system contains a single product service level.

If you installed the initial repositories without SMP/E, you now have separate directories that contain the initial product repositories for WebSphere Application Server Liberty for z/OS, IBM HTTP Server for z/OS, Web Server Plug-ins for WebSphere Application Server for z/OS, and IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty (optional).

These repositories can be supplemented with materials from the web-based service repository or from downloaded service repositories. Service repositories can be obtained from Fix Central.

These repositories contain the necessary files to install the product code for WebSphere Application Server Liberty for z/OS, including IBM HTTP Server for z/OS, Web Server Plug-ins for WebSphere Application Server for z/OS, and IBM WebSphere SDK Java Technology Edition Version 7.0 for Liberty.

## What to do next

When you use IBM Installation Manager to install WebSphere Application Server Liberty for z/OS, specify the path to the appropriate repository in the **-repositories** parameter of the **imcl** command.

## Creating custom installation repositories with IBM Packaging Utility

8.5.5.0

IBM WebSphere Application Server Liberty uses IBM Installation Manager for installation and lifecycle management. Installation Manager accesses source repositories that contain the content for a software product installation. Repositories are available on product media, in IBM-hosted web-based repositories, and from Passport Advantage. IBM Packaging Utility can help you create and customize enterprise repositories that contain the correct combination of products and maintenance levels needed for all aspects of your business.

### About this task

You use Installation Manager to connect to an Installation Manager repository (or set of repositories) to find products and service updates that are available to you for installation. An Installation Manager repository is simply a tree-structured file folder that includes product payload and metadata. You can install the software products that you need directly from an IBM web-based service repository or download and unpack compressed files from Passport Advantage and install the products from the resulting unpacked file folders. The result of unpacking the files is also considered to be an Installation Manager repository. Like any Installation Manager repository, these unpacked files can be hosted on an internal HTTP server, FTP server, or network mount in order to make them available to the organization.

Packaging Utility is a companion tool for Installation Manager with which you can create and manage custom Installation Manager repositories for your organization. You can copy multiple packages, maintenance levels, and fixes into a single repository. Packaging Utility copies from source repositories to your target custom repositories. Source repositories can include any accessible Installation Manager repository, including IBM web-hosted product repositories and unzipped Passport Advantage downloads.

For more information on Packaging Utility, go to the IBM Packaging Utility Information Center.

### Procedure

Use Packaging Utility to create custom or "enterprise" Installation Manager repositories that contain specific products and maintenance levels that fit the needs of your business.

As an administrator, you can control the content of your enterprise repository, which then can serve as the central repository to which your organization connects in order to perform product installations and updates.

Packaging Utility essentially copies from a set of source Installation Manager repositories to a target repository and eliminates duplicate artifacts, helping to keep the repository size as small as possible. You can also delete (or "prune") a repository, removing maintenance levels or products that are not needed. You can download the latest version of Packaging Utility from the IBM Support Portal.

Like Installation Manager, Packaging Utility has GUI and command-line interfaces. You must specify repository URLs for Installation Manager repositories that contain the offerings that you wish to copy. Installation Manager repository URLs follow this pattern:

[http://www.ibm.com/software/repositorymanager/offering\\_name](http://www.ibm.com/software/repositorymanager/offering_name)

**Note:** This location does not contain a web page that you can access using a web browser. For example, WebSphere Application Server Liberty product repositories are located at the following URLs:

- WebSphere Application Server Liberty Network Deployment Version 8.5  
`http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85`
- WebSphere Application Server Liberty Network Deployment Trial Version 8.5  
`http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.NDTRIAL.v85`

See Online product repositories for WebSphere Application Server offerings for additional product repositories.

The target repository that you create with Packaging Utility will always support a full installation; therefore, you cannot use Packaging Utility to create a repository that is only a copy of a fix pack. You can, however, create a repository that contains the minimum content to support direct installation to a fix-pack level. Consider the following two examples that use the Packaging Utility command-line interface (**PUCL.exe**) that is available in the Packaging Utility installation folder.

- **Example 1**

**Note:** Note that you must read the license agreement that you can find with the product files and then signify your acceptance of the license agreement by specifying **-acceptLicense** in the command as shown in the following example.

```
PUCL copy com.ibm.websphere.liberty.ND.v85
-repositories
  http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85
-target D:\LIB_ND_version
-prompt
-showProgress
-acceptLicense
```

Since no version number is specified with the offering name, this command will create a new repository that supports direct installation to the latest fix-pack level for WebSphere Application Server Liberty Version 8.5. This new repository does not support the installation of Version 8.5.5.0, but it does support the update from an existing Version 8.5.5.0 installation to the latest version.

- **Example 2**

```
PUCL copy com.ibm.websphere.liberty.ND.v85_8.5.5.0.20110503_0200
-repositories
  http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85
-target D:\LIB_ND
-prompt
-showProgress
-acceptLicense
```

```
PUCL copy com.ibm.websphere.liberty.ND.v85_8.5.5.1.20110829_1838
-repositories
  http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.ND.v85
-target D:\LIB_ND
-prompt
-showProgress
-acceptLicense
```

The first command creates a target repository with WebSphere Application Server Liberty Version 8.5.5.0. The second command adds the Version 8.5.5.1 fix pack to the same repository. You can now use this resulting repository to install Version 8.5.5.0, install Version 8.5.5.1, or update from Version 8.5.5.0 to Version 8.5.5.1.

**Tip:** With some offerings, such as WebSphere SDK Java Technology Edition Version 7.0 for Liberty, you can use Packaging Utility with the **-platform** option (sometimes called "platform slicing") to create a repository that is scoped to the platforms and architectures that are used by your organization. This feature is available in command-line mode by specifying the **-platform** option with the `os` and `arch` arguments as shown in the following example:

```

PUCL copy com.ibm.websphere.liberty.IBMJAVA.v70
-repositories http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v70
-platform os=linux,arch=ppc64
-target D:\LIB_ND
-prompt
-showProgress
-acceptLicense</p>

```

Your repository can be scoped for platforms other than the one on which it is created or stored. For example, you can run Packaging Utility on a Windows system to create a repository with the content needed to install on a Linux system. During installation on Linux, you point Installation Manager to your custom repository.

The following table lists valid combinations for creating a local WebSphere SDK Java Technology Edition Version 7.0 for Liberty offering repository that is sliced by operating system and architecture.

*Table 94. Valid combinations for creating a local WebSphere SDK Java Technology Edition Version 7.0 for Liberty offering repository using the Packaging Utility*

Platform	Options	Resulting Repository
Windows	os=win32,arch=x86	32-bit repository for 32-bit Windows OS and 64-bit Windows
	os=win32.arch=x86_64	64-bit repository for 64-bit Windows
Linux Intel	os=linux,arch=x86	32-bit repository for 32-bit Linux Intel and 64-bit Linux Intel
	os=linux.arch=x86_64	64-bit repository for 64-bit Linux Intel
Linux Power	os=linux,arch=ppc	32-bit repository for 32-bit Linux Power and 64-bit Linux Power
	os=linux.arch=ppc64	64-bit repository for 64-bit Linux Power
zLinux	os=linux,arch=s390	32-bit repository for 32-bit zLinux and 64-bit zLinux
	os=linux.arch=s390x	64-bit repository for 64-bit zLinux
AIX	os=aix,arch=ppc	32-bit repository for 32-bit AIX and 64-bit AIX
	os=aix.arch=ppc64	64-bit repository for 64-bit AIX
Solaris Sparc	os=solaris,arch=sparc	32-bit repository for 32-bit Solaris Sparc and 64-bit Solaris Sparc
	os=solaris,arch=sparc64	64-bit repository for 64-bit Solaris Sparc
Solaris Intel	os=solaris,arch=x86_64	64-bit repository for 64-bit Solaris Intel
HP-UX Itanium	os=hpux,arch=ia64	64-bit repository for 64-bit HP-UX Itanium
z/OS	os=zos,arch=s390x	64-bit repository for z/OS

The following table lists valid combinations for creating a local WebSphere SDK Java Technology Edition Version 6.0 for Liberty offering repository that is sliced by operating system and architecture.

Table 95. Valid combinations for creating a local WebSphere SDK Java Technology Edition Version 6.0 for Liberty offering repository using the Packaging Utility

Platform	Options	Resulting Repository
Windows	os=win32,arch=x86	32-bit repository for 32-bit Windows OS and 64-bit Windows
	os=win32.arch=x86_64	64-bit repository for 64-bit Windows
Linux Intel	os=linux,arch=x86	32-bit repository for 32-bit Linux Intel and 64-bit Linux Intel
	os=linux.arch=x86_64	64-bit repository for 64-bit Linux Intel
Linux Power	os=linux,arch=ppc	32-bit repository for 32-bit Linux Power and 64-bit Linux Power
	os=linux.arch=ppc64	64-bit repository for 64-bit Linux Power
zLinux	os=linux,arch=s390	32-bit repository for 32-bit zLinux and 64-bit zLinux
	os=linux.arch=s390x	64-bit repository for 64-bit zLinux
AIX	os=aix,arch=ppc	32-bit repository for 32-bit AIX and 64-bit AIX
	os=aix.arch=ppc64	64-bit repository for 64-bit AIX
Solaris Sparc	os=solaris,arch=sparc	32-bit repository for 32-bit Solaris Sparc and 64-bit Solaris Sparc
	os=solaris,arch=sparc64	64-bit repository for 64-bit Solaris Sparc
Solaris Intel	os=solaris,arch=x86_64	64-bit repository for 64-bit Solaris Intel
HP-UX Itanium	os=hpx,arch=ia64	64-bit repository for 64-bit HP-UX Itanium

For more information on platform slicing, go to the IBM Packaging Utility Information Center.

## Installing WebSphere Application Server Liberty for z/OS

### 8.5.5.0

The product code for WebSphere Application Server Liberty for z/OS is installed using IBM Installation Manager.

### Before you begin

Create an Installation Manager on your z/OS system. You will need to know the location of the binaries directory for the Installation Manager and have access to a user ID that can invoke the Installation Manager.

Obtain the product repository for WebSphere Application Server Liberty for z/OS. The repository can be mounted read-only.

### 8.5.5.2

To install assets from the IBM WebSphere Liberty Repository, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later.

### 8.5.5.6

If you want to install Liberty assets from local directory-based repositories or an instance of the Liberty Asset Repository Service, configure the repositories. For more information about the Liberty

asset repositories, see “Installing assets using Installation Manager” on page 1411.

## About this task

**8.5.5.4** To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

## Procedure

1. Choose an installation location for this copy of WebSphere Application Server Liberty for z/OS.

This copy of the product must be mounted at this location every time Installation Manager accesses it to install, uninstall, or modify it. This does not have to be the same location at which the product will be mounted when used in production.

Installation Manager requires that every installed product or group of products have its own installation location.

2. Mount an empty file system read/write at this location.

It will require a minimum of:

- 72 megabytes (2000 tracks (3390)) for WebSphere Application Server Liberty for z/OS with no optional features
- 132 megabytes (4000 tracks (390)) for WebSphere Application Server Liberty for z/OS with all optional features
- 426 megabytes (9000 tracks (3390)) for WebSphere Application Server Liberty for z/OS with all optional features and WebSphere SDK Java Technology Edition Version 7.0 for Liberty

Set the ownership for the file system to that of the Installation Manager user ID, and set the permissions to allow group-write if it will be access by a group-mode Installation Manager. For example:

```
chown IMADMIN:IMGROUP /usr/lpp/zWebSphere/V8R5
```

```
chmod 775 /usr/lpp/zWebSphere/V8R5
```

You can use the `zCreateFileSystem.sh` script in the `eclipse/tools` subdirectory of the Installation Manager binaries location to create this file system. For example:

```
cd /InstallationManager/bin/eclipse/tools
```

```
zCreateFileSystem.sh -name WAS.v85.SBBOHFS -type ZFS  
-megabytes 1800 200 -volume PRV005  
-mountpoint /usr/lpp/zWebSphere/V8R5  
-owner IMADMIN -group IMGROUP
```

If you installed the initial product repository with SMP/E, you can use sample job BBO1CFS in the SBBOJCL dataset to allocate and mount this file system.

3. Log in to the Unix System Services shell under the Installation Manager user ID, and change the directory to the `eclipse/tools` subdirectory of the Installation Manager binaries location.

For example:

```
cd /InstallationManager/bin/eclipse/tools
```

4. If you plan to use the web-based service repository, create a keyring file on z/OS to access this repository by running the `imutilsc` command.

```
installation_manager_binaries_directory/eclipse/tools/imutilsc saveCredential  
-keyring keyring_file  
-userName user_ID -userPassword user_password  
-url http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.zOS.v85/repository.xml
```

where *keyring\_file* is the path and file name of the keyring to be created, and *user\_ID* and *user\_password* are the universal IBM user ID and password that you use to access protected IBM software websites.

For example:

```

/InstallationManager/eclipse/tools/imutilsc saveCredential
-keyring /u/jane/IBM.software.keyring
-userName jsmith01 -userPassword 732Uke1ele
-url http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.z0S.v85/repository.xml

```

Make sure that the keyring file is readable by the Installation Manager user ID.

**Note:** Starting in Installation Manager Version 1.6.2, the **-keyring** and **-password** options that have been used to access credentials in a keyring file are deprecated. When you use Installation Manager Version 1.6.2 and later, use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential storage file. There is no migration path from keyring files to storage files because of the differences in the file structures. You must create a storage file to replace a keyring file. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

5. Verify that the product repositories are available.

You do this by issuing the following Installation Manager command-line command.

```
imcl listAvailablePackages -repositories list_of_repository_locations
```

You should see one or more levels of the WebSphere Application Server Liberty for z/OS offering, `com.ibm.websphere.liberty.z0S.v85`.

The `list_of_repository_locations` should include the path to the initial product repository and the paths to any additional service repositories. Separate URLs in the `list_of_repository_locations` with commas.

To use the web-based service repository, add the **-useServiceRepository** parameter and use the **-keyring** parameter to specify a keyring file containing your IBM Software ID and password. For example:

```

imcl listAvailablePackages
-repositories /usr/lpp/InstallationManagerRepository/HBB0850
-useServiceRepository
-keyring /u/jane/IBM.software.keyring

```

6. Read the product license, which can be found in the `lafiles` subdirectory of the product repository.
7. Run the Installation Manager command-line tool to install the WebSphere Application Server Liberty for z/OS product.

```

imcl install com.ibm.websphere.liberty.z0S.v85
-installationDirectory installation_location
-repositories list_of_repository_locations
-sharedResourcesDirectory shared_data_location
-acceptLicense
[-useServiceRepository -keyring keyring_file]
[-installFixes <all | recommended | none> ]

```

The **-sharedResourcesDirectory** parameter points to a directory in which Installation Manager will store artifacts from the repository during installation processing. This value is set the first time a product is installed with a particular Installation Manager. This directory should have at least 30,000 tracks of free space. You can omit this parameter after the shared resources directory has been set.

By specifying **-acceptLicense**, you accept the terms of the product license. The relevant terms and conditions, notices, and other information are provided in the license-agreement files in the `lafiles` or `product_name/lafiles` subdirectory of the installation image or repository for this offering.

If you do not specify the product version to be installed, Installation Manager will install the latest version of the product along with any fixes in the repository locations. You can prevent the installation of fixes by specifying `-installFixes none` or install only recommended fixes by specifying `-installFixes recommended`.

If you specify the product version to be installed, any fixes in the repository locations will only be installed if you specify `-installFixes recommended` or `-installFixes all`.

You can also follow the package name (and version) with a comma and a list of optional features separated by commas. The following features are available for WebSphere Application Server Liberty for z/OS. The keyword name for each feature is provided in parentheses.

- Embeddable EJB container and JPA client (`embeddablecontainer`)

This option installs the embeddable EJB container and JPA client.

The embeddable EJB container is a Java Archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition (SE) environment. You can run enterprise beans using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.

The JPA client can be used with the embeddable EJB container to provide Java Persistence API capability in a Java SE environment.

- Extended Programming Models - `extprogmodels` (Version 8.5.5.3 and previous)

The Extended Programming Models feature provides a rich set of programming models such as Web Services, JMS (including Message-Driven Beans), and Mongo 2.0.

 **8.5.5.4** As of Fix Pack 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` add-on, or install the individual features that you need. See the complete list of Liberty features.

#### Notes:

- When you install a new copy of the WebSphere Application Server Liberty for z/OS and do not specify the features to be installed, the following features are installed by default:
  - `embeddablecontainer`
  - `extprogmodels` (for fix pack 8.5.5.3 and previous versions)
- If any features are listed, the normal list of default features is ignored and only the listed features are installed.

-  **8.5.5.4** Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` add-on, or install the individual features that you need from the Liberty Repository. See the following topics for more information:

- Installing Liberty Repository assets
- Liberty features

-  **8.5.5.2** You can specify additional assets to install from the Liberty Repository. For a list of Liberty Repository assets, see the downloads page on WASdev.net.

If you want to install Liberty Repository features, specify the short names or symbolic names on the `user.feature` option of the `-properties` parameter. Multiple feature names are separated with double commas. The following example installs the Portlet Container and Portlet Serving features:

```
-properties user.feature=portlet-2.0,,portletserving-2.0,user.accept.license=true
```

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

In Version 8.5.5.2, you cannot install the `zosLocalAdapters-1.0` or `zosConnect-1.0` features by using Installation Manager. You must use the `featureManager` command to install these features. For more information, see

- “Enabling the Liberty server environment to use optimized local adapters” on page 1697
- “Setting up z/OS Connect” on page 1536

You can install the complete set of Extended Programming Model features by specifying the `user.addon` option:

```
-properties user.addon=extendedPackage-1.0,user.accept.license=true
```

If you upgrade WebSphere Application Server Liberty Version 8.5.5.3 or previous versions that contain the `extprogmodels` feature, Installation Manager automatically installs the `extendedPackage-1.0` add-on. You must specify the `user.accept.license` option:

```
-properties user.accept.license=true
```

**8.5.5.6** You can also install assets from instances of the Liberty Asset Repository Service or local directory-based repositories. For more information about these asset repositories, see “Installing assets using Installation Manager” on page 1411. Add the repository on the `-repositories` parameter. The repositories are accessed in the order that they are specified. By default, the Liberty

Repository is the last of the repositories that are accessed during installation. To disable access to the Liberty Repository, on the **-properties** parameter, set the **user.useLibertyRepository** option to **false**.

8.5.5.8

```
imcl install com.ibm.websphere.liberty.z05.v85
-properties user.useLibertyRepository=false,user.addon=extendedPackage-1.0,user.feature=portlet-2.0
-installationDirectory /usr/lpp/zWebSphere/Liberty/V8558 -acceptLicense
-repositories /usr/lpp/InstallationManagerRepository/HBB0850,
https://your_onprem_asset_repo_url,/WAS855/LocalAssetRepo,/WAS855/LocalAssetRepo2.zip
-sharedResourcesDirectory /InstallationManager/sharedResources
-showProgress
```

To learn more about the Liberty Repository and the assets it contains, see “Liberty: Liberty Repository” on page 965.

If you installed the initial product repository with SMP/E, you can use sample job BBO1INST in the SBBOJCL dataset to perform the product installation.

8. Product installation is complete when the Installation Manager completes without error messages. Logs for the installation can be found in the logs subdirectory of the Installation Manager runtime data location.
9. When product installation is complete, unmount the product filesystem and remount it read-only for use by Liberty servers.

## Installing IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty

8.5.5.0

You can install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty using IBM Installation Manager Version 1.5.2 or later.

### Before you begin

1. Create an Installation Manager on your z/OS system.  
You will need to know the location of the binaries directory for the Installation Manager and have access to a user ID that can invoke the Installation Manager.
2. Install a copy of WebSphere Application Server Liberty for z/OS Version 8.5.
3. Obtain the product repository for IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1. The repository can be mounted read-only.

The repository for IBM WebSphere SDK Java Technology Edition Version 7.0 is part of the WebSphere Application Server for z/OS Version 8.5 product. You can install the repository with SMP/E, download the installation files from the IBM Fix Central, or install the Java SDK directly from the service repository.

8.5.5.2

For WebSphere Application Server for z/OS Version 8.5.5.2 and later, you can also install IBM WebSphere SDK Java Technology Edition Version 7.1. You can download the installation files from the IBM Fix Central, or you can install the Java SDK directly from the service repository. The Java SDK is not available in SMP/E format.

For more information about obtaining product repositories, see “Obtaining repositories for installing Liberty on z/OS” on page 1348.

### Procedure

1. Choose the installed copy of WebSphere Application Server Liberty for z/OS Version 8.5 onto which you will install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty.
2. Mount the product file system for this copy of WebSphere Application Server Liberty for z/OS Version 8.5 at the same location at which it was originally installed with IBM Installation Manager.  
The file system will require a minimum of 7,500 tracks (3390) or 350 megabytes of available disk space to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty.

You can use the `zMountFileSystem.sh` script in the `eclipse/tools` subdirectory of the Installation Manager binaries location to mount this file system. For example:

```
cd /InstallationManager/bin/eclipse/tools
zMountFileSystem.sh -name WAS.V85.SBBOHFS -type ZFS
-mountpoint /usr/lpp/zWebSphere/V8R5
```

You can add the **-owner**, **-group**, and **-perm** options to this command to set the ownership and permissions for all files in the file system.

3. Log in to the Unix System Services shell under the Installation Manager user ID, and change the directory to the `eclipse/tools` subdirectory of the Installation Manager binaries location.

For example:

```
cd /InstallationManager/bin/eclipse/tools
```

4. If you plan to use the web-based service repository, create a keyring file on z/OS to access this repository by running the **imutilsc** command, where *keyring\_file* is the path and file name of the keyring to be created, and *user\_ID* and *user\_password* are the universal IBM user ID and password that you use to access protected IBM software websites.

IBM WebSphere SDK Java Technology Edition Version 7.0:

```
installation_manager_binaries_directory/eclipse/tools/imutilsc saveCredential
-keyring keyring_file
-userName user_ID -userPassword user_password
-url http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v70/repository.xml
```

**8.5.5.2**

IBM WebSphere SDK Java Technology Edition Version 7.1:

```
installation_manager_binaries_directory/eclipse/tools/imutilsc saveCredential
-keyring keyring_file
-userName user_ID -userPassword user_password
-url http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v71/repository.xml
```

The following example creates a keyring file for IBM WebSphere SDK Java Technology Edition Version 7.0:

```
/opt/IBM/InstallationManager/eclipse/tools/imutilsc saveCredential
-keyring /u/jane/IBM.software.keyring
-userName jsmith01 -userPassword 732Ukelele
-url http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v70/repository.xml
```

**8.5.5.2**

The following example creates a keyring file for IBM WebSphere SDK Java Technology Edition Version 7.1:

```
/opt/IBM/InstallationManager/eclipse/tools/imutilsc saveCredential
-keyring /u/jane/IBM.software.keyring
-userName jsmith01 -userPassword 732Ukelele
-url http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v71/repository.xml
```

Make sure that the keyring file is readable by the Installation Manager user ID.

**Note:** Starting in Installation Manager Version 1.6.2, the **-keyring** and **-password** options that have been used to access credentials in a keyring file are deprecated. When you use Installation Manager Version 1.6.2 and later, use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential storage file. There is no migration path from keyring files to storage files because of the differences in the file structures. You must create a storage file to replace a keyring file. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

5. Verify that the product repository is available.

You do this by issuing the following Installation Manager command-line command.

```
imcl listAvailablePackages -repositories list_of_repository_locations
```

You should see one or more levels of the IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty offering:

- **8.5.5.0** com.ibm.websphere.liberty.IBMJAVA.v70
- **8.5.5.2** com.ibm.websphere.liberty.IBMJAVA.v71

The *list\_of\_repository\_locations* should include the path to the initial product repository and the paths to any additional service repositories. Separate URLs in the *list\_of\_repository\_locations* with commas. To use the web-based service repository, add the **-useServiceRepository** parameter and use the **-keyring** parameter to specify a keyring file containing your IBM Software ID and password. For example:

```
imcl listAvailablePackages
-repositories /usr/lpp/InstallationManagerRepository/HBB0850
-useServiceRepository
-keyring /u/jane/IBM.software.keyring
```

**Note:** Starting in Installation Manager Version 1.6.2, the **-keyring** and **-password** options that have been used to access credentials in a keyring file are deprecated. When you use Installation Manager Version 1.6.2 and later, use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential storage file. There is no migration path from keyring files to storage files because of the differences in the file structures. You must create a storage file to replace a keyring file. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

6. Run the Installation Manager command-line tool to install IBM WebSphere SDK Java Technology Edition Version 7.0 or 7.1 for Liberty.

IBM WebSphere SDK Java Technology Edition Version 7.0:

```
imcl install com.ibm.websphere.liberty.IBMJAVA.v70
-installationDirectory installation_location
-repositories list_of_repository_locations
-sharedResourcesDirectory shared_data_location
-acceptLicense
[-useServiceRepository -keyring keyring_file]
[-installFixes <all | recommended | none> ]
```

### 8.5.5.2

IBM WebSphere SDK Java Technology Edition Version 7.1:

```
imcl install com.ibm.websphere.liberty.IBMJAVA.v71
-installationDirectory installation_location
-repositories list_of_repository_locations
-sharedResourcesDirectory shared_data_location
-acceptLicense
[-useServiceRepository -keyring keyring_file]
[-installFixes <all | recommended | none> ]
```

The **-sharedResourcesDirectory** parameter points to a directory in which Installation Manager will store artifacts from the repository during installation processing. This value is set the first time a product is installed with a particular Installation Manager. You can omit this parameter after the shared resources directory has been set.

If you do not specify the product version to be installed, Installation Manager will install the latest version of the product along with any fixes in the repository locations. You can prevent the installation of fixes by specifying **-installFixes none** or install only recommended fixes by specifying **-installFixes recommended**.

If you specify the product version to be installed, any fixes in the repository locations will only be installed if you specify **-installFixes recommended** or **-installFixes all**.

7. Product installation is complete when the Installation Manager completes without error messages. Logs for the installation can be found in the logs subdirectory of the Installation Manager runtime data location.
8. When product installation is complete, unmount the product file system and remount it read-only for use by Liberty servers.

## Installing IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty

### 8.5.5.5

You can install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty by using IBM Installation Manager Version 1.6.2 or later.

## Before you begin

1. Create an Installation Manager on your z/OS system.  
You need to know the location of the binaries directory for the Installation Manager and have access to a user ID that can invoke the Installation Manager.
2. Install a copy of WebSphere Application Server Liberty for z/OS Version 8.5.5.
3. Obtain the product repository for IBM WebSphere SDK Java Technology Edition Version 8.0. The repository can be mounted read-only.  
You can download the repository for IBM WebSphere SDK Java Technology Edition Version 8.0 from IBM Fix Central.  
For more information about obtaining product repositories, see “Obtaining repositories for installing Liberty on z/OS” on page 1348.

## Procedure

1. Choose the installed copy of WebSphere Application Server Liberty for z/OS Version 8.5.5 onto which you install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty.
2. Mount the product file system for this copy of WebSphere Application Server Liberty for z/OS Version 8.5.5 at the same location at which it was originally installed with IBM Installation Manager.  
The file system requires a minimum of 8,500 tracks (3390) or 400 megabytes of available disk space to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty.  
You can use the `zMountFileSystem.sh` script in the `eclipse/tools` subdirectory of the Installation Manager binaries location to mount this file system. For example:

```
cd /InstallationManager/bin/eclipse/tools
```

```
zMountFileSystem.sh -name WAS.V85.SBBOHFS -type ZFS  
-mountpoint /usr/lpp/zWebSphere/V8R5
```

You can add the **-owner**, **-group**, and **-perm** options to this command to set the ownership and permissions for all files in the file system.

3. Log in to the Unix System Services shell under the Installation Manager user ID, and change the directory to the `eclipse/tools` subdirectory of the Installation Manager binaries location.

For example:

```
cd /InstallationManager/bin/eclipse/tools
```

4. Use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential storage file.

For more information on using the **-secureStorageFile** and **-masterPasswordFile** options, see Installation Manager Version 1.6 documentation.

IBM WebSphere SDK Java Technology Edition Version 8.0:

```
installation_manager_binaries_directory/eclipse/tools/imutilsc saveCredential  
-url http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.IBMJAVA.v80/repository.xml  
-userName user_ID -userPassword user_password  
-secureStorageFile storage_file -masterPasswordFile master_password_file
```

5. Verify that the product repository is available.

You do this verify by issuing the following Installation Manager command-line command.

```
imcl listAvailablePackages -repositories list_of_repository_locations
```

You should see one or more levels of the IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty offering:

- `com.ibm.websphere.liberty.IBMJAVA.v80`

The `list_of_repository_locations` should include the path to the initial product repository and the paths to any additional service repositories. Separate URLs in the `list_of_repository_locations` with commas.

To use the web-based service repository, add the **-useServiceRepository** parameter. For example:

```
imcl listAvailablePackages  
-repositories /usr/lpp/InstallationManagerRepository/HBB0850  
-useServiceRepository  
-secureStorageFile storage_file -masterPasswordFile master_password_file
```

6. Run the Installation Manager command-line tool to install IBM WebSphere SDK Java Technology Edition Version 8.0 for Liberty.

IBM WebSphere SDK Java Technology Edition Version 8.0:

```
imcl install com.ibm.websphere.liberty.IBMJAVA.v80
-installationDirectory installation_location
-repositories list_of_repository_locations
-sharedResourcesDirectory shared_data_location
-acceptLicense
[-useServiceRepository -secureStorageFile storage_file -masterPasswordFile master_password_file]
[-installFixes <all | recommended | none> ]
```

The **-sharedResourcesDirectory** parameter points to a directory in which Installation Manager stores artifacts from the repository during installation processing. This value is set the first time a product is installed with a particular Installation Manager. You can omit this parameter after the shared resources directory has been set.

If you do not specify the product version to be installed, Installation Manager installs the latest version of the product along with any fixes in the repository locations. You can prevent the installation of fixes by specifying **-installFixes none** or install only recommended fixes by specifying **-installFixes recommended**.

If you specify the product version to be installed, any fixes in the repository locations are installed only if you specify **-installFixes recommended** or **-installFixes all**.

7. Product installation is complete when the Installation Manager completes without error messages. Logs for the installation can be found in the logs subdirectory of the Installation Manager runtime data location.
8. When product installation is complete, unmount the product file system and remount it read-only for use by Liberty servers.

## Updating Liberty from Version 8.5.0 to Version 8.5.5

Distributed operating systems

IBM i

8.5.5.0

If you are updating an existing WebSphere Application Server for z/OS Version 8.5.0.x Liberty feature, you must install WebSphere Application Server Liberty for z/OS Version 8.5.5.0 or later. You cannot make an in-place update of the Version 8.5.0.x Liberty feature. Afterwards, you can copy your data and server configurations to the new installation or, if your user data are kept in another location, follow typical procedures for managing your data and server configurations.

### About this task

In WebSphere Application Server Version 8.5.5.0, Liberty was promoted from a feature to an independently installable offering. You cannot make an in-place update of the Version 8.5.0.x Liberty feature. The `wlp` folder includes the Liberty runtime and any user data or server configurations that you have saved in the `wlp/usr` folder. If you have a combined full-profile and Liberty-profile Version 8.5.0.x installation, the update program will back up the `wlp` folder for the existing Version 8.5.0.x Liberty feature into the `wlp.bak_<timestamp>` folder and uninstall the feature during an update to Version 8.5.5.0 or higher. You can continue using Liberty from the backed-up location or copy it elsewhere. To update Liberty to Version 8.5.5.0 or higher, you then must install WebSphere Application Server Liberty for z/OS (with the `com.ibm.websphere.liberty.zOS.v85` offering ID). After installing WebSphere Application Server Liberty for z/OS, you can move any user data and server configurations from the `wlp.bak_<timestamp>` folder to the new Liberty installation.

**Note:** These instructions describe updating from a combined full-profile and Liberty-profile Version 8.5.0.x installation. If you have only the Version 8.5.0.x Liberty feature installed, you should install WebSphere Application Server Liberty for z/OS Version 8.5.5.0 or higher in a different location. Then, you can copy the contents of the `wlp/usr` directory from the old installation to the `usr` directory of the new installation. If you are using `WLP_USER_DIR` and `WLP_OUTPUT_DIR` environment variables, make sure that they are pointing to the desired locations.

## Procedure

1. Update your existing combined full-profile and Liberty-profile installation to Version 8.5.5 or later following the normal update procedure.

After updating your WebSphere Application Server for z/OS installation from Version 8.5.0.x to Version 8.5.5, you can find your Liberty installation in the `<was_home>/wlp.bak_<timestamp>` folder. This backup folder contains the Liberty runtime at the level that it was before you started the update.

2. Use the backed-up Liberty runtime.

A copy of the Installation Manager installation and history information for this snapshot is also stored in the root of the backup in the `installed.xml` and `history.xml` files.

To determine what fixes have been installed in this snapshot, you can use the **bin/productInfo** command in the backed-up Liberty folder. See “Liberty:productInfo command” on page 1415 for more information.

You can continue using the Liberty runtime folder from its backed-up location, or you can copy or move it to a new location. If you have set the `WLP_USER_DIR` or `WLP_OUTPUT_DIR` environment variables, make sure that they point to the location of your user data and the location of output resources generated by your server respectively.

**Note:** Do not move the backed-up `wlp.bak_<timestamp>` folder back to `wlp` in case you decide to roll back to Version 8.5.0.x later.

If `WLP_USER_DIR` has not been set, the server configuration and shared resources are stored in the `usr` directory at the root of the server's runtime environment (`wlp_bak_<timestamp>/usr` for example). In this case, no action is required to use the backed-up runtime because the user data can still be found under the `usr` directory of the new location.

If the `WLP_OUTPUT_DIR` value is not set, the default location is in the server root directory (`wlp_bak_<timestamp>/usr/servers/<server_name>` for example). If this environment variable is not set, no action is required to use the backed up runtime because logs continue to appear under the `usr/servers/<server_name>/logs` directory of the new location.

For more information on these environment variables, see this “Customizing the Liberty environment” on page 1565.

**Note:** If the `server.xml` file or any included XML configuration file references another resource outside the server configuration directory, ensure that these resources can be found from the new server location.

Start all Liberty servers with the **--clean** parameter as a launch option. For example:

```
server start --clean
```

You need to use the **--clean** option only once. All subsequent server starts will not require it.

If you need to apply fixes to the `wlp-bak` follow the instructions in “Applying a fix pack to a Liberty Java archive installation” on page 1380.

3. Install WebSphere Application Server Liberty for z/OS Version 8.5.5 or later.

See “Installing and uninstalling Liberty using Installation Manager” on page 1164 or “Installing and uninstalling Liberty using downloaded files and archives” on page 1371.

4. Start using the WebSphere Application Server Liberty for z/OS Version 8.5.5 installation.

If the `WLP_USER_DIR` and `WLP_OUTPUT_DIR` environment variables are set, then the new Liberty installation will continue using these locations to for user data, including server configurations, and to place server generated output. In this case, it is recommended that you make a backup of the directories referenced by `WLP_USER_DIR` and `WLP_OUTPUT_DIR` before beginning to use the new installation.

If the `WLP_USER_DIR` and `WLP_OUTPUT_DIR` environment variables are not set, Liberty will use folders relative to the installed runtime by default. In this case, you should copy the contents of the backed-up Liberty runtime user folder (`wlp.bak_<timestamp>/usr`) to the `usr` folder of your new installation.

For more information on these environment variables, see this “Customizing the Liberty environment” on page 1565.

**Note:** If the `server.xml` file or any included XML configuration file references another resource outside the server configuration directory, ensure that these resources can be found from the new server location.

## Installing the Extended Programming Models on z/OS

z/OS

8.5.5.4

Installing and updating Liberty with the Extended Programming Models differs depending on the version of WebSphere Application Server.

### About this task

The Extended Programming Models provide a rich set of programming models such as web services, JMS (including Message-driven beans), and MongoDB 2.0.

How you install the Extended Programming Models depends on your version of WebSphere Application Server:

- Up to Version 8.5.5.3: Extended Programming Models are available as the `extprogmodels` Installation Manager installable feature.
- Version 8.5.5.4 and later: Extended Programming Models are available as the `extendedPackage-1.0` Liberty Repository add-on

**Note:** If you are installing or updating to Version 8.5.5.3 or earlier using a remote repository, such as IBM Passport Advantage or a centrally-hosted HTTP server, internet access is required to update the Extended Programming Models.

After you install Liberty Version 8.5.5.4 or later, you can later install the `extendedPackage-1.0` add-on by using the **featureManager** command. For Version 8.5.5.6 and later, you can also use the **installUtility** command to install the add-on from multiple types of repositories. For more information, see “Installing assets using the featureManager command” on page 1403 and “Installing assets using the installUtility command” on page 1393.

### Procedure

Install or update Liberty with the Extended Programming Models using the command line.

- V8.5.5.3 and previous versions install the `extprogmodels` feature after the product:

```
imcl install com.ibm.websphere.liberty.zOS.v85,extprogmodels
-installationDirectory /usr/lpp/zWebSphere/Liberty/V8553 -acceptLicense
-repositories /usr/lpp/InstallationManagerRepository/HBB0850
-sharedResourcesDirectory /InstallationManager/sharedResources
-showProgress
```
- V8.5.5.4 and later versions install the `extendedPackage-1.0` add-on on the **-properties user.addon** parameter:

```
imcl install com.ibm.websphere.liberty.zOS.v85
-properties user.accept.license=true,user.addon=extendedPackage-1.0
-installationDirectory /usr/lpp/zWebSphere/Liberty/V8554 -acceptLicense
-repositories /usr/lpp/InstallationManagerRepository/HBB0850
-sharedResourcesDirectory /InstallationManager/sharedResources
-showProgress
```

## Updating and uninstalling Liberty on z/OS

8.5.5.0

You can use IBM Installation Manager to update or uninstall the WebSphere Application Server Liberty for z/OS offering.

## Optional features

Certain features can be added or removed from an installed copy of the WebSphere Application Server Liberty for z/OS offering. These are called optional features. Choose the optional features for each copy of the WebSphere Application Server Liberty for z/OS code according to your needs.

See “Adding and removing features from Liberty on z/OS.”

## Maintenance

IBM regularly provides updates to the WebSphere Application Server Liberty for z/OS offering to fix defects and add new function. Fix packs contain bundled service to bring WebSphere Application Server Liberty up to a new level. Interim fixes provide updates to correct individual defects. See “Installing Liberty interim fixes and fix packs on z/OS operating systems” on page 1366.

l **New:** Liberty now follows a continuous delivery process with a new fix pack numbering scheme. Fix  
l pack 16.0.0.2 is the next fix pack after 8.5.5.9. You can continue to use the same Version 8.5 Installation  
l Manager repositories and offering IDs to install or update to 16.0.0.2, or you can use the new versionless  
l repositories and offerings. For more information about fix pack 16.0.0.2, see What is new in Liberty in the  
l new location of the latest Liberty documentation.

## Uninstalling the offering

You can use IBM Installation Manager to uninstall individual copies of WebSphere Application Server Liberty for z/OS offering code.

See “Uninstalling the Liberty offering on z/OS” on page 1371.

## Adding and removing features from Liberty on z/OS: **8.5.5.0**

Use IBM Installation Manager to add and remove features for WebSphere Application Server Liberty for z/OS.

### Before you begin

Obtain the product repository for WebSphere Application Server Liberty for z/OS. The following instructions assume that the repository is mounted at `/usr/lpp/InstallationManagerRepository/HBB0850`. The repository can be mounted read-only.

Decide which features you need. Each installed copy of WebSphere Application Server Liberty for z/OS can have a different set of installed features.

The following optional features are available for WebSphere Application Server Liberty for z/OS. The keyword name for each feature is provided in parentheses.

- Embeddable EJB container and JPA client (`embeddablecontainer`)

This option includes the embeddable EJB container and JPA client.

The embeddable EJB container is a Java Archive (JAR) file that you can use to run enterprise beans in a standalone Java Platform, Standard Edition (SE) environment. You can run enterprise beans using this embeddable container outside the application server. The embeddable EJB container is a part of the EJB 3.1 specification and is primarily used for unit testing enterprise beans business logic.

The JPA client can be used with the embeddable EJB container to provide Java Persistence API capability in a Java SE environment.

- Extended Programming Models - `extprogmodels` (Version 8.5.5.3 and previous versions)  
The Extended Programming Models feature provides a rich set of programming models such as Web Services, JMS (including Message-Driven Beans), and Mongo 2.0.

### About this task

**8.5.5.4** To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

### Procedure

1. Mount the product file system for the product to which features are being added or removed.
2. Log in to the Unix System Services shell under the Installation Manager user ID, and change the directory to the `eclipse/tools` subdirectory of the Installation Manager binaries location.

For example:

```
cd /InstallationManager/bin/eclipse/tools
```

3. View a list of the features installed with the product.

You do this by issuing the following Installation Manager command-line command:

```
imcl listInstalledPackages -features -long
```

#### Tip:

- When you install a new copy of the WebSphere Application Server Liberty for z/OS and do not specify the features to be installed, the following features are installed by default:
  - `embeddablecontainer`
  - `extprogmodels` (Version 8.5.5.3 and previous versions)

To install the product with a different assortment of features, add a complete list of features that you want (separated by commas) after the package name in the `imcl` install command. For example, the following command:

```
imcl install com.ibm.websphere.liberty.zOS.v85,embeddablecontainer
-installationDirectory installation_location
-repositories list_of_repository_locations
-sharedResourcesDirectory shared_data_location
-acceptLicense
```

would install the product with the `embeddablecontainer` feature.

-  **8.5.5.4** Beginning with Version 8.5.5.4, the `extprogmodels` feature is no longer available. Instead, install the `extendedPackage-1.0` addon, or install the individual features that you need from the Liberty Repository. See the following topics for more information:
    - Installing Liberty Repository assets
    - Liberty features
4. To add one or more features to an existing product installation, issue the `imcl` command and specify the features to be added.

For example:

```
imcl modify com.ibm.websphere.liberty.zOS.v85
-addFeatures embeddablecontainer
-repositories http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.zOS.v85
-installationDirectory installation_location
```

This will add the `embeddablecontainer` feature if it is not already installed.

5. To remove one or more features from an existing product installation, issue the `imcl` command and specify the features to be removed.

For example:

```
imcl modify com.ibm.websphere.liberty.zOS.v85
-removeFeatures embeddablecontainer
-repositories http://www.ibm.com/software/repositorymanager/com.ibm.websphere.liberty.zOS.v85
-installationDirectory installation_location
```

This will remove the `embeddablecontainer` optional feature.

**Note:** Before removing optional features, make sure that none of your applications depend on the features being present.

6. When the appropriate features are added or removed, unmount the product file system and remount it read-only for use by Liberty servers.

## What to do next

Customize or make use of any new features that you added.

## Installing Liberty interim fixes and fix packs on z/OS operating systems: **8.5.5.0**

Fix packs contain bundled service to bring WebSphere Application Server Liberty for z/OS up to a new level. Interim fixes provide corrective service for specific known problems. You can use IBM Installation Manager to update the offering with the fixes that are available for your service level of WebSphere Application Server Liberty for z/OS.

### Before you begin

Contact the IBM Software Support Center for information about updates for WebSphere Application Server Liberty for z/OS. For more information about upgrades, see the *WebSphere Application Server for z/OS: Program Directory*. The most current information is available from the IBM Software Support Center and Fix Central.

**Tip:** Although almost all of the instructions in this section of the information center will work with earlier versions of IBM Installation Manager, the information here is optimized for users who have installed or upgraded to Installation Manager Version 1.5.2 or later.

### About this task

- | **New:** Fix pack 16.0.0.2 is the next fix pack after 8.5.5.9. You can continue to use the same Version 8.5
- | Installation Manager repositories and offering IDs to install or update to 16.0.0.2, or you can use the new
- | versionless repositories and offerings. For more information about fix pack 16.0.0.2, see What is new in
- | Liberty in the new location of the latest Liberty documentation.

**8.5.5.4** To install Version 8.5.5.4 and later of Liberty, you must have IBM Installation Manager Version 1.6.2 or later.

 **8.5.5.4** When fix packs are installed, any installed Liberty features are updated to the new fix pack level. At fix pack level 8.5.5.4 and later, a set of Liberty features at the appropriate level is included in each fix pack repository that is downloaded from Fix Central or installed with SMP/E. When upgrading a copy of Liberty with Liberty features or add-ons, you must add `-properties user.accept.license=true` to the `imcl install` command.

**8.5.5.5** For Version 8.5.5.5 and later, `user.accept.license=true` is not required.

### Procedure

1. Use Installation Manager to apply the required maintenance to your dataset and file-system structure.
  - a. For a list of fixes that are available for WebSphere Application Server Liberty for z/OS and specific information about each fix, perform the following actions.
    - 1) Go to Fix Central.
    - 2) Select **WebSphere** as the product group.
    - 3) Select **WebSphere Application Server Liberty for z/OS** as the product.

- 4) Select the version of the offering to be updated.
  - 5) Select z/OS as the platform, and click **Continue**.
  - 6) Select **Browse for fixes**, and click **Continue**.
  - 7) Click **More Information** under each fix to view information about the fix.
  - 8) **Recommendation:** Make a list of the names of the fixes that you would like to install.
- b. Update WebSphere Application Server Liberty for z/OS with the fixes using one of the following procedures.

- To update the offering with interim fixes or fix packs, access the live service repository that contains the fixes and use web-based updating.

Use Installation Manager on your local system to update WebSphere Application Server Liberty for z/OS with the interim fixes from the live web-based service repositories.

- For the live service repositories, use the same URLs as those used for the generally available product-offering repositories during installation. These URLs are based on the following pattern:

```
http://www.ibm.com/software/repositorymanager/offering_ID
```

where *offering\_ID* is the offering ID that you can find in WebSphere Application Server product offerings for supported operating systems.

- These locations do not contain web pages that you can access using a web browser. They are remote web-based repository locations that you specify for Installation Manager so that it can maintain the offering.

To install a fix from a service repository, perform the following actions:

- 1) Mount the product file system, read and write, at the path at which it was originally mounted with Installation Manager.
- 2) If you do not already have Installation Manager credential-storage and master-password files containing your IBM software user ID and password, create files that will allow you to access the repository.

**Note:** These are the credentials that you use to access protected IBM software websites.

Create a credential-storage file and master-password file:

```
imutilsc saveCredential
  -secureStorageFile storage_file -masterPasswordFile master_password_file
  -userName IBM_software_ID
  -userPassword IBM_software_password
  -url repository_URL
```

**Tip:** When creating a credential-storage file, append */repository.config* at the end of the repository URL location if the **imutilsc** command is unable to find the URL that is specified.

**Note:** When you use Installation Manager Version 1.6.2 and later, you should use the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file. In versions of Installation Manager earlier than Version 1.6.2, the **-keyring** and **-password** options were used to access credentials in a keyring file. These options were deprecated in Version 1.6.2. There is no migration path from keyring files to storage files because of the differences in the file structures. For more information on using the **-secureStorageFile** and **-masterPasswordFile** options to store credentials in a credential-storage file, see the Installation Manager Version 1.6 documentation. For more information on using the **-keyring** and **-password** options to store credentials in a keyring file, see the Installation Manager Version 1.5 documentation.

- 3) From the Installation Manager user ID, perform the following actions:
  - a) Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager.

b) Install the fix.

**To install an interim fix, use this command:**

```
imcl install fix_name
  -installationDirectory offering_installation_location
  -repositories repository_URL
  -secureStorageFile storage_file -masterPasswordFile master_password_file
```

**To install a fix pack, use this command:**

```
imcl install offering_ID_offering_version
  -installationDirectory offering_installation_location
  -repositories repository_URL
  -secureStorageFile storage_file -masterPasswordFile master_password_file
  -acceptLicense
```

**Tips:**

- The *offering\_ID* is the offering ID that is listed in WebSphere Application Server product offerings for supported operating systems.
- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (8.5.5.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the `-installFixes` argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the `-installFixes` option defaults to all.
  - If the offering version is specified, the `-installFixes` option defaults to none.

**8.5.5.2**

**To install Liberty Repository assets with a fix pack, use this command:**

```
imcl install offering_ID_and_version
  -properties user.feature=feature_shortOrSymbolicName
  -installationDirectory offering_installation_location
  -repositories repository_URL
  -secureStorageFile storage_file -masterPasswordFile master_password_file
  -acceptLicense
```

**Tips:**

- To install assets from the IBM WebSphere Liberty Repository, you must have access to the internet, and you must have IBM Installation Manager Version 1.6.2 or later. For a list of Liberty Repository assets, see the downloads page on WASdev.net.
- If you want to install Liberty Repository features, specify the short names or symbolic names on the **user.feature** option of the **-properties** parameter. Multiple feature names are separated with double commas.
- **8.5.5.4** When upgrading to fix pack 8.5.5.4 or later, the `extprogmodels` install feature is converted to a Liberty addon, `extendedPackage-1.0`. The Liberty Repository must be available to make this upgrade. Also, because this addon has its own license, you must add `-properties user.accept.license=true` to the `imcl install` command. Alternately, you can remove the `extprogmodels` feature before upgrading to fix pack 8.5.5.4; see "Adding and removing features from Liberty on z/OS" on page 1364.

After the upgrade to Version 8.5.5.4, add the extendedPackage-1.0 addon or the specific Liberty features you need; see “Liberty features” on page 826.

- **8.5.5.6** You can also install assets from instances of the Liberty Asset Repository Service or local directory-based repositories. For more information about these asset repositories, see “Installing assets using Installation Manager” on page 1411. Add the repository on the **-repositories** parameter. The repositories are accessed in the order that they are specified. By default, the Liberty Repository is the last of the repositories that are accessed during installation. To disable access to the Liberty Repository, on the **-properties** parameter, set the **user.useLibertyRepository** option to false.

c) **Optional:** List all installed packages to verify the installation:

```
imcl listInstalledPackages -long
```

- To update the offering with interim fixes or fix packs, download the files that contain the fixes from Fix Central and use local updating.

You can download compressed files that contain the fixes from Fix Central. Each compressed fix file contains an Installation Manager repository for the fix and usually has a .zip extension. After downloading the fix files, you can use Installation Manager to update WebSphere Application Server Liberty for z/OS with the fixes.

1) To download the fixes, perform the following actions:

- a) Go to Fix Central.
- b) Select **WebSphere** as the product group.
- c) Select **WebSphere Application Server Liberty for z/OS** as the product.
- d) Select the version of the offering to be updated.
- e) Select z/OS as the platform, and click **Continue**.
- f) Select **Browse for fixes**, and click **Continue**.
- g) Select the fixes that you want to download, and click **Continue**.
- h) Select your download options, and click **Continue**.
- i) Click **I agree** to agree to the terms and conditions.
- j) Click **Download now** to download the fixes.
- k) Transfer the compressed fix files in binary format to the z/OS system on which they will be installed.
- l) If you are installing a fix pack, extract the compressed repository files to a directory on your system.

2) To install a fix from a downloaded file, perform the following actions:

- a) Mount the product file system, read and write, at the path at which it was originally mounted with Installation Manager.
- b) From the Installation Manager user ID, perform the following actions:
  - i. Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager.
  - ii. Install the fix.

**To install an interim fix, use this command:**

```
imcl install fix_name  
-installationDirectory offering_installation_location  
-repositories compressed_file
```

**To install a fix pack, use this command:**

```
imcl install offering_ID_offering_version  
-installationDirectory offering_installation_location  
-repositories location_of_expanded_files  
-acceptLicense
```

**Tips:**

- The *offering\_ID* is the offering ID that is listed in WebSphere Application Server product offerings for supported operating systems.
- The *offering\_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (8.5.5.20110503\_0200 for example).
  - If *offering\_version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *offering\_version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

```
imcl listAvailablePackages -repositories source_repository
```

- You can also specify none, recommended or all with the `-installFixes` argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the `-installFixes` option defaults to all.
  - If the offering version is specified, the `-installFixes` option defaults to none.

iii. **Optional:** List all installed packages to verify the installation:

```
imcl listInstalledPackages -long
```

- To update the offering with fix packs, apply fix-pack PTFs to the SMP/E-managed repository and use local updating.

You can add a new fix-pack level of the offering to the SMP/E-managed repository that contains the base offering by applying PTFs for the fix pack to the repository. See the WebSphere Application Server Liberty for z/OS service page for a listing of available fix packs and PTFs. After installing the PTFs, you can use Installation Manager to update WebSphere Application Server Liberty for z/OS with the new fix pack.

- 1) Apply the PTFs for the fix pack to the WebSphere Application Server Liberty for z/OS repository (FMID HBB0850).
- 2) Perform the following actions:
  - a) Mount the product file system, read and write, at the path at which it was originally mounted with Installation Manager.
  - b) From the Installation Manager user ID, perform the following actions:
    - i. Change to the *Installation\_Manager\_binaries/eclipse/tools* directory, where *Installation\_Manager\_binaries* is the installation root directory for the Installation Manager.
    - ii. Use the **imcl install** command to install the new fix-pack level. For example:

```
imcl install com.ibm.websphere.liberty.z0S.v85_offering_version
-installationDirectory offering_installation_location
-repositories /usr/lpp/InstallationManagerRepository/HBB0850
-acceptLicense
```

**Tips:**

- *offering\_version* can be found attached to the end of the offering ID with an underscore when you run the following command against the repository. For example:

```
imcl listAvailablePackages
-repositories /usr/lpp/InstallationManagerRepository/HBB0850
```

- When the offering is installed for use with WebSphere Application Server Liberty for z/OS, it is installed into the WebSphere Application Server Liberty for z/OS product file system.

iii. **Optional:** List all installed packages to verify the installation:

```
imcl listInstalledPackages -long
```

For more information on updating WebSphere Application Server Liberty for z/OS, see “Updating and uninstalling Liberty on z/OS” on page 1363.

2. Remount the product file system at its production location.

The file system should normally be mounted read-only.

3. Perform any other migration actions as instructed in fix or APAR cover letters.

4. Start your server(s) to complete any necessary post-installation tasks.

At server startup, the post-installer will run automatically against each node in order to update the configuration file system to the new service level.

**Note:** In Network Deployment cells, the deployment manager node must be at the same or a later service level than the cell's application server nodes. You must ensure that the deployment manager node is upgraded to the new service level.

## Uninstalling the Liberty offering on z/OS: **8.5.5.0**

Use IBM Installation Manager to uninstall copies of the product code for WebSphere Application Server Liberty for z/OS, Web Server Plug-ins for IBM WebSphere Application Server for z/OS, or IBM HTTP Server for z/OS.

### Before you begin

Make sure that you no longer need this particular copy of the product code.

### Procedure

1. Mount the file system containing the product code to be uninstalled at the installation location that Installation Manager used to install it.
2. Log in to the Unix System Services shell under the Installation Manager user ID, and change the directory to the `eclipse/tools` subdirectory of the Installation Manager binaries location.

For example:

```
cd /InstallationManager/bin/eclipse/tools
```

3. Invoke the Installation Manager `uninstall` command to perform the product uninstallation.

```
imcl uninstall package_ID  
-installationDirectory installation_location
```

For example:

```
imcl uninstall com.ibm.websphere.liberty.zOS.v85  
-installationDirectory /usr/lpp/zWebSphere/V8R5
```

Product uninstallation is complete when the Installation Manager completes without error messages. Logs for the uninstallation can be found in the `logs` subdirectory of the Installation Manager runtime data location.

4. When product uninstallation is complete, delete any remaining files from the product location.

---

## Installing and uninstalling Liberty using downloaded files and archives

**Distributed operating systems** You can install Liberty by using the WebSphere Application Server Developer Tools for Eclipse, or by extracting an archive file. **z/OS** On the z/OS platform installing Liberty by extracting an archive file is not supported.

**Distributed operating systems** **IBM i**

## About this task

To try out Liberty and use Liberty to develop applications that run on WebSphere Application Server traditional or Liberty, you can download a no-charge, unsupported edition from the WASdev download page.

To use Liberty in a production environment with guaranteed service levels and IBM support, you must purchase WebSphere Application Server (base), WebSphere Application Server Network Deployment, WebSphere Application Server Express, or WebSphere Application Server Liberty Core. Liberty is included with these editions and can also be downloaded separately, as an edition-specific Java archive (JAR) file, from Passport Advantage Online. The associated service is available from Fix Central. If you download and install Liberty from an unsupported JAR or ZIP file, you can later purchase a supported edition and upgrade the license for your existing installation.

The following table lists where you can download each type of installation archive file.

Table 96. Installation archive file locations

File	Content	Passport Advantage Online	IBM Fix Central	WASdev website
JAR files for installing a supported edition-specific V8.5.5.8 or later Liberty runtime environment  Example: wlp-nd-all-8.5.5.x.jar	<b>Runtime</b> Edition-specific, V8.5.5.8 or later  <b>Features</b> All features that apply to that edition		⬆	
ZIP files for installing an unsupported V8.5.5.6 or later Liberty runtime environment with a limited production license  Can be upgraded to a supported edition by using the license upgrade JAR file  Example: wlp-webProfile7-8.5.5.x.zip	<b>Runtime</b> V8.5.5.6 or later  <b>Features</b> Optional Java EE 7 feature sets  <b>SDK</b> Optional IBM Java 8 SDK		⬆	⬆
JAR files for installing an edition-specific V8.5.5.0 Liberty runtime environment  Example: wlp-nd-runtime-8.5.5.0.jar	<b>Runtime</b> Edition-specific, V8.5.5.0  <b>Features</b> V8.5.5.0 features	⬆		

Table 96. Installation archive file locations (continued)

File	Content	Passport Advantage Online	IBM Fix Central	WASdev website
<p>JAR files for installing an edition-specific V8.5.5.1 or later Liberty runtime environment</p> <p>The unsupported JAR file can be upgraded to a supported edition by using the license upgrade JAR file</p> <p>Example: wlp-nd-runtime-8.5.5.6.jar</p>	<p><b>Runtime</b> Edition-specific, V8.5.5.1 or later</p> <p><b>Features</b> Up to the latest levels of the V8.5.5.2 feature set</p>		Fully supported JAR files	Unsupported JAR file only
<p>JAR files for license upgrades:</p> <ul style="list-style-type: none"> <li>• Upgrade trial or unsupported editions to supported editions</li> <li>• Upgrade supported editions to other supported editions with more functionality</li> </ul> <p>Example: wlp-nd-license-8.5.5.jar</p>	No runtime environment or features	△	△	

**Distributed operating systems** For Windows, Linux, and Mac OS, you can also install the WebSphere Application Server Developer Tools for Eclipse, then use the tools to install the profile. For more information, see “Installing Liberty developer tools and (optionally) Liberty” on page 1374.

**Distributed operating systems** IBM i

## Procedure

- **8.5.5.8** You can install Liberty and all features that apply to the edition from a self-extracting JAR file.
  1. Install Liberty from the JAR file.
  2. Optional: Upgrade your product edition or license. For example, you can upgrade from WebSphere Application Server Liberty - Express to WebSphere Application Server Liberty Network Deployment for access to advanced functions.
  3. Update your Liberty installation as needed.
- **8.5.5.6** You can install Liberty and optional features in a single step by extracting an installation ZIP file. Installing Liberty from the ZIP files enables no-charge, unsupported, unlimited use of Liberty in development environments and unsupported limited use in small-scale test and production environments.
  1. Review the available installation ZIP files. You can install only the Liberty kernel with no additional features, or you can install Liberty and a set of features that support application development in certain contexts, such as Java Platform, Enterprise Edition 7.  
If you want to install Liberty and IBM SDK Java Technology Edition Version 8, choose the `wlp-webProfile7-java8-<platform>-<architecture>-<version>.zip` that fits your system.
  2. Install Liberty from the ZIP file. After you install Liberty, you have everything that you need to get started with your chosen set of features.

3. Optional: Install additional Liberty Repository assets by using the **installUtility** command. You can also uninstall any unwanted features.
  4. Optional: Upgrade your Liberty profile to an unlimited production edition. Upgrading your license gives you full access to IBM support in an unlimited test or production environment.
  5. Update your Liberty installation as needed.
- You can install Liberty from a self-extracting JAR file. The JAR files contain the Version 8.5.5.2 feature set, but you can install additional features after you install Liberty.
    1. Install Liberty from the JAR file.
    2. Install Liberty Repository assets.
    3. Optional: Upgrade your product edition or license. For example, you can upgrade from WebSphere Application Server Liberty - Express to WebSphere Application Server Liberty Network Deployment for access to advanced functions.
    4. Update your Liberty installation as needed.

## Installing Liberty developer tools and (optionally) Liberty

### Distributed operating systems

The developer tools for Liberty are available as part of the IBM WebSphere Application Server Developer Tools for Eclipse. In addition, WebSphere Application Server Developer Tools for Eclipse is a lightweight set of tools for developing, assembling, and deploying Java EE, OSGi, Web 2.0, and mobile applications to WebSphere Application Server.

### About this task

To install WebSphere Application Server Developer Tools for Eclipse, see [Installing WebSphere Application Server Developer Tools for Eclipse](#).

### What to do next

After you install the developer tools, you can optionally install WebSphere Application Server Liberty. The developer tools can install Liberty for you when you create a server for the first time. For more information about installing Liberty by using the developer tools, see “Creating a Liberty server by using developer tools” on page 1424.

To learn more about Liberty, see [Liberty overview](#).

## Installing Liberty by extracting a Java archive file

### Distributed operating systems

### IBM i

By running a self-extracting Java archive (JAR) file that contains the distribution image, you can install Liberty and you are ready to create a server.

### Before you begin

Your system must meet the operating system and Java requirements for using Liberty. See [System Requirements for WebSphere Application Server V8.5.5](#).

**IBM i** For the IBM i platform, this topic assumes that the minimum supported Java level is installed at one of the following locations:

- /QOpenSys/QIBM/ProdData/JavaVM/jdk626/32bit
- /QOpenSys/QIBM/ProdData/JavaVM/jdk626/64bit

## Procedure

1. Get a copy of the distribution image JAR file.

- **8.5.5.8** You can download a single, edition-specific archive file that contains the Liberty runtime environment with all applicable features from IBM Fix Central.

These JAR files are called `wlp-edition-all-version.jar`, such as `wlp-nd-all-8.5.5.8.jar`.

- You can download separately packaged archive files that contain the Liberty runtime with the Version 8.5.5.2 feature set.

The edition-specific runtime JAR files are called `wlp-edition-runtime-version.jar`.

- Download the archive file for the no-charge, unsupported edition from the WASdev download page. If you install from this JAR file, you can upgrade later to a supported edition.
- Download the archive file for the initial release, which includes IBM support, from Passport Advantage online. The associated fix packs are available from Fix Central.

If you install a production-licensed edition of the Liberty runtime, you can download and install an archive that contains the programming model extension features. The programming model extensions are packaged as a JAR file called `wlp-extended-version.jar`.

For a list of all available archives, see “Liberty:List of installation Java archive files” on page 1377.

2. Extract the distribution images to your preferred directory.

To extract the distribution image by using the interactive install wizard, run `java -jar wlp-archive-name.jar`. All application server files are stored in subdirectories of the `wlp` directory.

**Note:** If you are installing the separate runtime-only and programming model extensions JAR files, first extract the runtime JAR file, then extract the programming model extensions JAR file.

For a list of the available extraction options, see “Java archive file extraction options” on page 1376.

3. Optional: Set the `JAVA_HOME` property for your environment.

Liberty runs in a Java Runtime Environment (JRE). You can specify the JDK or JRE location using the `JAVA_HOME` property in the `server.env` file, as described in “Customizing the Liberty environment” on page 1565. When you set the `JAVA_HOME` property in the `server.env` file, Liberty uses the same Java runtime location regardless of the user profile that Liberty server runs under.

**IBM i** On the IBM i platform, setting the `JAVA_HOME` property as a system-level environment variable is not recommended. The IBM i platform is a shared environment, and changing system-level environment variables might affect other applications.

**Distributed operating systems** On Linux or UNIX systems, you can instead set `JAVA_HOME` in the user `.bashrc` file, or append the JDK or JRE path to the `PATH` environment variable. On Windows systems, you can instead set `JAVA_HOME` as a system environment variable, or append the JDK or JRE path to the `PATH` system variable. For example, on Windows systems you can use the following commands to set the `JAVA_HOME` property, and to add the Java `/bin` directory to the path:

```
set JAVA_HOME=C:\Progra~1\Java\JDK16
set PATH=%JAVA_HOME%\bin;%PATH%
```

**Note:** **8.5.5.11** Support for using Java SE 6 with WebSphere Liberty ends in September 2017. After the end of support, the Liberty kernel will be recompiled and can no longer run with Java SE 6. If you continue to use Java SE 6 on earlier fix packs after the end of support date, you could expose your environment to security risks.

Java SE 8 is the recommended Java SDK because it provides the latest features and security updates. You can install it by installing the IBM SDK, Java Technology Edition, Version 8 package to the package group that contains WebSphere Liberty.

**Note:** The Liberty runtime environment searches for the `java` command in this order: `JAVA_HOME` property, `JRE_HOME` property, and system `PATH` property.

For more information about supported Java environments, and where to get them, see “Minimum supported Java levels” on page 2333.

4. Optional: Upgrade your Liberty installation to a more advanced supported edition. For example, you can upgrade from WebSphere Application Server Liberty Core to WebSphere Application Server Network Deployment. For more information, see “Upgrading Liberty installations” on page 1386.

## What to do next

After you install Liberty, you can further customize your environment by installing additional assets; see “Installing Liberty Repository assets” on page 1391.

**IBM i** On the IBM i platform, after you extract the distribution image, you can configure all servers to run as jobs in the batch subsystem under the QEJBSVR user profile that is provided with the product. For more information, see “Configuring the Liberty server to start as a job in the QWAS85 subsystem on IBM i” on page 1390.

## Java archive file extraction options

You can install Liberty by extracting a Java archive (JAR) file. By running a self-extracting JAR file that contains the distribution image, you can install Liberty and you are ready to create a server.

**8.5.5.0** You can also install programming model extensions by extracting a JAR file.

### Syntax

The command syntax is as follows:

```
java -jar archive-file-name.jar [Options] [install location]
```

where *archive-file-name.jar* is the name of the archive file you are extracting.

### Note:

- If you do not specify any options, the distribution image is extracted by using the interactive installer.
- If you do not specify an installation location, the default target directory is the location of the archive file.

## Options

The following options are available for the extraction command:

**--help** Display a short explanation about how to use the command and a list of available options

**--acceptLicense**  
Automatically indicate acceptance of license terms and conditions

**--verbose**  
Display detailed information during archive extraction

**--viewLicenseAgreement**  
View license agreement

**--viewLicenseInfo**  
View license information

## Usage

The following examples demonstrate the correct syntax:

```
java -jar myarchivefile.jar
java -jar myarchivefile.jar --help
java -jar myarchivefile.jar --acceptLicense C:\Liberty-install
java -jar myarchivefile.jar --verbose
java -jar myarchivefile.jar --viewLicenseAgreement
java -jar myarchivefile.jar --viewLicenseInfo
```

## Liberty:List of installation Java archive files

**8.5.5.0**

You can install Liberty by extracting a Java archive (JAR) file.

**Note:** **8.5.5.6** You can alternatively install Liberty and optional features from the installation ZIP files. For more information, see “Installing Liberty by extracting a ZIP archive file” on page 1381.

**8.5.5.8** Java archive files that contain all applicable features

The following JAR files contain the Liberty runtime and all features that apply to the specific edition.

### WebSphere Application Server Network Deployment

wlp-nd-all-<version>.jar

The WebSphere Application Server Network Deployment Liberty runtime environment and all Liberty features that apply to the edition.

### WebSphere Application Server (base)

wlp-base-all-<version>.jar

The single-server WebSphere Application Server Liberty runtime environment and all Liberty features that apply to the edition.

### WebSphere Application Server Liberty Core

wlp-core-all-<version>.jar

The WebSphere Application Server Liberty Core runtime environment and all Liberty features that apply to the edition.

## Java archive files that contain the Version 8.5.5.2 feature set

The following JAR files contain up to the Version 8.5.5.2 feature set at the latest level of code for the fix pack that you install. You can install additional assets from the Liberty Repository. For more information, see “Installing Liberty Repository assets” on page 1391.

### WebSphere Application Server Network Deployment

**wlp-nd-runtime-<version>.jar**

Liberty for the WebSphere Application Server Network Deployment edition.

**wlp-extended-<version>.jar**

Programming model extensions, licensed for use in production on any production licensed edition other than WebSphere Application Server Liberty Core. Before you can install wlp-extended-<version>.jar, you must install a production licensed edition of Liberty, other than WebSphere Application Server Liberty Core. For a list of the features provided by the programming model extensions archive, see Extended Programming Models.

**wlp-extras-<version>.jar**

The embeddable EJB Container, and JPA client, to help with developing and testing EJB Lite and JPA applications. You must install this JAR file in an empty directory.

## WebSphere Application Server for Developers (IPLA)

### wlp-developers-runtime-ipla-*<version>*.jar

The production (IPLA) licensed Liberty for the WebSphere Application Server for Developers edition.

### wlp-extended-*<version>*.jar

Programming model extensions, licensed for use in production on any production licensed edition other than WebSphere Application Server Liberty Core. Before you can install wlp-extended-*<version>*.jar, you must install a production licensed edition of Liberty, other than WebSphere Application Server Liberty Core. For a list of the features provided by the programming model extensions archive, see Extended Programming Models.

### wlp-extras-*<version>*.jar

The embeddable EJB Container, and JPA client, to help with developing and testing EJB Lite and JPA applications. You must install this JAR file in an empty directory.

## WebSphere Application Server for Developers (ILAN)

### wlp-developers-runtime-*<version>*.jar

The developer licensed Liberty for the WebSphere Application Server for Developers edition.

### wlp-developers-extended-*<version>*.jar

Programming model extensions, licensed for use in development on the WebSphere Application Server for Developers edition. Before you can install wlp-developers-extended-*<version>*.jar, you must install Liberty for the WebSphere Application Server for Developers edition.

### wlp-developers-extras-*<version>*.jar

The embeddable EJB Container, and JPA client, to help with developing and testing EJB Lite and JPA applications. You must install this JAR file in an empty directory.

## WebSphere Application Server Network Deployment trial

### wlp-nd-runtime-trial-*<version>*.jar

Liberty for the WebSphere Application Server Network Deployment edition, licensed for trial use.

## Features included in the JAR files

The following table compares the features that are included in the JAR files that contain the Version 8.5.5.2 feature set. For more information about these features, see “Liberty features” on page 826.

Table 97. Features included in the JAR files

Feature	WebSphere Application Server Liberty Core	WebSphere Application Server (base)	WebSphere Application Server Express	WebSphere Application Server Network Deployment	WebSphere Application Server for Developers (IPLA and ILAN)
Runtime JAR files	wlp-core-runtime- <i>&lt;version&gt;</i> .jar wlp-core-trial-runtime- <i>&lt;version&gt;</i> .jar	wlp-base-runtime- <i>&lt;version&gt;</i> .jar wlp-base-trial-runtime- <i>&lt;version&gt;</i> .jar wlp-runtime- <i>&lt;version&gt;</i> .jar	wlp-express-runtime- <i>&lt;version&gt;</i> .jar wlp-express-trial-runtime- <i>&lt;version&gt;</i> .jar	wlp-nd-runtime- <i>&lt;version&gt;</i> .jar wlp-nd-trial-runtime- <i>&lt;version&gt;</i> .jar	wlp-developers-runtime-ipla- <i>&lt;version&gt;</i> .jar wlp-developers-runtime-ilan- <i>&lt;version&gt;</i> .jar
Java EE 6 Web Profile

## Applying a fix pack to a Liberty Java archive installation

Distributed operating systems

IBM i

Liberty offers a self-extracting Java archive-based installation as an alternative to using IBM Installation Manager. If you installed Liberty by using the self-extracting archive, and want to upgrade to the latest fix pack version, you can apply a new fix pack archive to a new location, then move any required user files and server configuration data.

### About this task

If you used IBM Installation Manager to install Liberty, you must use Installation Manager to apply a fix pack.

**Important:** You must apply a new fix pack archive to a new location.

### Procedure

1. Install the new runtime environment.
  - a. Copy or download the new fix pack archive onto the target system.
  - b. Launch the archive by using a Java command. You must use a Java command because the archive is an executable JAR file. Run the following command:
    - `java -jar <downloaded_archive_location>/<downloaded_archive_file_name>`

For more information about using a Java command to launch an archive, see the instructions in “Installing Liberty by extracting a Java archive file” on page 1374.
  - c. Review the license terms, and accept them to continue with the installation.
  - d. Select the installation location. Use a different location to where the previous version is installed.
2. Move any user data and server configurations. Liberty defines two locations for storing user-generated content and server configurations:
  - WLP\_USER\_DIR; The location of server configuration files, including shared resources.
  - WLP\_OUTPUT\_DIR; The location of resources generated by the server. For example, log files and temporary disk storage.

If the WLP\_USER\_DIR environment variable has been set on your system, then the new runtime environment will continue to use the same location. This results in no backup of server configuration data. To ensure that your server configuration is backed up, copy the directory referenced by WLP\_USER\_DIR to a new location on your file system. To protect the original environment, change the value of WLP\_USER\_DIR to point to the new location. During uninstallation, reset the value of WLP\_USER\_DIR to the location of the original server configuration.

If WLP\_USER\_DIR has not been set, the server configuration and shared resources are stored in the usr directory at the root of the server's runtime environment (for example, `<liberty_server_runtime_root>/usr`). During uninstallation of the runtime environment, you can reset the WLP\_USER\_DIR environment variable.

If the WLP\_OUTPUT\_DIR environment variable is set on your system, the new server also uses this location. This can result in old log files being overwritten. To ensure that old log files are protected, either update or unset the WLP\_OUTPUT\_DIR environment variable. During uninstallation, reset this value to its original value.

If the WLP\_OUTPUT\_DIR value is not set, the default location is in the server root directory (for example `<liberty_server_runtime_root>/usr/servers/<serverName>`). If the new runtime environment is installed to a new location, no updates are required during installation or uninstallation because logs continue to appear under the `usr/servers/<serverName>/logs` directory of each respective installation.

**Note:** If the `server.xml` file, or any included XML configuration file, references another resource outside the server configuration directory, these resources must also be copied across, or the references will need to be updated. This also applies to any resources that the application references directly, such as references to hardcoded paths on file systems. During uninstallation of the fix pack, these values can be manually reset to their original values.

3. Start the new server. Run `<liberty_VX+>/bin/server start <server_name>`.

### Removing a fix pack from a Liberty Java archive installation:

Distributed operating systems

IBM i

If you installed Liberty by using the self-extracting Java archive, you can uninstall a fix pack from the Liberty runtime environment in a given location by migrating any user data and server configurations to the previous Liberty profile runtime environment in a different location, and deleting the fix pack runtime environment.

#### Procedure

1. Stop all servers running on the system.
  - `<liberty_VX>/bin/server stop <server_name>`
2. Move any user data and server configurations. For more information see the Move any user data and server configurations step in the installation task.
3. Delete the fix pack runtime environment.
4. Start the servers.
  - `<liberty_VX->/bin/server start <server_name>`

## Installing Liberty by extracting a ZIP archive file

Distributed operating systems

IBM i

8.5.5.6

You can install Liberty and optional features by extracting a ZIP archive file. These ZIP files are designed to help you quickly get started with Liberty.

### Before you begin

Your system must meet the operating system and Java requirements for using Liberty. See System Requirements for WebSphere Application Server V8.5.5.

**IBM i** For the IBM i platform, this topic assumes that the minimum supported Java level is installed at one of the following locations:

- `/QOpenSys/QIBM/ProdData/JavaVM/jdk626/32bit`
- `/QOpenSys/QIBM/ProdData/JavaVM/jdk626/64bit`

## About this task

Installing Liberty from the ZIP files enables no-charge, unsupported, unlimited use of Liberty in development environments and limited use in small-scale test and production environments. For more information, see the license information and license agreement files in the `wlp\laf\files` directory or WASdev.net. For access to IBM support and unlimited test and production use, you can later purchase and upgrade to a supported edition from your existing installation.

You can choose from several ZIP files to fit your needs:

- Java Platform, Enterprise Edition (Java EE) 7 technologies: Install the Liberty runtime environment plus features that support the Java EE 7 full platform, Web Profile, or application client
- IBM Java 8: Install the Liberty runtime environment, features that support the Java EE 7 Web Profile, and IBM SDK Java Technology Edition Version 8
- **8.5.5.9** OSGi technologies: Install the Liberty runtime environment and features that support the Java EE 7 Web Profile and OSGi
- Liberty kernel only: Install only the Liberty runtime environment

For a list of the available ZIP archive files, see “Liberty: List of installation ZIP archive files” on page 1383.

 **Watch:** Video: Installing Liberty from a ZIP file shows how you can quickly install Liberty from a ZIP archive file, start the server and add applications, and upgrade to a supported installation [Transcript]

## Procedure

1. Download the ZIP file of the distribution image from Fix Central or the product asset page on WASdev.net. The `wlp-<name>-<version>.zip` files contain logical groupings of features.
2. Extract the distribution image to your preferred directory. All of the application server files are stored in subdirectories of the `wlp` directory.
3. Optional: Set the **JAVA\_HOME** property for your environment.

Liberty runs in a Java Runtime Environment (JRE). You can specify the JDK or JRE location using the **JAVA\_HOME** property in the `server.env` file, as described in “Customizing the Liberty environment” on page 1565. When you set the **JAVA\_HOME** property in the `server.env` file, Liberty uses the same Java runtime location regardless of the user profile that Liberty server runs under.

**IBM i** On the IBM i platform, setting the **JAVA\_HOME** property as a system-level environment variable is not recommended. The IBM i platform is a shared environment, and changing system-level environment variables might affect other applications.

**Distributed operating systems** On Linux or UNIX systems, you can instead set **JAVA\_HOME** in the user `.bashrc` file, or append the JDK or JRE path to the **PATH** environment variable. On Windows systems, you can instead set **JAVA\_HOME** as a system environment variable, or append the JDK or JRE path to the **PATH** system variable. For example, on Windows systems you can use the following commands to set the **JAVA\_HOME** property, and to add the Java `/bin` directory to the path:

```
set JAVA_HOME=C:\Progra~1\Java\JDK16
set PATH=%JAVA_HOME%\bin;%PATH%
```

**Note:** **8.5.5.11** Support for using Java SE 6 with WebSphere Liberty ends in September 2017. After the end of support, the Liberty kernel will be recompiled and can no longer run with Java SE 6. If you continue to use Java SE 6 on earlier fix packs after the end of support date, you could expose your environment to security risks.

Java SE 8 is the recommended Java SDK because it provides the latest features and security updates. You can install it by installing the IBM SDK, Java Technology Edition, Version 8 package to the package group that contains WebSphere Liberty.

**Note:** The Liberty runtime environment searches for the **java** command in this order: **JAVA\_HOME** property, **JRE\_HOME** property, and system **PATH** property.

For more information about supported Java environments, and where to get them, see “Minimum supported Java levels” on page 2333.

4. Optional: Upgrade your Liberty installation to an unlimited production edition. Upgrading your license gives you full access to IBM support in an unlimited test or production environment. For more information, see “Upgrading Liberty installations” on page 1386.

## What to do next

After you install Liberty from a ZIP file, you can further customize your environment by installing additional assets; see “Installing Liberty Repository assets” on page 1391.

**IBM i** On the IBM i platform, after you extract the distribution image, you can configure all servers to run as jobs in the batch subsystem under the QEJBSVR user profile that is provided with the product. For more information, see “Configuring the Liberty server to start as a job in the QWAS85 subsystem on IBM i” on page 1390.

## Liberty: List of installation ZIP archive files

Distributed operating systems

IBM i

8.5.5.6

You can install Liberty by extracting a ZIP archive file. After you install Liberty, you can install additional features by using the **installUtility** command.

The following sections list Liberty ZIP archive files. For more information about each ZIP file, see the related product asset description on the WASdev community download page.

### WAS Liberty V8.5.5.x Kernel

**wlp-kernel-*<version>*.zip**

This basic ZIP file includes only the kernel of the Liberty server and no features.

### WAS Liberty V8.5.5.x with Java EE 7 Web Profile

**wlp-webProfile7-*<version>*.zip**

This ZIP file includes the Liberty server runtime environment and features that support the Java EE 7 Web Profile.

**wlp-webProfile7-java8-*<platform>*-*<architecture>*-*<version>*.zip**

These ZIP files include the Liberty server runtime environment, IBM SDK Java Technology Edition Version 8, and features that support the Java EE 7 Web Profile. There are individual ZIP files for each available platform and architecture. You can later update the IBM Java SDK; for more information, see “Updating the Java software development kit in a Liberty ZIP archive installation” on page 1386.

### WAS Liberty V8.5.5.x with Java EE 7 Full Platform

**wlp-javaee7-*<version>*.zip**

This ZIP file includes the Liberty server runtime environment and features that support Java EE 7.

### WAS Liberty V8.5.5.x with Java EE 7 Application Client

**wlp-javaeeClient7-*<version>*.zip**

This ZIP file includes the Liberty server runtime environment and the Java EE 7 application client.

## WAS Liberty V8.5.5.x with OSGi Applications

### wlp-osgi-<version>.zip

This ZIP file includes the Liberty server runtime environment and features that support OSGi applications.

### Features included in the installation ZIP files

The following table compares the features that are included in each of the available ZIP files. For more information about these features, see “Liberty features” on page 826.

Table 98. Features that are included in the installation ZIP files

Feature	WAS Liberty V8.5.5.x Kernel	WAS Liberty V8.5.5.x with Java EE 7 Web Profile	WAS Liberty V8.5.5.x with Java EE 7 Full Platform	WAS Liberty V8.5.5.x with Java EE 7 Application Client	WAS Liberty with Micro profile	WAS Liberty V8.5.5.x with OSGi Applications

## Applying a fix pack to a Liberty ZIP archive installation

Distributed operating systems

IBM i

8.5.5.6

Liberty offers a ZIP archive-based installation as an alternative to using IBM Installation Manager. If you installed Liberty from the ZIP archive file and want to upgrade to the latest fix pack version, you can apply a new fix pack archive to a new location, and move any required user files and server configuration data.

## About this task

If you used IBM Installation Manager to install Liberty, you must use Installation Manager to apply a fix pack.

**Important:** You must apply a new fix pack archive to a new location.

## Procedure

1. Install the new runtime environment by downloading the ZIP archive file from WASdev.net and extracting it. For more information, see “Installing Liberty by extracting a ZIP archive file” on page 1381.
2. Optional: Upgrade the new installation to an edition with advanced functionality. If you upgraded your previous installation, upgrade to a product edition with at least the same level of functionality to reduce the chance of any incompatibilities. For example, if you previously upgraded to WebSphere Application Server Liberty (base), upgrade to that same edition or WebSphere Application Server Liberty Network Deployment. For more information, see “Upgrading Liberty installations” on page 1386.
3. Optional: Install Liberty Repository assets to customize the new environment. For more information, see “Installing Liberty Repository assets” on page 1391.
4. Move any user data and server configurations. Liberty defines two locations for storing user-generated content and server configurations:
  - WLP\_USER\_DIR; The location of server configuration files, including shared resources.
  - WLP\_OUTPUT\_DIR; The location of resources generated by the server. For example, log files and temporary disk storage.

If the WLP\_USER\_DIR environment variable has been set on your system, then the new runtime environment will continue to use the same location. This results in no backup of server configuration data. To ensure that your server configuration is backed up, copy the directory referenced by WLP\_USER\_DIR to a new location on your file system. To protect the original environment, change the value of WLP\_USER\_DIR to point to the new location. During uninstallation, reset the value of WLP\_USER\_DIR to the location of the original server configuration.

If WLP\_USER\_DIR has not been set, the server configuration and shared resources are stored in the `usr` directory at the root of the server's runtime environment (for example, `<liberty_server_runtime_root>/usr`). During uninstallation of the runtime environment, you can reset the WLP\_USER\_DIR environment variable.

If the WLP\_OUTPUT\_DIR environment variable is set on your system, the new server also uses this location. This can result in old log files being overwritten. To ensure that old log files are protected, either update or unset the WLP\_OUTPUT\_DIR environment variable. During uninstallation, reset this value to its original value.

If the WLP\_OUTPUT\_DIR value is not set, the default location is in the server root directory (for example `<liberty_server_runtime_root>/usr/servers/<serverName>`). If the new runtime environment is installed to a new location, no updates are required during installation or uninstallation because logs continue to appear under the `usr/servers/<serverName>/logs` directory of each respective installation.

**Note:** If the `server.xml` file, or any included XML configuration file, references another resource outside the server configuration directory, these resources must also be copied across, or the references will need to be updated. This also applies to any resources that the application references directly, such as references to hardcoded paths on file systems. During uninstallation of the fix pack, these values can be manually reset to their original values.

5. Start the new server. Run `<liberty_VX+>/bin/server start <server_name>`.

## What to do next

After you verify that the new installation works correctly, you can remove the old installation. In the previous installation, stop all servers, then delete the wlp directory.

## Updating the Java software development kit in a Liberty ZIP archive installation

Distributed operating systems

IBM i

8.5.5.6

If you installed Liberty with IBM SDK, Java Technology Edition, Version 8 by extracting a ZIP archive file, you can update the Java software development kit (SDK) to incorporate Java service releases and interim fixes.

### About this task

The directories in the following procedures are based on Liberty installations that were installed by extracting a wlp-webProfile7-java8-*<platform>-<architecture>-<version>*.zip file, available from IBM Fix Central or WASdev.net. If you separately installed or moved the IBM Java SDK to a different location, you can update the SDK by replacing the files at their current location.

### Procedure

8.5.5.7 For Version 8.5.5.7 or later:

- Update the Java SDK in a Liberty ZIP archive installation.
  1. Download the IBM SDK, Java Technology Edition, Version 8 ZIP archive file from IBM Fix Central. If you are applying a Java service release or interim fix that is associated with a certain APAR, see the APAR text for download information.
  2. Extract the Java SDK ZIP archive file to a local directory.
  3. Back up the wlp/java/java directory in your Liberty installation by renaming the folder. For example, rename the wlp/java/java directory to wlp/java/java\_backup.
  4. Copy the sdk folder from the directory where you extracted the Java SDK ZIP archive file to the wlp/java directory. Rename the new wlp/java/sdk directory to wlp/java/java.

8.5.5.6 For Version 8.5.5.6 only:

- Update the Java SDK in a Liberty ZIP archive installation.
  1. Download the IBM SDK, Java Technology Edition, Version 8 ZIP archive file from IBM Fix Central. If you are applying a Java service release or interim fix that is associated with a certain APAR, see the APAR text for download information.
  2. Extract the Java SDK ZIP archive file to a local directory.
  3. Back up the wlp/java directory in your Liberty installation by renaming the folder. For example, rename the wlp/java directory to wlp/java\_backup.
  4. Copy the sdk folder from the directory where you extracted the Java SDK ZIP archive file to the wlp directory. Rename the new wlp/sdk directory to wlp/java.
  5. Copy the java.env file from the wlp/java\_backup backup directory to the wlp/java directory.

## What to do next

After you verify that IBM SDK, Java Technology Edition, Version 8 updated successfully, delete the Java backup directory.

## Upgrading Liberty installations

Distributed operating systems

IBM i

8.5.5.5

You can upgrade the edition or license of Liberty by using a self-extracting Java archive (JAR) file.

## Before you begin

To download the upgrade JAR files from IBM Fix Central or Passport Advantage, you must be enrolled as a customer.

Your system must meet the operating system and Java requirements for using Liberty. See System Requirements for WebSphere Application Server V8.5.5.

**IBM i** For the IBM i platform, the minimum supported Java level is installed at one of the following locations:

- /QOpenSys/QIBM/ProdData/JavaVM/jdk626/32bit
- /QOpenSys/QIBM/ProdData/JavaVM/jdk626/64bit

## About this task

Liberty offers installation from a ZIP archive file or a self-extracting Java archive (JAR) file as an alternative to using IBM Installation Manager. If you installed Liberty using one of these archive files, you can upgrade the product license by applying an executable JAR file, available from IBM Fix Central or the Passport Advantage website.

You might upgrade Liberty in the following example scenarios:

- Upgrade a trial edition or other unsupported edition to a supported production edition.
- Upgrade a basic edition to a more advanced edition for access to advanced features.

You can upgrade WebSphere Application Server Liberty offerings in the following paths:

*Table 99. Liberty offering upgrade paths*

License JAR file	Source edition	Target edition
wlp-core-license.jar	Unsupported ZIP or JAR file installations WebSphere Application Server Liberty Core Trial	WebSphere Application Server Liberty Core
wlp-base-license.jar	Unsupported ZIP or JAR file installations WebSphere Application Server Liberty Trial WebSphere Application Server Liberty Core WebSphere Application Server Liberty for Developers WebSphere Application Server Liberty - Express	WebSphere Application Server Liberty

Table 99. Liberty offering upgrade paths (continued)

License JAR file	Source edition	Target edition
wlp-nd-license.jar	Unsupported ZIP or JAR file installations WebSphere Application Server Liberty Network Deployment Trial WebSphere Application Server Liberty Core WebSphere Application Server Liberty for Developers WebSphere Application Server Liberty - Express WebSphere Application Server Liberty	WebSphere Application Server Liberty Network Deployment

For example, an installation of WebSphere Application Server Liberty Core also requires features from WebSphere Application Server Network Deployment. If you have the required entitlement, you can download the `wlp-nd-license.jar` license file and apply it to your Liberty installation, which upgrades the license from WebSphere Application Server Liberty Core to WebSphere Application Server Network Deployment. Upgrading the license does not install any features from WebSphere Application Server Network Deployment, but it enables you to install WebSphere Application Server Network Deployment features to your Liberty installation if needed.

## Procedure

1. Download the license upgrade archive for the edition that you want to upgrade to from IBM Fix Central or the IBM Passport Advantage website. You can apply the license JAR files to all fix packs of Liberty ZIP or JAR file installations.

For a list of the JAR files on IBM Fix Central, see license JAR files on the Fix Central website.

For a list of Passport Advantage part numbers, see How to download WebSphere Application Server Network Deployment V8.5.5 from Passport Advantage Online.

2. Apply the license archive to an existing Liberty installation. For example, to apply the license by using the installation wizard and the `wlp-nd-license.jar` file, run the following command:

```
java -jar wlp-nd-license.jar
```

## Applying an interim fix to a Liberty archive installation

Distributed operating systems

IBM i

Liberty offers a self-extracting archive-based installation as an alternative to using IBM Installation Manager. If you installed Liberty using the self-extracting archive, and want to install an interim fix, you can apply an executable JAR file.

### About this task

If you used IBM Installation Manager to install Liberty, you must use Installation Manager to apply an interim fix.

An archive-based interim fix is named `<Liberty profile level>-WS-WASProd_WLPArchive-<fix type><fix id>.jar`

- `<Liberty profile level>` refers to a 4-digit fix pack level identifier, which indicates the minimum level to which the fix applies. For example, 8.5.5.0.
- `<fix type>` refers to the type of fix. For example, IF is used for an interim fix, and TF for a diagnostic fix

- *<fix id>* refers to the APAR reference number. If a diagnostic fix is provided before an APAR is opened, the *<fix id>* is based on the PMR reference number.

Each interim fix is installed by executing the relevant JAR file, which extracts the content into the Liberty base folder (/wlp).

**Note:** When the interim fix is applied, no backup data is created. If you want to back out an interim fix, you must manually remove or restore files from the /wlp folder.

Each interim fix is provided with a `readme.txt` file, which contains backup and restore instructions specific to the fix content, in a section titled **Directions to apply fix**. If the `readme.txt` file does not specify any requirement to back up files, you can extract the fix and then restart the server at any time with the `--clean` parameter as a launch option.

## Procedure

1. Optional: If the fix contains files that will overwrite existing files, stop all servers that are running on the system.
2. Optional: If the `readme.txt` file indicates that a backup is required, create a backup of the `lib/features/component.mf` files. File locations are relative to your Liberty profile installation root.
3. Open a console and direct it to the location of your interim fix JAR file.
4. To view available options, run `java -jar interim_fix_jar_file -help`, where *interim\_fix\_jar\_file* is the name of the executable JAR file that contains the interim fix. The following launch options are available for the JAR file:

### `--installLocation [LibertyRootDir]`

The absolute or relative location of the Liberty installation directory.

By default the JAR file looks for a `wlp` directory in its current location. If your Liberty profile installation location is not the `wlp` folder, or is not in the same directory as the JAR file, then you can use this option to change where the JAR file will patch. `[LibertyRootDir]` can either be relative to the location of the JAR file, or an absolute file path.

### `--suppressInfo`

The only messages output from the JAR file will be error messages or confirmation that patching is complete.

5. Run the JAR file, using the `--installLocation` option to specify the installation location. For example, `java -jar interim_fix_jar_file --installLocation`. Optionally include `--suppressInfo`.
6. Start all Liberty profile servers with the `--clean` parameter as a launch option. For example, `server start --clean`. You use the `--clean` option only once; all subsequent server starts do not require it.

## Removing an interim fix from a Liberty archive install

Distributed operating systems

IBM i

If you installed Liberty by using the self-extracting archive, then to remove an interim fix you must manually remove files, and restore files, from the /wlp folder.

### About this task

If you used IBM Installation Manager to apply an interim fix, you can use Installation Manager to remove the interim fix.

The current set of fixes installed on a Liberty profile can be found in the `/lib/fixes` directory.

Each interim fix is provided with a `readme.txt` file, which contains backup and restore instructions specific to the fix content, in a section titled **Directions to apply fix**. If the `readme.txt` file does not

include any requirement to back up files, you can extract the fix and then restart the server at any time with the `--clean` parameter as a launch option.

## Procedure

1. Stop all servers running on the system. For more information, see Starting and stopping a server.
2. Delete or replace the files as detailed in the `readme.txt` file. File locations are relative to your Liberty profile install root. For example:
  - `lib/com.ibm.ws.component_1.0.0.20120803-1356.jar`
  - `lib/fixes/8.5.0.0-WASProd_WLPArchive-IFPM11111_8.5.0.20120803-1356.xml`
3. Start all Liberty profile servers with the `--clean` parameter as a launch option. For example, `server start --clean`. You only need to use the `--clean` option once. All subsequent server starts will not require it.

## What to do next

You can reapply the fix by following the instructions in “Applying an interim fix to a Liberty archive installation” on page 1388.

## Configuring the Liberty server to start as a job in the QWAS85 subsystem on IBM i

IBM i

You can optionally use the `iAdmin POSTINSTALL` command to configure the Liberty server to start as a job in the QWAS85 subsystem and to run under the `QEJBSVR` user profile.

### About this task

The `iAdmin POSTINSTALL` command configures the server start command to start servers as jobs in the QWAS85 subsystem. Additionally, the task can be used to:

- Configure Liberty to run servers under the `QEJBSVR` user profile.
- Configure the default JDK location by setting `WLP_DEFAULT_JAVA_HOME` in file `wlp/etc/default.env` to the location of the 32 bit version of the minimum supported Java level.
- Add an entry for the product in the IBM i native product registry.
- Create IBM i native libraries and objects such as the QWAS85 subsystem and the `QEJBSVR` user profile.

Call the `iAdmin POSTINSTALL` command only after Installing Liberty by extracting an archive file.

**Note:** You must have `*ALLOBJ` and `*SECADM` special authority to use the `iAdmin POSTINSTALL` command.

### Procedure

1. On the IBM i command line, run the `STRQSH` command to start the Qshell.
2. In the resulting Qshell session, change the directory to the `wlp` directory.
3. Run the following command.

```
lib/native/os400/bin/iAdmin POSTINSTALL
```

## Uninstalling Liberty application-serving environment from IBM i operating systems

IBM i

By calling the iAdmin PREUNINSTALL command, you can remove any IBM i native objects and libraries created by the iAdmin POSTINSTALL command. Then you can manually remove the files comprising your Liberty profile application-serving environment.

## Before you begin

After installing the Liberty application-serving environment by executing a JAR file on IBM i, you might have used the iAdmin POSTINSTALL command to configure the Liberty server to launch as a job in the QWAS85 subsystem and to run under the QEJBSVR user profile. If so, you must remove the IBM i native objects and libraries created at that time before you manually remove the files that comprise your Liberty profile application-serving environment.

**Note:** You must have \*ALLOBJ and \*SECADM special authority to use the iAdmin POSTINSTALL command.

## Procedure

1. On the IBM i command line, run the STRQSH command to start the Qshell.
2. In the resulting Qshell session, change the directory to the wlp directory.
3. Run the following command.

```
lib/native/os400/bin/iAdmin PREUNINSTALL
```

## What to do next

Manually remove the files that comprise your Liberty profile application-serving environment.

---

## Installing Liberty Repository assets

8.5.5.2

You can use a variety of tools to install the assets that are in the Liberty Repository or download them directly from the WASdev website.

## Before you begin

**Important:** Product documentation that is marked with the  icon indicates information about assets that are available only from the Liberty Repository.

The Liberty Repository provides an online mechanism to deliver Liberty and additional content, enabling a single point of access for various asset types. For more information, see “Liberty: Liberty Repository” on page 965.

### Note:

- To install assets from the Liberty Repository, you must have Liberty for WebSphere Application Server Version 8.5.5.2 or later.
- To access the IBM WebSphere Liberty Repository with limited internet access or through a firewall, ensure that you have access to the following hosts and ports:
  - public.dhe.ibm.com on port 443
  - asset-websphere.ibm.com on port 443

## About this task

You can use several methods to access and install Liberty Repository assets. Some methods, such as Installation Manager, require the completion of specific steps in the installation sequence before you can install the applicable assets.

### Procedure

- Review the list of available assets in the Liberty Repository. See the Downloads page on WASdev.net. You can sort assets by date, name, or rating, or you can filter assets by asset type or Liberty edition. For a list of Liberty features, see “Liberty features” on page 826
- Review the installation methods for the Liberty Repository assets. Use the following table to determine the appropriate installation methods for each asset type:

Table 100. Installation methods for Liberty Repository asset types

Asset type	installUtility command	featureManager command	configUtility command	Installation Manager	Developer tools <sup>a</sup>	WASdev site <sup>b</sup>
Addons	✓	✓		✓	✓	✓
Admin scripts					✓	
Config snippets			✓		✓	✓
Features	✓	✓		✓	✓	
Open source integrations	✓			✓	✓	✓
Products				✓ <sup>c</sup>	✓	✓
Product samples	✓			✓	✓	✓
Tools						✓

**Note:**

- Developer tools are available only for the Linux, Mac OS, and Windows platforms.
- You can download assets from the WASdev.net website to install separately.
- You can install product runtimes from Installation Manager, but they are not in the Liberty Repository.

- Choose the installation method for the Liberty Repository assets that fits your usage scenario.
  - 8.5.5.6 installUtility** command: Finds, obtains information about, and installs a variety of assets that are in a local directory-based repository, an instance of the Liberty Asset Repository Service, or the IBM WebSphere Liberty Repository. You can also download Liberty Repository assets to your local system for offline use. The **installUtility** command downloads and installs all dependencies for the asset. For more information, see “Installing assets using the installUtility command” on page 1393.
  - featureManager** command: Installs Liberty Repository features and addons to an existing installation of Liberty or downloads them to your local system for offline use. For more information, see “Installing assets using the featureManager command” on page 1403. For Version 8.5.5.6 and later, use the **installUtility** command instead because it enables you to work with more asset types and from multiple repositories.
  - 8.5.5.5 configUtility** command: Downloads config snippet assets and enables you to replace configuration snippet variables with your input values. For more information, see “Downloading and customizing configuration snippets from the command line” on page 1577.
  - IBM Installation Manager: Installs Liberty Repository assets during the installation or an upgrade to a new version of Liberty. You can use the Installation Manager graphical user interface, command-line interface, or the Installation Manager in silent mode with a response file. For more information, see “Installing assets using Installation Manager” on page 1411.

- **Distributed operating systems** Developer tools: Developer tools for WebSphere Application Server, such as WebSphere Developer Tools, provide a graphical user interface that you can use to install Liberty Repository assets. For more information, see “Installing assets by using developer tools” on page 1413.
- WASdev site: You can download a subset of the Liberty Repository assets directly from the WASdev site. See the installation instructions for each downloadable asset on WASdev.net.

## Installing assets using the `installUtility` command

8.5.5.6

You can use the `installUtility` command to install assets in your Liberty environment and view required asset information.

### About this task

After you install Liberty, you can install assets by running the `installUtility` command. The `installUtility` command automatically installs asset dependencies.

You can install assets from the following repositories:

- The IBM WebSphere Liberty Repository, a public IBM-hosted repository that is accessible through the internet. For more information, see “Liberty: Liberty Repository” on page 965.
- The Liberty Asset Repository Service, an open-source service that you can use to create an on-premises repository that is remotely accessible behind the firewall of an enterprise. For more information, see the WASdev/tool.lars project on GitHub.
- Local directory-based repositories that are created by using the `installUtility download` action. For more information, see “Downloading assets using the `installUtility` command” on page 1400.

By default, the `installUtility` command is configured to install assets only from the Liberty Repository. If you want to install assets from a local directory-based repository or an instance of the Liberty Asset Repository Service, you must configure these repositories in the `repositories.properties` file. For more information, see “Configuring repositories and proxy settings for the `installUtility` command” on page 1401.

For a list of the actions and options for the `installUtility` command, see “Liberty: `installUtility` command” on page 1394.

### Procedure

1. Review the available assets and obtain the `shortName` for each asset that you want to install. You can use the `installUtility` command to search for and review assets, or you can find them on the Downloads page on WASdev.net.
  - To review assets and obtain the asset `shortName` by using the `installUtility` command, use the `installUtility find` command.
    - To find assets that are applicable to your configuration, use the `searchString` option. The following example searches for all assets that match the search string `jca`:
 

```
installUtility find jca
```
    - To find a specific type of asset, use the `--type=[feature|sample|opensource|addon|all*]` option. The following example searches for features that match the search string `jca`:
 

```
installUtility find jca --type=feature
```
  - To review assets and obtain the asset `shortName` from the WASdev website, see the asset details page on the WASdev website for each feature that you want to install. The `shortName` is found in the installation instructions of the asset details page; for example: the Portlet Container `shortName` is `portlet-2.0`.

For a list of all Liberty features, see “Liberty features” on page 826.

2. Run the **installUtility install** command to install the assets.

For example, the following command installs the `jca-1.6` feature:

```
installUtility install jca-1.6
```

To install multiple assets, separate each *shortName* with a space. For example, the following command installs both the `jca-1.6` feature and the `adminCenter-1.0` feature:

```
installUtility install jca-1.6 adminCenter-1.0
```

**Tip:** To install all features that apply your edition, you can install a feature bundle addon.

For example, to install all features for WebSphere Application Server Network Deployment Liberty, install the `ndControllerBundle` addon on servers that manage Liberty collectives and the `ndMemberBundle` addon on servers that are clustered and auto-scaled in a Liberty collective.

```
installUtility install ndControllerBundle
```

**z/OS** To install all features for WebSphere Application Server for z/OS Liberty, install the `zosBundle` addon.

```
installUtility install zosBundle
```

For a list of available addons, see Addon downloads on WASdev.

## Liberty: installUtility command

8.5.5.6

Use the **installUtility** command to find, obtain information about, and install assets that are in a directory-based repository, an instance of the Liberty Asset Repository Service, or the IBM WebSphere Liberty Repository.

### Asset sources

The **installUtility** command can access assets in the following repositories:

- The IBM WebSphere Liberty Repository, a public IBM-hosted repository that is accessible through the internet. For more information, see “Liberty: Liberty Repository” on page 965.
- The Liberty Asset Repository Service, an open-source service that you can use to create an on-premises repository that is remotely accessible behind the firewall of an enterprise. For more information, see the WASdev/tool.lars project on GitHub.
- Local directory-based repositories that are created by using the **installUtility download** action. For more information, see “Downloading assets using the installUtility command” on page 1400.

**8.5.5.8** You can use the **installUtility** command to work with directory-based repository assets directly from compressed repositories, such as `wlp-featureRepo-<version>.zip`, without extracting the archives. For more information about the `wlp-featureRepo-<version>.zip` file, see “Downloading assets using the installUtility command” on page 1400.

### Syntax

The command syntax is as follows:

```
installUtility action [options]
```

The *action* variable can take one of the following values:

#### download

Download assets from the repositories.

**find** Find assets in the repositories that are applicable to your configuration, or view detailed information about assets.

**install** Install assets or an enterprise subsystem archive (ESA) file to the run time, or deploy a server package and install the required features of the package.

**testConnection**

Test the repository connection.

**uninstall**

Uninstall features by specifying either the feature short name or the feature symbolic name. You can specify multiple features, separated by a space.

**Note:** Ensure that all server processes are stopped before you uninstall a feature.

**viewSettings**

View a template for configuring repositories or a proxy, or view the settings for the configured repositories or proxy.

**8.5.5.7** For Version 8.5.5.7 and later, this action also validates the settings for any configured repositories or proxy in the `repositories.properties` file.

**help** Display help information for a specified action.

## Options

The following options are available for the **installUtility download** command:

**--acceptLicense**

Accepts the license agreement.

**--viewLicenseAgreement**

View the license agreement.

**--viewLicenseInfo**

View the license agreement.

**--location=*directoryPath***

Specify the destination directory for the downloaded assets. This option is required.

**--overwrite**

Use this option to overwrite the existing files when you download assets to the local directory. The default behavior without the option is to ignore all the existing files.

**--verbose**

Use this option to display additional information during the download.

**name** Specify asset IDs to download one or more of the following assets, separating multiple asset IDs with a space:

- Features
- Addons
- Open source integrations
- Samples

The following options are available for the **installUtility find** command:

**8.5.5.7** **--from**

Specify a single directory-based repository as the source of the assets for the **installUtility** command.

**8.5.5.8** The directory-based repository can be an uncompressed folder or a compressed archive file, such as `wlp-featureRepo-<version>.zip`.

To search for assets in multiple directory-based repositories, you must configure the repositories in the `repositories.properties` file. For more information, see “Configuring repositories and proxy settings for the `installUtility` command” on page 1401.

**--showDescriptions**

Displays the description for each of the features that are found by the search.

**--type=[feature | sample | opensource | addon | all\*]**

Searches for the specified type of assets.

**--name**

Searches the asset name for the specified *searchString*.

**--verbose**

Use this option to display any available additional information while the action runs.

**searchString**

Finds assets that are applicable to your configuration. If you do not specify a search string, the command searches for all applicable assets.

The following options are available for the **installUtility install** command:

**--to=install\_option**

The `install_option` option can take one of the following values:

- `usr`: The feature is installed as a user feature. This value is the default value.
- `extension`: The location to install the feature. You can install the feature to any configured product extension location.

8.5.5.7

**--from**

Specify a single directory-based repository as the source of the assets for the **installUtility** command.

8.5.5.8

The directory-based repository can be an uncompressed folder or a compressed archive file, such as `wlp-featureRepo-<version>.zip`.

To install assets from multiple directory-based repositories, you must configure the repositories in the `repositories.properties` file. For more information, see “Configuring repositories and proxy settings for the `installUtility` command” on page 1401.

**--acceptLicense**

Indicate acceptance of license terms and conditions.

**--viewLicenseAgreement**

View the license agreement.

**--viewLicenseInfo**

View the license information.

**--verbose**

Use this option to display any available additional information while the action runs.

**name** Specify one or more assets that you want to install. You can specify the assets in the following ways:

**Asset IDs**

You can specify asset IDs to install one or more of the following assets, separating multiple asset IDs with a space:

- Features
- Addons
- Open source integrations
- Samples

### Server name

You can install features based on an existing server in the same Liberty environment by specifying the server name. The command installs any applicable features that are defined in the `server.xml` file of that server that are not already installed in the Liberty environment.

### Server package

You can specify a server package that you created by using the `server package --include=usr` command. The server package deploys, and the required features, which are defined in the `server.xml` file, are installed from the repositories.

#### 8.5.5.7 `server.xml` file

To install features based on a server configuration file, you can specify a path to any local `server.xml` file, such as `C:\localDir\server.xml`. The command installs any applicable features that are defined in the `server.xml` file that are not already installed in the Liberty environment.

### .esa file

Install a feature from an `.esa` file on your local file system. This action uses the `OSGI-INF/SUBSYSTEM.MF` manifest file from the `.esa` file as a new feature manifest. The manifest file specifies the name, contents, and dependencies of a feature. If you specify the `--to` option, `installUtility` copies the manifest file into the `${wlp.user.dir}/extensions/lib/features` directory, or the product extension directory. All of the bundles for the subsystem are extracted into the `${wlp.user.dir}/extensions/lib` directory and renamed as `{bundle symbolic name}_{bundle version}.jar`. License files, checksum files, globalization files, and other subsystem content are extracted to the location defined in the subsystem manifest.

The following option is available for the `installUtility testConnection` command:

#### *repoName*

Specifies the name of the repository to be tested. If not specified, all repositories that are specified in the `repositories.properties` file are tested.

The following option is available for the `installUtility uninstall` command:

#### 8.5.5.8 `--force`

Uninstall the specified feature regardless of whether other installed features have dependencies on it.

**Note:** Uninstalling a feature that is required by other installed features might cause those features to stop working and might prevent servers from running correctly.

#### `--noPrompts`

Uninstalls the feature without prompts. The default is false.

#### `--verbose`

Use this option to display additional information during the uninstallation.

*name* Specify one or more features to uninstall, separating multiple names with a space. You can specify the following options:

- The short name of the subsystem archive (ESA file), such as `adminCenter-1.0`.
- The symbolic name of the subsystem archive (ESA file), such as `com.ibm.websphere.appserver.adminCenter-1.0`.

8.5.5.8 You can uninstall user features and product extensions by prefixing the feature name with the extension followed by a colon, such as `usr:webCacheMonitor-1.0`.

8.5.5.7 The following option is available for the `installUtility viewSettings` command:

## --viewValidationMessages

Use this option to display the detailed messages from the validation of the configured repositories.properties file. Each message contains an error code, the line number where the error was found, and the cause of the error.

## Usage examples

Use the following example to display help information for the **install** action:

```
installUtility help install
```

Use the following example to install a user feature:

```
installUtility install my_feature --to=usr
```

Use the following example to install a user feature to the *my\_extension* product extension location:

```
installUtility install my_feature --to=my_extension
```

Use the following example to install multiple features:

```
installUtility install feature1 feature2 feature3
```

Use the following example to install a sample:

```
installUtility install mongoDBSample
```

**8.5.5.7** Use the following example to install a feature bundle add-on from a single local directory-based repository:

```
installUtility install ndMemberBundle --from=c:\download\wlp-featureRepo-8.5.5.7
```

**8.5.5.8** Use the following example to install a feature bundle add-on from a single compressed directory-based repository archive:

```
installUtility install ndMemberBundle --from=c:\download\wlp-featureRepo-8.5.5.8.zip
```

Use the following example to install a server:

```
installUtility install myServer
```

Use the following example to install a server package compressed .jar file:

```
installUtility install c:\temp\myServer.jar
```

Use the following example to install a local .esa file:

```
installUtility install c:\temp\myFeature.esa
```

Use the following example to install a server package compressed file:

```
installUtility install c:\temp\myServer.zip
```

Use the following example to find assets that are applicable to your configuration:

```
installUtility find searchString
```

Use the following example to find samples that are applicable to your configuration:

```
installUtility find searchString --type=sample
```

Use the following example to find a particular feature that is applicable to your configuration:

```
installUtility find webCacheMonitor-1.0 --name --type=feature
```

Use the following example to list detailed information:

```
installUtility find searchString --showDescriptions
```

Use the following example to download required dependencies from the repositories to a local directory:  
`installUtility download feature_shortName --location=c:\temp\download --acceptLicense`

Use the following example to test the connection to the Liberty Repository:

```
installUtility testConnection default
```

Use the following example to uninstall a feature:

```
installUtility uninstall adminCenter-1.0
```

**8.5.5.8** Use the following example to uninstall a user feature or product extension:

```
installUtility uninstall usr:webCacheMonitor-1.0
```

Use the following example to uninstall multiple features:

```
installUtility uninstall feature1 feature2 feature3
```

Use the following example to uninstall multiple features without prompts:

```
installUtility uninstall --noPrompts feature1 feature2 feature3
```

## Return codes

Table 101. Return codes and explanations.

Return code	Explanation
0	The command successfully completed the requested operation.
20	One or more arguments are not valid.
21	A runtime exception occurred because of one or more of the following conditions: <ul style="list-style-type: none"> <li>A runtime exception occurred during the installation of the .esa subsystem archive file.</li> <li>A license is not accepted or acknowledged.</li> <li>The .esa subsystem archive file did not extract correctly.</li> </ul>
22	The feature to be installed exists.
23	The feature definition was not valid for one or more of the following reasons: <ul style="list-style-type: none"> <li>The feature does not have a valid manifest file.</li> <li>The version of the feature is not supported in this Liberty environment.</li> <li>The .zip or .jar file that contains the feature files does not exist.</li> </ul>
24	The .esa subsystem archive file is missing content.
25	A file to be installed exists.
26	The product is not a core product, and the product extension files cannot be found.
27	The product is not a core product, and the product extension is not defined in the <code>\${wlp.install.dir}/etc/extensions/<i>extension_name</i>.properties</code> file.
28	The manifest files for the feature in the product extension cannot be found.
29	The feature is not valid for the current product.
<b>8.5.5.7</b> 30	The repositories.properties file failed the validation.

Table 101. Return codes and explanations (continued).

Return code	Explanation
33	The connection to the repository failed.
34	The repository name is not found. The provided repository name does not exist in the configuration file.
35	The action was canceled by the user.

## Downloading assets using the `installUtility` command

8.5.5.6

You can use the `installUtility` command to download assets to your local file system.

### Before you begin

Before you can access the IBM WebSphere Liberty Repository using the `installUtility` command, you must install Liberty for WebSphere Application Server.

### About this task

After you install Liberty, you can download assets to your local file system by running the `installUtility` command. Assets can be downloaded to a new directory, which you can then use as a repository, or to an existing directory-based repository.

By default, the `installUtility` command is configured to download assets only from the public IBM WebSphere Liberty Repository. If you want to download assets from a local directory-based repository or an instance of the Liberty Asset Repository Service, you must configure these repositories in the `repositories.properties` file. For more information, see “Configuring repositories and proxy settings for the `installUtility` command” on page 1401.

For a list of the actions and options for the `installUtility` command, see “Liberty: `installUtility` command” on page 1394.

**Tip:** Rather than downloading individual assets, you can download a `wlp-featureRepo-<version>.zip` file from IBM Fix Central. The `.zip` file contains a directory-based repository of all features and add-ons for the particular fix pack of Liberty that you download from IBM Fix Central. Extract the archive file to populate a local directory-based repository or an instance of the Liberty Asset Repository Service with the feature and add-on ESA files. Assets that are not included in the `.zip` file must be downloaded by using the `installUtility` command.

**8.5.5.8** For Version 8.5.5.8 and later, you can use the `installUtility` command to work with repository assets directly from the `wlp-featureRepo-<version>.zip` file and other compressed directory-based repositories without extracting the archives.

### Procedure

1. Review the available assets and obtain the `shortName` for each asset that you want to download. You can use the `installUtility` command to search for and review assets, or you can find them on the Downloads page on WASdev.net.
  - To review assets and obtain the asset `shortName` using the `installUtility` command, use the `installUtility find` command.
    - To find assets that are applicable to your configuration, use the `searchString` option. The following example searches for all assets that match the search string `adminCenter`:
 

```
installUtility find adminCenter
```

- To find a specific type of asset, use the `--type=[feature|sample|opensource|addon|all*]` option. The following example searches for features that match the search string `adminCenter`:

```
installUtility find adminCenter --type=feature
```

- To review assets and obtain the asset *shortName* from the WASdev website, see the asset details page on the WASdev website for each feature that you want to install. The *shortName* is found in the installation instructions of the asset details page; for example: the Portlet Container **shortName** is *portlet-2.0*.

2. Run the **installUtility download** command to download the assets. You must specify a target directory for the downloaded assets on the `--location` option.

For example, the following command downloads the `adminCenter-1.0` feature to the `c:\temp\download` directory:

```
installUtility download adminCenter-1.0 --location=c:\temp\download
```

You can download multiple assets at once by separating each asset *shortName* with a space. For example, the following command downloads both the `jca-1.6` feature and the `adminCenter-1.0` to the `c:\temp\download` directory:

```
installUtility download jca-1.6 adminCenter-1.0 --location=c:\temp\download
```

## What to do next

After you download assets to your local file system, you can add a local directory to your repository configuration so that you can install assets from the directory. For more information about configuring repositories, see “Configuring repositories and proxy settings for the `installUtility` command.”

## Configuring repositories and proxy settings for the `installUtility` command

8.5.5.6

In the `repositories.properties` file, you can configure how the **installUtility** command accesses local directory-based repositories, instances of the Liberty Asset Repository Service, and the IBM WebSphere Liberty Repository.

### About this task

The **installUtility** command can access the following repositories:

- The IBM WebSphere Liberty Repository, a public IBM-hosted repository that is accessible through the internet. For more information, see “Liberty: Liberty Repository” on page 965.
- The Liberty Asset Repository Service, an open-source service that you can use to create an on-premises repository that is remotely accessible behind the firewall of an enterprise. For more information, see the WASdev/tool.lars project on GitHub.
- Local directory-based repositories that are created by using the **installUtility download** action. For more information, see “Downloading assets using the `installUtility` command” on page 1400.

Both the **installUtility** command and the **featureManager** command use the same configuration properties file, `repositories.properties`. The proxy settings are shared, but the repository settings are used only by the **installUtility** command. To manage assets and complete repository-based installation, find, or uninstallation operations, use the **installUtility** command instead of the **featureManager** command.

**Tip:** You can download or install assets from a single local directory-based repository by specifying the repository on the `--from` option. No additional configuration in the `repositories.properties` file is required. For more information, see “Liberty: `installUtility` command” on page 1394.

To access the IBM WebSphere Liberty Repository with limited internet access or through a firewall, ensure that you have access to the following hosts and ports:

- `public.dhe.ibm.com` on port 443

- `asset-websphere.ibm.com` on port 443

**Note:** The `installUtility` command supports only proxy servers with HTTP/HTTPS protocols.

## Procedure

1. Optional: When you first configure the repository or proxy settings, you can run the `installUtility viewSettings` command to output a configuration template for the `repositories.properties` file.

Copy the template into a new properties file at `${wlp.install.dir}/etc/repositories.properties`. The properties file must be in ASCII format for all platforms.

2. Define the settings in the `${wlp.install.dir}/etc/repositories.properties` file.

If you copied the template from the `installUtility viewSettings` command, modify the template by changing the example repository and proxy settings to refer to your environment. Lines that begin with a number sign (#) are not processed.

- To disable access to the Liberty Repository, set the `useDefaultRepository` property to `false`. The Liberty Repository is enabled by default and is the last repository that is accessed when you install or download assets.

```
useDefaultRepository=false
```

- To define a repository, add a property as `repoName.url=url`. Each repository name must be unique.

The defined repositories are accessed in the order that they are specified in the `repositories.properties` file. For Version 8.5.5.7 and later, you can also specify `repoName.url=file_path`.

### Windows

```
dev-rep.url=http://dev.repo.ibm.com:9080/ma/v1
local-rep2.url=file:///c:/IBM/localrepo2
```

8.5.5.7

`local-rep3.url=C:\IBM\localrepo3`

8.5.5.8

`local-rep4.url=C:\IBM\localrepo4.zip`

HP-UX

Solaris

Linux

UNIX

z/OS

```
dev-rep.url=http://dev.repo.ibm.com:9080/ma/v1
local-rep2.url=file:///usr/IBM/localrepo2
```

8.5.5.7

`local-rep3.url=/usr/IBM/localrepo3`

8.5.5.8

`local-rep4.url=/usr/IBM/localrepo4.zip`

- If a repository requires a user name and password, set the properties `repoName.user=userId` and `repoName.userPassword=password`.

If a user name and password are required and they are not set, you receive a prompt to provide them. For enhanced security, encode the password by using the `securityUtility encode` action; for more information, see Liberty `securityUtility` command. For Version 8.5.5.6, the password must be encoded to connect to the repository.

```
dev-rep.user=myname
dev-rep.userPassword={aes}AH5NLyd7DfGb12pK17Pw+
```

- If your system requires access to the IBM WebSphere Liberty Repository or an instance of the Liberty Asset Repository Service through a proxy server, set the `proxyHost`, `proxyPort`, `proxyUser`, and `proxyPassword` proxy properties.

For enhanced security, encode the value of the `proxyPassword` property by using the `securityUtility encode` action. If you do not set the user name and password, you receive a prompt to provide them. For Version 8.5.5.6, the password must be encoded to connect to the proxy.

For example:

```
proxyHost=my.proxy.server.ibm.com
proxyPort=9080
proxyUser=myname
proxyPassword={aes}AH5NLyd7DfGb12pK17Pw+
```

3. Save the changes to the `repositories.properties` file.
4. Review the repository and proxy settings by running the `installUtility viewSettings` command.

**8.5.5.7** When you run the **installUtility viewSettings** command, the repository and proxy configuration is automatically validated. To view detailed validation messages, run the command with the **--viewValidationMessages** option. **8.5.5.7**

```
>installUtility viewSettings
```

```
installUtility Settings
```

```
-----  
Properties File: c:\wlp\etc\repositories.properties  
Default Assets Repository: IBM WebSphere Liberty Repository  
Use Default Repository: True
```

```
Properties File Validation
```

```
-----  
Validation Results: The properties file successfully passed the  
validation.
```

```
Configured Repositories
```

```
-----  
Name: dev-rep  
Location: http://dev.repo.ibm.com:9080/ma/v1  
User Name: myname  
Password: <Unspecified>
```

```
Proxy Settings
```

```
-----  
Proxy Server: my.proxy.server.ibm.com  
Port: 9080  
User Name: myname  
Password: *****
```

5. Test the repository connection by running the **installUtility testConnection** command. If you do not set the user name and password, you receive a prompt to provide them. Use the following example to test the repository connection:

```
>installUtility testConnection  
Testing the connection to all configured repositories...  
This process might take several minutes to complete.
```

```
Configured Repositories
```

```
-----  
Name: dev-rep  
Location: http://dev.repo.ibm.com:9080/ma/v1  
Status: Successfully connected to the configured repository.
```

You can test all configured repositories in the `repositories.properties` file at once by running the **installUtility testConnection** command with no `repoName` specified. The repository name for the Liberty Repository is *default*. To test the connection to the Liberty Repository, run the following command:

```
installUtility testConnection default
```

## What to do next

You can use the **installUtility** command to search for assets and install or download them from the configured repositories.

## Installing assets using the `featureManager` command

**8.5.5.2**

You can use the **featureManager** command to install Liberty Repository features in your Liberty environment.

## Before you begin

Before you can access the Liberty Repository using the **featureManager** command, you must install Liberty for WebSphere Application Server Version 8.5.5.2 or later.

## About this task

After you install Liberty, you can install Liberty Repository features by running the **featureManager** command. The **featureManager** command automatically installs asset dependencies.

**Tip:**  Use the **installUtility** command instead of the **featureManager** command. With the **installUtility** command, you can manage more asset types and install, find, or download assets from multiple repositories. For more information, see “Installing assets using the installUtility command” on page 1393.

## Procedure

-  Review the assets that are located in the Liberty Repository and obtain the *feature\_shortName* for each asset that you want to install. The asset *feature\_shortName* is required to download and install assets. You can use the **featureManager** command to search for and review assets, or you can find them on the Downloads page on WASdev.net.
  - To review assets and obtain the asset *feature\_shortName* using the **featureManager** command, use the **featureManager find** command.
    - To find assets that are applicable to your configuration, specify a string to search for:  
`featureManager find searchString`
    - To view detailed information, use the **--viewInfo** option; for example:  
`featureManager find searchString --viewInfo`
  - To review assets and obtain the asset *feature\_shortName* from the WASdev website, see the asset details page on the WASdev website for each feature that you want to install. The *feature\_shortName* is found in the installation instructions of the asset details page; for example: the Portlet Container *feature\_shortName* is *portlet-2.0*.

For a list of all Liberty features, see “Liberty features” on page 826.

- Obtain the *feature\_shortName* from the asset details page on the WASdev website for each feature that you want to install. The *feature\_shortName* is found in the installation instructions of the asset details page; for example: the Portlet Container *feature\_shortName* is *portlet-2.0*.
- Run the **featureManager** command to install the assets. Run the following command:

```
bin/featureManager install feature_shortName --when-file-exists=ignore
```

To install multiple features, use spaces or commas to separate each *feature\_shortName*; for example:

```
bin/featureManager install feature_shortName1 feature_shortName2 --when-file-exists=ignore
```

 To download a feature to a local directory without installing the feature, use the **--downloadOnly** option; for example:

```
bin/featureManager install feature_shortName1 feature_shortName2 --downloadOnly=[all|required*|none]
```

You can configure this option to download all the dependent features, the dependent features required for this runtime, or none of the dependent features. The default is to download the required dependent features. To specify a local destination directory, use this option with the **--location=directoryPath** option.

 To install features from a local source directory, use the **--location=directoryPath** option; for example:

```
bin/featureManager install feature_shortName1 feature_shortName2 --location=directoryPath
```

**Note:** **z/OS** **8.5.5.4** Beginning with Version 8.5.5.4, the SMP/E-managed repository for WebSphere Application Server for z/OS Version 8.5 includes a complete set of Liberty features at the current fix pack level. You can access these with the **featureManager** command by specifying the following command:

```
--location=/usr/lpp/InstallationManagerRepository/HBB0850/WLP/fixpacks/<fix pack level>/files
```

For example:

```
--location=/usr/lpp/InstallationManagerRepository/HBB0850/WLP/fixpacks/8.5.5.4/files
```

**8.5.5.8** As of Version 8.5.5.8, the Liberty features in this repository are stored in the format that is required by the **installUtility** command and can no longer be installed with the **featureManager** command. Use the **installUtility** command to install the features. For more information, see “Installing assets using the installUtility command” on page 1393.

 **8.5.5.4** If you do not want to connect to the Liberty Repository, use the **--offlineOnly** option to install features from a local directory; for example:

```
bin/featureManager install feature_shortName1 feature_shortName2 --offlineOnly --location=directoryPath
```

4. Use the **featureManager** command to see what assets you have installed or to get help. For more information, see: “Liberty:featureManager command”

## Liberty:featureManager command

### 8.5.5.0

You can use the **featureManager** command to find, install, uninstall, or obtain details about features.

The feature that you want to install must be packaged as a subsystem archive (ESA file).

**8.5.5.5** You can access the Liberty Repository using the **featureManager** command through a proxy server. For more information, see “Configuring proxy server support for the featureManager command in Liberty” on page 1410.

**Tip:** **8.5.5.6** Use the **installUtility** command instead of the **featureManager** command. With the **installUtility** command, you can manage more asset types and install, find, or download assets from multiple repositories. For more information, see “Installing assets using the installUtility command” on page 1393.

## Syntax

The command syntax is as follows:

```
featureManager action [options]
```

where *action* can take one of the following values:

**install** Install a feature from an enterprise subsystem archive (ESA) file, a URL to an ESA file, a feature short name, or a feature symbolic name.

If you specify a feature short name or a symbolic name, the feature is downloaded from an online repository hosted by IBM.

The *install* action uses the OSGI-INF/SUBSYSTEM.MF file from the ESA file as a new feature manifest that can be copied into the `/${wlp.user.dir}/extensions/lib/features` directory (or product extension directory if a value is specified for the **--to** property) being renamed after the symbolic name of the subsystem. All of the bundles for the subsystem will be extracted into the `/${wlp.user.dir}/extensions/lib` directory and renamed as `{bundle symbolic name}_{bundle version}.jar`. License files, checksum files, localization files and other subsystem content will also be extracted to the location defined in the subsystem manifest.

### 8.5.5.2

The **featureManager** command can download assets from the Liberty Repository; for more information, see “Installing Liberty Repository assets” on page 1391.

#### 8.5.5.5

### **uninstall**

Uninstall features using either the feature short name or the feature symbolic name.

#### **Note:**

- Ensure that all server processes are stopped before you uninstall a feature.
- The **uninstall** command cannot uninstall user features; for example: `webCacheMonitor-1.0`.

### **featureList**

Generate an XML file that contains a report that details all the features that are installed.

#### 8.5.5.4

### **find**

Find assets in the Liberty Repository that are applicable to your configuration.

#### 8.5.5.4

### **classpath**

Generate a JAR file that can be added to a compiler classpath in order to use APIs from a list of features. This action enables you to compile build scripts against the API JARs that are included in the product without referencing specific JAR names, which can change when a fixpack is applied. The output JAR contains relative paths to the API JARs in the product. Therefore, you must not move the output JAR to another directory.

**Note:** The **--features** option must be specified with this action.

**help** Display help information for a specified action.

## **Options**

The following options are available for the **featureManager install** command:

### **--acceptLicense**

Automatically indicate acceptance of license terms and conditions.

#### 8.5.5.4

### **--downloadOnly=[all | required\* | none]**

Download the requested feature to a local directory without installing the feature. This option can be configured to download all the dependent features, the dependent features required for this runtime, or none of the dependent features. The default is to download the required dependent features. Specify the directory with the **--location** option.

**Note:** You cannot use this option if you specify the subsystem archive location with a file name or URL.

#### 8.5.5.4

### **--location=directoryPath**

Specifies the location of the subsystem archive that you want to install. When used with the **--downloadOnly** option, this option specifies a destination directory for downloaded features. This option is required when using the **--downloadOnly** and **--offlineOnly** options.

**Note:** You cannot use this option if you specify the subsystem archive location with a file name or URL.

#### 8.5.5.4

### **--offlineOnly**

Use this option if you do not want to connect to the Liberty Repository. Instead, the command only installs features from the local directory. The local directory is specified with the **--location** option.

**Note:** You cannot use this option if you specify the subsystem archive location with a file name or URL.

**--to=*install\_option***

where *install\_option* can take one of the following values:

- **usr**: The feature is installed as a user feature. This is the default value.
- **extension**: The location to which you want to install the feature. You can install the feature to any configured product extension location.

**--viewLicenseAgreement**

View license agreement.

**--viewLicenseInfo**

View license information.

**--when-file-exists=*exist\_option***

Specifies the action to take if a file to be installed already exists. *exist\_option* can take one of the following values:

- **fail**: Cancel the installation.
- **ignore**: Continue the installation and ignore the file that exists.
- **replace**: Overwrite the existing file.

**--verbose**

Use this option to display any available additional information while the action runs.

***subsystem\_archive***

Specifies the location of the subsystem archive that you want to install. You can specify the location in the following ways:

- A file name; for example: `my_feature.esa`.
- A URL, for example:

`http://myhost.ibm.com/liberty/assets/my_feature.esa`

- **8.5.5.2** The short name of the subsystem archive (ESA file), such as `adminCenter-1.0`
- **8.5.5.2** The symbolic name of the subsystem archive (ESA file), such as `com.ibm.websphere.appserver.adminCenter-1.0`

For more information, see the Downloads page on WASdev.net.

**Note:** Specify multiple features by separating the features with a comma or a space. For versions prior to Version 8.5.5.7, multiple features must be separated by a comma.

**8.5.5.5** The following options are available for the **featureManager uninstall** command:

**8.5.5.8** **--force**

Uninstall the specified feature regardless of whether other installed features have dependencies on it.

**Note:** Uninstalling a feature that is required by other installed features might cause those features to stop working and might prevent servers from running correctly.

**--noPrompts**

Uninstall features without any user interaction or confirmation messages.

**--verbose**

Use this option to display any available additional information while the action runs.

***name*** Specify the feature to uninstall. You can specify the following options:

- The short name of the subsystem archive (ESA file), such as `adminCenter-1.0`.
- The symbolic name of the subsystem archive (ESA file), such as `com.ibm.websphere.appserver.adminCenter-1.0`.

**Note:** Specify multiple features by separating the features with a comma or a space. For versions prior to Version 8.5.5.7, multiple features must be separated by a comma.

The following options are available for the **featureManager featureList** command:

**--encoding=*charset***

where *charset* is the character set to use when creating the XML report file.

**--locale=*language***

where *language* specifies the language to use when creating the XML report file. This consists of the ISO-639 two-letter lowercase language code, optionally followed by an underscore and the ISO-3166 uppercase two-letter country code.

**--productExtension=*name***

where *name* is the product extension name whose features are to be listed. If the product extension is installed in the default user location, use the keyword: `usr`. If this option is not specified, the action is taken on WebSphere Application Server Liberty Core.

**XML\_report\_file\_name**

Specifies the name of the XML report file that you want to create.

The following options are available for the **featureManager find** command:

**8.5.5.4 --viewInfo**

View detailed information.

**--verbose**

Use this option to display any available additional information while the action runs.

**8.5.5.4 searchString**

Use the *searchstring* option to find applicable features from the IBM WebSphere Liberty Repository

**8.5.5.4** The following options are available for the **featureManager classpath** command:

**--features=*feature1,feature2,...***

The list of features that contain the list of API JAR files. This option is required for the classpath action.

**fileName**

The name of the generated JAR file.

## Usage examples

The following example installs the subsystem archive `my_feature.esa` as a user feature:

```
featureManager install my_feature.esa --to=usr
```

The following example installs the subsystem archive `my_feature.esa` to the `my_extension` product extension location:

```
featureManager install my_feature.esa --to=my_extension
```

The following example generates a report for all installed features; the report is written to the file `my_feature_report.xml` using the Brazilian Portuguese language:

```
featureManager featureList my_feature_report.xml --locale=pt_BR
```

The following example generates a report that contains all installed features that are defined in the product extension that is installed in the default user location `wlp/usr/extension`, which is known by the runtime environment as the `usr` product extension. The report is written to the file `my_feature_report.xml`:

```
featureManager featureList --productExtension=usr my_feature_report.xml
```

The following example generates a report that contains all features that are defined in the product extension that is installed in the location pointed to by the content in the *productExtensionName.properties* file in the product installation's *etc/extensions* directory. The report is written to the file *my\_feature\_report.xml*:

```
featureManager featureList --productExtension=productExtensionName my_feature_report.xml
```

The following example displays help information for the *install* action:

```
featureManager help install
```

8.5.5.4

The following example finds applicable assets from the Liberty Repository:

```
featureManager find searchString
```

8.5.5.4

The following example lists detailed information:

```
featureManager find searchString --viewInfo
```

8.5.5.4

The following example downloads required dependencies from the Liberty Repository to a local directory and does not install them:

```
featureManager install feature_shortName --downloadOnly --location=c:\temp\download --acceptLicense
```

**Note:** You cannot use this option if you specify the subsystem archive location with a URL.

8.5.5.4

The following example downloads all dependencies from the Liberty Repository and does not install them:

```
featureManager install feature_shortName --downloadOnly=all --location=c:\temp\download --acceptLicense
```

**Note:** You cannot use this option if you specify the subsystem archive location with a URL.

8.5.5.4

The following example installs features that are located in a local directory. If there are missing dependencies, they are installed from the online repository:

```
featureManager install feature_shortName --location=c:\temp\download --acceptLicense
```

**Note:** You cannot use this option if you specify the subsystem archive location with a URL.

8.5.5.4

The following example installs assets from a local directory without downloading missing dependencies from the Liberty Repository:

```
featureManager install feature_shortName --location=c:\temp\download --offlineOnly
```

**Note:** You cannot use this option if you specify the subsystem archive location with a URL.

8.5.5.4

The following example creates a classpath JAR file and compiles an application class that uses it:

```
featureManager classpath --features=servlet-3.0 classpath.jar  
javac -cp classpath.jar TestServlet.java
```

8.5.5.5

The following example uninstalls a feature:

```
featureManager uninstall adminCenter-1.0
```

## Return codes

Table 102. Return codes and explanations

Return code	Explanation
0	The command successfully completed the requested operation.
20	One or more arguments are not valid.
21	A runtime exception occurred because of one or more of the following conditions: <ul style="list-style-type: none"><li>• A runtime exception occurred while installing the .esa subsystem archive file.</li><li>• A license is not accepted or acknowledged.</li><li>• The .esa subsystem archive file did not extract correctly.</li></ul>
22	The feature that you wanted to install already exists.
23	The feature definition was not valid for one or more of the following reasons: <ul style="list-style-type: none"><li>• The feature does not have a valid manifest file.</li><li>• The version of the feature is not supported in this Liberty environment.</li><li>• The .zip or .jar file that contains the feature files does not exist.</li></ul>
24	The .esa subsystem archive file is missing content.
25	A file that you wanted to install already exists, and you specified the <b>when-file-exists=fail</b> option.
26	The product is not a core product, and the product extension files cannot be found.
27	The product is not a core product, and the product extension is not defined in the <code>\${wlp.install.dir}/etc/extensions/<i>extension_name</i>.properties</code> file.
28	The manifest files for the feature in the product extension cannot be found.
29	The feature is not valid for the current product.

## Configuring proxy server support for the featureManager command in Liberty

8.5.5.5

You can access the Liberty Repository using a proxy server.

### Before you begin

Ensure that you have created the required directory structure. If the etc directory is not found in the Liberty installation directory, then you must create it.

### About this task

You can run the **featureManager** command to connect to the IBM WebSphere Liberty Repository through a user-specified proxy server.

#### Note:

- The **featureManager** command only supports proxy servers with HTTP/HTTPS protocols.

- The proxy server is only supported for the install and find options for the **featureManager** command.
- To access the IBM WebSphere Liberty Repository with limited internet access or through a firewall, ensure that you have access to the following hosts and ports:
  - public.dhe.ibm.com on port 443
  - asset-websphere.ibm.com on port 443

**8.5.5.6** Both the **featureManager** command and the **installUtility** command use the same configuration properties file, `repositories.properties`. The proxy settings are shared, but the repository settings are only used by the **installUtility** command. Using the **installUtility** command is recommended over the **featureManager** command because it enables you to work with more asset types and from multiple repositories; for more information see “Configuring repositories and proxy settings for the installUtility command” on page 1401.

To configure proxy server support for the **featureManager** command, complete the following steps.

### Procedure

1. In the `<Liberty_installation_dir>/etc` directory, create an ASCII properties file, and name it `repositories.properties`.
2. In the `repositories.properties` file, specify the following properties with the proxy server configurations:
  - a. Specify the proxy server host name with no protocol information.  
`proxyHost=proxy.xyz.com`
  - b. Specify the proxy server port number:  
`proxyPort=8080`
  - c. Specify the proxy server user name and encrypted password. The proxy server password must be encrypted by using the **securityUtility** command found in the `<Liberty_installation_dir>/bin/` directory.  
For more information about the encoding options, see: “Liberty:securityUtility command” on page 1844. If the proxy server does not require authentication, then the **proxyUser** and **proxyUserPassword** properties are not required.  
`proxyUser=user`  
`proxyUserPassword={aes}Ly0wJyYPKDs=`
3. Save the `repositories.properties` file.

### What to do next

Run the `featureManager install name` or `featureManager find searchString --viewInfo` commands to install or query applicable Liberty features from the IBM Liberty Repository through the specified proxy server. For more information, see “Liberty:featureManager command” on page 1405.

## Installing assets using Installation Manager

### 8.5.5.2

If you have IBM Installation Manager installed, you can download and install Liberty Repository assets when you install or upgrade Liberty.

### Before you begin

**Note:** To install Liberty Repository assets, you must have IBM Installation Manager Version 1.6.2 or later and be installing or upgrading to Liberty for WebSphere Application Server Version 8.5.5.2 or later.

## About this task

This task applies only to installing Liberty Repository features or add-ons during the installation or upgrade of Liberty for WebSphere Application Server Version 8.5.5.2 or later. For information about installing product samples and open source integrations, see Installation Manager repository for Liberty samples on WASdev.net. For a list of all assets and their descriptions, see the Downloads page on WASdev.net.

You can install Liberty Repository assets from the following repositories:

- The IBM WebSphere Liberty Repository, a public IBM-hosted repository that is accessible through the internet. For more information, see “Liberty: Liberty Repository” on page 965.
- **8.5.5.6** The Liberty Asset Repository Service, an open-source service that you can use to create an on-premises repository that is remotely accessible behind the firewall of an enterprise. For more information, see the WASdev/tool.lars project on GitHub.
- **8.5.5.6** Local directory-based repositories that are created by using the **installUtility download** action. For more information, see “Downloading assets using the installUtility command” on page 1400.

Rather than downloading individual assets, you can download a `wlp-featureRepo-<version>.zip` file from IBM Fix Central. The .zip file contains a directory-based repository of all features and add-ons for that fix pack. Downloading assets using these methods creates a `repository.config` file in the repository that you must point to from Installation Manager.

You can add the directory-based and Liberty Asset Repository Service repositories to Installation Manager in the same manner that you add the product offering repositories, then install assets from the repositories. Assets are installed from the repositories in the order that you specify them. If these repositories do not contain the assets that you want to install, the assets are installed from the IBM WebSphere Liberty Repository unless you disable it.

To access the IBM WebSphere Liberty Repository with limited internet access or through a firewall, ensure that you have access to the following hosts and ports:

- `public.dhe.ibm.com` on port 443
- `asset-websphere.ibm.com` on port 443

## Procedure

1. **8.5.5.6** Optional: Set up an instance of the Liberty Asset Repository Service or a local directory-based repository, then specify the repository URL or directory path in Installation Manager.  
**8.5.5.8** For Version 8.5.5.8 and later, you can also specify the file path of a directory-based repository compressed in an archive file.
2. Install Liberty and Liberty Repository assets.
  - **Distributed operating systems** Choose from the following options for working with Installation Manager:
    - Graphical User Interface (GUI) - The Installation Manager GUI provides a list of available assets and detailed descriptions of each asset. See “Installing Liberty on distributed operating systems using the GUI” on page 1171.
    - Command line - The **imcl** command can download and install assets. See “Installing Liberty on distributed operating systems by using the command line” on page 1174.
    - Response files - Installation Manager supports installing assets using recorded or manually created response files. See “Installing Liberty on distributed operating systems by using response files” on page 1178.
  - **IBM i** Choose from the following options for working with Installation Manager:

- Command line - The **imcl** command can download and install assets. See “Installing Liberty on IBM i operating systems using the command line” on page 1294.
- Response files - Installation Manager supports installing assets using recorded or manually created response files. For detailed steps about installing assets using Installation Manager in silent mode, see “Installing Liberty on IBM i operating systems using response files” on page 1299.
- **z/OS** The **imcl** command can download and install assets. See “Installing WebSphere Application Server Liberty for z/OS” on page 1353.

## Installing assets by using developer tools

Distributed operating systems

8.5.5.2

If you have developer tools installed, you can install feature assets, open source integration assets, product sample assets, runtime assets, add-on assets, and config snippet assets from the Liberty Repository.

### About this task

Developer tools for WebSphere Application Server, such as IBM WebSphere Application Server Developer Tools for Eclipse, provide a graphical user interface that you can use to install Liberty Repository assets. This task shows you how to install assets by using WebSphere Developer Tools, Version 8.5.5.2 and later versions.

### Procedure

- Optional: Install assets from the Servers view.

If you create a Liberty server and a Liberty runtime environment, either from an archive or from the Liberty repository, you can install the following assets on the new runtime environment in the Servers view:

- Feature assets
- Open source integration assets
- Product runtime environment assets
- Product sample assets
- Add-on assets

You can install configuration snippet assets after you create a Liberty server. For more information, see “Creating a Liberty server by using developer tools” on page 1424.

- Install assets from the Runtime Explorer view.

In the Runtime Explorer view, you can install the following assets when you create a runtime environment or when you create a server in a runtime environment:

- Feature assets
- Open source integration assets
- Product sample assets
- Add-on assets

For more information, see the “Exploring the runtime environment by using developer tools” on page 1561 topic.

- Review the assets on the Downloads page on WASdev.net.

You can use search and filters to narrow your search results. Assets that you can install by using WebSphere Developer Tools are included on the site, along with assets that you can download by other methods.

## Adding more repositories by using developer tools

8.5.5.7

You can configure the list of repositories that are available for access by the tools. You can add remote repositories or local, directory-based repositories.

### Before you begin

- To create an on-premises repository that is remotely accessible behind the firewall of an enterprise, see the `WASdev/tool.lars` project on GitHub.
- To create a local, directory-based repository by using the `installUtility` download action, see `Downloading assets using the installUtility command`.

### Procedure

1. Open the Runtime Explorer view.
  - a. Select **Window > Show View > Other** from the workbench toolbar.
  - b. Select **Server > Runtime Explorer** in the Show View window.
2. Right-click the runtime environment, and then select **Install additional content...**.  
The Install Additional Content window is displayed.
3. Click **Configure Repositories**.  
The Configure Repositories window is displayed.
4. Add a repository.
  - a. To add a repository, click **Add...**
  - b. Enter a name for the repository in the **Name** field.
  - c. Enter the location for the repository.
    - To use a remote repository, select **Remote Repository**, and then enter the connection information.
    - To use a repository in a local directory, select **Local Repository**. Then, enter or browse to the location of the assets, which you downloaded by using the `installUtility` command of the runtime environment, or from the Liberty Repository.
    - **8.5.5.8** To use a repository in a .zip file, select **Browse**, and then browse to your .zip file. You can download a `wlp-featureRepo-<version>.zip` file from IBM Fix Central. The .zip file contains a directory-based repository of all features and add-ons for that fix pack.
  - d. Click **OK**.

### What to do next

In the Configure Repositories window, you can add, edit, remove, and reorder repositories.

The repository list is in descending order of priority. If an asset is contained in more than one repository, then the repository that is found first in the list is used during installation. Ensure that your repository is selected.

---

## Verifying the integrity of Liberty installation

8.5.0.1

You can use the command utilities to verify the installation integrity of Liberty.

## About this task

After you have installed Liberty, you must make sure that the installation is completed successfully and that all required features or iFixes are installed. The `productInfo` command provides different options to complete the following tasks:

- Compare the differences between APAR fixes and the current installation.
- Validate the MD5 checksum file for server installation and each feature.
- Verify the version information of the current installation.
- Verify the feature list on the current installation.

## Liberty:productInfo command

8.5.0.1

Use the **productInfo** command to validate the product integrity, compare different versions of the Liberty servers, and verify the current product versions.

### Syntax

The command syntax is as follows:

```
productInfo action --[options]
```

Where the possible values of the *options* vary depending on the value of the *action* parameter.

### Parameters

The following *action* parameters and *options* values are available for the **productInfo** command:

#### compare

Allows you to compare APAR fixes that are installed in the current installation with a different version of Liberty.

**--target**=*path to directory or archive file*

Specifies the target file with which to compare the current installation. The value of **--target** can be either a directory or an archive file that must be a valid Liberty installation location. This option is required if **--apars** is not specified.

**--apars**=*a comma separated list of APAR IDs*

Checks the current installation against this comma-separated list of APAR IDs to see if it contains them, and then lists any APARs that are not included. This option is required if **--target** is not specified.

**--output**=*path to an output file*

Outputs the result from this command to the supplied file name. By default, the output is directed to standard output.

**--verbose**

Displays detailed error messages when an error occurs.

**Note:** At least one of **--target** or **--apars** must be supplied

#### featureInfo

Lists all the features that are installed on the current Liberty server including any installed product extensions.

**--output**=*path to an output file*

Outputs the result from this command to the supplied file name. By default, the output is directed to standard output.

## validate

Validates the Liberty server.

**--output=***path to an output file*

Outputs the result from this command to the supplied file name. By default, the output is directed to standard output.

## version

Displays the product name and version.

The output includes the name and version of product extensions if a *product\_extension.properties* file is provided in the product extension installations versions directory containing the following properties:

`com.ibm.websphere.productVersion=your_product_version.`

`com.ibm.websphere.productName=your_product_name.`

**--output=***filename*

Outputs the result from this command to the supplied file name. By default, the output is directed to standard output.

**--verbose**

Displays the whole content of each properties file.

**--ifixes**

Displays the APAR fixes that are applied to the system, and the interim fixes that applied them.

For more information, refer to “Provide product information for your feature extension” on page 1823

### 8.5.5.6 viewLicenseAgreement

Displays the license agreement for the Liberty edition that is installed.

### 8.5.5.6 viewLicenseInfo

Displays the license information for the Liberty edition that is installed.

**help** Displays help information for the specific action.

## Usage

The following examples demonstrate correct syntax: 8.5.5.6

```
productInfo compare --target=C:\wlp\newInstall\wlp
productInfo compare --target=C:\wlp\newInstall.jar --output=C:\wlp\compareOutput.txt
productInfo compare --apars=com.ibm.ws.apar.PM39074,com.ibm.ws.apar.PM39075,com.ibm.ws.apar.PM39080
productInfo featureInfo --output=c:\wlp\featureListOutput.txt
productInfo validate
productInfo help compare
productInfo version
productInfo viewLicenseAgreement
productInfo viewLicenseInfo
```

---

## Docker support in Liberty

### 8.5.5.5

Docker is an open source platform that uses Linux containerization and a layered file system. The image that is built by using Docker consists of layers that contain the application and the dependent binary files and libraries, but uses the kernel from the host operating system. The layering allows changes to be made quickly because only the modified layers are rebuilt and deployed.

Liberty is designed to run in a container on multiple platforms compatible with the Docker engine. Specifically, Liberty has been tested on IBM Containers, Docker Datacenter, and OpenShift V3. To qualify for support, the base operating system that is used within the container must be a platform supported by the Liberty product.

For more information about Docker and its advantages, see [What is Docker?](#)

Docker Hub is a public repository that hosts Docker images. A Docker image for WebSphere Application Server for Developers Liberty is available on Docker Hub along with the documentation that describes its usage.

Running Liberty under Docker is also supported for production usage. Instructions and Dockerfiles for building production licensed Docker images by using the installation files that are obtained from Passport Advantage can be found on WASdev GitHub.

---

## Accessing a remote Liberty server in a Docker container by using developer tools

8.5.5.8

You can set up your remote Liberty server in a Docker container so that you can access it by using WebSphere Developer Tools. After you complete this setup, you can use WebSphere Developer Tools to configure and start your remote Liberty server.

### Before you begin

1. Install Docker, Cloud Foundry Command Line Interface (CLI), and the Cloud Foundry plug-in for IBM Containers.

For more information about installation, see [IBM Containers plug-in](#).

2. Log in to your Bluemix account, choose your organization and space, and then log in to your IBM Containers service.

For more information about logging in to your accounts, see [Logging into the CLI](#).

**Tip:** You can either run `cf ic` commands or `docker` commands to set up a Liberty server in a Docker container. For more information about `cf ic` commands and `docker` commands, see the Step 5 section of [Logging into the CLI](#).

### Procedure

1. To access your remote Liberty server in a Docker container, use the following command:

```
docker exec -i ContainerID LibertyInstallDirectory/bin configUtility install remoteAdministration --vadminUser=User
```

**Remember:** To find the container ID, use the `docker ps` command. By default, the `KeystorePassword` value is `Liberty`.

Also, by default the `LibertyInstallDirectory` value is `/opt/ibm/wlp`, and the `bin` directory is in the `/opt/ibm/wlp` directory.

For more information about the `configUtility` command, see [Liberty: configUtility command](#).

2. When the script displays the configuration snippet, copy it into the `remoteAdministration.xml` file. The `remoteAdministration.xml` file is in the `LibertyInstallDirectory/usr/servers/serverName/configDropins/defaults` directory. If this directory and file do not exist, create the directory and then create the file.
3. Specify the `<remoteFileAccess>` parameter in the `remoteAdministration.xml` file by replacing its contents with the following text:

```
<writeDir>${server.config.dir}</writeDir>
<writeDir>${server.output.dir}</writeDir>
<writeDir>${wlp.user.dir}</writeDir>
```

4. Save the `remoteAdministration.xml` file.

## What to do next

You can configure and start a remote Liberty server that is in a Docker container.

For more information about how to configure and start a remote Liberty server, see “Creating a remote Liberty server by using developer tools” on page 1427.

---

## Liberty and Chef

Chef software is an open source configuration management tool that you can use to create and manage the installation of an Infrastructure as a Service (IaaS). You can use Chef to provision a Liberty installation.

Chef uses cookbooks, which are reusable sets of components that are written in the Ruby programming language. A cookbook provides all the necessary components that are needed to configure an associated piece of software, for example, Apache HTTP Server. An important distinction between using Chef and writing scripts is the ability of Chef to determine the differences between the current software configuration and a new configuration and make only the changes necessary to move from one to the other. For more information, see the online Chef documentation [About Cookbooks](#).

By using Chef, you can create scalable infrastructure with minimal configuration to maintain. You can easily expand your existing infrastructure, for example, by creating and starting a new application server or web server. Chef automatically connects the new servers into the existing infrastructure as necessary.

The `wlp` cookbook installs and configures the WebSphere Application Server Liberty. It provides recipes, resources, and libraries for creating, managing, and configuring Liberty server instances. For more information, see `wlp` cookbook.

To learn more about Chef, see the online Chef documentation [How Chef works](#).

To learn more about using Chef cookbooks, see [Getting started with the Chef cookbooks for Liberty](#).

---

## Installing the OpenShift Cartridge for Liberty

Distributed operating systems

IBM i

8.5.5.9

The downloadable OpenShift cartridge allows the Liberty server to be available on OpenShift.

### Before you begin

- You must have Ruby version 1.9.3 or later installed.
- This document details how to download the OpenShift cartridge by using the Linux command line.

### About this task

OpenShift is an open source platform that allows developers to quickly develop, build, deploy, and manage Linux containerized services and applications in a cloud environment. When you install the OpenShift cartridge for Liberty, both Liberty and JRE binary files are downloaded for each application.

The OpenShift cartridge is also available at <https://github.com/WASdev/cloud.openshift.cartridge.wlp> where you can find extra documentation.

For more information about OpenShift and its advantages, see OpenShift

**Note:** Only OpenShift version 2 can be used with this cartridge

## Procedure

Installing the cartridge into your OpenShift environment

1. Download the cartridge compressed file from IBM Fix Central.
2. Run the **unzip** command to extract the contents of the cartridge `ibm-websphere-liberty-cartridge-v*.zip` file to the following cartridge directory `cloud.openshift.cartridge.wlp`
3. The OpenShift cartridge downloads the default Liberty and IBM JRE binary files for development only. If you have licenses for other binary files that you want to use, they need to be accessible with HTTP. See “Structure a Liberty repository for personal binary files” on page 1421 for details on how to structure this repository.
  - a. Update the `ibm-websphere-liberty-buildpack/config/ibmjdk.yml` file to point to your JRE binary.
  - b. Update the `ibm-websphere-liberty-buildpack/config/liberty.yml` file to point to your Liberty binary.
4. Run the **chmod u+x ibm-websphere-liberty-buildpack/resources/download\_buildpack\_cache.rb** command and add the binary files from step 3 to the cartridge cache. Run the **ibm-websphere-liberty-buildpack/resources/download\_buildpack\_cache.rb ibm-websphere-liberty-buildpack/admin\_cache**
5. If you are licensed to deploy the cartridge into your environment, you can create a `ibm-websphere-liberty-buildpack/config/licenses.yml` file that contains the accepted license numbers before packaging.

```
IBM_JVM_LICENSE: <jvm license code>
IBM_LIBERTY_LICENSE: <liberty license code>
```

**Note:** When installed the cartridge can be made available to all users. If you are an administrator or own your OpenShift installation, you can have more control over how the cartridge behaves in these situations. After you add the license to the cartridge package, individual applications do not need to accept the license terms with environment variables.

6. Return to your original directory and copy the cartridge directory to each node host on your OpenShift machines.
  7. On each node host run:

```
oo-admin-cartridge --action install --source cloud.openshift.cartridge.wlp/
service ruby193-mcollective restart
```
  8. On the broker host run:

```
oo-admin-broker-cache --clear --console
oo-admin-ctl-cartridge -c import-node --activate
oo-admin-console-cache --clear
```
  9. Verify that the cartridge is installed by running the **rhc cartridges** command.
- Uninstalling the cartridge from your OpenShift environment
10. On the broker host run:

```
oo-admin-ctl-cartridge -c deactivate --name ibm-liberty-8.5.5
```
  11. On each node host run:

```
oo-admin-cartridge --action erase --name liberty --version 8.5.5 --cartridge_version <Cart_Version_Number>
```
  12. On the broker host run:

```
oo-admin-broker-cache --clear --console
oo-admin-console-cache --clear
```
  13. Verify that the cartridge uninstalled by running the **rhc cartridges** command.

## Results

The OpenShift cartridge is now installed.

---

# Installing the IBM WebSphere Application Server Liberty Buildpack into a Cloud Foundry Environment

Distributed operating systems

IBM i

8.5.5.9

The IBM WebSphere Application Server Liberty Buildpack makes the Liberty server available in Cloud Foundry.

## Before you begin

- You must have Ruby version 1.9.3 or later installed.
- This document details how to download the IBM WebSphere Application Server Liberty buildpack by using the Linux command line.

## About this task

Use this task to install the IBM WebSphere Application Server Liberty Buildpack into a Cloud Foundry Environment. If you are a Cloud Foundry administrator, you can install the Liberty buildpack as an admin buildpack making it available to all users within the Cloud Foundry.

**Note:** Buildpack users do not need to specify the `-b` option to use the buildpack directly from the administrator.

The IBM WebSphere Application Server Liberty Buildpack is also available at <https://github.com/cloudfoundry/ibm-websphere-liberty-buildpack> where you can find extra documentation.

## Procedure

Installing the buildpack into your Cloud Foundry environment

1. Download the buildpack compressed file from IBM Fix Central.
2. Run the **unzip** command to extract the contents of the buildpack `ibm-websphere-liberty-buildpack-v*.zip` file to the following buildpack directory `ibm-websphere-liberty-buildpack`
3. The IBM WebSphere Application Server Liberty buildpack downloads the default Liberty and IBM JRE binary files for development only. If you have licenses for other binary files that you want to use, they need to be accessible with HTTP. See “Structure a Liberty repository for personal binary files” on page 1421 for details on how to structure this repository.
  - a. Update the `config/ibmjdk.yml` file to point to your JRE binary.
  - b. Update the `config/liberty.yml` file to point to your Liberty binary.
4. If you are licensed to deploy the buildpack into your environment, you can create a `config/licenses.yml` file that contains the accepted license numbers before packaging.

```
IBM_JVM_LICENSE: <jvm license code>
IBM_LIBERTY_LICENSE: <liberty license code>
```

**Note:** After you add the license to the buildpack package, individual applications do not need to accept the license terms with environment variables.

5. Install Ruby gems that are needed to package an admin buildpack by running the **gem install bundler** and **bundle install** commands.
6. Run the **bundle exec rake** package task to create an admin buildpack.

```
rake 'package[zipfile,hosts,version]'
```

The **zipfile** parameter is the name of the generated admin buildpack and includes a relative location that is NOT the current directory. For example, `../my-admin-buildpack.zip` can be specified as the **zipfile** parameter to generate the `my-admin-buildpack.zip` file in the parent directory instead of the default `ibm-websphere-liberty-buildpack-480d2de.zip` file.

For example,

```
rake 'package[../my-admin-buildpack.zip]'
```

The **hosts** parameter is a list of sites that the package task pulls binary files from for inclusion in the admin buildpack. By default, only binary files from the public IBM site are pulled. IBM hosted sites do not include third-party binary files. A package parameter must be specified to indicate that third-party binary files can be included in the admin buildpack for cases where the admin buildpack is used in offline mode. Using `*` includes all the binary files in the admin buildpack if the download is possible during the packaging.

An example of this usage:

```
rake 'package[,*,]'
```

The **version** parameter is the version information that is displayed when an application is deployed to **CloudFoundry** with the Cloud Foundry command line interface. By default, the displayed version is the latest commit identifier, such as `480d2de`.

The following example illustrates the displayed version information defaults.

```
Liberty Buildpack Version: 480d2de | git@github.com:cloudfoundry/ibm-websphere-liberty-buildpack.git#480d2de
```

7. Install the admin buildpack with the `cf` client as follows:

```
cf create-buildpack ibm-websphere-liberty-buildpack ibm-websphere-liberty-buildpack-480d2de.zip 1
```

- `ibm-websphere-liberty-buildpack` is the name that is given to the admin buildpack.
- `ibm-websphere-liberty-buildpack-480d2de.zip` is the path to the compressed file that is created by the Rake task.
- `1` is the priority given to the admin buildpack. The lower the number, the higher the priority.

See the Cloud Foundry documentation for further details.

## Results

The IBM WebSphere Application Server Liberty Buildpack is now installed.

## Structure a Liberty repository for personal binary files

8.5.5.9

The OpenShift cartridge and the IBM WebSphere Application Server Liberty Buildpack both download the default Liberty and IBM JRE binary files for development only. If you want to use your own binary files that you have other licenses for, the files must be accessible with HTTP.

### Repository structure

The repository is an HTTP-accessible collection of files. The repository root must contain an `index.yml` file that is a mapping of concrete versions to absolute URIs. For example,

```
<version>:
  uri: <URI of binary>
  license: <URI of license>
```

You can store your files in the repository. For example,

```
/index.yml
/ibm-java-jre-7.0-5.0-x86_64-archive.bin
/ibm-java-jre-7.0-5.0-x86_64-License.html
```

Versions are composed of the following four parts: major, minor, micro, and optional qualifier. The version format is <major>.<minor>.<micro>[\_<qualifier>].

Table 103. Part Requirements

Part	Requirement
Major	Numeric
Minor	Numeric
Micro	Numeric
Optional qualifier	Letters, digits, and hyphens with lexical order: <ol style="list-style-type: none"> <li>1. Hyphen</li> <li>2. Lowercase letter</li> <li>3. Uppercase letters</li> <li>4. Digits</li> </ol>

Aside from declaring a specific version to use, you can also specify a bounded range of versions. You can append the + symbol to a version prefix to use the latest version that begins with the prefix.

Table 104. Version Declarations

Example	Description
1.+	Selects the greatest available version less than 2.0.0.
1.7.+	Selects the greatest available version less than 1.8.0.
1.7.0+	Selects the greatest available version less than 1.7.1. <b>Note:</b> Use this syntax to stay up to security releases in a particular version.

For examples of `index.yml` files that illustrate the guidelines for the repository structure detailed in this document, see

<https://public.dhe.ibm.com/ibmdl/export/pub/software/websphere/wasdev/downloads/wlp/index.yml>

<https://public.dhe.ibm.com/ibmdl/export/pub/software/websphere/wasdev/downloads/jre/index.yml>

---

## Chapter 5. Setting up Liberty

Define directory locations and variables, create and configure servers, and add and remove Liberty features that specify the capabilities of your server.

### Procedure

- Defining directory locations and properties.
- **8.5.0.1** “Verifying the integrity of Liberty installation” on page 1414.
- **Distributed operating systems** “Creating a Liberty server by using developer tools” on page 1424.
- “Creating a Liberty server manually.”
- “Specifying Liberty bootstrap properties” on page 1437.

The default HTTP port is 9080 and HTTPS port is 9443 for Liberty. You can manually assign appropriate port numbers in the `server.xml` files when multiple Liberty servers are running on the same machine.

---

## Creating a Liberty server manually

You can create a server from the command line.

### **Distributed operating systems**

#### Before you begin

### **Distributed operating systems**

You can create a server as described here, or as described in “Creating a Liberty server by using developer tools” on page 1424.

### Procedure

1. Open a command line, then change directory to the `wlp/bin` directory.  
Where *path\_to\_liberty* is the location you installed Liberty on your operating system.  
Example on Windows: `C:\Users\mo> cd path_to_liberty\wlp\bin`  
Example on Linux: `mo@machine01:~> cd path_to_liberty/wlp/bin`
2. Run the following command to create a server. If you do not specify a server name, `defaultServer` is used.

Where *server\_name* is the name you want to give your server.

Example on Windows: `C:\wlp\bin> server create server_name`

Example on Linux: `mo@machine01:~> server create server_name`

Windows

AIX

Linux

UNIX

HP-UX

Solaris

z/OS

IBM i

```
server create server_name
```

*server\_name* must use only Unicode alphanumeric (for example, 0-9, a-z, A-Z), underscore (`_`), dash (`-`), plus (`+`), and period (`.`) characters. The name cannot begin with a dash or period. Your file system, operating system, or compressed file directory might impose additional restrictions.

## Results

If the server is created successfully, you receive message: Server *server\_name* created.

If the specified server already exists, no server is created and you receive an exception message:

```
CWWKE0005E: The runtime environment could not be launched.  
CWWKE0045E: It was not possible to create the server called server_name because  
the server directory C:\wlp\usr\servers\server_name already exists.
```

A directory with the name of the new server is created under the `${wlp.user.dir}/servers` directory, containing the configuration of the new server. The HTTP port numbers for the new server are assigned to default values and are shown in the generated `server.xml` file to make it easy to edit them. You can also set these values by using variables in a `bootstrap.properties` file in the same directory. For more information, see “Specifying Liberty bootstrap properties” on page 1437.

## What to do next

Configure your server to have the features that your application requires. See “Configuring the Liberty runtime environment ” in the “Administering” book.

---

## Creating a Liberty server by using developer tools

### Distributed operating systems

You can use developer tools to create and start a Liberty server. If you have not yet installed Liberty, the developer tools can install it for you when you create a server for the first time.

## Before you begin

Make sure that you installed the developer tools as described in “Installing Liberty developer tools and (optionally) Liberty” on page 1374.

You can create a server as described in this topic, or as described in “Creating a Liberty server manually” on page 1423.

When you create a new server using the tools, you specify the installation of Liberty that you want to use. You are offered three options:

- **Select an existing installation.**
- **Install from a previously downloaded archive file.**
- For the no-charge developer edition, **Download and install.**

If you want to use the tools to install a Liberty edition (other than the no-charge developer edition) from an archive file, make sure that you have downloaded the archive file.

8.5.5.5

If you need to use a proxy server to connect to the Liberty repository, first configure the proxy settings by selecting **Window > Preferences > General > Network Connections** from the main menu in Eclipse. Enter the information there.

## About this task

Complete the following steps to create and start a Liberty server.

As you go through the steps, you can download add-ons in the Liberty Repository from the WASdev community download site.

## Procedure

1. In the workbench, open the Servers view by clicking the **Servers** tab.

**Tip:** If the Servers view is not visible, navigate to **Window > Show view > Other...** and type **Server** in the filter text. Then, select **Servers**.

2. Right-click the **Servers** view and select **New > Server**.
3. Under the server type list, expand **IBM** and select the  **8.5.5.4 WebSphere Application Server Liberty** server type.  **8.5.5.4** The WebSphere Application Server Liberty server type replaces the old WebSphere Application V8.5 Liberty server type and supports all versions of the WebSphere Application Server Liberty server. Existing servers in a workspace that were created with the old server type still work.
4. Click **Next**. The Liberty Runtime Environment page is displayed.
- 5.

**Tip:** If you already have a Liberty run time that is installed, you will go directly to the **New Remote Liberty Server** page, skip to Step 7.

Select an installation, install from an archive file, or (for the no-charge developer edition) download and install, Liberty.

If you previously installed Liberty, complete the following steps:

- a.  **8.5.5.4** Select **Choose an existing installation**.
- b.  **8.5.5.4** In the **Path** field, type or browse for the directory where you installed the Liberty runtime environment.
- c.  **8.5.5.4** On the Liberty Runtime Environment page, click **Next**.  
The application-serving environment is selected, and now you can skip to Step 7.

If you want to install Liberty from an archive file that was previously downloaded, complete the following steps:

- a.  **8.5.5.4** Select **Install from an archive or repository**, and click **Next**.
- b.  **8.5.5.4** In the **Destination** field, type or browse for the directory where you want to install the Liberty runtime environment.  
If you type a path that does not exist, then a folder for that path is created automatically at the end of Step 10.
- c.  **8.5.5.4** Select **Install a new runtime environment from an archive**.
- d.  **8.5.5.4** In the **Path** field, either type or browse to the archive file on the local file system, and click **Next**.
- e. In the Install Add-ons page, click **Install** or **Install Pending** to make your selection of add-on archive files that you want to install on the Liberty runtime environment.

You can install an add-on archive file from your local file system, download, or use a combination of both when you install multiple add-on archive files. If the workbench is connected to the internet, the Install Add-ons page is populated with add-on archive files available for download from the WAS dev community download site.

This download site includes add-ons that you can select from the Liberty Repository, such as runtime features, samples, or open source integration.

If you want to install add-on archive files from your local file system, click **Add Archive**. In the **Add-on archive** field, type or browse for the add-on archive file on the local file system, and then click **OK**. If you have more add-on archive files to install from your local file system, repeat this step until you are done.

8.5.5.6

If you want to install add-on files from a custom repository, first add the repository by clicking **Configure Repositories**. Click **New...** to add the repository. The files are then added to the list of add-on files.

After you complete your selection in the Install Add-ons page, click **Next**.

- f. In the License Acceptance page, if you accept the license terms, select **I accept the terms of all the license agreements** then click **Next**.

Now you can skip to Step 7.

If you want to download and install the no-charge developer edition of Liberty, complete the following steps:

8.5.5.4

- a. Select **Install from an archive or repository**, and click **Next**.

8.5.5.4

- b. In the **Destination** field, type or browse for the directory where you want to install the Liberty runtime environment.

If you type a path that does not exist, then a folder for that path is created automatically at the end of Step 10.

8.5.5.4

- c. Select **Download and install a new runtime environment from ibm.com**, choose a runtime environment version, and then click **Next**.

- d. In the Install Add-ons page, click **Install** or **Install Pending** to make your selection of add-on archive files that you want to install on the Liberty runtime environment.

You can install an add-on archive file from your local file system, download, or use a combination of both when you install multiple add-on archive files. If the workbench is connected to the internet, the Install Add-ons page is populated with add-on archive files available for download from the WAS dev community download site.

This download site includes add-ons that you can select from the Liberty Repository, such as runtime features, samples, or open source integration.

If you want to install add-on archive files from your local file system, click **Add Archive**. In the **Add-on archive** field, type or browse for the add-on archive file on the local file system, and then click **OK**. If you have more add-on archive files to install from your local file system, repeat this step until you are done.

If you want to install add-on files from a custom repository, first add the repository by clicking **Configure Repositories**. Click **New...** to add the repository. The files are then added to the list of add-on files.

After you complete your selection in the Install Add-ons page, click **Next**.

- e. In the License Acceptance page, if you accept the license terms, select **I accept the terms of all the license agreements** then click **Next**.

Now you can skip to Step 7.

- 6. If the Liberty Server page displays, in the **Liberty server** field, use the drop-down list to select an existing server. Or click **New** to create a new server.

**Note:** This step is skipped and the New Liberty Server dialog is displayed directly if there are no defined Liberty Servers to choose from.

- 7. If you are creating a new server, in the **Server name** field of the New Liberty Server page, enter a server name of your choice or use the default server name, defaultServer. Then, click **Next** if available, otherwise click **Finish**.
- 8. In the Liberty Server, click **Next**.
- 9. Optional: Add the projects of your application to the server. On the **Add and Remove** page, under the **Available** list, select the projects that you want to add to the server and click **Add**. The project appears in the **Configured** list.
- 10. Click **Finish**.

## What to do next

- Edit the server configuration. For more information, see topic “Editing the Liberty configuration by using developer tools” in the “Administering” book.
- Start the server in “start” mode or in “debug” mode, stop the server, add or remove applications on the server, and many other tasks. You can perform these tasks by using the server context menu (right-click on the server to open the pop-up menu) or by selecting the tray buttons in the Servers view.

**Tip:** In the Servers view, you must select the server entry to perform these tasks. Do not select the server configuration, such as the Server Configuration [server.xml] entry for performing these tasks.

- Optionally configure your server to do specific tasks such as configure Liberty to authenticate users with Tivoli Directory Server: Right-click **Servers**. Select **Utilities> Add config snippets**. After you select the snippets and accept any licenses, the selected configuration snippets are then downloaded and included in the **server.xml** file.

---

## Creating a remote Liberty server by using developer tools

Distributed operating systems

8.5.5.4

You can use developer tools to create and start a remote Liberty server.

### Before you begin

You must meet prerequisites for your local system and your remote system.

- The local system refers to the system where you installed the developer tools.
- The remote system refers to the system where you have Liberty runtime environment that is installed and a Liberty server created.

For your local system, ensure that you meet these prerequisites:

1. The developer tools are installed.

For more information, see “Installing Liberty developer tools and (optionally) Liberty” on page 1374.

2. The Liberty runtime environment is installed. For more information, see “Installing and uninstalling Liberty using downloaded files and archives” on page 1371.

For your remote system, ensure that you call the `configUtility` to download and set up the `remoteAdministration` snippet from the repository. Copy the config text that is retrieved by the `configUtility` into the `server.xml` file. For more information, see “Liberty:configUtility command” on page 1575.

You can use the following sample remote configuration as an example for your `server.xml` file:

```
<server description="new server">
<!-- Enable features-->
<featureManager>
<feature>restConnector-1.0</feature>
</featureManager>

<keyStore id="defaultKeyStore" password="password" />

<quickStartSecurity userName="admin" userPassword="password"/>

<httpEndpoint id="defaultHttpEndpoint" host="*" httpPort="9080" httpsPort="9443"/>

<remoteFileAccess>
<writeDir>${server.config.dir}</writeDir>
```

```
<writeDir>${server.output.dir}</writeDir>
<writeDir>${wlp.user.dir}</writeDir>
</remoteFileAccess>
</server>
```

## Procedure

1. In the workbench, open the Servers view by clicking the **Servers** tab.

**Tip:** If the Servers view is not visible, navigate to **Window > Show view > Other...** and type **Server** in the filter text. Then, select **Servers**.

2. Right-click within the **Servers** view and select **New > Server**.
3. Under the server type list, expand **IBM** and select the **WebSphere Application Server Liberty** server type.
4. Enter the host name of the remote server.
5. Click **Next**. The Liberty Runtime Environment page is displayed.
- 6.

**Tip:** If you already have a Liberty run time that is installed, you will go directly to the **New Remote Liberty Server** page, skip to Step 7.

Select an installation, install from an archive file, or (for the no-charge developer edition) download and install Liberty.

If you previously installed Liberty, complete the following steps:

- a.  **8.5.5.4** Select **Choose an existing installation**.
- b.  **8.5.5.4** In the **Path** field, type or browse for the directory where you installed the Liberty runtime environment.
- c.  **8.5.5.4** On the Liberty Runtime Environment page, click **Next**.

The application-serving environment is selected, and now you can skip to Step 7.

If you want to install Liberty from an archive file that was previously downloaded, complete the following steps:

- a.  **8.5.5.4** Select **Install from an archive or repository**, and click **Next**.
- b.  **8.5.5.4** In the **Destination** field, type or browse for the directory where you want to install the Liberty runtime environment.  
If you type a path that does not exist, then a folder for that path is created automatically at the end of Step 12.
- c.  **8.5.5.4** Select **Install a new runtime environment from an archive**.
- d.  **8.5.5.4** In the **Path** field, either type or browse to the archive file on the local file system, and click **Next**.
- e. In the Install Add-ons page, click **Install** or **Install Pending** to make your selection of add-on archive files that you want to install on the Liberty runtime environment.

You can install an add-on archive file from your local file system, download, or use a combination of both when you install multiple add-on archive files. If the workbench is connected to the internet, the Install Add-ons page is populated with add-on archive files available for download from the WAS dev community download site.

This download site includes add-ons that you can select from the Liberty Repository, such as runtime features, samples, or open source integration.

If you want to install add-on archive files from your local file system, click **Add Archive**. In the **Add-on archive** field, type or browse for the add-on archive file on the local file system, and then click **OK**. If you have more add-on archive files to install from your local file system, repeat this step until you are done.

If you want to install add-on files from a custom repository, first add the repository by clicking **Configure Repositories**. Click **New...** to add the repository. The files are then added to the list of add-on files.

After you complete your selection in the Install Add-ons page, click **Next**.

- f. In the License Acceptance page, if you accept the license terms, select **I accept the terms of all the license agreements** then click **Next**.

Now you can skip to Step 7.

If you want to download and install the no-charge developer edition of Liberty, complete the following steps:

- a.  **8.5.5.4** Select **Install from an archive or repository**, and click **Next**.
- b.  **8.5.5.4** In the **Destination** field, type or browse for the directory where you want to install the Liberty runtime environment.  
If you type a path that does not exist, then a folder for that path is created automatically at the end of Step 12.
- c.  **8.5.5.4** Select **Download and install a new runtime environment from ibm.com**, choose a runtime environment version, and then click **Next**.
- d. In the Install Add-ons page, click **Install** or **Install Pending** to make your selection of add-on archive files that you want to install on the Liberty runtime environment.

You can install an add-on archive file from your local file system, download, or use a combination of both when you install multiple add-on archive files. If the workbench is connected to the internet, the Install Add-ons page is populated with add-on archive files available for download from the WAS dev community download site.

This download site includes add-ons that you can select from the Liberty Repository, such as runtime features, samples, or open source integration.

If you want to install add-on archive files from your local file system, click **Add Archive**. In the **Add-on archive** field, type or browse for the add-on archive file on the local file system, and then click **OK**. If you have more add-on archive files to install from your local file system, repeat this step until you are done.

If you want to install add-on files from a custom repository, first add the repository by clicking **Configure Repositories**. Click **New...** to add the repository. The files are then added to the list of add-on files.

After you complete your selection in the Install Add-ons page, click **Next**.

- e. In the License Acceptance page, if you accept the license terms, select **I accept the terms of all the license agreements** then click **Next**.

Now you can skip to Step 7.

7. Complete the user ID, password, and port information for the remote server and click **Verify**.

**Important:**

- The user ID and password must have the appropriate security credentials as defined by the quickStartSecurity configuration item or the user registry of the remote Liberty server.
- The port is the HTTPS port that is configured in the server.xml file.

After you click **Verify**, if you see the following message, a local server or remote server is already created with the same name.

You can verify this situation by expanding the following folders in the Enterprise Explorer view and seeing the listed servers in the following projects:

- WebSphere Application Server Liberty
- WebSphere Application Server Liberty (Remote)

The remote directory is shown on the same page if the connection is successful. To resolve this issue of two servers with the same name, you can rename the Remote Directory folder on the remote system.

8. In the New Remote Liberty Server page, click **Next**.

The Remote WebSphere Application Server Settings page is displayed.

9. If you do not want to enable remote start, stop, and restart, ensure that **Enable the server to start remotely** is cleared, click **Next**, and skip the next step.

10. Enable remote start, stop, and restart.

- a. Select **Enable the server to start remotely**.
- b. Select whether your remote server is installed on the Windows operating system or other operating systems.
- c. Enter the location of the runtime installation and server configuration.

For more information, see the “Liberty:Directory locations and properties” on page 1434 topic.

- d. Enter the remote server authentication information.

For authentication, complete one of the following options.

- To access the remote server with logon credentials, enter your user name and password.
- To access the remote server with Secure Sockets Layer (SSL), copy the private key file to the computer where the workbench is installed, and specify the key file location and user ID.

For more information about starting a remote server, see the Starting a remote WebSphere Application Server topic.

11. Optional: Add the projects of your application to the server. On the **Add and Remove** page, under the **Available** list, select the projects that you want to add to the server and click **Add**. The project appears in the **Configured** list.
12. Click **Finish**.

## What to do next

- Edit the server configuration. When you make edits, the remote servers synchronize configuration changes with the remote version of the file. If the configuration files are out of sync with the remote server, then the developer tools prompt you before they overwrite any remote files. For more information, see topic “Editing the Liberty configuration by using developer tools” in the “Administering” book.
- Start the server in “start” mode or in “debug” mode, stop the server, add or remove applications on the server, and many other tasks. You can perform these tasks by using the server menu (right-click on the server to open the pop-up menu) or by selecting the tray buttons in the Servers view.

**Tip:** In the Servers view, you must select the server entry to perform these tasks. Do not select the server configuration, such as the Server Configuration [server.xml] entry for performing these tasks.

---

## Creating a workbench Liberty server in a Docker container by using developer tools

You can use WebSphere Developer Tools to create a reference in the workbench to a Liberty server that is running in a Docker container. You can use this reference to handle your server requests from the workbench.

## Before you begin

- Install WebSphere Developer Tools. For more information about installing WebSphere Developer Tools, see *Installing the Liberty developer tools and (optionally) Liberty*.
- Start a Liberty server in a local Docker container and ensure that both the HTTP and HTTPS ports are mapped to the host. For more information about starting a Liberty server in a local Docker container, see *WASdev GitHub*.

## About this task

**Remember:** You can create a reference in the workbench to a Liberty server that is running in a Docker container.

As you complete the steps, you can install WebSphere Application Server Liberty and download add-ons in the Liberty Repository from the WASdev community download site. After you install Liberty, you can select your Docker container. Then, you can enter the Liberty server security credentials for your Liberty server to create a workbench reference to your Liberty server in your Docker container.

## Procedure

1. In the workbench, open the Servers view by clicking the **Servers** tab.

**Tip:** If the Servers view is not visible, select **Window > Show view > Other...** and type **Server** in the filter text. Then, select **Servers**.

2. Right-click the **Servers** view and select **New > Server**.
3. To select your server type, select **IBM > WebSphere Application Server Liberty**.
4. Enter the localhost value in the **Server's host name** field.
5. Click **Next**.
6. If the tools prompt you to install WebSphere Application Server Liberty, either because it is not installed or because you need to input the directory where it is installed, complete one of the following options. Otherwise, skip this step.

You need Liberty to be installed so that you can create a workbench reference to a Liberty server in a Docker container.

If you previously installed Liberty, complete the following steps to select the directory where you installed it:

- a. Select **Choose an existing installation**.
- b. In the **Path** field, type or browse for the directory where you installed the WebSphere Application Server Liberty.
- c. On the Liberty Runtime Environment page, click **Next**.

The application-serving environment is selected. Skip the rest of this step.

If you want to install Liberty from an archive file that was previously downloaded, complete the following steps:

- a. Select **Install from an archive or repository**, and click **Next**.
- b. In the **Destination** field, type or browse to the directory where you want to install the Liberty runtime environment.

If you type a path that does not exist, then a folder for that path is created automatically at the end of the procedure when you click **Finish**.

- c. Select **Install a new runtime environment from an archive**.
- d. In the **Path** field, either type or browse to the archive file on the local file system, and click **Next**.

- e. In the Install Add-ons page, click **Install** or **Install Pending** to make your selection of add-on archive files that you want to install on the Liberty runtime environment.

You can install an add-on archive file from your local file system, download an add-on archive file, or use a combination of both when you install multiple add-on archive files. If the workbench is connected to the internet, the Install Add-ons page is populated with add-on archive files available for download from the WAS dev community download site.

This download site includes add-ons that you can select from the Liberty Repository, such as runtime features, samples, or open source integration.

If you want to install add-on archive files from your local file system, complete the following steps:

- 1) Click **Add Archive**.
- 2) In the **Add-on archive** field, type or browse to the add-on archive file on the local file system.
- 3) Click **OK**.

If you have more add-on archive files to install from your local file system, repeat this procedure until you are done.

If you want to install add-on files from a custom repository, complete the following steps:

- 1) To add the repository, click **Configure Repositories**.
- 2) Click **New...**

The files are then added to the list of add-on files.

After you complete your selection in the Install Add-ons page, click **Next**.

- f. In the License Acceptance page, if you accept the license terms, select **I accept the terms of all the license agreements** then click **Next**.

If you want to download and install the no-charge developer edition for Liberty, complete the following steps:

- a. Select **Install from an archive or repository**, and click **Next**.
- b. In the **Destination** field, type or browse to the directory where you want to install the Liberty runtime environment.

If you type a path that does not exist, then a folder for that path is created automatically at the end of the main procedure when you click **Finish**.

- c. Select **Download and install a new runtime environment from ibm.com**, choose a runtime environment version, and then click **Next**.
- d. In the Install Add-ons page, click **Install** or **Install Pending** to make your selection of add-on archive files that you want to install on the Liberty runtime environment.

You can install an add-on archive file from your local file system, download, or use a combination of both when you install multiple add-on archive files. If the workbench is connected to the internet, the Install Add-ons page is populated with add-on archive files available for download from the WAS dev community download site.

This download site includes add-ons that you can select from the Liberty Repository, such as runtime features, samples, or open source integration.

If you want to install add-on archive files from your local file system, click **Add Archive**. In the **Add-on archive** field, type or browse for the add-on archive file on the local file system, and then click **OK**. If you have more add-on archive files to install from your local file system, repeat this step until you are done.

If you want to install add-on files from a custom repository, first add the repository by clicking **Configure Repositories**. Click **New...** to add the repository. The files are then added to the list of add-on files.

After you complete your selection in the Install Add-ons page, click **Next**.

- e. In the License Acceptance page, if you accept the license terms, select **I accept the terms of all the license agreements** then click **Next**.

7. On the Liberty Server Type page, select **Server in a Docker container**.
8. Click **Next**.  
The tools display the New Liberty Server in Docker Container page.
9. Select your Docker container from the **Container name** menu.
10. Enter the Liberty server security credentials.  
Your values for the **User name** and **Password** fields must correspond to a user that is defined in a user registry that has an administrator role. If the tools cannot find a basic user registry that defines the specified user, the tools display the Security Verification window. If the tools display the Security Verification window, complete one of the following options:
  - Select **Create** to add a basic user registry that defines a user with your values and an administrator role.
  - Select **Proceed** to proceed if the user is defined in another user registry type.
  - Select **Cancel** to make changes to the **User name** and **Password** that you entered.
11. Enter the value for the **Host mapped secured port** field that corresponds to the HTTPS port in the server configuration.
12. Click **Finish**.

## Results

You created a workbench server reference to a server that is running in a Docker container.

- To see the server that you created and its server configuration, open the Servers view.
- To see the project, the server folder, and the server configuration files, open the Enterprise Explorer view.

## What to do next

- You can edit the server configuration. For more information, see “Editing the Liberty configuration by using developer tools” on page 1556
- To start or stop a server, or add or remove applications on the server, right-click your server to use the server context menu or use the tray buttons in the Servers view. For more information, see “Starting and stopping a server by using developer tools” on page 1558.

**Remember:** To access these options, select the **Server Entry** in the Servers view. Do not select a server configuration such as the **Server Configuration** or `server.xml` entry.

**Tip:** The application address that the server logs in the Console view is valid within the Docker container only. To load an application in a browser, use the host mapped IP address and host mapped HTTP or HTTPS port. If you use the **Run on Server** or **Debug on Server** options, the application is automatically loaded with the correct IP address and port.

To make it easier to determine the correct port, map the ports to specific ports on the host by using the `-p` option rather than the `-P` option when you create the Docker container.

- You can configure your Liberty server to authenticate users with Tivoli Directory Server.
  1. Right-click **Servers**.
  2. Select **Utilities > Add config snippets**.
  3. Select the snippets and accept the licenses agreements.

The tools download the configuration snippets that you selected and add them to the `server.xml` file.

## Liberty:Directory locations and properties

In Liberty, many directories have properties that are associated with them. These properties can be used to specify file locations when you configure the server.

*Table 105. Runtime environment default directory structure.* Column 1 contains a file and directory tree. If a directory has a property that is associated with it, this is given in column 2. A description of each file or directory is given in Column 3.

Directory or file	Property	Description
wlp/ +- bin/ +- clients/ +- jython/ +- dev/ +- api/ +- ibm/ +- javadoc/ +- spec/ +- third-party/  +- spi/ +- ibm/ +- javadoc/ +- spec/ +- tools/ +- etc/ +- server.env +- client.env +- jvm.options +- lafiles/ +- lib/ +- templates/  8.5.5.6 +- client/	wlp.install.dir	Root of installation  Scripts for managing the installation. For example, server.  Liberty client and thin client libraries. For example restConnector.jar.  Jython-based scripts  Root for developer resources (APIs, SPIs, specifications, and tools)  Public APIs available for both compile and run time by default  APIs available in Liberty  Java document archives  Public specification APIs available for both compile and run time by default  Third-party APIs that are available at compile time by default and must be specified in the configuration using the apiTypeVisibility attribute of the classloader element for applications at run time.  Public SPIs available for both compile and run time by default  SPIs available in Liberty  Java document archives for SPI  Public specification SPIs available for both compile and run time by default  Ant plug-in for Liberty  User customized server variables that apply to all servers (optional)  Default server script environment variables (optional)  Default client script environment variables (optional)  Default JVM options (optional)  License information files  Platform runtime environment  Runtime customization templates and examples  8.5.5.6 Client template when creating a client

Table 105. Runtime environment default directory structure (continued). Column 1 contains a file and directory tree. If a directory has a property that is associated with it, this is given in column 2. A description of each file or directory is given in Column 3.

Directory or file	Property	Description
+ server/		Server template when creating a server
+ usr/	wlp.user.dir	User directory
+ extension/	usr.extension.dir	User-developed features
+ shared/		
+ apps/	shared.app.dir	Shared applications
+ config/	shared.config.dir	Shared configuration files
+ resources/	shared.resource.dir	Shared resource definitions: adapters, data sources
8.5.5.7 +- stackGroups/	shared.stackgroup.dir	Shared stack groups for remote deployment of packages and installables
+ servers/		Shared servers directory
+ server_name	server.config.dir	Server configuration directory. Use <code>\${server.config.dir}</code> to reference server-specific configuration (applications).
+ bootstrap.properties		Server bootstrap properties (optional)
+ jvm.options		Server JVM options, which replace the values in <code>wlp/etc/jvm.options</code> (optional)
+ server.env		Server script environment variables, which are merged with <code>wlp/etc/server.env</code> (optional)
+ server.xml		Server configuration overlays (required)
+ apps/		Server configuration for applications
+ dropins/		Server default application dropins folder (optional)
+ application_name		Application folder or archive (optional)
8.5.5.5 +- configDropins/		Server configuration dropins folder (optional)
8.5.5.5 +- defaults		Default server configuration dropins folder (optional)
8.5.5.5 +- overrides		Server configuration overrides dropins folder (optional)
+ server_name	server.output.dir	Server output directory. Use <code>\${server.output.dir}</code> to describe artifacts generated by the server (log files and workarea).
+ logs/		Server log files, including FFDC logs (directory is present after server is first run)
+ console.log		Basic server status and operations messages
+ trace_timestamp.log		Time-stamped trace messages, with the level of detail determined by the current tracing configuration

Table 105. Runtime environment default directory structure (continued). Column 1 contains a file and directory tree. If a directory has a property that is associated with it, this is given in column 2. A description of each file or directory is given in Column 3.

Directory or file	Property	Description
<pre> +- ffdc/     +- ffdc_timestamp/ +- workarea/                     </pre>		<p>First Failure Data Capture (FFDC) output directory</p> <p>First Failure Data Capture (FFDC) output that typically includes selective memory dumps of diagnostic data related to the failure of a requested operation</p> <p>Files created by the server as it operates (directory is present after server is first run)</p>
<pre> 8.5.5.6 +- clients/ +- client_name +- bootstrap.properties +- client.jvm.options  +- client.xml +- apps/ +- logs/  +- trace_timestamp.log  +- ffdc/     +- ffdc_timestamp/  +- workarea/                     </pre>		<p>Shared clients directory</p> <p>Client configuration directory.</p> <p>Client bootstrap properties (optional)</p> <p>Client JVM options, which replace the values in <code>wlp/etc/client.jvm.options</code> (optional)</p> <p>Client configuration overlays (required)</p> <p>Client configuration for applications</p> <p>Client log files, including FFDC logs (directory is present after client is first run)</p> <p>Time-stamped trace messages, with the level of detail determined by the current tracing configuration</p> <p>First Failure Data Capture (FFDC) output directory</p> <p>First Failure Data Capture (FFDC) output that typically includes selective memory dumps of diagnostic data related to the failure of a requested operation</p> <p>Files created by the client as it operates (directory is present after client is first run)</p>

You can use the properties that are associated with each directory, if any, to specify file locations when you configure the server.

**Tip:** To ensure configuration portability, use the most specific property that is appropriate, and do not rely on the relationship between resources. For example, in some configurations the installation location, `${wlp.install.dir}` might not be the parent of the customized instance `${wlp.user.dir}`.

## Programmatic access to location properties

Location properties can be bound into the JNDI namespace under names of your choice, using the `jndiEntry` configuration elements in the `server.xml` file, for example:

```
<jndiEntry jndiName="serverName" value="${wlp.server.name}"/>
```

Such entries are accessible by any code that runs in the server (applications, shared libraries or features) through a JNDI lookup:

```
Object serverName = new InitialContext().lookup("serverName");
```

For more information on how to use JNDI entries in configuration, see “Using JNDI binding for constants from the server configuration files” on page 2146.

Feature code can also use a system programming interface (SPI) provided by the kernel to resolve the values of these properties, for example:

```
ServiceReference <WsLocationAdmin>locationAdminRef = bundleContext.getServiceReference(WsLocationAdmin.class);  
WsLocationAdmin locationAdmin = bundleContext.getService(locationAdminRef);  
String serverName = locationAdmin.resolveString("${wlp.server.name}");
```

---

## Specifying Liberty bootstrap properties

Bootstrap properties initialize the runtime environment for a particular server. Generally, they are attributes that affect the configuration and initialization of the runtime core.

### About this task

Bootstrap properties are set in a text file named `bootstrap.properties`. This file is not required, so it does not exist unless you create it. You must create this file in the server directory, which also contains the configuration root file `server.xml`. By default, the server directory is `usr/servers/server_name`. You can change the server directory as described in [8.5.0.1](#) “Customizing the Liberty environment” on page 1565.

You can create a `bootstrap.properties` file by using the editor in WebSphere Application Server Developer Tools for Eclipse. From the **Servers** view, right-click on the server you want to configure, then select **New**, then **Server Environment File**, then `bootstrap.properties`, and the file is created from a template and opened in an editor. Along with the `server.xml` and `server.env` files, the `bootstrap.properties` file appears in the **Servers** view under the server that it is associated with and can be edited by double-clicking it.

You can edit the `bootstrap.properties` file by using a text editor or the editor in the WebSphere Application Server Developer Tools for Eclipse. See “Editing the Liberty configuration by using developer tools” on page 1556.

If you update the `bootstrap.properties` file, you must restart the server for the changes to take effect.

The `bootstrap.properties` file contains two types of properties:

- A small, predefined set of initialization properties.
- Any custom properties that you choose to define. You can then use these custom properties as variables in other configuration files such as `server.xml` and included files.

If you update the `bootstrap.properties` file, you must restart the server for the changes to take effect.

### Procedure

- Use predefined properties to configure trace and logging.

For example:

- To change the name of your trace file, specify the property `com.ibm.ws.logging.trace.file.name` with a file name of your choice, as follows:

```
com.ibm.ws.logging.trace.file.name = trace.log
```

- To enable binary logging, specify the `websphere.log.provider` property as follows:

```
websphere.log.provider = binaryLogging-1.0
```

For more information, see “Configuring binary logging in Liberty” on page 1031

- Use predefined properties for OSGi framework diagnostics. For example, set the port for the OSGi console as follows:

```
osgi.console = 5678
```

For more information, see “Using an OSGi console” on page 1587

- Use predefined properties for OSGi framework extensions. Specify the **org.osgi.framework.bootdelegation** if this property is required by external monitoring tools. The value is a comma-delimited list of packages.
- Use predefined properties for configuration password encryption. For more information, see “Liberty: The limits to protection through password encryption” on page 1009.
- Use custom properties to define the default ports for web applications.

You can share `server.xml` and use XML configuration files across various development environments that allow machine- or environment-specific customization. For example:

1. Specify the properties **default.http.port** and **default.https.port** in the `bootstrap.properties` file:

```
default.http.port = 9081
default.https.port = 9444
```

**Note:** If you do not specify the properties, the default HTTP port is 9080 and HTTPS ports is 9443. To override the default HTTP endpoint definition, set the `id` attribute of the `httpEndpoint` element to `defaultHttpEndpoint` in the server configuration.

2. Use the following properties in the `server.xml` configuration file:

```
<httpEndpoint id="defaultHttpEndpoint"
  host="*"
  httpPort="${default.http.port}"
  httpsPort="${default.https.port}" />
```

**Note:** `host="*"` means “listen on all adapters”. By default, the server is listening only on address `127.0.0.1/localhost`. You can also use the **host** property to specify a single IP address, and then the system listens only on the specified adapter.

- **8.5.5.2** Use custom properties to set the command port.

Set the command port to enable the server script to communicate with the running Liberty server and request certain operations, such as stopping the Liberty server or issuing a Java dump.

#### Distributed operating systems

IBM i

By default, the Liberty server acquires an ephemeral port to be used by the command listener. **z/OS** If you start the Liberty server from the shell script on z/OS, by default the Liberty server acquires an ephemeral port to be used by the command listener. If you start the Liberty server as a started task on z/OS, by default the command port is initially disabled, and all server administration tasks are accomplished by using `modify` commands that are issued to the z/OS operator console. These commands are described in *Administering Liberty on z/OS*. You can override the default behavior of the Liberty server by using the **command.port** property.

#### Valid values

- 1 Command port is disabled.
- 0 Ephemeral port is chosen at run time.
- 1-65535 User-specified port.

#### Default value

0 **Distributed operating systems** **IBM i** Ephemeral port is chosen at run time. **z/OS** If server is started from the shell script on z/OS, ephemeral port is chosen at run time.

**z/OS** -1

If server is started as a started task on z/OS, command port is disabled.

**Note:** **Distributed operating systems** **IBM i** You are discouraged from disabling the command port. If you disable the command port, you cannot use the server script to request some operations, for example, stopping the Liberty server or issuing a Java dump. **z/OS** You are discouraged from disabling the command port unless the server is running as a started task on z/OS. If you disable the command port, you cannot use the server script to request some operations, for example, stopping the Liberty server or issuing a Java dump.

- Use custom properties to configure server start wait time.

You can increase the server start wait time beyond the product default setting by adding the `server.start.wait.time` property to the `bootstrap.properties` file. The `server.start.wait.time` is specified in seconds.

1. Specify the `server.start.wait.time` property in the `bootstrap.properties` file. The following example sets the server start time to 25 seconds.

```
server.start.wait.time = 25
```

This setting means that as the server starts, the reporting mechanism for the server attempts to report on the completed stages of the start. If the reporting mechanism for the server cannot perform its function within 25 seconds, an error 22 occurs.

If you do not add the `server.start.wait.time` property to the `bootstrap.properties` file, the default server start wait time is internally set to 30 seconds.

- To apply the changes, restart the server.

---

## Setting the default host name of a Liberty server

### 8.5.5.0

You can add the `defaultHostName` variable to the `server.xml` file to set the default host name by which a Liberty server is identified.

### About this task

This variable is available for use by service configurations. Setting this value is particularly important for multihomed systems (with multiple NICs and multiple mapped host names for example).

#### Notes:

- This variable is currently used by the `<httpEndpoint>` `host` attribute and the `<hostAuthInfo>` `rpcHost` attribute
- The default host name should be the fully qualified host name of the system.
- The value should not contain any wildcards (\* for example).
- The variable default is `localhost`.

### Procedure

To set the default host name by which a Liberty server is identified, add the `defaultHostName` variable to the `server.xml` file.

For example:

```
<variable name="defaultHostName" value="localhost" />
```

## Liberty: Default port numbers

Some parts of Liberty use default TCP/IP port numbers. You can override the default port numbers by specifying a different port number in your server configuration.

### Runtime environment port numbers

For the command port, the Liberty server acquires an ephemeral port to be used by the command listener. You can configure this port in the `bootstrap.properties` file. For more information, see “Specifying Liberty bootstrap properties” on page 1437.

### Feature port numbers

The following table lists the default port numbers of Liberty features and an example of how you can override the default port in your server configuration.

Table 106. Default port numbers of Liberty features

Feature	Default port and configuration example
collectiveController-1.0	Replication port: 10010 <code>&lt;collectiveController   replicaPort="10012"/&gt;</code>  REST and JMX connections depend on the <code>restConnector-1.0</code> port.
8.5.5.6 <code>ejbRemote-3.2</code>	<ul style="list-style-type: none"><li>• IIOP port: 2809</li><li>• IIOP/SSL port: 9402</li></ul> <code>&lt;iiopEndpoint id="defaultIiopEndpoint" iiopPort="2809"&gt;   &lt;iioptionsOptions iiopsPort="9402" sslRef="defaultSSLConfig"/&gt; &lt;/iiopEndpoint&gt;</code>
8.5.5.7 <code>rtcomm-1.0</code>	<ul style="list-style-type: none"><li>• MQTT over TCP port: 1883</li><li>• MQTT over SSL port: 8883</li></ul> <code>&lt;mqtTtcpEndpoint id="defaultMqtTtcpEndpoint"   mqtTtcpPort="1885"   mqtTsslPort="8885"/&gt;</code>
<code>servlet-3.0</code>	<ul style="list-style-type: none"><li>• HTTP port: 9080</li><li>• HTTPS port: 9443</li></ul> <code>&lt;httpEndpoint id="defaultHttpEndpoint"   httpPort="9082"   httpsPort="9445" /&gt;</code>
8.5.5.7 <code>sipServlet-1.1</code>	<ul style="list-style-type: none"><li>• TCP port: 5060</li><li>• TLS port: 5061</li><li>• UDP port: 5060</li></ul> <code>&lt;sipEndpoint id="defaultSipEndpoint"   sipTCPport="5062"   sipUDPport="5062"   sipTLSport="5063" /&gt;</code>
<code>wasJmsServer-1.0</code>	<ul style="list-style-type: none"><li>• Incoming unsecure port: 7276</li><li>• Incoming secure port: 7286</li></ul> <code>&lt;wasJmsEndpoint id="InboundJmsEndpoint"   wasJmsPort="7278"   wasJmsSSLPort="7288"&gt; &lt;/wasJmsEndpoint&gt;</code>

---

## Using virtual hosts

8.5.5.7

You can use virtual hosts if you want isolation between applications and the endpoints that serve them.

A single application server is often responding to requests from multiple different host and port configurations. This occurs for a combination of reasons, such as it is running on a machine with multiple network interfaces with different names or it is routed to from an http server, proxy, or load balancer. In these cases, you might want to control which application can be contacted from a specific host. Virtual hosts provide this capability. It matches the requested host name and port number (as determined from the HTTP Host header) against the configured list of host aliases.

In WebSphere Application Server Liberty, the default configuration is sufficient. The default virtual host (default\_host) matches requests from any incoming host and port combination, and forwards them on to the default application container.

The following list illustrates the key configuration elements when you are configuring virtual hosts.

- The virtualHost configuration element ID value.
- The hostAlias subelement configuration.
- The allowFromEndpoint subelement configuration (if used).
- The virtual host configuration in the `ibm-web-bnd.xml` or `ibm-web-bnd.xmi` file of the WAR.
- The host attribute value of the `httpEndpoint`.
- The ID attribute value of the `httpEndpoint`.

### Isolating two applications from each other

The following example illustrates one of the more common usages of virtual hosting to give an understanding of some of the configuration that is required. This example shows how to configure two applications that run on differing ports. Further in this example illustrates that one application is only available on the localhost interface.

```
<httpEndpoint id="defaultHttpEndpoint" host="*" httpPort="9080" />
<httpEndpoint id="alternateEndpoint" host="*" httpPort="9081" />

<virtualHost id="application-1">
  <hostAlias>your_host_name:9080</hostAlias>
</virtualHost>

<virtualHost id="application-2">
  <hostAlias>localhost:9081</hostAlias>
</virtualHost>

<enterpriseApplication location="myApp.ear" name="App1"/>
<webApplication location="myApp2.war" name="App2" />
```

The `defaultHttpEndpoint` exposes all interfaces on port 9080, and the `alternateEndpoint` exposes all interfaces on port 9081.

If App1 has a WAR file with an `ibm-web-bnd.xml` file that specifies `<virtual-host name="application-1"/>`, then this application can be accessed only at `your_host_name:9080/app1_context_root`.

If App2 (which is a WAR) has an `ibm-web-bnd.xml` file that specifies `<virtual-host name="application-2"/>`, then this application can be accessed only at `localhost:9081/app2_context_root`.

If a third application was deployed which specified no specific virtual host, in this configuration, that application would be accessible only if it were a proxied request that contained HOST header that

specifies a different port. For example, if the request was made to a proxy on port 80, that port is not listed in any of the hostAlias specifications, and so the request would be routed to the default\_host virtual host.

## Isolating applications based on the requested host or port

The default virtual host in Liberty is also used for JMX communications. If you wanted to isolate JMX communications from application traffic, you would need to complete the following steps.

1. Decide on your virtual host name, and update your application to reference the new (non-default) host. Add a virtual-host element to the `ibm-web-bnd.xml` or `ibm-web-bnd.xmi` file of the WAR.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-bnd
  xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xmk/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-bnd_1_0.x
  version="1.0" />

  <virtual-host name="proxiedRequests" />

</web-bnd>
```

2. Add a virtualHost element to your `server.xml` file. The name must match what is specified in the application, and must define hostAliases that are routed to the new virtual host.

**Note:** The host name and the port that is being matched is the one that is originally requested by the user, which might or might not match the host and port that Liberty is using. The following example illustrates a virtual host element added to your `server.xml` file.

```
<virtualHost id="proxiedRequests">
  <hostAlias>external.host.name:80</hostAlias>
  <hostAlias>external.host.name:443</hostAlias>
</virtualHost>
```

If requests are coming from a proxy, this configuration alone routes any request that is made to the proxy's host and port to the "proxiedRequests" virtual host.

## Restricting access based on originating endpoint

If you want to restrict access to the default/system applications that are using the defaultHttpEndpoint, there are more steps to take.

1. Define another httpEndpoint. The following example illustrates another httpEndpoint.

```
<httpEndpoint id="localhostOnly" host="localhost" httpPort="9081" httpsPort="9444"/>
```

This http endpoint specifies that `host="localhost"`, meaning that ports 9081 and 9444 are exposed only on the localhost interface.

2. Update virtualHost definitions to specify the `allowFromEndpointRef` attribute. When this attribute is specified, a virtualHost accepts requests only from the specified endpoint. For example:

```
<virtualHost id="default_host" allowFromEndpointRef="localhostOnly">
  <hostAlias>*:9081</hostAlias>
  <hostAlias>*:9444</hostAlias>
</virtualHost>

</virtualHost id="proxiedRequests">
  <hostAlias>*:9080</hostAlias>
  <hostAlias>*:9443</hostAlias>
  <hostAlias>external.host.name:80</hostAlias>
  <hostAlias>external.host.name:443</hostAlias>
</virtualHost>
```

With this configuration:

- The `default_host` virtual host now accepts requests that are directed only at `localhost:9081` and `localhost:9444` that also originate from the `localHostOnly` endpoint. Any other request to ports 9081 and 9444 are refused. For example, a request from the `defaultHttpEndpoint` with Host headers that reference `localhost:9081` is refused.
- The `proxiedRequests` virtual host now accepts any request that is issued to port 9080, or 9443 (which are the default ports that are used by the `defaultHttpEndpoint`), in addition to those that have a Host header that references the external host name from the proxy and port 80 or 443.

## Virtual hosts

8.5.5.7

A virtual host is a configuration entity that enables a single host machine to resemble multiple host machines.

A virtual host maintains a list of Multipurpose Internet Mail Extensions (MIME) types that it processes. You can associate a virtual host to one or more Web modules, but you can associate each web module with only one virtual host. Resources that are associated with one virtual host cannot share data with resources associated with another virtual host, even if the virtual hosts share a physical machine.

Each virtual host has a logical name and a list of one or more DNS aliases by which it is known. A DNS alias is the TCP/IP hostname and port number that is used to request the servlet, for example `yourHostName:80`. When no port number is specified, 80 is assumed.

The virtual host configuration uses wildcard entries with the ports for its virtual host entries.

- The default alias is `*:80` using an external port that is not secure.
- Aliases of the form `*:9080` use the internal port that is not secure.
- Aliases of the form `*:9443` use the secure internal port.
- Aliases of the form `*:443` use the secure external port.

A client request for a servlet, JavaServer Pages file, or related resource, contains a DNS alias and a Uniform Resource Indicator (URI) that is unique to that resource. When a client request for a servlet, JavaServer Pages file, or related resource is received, the DNS alias is compared to the list of all known virtual host groups to locate the correct virtual host. The URI is compared to the list of all known URI groups to locate the correct URI group. If the virtual host group and URI group are found, the request is sent to the corresponding server group for processing and a response is returned to browser. If a matching virtual host group or URI group is not found, an error is returned to the browser.

A virtual host is not associated with a particular node or machine. It is a configuration, rather than a live object, which is why you can create it, but cannot start or stop it. A default virtual host, named `default_host`, is automatically configured the first time that you start an application server. Unless you specifically want to isolate resources from one another on the same node, or physical machine, you probably do not need any virtual hosts in addition to the default host.

The DNS aliases for the default virtual host are configured as `*:80` and `*:9080`, where port 80 is the HTTP server port and port 9080 is the port for the default server's HTTP transport. The default virtual host includes common aliases, such as the machine's IP address, short host name, and fully qualified host name. One of these aliases comprises the first part of the path for accessing a resource such as a servlet. For example, the alias `localhost:80` is used in the request `http://localhost:80/myServlet`.

When you request a resource, the product tries to map the request to an alias of a defined virtual host. The `http://host:port/` portion of the virtual host is not case sensitive, but the URL that follows is case sensitive. The match for the URL must be alphanumerically exact. Different port numbers are treated as different aliases.

For example, the request `http://www.myhost.com/myservlet` maps successfully to `http://WWW.MYHOST.COM/myservlet` but not to `http://WWW.MYHOST.COM/MYSERVLET` or `Www.Myhost.Com/Myservlet`. In the latter two cases, these mappings fail because of case sensitivity. The request `http://www.myhost.com/myservletdoes` does not map successfully to `http://myhost/myservlet` or to `http://myhost:9876/myservlet`. These mappings fail because they are not alphanumerically correct.

You can use wildcard entries for aliases by port and specify that all valid host name and address combinations on a particular port map to a particular virtual host.

If you request a resource by using an alias that cannot be mapped to an alias of a defined virtual host, you receive a 404 error in the browser that you used to issue the request. A message states that the virtual host could not be found.

Two sets of associations occur for virtual hosts. Application deployment associates an application with a virtual host. Virtual host definitions associate the network address of the machine and the HTTP transport or web server port assignment of the application server with the virtual host. Looking at the flow from the web client request for the snoop servlet, for example, the following actions occur:

1. The web client asks for the snoop servlet: at web address `http://www.some_host.some_company.com:9080/snoop`
2. The `some_host` machine has the 9080 port that is assigned to the stand-alone application server, `server1`.
3. `Server1` looks at the virtual host assignments to determine the virtual host that is assigned to the alias `some_host.some_company.com:9080`.
4. The application server finds that no explicit alias for that DNS string exists. However, a wildcard assignment for host name `*` at port 9080 does exist, so this wildcard is a match. The virtual host that defines the match is `default_host`.
5. The application server looks at the applications that are deployed on the `default_host` and finds the snoop servlet.
6. The application server serves the application to the web client and the requester is able to use the snoop servlet.

*Table 107. Aliases for a virtual host*

Virtual host	Alias	Port number
default_host	*	9080
default_host	localhost	9080
default_host	my_machine	9080
default_host	my_machine.my_company.com	9080
default_host	localhost	80

You can have any number of aliases for a virtual host. You can even have overlapping aliases, such as:

The Application Server looks for a match by using the explicit address that is specified on the web client address. However, it might resolve the match to any other alias that matches the pattern before it matches the explicit address. Defining an alias first in the list of aliases does not guarantee the search order whenever the product is looking for a matching alias.

Virtual hosts with overlapping aliases. Assume that you define overlapping aliases for both virtual hosts because you accidentally defined port 9080 for the `admin_host` instead of port 9060:

A problem can occur if you use the same alias for two different virtual hosts. For example, assume that you installed the default application and the snoop servlet on the default\_host. You also have another virtual host that is called the admin\_host. However, you have not installed the default application or the snoop servlet on the admin\_host.

Table 108. Virtual hosts with overlapping aliases.

Virtual host	Alias	Port number
default_host	*	9080
default_host	localhost	9080
admin_host	*	9060
admin_host	my_machine.com	9080

Assume that a web client request comes in for `http://my_machine.com:9080/snoop`.

If the application server matches the request against `*:9080`, the application is served from the default\_host. If the application server matches the request to `my_machine.com:9080`, the application cannot be found. A 404 error occurs in the browser that issues the request. A message states that the virtual host could not be found.

This problem is the result of not finding the requested application in the first virtual host that has a matching alias. The correct way to code aliases is for the alias name on an incoming request to match only one virtual host in all of your virtual host definitions. If the URL can match more than one virtual host, you see the problem that is described.

---

## Preparing and running an application client

8.5.5.6

Learn how to prepare your server and client to run an application client from Liberty application client container.

### About this task

Running an application client successfully requires updates to both the `server.xml` and `client.xml` files.

### Procedure

Prepare your server, as follows:

1. Package a client module (`.jar`) and other modules, such as an EJB module (`.jar`), in an application EAR file.
2. Place the EAR file in the apps directory; for example, `wlp/usr/servers/your_server/apps`.
3. Update the `server.xml` configuration file by adding the `appClientSupport-1.0` feature, along with other necessary features.

**Important:** This step is not required if your application client is a stand-alone application.

4. Update the `server.xml` configuration file by configuring `<application/>` with your application information; for example:

```
<?xml version="1.0" encoding="UTF-8"?>
<server description="new server">
  <!-- Enable features -->
  <featureManager>
    <feature>javaee-7.0</feature>
  </featureManager>
  <application id="techsample" name="techSample" type="ear" location="TechnologySamples.ear"/>
</server>
```

Prepare your client, as follows:

5. Place the EAR file in the apps directory; for example, `wlp/usr/clients/your_client/apps`.
6. Update the `client.xml` configuration file by configuring `<application/>` with your application information; for example:

```
<?xml version="1.0" encoding="UTF-8"?>
<client description="new client">
  <!-- Enable features -->
  <featureManager>
    <feature>javaeeClient-7.0</feature>
  </featureManager>
  <application id="techsample" name="techSample" type="ear" location="TechnologySamples.ear"/>
</client>
```

7. Optional: Add the `appClientSecurity-1.0` feature to the `client.xml` file. Read about “Creating a Liberty application client manually.”
8. Start the server.
9. Run the client by entering `client run your_client`. If your client application uses command-line arguments, use the following format:  
`client run {your_client} -- arg1 arg2 ... argn`

There are additional steps to take if your server and client are running on different computers. By default, the server and client are using `localhost:2809`. You must configure IIOP to establish a connection between the server and client, as follows:

10. Stop the server.
11. Update the `server.xml` file with the IIOP configuration; for example:  
`<iiopEndpoint id="defaultIiopEndpoint" host="user.host.ibm.com" iiopPort="2814" />`
12. Update the `client.xml` file with the IIOP configuration; for example:  
`<orb id="defaultOrb" nameService="corbaname::user.host.ibm.com:2814" />`
13. Start the server.

## Creating a Liberty application client manually

8.5.5.6

You can create a Liberty application client from the command line.

### Before you begin

You enable the Java EE Application Client 7.0 feature in the `client.xml` file only.

### Procedure

1. Open a command line, then change directory to the `wlp/bin` directory. In the following examples, `path_to_liberty` specifies the location where you installed Liberty on your operating system.

**Windows** Example on Windows systems: `C:\Users\mo> cd path_to_liberty\wlp\bin`

**Linux** Example on Linux: `mo@machine01:~> cd path_to_liberty/wlp/bin`

2. Run the following command to create a client, where `client_name` is the name that you want to give your client. If you do not specify a client name, `defaultClient` is used.

**Windows** Example on Windows systems: `C:\wlp\bin> client create client_name`

**Linux** Example on Linux: `mo@machine01:~> client create client_name`

```
client create client_name
```

If the client is created successfully, you receive the following message:

```
Client client_name created.
```

You can find the `client.xml` file in the `wlp/usr/clients/client_name` directory. The file contains the `javaeeClient-7.0` feature.

**Attention:** If a default client exists, you get an error. If a default client does not exist, `defaultClient` is created.

3. Run your client application by preparing an application (`.ear`) file with a client module (`.jar`) in it. Specify a main class in the `MANIFEST.MF` of the client module, for example:

```
Manifest-Version: 1.0
Main-Class: com.ibm.ws.addressbook.ContactServiceClient_XMLInject
```

4. Place the EAR file under the `wlp/usr/clients/client_name/apps` directory.
5. Update the `client.xml` file to configure your application, for example:

```
<client>
  <featureManager>
    <feature>javaeeClient-7.0</feature>
  </featureManager>
  <application id="CLIENT_APP" name="CLIENT_APP" type="ear" location="clientApp.ear"/>
</client>
```

If the specified client already exists, no client is created and you receive an exception message:

```
CWWKE0005E: The runtime environment could not be launched.
CWWKE0904E: It was not possible to create the client called client_name because
the client directory C:\wlp\usr\clients\client_name already exists.
```

## What to do next

You can enable security (SSL, CSiv2, JAAS) for your application client by adding the `appSecurityClient-1.0` feature to your `client.xml` file:

```
<featureManager>
  <feature>javaeeClient-7.0</feature>
  <feature>appSecurityClient-1.0</feature>
</featureManager>
```

For more information about configuring security on the application client, see  [8.5.5.6](#) “Configuring security for the Liberty application client container and its applications” on page 1984.

## Creating a Liberty application client with multiple client modules

8.5.5.6

You can create a Liberty application client with multiple client modules in the same EAR file.

### About this task

You can specify more than one client application (packaged in a client module) in your application EAR file. If you would like to package multiple client applications in the same EAR file, you must use the `defaultClientModule` attribute in `<enterpriseApplication/>`.

### Procedure

Specify the client that you want to run by updating the `defaultClientModule` attribute in both the `client.xml` and `server.xml` files.

```
<client>
  <featureManager>
    <feature>javaeeClient-7.0</feature>
  </featureManager>
  <enterpriseApplication id="MultipleAppClientModules" name="MultipleAppClientModules" type="ear"
    defaultClientModule="HelloAppClient.jar" location="MultipleAppClientModules.ear"/>
</client>
```

**Important:** You can run one application at a time.

---

## Setting up the server-management environment for Liberty by using collectives

### 8.5.5.0

To set up the server-management environment for Liberty by using collectives, define the appropriate features in the `server.xml` file and run the corresponding collective command-line tasks to establish the administrative domain security configuration.

### About this task

You can use collectives to manage multiple servers from a single management domain. For high availability, you can configure collective replica sets, clusters, or scaling. For general information about collectives, see “Liberty: Collective architecture” on page 1450.

Liberty provides multiple-server management in the following features:

- **collectiveController-1.0**

The `collectiveController-1.0` feature enables controller functionality for a management collective and includes collective- and cluster-management MBeans that are accessible using the REST JMX connector that is provided by the `restConnector-1.0` feature. The collective controller acts as a storage and collaboration mechanism to which collective members can connect. The administrative domain security configuration for the `collectiveController-1.0` feature is established using the **collective** command-line **create** and **replicate** tasks.

**Distributed operating systems**

IBM i

The `collectiveController-1.0` feature and its capabilities are available only in multiple-server products such as WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in single-server products such as WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a multiple-server product installation, you can use its `collectiveController-1.0` feature to work with collective members from single-server products.

- **collectiveMember-1.0**

The `collectiveMember-1.0` feature enables a server to be a member of a management collective and be managed by the collective controller. The administrative domain security configuration for the `collectiveMember-1.0` feature is established using the **collective** command-line **join** task.

**Tip:** All servers enabled with the `collectiveController-1.0` feature are managed; therefore, you do not need to specify `collectiveMember-1.0` if the server already has the `collectiveController-1.0` feature enabled.

- **clusterMember-1.0**

The cluster member feature enables a collective member to participate in a static cluster.

8.5.5.4

- **dynamicRouting-1.0**

The dynamic routing feature is an Intelligent Management feature of the WebSphere plug-in for Apache and IHS that provides On Demand Router capabilities for the plug-in. The dynamic routing feature enables a server to run a REST service to which the plug-in can connect in order to dynamically route to all servers in a collective.

8.5.5.4

- **scalingController-1.0**

The scaling controller feature enables a collective controller to expand or contract an auto scaling cluster and manage the scaling controller. If an environment has many scaling controllers, only one of the running scaling controllers can make decisions. If that controller is stopped, another running

scaling controller takes over for it. The scaling controller can start an auto scaling cluster member in response to increased resource usage, or it might stop an auto scaling cluster member in response to decreased resource usage.

- **8.5.5.4 scalingMember-1.0**

The scaling member feature monitors the workload within a server and its host, then sends this information to the scaling controller. The scaling controller feature is enabled in the collective controllers that are part of the collective. This feature also enables dynamic clustering of the collective members and allows the servers to dynamically start or stop based on criteria that is specified by the scaling policy. If more than one scaling member is on the same host, each scaling member must define a `hostSingleton` element with a port in the `server.xml` file. All scaling members on the same host must use the same port to identify a host leader. The host leader is the only scaling member that communicates with the scaling controller. It communicates metric data from the members to the controller and communicates scaling decisions that are made by the controller to the members in the host.

## Procedure

- Configure a server to act as collective controller.
  - Create a collective controller server using commands and then configure the controller `server.xml` file. See step 1 of “Configuring a Liberty collective” on page 1136.
  - Create a collective controller using developer tools. See step 1 of “Configuring a Liberty collective using the developer tools” on page 1460.
- Join a server to a collective as a member.
  - Join a server to a collective using commands and then configure the member `server.xml` file. See step 2 of “Configuring a Liberty collective” on page 1136.
  - Join a server to a collective using developer tools. See step 2 of “Configuring a Liberty collective using the developer tools” on page 1460.
- Change the collective configuration as needed for your environment.
  - Register host computers with a collective.
  - Override host information by revising parameters in the `hostAuthInfo` element of the member `server.xml` file.
  - Set up Remote Execution and Access (RXA) to enable collective controllers to start and stop servers.
  - Set the `JAVA_HOME` variable for Liberty collective members.
  - Generate collective controller SSL keys.
  - **8.5.5.5** Set administrative metadata for Liberty resources in an `admin-metadata.xml` file.
- Create a replica set, which is a set of collective controllers that are configured to work together, to provide management high availability.
  - **8.5.5.5** Automatically share configurations among replicas.
  - **8.5.5.7** Change the port of a replica.
- Backup, upgrade, or remove a collective controller, replica set, or member.
- Set up static cluster members to provide application high availability and scale.
- **Distributed operating systems** **z/OS** Set up dynamic routing of HTTP requests to collective members.
- **Distributed operating systems** **z/OS** **8.5.5.4** Set up autonomic scaling of collectives.
  - Set up auto scaling for use with Intelligent Management dynamic routing.
  - Configure auto-scalable clusters for JVM elasticity.
  - **8.5.5.7** Configure provisionable clusters for Liberty elasticity.
  - Define scaling policies.
  - **8.5.5.5** Set scaling policies for an auto-scalable cluster in a `scaling-metadata.xml` file.
- **8.5.5.7** Enter maintenance mode before you perform diagnostic tests, maintenance, or tuning on a host or server.
- **8.5.5.7** Configure health management to prevent disruption of service by detecting common problems and generating diagnostic actions based on configured health policies.

## What to do next

You can administer the collective using the following tools:

- Use Jython scripts or a Java client such as JConsole to perform collective controller MBean operations.
- Run collective commands from a command line at the bin directory of your Liberty installation. For information about collective commands, run the collective **help** command:

```
wlp/bin/collective help
```

To view details about a specific command, include the command name; for example, to view details about the collective **create** command, run:

```
wlp/bin/collective help create
```

**Tip:** The example commands in this documentation are prefaced with `wlp/bin/`. This means to open a command line at the `bin` directory of your Liberty installation, such as `C:\wlp\bin` on Windows operating systems, and run the command.

- **8.5.5.2** Use WebSphere Liberty Administrative Center ("Admin Center") to administer Liberty servers, applications, and other resources in the collective from a web browser on a smartphone, tablet, or computer.
  1. Add the `adminCenter-1.0` feature to the collective controller `server.xml` file.
  2. To access Admin Center from a smartphone, tablet, or remote computer, ensure that the `server.xml` file sets the `host` attribute of the `httpEndpoint` element to `*` (asterisk) or to a defined host name.
  3. Point a web browser at Admin Center. The URL uses the form:  
`https://collective_controller_host_name:collective_controller_port/adminCenter/`
  4. If your browser prompts you to confirm that the connection is trusted, specify an exception or otherwise enable the connection to continue to Admin Center.
  5. Log in using your collective controller administrative user name and password.
  6. From the Toolbox, open the Server Config tool or Explore tool.
    - **8.5.5.7** Select . Use the Server Config tool to view and edit server configuration files such as `server.xml` files in the collective. For information about the Server Config tool, see "Editing server configuration files in Admin Center" on page 1748.
    - **8.5.5.5** Select . Use the Explore tool to manage applications, clusters, servers, and hosts in the collective. For information about the Explore tool, see "Exploring and managing resources with Admin Center" on page 1749.

For other information about enabling and using Admin Center, see "Administering Liberty using Admin Center" on page 1741.

To ensure that you can remotely start and stop servers, complete the steps for your operating system in "Setting up RXA for Liberty collective operations" on page 1491.

## Liberty: Collective architecture

The set of Liberty servers in a single management domain is called a *collective*. A collective consists of at least one server with the `collectiveController-1.0` feature enabled that is called a *collective controller*. Optionally, a collective can have many servers with the `collectiveMember-1.0` feature enabled that are called *collective members* and a collective can be configured to have many collective controllers.

**Note:** **Distributed operating systems**  The `collectiveController-1.0` feature and its capabilities are available only in multiple-server products such as WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in single-server products such as WebSphere Application Server Liberty or WebSphere Application Server Liberty Core. If you have a multiple-server product installation, you can use its `collectiveController-1.0` feature to work with collective members from single-server products.

The collective controller provides for a centralized administrative control point to perform operations such as MBean routing, file transfer, and cluster management. A core role of collective controllers is to receive information, such as MBean attributes and operational state, from the members within the collective so that the data can be retrieved readily without having to invoke an operation on each individual member.

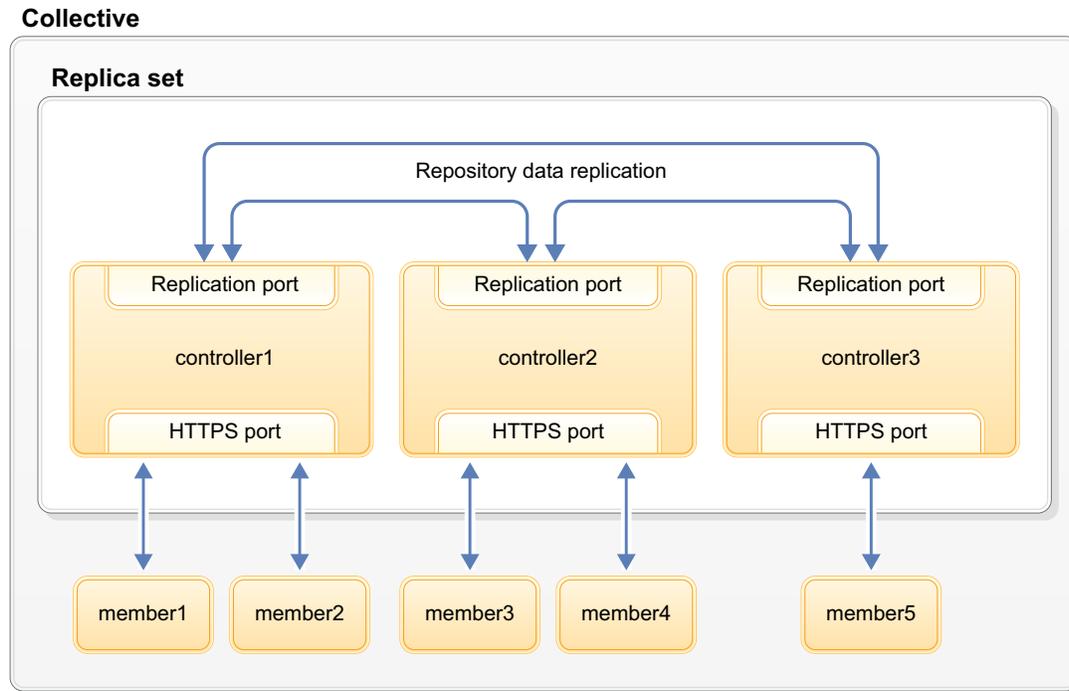

Figure 23. Liberty collective architecture

A set of collective controllers is called a *replica set*. There is only one replica set per collective, and all controllers must be part of the replica set. When there is more than one collective controller, each collective controller replicates its data to the other collective controllers in the replica set to allow for high availability and data protection. The replica set is logically present even when only one controller is in use. When changing your configuration to multiple replicas in a set, include at least three replicas in the set. The controllers in the replica set communicate with each other using a collaboration scheme to ensure that data is replicated across the set of controllers no matter which controller in the set receives an operation to store data. Each controller has a dedicated port for use by the replication protocol. Communication between the controllers in the replica set is always authenticated and protected with SSL.

A collective member can be configured with multiple collective controller endpoints. A collective member only communicates with one collective controller at a time; however, a configuration with more than one collective controller endpoint provides failover and workload balancing. Member-to-controller communication is always in the form of MBean operations that are performed over the IBM JMX Rest Connector. Communication between controllers and members is always authenticated and protected with SSL.

See “Setting up the server-management environment for Liberty by using collectives” on page 1134 for more information.

#### Administrative domain security configuration:

The administrative domain security configuration is made up of two parts:

- User domain

This domain relies on Java role-based security that defines the Administrator role. This can be mapped to users within the configured user registry.

- Server domain

This domain relies on SSL certificate-based authentication.

For more on collective security, see “Liberty: Collective security” on page 1453.

## Configured and standby replicas

Replicas that have been added to a configured replica set are running (*active replicas*) or stopped (*inactive replicas*). A replica that is started and that has never been added to a configured replica set, or was removed from a configured replica set, is called a *standby replica*.

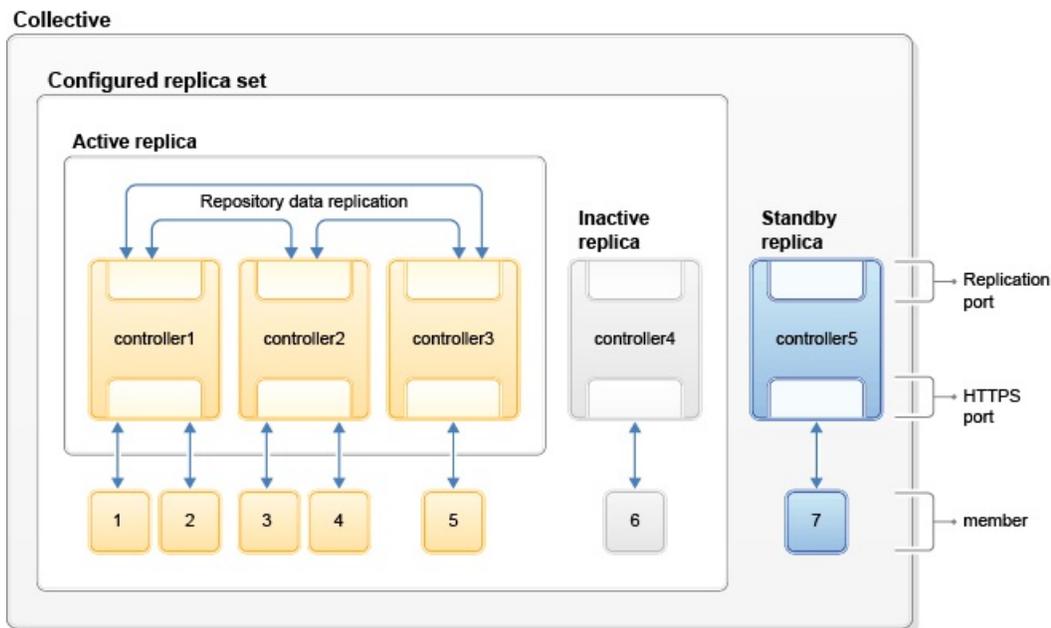

Figure 24. Configured and standby replicas in a collective controller

## Summary of collective architecture terms

### collective

The set of Liberty servers in a single management domain.

### collective controller

A server that has the `collectiveController-1.0` feature enabled.

### collective member

A server that has the `collectiveMember-1.0` feature enabled.

### replica set

A set of collective controllers. For optimal functionality and high availability, a replica set must have at least three controllers.

### replica port

A dedicated port on a controller that is used by the replication protocol.

### configured replica set

The union of the active replicas and inactive replicas.

### active replicas

The started replicas that have been added to the configured replica set.

### inactive replicas

The stopped replicas that have been added to the configured replica set.

### standby replica

The started replicas that have not been added to the configured replica set or that were removed from the configured replica set.

## Liberty: Collective security

8.5.5.0

You can use the principles of collective security in Liberty to address data in motion and data at rest.

The two principal areas of collective security are:

- Administrative domain security configuration  
Addresses data in motion, authentication and authorization
- Collective repository data security  
Addresses data at rest, authentication and authorization

### Administrative domain security configuration

The administrative domain security configuration for collectives is comprised of two parts:

- User domain  
This domain relies on Java role-based security that defines the Administrator role. This can be mapped to users within the configured user registry.
- Server domain  
This domain relies on SSL certificate-based authentication.

In order for users to access the collective controller's MBeans, they must be in the Administrator role. All administrative actions through the collective require that the user be granted the Administrator role. See “Configuring secure JMX connection to Liberty” on page 1642 for complete details.

Server-to-server communication falls within the server domain and no user identities or passwords are used to communicate between members of a collective. Each member of the collective has a unique identity within the collective that is comprised of its host name, user directory, and server name. Each member within the collective defines its server domain configuration, which consists of the `serverIdentity.jks` and `collectiveTrust.jks` files. These files contain the SSL certificates that are necessary to establish secure communications within the collective. The HTTPS key configuration must have specific trust settings, which are established by default.

The server domain SSL configuration can be customized by adding additional trusted certificate entries to the `collectiveTrust.jks` keystore. All trust is copied when a controller is replicated; therefore, SSL customization should be applied to the initial controller. Adding trust to the `collectiveTrust.jks` keystore is only necessary if the default HTTPS certificates are not used. If the HTTPS SSL configuration is modified, the following certificate rules apply:

- HTTPS trust must be established by all controllers and members within the collective. If the HTTPS SSL certificates are modified, the following root signers from the collective controller must be added to the HTTPS SSL truststore:
  - The `controllerRoot` signer from the `rootKeys.jks` keystore must be added to all collective members HTTPS SSL truststore.
  - The `controllerRoot` signer and the `memberRoot` signer from the `rootKeys.jks` keystore must be added to all collective controllers' HTTPS SSL truststore.
- Each member can make an outbound connection to a collective controller. The collective controller's `collectiveTrust.jks` keystore must contain a certificate chain that trusts the

HTTPS SSL certificate for each member. It is highly recommended that all HTTPS certificates be signed by a root signer, which then can be added to the `collectiveTrust.jks` keystore. Using individual SSL certificates that do not have a common root signer is sufficient to establish trust but will not scale.

- Each controller can make an outbound connection to a collective member. The collective member's `collectiveTrust.jks` keystore must contain a certificate chain that trusts the HTTPS SSL certificate for each controller. It is highly recommended that all HTTPS certificates be signed by a root signer, which then can be added to the `collectiveTrust.jks` keystore. Using individual SSL certificates that do not have a common root signer is sufficient to establish trust but will not scale.

Server-to-server communication requires that SSL authentication be supported. If the HTTPS SSL configuration is customized, the SSL configuration must specify `clientAuthenticationSupported="true"`. For example:

```
<!-- clientAuthenticationSupported set to enable bidirectional trust -->
  <ssl id="defaultSSLConfig"
    keyStoreRef="defaultKeyStore"
    trustStoreRef="defaultTrustStore"
    clientAuthenticationSupported="true" />
```

Setting `clientAuthentication="true"` on the collective controller is inadvisable and prevents some common and expected behaviors. For example, this setting prevents authentication with user names and passwords in Admin Center and collective command line utilities.

Setting `clientAuthentication="true"` on a collective member might be desirable to prevent user name and password logins. This setting does not break collective operations as all operations originating from the controller are authenticated using the certificate.

Members can be prevented from publishing information to the collective controller by using the `CollectiveRegistration` MBean. The `disavow` and `avow` methods prevent authentication and enable authentication.

### Collective repository data security

The collective repository data security policy covers the policy for data at rest - specifically, the policy of accessing the contents of the collective repository.

The current security policy for collective data is as follows:

- The system reserves three node names: `sys.host.auth.info`, `sys.jmx.auth.info`, and `sys.nologin`. These nodes are under a host or server's repository namespace. User-created nodes should avoid using the `sys.` prefix.
- The `sys.host.auth.info` and `sys.jmx.auth.info` nodes are not accessible through the MBean to prevent disclosure of system credentials. Accessing the data stored at these nodes will result in a null response.
- A collective member is restricted to modifying only its own information in the repository. Authenticated administrative users have unrestricted access to information in the repository except as previously noted. Authenticated administrative users are all users granted the Administrative role.

Because the collective repository ultimately resides on the disk, the file system permission settings must be secure for the environment. It is recommended that the collective controller's configuration be readable and writable only by the user, readable only by the group, and not accessible at all by the world - in other words, `chmod 0640`. Follow any security guidelines that your organization might have established.

## Configuring a Liberty collective

You can organize Liberty servers into collectives to support clustering, administration, and other operations that act on multiple Liberty servers. By using collectives, you can efficiently and accurately deliver application services to your organization.

## Before you begin

The `collectiveController-1.0` feature and its capabilities are available only in WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a WebSphere Application Server Liberty Network Deployment installation, you can use its `collectiveController-1.0` feature to work with collective members from WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core installations.

## About this task

A Liberty collective is a set of Liberty servers that are configured as part of the same administrative and operational domain.

Configuration and state data about a Liberty collective is housed in an active operational repository.

Membership in a Liberty collective is optional. Liberty servers join a collective by registering with a collective controller to become members. Members share information about themselves through the operational repository of the controller.

The following rules apply:

- A Liberty server can be a member of only one collective.
- Different Liberty servers on the same host can be in different collectives.
- Liberty servers on the same host that are members of a collective can coexist with Liberty servers that are not members of a collective.

 **Watch:** Introduction to creating a collective demonstrates the procedure. This video, and other information about collectives, is available on the WASdev website. [Transcript]

## Procedure

1. Create and configure your controller.
  - a. Create a server to act as the collective controller.

```
wlp/bin/server create myController
```

- b. Create the collective controller configuration.

The collective controller configuration consists primarily of the administrative domain security configuration that is used for secure communication between controllers and members.

```
wlp/bin/collective create myController --keystorePassword=controllerKSPassword
```

**8.5.5.2** By default, this collective command writes all output to a console screen. In the next step, you copy the configuration output into the `server.xml`. To write the configuration to a file instead of to a console screen, specify a `--createConfigFile=outputFilePath` parameter, for example:

```
wlp/bin/collective create myController --keystorePassword=controllerKSPassword --createConfigFile=c:\wlp\usr\servers\myController\
```

After you run the **create** command, the `include` statement to use is displayed. To include the outputted file in the collective configuration, add the `include` statement to the `server.xml` file, for example:

```
<include location="c:\wlp\usr\servers\myController\collective-create-include.xml" />
```

- c. Update the `server.xml` file of the collective controller.

- Copy and paste output.

If the command wrote output to a console screen, proceed with the following steps:

- 1) Copy output from the collective command and paste it into the server.xml file.
- 2) Specify administrative user ID and password values for the collective. For example, change:

```
<quickStartSecurity userName="" userPassword="" />
```

to:

```
<quickStartSecurity userName="adminUser" userPassword="adminPassword" />
```

The default path for the collective controller server.xml file is `${wlp.install.dir}/usr/servers/myController/server.xml` or, if the `$WLP_USER_DIR` variable is set in a server.env file or command window, `$WLP_USER_DIR/servers/myController/server.xml`. After editing, the file will resemble the following example:

```
<server description="controller server">
  <!-- Enable features -->
  <featureManager>
    <feature>jsp-2.2</feature>
  </featureManager>
  <httpEndpoint id="defaultHttpEndpoint"
    host="*"
    httpPort="9080"
    httpsPort="9443" />
  <featureManager>
    <feature>collectiveController-1.0</feature>
  </featureManager>
  <!-- Define the host name for use by the collective.
  If the host name needs to be changed, the server should be
  removed from the collective and re-joined or re-replicated. -->
  <variable name="defaultHostName" value="controllerHostname" />
  <!-- TODO: Set the security configuration for Administrative access -->
  <quickStartSecurity userName="adminUser" userPassword="adminPassword" />
  <!-- clientAuthenticationSupported set to enable bidirectional trust -->
  <ssl id="defaultSSLConfig"
    keyStoreRef="defaultKeyStore"
    trustStoreRef="defaultTrustStore"
    clientAuthenticationSupported="true" />
  <!-- inbound (HTTPS) keystore -->
  <keyStore id="defaultKeyStore" password="yourPassword"
    location="${server.config.dir}/resources/security/key.jks" />
  <!-- inbound (HTTPS) truststore -->
  <keyStore id="defaultTrustStore" password="yourPassword"
    location="${server.config.dir}/resources/security/trust.jks" />
  <!-- server identity keystore -->
  <keyStore id="serverIdentity" password="yourPassword"
    location="${server.config.dir}/resources/collective/serverIdentity.jks" />
  <!-- collective trust keystore -->
  <keyStore id="collectiveTrust" password="yourPassword"
    location="${server.config.dir}/resources/collective/collectiveTrust.jks" />
  <!-- collective root signers keystore -->
  <keyStore id="collectiveRootKeys" password="yourPassword"
    location="${server.config.dir}/resources/collective/rootKeys.jks" />
</server>
```

- **8.5.5.2** Add an include statement.

If you wrote the output to a file by using the `--createConfigFile=outputFilePath` parameter, add an include statement to `$WLP_USER_DIR/servers/myController/server.xml` to include the outputted file in the collective configuration. For example:

```

<server description="controller server">
  <!-- Enable features -->
  <featureManager>
    <feature>jsp-2.2</feature>
  </featureManager>
  <httpEndpoint id="defaultHttpEndpoint"
    host="*"
    httpPort="9080"
    httpsPort="9443" />
  <include location="c:\wlp\usr\servers\myController\collective-create-include.xml" />
</server>

```

Ensure the outputted file sets administrative user ID and password values for the collective, for example:

```
<quickStartSecurity userName="adminUser" userPassword="adminPassword" />
```

d. Start the collective controller server.

```
wlp/bin/server start myController
```

Figure 25. Collective of one

e. Verify that the collective controller server started correctly and is ready to receive members.

- 1) Open an editor on the collective controller messages log, \$WLP\_USER\_DIR/servers/myController/logs/messages.log.
- 2) Look for the following message:

```
CWWKX9003I: CollectiveRegistration MBean is available.
```

```

| If you want to enable a collective controller and its members to use the security TLSv1.2 protocol
| for the Secure Sockets Layer (SSL) context, see "Setting up Liberty to run in SP800-131a" on page
| 1848. The server.xml files of the controller and members need ssl id elements and each host
| computer needs a server.env file with the JVM_ARGS=-Dhttps.protocols=TLSv1.2 statement in its
| ${wlp.install.dir}/etc directory.

```

2. Create and configure a member to join the collective.

The controller and members can be on separate hosts. In this example, the controller and member are on the same host.

a. Create a member server.

```
wlp/bin/server create myMember
```

b. Join the member.

Run the collective **join** command to join the server to the collective as a member.

The **join** command requires a network connection to the collective controller and an administrative user ID and password for performing MBean operations on the controller. Look at the server.xml file of the collective controller to find the values for the --host, --port, --user, and --password parameters. For --keystorePassword, set a value to use for the member keystore password, such as memberKSPassword. You can specify different --keystorePassword values for each server that is joined to the collective.

```
wlp/bin/collective join myMember --host=controllerHostname --port=9443 --user=adminUser --password=adminPassword --keystorePassword=memberKSPassword
```

The optional parameter --hostname specifies the host name to use for the system. Set --hostname only if the system has multiple host names or does not have its host name configured. If set, the value must match the defaultHostName variable that is defined in the server.xml file.

**8.5.5.2** To write the output of this collective command to a file, instead of to a console screen, specify an optional `--createConfigFile=outputFilePath` parameter. Then, include the outputted file in the collective configuration by adding an `include` statement to the member `server.xml` file:

**8.5.5.2**

```
<include location=outputFilePath />
```

**8.5.5.4** By default, the **join** operation leaves remote procedure call (RPC) credentials undefined. You must specify values for `rpcUser`, `rpcUserPassword`, and the operating system login user and password for the host on which the member server resides. If the member host is registered with the collective controller and the member host is not enabled for SSH, specify an optional `--useHostCredentials` parameter to enable the member to inherit RPC credentials from its host registration on the controller. Typically, Linux hosts are enabled for SSH and Windows hosts are not enabled for SSH; thus, the `--useHostCredentials` parameter is useful for Windows member hosts. Specifying `--useHostCredentials` adds `<hostAuthInfo useHostCredentials="true" />` to the member `server.xml` file. You then can run collective member server commands such as **start** or **stop** without specifying RPC credentials because the member inherits credentials from its host. See “Overriding Liberty server host information” on page 1144 for information about `hostAuthInfo`, the `--useHostCredentials` parameter, and connecting the collective controller to the server.

For information about these required parameters and about optional parameters, run `collective help join` at a command line.

- c. If prompted to accept the certificate chain, enter `y` (yes).
- d. Update the member `server.xml` file.
  - Copy and paste output.

If the command wrote output to a console screen, proceed with the following steps:

- 1) Copy output from the collective command and paste it into the member `server.xml` file.
- 2) Modify the ports so that the server can open its HTTP ports. Ensure the member `server.xml` sets unique HTTP port numbers on its host. For example, if the member is on the same host as the collective controller, change the HTTP port numbers:

```
<httpEndpoint id="defaultHttpEndpoint" httpPort="9081" httpsPort="9444" />
```

Optionally, to access the member server from a remote client, also set `host="*"` in the `httpEndpoint` element.

In `$WLP_USER_DIR/servers/myMember/server.xml`, for example:

```
<server description="member server">
  <!-- Enable features -->
  <featureManager>
    <feature>jsp-2.2</feature>
  </featureManager>
  <httpEndpoint id="defaultHttpEndpoint"
    host="*"
    httpPort="9081"
    httpsPort="9444" />
  <featureManager>
    <feature>collectiveMember-1.0</feature>
  </featureManager>
  <!-- Define the host name for use by the collective.
  If the host name needs to be changed, the server should be
  removed from the collective and re-joined or re-replicated. -->
  <variable name="defaultHostName" value="memberHostname" />
```

**8.5.5.4** `<!-- Remote host authentication configuration --> <hostAuthInfo rpcUser="admin_user_id" rpcUserPassword="admin_user_password" /> <!-- Connection to the`

```

collective controller --> <collectiveMember controllerHost="controllerHostname"
controllerPort="9443" /> <!-- clientAuthenticationSupported set to enable bidirectional trust -->
<ssl id="defaultSSLConfig" keyStoreRef="defaultKeyStore" trustStoreRef="defaultTrustStore"
clientAuthenticationSupported="true" /> <!-- inbound (HTTPS) keystore --> <keyStore
id="defaultKeyStore" password="yourPassword" location="{server.config.dir}/resources/
security/key.jks" /> <!-- inbound (HTTPS) truststore --> <keyStore id="defaultTrustStore"
password="yourPassword" location="{server.config.dir}/resources/security/trust.jks" /> <!--
server identity keystore --> <keyStore id="serverIdentity" password="yourPassword"
location="{server.config.dir}/resources/collective/serverIdentity.jks" /> <!-- collective truststore
--> <keyStore id="collectiveTrust" password="yourPassword" location="{server.config.dir}/
resources/collective/collectiveTrust.jks" /> </server>

```

- **8.5.5.2** Add an include statement.

If you wrote the output to a file by using the `--createConfigFile=outputFilePath` parameter, add an include statement to `$WLP_USER_DIR/servers/myMember/server.xml` to include the outputted file, for example:

```

<server description="member server">
    <!-- Enable features -->

    <featureManager>
        <feature>jsp-2.2</feature>
    </featureManager>

    <httpEndpoint id="defaultHttpEndpoint"
        host="*"
        httpPort="9081"
        httpsPort="9444" />

    <include location="c:\wlp\usr\servers\myMember\collective-join-include.xml" />
</server>

```

- e. **8.5.5.4** If you did not specify `--useHostCredentials` in the `join` command and the member host is not enabled for SSH, set RPC credentials for `hostAuthInfo` in the member `server.xml` file or the outputted file. You can set RPC credentials for the member server in either of two ways:

- Set `hostAuthInfo` RPC user and password values. Set `rpcUser` to an operating system login user ID for the host on which the member server resides, and set `rpcUserPassword` to the operating system login password for the user ID. For example, if you log into the member computer with user `test1` and password `test1pwd`, then change the `hostAuthInfo` element to the following:

```
<hostAuthInfo rpcUser="test1" rpcUserPassword="test1pwd" />
```

- If the member host is registered with the collective controller, set `hostAuthInfo useHostCredentials` to `true` for the member server to inherit RPC credentials from its host.

```
<hostAuthInfo useHostCredentials="true" />
```

See “Overriding Liberty server host information” on page 1144 for information about `hostAuthInfo` settings and for an example that shows how to register a member host and run the `join` command with `--useHostCredentials`.

- f. **z/OS** For z/OS only, issue the `updateHost` command to specify the member `JAVA_HOME` directory for the controller.

```

collective updateHost controllerHostname --host=controllerHostname
--port=9443 --user=adminUser --password=adminPassword
--hostWritePath=/dir1 --rpcUser=rpcUser
--rpcUserPassword=rpcUserPassword --hostJavaHome=JAVA_HOME

```

The `hostWritePath` parameter specifies the directories to which the collective controller can write. Paths that are specified by the `hostWritePath` parameter are also readable.

The `hostJavaHome` parameter specifies the absolute path to where the JVM is on the system and where the member server runs, for example `/usr/lpp/java/java_1.7_64`

- g. Start the member server.

```
wlp/bin/server start myMember
```

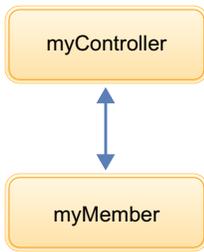

Figure 26. Simple collective

- h. Verify that the member server started correctly and is publishing information to the controller.
  - 1) Open an editor on the member messages log, `$WLP_USER_DIR/servers/myMember/logs/messages.log`.
  - 2) Look for the following messages in any order:
 

```

CWWKX8112I: The server's host information was successfully published to the collective repository.
CWWKX8114I: The server's paths were successfully published to the collective repository.
CWWKX8116I: The server STARTED state was successfully published to the collective repository.
          
```

## Configuring a Liberty collective using the developer tools

### 8.5.5.1

Using the Liberty **Utilities** menu in the developer tools, you can create a collective controller or join a collective.

### Before you begin

Using the developer tools simplifies the process of configuring a Liberty collective by providing convenient utilities for creating collective controllers or joining collectives. For more information about Liberty collectives, see “Configuring a Liberty collective” on page 1136.

### Procedure

1. Creating a collective controller:

**Note:** Creating a collective controller can be done only with the following editions:

- WebSphere Application Server Liberty Network Deployment
  - WebSphere Application Server Liberty for z/OS
- a. In the Servers view, right-click your Liberty server, and select **Utilities > Create Collective Controller**.
  - b. In the **Keystore password** field, type a password for your collective.
  - c. Click **Finish**.

Results:

An information dialog appears after the collective configuration is complete. This dialog informs you that the `server.xml` file was already updated to include the generated configuration file. If there are instructions to add the configuration lines to the `server.xml` in the console output, they can be ignored. However, Administrative Security and other settings might still need to be configured within the included configuration file before any collective members can join.

2. Joining a collective controller:

**Note:** You must have a collective controller available before a server can be added to a collective. Joining a collective can be done with the following editions:

- WebSphere Application Server Liberty

- WebSphere Application Server Liberty - Express
- WebSphere Application Server Liberty Core

  - a. In the Servers view, right-click your Liberty server, and select **Utilities > Join Collective**.
  - b. On the Join Collective page, specify the information of the collective controller you would like to join.
  - c. In the **Host** field, type in the host name for the collective controller.
  - d. In the **Port** field, type in the port number for the collective controller.
  - e. In the **User** field, type in the user name for the collective controller.
  - f. In the **Password** field, type in the password for the collective controller.
  - g. In the **Keystore password** field, type the keystore password for the collective controller if encryption was used.
  - h. Click **Finish**.

Results:

An information dialog appears after the collective configuration is complete. This dialog informs you that the `server.xml` file was already updated to include the generated configuration file. If there are instructions to add the configuration lines to the `server.xml` in the console output, they can be ignored.

## Overriding Liberty server host information

### 8.5.5.0

The `collectiveMember-1.0` feature enables a server to be managed by the collective controller. Most server host information can be automatically detected. In certain scenarios, however, you must provide additional host information so that the collective controller can establish a connection to the server.

**Note:** **Distributed operating systems** **IBM i** The `collectiveController-1.0` feature and its capabilities are available only in WebSphere Application Server Liberty Network Deployment and WebSphere

Application Server Liberty for z/OS. **8.5.5.0** The feature is not available in WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a WebSphere Application Server Liberty Network Deployment installation, you can use its `collectiveController-1.0` feature to work with collective members from WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core installations.

To enable the host information override, add the following element to the `server.xml` file:

```
<hostAuthInfo rpcPort="ssh_port"
  rpcUser="user_ID"
  rpcUserPassword="password"
  rpcUserHome="user_home"
  rpcHost="host_name"
  sudoUser="sudo_user"
  sudoPassword="sudo_user_password"
  sshPublicKeyPath="public_key_path"
  sshPrivateKeyPath="private_key_path"
  sshPrivateKeyPassword="private_key_password"
```

**8.5.5.4** `useHostCredentials="true_or_false"/>`

#### **rpcPort**

This parameter specifies the port for the RPC mechanism, which is SSH port 22 by default. If your system uses a nonstandard port, set this value accordingly. If this value is not specified, the default value is 22.

### **rpcUser**

This parameter specifies the user ID that the collective controller will use to connect to the server. If the host does not support SSH or using SSH keys is not desired, you can use this parameter to specify an operating system login user. For example, if you log in to the host with the myID user, then you specify `rpcUser="myID"`. If this value is not specified, the default value is `System.getProperty("user.name")`.

### **rpcUserPassword**

This parameter specifies the password for the specified user ID. For example, if you log in to the host with the myID user and the myPwd password, then you specify `rpcUser="myID"` and `rpcUserPassword="myPwd"`. If this value is not specified, the server will either generate an SSH key pair or use the SSH key pair for the connection that is specified using the **privateKeyPath** and **publicKeyPath** parameters. If SSH is not installed on the server (such as on a Windows or OS/400 operating system), the password is required.

### **rpcUserHome**

This parameter specifies the home directory of the user. If this value is not specified, the default value is `System.getProperty("user.home")`. If **rpcUser** is specified, you should specify **rpcUserHome**.

### **rpcHost**

This parameter specifies the host on which the RPC mechanism is configured to listen. If this value is not specified, the default value is the value of the **defaultHostName** variable. If your system uses a host other than the **defaultHostName**, set this value accordingly.

### **sudoUser**

If this value is specified, it allows the collective controller to run commands as another, or "sudo", user instead of as the user ID used for the connection. This parameter applies only to servers that have an SSH server installed. This parameter has no default value.

### **sudoPassword**

This parameter specifies the password for the sudo user specified by the **sudoUser** parameter. This parameter applies only to servers that have an SSH server installed. This parameter has no default value.

### **sshPublicKeyPath**

This parameter specifies the path and file name of a user-specified public key file. If this value is not specified, the default is `${server.output.dir}/resources/security/ssh/id_rsa.pub`. If the specified file (or default file) does not exist, a new public key file will be generated.

### **sshPrivateKeyPath**

This parameter specifies the path and file name of a user-specified private key file. If this value is not specified, the default is `${server.output.dir}/resources/security/ssh/id_rsa`. If the specified file (or default file) does not exist, a new private key file will be generated.

### **sshPrivateKeyPassword**

This parameter specifies the password for the private key. This parameter has no default value.

8.5.5.4

### **useHostCredentials**

This parameter specifies whether collective member server commands inherit RPC credentials from the host. The default is `false`, requiring the user to specify RPC credentials for the controller to remotely start or stop the member. When set to `true`, collective member server commands inherit RPC credentials from the host registration and ignore all other RPC credentials in the `hostAuthInfo` configuration element.

## **Examples**

Scenario 1: Server is on Windows operating system, no SSH is installed

```
<hostAuthInfo rpcUserPassword="myPassword"/>
```

Scenario 2: Server has SSH installed, SSH is running on port 2222

```
<hostAuthInfo rpcPort="2222"/>
```

Scenario 3: Need to run commands as another user

```
<hostAuthInfo sudoUser="anotherUser" sudoPassword="anotherPassword"/>
```

Scenario 4: Server is on a Windows operating system and ssh (e.g. Cygwin) is installed. With the following server configuration, the controller connects the member server with ssh. In this case, the requirement to disable Windows User Account Control (UAC) does not apply. The parameter `<user's home directory>` is the user default home directory, for example: `C:\cygwin\home\bob`

```
<hostAuthInfo rpcUserHome="<user's home directory"> />
```

8.5.5.4

Scenario 5: The collective controller and member are on separate hosts, and not on the same host. To specify that the member inherit RPC credentials from the host, set `useHostCredentials` to `true` in the `server.xml` file of the member. Complete the following steps to configure the member to inherit RPC credentials from the host by specifying `--useHostCredentials` in the `join` command that joins a server as a member to the collective.

1. Create, configure, and start a collective controller named `myController` as shown in step 1 of “Configuring a Liberty collective” on page 1136.
2. Register the host for the member with the collective. The member and the collective controller are on different hosts.

In this scenario, the `registerHost` command uses the collective controller host `hostA.ibm.com` with port number 9443, user `admin`, and password `adminpwd`. The command registers the member host `hostB.ibm.com` with the collective, and sets `rpcUser` to an operating system login user ID for the member host `osUser1`, and `rpcUserPassword` to the operating system login password for the user ID for the member host `osUser1Pwd`. Run the `registerHost` command on the collective controller host.

```
wlp/bin/collective registerHost hostB.ibm.com --host=hostA.ibm.com --port=9443 --user=admin --password=adminpwd --rpcUser=osUser1
```

Enter `y` (yes) when prompted to accept the certificate chain. After registration, the Host `hostB.ibm.com` successfully registered. message displays. The collective controller host now has the operating system user ID and password of the member host.

3. On the member host, create a server named `myMember` to use as a collective member.

```
wlp/bin/server create myMember
```

4. Add the `myMember` server to the collective controller, specifying to use host credentials. In the `join` command, which is run on the member host, specify `--useHostCredentials` so that the member inherits RPC credentials from the host registration.

```
wlp/bin/collective join myMember --host=hostA.ibm.com --port=9443 --user=admin --password=adminpwd --keystorePassword=memberKSPas
```

5. Update the member `server.xml` file as shown in step 2 of “Configuring a Liberty collective” on page 1136.

Because you specified `--useHostCredentials` in the `join` command, the configuration generated for the member `server.xml` file sets `useHostCredentials` to `true`:

```
<!-- Remote host authentication configuration -->  
<hostAuthInfo useHostCredentials="true" />
```

With the `--useHostCredentials` option, you do not need to specify the operating system user ID and password in the member `server.xml` file because the member inherits credentials from the host. Later, if the operating system user ID or password of the member server changes, run the `updateHost` command to change the user ID or password. For more information about the `registerHost` and `updateHost` commands, see “Registering host computers with a Liberty collective” on page 1142.

## Starting and stopping a Liberty collective member

8.5.5.0

The collective controller provides a `ServerCommands` MBean that can be used to start or stop a collective member. The MBean `startServer` and `stopServer` methods start and stop a member. You also can run server **start** and **stop** commands from a command line.

## Prerequisites

- The member server must have the `collectiveMember-1.0` feature enabled in its `server.xml` file.
- The member must be joined to the collective. See “Configuring a Liberty collective” on page 1136.

## Set up

To enable the collective controller to stop and start a member server, it might be necessary to add the `<hostAuthInfo>` element to the member's `server.xml` file. By default, each member attempts to use SSH key-based authentication. A pair of RSA keys is generated on server startup under `${server.config.dir}/resources/security/ssh`. The public key is added to the user's `authorized_keys` file automatically. The private key is sent to the controller. If SSH is not available:

- **Windows** For Windows members, you must provide an administrator user ID and password in the `<hostAuthInfo>` element.
- **AIX** **HP-UX** **Linux** **Solaris** **z/OS** For AIX, HP-UX, Linux, Solaris, or z/OS members, use of SSH key-based authentication is recommended. To use a username and password for authentication, specify them in a `<hostAuthInfo>` element in the `server.xml` file.

See “Overriding Liberty server host information” on page 1144 and “Setting up RXA for Liberty collective operations” on page 1491 for details.

## Procedure

- Use the `ServerCommands` MBean `startServer` and `stopServer` methods to start and stop a collective member.

For information on running the `ServerCommands` MBean from the controller, see the API documentation for the `ServerCommands` MBean.

- Run server **start** and **stop** commands from a command line. See “Starting and stopping a server from the command line” on page 1584.

## Registering host computers with a Liberty collective

8.5.5.0

You can register a host computer with a Liberty collective controller, update host information, or unregister a host. Registration enables the collective controller to access applications, command files, and other resources on the host. Registered hosts are members of the collective.

### Before you begin

1. Construct a Liberty collective. See “Configuring a Liberty collective” on page 1136.

#### Distributed operating systems

IBM i

The `collectiveController-1.0` feature and its capabilities are available only in multiple-server products such as WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in single-server products such as WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a multiple-server product installation, you can use its `collectiveController-1.0` feature to work with collective members from single-server products.

2. To enable connections to servers on local and remote hosts, complete the steps for your host operating system in “Setting up RXA for Liberty collective operations” on page 1491. The topic provides information about the Tivoli Remote Execution and Access (RXA) toolkit and enabling Secure Shell

(SSH) protocol. You can use RXA to remotely start and stop servers, including starting and stopping servers on your local computer, and to transfer files to and from registered hosts.

**Note:** Windows In Windows, system environment variables are visible only inside the shell that RXA connects to. Setting PATH in the command window is not sufficient. You must set PATH in the system variable section of the environment variables, or use `-hostJavaHome <PATH TO IBM JAVA>` with the `updateHost` option.

3. If you want to enable a collective controller and its members to use the security TLSv1.2 protocol for the Secure Sockets Layer (SSL) context, see “Setting up Liberty to run in SP800-131a” on page 1848. The `server.xml` files of the controller and members need `ssl id` elements and each host computer needs a `server.env` file with the `JVM_ARGS=-Dhttps.protocols=TLSv1.2` statement in its `${wlp.install.dir}/etc` directory.

## About this task

A host computer is not required to have any WebSphere Application Server products installed. There are no software requirements for a host beyond its operating system. The host can be the same computer on which the product is installed or a different computer.

To register a host with a collective controller, update host information, and unregister a host, use the **registerHost**, **updateHost**, and **unregisterHost** commands. Specify the host computer name in one of the following formats:

- Fully qualified domain name servers (DNS) host name string, such as `xmachine.ibm.com`
- Default short DNS host name string, such as `xmachine`
- Numeric IP address, such as `127.1.255.3`

**Note:** When a Liberty server is joined to a collective, the associated host is automatically registered with the collective controller if it is not already registered.

A host can be registered with the collective under different names. Ensure that the host name specified for **registerHost**, **updateHost**, and **unregisterHost** is consistent with the host name used for the registered collective members. The `defaultHostName` variable in the registered server member's `server.xml` file controls the host name to which the server considers itself to belong.

## Procedure

- Register a host with a collective controller.

To register the current host where both the collective controller host and the remote target host are the same computer, run the **registerHost** command on the collective utility script with no explicit host target. Specify the collective controller's host name, port, and administrative user name and password. For example:

```
wlp/bin/collective registerHost --host=controllerHost --port=controllerHTTPSPort
--user=controllerAdmin --password=controllerAdminPassword
```

This example command generates a unique SSH key pair for authenticating to the SSH server of a specified host computer. If you are registering a remote host for which an SSH key pair is already generated, you can specify the path of the SSH private key file. The following **registerHost** command assumes that the SSH private key is stored on the local controller computer at `/home/user1/.ssh/id_rsa`. The other file in the SSH key pair is the `/home/user1/.ssh/authorized_keys` public key file on the remote target host.

```
wlp/bin/collective registerHost remotehost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
--sshPrivateKey=/home/user1/.ssh/id_rsa
```

If the remote target host does not support SSH or you do not want to use SSH keys, you can specify an operating system login user for `rpcUser` and login password for `rpcUserPassword`. If you include `rpcUser` with `rpcUserPassword`, do not include `sshPrivateKey`. The command to specify operating system login user and password resembles:

```
wlp/bin/collective registerHost remotehost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
--rpcUser=osUserForRemoteHost --rpcUserPassword=osUserPasswordForRemoteHost
```

### 8.5.5.2

To transfer files to and from a host, you must specify host read and write paths. Unless the **registerHost** command specifies the paths, you cannot deploy a Liberty archive to the host. The **hostReadPath** specifies the directories that the collective controller can read. The **hostWritePath** specifies the directories to which the collective controller can write. Paths that are specified by **hostWritePath** are also readable. For example, to upload an archive to /opt/wlp, you must specify **--hostWritePath=/opt**. Specify a parameter multiple times for multiple paths.

```
wlp/bin/collective registerHost myHost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
--rpcUser=osUser --rpcUserPassword=osUserPassword
--hostReadPath=/opt --hostWritePath=/dir1 --hostWritePath=/dir2
```

To use the Deploy tool of the WebSphere Liberty Administrative Center ("Admin Center"), you must set **hostWritePath** to the path to which you want to deploy a server package. To transfer files to multiple directories, include multiple instances of the **hostWritePath** parameter in the command. For example:

```
wlp/bin/collective registerHost myHost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin
--password=controllerAdminPassword --rpcUser=osUser --rpcUserPassword=osUserPassword
--hostWritePath=c:\was\liberty\brokerageAppTest --hostWritePath=c:\wlp_backup
```

### Windows

Before you deploy a server package by using the Deploy tool of Admin Center, complete the steps for your host operating system in "Setting up RXA for Liberty collective operations" on page 1491.

Optionally, specify the path to the Java home directory of the host with the **-hostJavaHome** parameter. For example: **-hostJavaHome=c:\java\jre**

- Update registered host authentication information.

Run the **updateHost** command on the collective utility script to change the authentication information of a registered host. For example, if the user password changes, the following command updates the host password that is used by the collective:

```
wlp/bin/collective updateHost myHost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
--rpcUser=osUser --rpcUserPassword=newOsUserPassword
```

- **8.5.5.2** Update registered host read or write paths.

Run the **updateHost** command on the collective utility script to change the host read and write paths. Paths in this command override the previously set paths for **hostReadPath** and **hostWritePath**, and do not add to the existing paths.

```
wlp/bin/collective updateHost myHost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
--rpcUser=osUser --rpcUserPassword=osUserPassword
--hostReadPath=/optNew --hostWritePath=/opt --hostWritePath=/home/osUser
```

- Unregister a host from a collective controller.

Run the **unregisterHost** command on the collective utility script; for example:

```
wlp/bin/collective unregisterHost myHost.ibm.com --host=controllerHost
--port=controllerHTTPSPort --user=controllerAdmin --password=controllerAdminPassword
```

Unregistering a host removes all the registered servers on that host and any other host-based information from the collective controller.

## What to do next

For information about all parameters of the **registerHost**, **updateHost**, and **unregisterHost** commands, see the API documentation for the `CollectiveRegistration` MBean.

## Configuring Liberty collective replica sets

You can configure collective replica sets. A replica set provides highly available management capabilities for a Liberty administrative domain.

Distributed operating systems

IBM i

### Before you begin

The `collectiveController-1.0` feature and its capabilities are available only in WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a WebSphere Application Server Liberty Network Deployment installation, you can use its `collectiveController-1.0` feature to work with collective members from WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core installations. A collective member can be from any WebSphere Application Server Liberty release.

### About this task

A *replica set* is a set of collective controllers that are configured to work together. Each replica contains all the repository updates that the other replicas within the set have processed. Therefore, there is no need for a member or client to connect with a particular collective controller each time that it interacts with the collective; any of the collective controllers that are configured in the replica set can provide the same data.

For detailed instructions about creating and configuring a collective controller, see “Configuring a Liberty collective” on page 1136.

You can complete the following procedures to configure a collective replica set:

1. Add a replica to an existing replica set.
2. Modify the default configuration of the initial replica set.

See Example: Create and activate a replica set for an example of creating a replica set consisting of three collective controllers on the same host.

### Procedure

1. Add a replica to an existing replica set.

During the life of a replica set, it might become necessary to add one or more replicas to an existing set, to increase capacity for example.

The existing replicas in the replica set do not require any updates to their configuration. You can update them so that their configurations in the `server.xml` files more accurately reflect the replicas that form the replica set, but this update is unnecessary and does not affect their behaviors.

**Note:** It is not necessary to change the `replicaSet` value in the `server.xml` file of an existing replica in the set. No change to the configuration of an existing replica is required. If you do want to update the `replicaSet` values in the configurations of existing replicas in the set so that the configuration values are consistent across all replicas in the set, you must set the `isInitialReplicaSet` value in the configurations of the existing replicas to `false`. After you alter the `replicaSet` value, it describes a changed replica set rather than the initial replica set.

**Note:** When you refer to a replica, you must be consistent and use the same `host:port` value. If a hostname is used, it must always be used. Or, if an IP address is used, it must always be used.

To add a replica, follow these steps:

- a. Ensure that the existing replica set is running and that most of the replicas are available.

- b. Create a server to be the new collective controller.

```
wlp/bin/server create MyNewController
```

- c. Replicate to transform the new server into a collective controller.

```
wlp/bin/collective replicate MyNewController
--host=host_of_running_controller
--port=https_port_of_running_controller
--user=userName_for_running_controller
--password=userPassword_for_running_controller
--keystorePassword=keystore_password_for_new_controller
```

The **replicate** command writes XML output to a console screen. You copy the output into the `server.xml` file.

**8.5.5.2** To write the output of the command to a file, instead of to a console screen, specify the `--createConfigFile=output_file_path` parameter. Then, include the outputted file in the collective configuration by adding an `include` statement to the `server.xml` file:

```
<include location=output_file_path />
```

- d. Configure the new replica's `server.xml` file by using output of the **replicate** command.

Copy the XML output of the **replicate** command into the `server.xml` file. You can modify the replica configuration as follows:

- **Required settings:**

The values must be explicitly set. The XML printed by the **replicate** command contains this configuration and is sufficient for these settings.

**8.5.5.4 hostAuthInfo**

Host authentication information containing properties that a remote client needs to start the server. This setting is only required when the host of the new replica is not enabled for SSH. Typically, Linux hosts are enabled for SSH and Windows hosts are not enabled for SSH. Thus, this setting might only be needed on Windows hosts. Set RPC credentials for the replica in either of two ways:

- Set `rpcUser` to an operating system login user ID for the host on which the replica resides, and set `rpcUserPassword` to the operating system login password for the user ID. For example, if you log into the replica computer with user `test1` and password `test1pwd`, then change the `hostAuthInfo` element to the following:

```
<hostAuthInfo rpcUser="test1" rpcUserPassword="test1pwd" />
```

- If the replica host is registered with the collective controller, set `hostAuthInfo useHostCredentials` to `true` for the replica to inherit RPC credentials from its host.

```
<hostAuthInfo useHostCredentials="true" />
```

See “Overriding Liberty server host information” on page 1144 for information about `hostAuthInfo` settings.

**replicaSet**

Space-delimited list that contains the `host:port` for each of the `replicaHosts` and `replicaPorts` in the replica set, excluding the values for the collective controller now being added to the set

For example,

```
original.host.com:10001 some.other.host.com:10003
```

At least one of the values in this set must already be a replica of the existing replica set.

- **Optional settings:**

These settings default, but can be altered.

**isInitialReplicaSet**

False

**replicaHost**

Hostname for each individual replica

**replicaPort**

Port for each individual replica

This port is not the http or https port of the collective controller, but it is a unique port that is used for communication between the replicas of the replica set.

**repositoryDir**

Directory location that is used to store repository data

Here is an example of what you might add to a new replica `server.xml` file:

```
<collectiveController replicaHost="localhost"
  replicaPort="10012"
  replicaSet="localhost:10010 localhost:10011"
  isInitialReplicaSet="false"/>
```

The XML printed by the **replicate** command requires updating the server's security configuration and specifying the `collectiveRootKeys` keystore password. The server's security configuration should be identical to the original collective controller's configuration, and the `collectiveRootKeys` keystore password should be the password that is used for the original collective controller's `collectiveRootKeys` keystore password. If the replica was created from the controller that is created in "Configuring a Liberty collective" on page 1136, the new controller's configuration should contain the following:

```
<quickStartSecurity userName="adminUser" userPassword="adminPassword" />
<!-- collective root signers keystore -->
<keyStore id="collectiveRootKeys" password="yourPassword"
  location="{server.config.dir}/resources/collective/rootKeys.jks" />
```

- e. Start the new replica by starting the new collective controller.
- f. Confirm that the original collective controller successfully connected to the new replica. Look for message CWWKX6009I in the `messages.log` file of the original collective controller and the replica.

**Tip:** For scripts that run the **replicate** and **addReplica** commands, add a 10-second wait after the **replicate** command runs to ensure the original collective controller and replica connect before running the **addReplica** command.

- g. Invoke the `addReplica` operation on the collective utility to activate the new replica. The argument to the `addReplica` set must be the replica endpoint (in the form "replicaHost:replicaPort") of the replica to add.

```
wlp/bin/collective addReplica localhost:10012
  --host=host_of_running_controller
  --port=port_of_running_controller
  --user=user_for_running_controller
  --password=user_password
```

2. Optional: If necessary, you can modify the default configuration of the initial replica set. This step is recommended but not required.

The configuration of the initial replica set occurs when the initial collective controller is created. If it is necessary to modify the default replica configuration, the following properties can be changed in the `server.xml` file:

**Optional settings:** These values default, but can be altered.

**replicaHost**

Hostname for each individual replica

**replicaPort**

Port for each individual replica

This port is not the http or https port of the collective controller, but it is a unique port that is used for communication between the replicas of the replica set.

**repositoryDir**

Directory location that is used to store the repository data

## Example: Creating and activating a replica set

This example describes how to create a replica set and then activate it. A replica set must have at least three replicas, preferably on different hosts, for high availability. This example has the replicas on the same host, which requires that you assign unique port numbers for the replicas. When replicas are on different hosts, the replicas can use the same port numbers.

### 1. Create a replica set.

To create a replica set, you increase the number of collective controllers and configure them so that they can communicate with each other. Each new collective controller is called a *replica* because the added collective controllers have the same security configuration as the original controller and because all information written to any one controller is automatically replicated to all other active controllers. Once configured, all collective controllers in the replica set can perform the same operations as the original controller.

- a. If you do not have a collective controller, create one. See step 1 of “Configuring a Liberty collective” on page 1136.
- b. Ensure the existing collective controller is running. For an existing controller named `myController`, run the **status** command:

```
wlp/bin/server status myController
```

If the collective controller is not running, then start it using the **start** or **run** command:

```
wlp/bin/server start myController
```

- c. Create a server to be the new collective controller.

```
wlp/bin/server create myController2
```

- d. Replicate the existing collective controller configuration into the new collective controller. The new collective controller is called a *replica*.

Run a **replicate** command that uses the administrative security domain configuration of the existing collective controller and sets a new keystore password for the replica. Look at the `server.xml` file of the existing collective controller to find the values for the `--host`, `--port`, `--user`, and `--password` parameters. For `--keystorePassword`, set a value to use for the keystore, such as `myController2`. For information about these required parameters and about optional parameters, run `collective help replicate` at a command line.

```
wlp/bin/collective replicate myController2 --host=host_of_existing_controller --port=https_port_of_existing_controller --user=userName
```

If prompted to accept the certificate chain, enter `y` (yes).

The **replicate** command writes XML output to a console screen. You copy the output into the `server.xml` file.

**8.5.5.2** To write the output of the command to a file, instead of to a console screen, specify the `--createConfigFile=output_file_path` parameter. Then, include the outputted file in the collective configuration by adding an `include` statement to the `server.xml` file:

```
<include location=output_file_path />
```

- e. Add the XML output of the **replicate** command into the `server.xml` file of the replica and edit the parameter values as needed.
  - Ensure that the `httpEndpoint` element sets `replica httpPort` and `httpsPort` values that are unique port numbers on the host. For example, suppose the original controller named `myController` and the replica are both on the same localhost and `myController` has the following the `httpEndpoint` element:

```
<httpEndpoint id="defaultHttpEndpoint"
  host="*"
  httpPort="9080"
  httpsPort="9443" />
```

Change the values for `myController2` to:

```
<httpEndpoint id="defaultHttpEndpoint"
  host="*"
  httpPort="9085"
  httpsPort="9448" />
```

- **8.5.5.4** Set RPC credentials for hostAuthInfo. You can set RPC credentials for the replica in either of two ways:

- Set hostAuthInfo RPC user and password values. Set rpcUser to an operating system login user ID for the host on which the replica resides, and set rpcUserPassword to the operating system login password for the user ID. For example, if you log into the replica computer with user test1 and password test1pwd, then change the hostAuthInfo element to the following:

```
<hostAuthInfo rpcUser="test1" rpcUserPassword="test1pwd" />
```

- If the replica host is registered with the collective controller, set hostAuthInfo useHostCredentials to true for the replica to inherit RPC credentials from its host.

```
<hostAuthInfo useHostCredentials="true" />
```

See “Overriding Liberty server host information” on page 1144 for information about hostAuthInfo settings.

- Ensure that replicaPort sets a port number for the replica that is unique among the replica set and that replicaSet sets host:port values that identify the replica set. For example, if the original controller named myController and the replica are both on the same localhost, change the values for myController2 from null:

```
<collectiveController replicaPort="null"
  replicaSet="localhost:null"
  isInitialReplicaSet="false" />
```

to 10011 for the replica port and 10010 for the replica set port:

```
<collectiveController replicaPort="10011"
  replicaSet="localhost:10010"
  isInitialReplicaSet="false" />
```

- Ensure the security configuration sets the same values as those used by the original controller. For example, both myController and the myController2 replica use:

```
<quickStartSecurity userName="adminUser" userPassword="adminPassword" />
```

- Ensure the collective root signers keystore element sets the same password as that used by the original controller. For example, copy the collectiveRootKeys keystore password from the myController server.xml file and paste it into the myController2 replica server.xml file. This example shows a generated password:

```
<!-- collective root signers keystore -->
<keyStore id="collectiveRootKeys" password="{xor}Lz4sLCgwLTs="
  location="{server.config.dir}/resources/collective/rootKeys.jks"/>
```

- f. Start the new replica by starting the new collective controller.

```
wlp/bin/server start myController2
```

- g. Verify that the original collective controller can communicate with the new replica.

- 1) Open an editor on the original controller messages log, \$WLP\_USER\_DIR/servers/myController/logs/messages.log.

- 2) Look for the following message, which might have different IP addresses in your environment:

```
CWWKX6009I: The collective controller successfully connected to replica 127.0.0.1:10011. Current active replica set is [127.0.0.1:
```

- h. Verify that the new replica can communicate with the original collective controller.

- 1) Open an editor on the replica messages log, \$WLP\_USER\_DIR/servers/myController2/logs/messages.log.

- 2) Look for the following message, which might have different IP addresses in your environment:

```
CWWKX6009I: The collective controller successfully connected to replica 127.0.0.1:10010. Current active replica set is []. The con
```

2. Activate the new replica.

Run an **addReplica** command that uses the administrative security domain configuration of the collective controller and specifies the endpoint of the replica that you want to activate in the form

*replicaHost:replicaPort*. Look at the `server.xml` file of the collective controller to find the values for the `--host`, `--port`, `--user`, and `--password` parameters. Look at the `server.xml` file of the replica to find the values for *replicaHost:replicaPort*. For information about these parameters, run `collective help addReplica` at a command line.

```
wlp/bin/collective addReplica replicaHost:replicaPort --host=host_of_existing_controller --port=port_of_existing_controller --user=u
```

For this example, which has the existing collective controller and the replica on the same host, `localhost`, run:

```
wlp/bin/collective addReplica localhost:10011 --host=localhost --port=9443 --user=adminUser --password=adminPassword
```

If prompted to accept the certificate chain, enter `y` (yes).

- Repeat steps 1 and 2 for additional replicas. For example, add a third replica to the replica set. Name the new replica `myController3` and specify `replicaPort="10012"`. A replica set must have at least three replicas for high availability.

After the third replica is added to the replica set, you can verify that the original collective controller and new replicas synchronized successfully.

- Look for the following messages in the original controller messages log. The messages might have different IP addresses in your environment:

```
CWWKX6015I: A request to change the active collective controller replica set was received and is now processing. The current active r
```

```
CWWKX6016I: The active collective controller replica set changed successfully. The current active replica set is {127.0.0.1:10010,127
```

```
CWWKX6011I: The collective controller is ready, and can accept requests. The leader is 127.0.0.1:10010. Current active replica set is
```

```
CWWKX6014I: This collective controller replica finished synchronizing the data with the other replicas.
```

- Look for the following messages in the messages logs of the added replicas. The messages might have different IP addresses in your environment:

```
CWWKX6016I: The active collective controller replica set changed successfully. The current active replica set is {127.0.0.1:10010,127
```

```
CWWKX6011I: The collective controller is ready, and can accept requests. The leader is 127.0.0.1:10010. Current active replica set is
```

```
CWWKX8112I: The server's host information was successfully published to the collective repository.
```

```
CWWKX8114I: The server's paths were successfully published to the collective repository.
```

```
CWWKX8116I: The server STARTED state was successfully published to the collective repository.
```

## Automatically sharing configurations among replicas

8.5.5.5

You can configure one collective controller `server.xml` include file in a replica set and automatically update the configuration of other replicas in the set. Automatic sharing of configurations means that you do not need to manually update the configurations of other replicas. Automatic sharing of configurations is especially useful for collectives that use auto scaling.

### Before you begin

Create a replica set. See “Configuring Liberty collective replica sets” on page 1148. The topic includes Example: Create and activate a replica set, an example of creating a replica set consisting of three collective controllers on the same host.

### About this task

You can drop the include file for a controller configuration into the `configDropins/defaults` directory of that controller to automatically update the configuration of replicas. Alternatively, you can use `ControllerConfigMBean` operations to list, add, or remove the shared configuration files of a collective controller.

## Procedure

1. Create a `configDropins` directory for the controller with the configuration you want to share among replicas.

If the controller of the replica set does not already have the `configDropins/defaults` directory, create the `$WLP_USER_DIR/servers/server_name/configDropins/defaults` directory for the controller.

**Note:** For information about precedence among files in `configDropins` subdirectories, see “Using the configuration dropins folder to specify server configuration” on page 1593. The topic mentions both the `configDropins/defaults` directory and a `configDropins/overrides` directory. Controller configurations dropped into a `configDropins/overrides` directory are not shared among replicas. To share configurations among replicas, you must use the `configDropins/defaults` directory.

2. Share the controller configuration with other replicas in the replica set.

- Drop the configuration of the replica set controller into its `configDropins/defaults` directory.

For example, copy the `server.xml` include file of the controller to its `configDropins/defaults` directory.

- Use `ControllerConfigMBean` operations to list, add, or remove the shared configuration files of a collective controller.

Configuration files are stored in the `$WLP_USER_DIR/servers/server_name/configDropins/defaults` directory of the controllers and are shared with the `configDropins/defaults` directory of the replicas.

Use Jython scripts or a Java client such as JConsole to perform the following collective controller `ControllerConfigMBean` operations:

### **listSharedConfig**

The **listSharedConfig** operation lists the files in the shared configuration directory of the replica.

### **addSharedConfig**

The **addSharedConfig** operation adds a configuration to a file and stores the file in the `configDropins/defaults` directory of each replica. You must specify two parameters for the operation:

#### **fileName**

The file name of the controller configuration to share. If you specify a file name that exists in the shared configuration directory, the existing file is overwritten. (String)

**config** The content of a valid `server.xml` include file. (String)

For example:

```
<?xml version="1.0" encoding="UTF-8" ?>
<server>
  <logging traceSpecification="com.ibm.ws.collective.repository.internal.SharedConfigManager=all"/>
</server>
```

### **removeSharedConfig**

The **removeSharedConfig** operation removes a file from the `configDropins/defaults` directory of each replica. You must specify a parameter for the operation:

#### **fileName**

The file name of the controller configuration to delete from the shared configuration directory of each replica. (String)

The controller configuration automatically synchronizes with the configuration dropins directories of every other replica in the replica set. When you add a replica to a controller that automatically shares its configuration, the content of the `configDropins/defaults` directory of the controller is replicated to the new replica. Any changes that you make to scaling policy definitions for one controller automatically synchronize with configurations in the configuration dropins directories of the other replicas.

If the controller configuration does not automatically synchronize with the configuration of other replicas, check the controller and replica logs. Also, if you used the `configDropins/defaults` directory to share the controller configuration, ensure that configuration monitoring is not turned off. By

default, configuration monitoring is enabled. If configuration monitoring is disabled, you can use the FileNotificationMBean to inform the controller of configuration changes, and then the changes are shared with the replicas. Configurations stored by ControllerConfigMBean operations are automatically shared among replicas whether configuration monitoring is enabled or not. See “Controlling dynamic updates” on page 1594.

### Example: Use JConsole to share the controller configuration among replicas

This example describes how you might use JConsole to share the server.xml include file in the controller configDropins/defaults directory with all replicas:

1. Connect JConsole to the collective controller process.
  - a. Ensure the collective controller is running.

```
wlp/bin/server status collective_controller_name
```

Replicas do not need to be running. Replicas that are not running synchronize the shared configuration when they start.
  - b. Start JConsole if it is not running. On Windows, run the `Java_installation\bin\jconsole.exe` file.
  - c. Select the process for the collective controller.  
To use the REST Connector with JConsole to access MBeans remotely through an underlying HTTPS connection, see [Creating remote JMX connections in Liberty](#).
2. Run the ControllerConfigMBean **addSharedConfig** operation in JConsole to add the controller server.xml include file to the configDropins/defaults directory of each replica.
  - a. On the JConsole **MBeans** tab, select the ControllerConfigMBean **addSharedConfig** operation.
  - b. For **fileName**, specify the path of the server.xml include file; for example:

```
$WLP_USER_DIR/servers/collective_controller_name/trace.xml
```
  - c. For **config**, specify the configuration to add; for example:

```
<?xml version="1.0" encoding="UTF-8" ?>
<server>
  <logging traceSpecification="com.ibm.ws.collective.repository.internal.SharedConfigManager=all"/>
</server>
```
  - d. Click **addSharedConfig** to run the operation.
3. Confirm that the operation successfully shared the controller configuration among the replicas.

### Changing the port of a replica

8.5.5.7

To change the port of a replica that is in a replica set which has many replicas, you must stop and start replicas in a specific order and not change the port of at least one replica until after you change the ports of the other replicas.

#### Before you begin

Create a replica set. See “Configuring Liberty collective replica sets” on page 1148. The topic includes Example: Create and activate a replica set, an example of creating a replica set consisting of three collective controllers on the same host.

#### About this task

When you added a replica to a replica set, you specified a port number for the replica. For example, the following element in a replica server.xml file specifies a replica port of 10011:

```
<collectiveController replicaPort="10011"
  replicaSet="localhost:10010"
  isInitialReplicaSet="false" />
```

When a replica set contains only one replica, you can simply change the `replicaPort` value. However, when the replica set has many replicas, you must stop a replica before changing its port. Also, one replica in the replica set must remain running and must not have its port changed until after you change the ports of the stopped replicas successfully.

## Procedure

1. Stop the replicas for which you want to change ports. Do not stop at least one replica or change its port.
2. Change the `replicaPort` value in the `server.xml` files of the stopped replicas.
3. Start the stopped replicas.
4. Check the `messages.log` of the replicas, and verify that the changed replicas can communicate.

Look for the `CWWKX6011I` message in the replica messages to see if the replica synchronized correctly:

```
CWWKX6011I: The collective controller is ready, and can accept requests. The leader is replicaHost:replicaPort. Current active re
```

5. If you want to change the port of the replica that remained running, you now can stop the replica, change its port, restart it, and verify that it can communicate with the other replicas.

## Generating collective controller SSL keys

8.5.5.4

You can use the collective utility **genKey** command to generate a keystore in Java keystore (JKS) format. The keystore contains a personal certificate that enables Secure Sockets Layer (SSL) communication with the collective controller.

### Before you begin

Create a collective controller. See “Configuring a Liberty collective” on page 1136.

- | If you want to enable a collective controller and its members to use the security TLSv1.2 protocol for the Secure Sockets Layer (SSL) context, see “Setting up Liberty to run in SP800-131a” on page 1848. The `server.xml` files of the controller and members need `ssl id` elements and each host computer needs a `server.env` file with the `JVM_ARGS=-Dhttps.protocols=TLSv1.2` statement in its `${wlp.install.dir}/etc` directory.

### About this task

Remote JMX connections to a collective controller use SSL and require suitable SSL keys. The collective utility **genKey** command generates a keystore that contains a personal certificate which the collective controller trusts. The generated keystore also includes a public signer certificate so it can function as a trust store.

For a Java virtual machine (JVM), such as a collective member server or a non-Liberty server, to connect to a collective controller, the JVM must have a keystore that contains a key which the collective controller trusts. The **genKey** command generates this keystore. After the JVM has the keystore, the JVM can connect to the collective controller and the collective controller can return its key. This return of the collective controller key to the JVM is called the *SSL handshake*.

- | For the JVM to add the collective controller key to the JVM truststore, the `--autoAcceptCertificates` option must be used. If the `--autoAcceptCertificates` option is not used, the user is prompted to add the key to the truststore.

## Procedure

Run the collective **genKey** command to generate a JKS keystore.

```
wlp/bin/collective genKey [--host=collectiveControllerHost --port=collectiveControllerHTTPSPort --user=collectiveControllerAdminUser
```

For example, for a collective controller on host *machineA* that uses port 1090 and has a collective controller administrative user *Admin1* with password *Admin1pwd*, run the following command to generate a keystore and set its password to *kspwd*:

```
collective genKey --host=machineA --port=1090 --user=Admin1 --password=Admin1pwd --keystorePassword=kspwd --autoAcceptCertificates
```

This example includes the required settings for the **genKey** command:

**--host=*collectiveControllerHost***

The host name of the target collective controller

**--password=*collectiveControllerAdminUserPassword***

The password of the administrative user for the target collective controller. If no password is defined, you are prompted for the password of the administrative user specified by the **--user** setting.

**--port=*collectiveControllerHTTPSPort***

The HTTPS port number of the target collective controller

**--user=*collectiveControllerAdminUserID***

An administrative user of the target collective controller

**--keystorePassword=*generatedKeystorePassword***

The password for the generated keystore. If you specify a password and no value is defined, you are prompted for a password.

The **genKey** command also has optional settings:

**--autoAcceptCertificates**

Automatically trust SSL certificates during this command.

**--certificateSubject=*DN***

The distinguished name (DN) of the generated SSL certificate. The default DN is:

```
CN=localhost,OU=client,O=ibm,C=usCN=localhost,OU=client,O=ibm,C=usCN=localhost,OU=client,O=ibm,C=us
```

**--certificateValidity=*numberOfDays***

The number of days the generated SSL certificate is valid. The default validity period is 1825 days, or 5 years. The minimum validity period is 365 days.

**--keystoreFile=*filePath***

The file to which the keystore is written. The default is the *key.jks* file in the current directory.

**--key=*key***

A key to use for aes encoding. The product hashes the specified key string to produce an encryption key to use to encrypt and decrypt the password. To provide the key to the server, define a variable *wlp.password.encryption.key* whose value is the key. If you do not specify this option, the product supplies a default key.

## Setting administrative metadata for Liberty resources

8.5.5.5

You can use the *admin-metadata.xml* file to set administrative metadata for server, cluster, application, and runtime resources. Administrative metadata enables you to associate information such as tags, owners, contacts, and notes with resources. The metadata can simplify resource management and make it easier to find information about resources in large topologies. For example, server metadata that shows the owner of a server can assist you in more quickly finding the correct person to contact if the server

requires changes. The `admin-metadata.xml` file uses XML format and does not exist by default. You must create the file and place it in a server configuration directory or in the Liberty runtime etc directory. After placing the `admin-metadata.xml` file in a supported directory, you can view the metadata in Admin Center or augment the metadata through application programming interfaces (APIs).

## Procedure

1. Determine whether you want the `admin-metadata.xml` file to set metadata for a particular server or for all servers in the runtime environment.

**server** An `admin-metadata.xml` file in a server configuration directory sets metadata for the server, its cluster, and its applications. The file path is `${wlp.install.dir}/usr/servers/server_name/admin-metadata.xml` or, if the `$WLP_USER_DIR` variable is set in a `server.env` file or command window, `$WLP_USER_DIR/servers/server_name/admin-metadata.xml`.

### runtime

An `admin-metadata.xml` file in the runtime etc directory sets metadata for runtime resources. The file is visible to all servers that use the runtime environment. The file path is `${wlp.install.dir}/etc/admin-metadata.xml`. The etc directory does not exist by default; you must create the etc directory.

2. Configure administrative metadata in the `admin-metadata.xml` file.
  - a. Create a text file named `admin-metadata.xml` in the location determined in step 1. If the file already exists, open an editor on the file.
  - b. In an editor, specify administrative metadata for any of the following resource objects:
    - `<server>` - Set no more than one server metadata.
    - `<cluster>` - Set no more than one cluster metadata.
    - `<application>` - Set any number of application metadata.
    - `<runtime>` - Set no more than one runtime metadata.

**Restriction:** You cannot set host metadata in an `admin-metadata.xml` file. You must manage host metadata using Admin Center or `AdminMetadataManager` MBean APIs or scripts.

For each resource object, specify up to four types of metadata:

- `tag` - Assign zero or more tags to a resource object. You use a tag to search for resources.
- `owner` - Assign no more than one owner to a resource object. An owner is typically a person or entity responsible for the metadata. The owner can provide a key for the metadata.
- `contact` - Assign zero or more contacts to a resource object. A contact is a person or entity who can provide information about the resource object.
- `note` - Assign no more than one note to a resource object. A note is arbitrary text.

For guidance on file contents, see Example: `admin-metadata.xml` in a server configuration directory and Example: `admin-metadata.xml` in the runtime etc directory.

Tags that contain uppercase characters are converted to lowercase before deployment to the collective repository. Thus, `<tag>MyTag</tag>` in an `admin-metadata.xml` file displays as `mytag` in Admin Center.

- c. Save the file changes.

## Results

Server metadata in the server configuration directory is deployed to, or undeployed from, the collective repository when the following events occur:

- The server joins to the collective controller through the collective **join** command
- The controller or member server starts
- A member is removed from the collective controller through the collective **remove** command
- The `admin-metadata.xml` file changes

The product monitors the `admin-metadata.xml` file after the server starts and dynamically updates server metadata in the collective repository to reflect any file changes.

| **Important:** Ensure the server is running when you delete an admin-metadata.xml file. If an  
| admin-metadata.xml file is deleted while the server is running then the product removes the metadata  
| from the repository. If some elements are deleted from the file when the server is stopped, the product  
| removes those elements from the repository when the server starts. However, if the  
| admin-metadata.xml file is deleted while the server is stopped, the metadata will not be removed from  
| the repository when the server starts.

Cluster metadata is deployed to, or undeployed from, the collective repository when the following events occur:

- A cluster member connects with the controller, such as when a cluster member starts
- The admin-metadata.xml file changes for a cluster member
- The last cluster member is removed, such as when the last cluster member stops

Application metadata is deployed to the collective repository when the following events occur:

- An application is installed on a server or cluster
- The admin-metadata.xml file changes for an application

Runtime metadata is deployed to, or undeployed from, the collective repository when the following events occur:

- A server joins the collective controller through the collective **join** command
- The runtime installation directory (`${wlp.install.dir}`) is unregistered, resulting in undeployment
- No dynamic updating through the file monitor or AdminMetadataManager MBean

The product does not monitor the admin-metadata.xml file in the etc directory. You must restart the server to update the runtime metadata in the collective repository.

**Note:** Changes made to metadata in the repository using Admin Center are not removed unless the resource is completely removed from the collective.

## Example admin-metadata.xml files

The following examples show admin-metadata.xml files for server and runtime metadata:

Example: admin-metadata.xml in a server configuration directory

```
<admin-metadata>

  <server owner="John Doe">
    <tag>servertag1</tag>
    <tag>servertag2</tag>
    <tag>servertag3</tag>
    <contact>Mike</contact>
    <contact>Fred</contact>
    <contact>Susan</contact>
    <note>This server is the best server.</note>
  </server>

  <cluster name="cluster1" owner="Tom Wood">
    <tag>clustertag1</tag>
    <tag>clustertag2</tag>
    <tag>clustertag3</tag>
    <contact>Roger</contact>
    <contact>Steve</contact>
    <contact>David</contact>
    <note>This cluster is the best cluster.</note>
  </cluster>

  <application name="app1" owner="Sam Hardison">
    <tag>appltag1</tag>
    <tag>appltag2</tag>
    <tag>appltag3</tag>
  </application>
</admin-metadata>
```

```

    <contact>Jack</contact>
    <contact>Tom</contact>
    <contact>Michael</contact>
    <note>Liberty 8.5.5.x with IBM JDK</note>
</application>

<application name="app2" owner="Michael Dell">
  <tag>app2tag1</tag>
  <tag>app2tag2</tag>
  <tag>app2tag3</tag>
  <contact>Susan</contact>
  <contact>Roger</contact>
  <contact>Fred</contact>
  <note>Liberty 8.5.5.x with IBM JDK</note>
</application>
</admin-metadata>

```

Example: admin-metadata.xml in the runtime etc directory

```

<admin-metadata>
  <runtime owner="Admin Boss">
    <tag>runtimetag1</tag>
    <tag>runtimetag2</tag>
    <tag>runtimetag3</tag>
    <contact>Steven</contact>
    <note>Liberty 8.5.5.x with IBM JDK</note>
  </runtime>
</admin-metadata>

```

## What to do next

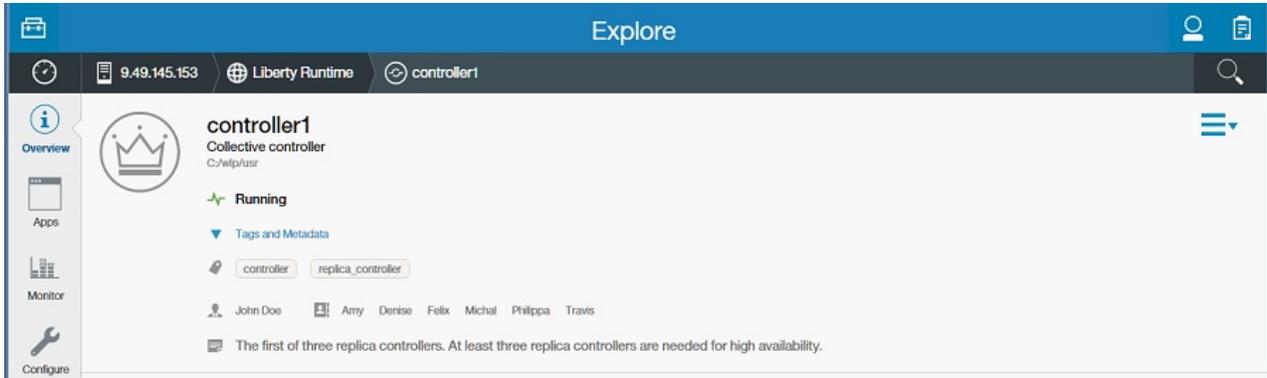

You can view administrative metadata in Admin Center. For example, suppose a collective controller named controller1 has the following admin-metadata.xml file in its server configuration directory, \$WLP\_USER\_DIR/servers/controller1:

```

<admin-metadata>
  <server owner="John Doe">
    <tag>controller</tag>
    <tag>replica_controller</tag>
    <contact>Michal</contact>
    <contact>Felix</contact>
    <contact>Travis</contact>
    <contact>Philippa</contact>
    <contact>Amy</contact>
    <note>The first of three replica controllers. At least three replica controllers are needed for high availability.</note>
  </server>
</admin-metadata>

```

When the controller has <feature>adminCenter-1.0</feature> in its <featureManager> configuration, the Admin Center Explore tool displays the metadata in details about the controller1 server:

**Restriction:** At this time, tags display in the Explore tool only for server, cluster, and application resources. Tags for runtime resources do not display.

For information about viewing administrative metadata in the Explore tool, see “Setting and viewing administrative metadata in Admin Center” on page 1757.

Also, you can use methods in `AdminMetadataManagerMBean` to add, retrieve and set application metadata in the collective repository, as well as remove it from the collective repository.

## Updating a Liberty collective

You can update Liberty collectives by replacing or removing existing collective controllers, members or replica sets or by adding new members or replicas. Before updating a collective, back up its members and replica sets so that you can restore them, if needed, in the future.

### About this task

A Liberty collective can contain members, controllers, and replica sets. See “Liberty: Collective architecture” on page 1450. Over time, you might need to upgrade members or replica sets in the collective or otherwise change the collective configuration.

### Backing up and restoring a Liberty collective

Before changing a collective controller, member or replica set, it is recommended to store a copy of the collective server files so that you can restore the collective, if needed, in the future. You might restore a backed-up copy to fix corrupted files or to downgrade the collective to a previous configuration. When restoring a replica set, it is important to start restored replicas one at a time to synchronize data.

### Procedure

- Back up a collective.

To back up a collective controller, member or replica set, copy the server files that you want to preserve to a safe location. The server files are in the `$WLP_USER_DIR/servers/server_name` directory and its subdirectories. To avoid locking problems when copying the files, stop the server before backing up its files.

- Restore a collective controller or member.

To restore a backed-up collective controller or member server, you can use files in the backed-up directory to configure a new server or, if the Liberty version is the same, copy the backed-up files into the Liberty installation. You do not need to copy the logs and workarea directories into the target installation. Ensure the `server.xml` file of a restored server sets the correct host value and has unique port values in the target installation.

Optionally, start the restored server with the `--clean` parameter to clean cached server information:

```
server start server_name --clean
```

You use the `--clean` option only once; all subsequent server starts do not require it.

- **8.5.5.4** Restore or downgrade a replica set.

1. Stop all replicas in the replica set.

2. Restore the frappe database (`fdb`) directory on one replica from a backup.

Replace the frappe database of the replica that you want to restore with the frappe database of the backed-up replica. The frappe database is the `$WLP_USER_DIR/servers/collective_controller_name/resources/collective/repository/fdb` directory of the replica.

3. Delete the `fdb` directory contents of all other replicas in the replica set.

4. If you want to downgrade to a previous version, replace the Java archive (JAR) files on all replicas with older versions of the JAR files to roll back the replicas to a previous version.

5. Start the replica with the restored `fdb` directory.

6. Look for the `CWWKX6012I` message in the messages for the restored replica.

To see the replica messages, open an editor on the `$WLP_USER_DIR/servers/collective_controller_name/logs/messages.log` file. The message resembles:

```
CWWKX6012I: The collective controller is temporarily unavailable, probably due to a change in the replica set. It should become av
```

7. Start only a minimal majority of the replicas.

Include the restored replica in the number of minimal majority replicas. For example, if a replica set has 5 replicas, a minimal majority is 3 replicas. Because the restored replica is already running, you would start 2 replicas in step 7a.

- a. Start a minimal majority of the replicas.

- b. After these replicas are running, look for the `CWWKX6011I` message in the messages of each replica that you started. The message resembles:

```
CWWKX6011I: The collective controller is ready, and can accept requests. The leader is replicaHost:replicaPort. Current active rep
```

The `CWWKX6011I` message indicates that the replicas synchronized correctly, with the restored `fdb` directory fully replicated in the majority replicas.

Verify that the `[active_replicas]` section in the message lists all the majority replicas that you have started. Also verify that the `[configured_replicas]` section lists all the replicas in the replica set, including replicas that you have not started yet.

8. Start all remaining replicas.

- a. Start the remaining replicas.

- b. After the replicas are running, look for the `CWWKX6011I` message in the messages of each replica.

Verify that the `[active_replicas]` and `[configured_replicas]` sections in the message list all the replicas in the replica set.

The replicas are now running on the restored version.

## Upgrading a Liberty collective

### 8.5.5.4

You can upgrade a collective by replacing existing collective members or replica sets or by adding new members or replicas.

### About this task

A Liberty collective can contain members, controllers, and replica sets. See “Liberty: Collective architecture” on page 1450. Over time, you might need to upgrade replica sets or members in the collective or otherwise change the collective configuration.

### Procedure

- Upgrade a replica set.

1. Choose one replica in the replica set to upgrade. You upgrade replicas one at a time. If the replica is running, stop it.
2. Back up the replica.

You can back up the entire replica server directory, `$WLP_USER_DIR/servers/server_name` directory and its subdirectories. Or, at minimum, back up the frappe database (fdb) directory that holds the replica data, `$WLP_USER_DIR/servers/collective_controller_name/resources/collective/repository/fdb`. See “Backing up and restoring a Liberty collective” on page 1480.

You can use the first replica backup for the remaining replicas.

3. Upgrade the Java archive (JAR) files for the replica. See “Installing Liberty Repository assets” on page 1391.

**Distributed operating systems**

IBM i

Also see “Installing Liberty by extracting a Java archive file” on page 1374.

4. Start the upgraded replica.
5. After the replica is running, look for the CWWKX6011I message in the replica messages to see if the replica synchronized correctly. The message resembles:

CWWKX6011I: The collective controller is ready, and can accept requests. The leader is *replicaHost:replicaPort*. Current active repli

6. After verifying that the replica synchronized, complete steps 1 through 5 for another replica. You can skip step 2 if you use the first replica backup.

Repeat this step 6 until all replicas in the replica set have been upgraded and started one at a time and messages show that the replicas synchronized correctly.

After all replicas are upgraded, the messages.log file for each replica contains message CWWKX6047I, which resembles:

CWWKX6047I: The active collective controller replica set was upgraded successfully. The current active replica version is *version\_num*

- Add a new member to an existing collective.

Use the collective **join** command to add a Liberty server as a member to a collective. See step 2 in “Configuring a Liberty collective” on page 1136.

- Add a new replica to an existing collective.

Use the collective **addReplica** command to add a replica to a collective. See “Configuring Liberty collective replica sets” on page 1148.

## Removing members from a Liberty collective

You can use the collective utility **remove** command to remove a member server from a collective. The **remove** command unregisters the member server from the collective and removes member files that pertain to the collective. The **remove** command does not delete the member server or change the member server.xml file.

### About this task

Administrators of a collective can add a server to the collective using the **join** command and, after the member server is no longer needed, remove the server from the collective using the **remove** command.

The **remove** command can remove a member server that does not exist. For example, the command can remove information about the member from the collective controller in the following situations:

- If the member is deleted accidentally or intentionally
- If deployment fails and the member is partially created or the member configuration contains errors, but the **join** command completed

If the entire wlp/usr user directory on the member host was deleted, you might need to use a client such as JConsole to delete references to the member server from the collective.

## Procedure

1. Stop the member server or remove collective-related elements from the member server configuration.

To stop the member server, run the server **stop** command at a command line:

```
wlp/bin/server stop memberServerName
```

If you want to keep the member server running, remove any of the following elements from the `server.xml` file of the member server:

```
<featureManager>
  <feature>collectiveController-1.0</feature>
  <feature>collectiveMember-1.0</feature>
</featureManager>
<collectiveMember ... />
<hostAuthInfo ... />
```

2. Use a command line to remove a member server.

- a. Run the collective **remove** command at a command line.

```
wlp/bin/collective remove memberServerName --host=collectiveControllerHost --port=collectiveControllerHTTPSPort --user=collectiveControllerAdminUserID
```

For example, for a collective controller on host machineA that uses port 1090 and that has a collective controller administrative user Admin1 with password Admin1pwd and member server member1, run the following command to remove the member server:

```
wlp/bin/collective remove member1 --host=machineA --port=1090 --user=Admin1 --password=Admin1pwd
```

This example includes the required settings for the **remove** command:

**--host=collectiveControllerHost**

The host setting specifies the name of the host on which the collective controller server resides. The defaultHostName variable in the `server.xml` file of the collective controller server sets the host name.

**--port=collectiveControllerHTTPSPort**

The port setting specifies the HTTPS port number of the target collective controller. The httpsPort variable in the `server.xml` file of the collective controller server sets the port number.

**--user=collectiveControllerAdminUserID**

The user setting specifies an administrative user of the target collective controller. A userName variable in the `server.xml` file of the collective controller server sets a user name.

**--password=collectiveControllerAdminUserPassword**

The password settings specifies the password of the administrative user for the target collective controller. A userPassword variable in the `server.xml` file of the collective controller server sets a user password. If no password is defined, you are prompted for the password of the administrative user specified by the **--user** setting.

- b. If prompted to accept a certificate chain, enter y (yes).

The **remove** command deletes the `wlp/usr/servers/member1/resources/collective` directory. The product prints messages resembling the following:

```
Server member1 successfully unregistered.
```

```
Attempting to remove resources for the collective from the server...
The resources for collective membership were successfully removed.
```

Please update the `server.xml` and remove any of the following elements:

```
<featureManager>
  <feature>collectiveController-1.0</feature>
  <feature>collectiveMember-1.0</feature>
</featureManager>
<collectiveMember ... />
<hostAuthInfo ... />
```

- c. If you want to keep the server, complete all instructions in the messages. For example, remove the elements listed in the messages from the `server.xml` file of the removed member server.

If you no longer need the server, delete the server directory. For example, delete `wlp/usr/servers/member1`.

3. If the entire `wlp/usr` user directory was deleted on the member host prior to running the **remove** command, delete any references to the removed member server from the collective using the **delete** operation on a client such as JConsole.
  - a. Connect JConsole to the collective controller process.
    - 1) Ensure the collective controller is running.  
`wlp/bin/server status collective_controller_name`
    - 2) Start JConsole if it is not running. On Windows, run `Java_installation\bin\jconsole.exe`.
    - 3) Select the process for the collective controller.  
To use the REST Connector with JConsole to access MBeans remotely through an underlying HTTPS connection, see *Creating remote JMX connections in Liberty*.
  - b. Run the CollectiveRepository **getDescendantData** operation in JConsole to check for references to the removed member server.
    - 1) On the JConsole **MBeans** tab, select the CollectiveRepository **getDescendantData** operation and specify the name of the node on which the collective resides. The node name resembles `/sys.was.collectives/local/hosts/host_name`; for example, `/sys.was.collectives/local/hosts/machineA`.
    - 2) Look for references to the removed member server in the list of data. If the name of the removed member server is not in the list of data, then the server is no longer a member of the collective. The member was successfully removed from the collective.  
However, if references to the member exist in the data, proceed to the next step. You must run the **delete** operation to remove the member.
  - c. Run the CollectiveRepository **delete** operation in JConsole to delete remaining references to the removed member server from the collective.
    - 1) On the JConsole **MBeans** tab, select the CollectiveRepository **delete** operation.
    - 2) For **nodeName**, specify the fully qualified node name of the member server that you want to delete. The operation deletes the member server node and all nodes under it.  
The node name on a local process where the collective controller is on host machineA and the member path was `C:\wlp\usr\servers\member1` on a Windows computer resembles:  
`/sys.was.collectives/local/hosts/machineA/userdirs/C%3A%2Fwlp%2Fusr/servers/member1`
    - 3) Click **delete**.
  - d. To confirm that the server is no longer a member of the collective, repeat step 2b. Run the CollectiveRepository **getDescendantData** operation in JConsole and check for references to the removed member server.

## Removing a controller from a Liberty collective replica set

During the life of a replica set, it might become necessary to remove one or more replicas from the replica set. You can use the collective utility **removeReplica** command to remove a replica from a replica set. A replica is a collective controller. The **removeReplica** command does not delete the collective controller server.

### About this task

Administrators of a collective can enable a Liberty server to act as a collective controller using the **replicate** and **addReplica** commands and, after the controller is no longer needed, remove the controller from the collective using the **removeReplica** command.

After removal of a replica, the remaining replicas in the replica set do not require any updates to their configuration. However, you might want to update them so that their configurations in the `server.xml` files more accurately reflect the updated replica set.

**Note:** It is not necessary to change the **replicaSet** value in the `server.xml` file of a remaining replica in the set. No change to the configuration of a remaining replica is required. If you do want to update the **replicaSet** values in the configurations of remaining replicas in the set so that the configuration values are consistent across all replicas in the set, you must set the **isInitialReplicaSet** value in the configurations of the remaining replicas to `false`. This is because after you change the **replicaSet** value, it no longer describes the initial replica set; it now describes a changed replica set.

## Procedure

1. Optional: Back up the replica set.
2. Ensure the collective controller is running. For a controller named `myController`, run the **status** command:

```
wlp/bin/server status myController
```

If the collective controller is not running, then start it using the **start** or **run** command:

```
wlp/bin/server start myController
```

3. Remove a collective controller or replica from the replica set.

Run a **removeReplica** command that uses the administrative security domain configuration of the collective controller and specifies the endpoint of the replica that you want to remove in the form `replicaHost:replicaPort`. Look at the `server.xml` file of the collective controller to find the values for the `--host`, `--port`, `--user`, and `--password` parameters. For information about these required parameters and about optional parameters, run `collective help removeReplica` at a command line.

```
wlp/bin/collective removeReplica replicaHost:replicaPort --host=host_of_running_controller --port=https_port_of_running_controller
```

For example, to remove `myController2` from the example replica set in “Configuring Liberty collective replica sets” on page 1148, run the following command:

```
wlp/bin/collective removeReplica localhost:10011 --host=host_of_myController --port=https_port_of_myController --user=user_for_myController
```

## Setting up Liberty server clusters

8.5.5.0

A Liberty can be configured into a server cluster for application high availability and scale.

### Distributed operating systems

IBM i

The `collectiveController-1.0` feature and its capabilities are available only in multiple-server products such as WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in single-server products such as WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a multiple-server product installation, you can use its `collectiveController-1.0` feature to work with collective members from single-server products.

A Liberty server cluster is comprised of two or more Liberty servers configured into a server cluster within a Liberty collective. A Liberty server cluster has a unique name within the collective. The `collectiveController-1.0` feature supports several operations on Liberty server clusters through the `ClusterManager` MBean:

- List clusters
- Start cluster
- Stop cluster
- List cluster members
- Generate cluster plug-in configuration

To be part of a server cluster, a Liberty must be a member of a Liberty collective and also be configured with the `clusterMember` feature.

A collective member can be a member of only one server cluster. All cluster members must be members of the same collective. Multiple server clusters can be configured within the same collective. The following diagram illustrates these relationships.

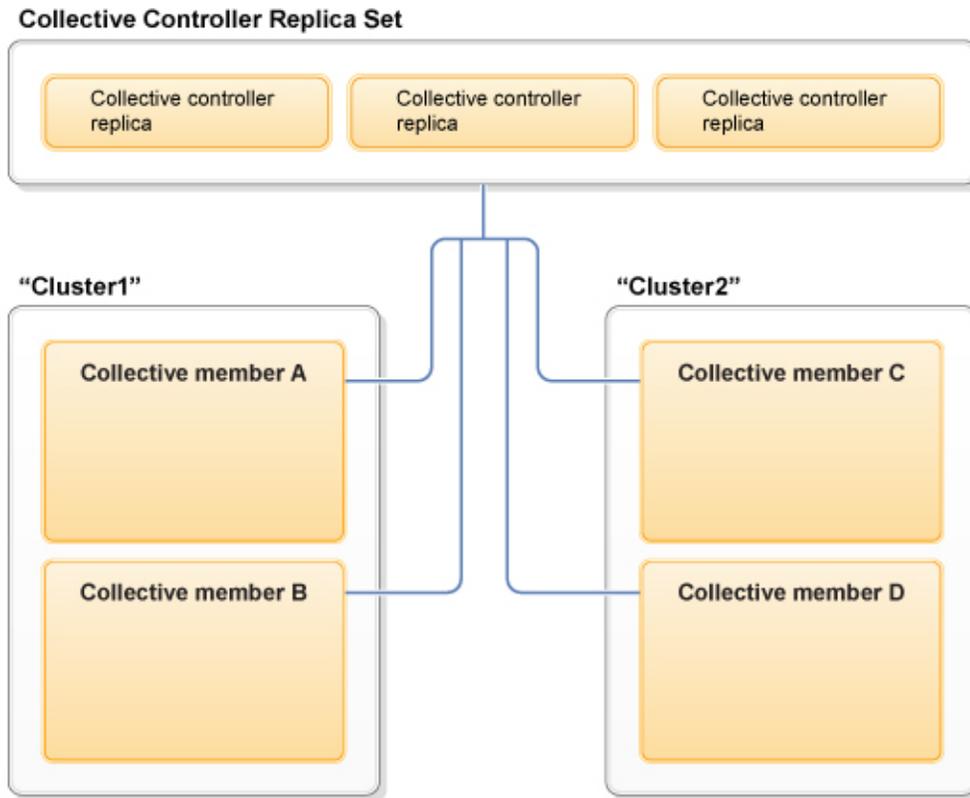

Figure 27. Liberty server clusters

## Configuring a Liberty server cluster

You can configure a collective member to be part of a server cluster by adding the `clusterMember-1.0` feature to the member `server.xml` file. Optionally, you can specify a cluster name to place the member in a particular server cluster. A server cluster has a unique name within a Liberty collective. All Liberty servers that specify the same cluster name within the same collective are members of the same server cluster.

### Before you begin

To be a member of a server cluster, a Liberty server must also be a member of a Liberty collective. If you do not have a Liberty collective and member already, create a collective controller and member server to join the collective. See "Configuring a Liberty collective" on page 1136.

### Procedure

1. Add the `clusterMember-1.0` feature to the feature manager of the member `server.xml` file.
 

```
<featureManager>
  <feature>collectiveMember-1.0</feature>
  <feature>clusterMember-1.0</feature>
</featureManager>
```
2. Optional: To designate that the member belong to a particular server cluster, add a `clusterMember` element that specifies a cluster name.  
For example, place the member in the `myCluster` cluster:

```

<featureManager>
  <feature>collectiveMember-1.0</feature>
  <feature>clusterMember-1.0</feature>
</featureManager>
<clusterMember name="myCluster"/>

```

The default cluster name is `defaultCluster`. If the member `server.xml` does not have a `clusterMember` element that specifies a valid cluster name, then the member is added to `defaultCluster`.

Only specify one cluster name. A single collective can have multiple clusters, but a server can only be part of one cluster at a time.

3. If the collective controller and member server are not running, then start them.

The collective controller and member server must be running for the member to be added to the cluster. For example, use the **start** command to start a collective controller named `myController` and a member named `myMember`:

```
wlp/bin/server start myController
```

```
wlp/bin/server start myMember
```

You can configure a collective member to be a cluster member while the member server is running. The new configuration is updated dynamically and published to the collective controller. If you configure a collective member to be a cluster member while the member server is stopped, the member server will not become a member of a cluster until the server starts.

4. Verify that the member is part of the cluster.

- a. Look for a message that indicates the collective member now belongs to the cluster in the collective controller messages log.

The default path for the log is `${wlp.install.dir}/usr/servers/myController/logs/messages.log` or, if the `$WLP_USER_DIR` variable is set in a `server.env` file or command window, `$WLP_USER_DIR/servers/myController/logs/messages.log`.

```
CWWKX9051I: The myMember server has been added to the myCluster cluster.
```

- b. Look for messages that indicate the collective member is now a cluster member in the member messages log, `$WLP_USER_DIR/servers/myMember/logs/messages.log`.

```
CWWKX7400I: The ClusterMember MBean is available.
           myCluster
```

```
CWWKF0012I: The server installed the following features: [clusterMember-1.0].
```

## What to do next

To enable application security for the cluster, copy the LTPA key file from one of the cluster members to all the other members in the cluster. See “Creating a Liberty cluster with security considerations” on page 1488.

To administer the cluster, you can run collective controller `ClusterManager` MBean operations such as start or stop the server cluster, list clusters and cluster members in the collective, or generate a plug-in configuration file. You can run the operations using Jython scripts or a Java client such as `JConsole`.

**8.5.5.4** Also, you can use WebSphere Liberty Administrative Center (“Admin Center”) to administer the cluster and its servers, applications, and other resources from a web browser. See “Administering Liberty using Admin Center” on page 1741.

**8.5.5.4** After configuring a *static cluster*, which this topic describes, you can route application requests to Liberty servers using IBM HTTP Server (IHS). Static clusters can receive requests through either static or dynamic routing. For information about static routing, see “Generating a Liberty server cluster plug-in configuration” on page 1489. **Distributed operating systems** **z/OS** For information about dynamic routing, see “Setting up dynamic routing for Liberty collectives” on page 1493 and “Generating a plugin-cfg.xml to route to multiple collectives” on page 1499.

**8.5.5.4** To configure an *auto scaling cluster*, which expands and contracts depending on the workload in your environment, see “Setting up auto scaling for Liberty collectives” on page 1503. Auto scaling clusters can receive requests only through dynamic routing.

## Creating a Liberty cluster with security considerations

For secure applications to work in a Liberty clustered environment, all the members in the cluster must have the same LTPA keys.

### About this task

The following information provides details on what must be done for secure applications to work in a Liberty clustered environment when you use IHS or the plug-in.

### Procedure

1. Choose the LTPA key file from one of the cluster members and copy it to all of the other members in the cluster. The default LTPA key file is `${server.ouput.dir}/resources/security/ltpa.keys`.  
Alternatively, you can create a new LTPA key file and store the file at the default location and customize the LTPA key configuration.
2. If the LTPA keys do not dynamically reload after the LTPA key file update, restart the cluster members or enable the dynamic reloading of the LTPA keys. For more information, see “Configuring LTPA in Liberty” on page 1872.

## Starting and stopping a Liberty server cluster

The collective controller provides a `ClusterManager` MBean that can be used to start or stop a Liberty server cluster. The MBean `startCluster` and `stopCluster` methods start and stop all of the members in the cluster serially. To start or stop cluster members individually, you can use `startServer` and `stopServer` methods in the `ServerCommands` MBean or run `server start` and `server stop` commands from a command line.

### Before you begin

- All of the members of the server cluster must have the `clusterMember-1.0` feature enabled in their `server.xml` files.
- All of the members of the server cluster must be configured for collective member starting and stopping. See “Starting and stopping a Liberty collective member” on page 1463 for more information.

### Procedure

- To start and stop all of the servers in the cluster serially, use the `ClusterManager` MBean `startCluster` and `stopCluster` methods. If the size of a cluster is large, the operation can take a long time to complete. The expected execution time is  $O(N)$  where  $N$  is the number of servers in the cluster. The total time for the operation is approximately  $N * (server\_start\_time)$ . If you are starting 100 servers that take 6 seconds to start, for example, the `startCluster` operation will take approximately 600 seconds (10 minutes).
- To start or stop cluster members individually, you can use the `ServerCommands` MBean `startServer` and `stopServer` methods to start and stop a collective member. See “Starting and stopping a Liberty collective member” on page 1463.
- To start or stop cluster members or the collective controller individually, you can run `server start` and `server stop` commands from a command line. See “Starting and stopping a server from the command line” on page 1584.

## Listing Liberty server clusters and cluster members

The collective controller provides a `ClusterManager` MBean that can be used to list Liberty server clusters and cluster members.

## Before you begin

- All of the members of the server cluster must have the `clusterMember-1.0` feature enabled in their `server.xml` files.
- All of the members of the server cluster must be part of a Liberty collective.  
See “Configuring a Liberty collective” on page 1136 for more information.

## Generating a Liberty server cluster plug-in configuration

The collective controller provides a `ClusterManager` MBean that can be used to generate a plug-in configuration file for the HTTP Server for WebSphere Application Server plug-in.

## Before you begin

- All of the members of the server cluster must have the `clusterMember-1.0` feature enabled in their `server.xml` files.
- All of the members of the server cluster must be part of a Liberty collective.
- At least two members of the server cluster must be running when you generate the `plugin-cfg.xml` file.

## Procedure

- Call the `ClusterManager` MBean `generateClusterPluginConfig` operation to create a single, merged `plugin-cfg.xml` file that instructs a web server plug-in to redirect requests to multiple application servers residing on multiple hosts. See “Generating a merged plug-in configuration for Liberty servers” on page 1606.
- For additional information about `plugin-cfg.xml` files, see “Configuring a web server plug-in for Liberty” on page 1604.

## Managing a Liberty server cluster configuration

There are two possible strategies for managing a Liberty server cluster configuration—shared and nonshared.

## About this task

Each Liberty instance comprising a Liberty server cluster has its own configuration documents, such as an `server.xml` file. Although each Liberty instance in a server cluster has unique information in its configuration, such as host name, other information is typically the same across the Liberty instances that comprise the server cluster—deployed applications for example. There are two strategies for managing the configuration for a Liberty server cluster.

## Procedure

- Shared configuration strategy

In this approach, the configuration specification that is common across all cluster members is stored in a common location and included in each cluster member's `server.xml` file using the `<include>` element. See “Using include elements in configuration files” on page 1588 for more information. Changes made to the cluster are made to the shared include.

- Nonshared configuration strategy

In this approach, each cluster member has its own complete `server.xml` file. When you use this strategy, take care when making updates to the cluster members to ensure that each cluster member is updated so that the server cluster remains consistent.

## Liberty cluster troubleshooting

There are common issues that you might encounter with Liberty clusters.

### Problem:

The server is configured to be part of a cluster but the member is not shown to be part of the cluster.

## Solution:

A collective server can be configured to be a cluster member while it is running. The new configuration is dynamically updated and published to the collective controller. If there is a problem publishing to the controller, this will affect the server joining the cluster. If a collective server is configured to be a cluster member while the server is stopped, the server will not be a member of a cluster until the server is started.

## Setting the JAVA\_HOME variable for Liberty collective members

All Liberty collective members must have a Java Runtime Environment (JRE) installed that meets the minimum requirements of the Liberty server. After a JRE is installed on the host computer, you can set the JAVA\_HOME variable so that the Liberty operation can locate the JRE.

### About this task

In order for the collective controller to perform remote operations on Windows members such as starting or stopping a member server, the collective controller must run with an IBM JRE. Third-party JREs do not contain the required security classes. You can get a JRE that supports Liberty products and SSL from Installation Manager offerings or developerWorks:

- Using Installation Manager, select the Liberty product first and then select WebSphere SDK for Liberty. Use Installation Manager to install the Liberty product and software development kit (SDK). The WebSphere SDK for Liberty includes the needed support for Liberty products and SSL and offers a Java client, JConsole.
- Go to <http://www.ibm.com/developerworks/java/jdk/index.html> on the developerWorks website and download an IBM Java development kit (JDK) for your operating system. The developerWorks website does not have a JRE for all operating systems. For example, you have to get the JDK from Eclipse for Windows operating systems.

You can set the JAVA\_HOME variable in operating system settings or at a command line. Setting set the JAVA\_HOME variable enables remote operations to locate the JRE.

### Procedure

- **Windows** To set JAVA\_HOME on a Windows system, perform the following actions.

1. On the Control Panel, do the following:
  - Click **System**.
  - Click **Advanced system settings**.

The System Properties window opens.

2. Click the **Environment Variables** button.
3. Click the *New* button in the system-variables section.
4. Add the JAVA\_HOME variable name and specify a path to the jre directory; for example:  
C:\wlp\_855\IBM\WebSphere\Liberty\java\java\_1.7.1\_64\jre

Some collective controller commands require that the path to the Java installation jre\bin directory be available in the System path, so also add a path to the jre\bin directory.

5. Save the changes. You might need to reboot the computer for the changes to take effect.
6. To verify the changes, at a command line enter set JAVA\_HOME. The command displays the JAVA\_HOME settings; for example:

```
JAVA_HOME=C:\wlp_855\IBM\WebSphere\Liberty\java\java_1.7.1_64\jre
```

**Note:** Rather than change operating system settings, you can set JAVA\_HOME at a command line by entering `set JAVA_HOME=path_to_jre`. A limitation is that the JAVA\_HOME setting only applies to commands entered in the same command window.

- **AIX** **HP-UX** **Linux** **Solaris** If you are running bash shell, you can add the JAVA\_HOME environment variable to the .bashrc file in the user's home directory.
- One option for setting JAVA\_HOME is to create a server.env file in the \${server.config.dir} where server.xml is residing and add JAVA\_HOME there.

For example:

```
JAVA_HOME=/java/jre
```

**Linux** Some collective controller commands require that the path to the Java installation jre/bin directory be available in the .bashrc file, so set a path to jre/bin in the .bashrc file.

## Setting up RXA for Liberty collective operations

Liberty collective controllers use the Tivoli Remote Execution and Access (RXA) toolkit to perform selected operations on collective members. Use RXA to remotely start and stop servers, including starting and stopping servers on your local computer.

### Procedure

- **AIX** **HP-UX** **Linux** **Solaris** **z/OS** **Set up Linux, UNIX or z/OS machines**

Install and enable SSH on your machine. For Linux and UNIX machines, ensure that the configuration is set according to the following instructions. For z/OS machines, consult the following instructions for guidance.

To enable SSH, configure OpenSSH 3.6.1, OpenSSH 4.7 (on AIX), or Oracle SSH 1.1 so that it supports RXA connections. OpenSSH 3.7.1 or later contains security enhancements not available in earlier releases and is recommended.

**Avoid trouble:** OpenSSH Version 4.7.0.5302 for IBM AIX Version 5.3 is not compatible with RXA Version 2.3. If machines are running AIX Version 5.3 with OpenSSH Version 4.7.0.5302 installed, file transfers might not complete. To avoid this problem, revert from OpenSSH Version 4.7.0.5302 to Version 4.7.0.5301.

### Using Secure Shell (SSH) protocol

RXA does not supply SSH code for UNIX operating systems. You must ensure that SSH is installed and enabled on all machines that include collective members.

In all UNIX environments except Solaris, the Bourne shell (sh) is used. On Solaris machines, the Korn shell (ksh) is used instead due to problems encountered with the Bourne shell (sh).

To use password-based authentication for SSH communications, edit the /etc/ssh/sshd\_config file on each machine that includes one or more collective members. Set the PasswordAuthentication property to yes. For example:

```
PasswordAuthentication yes
```

The default value for the PasswordAuthentication property is no.

After you change this setting, stop and restart the SSH daemon by using the following commands:

```
/etc/init.d/sshd stop
/etc/init.d/sshd start
```

**Linux** Some collective controller commands require that the path to the Java installation jre/bin directory to be available in the .bashrc file, so set a path to jre/bin in the .bashrc file.

- **IBM i** **Set up IBM i machines**  
Using SSH public/private key authentication to IBM i machines is not supported.
- **Windows** **Set up Windows machines**
  1. Ensure that your collective controller is running with an IBM JDK.

RXA requires some security classes that are in the IBM JDK, and that are not available in the Oracle or OpenJDK JVMs.

2. Ensure the system environment variables JAVA\_HOME and PATH are set to the Java path (jre directory) on the computer. Some collective controller commands require that the path to the Java installation jre\bin directory is available in the System path, so also add a path to the jre\bin directory.

In Windows, system environment variables are visible only inside the shell that RXA connects to. Setting PATH in the command window is not sufficient. You must set PATH in the system variable section of the environment variables, or use -hostJavaHome <PATH TO IBM JAVA> with the updateHost option.

See "Setting the JAVA\_HOME variable for Liberty collective members" on page 1147.

3. Ensure that the server.xml file of each server to be managed specifies the account user name and password.

Specify the user name and password in a hostAuthInfo statement in the server.xml file:

```
<hostAuthInfo rpcUser="Windows_user_ID" rpcUserPassword="Windows_user_password" />
```

4. Enable connections to member servers on Windows computers.

To enable connections to Windows members, you can use a third-party SSH service such as Cygwin on your Windows member computer or change Windows operating system settings on a member computer that does not have an SSH service installed.

- Use a third-party SSH service such as Cygwin on the Windows member computer.

If the member computer uses an SSH service, the controller connects the member server with SSH. Specify a hostAuthInfo rpcUserHome parameter and the RPC user name and password in the member server.xml file because the third-party SSH service might have a different home directory than the one Windows uses:

```
<hostAuthInfo rpcUser="Windows_user_ID" rpcUserPassword="Windows_user_password" rpcUserHome="user_home_directory"/>
```

For *user\_home\_directory*, specify the user home for the SSH service; for example:

rpcUserHome="C:\cygwin\home\user1". The SSH public and private key pair is generated in the .ssh directory under this user home directory.

- If the Windows member computer does not use a third-party SSH service such as Cygwin, change the Windows operating system settings of the member computer to enable connections.

- Ensure that your user account belongs to the Administrators group.

Many RXA operations require access to resources that standard user accounts cannot access. Thus, the configuration of a collective member must include the name and password of a Windows user who belongs to the Administrators group.

- Ensure File and Printer Sharing for Microsoft Networks is enabled for your network stack.
  - a. Click **Start > Control Panel > Network and Sharing Center > Change advanced sharing settings**.
  - b. Select **Turn on file and printer sharing**.
  - c. Save the changes.

Ensure that file sharing operations (on port 445) are not blocked on machines that include collective controllers or collective members. For more information, see the documentation for your operating system or your firewall software.

- Start the Remote Registry service.

The Remote Registry service must be running on computers that include collective members for the collective controllers to remotely run commands and scripts.

- a. Click **Start > Administrative Tools > Services**.
  - b. Within the list of services, locate the Remote Registry entry and verify that the status is **Started**. If you intend to use RXA regularly, consider setting the Remote Registry **Startup type** property to **Automatic**.
- Disable User Account Control.
    - a. Click **Start > Control Panel > User Accounts > Change User Account Control settings**.

- b. Set the User Account Control level to **Never notify**.
- c. Click **OK**.
- d. Restart the computer for the changes to take effect.

For more information, see *Liberty Collectives Remote Operation Configuration*.

## What to do next

If you modified the `server.xml` of a managed server, manually start the server so that it publishes the new data to the controller.

After you enable RXA, test the host configuration and verify RXA connectivity:

## Setting up dynamic routing for Liberty collectives

8.5.5.4

The Dynamic Routing feature enables routing of HTTP requests to members of Liberty collectives without having to regenerate the WebSphere plug-in configuration file when the environment changes. When servers, cluster members, applications, or virtual hosts are added, removed, started, stopped, or modified; the new information is dynamically delivered to the WebSphere plug-in. Requests will be routed based on up-to-date information. The feature provides the Dynamic Routing service, which dynamically retrieves routing information from the collective repository and delivers this information to the WebSphere plug-in. The feature also provides three new collective command actions. These actions are used together to generate a keystore that is needed for secure communication between the plug-in and the Dynamic Routing service, as well as a plug-in configuration file that enables Intelligent Management in the WebSphere plug-in.

### Before you begin

For the Dynamic Routing function to work, the `dynamicRouting` feature is required in collective controllers only. There is no requirement to upgrade every collective member. Dynamic Routing can be used to route to applications installed in any Liberty server in a collective, including Network Deployment, Core and Base editions.

**Important:** The interim fix for Intelligent Management in the web server plug-in for WebSphere Application Server APAR number PI27023 is necessary to use the Dynamic Routing feature. You must install a web server that is supported by the web server plug-in for WebSphere Application Server, such as the IBM HTTP Server, install an 8.5.5 or higher web server plug-ins for WebSphere Application Server, then install the interim fix before enabling the Dynamic Routing feature.

1. Download and install the latest version of the IBM Installation Manager. For more information on installing IBM Installation Manager, see *Installing Installation Manager and preparing to install the product*.
2. Use Installation Manager to access online product repositories to install the Web Server Plug-in for WebSphere Application Server and the needed interim fix for the Dynamic Routing feature. Open the Installation Manager GUI preferences page by selecting **File > Preferences**. Use the Installation Manager to install the product from the web-based repository that is located at

<http://www.ibm.com/software/repositorymanager/com.ibm.websphere.PLGILAN.v85>

**Note:** You need an IBM ID to access the repository. This repository is only for Distributed platforms.

3. Use the Install wizard to install both the web server plug-ins and the required interim fix.
4. When prompted by the wizard, specify the installation location and proceed with the installation.

 **Watch:** The *Enabling IHS for Liberty Dynamic Routing* video shows how to install IHS, install Web Server Plug-in for WebSphere Application Server, and apply the interim fix for Dynamic Routing. [Transcript]

## About this task

To use Intelligent Management to route HTTP requests to a Liberty Collective the user must enable the **Dynamic Routing** feature on one or more collective controllers in a collective.

### Procedure

1. Enable Dynamic Routing in a controller by adding the following code to the **featureManager** tag in the `server.xml` of the controller.

```
<feature>dynamicRouting-1.0</feature>
```

2. Start all of the controllers that have the Dynamic Routing feature enabled.

3. Run the **dynamicRouting setup** command on one of the controllers to generate the keystore and plug-in configuration files. For example:

```
./dynamicRouting setup --port=9444 --host=controller1.acme.com --user=admin --password=passw0rd --keystorePassword=webAS --pluginIns
```

For more information on Dynamic Routing commands, see “Dynamic Routing Liberty collective command actions” on page 1495.

**Note:** Make sure a specified user name (value of the `--user` argument) is present in a user registry and has an administrative role assigned.

4. Copy the generated `plugin-key.jks` and `plugin-cfg.xml` files to a temporary directory on the web server host.

5. On the web server host, run `gskcmd` (included in the IHS package) to convert the keystore to CMS format and to set personal certificate as the default. CMS format is the supported format of the WebSphere Plug-in. For example:

```
gskcmd -keydb -convert -pw webAS -db /tmp/plugin-key.jks -old_format jks -target /tmp/plugin-key.kdb -new_format cms -stash  
gskcmd -cert -setdefault -pw <<password>> -db /tmp/plugin-key.kdb -label default
```

For z/OS, see “Conversion of the keystore to CMS format on z/OS” on page 1502.

6. Copy the `plugin-key.kdb`, `plugin-key.rdb`, and `plugin-key.sth` files that are created by `gskcmd` from the temporary directory to the directory `<value of the --pluginInstallRootargument>/config/<web server name>/`

7. Copy the `plugin-cfg.xml` to the directory specified in the **WebSpherePluginConfig** directive in the IBM HTTP Server (IHS) `httpd.conf` file. The `plugin-cfg.xml` is generated with the `<IntelligentManagement>` stanza. When Dynamic Routing is enabled in a collective, there is one `<Connector>` stanza for each collective controller.

For example:

```
<IntelligentMangement>  
<Property name="webserverName" value="webServer1"/>  
<ConnectorCluster enabled="true" maxRetries="-1" name="default" retryInterval="60">  
<Property name="uri" value="/ibm/api/dynamicRouting"/>  
<Connector host="controller1.acme.com" port="9444" protocol="https">  
<Property name="keyring" value="/opt/HTTPServer_Plugins/config/webserver1/plugin-key.kdb"/>  
</Connector>  
</ConnectorCluster>  
</IntelligentManagement>
```

8. Start the web server and begin routing to the application installed in the collective.

Optionally, the `<dynamicRouting>` tag can be added to the `server.xml` of the controller to specify `<ConnectorCluster>` properties such as **maxRetries** and **retryInterval**. For example:

```
<dynamicRouting maxRetries="4" retryInterval="20" connectorClusterName="collective1"/>  
<TraceSpecification name="default" specification=":DEBUG"/>  
</dynamicRouting>
```

The generated `plugin-cfg.xml` looks like this:

```
<IntelligentMangement>  
<TraceSpecification name="default" specification=":DEBUG"/>  
<Property name="webserverName" value="webServer1"/>  
<ConnectorCluster enabled="true" maxRetries="4" name="collective1" retryInterval="20">  
<Property name="uri" value="/ibm/api/dynamicRouting"/>  
<Connector host="controller1.acme.com" port="9444" protocol="https">
```

```
<Property name="keyring" value="/opt/HTTPServer_Plugins/config/webServer1/plugin-key.kdb"/>
</Connector>
</ConnectorCluster>
</IntelligentManagement>
```

## Results

With the **Dynamic Routing** feature enabled, Intelligent Management can now dynamically route HTTP requests to Liberty collectives.

## Dynamic Routing Liberty collective command actions

8.5.5.4

The **setup**, **genPluginCfg**, and **genKeystore** dynamicRouting command actions are used to generate the plug-in configuration and keystore files. The **genPluginCfg** dynamicRouting command action is used any time after the initial setup to regenerate the `plugin-cfg.xml` file. For example, when the **Dynamic Routing** feature is enabled on a new controller or a new web server is added. The **genKeystore** dynamicRouting command action is used to generate the keystore file. Each of the dynamicRouting command actions supports online help.

The commands for the **Dynamic Routing** feature are:

- `setup`
- `genPluginCfg`
- `genKeystore`

### setup

The **setup** dynamicRouting command generates a keystore in PKCS12 or JKS format and one or more WebSphere plug-in configuration files. The keystore contains a personal certificate and both the **memberRoot** and **controllerRoot** signer certificates that allow secure communication between the WebSphere plug-in and the Dynamic Routing service. The same keystore is also be used to send HTTPS requests to applications in the Liberty collective members. The plug-in configuration file contains the `<IntelligentManagement>` stanza, which enables Intelligent Management in a WebSphere plug-in. The `<IntelligentManagement>` stanza contains one `<ConnectorCluster>` stanza that represents the collective. The `<ConnectorCluster>` stanza contains one `<Connector>` stanza for each controller where the **Dynamic Routing** feature is enabled.

To get command help, issue `<Controller root>/bin/dynamicRouting help setup`, which displays:

#### Description

The **setup** dynamicRouting command generates a keystore that contains a personal certificate and signer certificates that are required to enable secure communication between the Dynamic Routing service and clients. It also generates WebSphere plug-in configuration file with `<IntelligentManagement>` stanza, which enables Intelligent Management in the WebSphere plug-in.

#### Usage

`dynamicRouting setup [options]`

#### Options

**--host=name**

Required. The host name of the target Collective Controller.

- password[=pwd]**  
Required. The password for the Administrator user for the target Collective Controller. If no value is defined, you are prompted.
- port=num**  
Required. The HTTPS port number of the target Collective Controller.
- user=name**  
Required. An Administrator user for the target Collective Controller.
- pluginInstallRoot=path**  
Required. Fully qualified path of the WebSphere plug-in root directory on the web server host.
- webServerNames=webServerName[,webServerName1]**  
Required. Comma separated names of the web servers for which WebSphere plug-in configuration files need to be generated.
- keystorePassword[=pwd]**  
Required. The password for the generated keystore. If specified and no value is defined, you are prompted.
- keystoreType=type**  
Optional. The type of the generated keystore. Default type is *JKS*. Valid values are *JKS* and *PKCS12*.
- certificateSubject=DN**  
The DN for the generated SSL certificate. The default value, if unspecified is `CN=<value of --user argument>,OU=client,O=ibm,C=us`.

**Note:** When you use an LDAP user registry, you must specify the fully qualified DN of the administrator by using **--certificateSubject** as the default form is probably not valid for your LDAP.

SSL certificates can be automatically trusted by setting the JVM property `com.ibm.websphere.collective.utility.autoAcceptCertificates` to **true**.

**Note:** The keystore that is generated by the **setup** and **genKeystore** commands is in *JKS* or *PKCS12* format. It needs to be copied to a directory on the web server machine and converted to a CMS formatted store by running **gskcmd**. The CMS formatted store file (*.kdb*) must be moved to the directory `<value of the --pluginInstallRoot argument>/config/<web server name>`. The *.rdb* and *.sth* files must also be moved to the same directory.

Following is the output of the command when run with all required arguments:

```
./dynamicRouting setup --port=9444 --host=controller1.acme.com --user=admin --password=password
--keystorePassword=keypass --pluginInstallRoot=/opt/HTTPServer_Plugins
--webServerNames=webServer1,webServer2
```

```
Generating WebSphere plug-in configuration files for web servers webServer1, webServer2
```

```
Auto-accepting the certificate chain for target server.
Certificate subject DN: CN=admin, OU=controller1, O=ibm, C=us
```

```
Successfully completed MBean request to the controller.
Successfully generated WebSphere plug-in configuration files plugin-cfg-webServer1.xml, plugin-cfg-webServer2.xml
Generating keystore for web servers webServer1, webServer2
Successfully completed MBean request to the controller.
Successfully generated keystore plugin-key.jks.
```

```
Generated WebSphere plug-in configuration files plugin-cfg-webServer1.xml, plugin-cfg-webServer2.xml for web servers webServer1, webServer2
Also generated keystore file plugin-key.p12 that enables secure communication between the Dynamic Routing service and client
```

Copy the WebSphere plug-in configuration file to the directory specified in the `WebSpherePluginConfig` directive in the IBM HTTP Server `httpd.conf` file.

Copy keystore file plugin-key.jks to a directory on the web server host, and run "gskcmd" to convert the keystore to CMS format and to set personal certificate as the default.  
For example:

```
gskcmd -keydb -convert -pw <<password>> -db /tmp/plugin-key.jks -old_format jks -target /tmp/plugin-key.kdb -new_format  
gskcmd -cert -setdefault -pw <<password>> -db /tmp/plugin-key.kdb -label default
```

Copy resulting /tmp/plugin-key.kdb, .sth, .rdb files to the directory /opt/HTTPServer\_Plugins/config/webServer1/

## genPluginCfg

This action generates the plug-in configuration files. Each plug-in configuration file contains the <IntelligentManagement> stanza, which enables the Intelligent Management features of the plug-in. The <IntelligentManagement> stanza contains one <ConnectorCluster> stanza that represents the collective. The <ConnectorCluster> stanza contains one <Connector> stanza for each controller where **Dynamic Routing** feature is enabled. Comma-separated web server names are specified to the --webServerNames argument. For example, if --webServerNames=webServer1,webServer2 is specified, plugin-cfg-webServer1.xml and plugin-cfg-webServer2.xml files are generated.

To get online help, issue <Controller root>/bin/dynamicRouting help genPluginCfg, which displays:

### Description

Generates a WebSphere plug-in configuration file with a <IntelligentManagement> stanza that enables Intelligent Management in the WebSphere plug-in.

### Usage

dynamicRouting **genPluginCfg** [options]

### Options

**--host=name**

Required. The host name of the target Collective Controller.

**--password[=pwd]**

Required. The password for the Administrator user for the target Collective Controller. If no value is defined, you are prompted.

**--port=num**

Required. The HTTPS port number of the target Collective Controller.

**--user=name**

Required. An Administrator user for the target Collective Controller.

**--pluginInstallRoot=path**

Required. Fully qualified path of the WebSphere plug-in root directory on the web server host.

**--webServerNames=webServerName[,webServerName1]**

Required. Comma separated names of the web servers for which WebSphere plug-in configuration files need to be generated.

SSL certificates are automatically trusted by setting the JVM property com.ibm.websphere.collective.utility.autoAcceptCertificates to **true**.

Following is the output of the command when run with all required arguments:

```
./dynamicRouting setup --port=9444 --host=controller1.acme.com --user=admin --password=password
--keystorePassword=keypass --pluginInstallRoot=/opt/HTTPServer_Plugins
--webServerNames=webServer1,webServer2
```

This action generates the plug-in configuration files.

Generating WebSphere plug-in configuration file for web server webServer1

Auto-accepting the certificate chain for target server.  
Certificate subject DN: CN=admin, OU=controller1, O=ibm, C=us

Successfully completed MBean request to the controller.  
File /home/user1/Liberty/wlp/bin/plugin-cfg.xml exists.  
Saving to /home/user1/Liberty/wlp/bin/plugin-cfg.xml.old.  
Successfully generated WebSphere plug-in configuration file plugin-cfg.xml

Generated WebSphere plug-in configuration file plugin-cfg.xml for web server webServer1.  
Copy the WebSphere plug-in configuration file to the directory specified in the WebSpherePluginConfig directive in the IBM

## genKeystore

This action generates a keystore in PKCS12 or JKS format. Use the **--keystoreType** action to specify the keystore format. Generation of the PKCS12 keystore is only supported when you use IBM Java. The keystore contains a personal certificate and both the **memberRoot** and **controllerRoot** signer certificates that allow secure communication between the WebSphere plug-in and the Dynamic Routing service. The same keystore is also be used to send HTTPS requests to applications in the Liberty collective members.

To get online help, issue **<Controller root>/bin/dynamicRouting help genKeystore**, which displays:

### Description

Generates a keystore that contains a personal certificate and signer certificates that are required to enable secure communication between the Dynamic Routing service and clients.

### Usage

dynamicRouting **genKeystore** [options]

### Options

**--host=name**

Required. The host name of the target Collective Controller.

**--password[=pwd]**

Required. The password for the Administrator user for the target Collective Controller. If no value is defined, you are prompted.

**--port=num**

Required. The HTTPS port number of the target Collective Controller.

**--user=name**

Required. Specifies an Administrator user for the target Collective Controller.

**--keystorePassword[=pwd]**

Required. The password for the generated keystore. If specified and no value is defined, you are prompted.

**--keystoreType=type**

Optional. The type of the generated keystore. Default type is *JKS*. Valid values are *JKS* and *PKCS12*.

### **--certificateSubject=DN**

The DN for the generated SSL certificate. The default value, if unspecified is CN=<value of --user argument>,OU=client,O=ibm,C=us.

**Note:** When you use an LDAP user registry, you must specify the fully qualified DN of the administrator by using **--certificateSubject** as the default form is probably not valid for your LDAP.

SSL certificates are automatically trusted by setting the JVM property `com.ibm.websphere.collective.utility.autoAcceptCertificates` to **true**.

Following is the output of the command when run with all required arguments:

```
./dynamicRouting genKeystore --port=9444 --host=contoller1.acme.com --user=admin  
--password=password --keystorePassword
```

```
Enter password --keystorePassword:  
Re-enter password --keystorePassword:
```

```
Auto-accepting the certificate chain for target server.  
Certificate subject DN: CN=admin, OU=mycontroller, O=ibm, C=us
```

```
Generating keystore...  
Successfully completed MBean request to the controller.  
Successfully generated keystore plugin-key.jks.
```

Generated keystore file `plugin-key.jks` that enables secure communication between the Dynamic Routing service and clients. Copy keystore file `plugin-key.jks` to a directory on the web server host, and run "gskcmd" to convert the keystore to CMS. For example:

```
gskcmd -keydb -convert -pw <<password>> -db /tmp/plugin-key.jks -old_format jks -target /tmp/plugin-key.kdb -new_format CMS  
gskcmd -cert -setdefault -pw <<password>> -db /tmp/plugin-key.kdb -label default
```

Copy resulting `/tmp/plugin-key.kdb`, `.sth`, `.rdb` files to the keyring directory specified in the WebSphere plug-in configuration.

## **Generating a plugin-cfg.xml to route to multiple collectives**

8.5.5.4

Generate a `plugin-cfg.xml` that enables Intelligent Management in the WebSphere plug-in to route to multiple collectives.

### **Procedure**

1. For each collective that you want Intelligent Management in the WebSphere plug-in to route requests to, do the following:
  - a. Select a collective controller
  - b. Edit the `server.xml` of the collective controller and add the `dynamicRouting` tag. Specify a unique name for the `connectorClusterName` property. For example: `<dynamicRouting connectorClusterName="collective1" />`
  - c. On the selected collective controller machine, use the following collective **dynamicRouting setup** command to generate the `plugin-cfg.xml` and `plugin-key.p12` files.

```
<Liberty server root>/bin/dynamicRouting setup --port=<controllerport> --host=<controller host> --user=<administrator id> --password=<administrator password>  
--keystorePassword=<keystore password> --pluginInstallRoot=<root directory of the  
WebSphere plugin on the WebServer host> --webServerNames=<web server name>  
--keystoreType=pkcs12
```
2. Merge `<ConnectorCluster>` tags from the generated `plugin-cfg.xml` files.
  - a. Copy the `<ConnectorCluster>` elements from all `plugin-cfg.xml` files into one `plugin-cfg.xml` file.

For example, if you have two collectives, copy `<ConnectorCluster>` stanza from `plugin-cfg.xml` of the "collective2" into the `plugin-cfg.xml` of the "collective1".

The merged `plugin-cfg.xml` file appears similar to the following example:

```
<?xml version="1.0" encoding="UTF-8"?><!--HTTP server plug-in config file for defaultServer generated on 2014.05.13
<Config ASDisableNagle="false" AcceptAllContent="false" AppServerPortPreference="HostHeader" ChunkedResponse="false"
  <Property Name="ESIEnable" Value="true"/>
  <Property Name="ESIMaxCacheSize" Value="1024"/>
  <Property Name="ESIInvalidationMonitor" Value="false"/>
  <Property Name="ESIEnableToPassCookies" Value="false"/>
  <Property Name="PluginInstallRoot" Value="/opt/IBM/HTTPServer_Plugins/">
  <!-- Configuration generated using httpEndpointRef=defaultHttpEndpoint-->

  <Property Name="Keyfile" Value="/opt/IBM/HTTPServer_Plugins/config/webserver1/plugin-key-collective1.kdb"/>
  <Property Name="Stashfile" Value="/opt/IBM/HTTPServer_Plugins/config/webserver1/plugin-key-collective1.sth"/>

  <IntelligentManagement>
  <TraceSpecification name="default" specification=":DEBUG"/>
  <Property name="webserverName" value="webserver1"/>

  <ConnectorCluster enabled="true" maxRetries="10" name="collective1" retryInterval="30">
  <Property name="uri" value="/ibm/api/dynamicRouting"/>
  <Connector host="controller1.acme.com" port="9443" protocol="https">
  <Property name="keyring" value="/opt/IBM/HTTPServer_Plugins/config/webserver1/plugin-key-collective1.kdb"/>
  </Connector>
  </ConnectorCluster>

  <ConnectorCluster enabled="true" maxRetries="10" name="collective2" retryInterval="30">
  <Property name="uri" value="/ibm/api/dynamicRouting"/>
  <Connector host="controller2.acme.com" port="9443" protocol="https">
  <Property name="keyring" value="/opt/IBM/HTTPServer_Plugins/config/webserver1/plugin-key-collective2.kdb"/>
  </Connector>
  </ConnectorCluster>

  </IntelligentManagement>
</Config>
```

3. For each collective, convert the pkcs12 formatted keystore to a CMS format.

- a. Copy generated `plugin-key-<connectorClusterName>.p12` file to `/tmp` directory on the IHS host.
- b. Run `gskcmd` to convert it to a CMS formatted store as instructed in the **dynamicRouting setup** command output.

```
./gskcmd -keydb -convert -pw <<password>> -db /tmp/plugin-key-collective1.p12 -old_format p12 -target /tmp/plugin-key-
```

- c. Copy resulting `.kdb`, `.sth` and `.rdb` stores to the `<plugininstallRoot>/config/<webServerName>` directory.

4. Extract all memberroot certificates from each collective `kdb` store and import it into a new keystore, which is used for front-end user requests over SSL.

For example, run the following command to extract the memberroot certificate:

```
./gskcmd -cert -extract -db /tmp/plugin-key-collective1.kdb -label memberroot -pw <<password>> -target /tmp/memberroot.
```

Create a new CMS formatted store that is called `plugin-key.kdb`, and import the memberroot certificates into it.

```
./gskcmd -cert -add -db /tmp/plugin-key.kdb -pw <<password>> -file /tmp/memberroot.cer -label memberroot
```

Copy the resulting plugin-key `.kdb`, `.sth` and `.rdb` files to the `<plugininstallRoot>/config/<webServerName>` directory.

5. Modify the merged `plugin-cfg.xml` to change the `keyfile` and `Stashfile` properties to use the `plugin-key.kdb` and `plugin-key.sth`. The modified `plugin-cfg.xml` appears similar to the following example:

```
<?xml version="1.0" encoding="UTF-8"?><!--HTTP server plug-in config file for defaultServer generated on 2014.05.13 at 1
  <Config ASDisableNagle="false" AcceptAllContent="false" AppServerPortPreference="HostHeader" ChunkedResponse="false"
  <Log LogLevel="Error" Name="/opt/IBM/HTTPServer_Plugins/logs/webserver1/http_plugin.log"/>
  <Property Name="ESIEnable" Value="true"/>
```

```

<Property Name="ESIMaxCacheSize" Value="1024"/>
<Property Name="ESIInvalidationMonitor" Value="false"/>
<Property Name="ESIEnableToPassCookies" Value="false"/>
<Property Name="PluginInstallRoot" Value="/opt/IBM/HTTPServer_Plugins/" />
<!-- Configuration generated using httpEndpointRef=defaultHttpEndpoint-->

<Property Name="Keyfile" Value="/opt/IBM/HTTPServer_Plugins/config/webserver1/plugin-key.kdb"/>
<Property Name="Stashfile" Value="/opt/IBM/HTTPServer_Plugins/config/webserver1/plugin-key.sth"/>

<IntelligentManagement>
  <TraceSpecification name="default" specification=":DEBUG"/>
  <Property name="webserverName" value="webserver1"/>

  <ConnectorCluster enabled="true" maxRetries="10" name="collective1" retryInterval="30">
    <Property name="uri" value="/ibm/api/dynamicRouting"/>
    <Connector host="controller1.acme.com" port="9443" protocol="https">
      <Property name="keyring" value="/opt/IBM/HTTPServer_Plugins/config/webserver1/plugin-key-collective1.kdb"/>
    </Connector>
  </ConnectorCluster>

  <ConnectorCluster enabled="true" maxRetries="10" name="collective2" retryInterval="30">
    <Property name="uri" value="/ibm/api/dynamicRouting"/>
    <Connector host="controller2.acme.com" port="9443" protocol="https">
      <Property name="keyring" value="/opt/IBM/HTTPServer_Plugins/config/webserver1/plugin-key-collective2.kdb"/>
    </Connector>
  </ConnectorCluster>

</IntelligentManagement>
</Config>

```

## Enabling Intelligent Management in the WebSphere plug-in trace

8.5.5.4

Intelligent Management in the WebSphere plug-in trace is enabled by using the **<traceSpecification>** tag.

### About this task

Use the **<traceSpecification>** tag to enable both control and request-based tracing. To enable this tracing, see, *Configuring trace on the web server plug-in*.

For more information on the properties of the **<traceSpecification>** tag, see “Dynamic Routing” on page 872.

### Procedure

1. To set the **:DEBUG** control trace for *webserver1* and *webserver2*, add the following code to the *server.xml* of the controller.

```

<dynamicRouting>
  <traceSpecification name="default" specification=":DEBUG" webservers="webserver1, webserver2" />
</dynamicRouting>

```

This change is communicated to the web server if it is already connected to the Dynamic Routing service.

**Note:** Set the **name** parameter to **default** to use the control trace specification. See *Configuring trace on the web server plug-in* for more information.

Configure different control trace specifications for different web servers. For example:

```

<dynamicRouting>
  <traceSpecification name="default" specification=":DEBUG" webservers="webserver1" />
  <traceSpecification name="default" specification="request.http:DEBUG" webservers="webserver2" />
</dynamicRouting>

```

2. To configure request-based trace specifications for *webserver1*, add the following code to the *server.xml* of the controller.

```
<dynamicRouting>
  <traceSpecification name="custom1" specification="request.http:DEBUG" condition="uri = '/foo'" webservers="webserver1"
</dynamicRouting>
```

**Note:** The **condition** property is required for request-based trace specifications. The **condition** property specifies an expression that is evaluated by Intelligent Management in the plug-in for each request. The specified trace specification is set for the requests that match the expression. For information regarding the format of the condition parameter, see *Configuring trace on the web server plug-in*.

Request-based trace specifications are evaluated in the order they are specified. If two trace specifications with same name are specified, the one that comes later takes precedence. In the following example, *control.process:DEBUG* is used for the control specification for *webserver1*:

```
<dynamicRouting>
  <traceSpecification name="default" specification=":DEBUG" webservers="webserver1" />
  <traceSpecification name="default" specification="control.process:DEBUG" webservers="webserver1" />
</dynamicRouting>
```

Use "\*" to set the trace specification for all the web servers that are connected to the Dynamic Routing service. If you have a specification value that contains actual webserver names, the webserver specification replaces the "\*" specification, regardless of order, because of specificity. The order replacement occurs when both specifications are equally targeted for "\*" or for the same webservers.

```
<dynamicRouting>
  <traceSpecification name="default" specification=":DEBUG" webservers="*" />
  <traceSpecification name="custom1" specification="http.request.rules:DEBUG" condition="uri = '/foo'" webservers="webserver1" />
  <traceSpecification name="custom2" specification="http.response:DEBUG" condition="uri = '/foo'" webservers="webserver1" />
  <traceSpecification name="custom3" specification="http.request.select:DEBUG" condition="virtualhost = 'ibm.com'" webservers="webserver1" />
</dynamicRouting>
```

## Conversion of the keystore to CMS format on z/OS

You can set up dynamic routing for Liberty collectives on a z/OS system. An element of that task is to convert the keystore to a CMS format.

The sample script that is provided here is a suggestion of how to set up the CMS provider for the **ikeycmd**. However, your environment might be different and you must ensure that you locate the CMS provider and specify the correct provider offset.

Both the **gskcmd** commands in step 5 of *Setting up dynamic routing for Liberty collectives* must be run for z/OS by using **ikeycmd** in place of **gskcmd**. The **ikeycmd** commands must include the additional `-Djava.security.properties` as indicated in the sample script to append the CMS provider with an appropriate provider offset. The `-Djava.security.properties` parameter must precede the other parameters that are specified in step 5 of *Setting up dynamic routing for Liberty collectives* for each command.

```
#!/bin/sh

# z/os ikeycmd wrapper that adds CMS v3 support.
# Author:

if [ -n "$JAVA_HOME" ]; then
  echo "Using JAVA_HOME=$JAVA_HOME"
else
  JAVA_HOME=/usr/lpp/java/java800/J8.0_64/
fi

# Should not require edits below this line

> /tmp/java.security.append

# Check for non-v3 CMS provider in java.security.
```

```

if grep CMSProvider $JAVA_HOME/lib/security/java.security >/dev/null; then
  if ! grep -i "CMSProvider V3" $JAVA_HOME/lib/security/java.security; then
    echo "CMS Provider already present, but no 'V3' argument: $JAVA_HOME/lib/security/java.security"
    exit 1
  fi
else
  # Need to add CMSv3 provider.
  # Hunt for the next provider offset
  let NEXT_PROVIDER=1
  for PROVIDER in 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15; do
    if grep security.provider.$PROVIDER $JAVA_HOME/lib/security/java.security >/dev/null; then
      let NEXT_PROVIDER=$NEXT_PROVIDER+1
    fi
  done

  # Stash the provider line in a file
  echo "security.provider.$NEXT_PROVIDER=com.ibm.security.cmskeystore.CMSProvider V3" > /tmp/java.security.append
fi

if [ $# -eq 0 ]; then
  $JAVA_HOME/bin/ikkeycmd -Djava.security.properties=/tmp/java.security.append -help
else
  $JAVA_HOME/bin/ikkeycmd -Djava.security.properties=/tmp/java.security.append "$@"
fi

```

## Setting up auto scaling for Liberty collectives

8.5.5.4

Auto scaling provides an autonomic scaling capability of Liberty servers. The auto scaling functionality is enabled by two Liberty features, scaling controller and scaling member. Auto scaling dynamically adjusts the number of Java virtual machines (JVMs) used to service your workload. This feature provides operational agility and decreases administrative overhead to enhance the resiliency of your middleware environment. The conditions for auto scaling are defined by scaling policies. These conditions include the minimum or maximum number of server instances and the threshold values for each of the server resources.

### Before you begin

This feature does not require the use of Dynamic Routing, however auto scaling performs well when both features are used together. It is recommended to use the two features together. For more information on Dynamic Routing, see “Setting up dynamic routing for Liberty collectives” on page 1493.

Liberty collective controllers can use the Tivoli Remote Execution and Access (RXA) toolkit to perform selected operations on collective members. Review the tasks in “Setting up RXA for Liberty collective operations” on page 1491 to learn more about installing and using SSH.

You must also set your JAVA\_HOME path before setting up auto scaling. Review the tasks in “Setting the JAVA\_HOME variable for Liberty collective members” on page 1147.

### About this task

An auto scaling cluster is a server cluster that can expand and contract depending on the workload in your environment. The Liberty scaling controller controls the starting and stopping of scaling members that are based on performance information that is collected from the scaling members and configurable scaling policies. To be a scaling member of a server cluster, a Liberty scaling controller must also be a member of a Liberty collective. A server cluster has a unique name within a Liberty collective. In Liberty, members of the same server cluster will have the same cluster name, if they are within the same collective. Auto scaling capabilities are controlled by using policies when the consumption of resources rises above an upper threshold or falls below a lower threshold.

The auto scaling functionality is enabled by two Liberty features, scaling controller and scaling member.

- **scalingController-1.0**

The scaling controller feature decides when to expand or contract an auto scaling cluster. Collective controllers are required because they provide administration functionality that leverages the ability of the collective controller to manage the scaling controller. Only one of the running scaling controllers can make decisions. For more information on collective controllers and how to configure your controllers for high availability, see “Configuring a Liberty collective” on page 1136. The scaling controller can start an auto scaling cluster member in response to increased resource usage, or it might stop an auto scaling cluster member in response to decreased resource usage across the entire cluster. If replica sets are being used, all collective controller members must be scaling controllers. When using replica sets if a controller is stopped, another running scaling controller takes over for it. For more information about replica sets, see “Configuring Liberty collective replica sets” on page 1148.

**Note:** The scaling controller keeps the last known state of the scaling members. Stopping the scaling controller and changing the state of the scaling members may cause some invalid actions at the scaling controller restart, until the scaling controller has gathered the latest scaling member state.

The scaling controller supports the following usage scenarios:

- JVM elasticity

The scaling controller starts and stops existing Liberty servers that are based on resource usage and optional scaling policies. There is no provisioning of new servers.

- **8.5.5.7** Liberty elasticity

The scaling controller can install Liberty software onto registered hosts and provision new servers, and then start and stop those servers, based on resource usage and optional scaling policies.

- **scalingMember-1.0**

The scaling member feature monitors the workload within the server and its host, when needed it sends this information back to the scaling controller. The scaling member feature must be enabled as a collective member in a collective.

**Note:** All scaling member servers must also belong to a cluster because all policy information is applied at the cluster member.

If there are two or more scaling members on a host, then the scaling members are organized so that only one scaling member communicates with the scaling controller. The host leader is nominated from among all the scaling members on a host. If the host leader stops, then another scaling member will take over as the host leader.

Each scaling member needs to define a **hostSingleton** element with a port in the `server.xml`. All the scaling members on the same host and cluster must use the same port. This port is used by an election service to identify a host leader. The host leader is the only scaling member that communicates with the scaling controller. The host leader communicates metric data from the members to the controller and communicates scaling decisions that are made by the controller to the members in the host. For example:

```
<hostSingleton name="ScalingMemberSingletonService" port="5164" />
```

For more information about the **hostSingleton** element, see “Collective Member” on page 866.

The scaling member monitors the use of the following resources within the server process:

- CPU
- Heap
- Memory

The scaling member monitors the use of the following resources at the host level:

- CPU
- Memory

## Procedure

1. Create a collective to use for auto scaling.
  - Configure auto-scalable clusters for JVM elasticity.
  - **8.5.5.7** Configure provisionable clusters for Liberty elasticity.
2. Define scaling policies to change the criteria that the scaling controller uses to manage workload. See “Defining scaling policies to manage workload” on page 1511 for more information.

## Results

With the auto scaling feature enabled, you can now dynamically adjust the number of Java virtual machines (JVMs) used to service your workload.

**Note:** The auto scaling cluster capabilities are only available in WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS.

## Configuring auto-scalable clusters for JVM elasticity

**8.5.5.5**

You can configure a collective to support Java virtual machine (JVM) elasticity. With JVM elasticity, the scaling controller can start or stop Liberty servers based on resource use and scaling policies. Only the servers that are already in the collective are eligible for scaling. There is no provisioning of new servers.

### Before you begin

The types of collected resource usage information vary among JDKs. IBM JDK 1.7 for Windows and Linux operating systems provides all necessary usage information for auto scaling and is the preferred JDK. Other JDKs may not provide all necessary usage information for auto scaling based on the individual JVM resource usage.

**Avoid trouble:** The administrative console allows a start and a stop of a Liberty server that is a cluster member of an auto-scalable cluster, but only when the server is in maintenance mode. Starting or stopping a Liberty server from the command line when the Liberty server is a cluster member of an auto-scalable cluster can lead to unpredictable results.

## Procedure

1. Create a collective.

For details on creating a collective controller and member server, see “Configuring a Liberty collective” on page 1136.

**Note:** We recommend that you complete the first step before continuing. Step one instructs the user to create the collective, add members, and start the controllers and members.

2. Add the **scalingController-1.0** feature to the `server.xml` file of one or more collective controllers. When you save the `server.xml` file, default policies will be enforced unless otherwise specified.

```
<featureManager>
  <feature>jsp-2.2</feature>
  <feature>collectiveController-1.0</feature>
  <feature>scalingController-1.0</feature>
</featureManager>
```

After adding the feature, the following messages display in any order in the `messages.log` of the collective controller, provided the collective controller is running:

```
CWWKV0300I: The StackManager service started.
CWWKV0302I: The existing stacks are []
CWWKV0100I: The ScalingController feature is activated.
CWWKX1002I: Singleton service ScalingControllerSingletonService for scope
CWWKV0102I: This server is elected to be the primary scaling controller.
CWWKF0012I: The server installed the following features: [scalingController-1.0].
```

**Note:** Since Liberty configuration is dynamic, when you add the scaling controller, the controller's default scaling policy will take effect and you may get unexpected results. For example, the default policy has `min=2` servers, so when you save the scaling controller `server.xml` file the controller will attempt to start two servers. If you don't want that behavior, you may want to define a policy for the controller at the same time.

**Note:** It might take some time for the scaling controller to register the member and display the `CWWKV0121I` message.

3. Optional: Change the default scaling policies to meet the needs of your environment. Refer to "Defining scaling policies to manage workload" on page 1511 for more information.
4. Add both the **clusterMember-1.0** and **scalingMember-1.0** features to all collective members which you want the scaling controller to control. Define a `hostSingleton` element with a port in the member `server.xml` files. Each scaling member needs to define a `hostSingleton` element with a port in the `server.xml`. All scaling members on the same host must use the same port. You can specify any port number, but the port number must be unique on the host computer. The following example uses port number 20020 :

```
<featureManager>
  <feature>jsp-2.2</feature>
  <feature>clusterMember-1.0</feature>
  <feature>scalingMember-1.0</feature>
</featureManager>
```

```
<hostSingleton name="ScalingMemberSingletonService" port="20020" />
```

If the server is not started when you add the features and the `hostSingleton` element, you must start it manually once for the scaling controller to recognize the added features. The following messages display in any order in the `messages.log` of the collective member:

```
CWWKX1000I: The SingletonMessenger MBean is available.
CWWKX7400I: The ClusterMember MBean is available.
CWWKX1002I: Singleton service ScalingMemberSingletonService for scope host is created.
CWWKV0200I: The ScalingMember feature is activated.
CWWKX1004I: Messenger connection is connected to host=controller_host_name, port=controller_port_number.
```

Only one scaling member per host communicates with the scaling controller. The first scaling member to connect to the **ScalingMemberSingletonService** is elected as the host leader. If the host leader stops, then another scaling member will take over as the host leader via an election process arbitrated by the **scalingMemberSingletonService**. All the scaling members on the same host and cluster must use the same **ScalingMemberSingletonService** port.

**Note:** When a scaling member is elected as the host leader, you will see the following message in the `messages.log` of the collective member:

```
CWWKV0203I: Server host=host_name; userdir=path_to_usr_directory; server=member_name; port=member_port_number; service=
```

**Note:** If you do not add the **hostSingleton** element to the scalingMember `server.xml` or if you use different ports on each scalingMember on the same host, multiple host leaders may be elected. This can result in incorrect scaling decisions. You will see this message in the controller's `messages.log`:

```
CWWKV0123E: Duplicate host singleton leaders have been detected on host host_name. This condition may degrade scaling o
```

For more information about the **hostSingleton** element, see "Collective Member" on page 866.

8.5.5.5

**Watch:** The Configuring a Liberty auto-scalable cluster for JVM elasticity video demonstrates the procedure. [Transcript]

## Configuring provisionable clusters for Liberty elasticity

8.5.5.7

You can configure a collective to support Liberty elasticity. With Liberty elasticity, the scaling controller can install Liberty software onto a registered host and create a new server. Also, because support for Liberty elasticity includes support for JVM elasticity, the scaling controller can start or stop Liberty

servers based on resource use and optional scaling policies. The number of available servers grows when application demand is high and shrinks when application demand is low.

## Before you begin

Determine the target hosts onto which you want to install Liberty software and the Liberty software to install. Minimally, you want the scaling controller to install the following installable and package files on a target host:

- A package that provides a stand-alone Liberty server with one application. Step 5c explains how to create the server package.
- An installable that provides a Liberty server that contains the `wlp` directory, but does not contain the `usr` directory. Step 5a explains how to create the Liberty runtime archive installable.

Each target host needs RXA or SSL and a Java Runtime Environment (JRE) installed that meets the minimum requirements of the Liberty server. See “Setting up RXA for Liberty collective operations” on page 1491 and “Setting the `JAVA_HOME` variable for Liberty collective members” on page 1147.

If a target host does not have a JRE installed with its `JAVA_HOME` variable and System `PATH` variable providing a path to the JRE, the scaling controller can install the JRE on the target host. Step 5b explains how to create a JRE archive, an installable.

 **Watch:** The Configuring an auto-scalable cluster for Liberty elasticity video shows how to configure a provisionable cluster. [Transcript]

## Procedure

1. Configure a collective to support Java virtual machine (JVM) elasticity. Ensure that the collective has at least one dynamic cluster member.

For details on configuring scaling controllers with dynamic cluster members, see “Configuring auto-scalable clusters for JVM elasticity” on page 1505.

2. Ensure that each existing dynamic cluster member belongs to a cluster named with the `StackGroupName.PackageName` naming convention.

Existing dynamic cluster members and servers that the scaling controller will provision will be members of this cluster. `StackGroupName` is the name of a shared directory which will hold installables and packages that a scaling controller will provision to target hosts based on scaling policies. `PackageName` is the name of the server package that the scaling controller will provision to target hosts.

For a cluster named `myStackGroup.cluster1`, put the following statement into the `server.xml` file of each existing dynamic cluster member:

```
<clusterMember name="myStackGroup.cluster1"/>
```

You will use the cluster name for steps 5c and 7 of this topic. In step 5c, use `cluster1.zip` for the server package name. In step 7, create the `myStackGroup` directory for the installables and packages to be deployed.

3. Optional: Add scaling policies to the scaling controller. See Defining scaling policies.
4. Register each target host with a scaling controller.

Registering a host enables the scaling controller to transfer files to that host, as well as access files, commands, and other resources on the host. Use the `registerHost` command to register a target host. Look at the `server.xml` file of the scaling controller to find the values for the `--host`, `--port`, `--user`, and `--password` parameters. To not use an SSH private key file, such as for target hosts on Linux or Windows operating systems, include an operating system login user and password by setting `--rpcUser` and `--rpcUserPassword` parameters. The user specified by `--rpcUser` must have operating system rights to the target deployment location.

```
wlp/bin/collective registerHost targetHost --host=controllerHost --port=controllerHTTPSPort --user=controllerAdmin --password=con
```

To transfer files to target hosts, you do not need to include a `--hostWritePath` parameter in the command; the stack provisioning code sets write paths for you. If a host is already registered, you can use the **updateHost** command to reset registration information. For more information, see “Registering host computers with a Liberty collective” on page 1142.

If the target host is on the same computer as the controller host, you must also run the **updateHost** command for the controller host.

5. Create and configure installables and packages that a scaling controller can deploy onto a registered host.

An *installable* is a binary file the application you want to install on a registered host needs to run, such as a Liberty runtime or JRE. A *package* is that application packaged into a compressed file.

- a. Create a Liberty runtime archive that contains the `wlp` directory, but does not contain the `usr` directory. The naming convention for this installable is *type.name.zip*; for example, `wlp.855.zip`. To create a Liberty runtime archive, you have the following options:

- Run the Liberty server **package** command with the `--include=wlp` option; for example:

```
wlp/bin/server package --include=wlp
```

To specify a file name and target location, add the `--archive=archive_path_name` option; for example:

```
wlp/bin/server package --include=wlp --archive=c:\temp\wlp.855.zip
```

If you do not specify a valid file name or target location with the `--archive` option, then the command creates the `wlp.zip` runtime archive in the `$WLP_OUTPUT_DIR` location, which is the `${wlp.install.dir}/usr/servers` directory by default. The target location must exist before running the command. Thus, if the target location is `c:\temp`, the `C:\temp` directory must exist and have write permission for the command to write the archive to the `C:\temp` directory.

- Run the **package** command with the `--include=all` option and then delete the `usr` directory. The **package** command resembles:

```
wlp/bin/server package myServer --include=all --archive=myArchive.zip
```

- Create a compressed (`.zip`) file that contains the `wlp` directory, without the `usr` directory.

After you create the Liberty runtime archive, ensure that the archive name follows the naming convention, *wlp.name.zip*.

- b. Create or obtain archives for the Java development kit (JDK) and any other required installable. The naming convention for an installable is *type.name.zip*; for example, `jre.17.zip`. Valid type values for installables are:

- `wlp` for a Liberty runtime.
- `jre` for a Java runtime environment.
- `other` for a different file type. This is the default.

For example, to create an archive for a JRE, create a compressed (`.zip`) file that contains the contents of the `java` directory of your IBM JRE installation. Do not include the `java` directory, but include all folders and files in the `java` directory. Follow the *jre.name.zip* naming convention when naming the archive.

- c. Create a server package that contains a Liberty server and applications. The naming convention for a server package is *package\_name.zip*; for example, `cluster1.zip`. Options for creating a server package include:

- Run the **package** command:

```
wlp/bin/server package cluster1 --include=usr
```

The command creates a server package named, for example, `C:\wlp\usr\servers\cluster1\cluster1.zip`.

- Run the **package** command with the `--include=all` option and then delete the `wlp` directory. The **package** command resembles:

```
wlp/bin/server package cluster1 --include=all --archive=cluster1.zip
```

- Create a compressed (`.zip`) file that contains the `usr` directory, without the `wlp` directory.

For example, to create a server package named `cluster1.zip` that consists of a stand-alone Liberty server with one application:

- 1) Create a server:

```
wlp/bin/server create cluster1
```

- 2) Copy an application to the `dropins` directory of the `cluster1` server.

- 3) Package the server:

```
wlp/bin/server package cluster1 --include=usr
```

The `wlp/usr/servers/cluster1/cluster1.zip` file is created.

**Important:** Ensure any `server.env` file in the package has environment settings that are valid on the target hosts. For example, if `JAVA_HOME` is set, it must be set to a location that exists on the target hosts to prevent failed deployments.

**Note:** Windows For Windows target hosts, create a `server.env` file that sets `JAVA_HOME` to the JRE location on the target hosts. After running the **package** command, place the `server.env` in the same directory as the `server.xml` file in the server package ZIP. Example `server.env` contents are:

```
JAVA_HOME=C:\wlp\jre\jre.17.zip\jre
```

6. Set a user name and password for the stack manager in the scaling controller `server.xml` file.

```
<stackManager controllerUser="adminUser" controllerUserPassword="adminPassword" />
```

7. Place the installables and packages in the `WLP_STACK_GROUPS_DIR` location, which by default is `$WLP_USER_DIR/shared/stackGroups`.

Scaling controllers monitor default installable and package locations in the file system and dynamically react to updates. If you place the installables and packages in the default locations, you do not need to change any of the default attributes.

You can use the default stack group, `defaultStackGroup`. Or you can create your own subdirectory of `stackGroups`, such as `myStackGroup`, and add to it the `installables` and `packages` subdirectories.

```
wlp/usr
  /servers
  /shared
  ...
  /stackGroups
    /defaultStackGroup
      /installables
      /packages
    /myStackGroup
      /installables
      /packages
```

The scaling controllers deploy the installables and packages onto the registered host and create a new server.

**Tip:** A new server is created only if the scaling policy is enabled and requires a new server. To force a scaling controller to create a new server, adjust the `min` value and possibly the `max` value of the scaling policy for the scaling controller. For example, if your scaling controller does not have a scaling policy and your collective has three scaling members, add to the scaling controller `server.xml` file a policy that forces the scaling controller to have at least four running members:

```
<scalingDefinitions>
  <defaultScalingPolicy enabled="true" min="4" max="6"/>
</scalingDefinitions>
```

The cluster naming convention for Liberty elasticity is `StackGroupName.PackageName`. When a stack is deployed, `<clusterMember name="StackGroupName.PackageName">` is automatically set in the `server.xml` file of the deployed server. The corresponding `<scalingPolicy>` element includes a `<bind clusters="StackGroupName.PackageName"/>` statement.

Table 109. Default installable and package locations. Liberty environment variables set the default installation directories. To override the default locations, see “Customizing the Liberty environment” on page 1565.

File	Default installation directory
Installable type wlp	/wlp
Installable type jre	/wlp.jre
Installable type other	/wlp.other
Package	/wlp.usr

- Examine the configuration attributes for stack groups and installables and change the configurations of your stack groups and installables as needed to define when and where to run Liberty provisioning. You might need to override the default configurations.

Override default configurations by setting new values in the `stackGroup` and `installable` elements of the scaling controller `server.xml` file. See *Scaling Controller* for information about the `stackGroup` and `installable` elements.

Tips for overriding default values for some elements follow:

- The `installable` element defines an installable for a stack group. The `installable` element can be a child element of the `stackGroup` element or a sibling referenced by an `installableRef` child element of the `stackGroup` element.

**8.5.5.7** The following examples show how you can change the settings in the scaling controller `server.xml` file to override the default value for the `installable` attribute of a stack group:

```
<stackGroup name="myStackGroup">
  <installable name="wlp.v8555.zip" sourceDir="c:\myStackGroup\installables"/>
</stackGroup>
```

or

```
<stackGroup name="myStackGroup" installDir="/myInstallDir" installableRef="myInstallable1, myInstallable2"/>
<installable name="wlp.v8555.zip" id="myInstallable1" sourceDir="c:\myStackGroup\installablesOne" />
<installable name="jre.v1.6.zip" id="myInstallable2" sourceDir="c:\myStackGroup\installablesTwo"/>
```

- The `deployVariable` child element specifies a substitution variable which gets injected into the deployed stack. You can specify that the substitution variable automatically increment each time the stack is deployed. For example, use a `deployVariable` attribute to specify an initial port number value and increment the value each deployment. The purpose of `deployVariable` in this situation is to avoid port conflicts on the target host. The `deployVariable` element uses arithmetic in the `server.xml` file of the deployed server to derive the runtime port number.

For example, to define a starting port value and amount to increment:

- Set `httpPort="{http.port}"` in the `httpEndpoint` element of the packaged server `server.xml` file:

```
<httpEndpoint ... httpPort="{http.port}" />
```

- Add a `deployVariable` definition that sets the starting port and increment values to the scaling controller `server.xml` file:

```
<stackGroup name="DefaultStackGroup" installDir="">
  <deployVariable name="http.port" value="9080" increment="1"/>
</stackGroup>
```

Then, each successive time the stack is deployed to the host, the `httpPort` value increments by 1. Thus, the first time the stack is deployed to `host1`, the HTTP endpoint element is:

```
<httpEndpoint ... httpPort="9080" />
```

and the second time the stack is deployed to `host1`, the element is:

```
<httpEndpoint ... httpPort="9081" />
```

As to the `deployVariable` attribute, the default value for `value` is `null`. The default value for `increment` is 0 (zero).

If `deployVariable` is specified in the scaling controller `server.xml` file, the runtime port number of a deployed server is the initial port value String increased by the increment integer.

- If the scaling controller `server.xml` defines the stack group as follows, do not define `httpPort` again in the `bootstrap.properties` file for the server directory with which you create a server package. If you do, the `httpPort` value defined in `bootstrap.properties` is used, not the one generated by the `deployVariable` configuration element.

```
<stackGroup name="DefaultStackGroup" installDir="">
  <deployVariable name="http.port" value="9080" increment="1"/>
</stackGroup>
```

9. Optional: Change the interval at which the scaling controller checks the file system for stack group additions, updates, and deletions.

The scaling controller scans the contents of the `stackGroups` directory and its subdirectories for changes. Content changes can cause the controller to provision clusters that previously did not have packages available. Updating packages does not cause the controller to provision existing clusters again.

By default, the controller scans the `WLP_STACK_GROUPS_DIR` location every 5000 milliseconds (five seconds). To change the scanning interval or disable scanning, set new values for the stack manager attributes `scanningInterval` and `scanningEnable` in the scaling controller `server.xml` file. For example, to set the scanning interval to six seconds and enable scanning, add a statement resembling the following to the scaling controller `server.xml` file:

```
<stackManager groupsDir="{wlp.install.dir}/usr/shared/stackGroups/"
  controllerUser="adminUser" controllerUserPassword="adminPassword"
  scanningInterval="6000" scanningEnable="true">
</stackManager>
```

To disable scanning, set `scanningEnable` to `false`.

10. Optional: Instruct the scaling controller to scan the file system for new stack group additions, updates, and deletions.

Run a `StackManager` MBean operation to force the scaling controller to check the `WLP_STACK_GROUPS_DIR` location for stack group additions, updates, and deletions. Even if the scaling controller `server.xml` file has `scanningEnable="false"`, you can run a `StackManager` MBean operation to force a scanning for additions, updates, and deletions.

See “Liberty: List of provided MBeans” on page 1647 for information about the `StackManager` MBean.

11. Optional: Start IHS to enable routing to servers.

For IBM HTTP Server (IHS) to discover and route to web applications on dynamically provisioned clusters, enable dynamic routing on the host where the scaling controller will reside. IHS will retrieve the routing information for the provisioned servers from the dynamic routing service. If server status is enabled, you can view the routing information.

If you do not have IHS installed, see “Setting up dynamic routing for Liberty collectives” on page 1493. Also, the following video demonstrates how to install support for dynamic routing using IBM Installation Manager:

 **Watch:** The Enabling IHS for Liberty Dynamic Routing video shows how to install IHS, install Web Server Plug-in for WebSphere Application Server, and apply the interim fix for Dynamic Routing. [Transcript]

## Defining scaling policies to manage workload

8.5.5.4

Scaling policies are used to start and stop dynamic cluster members based on configurable metrics. Scaling Policy can be defined for all or specific clusters. If no policy is defined, a built-in policy will be used.

## About this task

The scaling controller uses scaling policies to make decisions about managing workload. By default, a built-in scaling policy is embedded in the scaling controller. Optionally, you may override the built-in scaling policy by defining either or both top level elements, default scaling policy and scaling policy. The built-in scaling policy is as follows:

- A minimum of two cluster members, if available, are kept active. The minimum number might not be met if some or all of the members are exceeding the metric thresholds.
- An additional cluster member is started when the average CPU, heap, or memory use of all active members exceeds 90%.
- A cluster member is stopped when the average CPU and heap use drops below 30%.

Scaling policy may be defined for all clusters using the default scaling policy. The default scaling policy inherits built-in scaling policy metrics, including `min` and `max` instance values. Any changes made to the default scaling policy, specified by the user, will override the built-in value. Values that are not specified in your default scaling policy will be inherited from the built-in scaling policy.

Unlike default scaling policy, scaling policy metrics are not inherited from either the built-in or default scaling policy. However, `min` and `max` instance values are initialized to the built-in policy values. Because scaling policy metrics are considered optional values, only the metrics specified in the policy are included in scaling decisions. Metrics not included in the scaling policy are not analyzed when making scaling decisions.

There are two levels of scaling policies. You can override the built-in scaling policy by defining either or both top level elements. Here are the two levels that can be defined:

- **Default scaling policy**

You can define a single default scaling policy to manage all clusters that do not need a more specific scaling policy defined.

The following example shows how to define a default scaling policy that sets the minimum number of active cluster members to 3.

```
<scalingDefinitions>
  <defaultScalingPolicy min="3"/>
</scalingDefinitions>
```

- **Scaling policy**

You can define a scaling policy to manage one or more clusters with targeted criteria that is specified in the scaling policy. Because scaling policy definitions do not inherit metric thresholds, only metric thresholds that are specified will be monitored. All other thresholds will be ignored as it relates to scaling decisions. Built-in scaling policy values for `min` and `max` instances will still be respected if they are not specified.

The following example shows how to define a scaling policy that changes the CPU use thresholds for starting and stopping servers in a cluster named `cluster1`.

```
<scalingDefinitions>
  <scalingPolicy id="cluster1Policy">
    <bind clusters="cluster1"/>
    <metric name="CPU" min="10" max="70"/>
  </scalingPolicy>
</scalingDefinitions>
```

The value of the `clusters` attribute of the `bind` element is a comma-separated list of cluster names. An asterisk can be used at the end of the name only as a wildcard to match zero-or-more characters. For example:

```
<bind clusters="west,south*"/>
```

In this example, the scaling policy applies to a cluster named *west* and all clusters whose name starts with *south*. If a cluster name matches multiple policies, the scaling controller uses the following rules to choose a policy:

- An exact match is preferred to a wildcard match.
- If there are multiple wildcard matches, the policy with the longest prefix is used.

The policy will scale based on default min and max values. In the previous example, the clusters will only scale based on the CPU values specified, where min=10 and max=70.

Metric-based scaling decisions are made on a cluster level. Each cluster member monitors its own metrics. The CPU and Memory metric value for a server is actually the greater of the server JVM process or the server's host. The Heap metric value is only taken from the server JVM process. If a measurable change in a monitored metric is detected, that metric is sent to the controller for analysis. All cluster member metrics are accumulated and a cluster average is calculated for each metric. The calculated value for each metric is then compared to the defined upper or lower threshold to determine if a scaling decision will be triggered.

*Scale out* decisions are made on an individual metric basis. All monitored metrics are analyzed for the cluster and if any one of the metrics exceeds the policy max threshold, a scale out event is triggered. *Scale in* decisions are made based on all monitored metrics. The cluster average for each monitored metric is analyzed. If all metrics are below their policy min threshold, a scale in event is triggered.

After a scaling decision is made, the scaling controller selects a scaling target. The scaling target is the host on which the server stop (for scale in) or server start (for scale out) action is run. When determining a target for a scale out action, the host level metrics are taken into consideration. If any of the host level metrics exceed that metric's policy max threshold, the scaling controller avoids that host and chooses another host for the scale out action.

**8.5.5.8** The scaling policy can influence the selection of the scaling target. If the policy specifies `scalingPreference="horizontal"`, the scaling controller starts a server on the eligible host with the fewest active servers and stops a server on the host with the most active servers. If the policy specifies `scalingPreference="vertical"`, the scaling controller starts a server on the eligible host with the most active servers and stops a server on the host with the fewest active servers. The scaling controller attempts to place servers in the same cluster on different hosts when possible, regardless of which `scalingPreference` is chosen.

For more information on **scalingPolicy** metrics see, “Scaling Controller” on page 950.

You can use the **hostGroup** element to limit which hosts can be selected to provision a new server. The `tags` attribute specifies a list of administrative metadata tags. When the scaling controller needs to provision a server, it can only select a host that has at least one matching tag. For example, the policy below says that servers can be provisioned on a host that has *tag1* or a host that has *tag2* associated with it.

```
<scalingDefinitions>
  <scalingPolicy id="provisionPolicy">
    <bind clusters="defaultStackGroup.deployMember"/>
    <hostGroup tags="tag1 tag2"/>
  </scalingPolicy>
</scalingDefinitions>
```

**Note:** If you do not specify the **hostGroup** element, the scaling controller can provision a server on any host that is registered with the collective.

For more information on setting administrative metadata tags see, “Setting administrative metadata for Liberty resources” on page 1476.

## Procedure

1. In the server.xml file of the scaling controller, add the default scaling definitions.

```
<scalingDefinitions>
<defaultScalingPolicy enabled="true" min="1" max="2"/>
</scalingDefinitions>
```

2. When a scaling policy is modified, the server.xml in the controller is also modified. You can check the messages.log file for the following messages to verify that the controller was successfully updated.

```
CWWKG0016I: Starting server configuration update.
CWWKG0028A: Processing included configuration resource: /opt/IBM/Liberty/wlp/usr/
CWWKG0017I: The server configuration was successfully updated in 0.052 seconds
```

You will see the following error messages in the messages.log file if the scaling policy is missing necessary metric thresholds. Follow the user action to correct the error.

```
CWWKV0126W: The configuration of scaling policy {0} does not contain a min or max threshold.
CWWKV0127W: The configuration of scaling policy {0} does not contain a max threshold.
CWWKV0128W: The configuration of scaling policy {0} does not contain a min threshold.
```

## Results

Your scaling policies are now defined.

## Intelligent Management: supported server virtualization environments for CPU metric policy

Before you deploy Intelligent Management on virtualized servers, you must understand the limitations for the server virtualization platform that you are using.

**Remember:** This topic lists the most up to date information on the support of various server virtualization platforms.

Table 110. Server virtualization environments

Virtualization platform	Restrictions	Supported processor sharing mode
AIX 5.3 and AIX 6.1 on POWER5 and POWER6® (Micro-Partitioning®)	None.	Dedicated.
HP-UX 11i v3 on HP using Virtual Partitions (vPars) or Integrity VMs	Currently not supported.	None.
KVM in SUSE Linux Enterprise Server (SLES) 11	Specify 100% affinity to a set of CPU's.	Dedicated.
Linux on POWER® (Micro-Partitioning)	None.	Dedicated.
Linux on z/VM®	None.	Dedicated.
Linux Xen	None.	Dedicated.
Microsoft Hyper-V	Specify 100% affinity to a set of CPU's.	Dedicated.
Solaris Operating Environment 10 on Sun (Zones)	None.	Dedicated.
VMware ESX 3.5, 4.0, 4.1, 5.0 VMware vSphere 4, 5	Guest CPU utilization reporting accuracy is dependent on the following: <ul style="list-style-type: none"> <li>• Guest Operating System</li> <li>• Virtual Machine Reservation</li> <li>• Limit Settings</li> </ul>	Dedicated.

## Deploying scaling policies to a Liberty collective

8.5.5.5

You can use the `scaling-metadata.xml` file to set scaling policies for an auto-scalable cluster. The `scaling-metadata.xml` file uses XML format and does not exist by default. You must create the file and place it in a cluster member configuration directory. After creating the `scaling-metadata.xml` file, you can deploy it through a server package to a Liberty collective.

### Procedure

1. Create an auto-scalable cluster with `<scalingMember metadataMonitorEnabled="true"/>` in its configuration. Optionally, specify a cluster name for the collective member.

The following example defines an auto-scalable cluster member in a cluster named `cluster1`:

```
<featureManager>
  <feature>collectiveMember-1.0</feature>
  <feature>clusterMember-1.0</feature>
  <feature>scalingMember-1.0</feature>
</featureManager>
<clusterMember name="cluster1"/>
<scalingMember metadataMonitorEnabled="true"/>
```

This example changes two default settings:

- The `<clusterMember name="cluster1"/>` statement assigns the member to the `cluster1` cluster. This statement is optional. Without this statement, the cluster member is assigned to `defaultCluster`.
- The `<scalingMember metadataMonitorEnabled="true">` statement enables monitoring for the `scaling-metadata.xml` file. The default is `metadataMonitorEnabled="false"`, which disables monitoring.

Optionally, you can omit `<feature>clusterMember-1.0</feature>` from the auto-scalable cluster configuration because the `scalingMember-1.0` feature enables the `clusterMember-1.0` feature. The `clusterMember-1.0` feature is shown in this example for clarity.

For information about creating an auto-scalable cluster, see “Configuring auto-scalable clusters for JVM elasticity” on page 1505.

2. Create a text file named `scaling-metadata.xml` that defines a scaling policy.

```
<?xml version="1.0" encoding="UTF-8" ?>
<server description="Scaling Policy for cluster1">
  <scalingDefinitions>
    <scalingPolicy name="cluster1">
      ...
      <bind clusters="cluster1"/>
    </scalingPolicy>
  </scalingDefinitions>
</server>
```

The `bind` element must specify the name of the cluster to be deployed in a server package. In this example, the `bind` element specifies `cluster1`. If your cluster member definition does not specify a cluster name, specify `defaultCluster`.

3. Place the `scaling-metadata.xml` file in the cluster member configuration directory.

The directory is `${wlp.install.dir}/usr/servers/cluster_member_name` or, if the `$WLP_USER_DIR` variable is set in a `server.env` file or command window, `$WLP_USER_DIR/servers/cluster_member_name`.

The product deploys the scaling policy to the collective repository when the following events occur:

- The cluster member connects with the controller, such as when the cluster member starts
- The `clusterMember` feature name attribute changes
- The `scaling-metadata.xml` file changes for the cluster member

The product monitors the `scaling-metadata.xml` file after the cluster member starts and dynamically deploys any file changes to the collective repository. If the cluster member is removed from the collective controller through the collective remove command, the product undeploys the scaling policy from the collective repository.

4. Optional: Package the cluster member into a server package and deploy the package.

- a. Package the cluster member into a server package.

Available tools for packaging archives include:

- The Liberty server **package** command. Sample command syntax is:

```
wlp/bin/server package cluster_member_name --include=all | minify --archive=cluster_member_name.zip | jar | pax
```

- The **package** action in the WebSphere Developer Tools for Eclipse product.

For example, to use the package command:

- 1) Stop the cluster member if it is running.
- 2) Run the **package** command to create the server package. For example, if the cluster member name is clusterMember1, run:

```
wlp/bin/server package clusterMember1
```

The command creates a server package named, for example, C:\wlp\usr\servers\clusterMember1\clusterMember1.zip on Windows computers.

You might need to customize the installation by changing port numbers, database connections, or messaging system connections.

- b. Deploy the server package to host computers.

Available tools for deploying packages include:

- Deploy tool of Admin Center
- FileTransfer MBean
- Server package deployment through DevOps, such as Chef. For information about DevOps, see the WASdev website.
- Server package manual deployment
- Change to deployed server

## Entering maintenance mode for Liberty collectives

8.5.5.7

Enter maintenance mode before you perform diagnostic tests, maintenance, or tuning, on a host or server. Maintenance mode can prevent the disruption of client requests by routing client traffic around a server that is in maintenance mode, to another server.

### About this task

When a server that is a scaling member is in maintenance mode, the scaling controller cannot start or stop that server. The server does not count toward the minimum or maximum running instance settings for the cluster.

**Note:** To achieve the full advantages of using maintenance mode in a Liberty collective, it is recommended that you enable the dynamic routing feature, auto scaling feature, or both of these features. For more information about the dynamic routing and auto scaling features, see “Setting up dynamic routing for Liberty collectives” on page 1493 and “Setting up auto scaling for Liberty collectives” on page 1503.

When a host is in maintenance mode, the scaling controller cannot provision a new server on that host.

You can enter maintenance mode on a server that is joined to a collective or on a host that is registered to a collective.

You can use maintenance mode to alter the routing of requests by a web server that is enabled for Intelligent Management.

Entering a server or a host into maintenance mode is a persistent change. A server or host remains in maintenance mode even if the server is restarted until the mode is explicitly changed.

## Procedure

1. Use the collective **enterMaintenanceMode** command to place a server or a host and its servers into maintenance mode.

```
wlp/bin/collective enterMaintenanceMode
  --host=controllerHostName
  --port=controllerHttpsPortNumber
  --user=adminUser
  --password=adminPassword
  --hostName=serverHostName
  [--usrDir=serverUserDirectory]
  [--server=serverName]
  [--break]
  [--force]
```

The `--host` and `--port` arguments identify which collective controller can process the command. The `--user` and `--password` arguments are the administrative user ID and password for authenticating with the controller.

The `--hostName`, `--usrDir`, and `--server` arguments identify the server to be placed into maintenance mode. If you want to place a host and its servers into maintenance mode, provide the `--hostName` argument only and omit the `--usrDir` and `--server` arguments.

By default, the web server continues to send requests with affinity to a server in maintenance mode. Use `--break` to stop any traffic from being routed to the server, including requests with affinity to the server.

The scaling controller starts another server to replace each scaling member that is placed into maintenance mode. Another server will be started to meet the minimum number of instances of the cluster or to meet current workload demand. By default, if the scaling controller cannot find another server to act as a replacement the server is not placed into maintenance mode. Use the `--force` argument to cause a server to be placed into maintenance mode even if no replacement server is available.

2. Use the collective **exitMaintenanceMode** command to take a server or a host and its servers out of maintenance mode.

```
wlp/bin/collective exitMaintenanceMode
  --host=controllerHostName
  --port=controllerHttpsPortNumber
  --user=adminUser
  --password=adminPassword
  --hostName=serverHostName
  [--usrDir=serverUserDirectory]
  [--server=serverName]
```

3. Use the collective **getMaintenanceMode** command to display whether a server or a host and its servers are in maintenance mode.

```
wlp/bin/collective getMaintenanceMode
  --host=controllerHostName
  --port=controllerHttpsPortNumber
  --user=adminUser
  --password=adminPassword
  --hostName=serverHostName
  [--usrDir=serverUserDirectory]
  [--server=serverName]
```

## Example

In this example, the **hostc** has a collective controller. The collective controller has the scaling controller and dynamic routing features enabled. In the `server.xml` file of the scaling controller, the minimum number of active cluster members is set to 1. **Host1** has two started cluster members, *memberA1* for *cluster A* and *memberB1* for *cluster B*. **Host2** has one stopped cluster member, *memberA2* for *cluster A*. All cluster members have the scaling member feature enabled. A web server that is enabled for Intelligent Management also exists, which is routing requests to the cluster members.

To put **host1** into maintenance mode, enter the following command:

```
wlp/bin/collective enterMaintenanceMode
--host=hostc
--port=controller1HttpsPortNumber
--user=adminUser
--password=adminPassword
--hostName=host1
```

The command issues the following response:

Successfully enter maintenance mode for host1.

An alternate server must be started. Maintenance mode will be set for memberA1 when the alternate server is started. Could not enter maintenance mode for memberB1 because an alternate server is not available.

The scaling controller starts *memberA2* as a replacement for *memberA1*. After *memberA2* is started, then *memberA1* is placed into maintenance mode. The web server no longer routes HTTP requests to *memberA1*.

The scaling controller cannot replace *memberB1*, therefore the member is not placed into maintenance mode. You can run the command again by using the `--force` argument to force *memberB1* to be placed into maintenance mode, which can affect the performance of the requests running in *clusterB*.

## What to do next

The health controller also uses server maintenance mode as an action that is taken when the health policy is breached. For example, if you are using an excessive response time condition, and the response time exceeds the specified average response time threshold for a server, then the server can move to maintenance mode.

## Maintenance mode

8.5.5.7

The maintenance mode feature allows a host or server to be taken offline without disrupting service. Maintenance mode works with the dynamic routing and auto scaling features to prevent the disruption of client requests by routing client traffic that is targeted for a server that is in maintenance mode, to another server. Enter maintenance mode before you perform diagnostic tests, maintenance, or tuning, on a host or server.

### Server maintenance mode

- A server in maintenance mode is not included in the count of active servers in an auto scaled cluster.
- When a server is in maintenance mode the dynamic routing feature routes requests to other servers in the collective.

### Host maintenance mode

- All servers on the host are entered in to maintenance mode when the host is placed in maintenance mode.
- All servers move out of maintenance mode when a host is taken out of maintenance mode.
- A host in maintenance mode makes that host unavailable for provisioning a new Liberty instance.
- Any server on a host in maintenance mode may be individually taken out of maintenance mode while a host remains in maintenance mode.

## Maintenance mode collective command options

Maintenance mode is controlled by an administrator by using the collective command. This command is expanded to include syntax for entering or exiting maintenance mode.

## Command Syntax

- `collective enterMaintenanceMode [options]`
- `collective exitMaintenanceMode [options]`
- `collective getMaintenanceMode [options]`

## Base collective command options

### **--host="controller host name"**

Required – Name of the host on which the collective controller resides.

### **--port="controller HTTPS port"**

Required – Specifies the HTTPS port number of the target collective controller.

### **--user="user"**

Required – The administrative user of the target collective controller.

### **--password="password"**

Required – The administrative user's password.

## Maintenance mode specific options

### **--hostName="target Host Name"**

Required – The name of the host going into maintenance mode or the host that contains the server going into maintenance mode.

### **--usrDir="Liberty installation directory"**

Required for Server – The root directory where Liberty is installed on the host.

### **--server="server Name"**

Required for Server – The name of the server being placed into maintenance mode

### **--break**

Applies to `enterMaintenanceMode` only.

When not specified the default is to stop new traffic to the server, but allow traffic with affinity to continue to use the server that has entered maintenance mode. When `--break` is specified all requests are routed to another server.

### **--force**

Applies to `enterMaintenanceMode` only.

When `--force` is specified, the server will be forced to enter maintenance mode even if an auto scaling policy will be violated.

## Configuring health management for Liberty

8.5.5.7

Health management in a Liberty collective can prevent the disruption of service by detecting common problems and generating diagnostic actions based on configured health policies. The health management functions are enabled by two Liberty features, health manager and health analyzer.

### Before you begin

- Create the environment that you want to monitor. When creating a health policy, have in mind the target of the policy (server, cluster or host).
- If you want to gain the full functionality of the health management feature, it is recommended that both the auto scaling and dynamic routing features be enabled. For more information, see “Setting up auto scaling for Liberty collectives” on page 1503 and “Setting up dynamic routing for Liberty collectives” on page 1493.

- The types of collected resource usage information varies among JRE/JDKs. Go to <http://www.ibm.com/developerworks/java/jdk/index.html> on the developerWorks website and download an IBM JRE/JDK for your operating system. The developerWorks website does not have a JRE for all operating systems. For example, you must get the JDK from Eclipse for Windows operating systems. The following IBM Java versions for Windows and Linux operating systems provide all necessary usage information and are the preferred JRE/JDKs.
  - Java 8
  - Java 7 Fix Pack 8 and above
  - Java 6 Fix Pack 7 and above

**Note:** Health Center generates temporary tmp files in the /tmp space, and depending on /tmp space limits, you might want to change the java.io.tmpdir to avoid filling the /tmp space, which can cause unrecoverable issues on some platforms.

```
-Djava.io.tmpdir=/path/to/tmpdir
```

**Note:** Windows For Windows users, the root user does not have read/write permission to the C:\Windows\Temp directory unless you are an administrator. You might want to change the permission of the C:\Windows\Temp directory to avoid this issue.

## About this task

You can create health policies for common server health conditions. For more information, see “Health management” on page 1521.

You can also assign the following actions for health conditions:

- Capture diagnostics (heap dump and thread dump)
- Restart server
- Enter server into maintenance mode
- Exit server out of maintenance mode. For use within the same health policy, where an earlier action entered maintenance mode prior to performing other actions.

 **Watch:** Video: Health management for Liberty collectives provides an overview of health management and demonstrates how it can help find and mitigate problems in your Liberty applications. [Transcript]

## Procedure

1. Create a collective. For details on creating a collective controller and member server, see “Configuring a Liberty collective” on page 1136.
2. Add the healthManager-1.0 feature to the feature manager stanza in the server.xml file of one or more collective controllers. This feature can only be added to collective controllers.

```
<featureManager>
  <feature>jsp-2.2</feature>
  <feature>collectiveController-1.0</feature>
  <feature>healthManager-1.0</feature>
</featureManager>
```

After you add the feature, the following message in the messages.log file of the collective controller, provided the collective controller is running,

```
CWWKV0600I: The HealthManager feature is activated.
```

3. Add the `healthAnalyzer-1.0` feature to the feature manager stanza of the `server.xml` file of the collective member. The `healthAnalyzer` feature is necessary for monitoring excessive memory usage and memory leak.

```
<featureManager>
  <feature>collectiveMember-1.0</feature>
  <feature>healthAnalyzer-1.0</feature>
</featureManager>
```

After you add the feature, the following message displays in the `messages.log` file of the collective controller, provided the collective controller is running.

```
CWKKV0750I: The healthAnalyzer feature has been activated.
```

When the `healthAnalyzer` feature is activated on the collective member, the following message displays in the `messages.log` file of the collective controller.

```
CWKKV0612I: The Health Analyzer is activated in member_host_name,path_to_usr_directory,member_name.
```

**Note:** If you want to activate both the `healthAnalyzer` and `scalingMember` features, the `hostSingleton` specification must have a unique port separately set for each service .

```
<hostSingleton name="ScalingMemberSingletonService" port="33333">
<hostSingleton name="HealthAnalyzerSingletonService" port="33334">
```

4. If you want to target clusters, you must also configure the collective members to be a part of a server cluster.

For more information about server clusters, see “Setting up Liberty server clusters” on page 1153.

5. Add one or more `healthPolicy` elements to the `server.xml` file of the collective controller. Each `healthPolicy` element defines a single health policy. If more than one policy is needed, multiple health policy elements can be added to the `server.xml` file. For more information about adding `healthPolicy` elements to the `server.xml` file, see “Health management policies for Liberty” on page 1523.

## Results

With health policies enabled, Intelligent Management can monitor collective members for problems, and perform diagnostic actions.

## Health management

8.5.5.7

With the health management feature in Liberty, you can take a policy-driven approach to monitoring the application server environment and take action when unhealthy criteria is discovered.

You can define the health policies, which include the health conditions to be monitored in your environment and the health actions to take if these conditions are met.

### Health conditions

Health conditions define the variables that you want to monitor in your environment. The condition element defines what behavior can trigger this health policy. Only one condition element can be defined per health policy. You can choose from the following predefined health conditions:

#### Excessive request timeout condition

Specifies a percentage of HTTP requests that can time out. When the percentage of requests exceeds the defined value, the health actions run. The timeout value depends on your environment configuration.

```
<excessiveRequestTimeout timeoutPercentage="5"/>
```

**Note:** Dynamic Routing must be enabled to use this condition.

### Excessive response time condition

Tracks the average amount of time that requests take to complete. If the time exceeds the defined response time threshold, the health actions run.

```
<excessiveResponseTime responseTime="10s"/>
```

**Note:** Requests that exceed the timeout value that is configured for the excessive request timeout condition are not counted towards this health condition. For example, if the default timeout value is set to 60 seconds, then any request that exceeds 60 seconds will time out and is not included in the average response time calculation for this health condition. This restriction applies even if you do not have an excessive request timeout condition defined.

**Note:** Dynamic Routing must be enabled in to use this condition.

### Memory condition: excessive memory usage

Tracks the memory usage for a member. When the memory usage exceeds a percentage of the heap size for a specified time, health actions run.

```
<excessiveMemoryUsage heapSizePercentage="85" timePeriod="5m"/>
```

### Memory condition: memory leak

When a downward trend in free memory is detected, health actions run.

```
<memoryLeak/>
```

## Health actions

Health actions define the activities to perform when a health condition is not met. Action elements define what action will be taken in response to a detected condition. All actions share the element type of `<action>`. The action attribute determines which action is taken and multiple actions can be defined for each health policy. Actions are run in the order they are specified in the policy. The following table lists the health actions that are supported in Liberty server environments:

Table 111. Predefined health action support for Liberty servers

Health action	Liberty servers that run in the same collective controller
Restart server	Supported
Take thread dumps	Supported
Take Java virtual machine (JVM) heap dumps	Supported for servers that are running on the IBM JRE or JDK
Enter server into maintenance mode	Supported
Exit server out of maintenance mode	Supported

```
<action action="generateThreadDump"/>  
<action action="generateHeapDump"/>  
<action action="restartServer"/>  
<action action="enterMaintenanceMode"/>  
<action action="exitMaintenanceMode"/>
```

## Health targets

Target elements define the scope of the topology that is being monitored for the condition. There are three target types:

- A host  

```
<host hostName="someHost"/>
```
- Each of the servers in a cluster  

```
<cluster clusterName="someCluster"/>
```
- A single-server

```
<server hostName="Host" wlpUsrDirectory="/opt/ibm/liberty/wlp" serverName="Server"/>
```

Each target type has a unique element that is used to define it within the `healthPolicy` element. More than one target can be specified per health policy.

## Health management policies for Liberty

8.5.5.7

You can define the health policies, which include the health conditions that you want to monitor in your environment and the health actions to take if these conditions are met.

### About this task

Health policies are configured in the same manner as other Liberty features. Within the `server.xml` file configuration, a new element type of `<healthPolicy>` is used to define a single health policy. If more than one policy is needed, multiple health policy elements can be added to the `server.xml` file.

### Procedure

1. Insert the health policy into the `server.xml` file and provide an identity for the health policy.
2. Add the desired target elements to the health policy stanza in the `server.xml` file.

**Note:** More than one target can be specified per health policy.

3. Specify the condition that is being monitored within the health policy stanza.

**Note:** Only one condition per policy is allowed.

4. Specify the actions within the health policy stanza.

**Note:** You can specify more than one action per health policy. If more than one action is specified, the actions are run in the order they are defined in the policy.

For more information about health policy target elements, see “Health management” on page 1521.

### Example

In this example, the health policy specifies that all servers in cluster `mycluster1` and all servers on host `myHost` are monitored for excessive memory usage. The policy monitors the `excessiveMemoryUsage` condition based on the specified thresholds. The policy instructs the health management controller to place the server experiencing the excessive memory usage into maintenance mode and request a heap dump from that server.

```
<healthPolicy id="myHealthPolicy" >
  <cluster clusterName="mycluster1"/>
  <host hostName="myHost"/>
  <excessiveMemoryUsage heapSizePercentage="85" timePeriod="5m"/>
  <action action="enterMaintenanceMode"/>
  <action action="generateHeapDump"/>
</healthPolicy>
```

When a health policy is added, the following messages display in any order in the `messages.log` file of the collective controller.

```
CWWKV0609I: The health policy myHealthPolicy is added.
```

```
CWWKV0603I: The health condition com.ibm.ws.health.manager.healthPolicy.condition.excessiveMemoryUsage is being monitored
```

```
CWWKV0607I: The health policy myHealthPolicy is activated for member_host_name,path_to_usr_directory,member_name.
```

**Note:** Messages CWWKV0603I and CWWKV0607I display when there is at least one member server in the collective that is identified in a target element.

When a health policy is modified, the following messages display in any order in the `messages.log` file of the collective controller.

```
CWWKV0610I: The health policy myHealthPolicy is removed.
```

```
CWWKV0604I: The health condition com.ibm.ws.health.manager.healthPolicy.condition.excessiveMemoryUsage is no longer being m
```

```
CWWKV0609I: The health policy myHealthPolicy is added.
```

```
CWWKV0603I: The health condition com.ibm.ws.health.manager.healthPolicy.condition.excessiveMemoryUsage is being monitored o
```

## Liberty collective troubleshooting

### 8.5.5.0

There are a number of common issues you might encounter when troubleshooting Liberty. As to collectives, the issues typically relate to configuration of the collective controller, member, or host system. Browse the list of issues to learn how to resolve the issues.

- Issues involving connection
  - “CWWKO0801E: Unable to initialize SSL connection. Unauthorized access was denied or security settings have expired.”
  - CWWKX0217E: No MBean is currently registered with the given *object\_name*
  - CWWKX0215E: There was a problem with the user name or password provided
  - CWWKX8057I: The collective member is unable to establish a connection to any of the collective controllers. Configured controllers: [*host\_name:port\_number*]
  - Error: Connection refused: connect
  - `java.net.SocketException` error
- Issues involving **start** and **stop** commands
  - Starting or stopping the servers remotely causes a Java not found error
  - CTGRI0000E: Could not establish a connection to the target machine with the authorization credentials that were provided
  - CTGRI0001E: The application could not establish a connection to *host\_name*
  - **8.5.5.4** CTGRI0026E A connection could not be completed to *host\_name* during the specified timeout interval
  - CWWKX6027E: The collective controller initialization did not succeed. The socket bind did not succeed for host *host\_name* and port *port\_number*. The port might already be in use or the host does not match the system configuration.
  - CWWKX7204E: Cannot connect to host *host\_name* with the credentials provided

For fixes to other issues, see “Liberty:Runtime environment known issues and restrictions” on page 2333.

## Issues involving connection

**CWWKO0801E: Unable to initialize SSL connection. Unauthorized access was denied or security settings have expired.**

Message:

```
CWWK00801E: Unable to initialize SSL connection.  
Unauthorized access was denied or security settings have expired.  
Exception is javax.net.ssl.SSLHandshakeException:  
Client requested protocol TLSv1 not enabled or not supported
```

Cause:

TLSv1.2 security might be improperly configured for a collective controller and its member servers. The members cannot communicate with the controller.

Ensure the `server.xml` file for the controller and each member has `ssl id` elements for the TLSv1.2 SSL protocol; for example:

```
<ssl id="defaultSSLConfig"  
    sslProtocol="TLSv1.2"  
    keyStoreRef="defaultKeyStore"  
    trustStoreRef="defaultTrustStore"  
    clientAuthenticationSupported="true" />
```

```
<ssl id="controllerConnectionConfig"
    sslProtocol="TLSv1.2"/>

<ssl id="memberConnectionConfig"
    sslProtocol="TLSv1.2"/>
```

To enable members to communicate with the controller, you might also need to add an `etc` directory to the main Liberty installation directory on each host and add a `server.env` file to the `${wlp.install.dir}/etc` directory. Ensure the `server.env` file has the following content:

```
JVM_ARGS=-Dhttps.protocols=TLSv1.2
```

See “Setting up Liberty to run in SP800-131a” on page 1848.

#### **CWWKX0217E: No MBean is currently registered with the given *object\_name***

Message:

```
Error: CWWKX0217E: No MBean is currently registered with the given ObjectName 'WebSphere:feature=collectiveController,type=Collect
```

Cause:

The MBean might not be available yet. Check the server logs to see if the MBean has reported ready.

There might have been a problem starting the collective repository. Check to see if the collective repository has started.

If the target is a collective controller, verify that the replica set is active. If a majority of the collective controller replicas are not started, this message will be seen. Start the remaining replicas.

The servers configuration might be incomplete. Make sure that the server is properly configured.

#### **CWWKX0215E: There was a problem with the user name or password provided.**

Message:

```
Error: CWWKX0215E: There was a problem with the user name or password provided. The server responded with code 401 and message 'Un
```

Cause:

The username and password might be incorrect. Make sure that the username and password are correct for the target server.

The user might not be granted the Administrator role. Make sure that the user is granted the Administrative role, or choose a different user.

The security configuration for the target server might be incomplete. Make sure that the security configuration is defined and the security service reports as ready (CWWKS0008I).

#### **| CWWKX8057I: The collective member is unable to establish a connection to any of the collective | controllers. Configured controllers: [host\_name:port\_number]**

Message:

```
CWWKX8057I: The collective member is unable to establish a connection to any of the collective controllers. Configured controllers
```

Cause:

The servers might not be running. Verify that the collective controller and member servers are running.

If the servers are running, determine whether the SSL configuration in the `server.xml` of the controller or a member changed recently. If this CWWKX8057I message occurs in the member, then the controller is more likely to have an incorrect SSL configuration. If this message occurs in the controller, then a member is more likely to have an incorrect SSL configuration. The problem can occur when a configuration does not use a `quickStartSecurity` element.

To fix a problem with the SSL configuration, check the following in the `server.xml` file:

1. Ensure the administrator role is configured. “Mapping the administrator role for Liberty” on page 1644 compares `quickStartSecurity` element settings to those for basic or LDAP registry.
2. Review and update the SSL configuration as needed.

- a. Check any default SSL configuration. Look for `<sslDefault sslRef="LDAPSSLSettings"></sslDefault>` to see if the `server.xml` file contains a default configuration and to see if it is necessary to specify one SSL configuration as the default.

If the `<sslDefault sslRef="LDAPSSLSettings"></sslDefault>` configuration is not necessary, remove it so the configuration has two or more SSL configurations (for example, one for the collective, one for LDAP) to use.

If the default configuration is necessary, keep the `<sslDefault sslRef="LDAPSSLSettings"></sslDefault>` line and proceed to steps b and c to add client authentication and import certificates to the default SSL configuration. See “Configuring LDAP user registries in Liberty” on page 1852.

- b. Enable client authentication. Configure the HTTPS port for the server with `clientAuthenticationSupported="true"`.

For example, a collective controller that uses LDAP SSL default for security must have `clientAuthenticationSupported="true"` in its `ssl` element to work with a collective member.

- c. Import necessary certificates. You can use `keytool` to import certificates. The default truststore must include certificates from `collectiveTrust.jks`.

Background information:

By default, `<sslDefault sslRef>` points to `defaultSSLSettings`. Changing `<sslDefault sslRef>` in the collective controller configuration to point to something other than `defaultSSLSettings`, such as `<sslDefault sslRef="LDAPSSLSettings"/>`, causes the CWWKX8057I error unless the configuration has `clientAuthenticationSupported="true"` and the Liberty server trusts any SSL peer that has a client certificate.

SSL settings for HTTPS must trust the collective certificates. Changing `<sslDefault sslRef>` to point to something other than `defaultSSLSettings` without `clientAuthenticationSupported="true"` can unbind the `defaultSSLSettings` from their HTTPS configuration. The collective SSL settings are part of the default configuration.

For more information, see “Mapping the administrator role for Liberty” on page 1644, “Configuring LDAP user registries in Liberty” on page 1852, and “Configuring an `httpEndpoint` to use an SSL configuration other than the default” on page 1850.

#### **Error: Connection refused: connect**

Message:

Error: Connection refused: connect

Cause:

The host and port might be incorrect. Make sure that the host and port are correct for the target server.

The server might not be running. Make sure that the server is running.

#### **java.net.SocketException error**

Message:

java.net.SocketException: java.security.NoSuchAlgorithmException: Error constructing implementation (algorithm: Default, provider: Su

Cause:

The truststore and truststore password might be incorrect. Make sure that the truststore path, truststore password, and contents of the truststore are correct.

## Issues involving start and stop commands

### Starting or stopping the servers remotely causes a Java not found error

Message:

Starting or stopping the servers remotely (using **ClusterManager.startCluster** or **ServerCommands.startServer** for example) encounters the following error:

```
{stderr=java: javaCmd 14: serverCmd 32: ./server 873: FSUM7351 not found, stdout=, returnCode=127}
```

Solution:

The member servers need a `server.env` file that specifies a `JAVA_HOME` variable.

### CTGRI0000E: Could not establish a connection to the target machine with the authorization credentials that were provided.

Message:

```
CTGRI0000E Could not establish a connection to the target machine with the authorization credentials that were provided.
```

Cause:

Authentication fails using user name or password:

- Make sure that the user name and password are correct in the target server's `server.xml` `<hostAuthConfig>` element.
- Update the host authentication configuration using the collective **updateHost** command.

Authentication fails using ssh keys:

- Check permissions on:
  - `~/ssh` should be `0700`
  - `~/ssh/authorized_keys` should be `0600`
- `~/ssh` and all children must be correct if using SELinux. Use **restorecon -R** to fix the permissions.

### CTGRI0001E: The application could not establish a connection to *host\_name*.

Message:

```
{ExceptionMessage=ConnectException caught while performing stopCluster operation on member webpla.ibm.com,/P1A/WebSphere_LP/usr,me  
CTGRI0001E The application could not establish a connection to webpla.ibm.com., Exception=java.net.ConnectException: CTGRI0001E Th
```

Cause:

Starting or stopping the servers remotely using commands such as **ClusterManager.startCluster** or **ServerCommands.startServer** can cause the error.

**8.5.5.4** Message CTGRI0001E, along with message CTGRI0026E, can indicate that too many concurrent SSH connections are made to a host. Possible causes are:

- Autonomics such as scaling controller
- Running **ClusterManager.startCluster**, **ServerCommands.startServer**, or other system management commands on a number of servers on a single host that exceeds the maximum number of concurrent unauthenticated connections to the SSH daemon.

Solution:

Confirm that the RPC mechanism (such as SSH) is started. Also confirm that the configured settings, such as host and port, are correct.

**8.5.5.4** If your environment uses SSH, change the settings in the SSH configuration file. The SSH configuration `MaxStartups` setting has a default of 10 concurrent unauthenticated connections. Changing the `MaxStartups` setting in the SSH configuration file,

`/etc/ssh/sshd_config`, can solve the problem. The `MaxStartups` setting specifies the maximum number of concurrent unauthenticated connections to the SSH daemon. Additional connections are dropped until authentication succeeds or the `LoginGraceTime` expires for a connection. You can enable random early drop by specifying the three colon separated values `start:rate:full` (for example, `10:30:60`). `sshd(8)` refuses connection attempts with a probability of `rate/100` (30%) if there are currently `start` (10) unauthenticated connections. The probability increases linearly and all connection attempts are refused if the number of unauthenticated connections reaches `full` (60). The following sample SSH configuration file settings specify `MaxStartups` and other settings that can alleviate connection problems:

```
ClientAliveInterval 60
ClientAliveCountMax 3
MaxSessions 100
MaxStartups 100:30:200
LoginGraceTime 180
```

For more information about Secure Shell (SSH) protocol and changing `/etc/ssh/sshd_config` settings, see “Setting up RXA for Liberty collective operations” on page 1491.

**8.5.5.4 CTGRI0026E A connection could not be completed to `host_name` during the specified timeout interval.**

Message:

```
CTGRI0026E A connection could not be completed to webpla.ibm.com during the specified timeout interval.
```

Cause:

Too many concurrent SSH connections to a host can cause this error.Solution:

See the solution for message CTGRI0001E.

**CWWKX6027E: The collective controller initialization did not succeed. The socket bind did not succeed for host `host_name` and port `port_number`. The port might already be in use or the host does not match the system configuration.**

Message:

```
CWWKX6027E: The collective controller initialization did not succeed. The socket bind did not succeed for host * and port 10,010. The
```

Solution:

Ensure that the host value specified in the collective controller configuration is correct. For example, if the collective controller resides on `myhost.com`, check the `server.xml` file of the controller to ensure the host value is correct:

```
<variable name="defaultHostName" value="myhost.com" />
```

The example message shows an asterisk (\*) for host, suggesting that the host value probably did not cause the problem. The likely cause of the problem is a port conflict.

Ensure that the port number in the message is not already in use. At a command line on the host computer where the collective controller resides, run `netstat -a` to see a list of port numbers and the status of the connections. If the port number is in use, the list contains an entry such as the following for port 10,010:

```
TCP 127.0.0.1:10010 myhost:0 LISTENING
```

To fix this port conflict, open an editor on the `server.xml` file of the collective controller and add a statement that sets `replicaPort` to a port number that is not in use on the computer. Any of the following statements can set a `replicaPort` value:

- `<collectiveController replicaPort="10011"/>`
- `<collectiveController replicaHost="myhost.com" replicaPort="10011"/>`
- `<collectiveController replicaPort="{prop.controller_1.replica}"/>`

Set the variable for the port number, which has the name `prop.controller_1.replica` in this statement but which can have any variable name you choose, in a `bootstrap.properties` file or in a `<variable name="name" value="value"/>` XML tag.

#### **CWWKX7204E: Cannot connect to host *host\_name* with the credentials provided.**

Message:

```
localhost,C:/wlp,member1 stop operation resulted in an Exception: ConnectException caught while performing stopCluster operation o
CWWKX7204E: Cannot connect to host localhost with the credentials provided.
```

Solution:

Make sure that the cluster member authentication information is set correctly and that all Remote Execution and Access (RXA) requirements are met. Many RXA operations require access to resources that are not generally accessible by standard user accounts. See “Setting up RXA for Liberty collective operations” on page 1491 for more information.

---

## Setting up a Liberty server to use Bluemix services

8.5.5.9

You can configure a Liberty server to use Bluemix services. Not all Bluemix services are available for configuration.

### bluemixUtility command

8.5.5.9

Use the IBM Bluemix command-line utility to configure your on-premises Liberty server to use certain Bluemix cloud services.

#### Sources

Learn about Bluemix services, such as Watson and Cloudant® services, that you can use with the command-line utility.

- To register for or log in to a Bluemix account, see [Sign up for IBM Bluemix](#).
- To learn more about Watson, see [Watson services](#).
- To learn more about Cloudant services, see [Getting started with Cloudant NoSQL DB](#).

#### Syntax

The command syntax is as follows:

```
bluemixUtility action [options]
```

Use the following *action* commands:

**login** Log in to Bluemix. If you run the **login** command without any options, the tool prompts you for more information, such as username and password. After a successful login, Bluemix credentials are saved to a file so that you can run other commands without specifying username and password again.

If you log in to Bluemix with the Cloud Foundry (cf) client, the `bluemixUtility` uses the credentials saved by the `cf` client. For more information, see [Cloud Foundry \(cf\) commands](#).

#### **marketplace**

List all the Bluemix services that can be configured by using the command-line utility.

#### **createService**

Create a service instance from the Bluemix catalog.

**listServices**

List all the available Bluemix service instances.

**showService**

Show information about a service instance.

**import**

Import a configuration for a service. The imported service configuration and its dependencies are placed in the following directory:

```
`${wlp.user.dir}/shared/config/services/serviceName
```

**listImports**

List all imported service configurations that can be bound to a Liberty server.

**bind**

Bind a Bluemix service configuration to a Liberty server. The configuration for a service may provide default values for certain options, such as the `jndiName` of a `dataSource` element. In some cases, the default values do not match what the application expects. Use the `--v` option to override a default value with the value that your application expects.

**unbind**

Unbind a service configuration from a Liberty server.

**deleteService**

Delete a service instance.

**switch** Switch to a different Bluemix organization or space.

**info** View Bluemix connection information.

**help** Use the help action on each command to view descriptions, usage, and options.

**logout** Log out of Bluemix. The **logout** command deletes the file that was created when you logged in with Bluemix credentials.

## Usage

View usage examples that you can run for each action.

Use the following command to run the **login** action:

```
bluemixUtility login [options]
```

Use the following command to run the **marketplace** action:

```
bluemixUtility marketplace [serviceType...]
```

Use the following command to run the **createService** action:

```
bluemixUtility createService [options] serviceType servicePlan serviceName
```

Use the following command to run the **listServices** action:

```
bluemixUtility listServices
```

Use the following command to run the **showService** action:

```
bluemixUtility showService [options] serviceName
```

Use the following command to run the **import** action:

```
bluemixUtility import [options] serviceName
```

Use the following command to run the **listImports** action:

```
bluemixUtility listImports [serverName]
```

Use the following command to run the **bind** action:

```
bluemixUtility bind [options] serverName serviceName
```

Use the following command to run the **unbind** action:

```
bluemixUtility unbind serverName serviceName
```

Use the following command to run the **deleteService** action:

```
bluemixUtility deleteService [options] serviceName
```

Use the following command to run the **switch** action:

```
bluemixUtility switch [options]
```

Use the following command to run the **logout** action:

```
bluemixUtility logout
```

## Options

View the available options for each action.

The following options are available for the **bluemixUtility login** command:

### **--api=url**

Bluemix API endpoint, for example, `https://api.ng.bluemix.net`. The API endpoint can also be set as the Bluemix region name. For example, it can be set to `us-south` for the US South region, `eu-gb` for the London, UK region, and `au-syd` for the Sydney, Australia region.

### **--user=username**

User name of Bluemix account.

### **--password=password**

Password of Bluemix account.

### **--org=organizationName**

Organization name.

### **--space=spaceName**

Space name.

The following options are available for the **bluemixUtility marketplace** command:

### **[serviceType...]**

Show detailed information about a particular Bluemix service. Specify multiple service names by separating them with a space.

The following options are available for the **bluemixUtility createService** command:

### **--credentialName=name**

The name of the service credential. By default, `credential-1` is used.

### **serviceType**

The type of service to create.

### **servicePlan**

The name of service plan.

### **serviceName**

The name of service to create.

No options are available for the **bluemixUtility listServices** command.

The following options are available for the **bluemixUtility showService** command:

**--showCredentials**  
Display service credentials.

**serviceName**  
The name of a Bluemix service.

The following options are available for the **bluemixUtility import** command:

**--acceptLicense**  
Automatically indicate acceptance of license terms and conditions.

**--credentialName=name**  
The name of the service credential. By default, the first credential that is found is used.

**--encodeAlgorithm=[xor|aes]**  
Specifies how to encode sensitive information in the imported service configuration. Supported encodings values are **xor** and **aes**. The default encoding algorithm is **xor**.

**--encodeKey=key**  
Specifies the key to be used when you are encoding with AES encryption. If this option is not provided, a default key is used.

**--p[parameter]=value**  
Specifies parameters that help in generating and importing a configuration for a service.

**serviceName**  
The name of a Bluemix service.

The following options are available for the **bluemixUtility listImports** command:

**[serverName]**  
List the services that are already bound to this particular server.

The following options are available for the **bluemixUtility bind** command:

**--v[variable]=value**  
Override variables in the imported service configuration.

**--acceptLicense**  
Automatically indicate acceptance of license terms and conditions.

**serverName**  
Name of the server to bind to the service configuration.

**serviceName**  
Name of the imported service configuration.

The following options are available for the **bluemixUtility unbind** command:

**serverName**  
Name of the server to unbind the service configuration from.

**serviceName**  
Name of the service configuration to unbind.

The following options are available for the **bluemixUtility deleteService** command:

**--force** Force deletion without confirmation.

**serviceName**  
Name of the service to delete.

The following options are available for the **bluemixUtility switch** command:

**--org=organizationName**  
Organization name.

**--space=spaceName**  
Space name.

No options are available for the **bluemixUtility info** command.

No options are available for the **bluemixUtility logout** command.

## Return codes

Table 112. Return codes and explanations

Return code	Explanation
0	The command successfully completed the requested operation.
20	One or more command-line arguments or options are not valid.
21	An unknown runtime exception has occurred.
22	An IO error occurred, typically when trying to delete a file from the file system.
24	User abort. Occurs when user fails to respond to a prompt or cancels the operation.
26	An unknown exception has occurred.
27	Bluemix authentication error when attempting to log in, or attempting to perform a task without being logged in.
28	A generic error when communicating with Bluemix.
29	A generic error when communicating with the configuration service.
30	A generic service configuration error has occurred.
31	A generic feature installation error has occurred.
255	An unknown error has occurred.

## Configuring Liberty for Bluemix Cloudant services

8.5.5.9

Use the IBM Bluemix utility command-line integration tool to configure your Liberty server to use the Bluemix Cloudant service.

### Before you begin

Before you configure your Liberty server to use Bluemix services, you must create an account. See Sign up for IBM Bluemix to create your Bluemix account.

### About this task

Configure your Liberty server to use the Cloudant service. For more information about Cloudant, see Getting started with Cloudant NoSQL DB.

## Procedure

1. Log in using the **bluemixUtility login** command. After your initial login, you do not have to complete this step again.
2. Run the **bluemixUtility marketplace** command to list details about all the Bluemix services that can be used with the command-line utility. See the following example:

Service: cloudbantNoSQLDB

Description: Cloudant NoSQL DB is a fully managed data layer designed for modern web and mobile applications that leverage Cloudant is built upon and compatible with Apache CouchDB and accessible through a secure HTTPS API, which scales as you Cloudant is ISO27001 and SOC2 Type 1 certified, and all data is stored in triplicate across separate physical nodes in a Documentation: <https://console.ng.bluemix.net/docs/#services/Cloudant/index.html#Cloudant>  
Plans: Standard, Lite

3.

**Note:** If you already created an instance, skip to step 4. You can also create an instance from the Bluemix dashboard.

Run the `bluemixUtility createService [options] serviceType servicePlan serviceName` command to create an instance of the Bluemix services that you want to use. See the following example and description of a service listed:

```
bluemixUtility createService cloudbantNoSQLDB Lite myCloudantService
```

4. Optional: Run the **bluemixUtility listServices** command to view the Name, Type, and Plan of all the services instances that you created. See the following example:

```
myCloudantService cloudbantNoSQLDB Lite
```

5. Run the **bluemixUtility import myCloudantService --pversion=v2** command to import the configuration.

**Important:** The `--pversion=v2` option installs the `cloudbant-1.0` feature and downloads the official Cloudant library for Java. For API information, see the official Cloudant Java library API documentation. If you omit the `--pversion=v2` option, the `couchdb-1.0` feature is installed and Ektorp libraries are used instead to communicate with the Cloudant instance.

- a. Accept the license terms and conditions of the necessary libraries that are needed to access the service.
- b. After the configuration is successfully imported, complete any additional steps to use the imported configuration in your application, such as adding a classloader reference to the library. For example, you must add the following classloader reference to your application to use the downloaded libraries.

```
<application id="myCloudantApp">  
    <classloader commonLibraryRef="cloudbantNoSQLDB-library"/>  
</application>
```

6. Optional: Run the **bluemixUtility listImports** command to view the service configurations that you imported.

The following IBM Bluemix service configurations have been imported:  
myCloudantService

7. Run the `bluemixUtility bind [options] serverName serviceName` to bind the configuration to a Liberty server. Accept the license terms and conditions, if you are prompted. See the following example and description of a service listed:

```
bluemixUtility bind defaultServer myCloudantService
```

Checking if features required for the myCloudantService are installed.  
All required features are installed.  
The myCloudantService is now bound to defaultServer server.

If you imported the service with the `--pversion=v2` option to use the official Cloudant Java libraries, the default JNDI name for the Cloudant database is `cloudbant/serviceName`. If you did not specify that option, the default JNDI name is `couchdb/serviceName`. If your application references the database by using a different JNDI name, use `--vjndiName` option to specify the JNDI name.

```
$ bluemixUtility bind defaultServer myCloudantService --vjndiName=couchdb/connector
```

## Results

You can now use Cloudant services with your Liberty server.

## Configuring Liberty for Bluemix Watson services

8.5.5.9

Use the IBM Bluemix utility command-line integration tool to configure your on-premise Liberty server to use Bluemix Watson services.

### Before you begin

Before you configure your Liberty server to any Bluemix service, you must create an account. See

Sign up for IBM Bluemix to create your Bluemix account.

### About this task

Configure your Liberty server to use Watson services. Your application must use the Watson Developer Cloud Java SDK to access the Watson service. For more information, see [Watson Developer Cloud Java SDK services](#). For more information about Watson, see [Watson services](#).

### Procedure

1. Log in using the **bluemixUtility login** command. After you initially log in, you do not have to complete this step again.
2. Run the **bluemixUtility marketplace** command to list details about all the Bluemix services that can be used with the command-line utility. See the following example of the Concept Insights description:

```
Service: personality_insights
```

```
Description: The Watson Personality Insights derives insights from transactional and social media data to identify ps
```

```
Documentation: https://www.ibm.com/watson/developercloud/personality-insights.html
```

```
Plans: tiered, premium
```

3.

**Note:** If you already created an instance, skip to step 4. You can also create an instance from the Bluemix dashboard.

Run the `bluemixUtility createService [options] serviceType servicePlan serviceName` command to create an instance of the service that you want to use. You can choose a unique `serviceName` for your service instance. The following example creates an instance of the Personality Insights service:

```
bluemixUtility createService personality_insights premium myWatsonService
```

4. Optional: Run the **bluemixUtility listServices** command to view the Name, Type, and Plan of all the service instances that you created. See the following example:

```
myWatsonService personality_insights premium
```

5. Run the **bluemixUtility import myWatsonService** command to import the configuration.
  - a. Accept the license terms and conditions of the necessary libraries that are needed to access the service.
  - b. After the configuration is successfully imported, complete any additional steps to use the imported configuration in your application, such as adding a classloader reference to the library. The classloader element must be added to each application that is using the service. The classloader reference ID is different from each unique Watson service. For example, you must add the following classloader reference to your application to use the Watson Java SDK libraries.

```
<application id="myWatsonApp">
  <classloader commonLibraryRef="personality_insights-library"/>
</application>
```

- Optional: Run the **bluemixUtility listImports** command to view the service configurations that you imported.

The following IBM Bluemix service configurations have been imported:  
myWatsonService

- Run the **bluemixUtility bind** *[options] serverName serviceName* to bind the configuration to a Liberty server. See the following example and description of a service listed:

```
bluemixUtility bind defaultServer myWatsonService
```

Checking if features required for the myWatsonService are installed.

All required features are installed.

The myWatsonService is now bound to defaultServer server.

## Results

You can now use Watson services with your Liberty server.

---

## Setting up a Liberty Server for use with z/OS Connect

z/OS

8.5.5.2

### Setting up z/OS Connect

The z/OS Connect feature runs in a WebSphere Application Server for z/OS, Liberty environment and is installed from the Liberty Repository.

#### Before you begin

8.5.5.2

Use IBM Installation Manager to install Liberty for WebSphere Application Server Version 8.5.5.2, along with the following interim fixes:

- 8.5.5.2-WS-WLP-OS390-IFPI18279
- 8.5.5.2-WS-WLP-OS390-IFPI18379

Download the interim fixes from IBM Fix Central, or install the interim fixes directly from the service repository.

8.5.5.3

Use IBM Installation Manager to install Liberty for WebSphere Application Server version 8.5.5.3 or later.

Use the **featureManager** command for Liberty to install the z/OS Connect feature from the Liberty Repository. This command requires that the file system for Liberty have read/write access. You can either enable the Liberty file system as read/write, or copy the contents into a read/write file system so new features can be added from the Liberty Repository.

#### Procedure

- Change to the **bin** subdirectory under the directory where Liberty is installed. The directory must be enabled for read/write access.

```
cd ${wlp.install.dir}/bin
```

- Use the **featureManager** command to install the z/OS Connect feature:

```
featureManager install zosConnect-1.0
```

The feature is downloaded from the online Liberty Repository and installed. You must have Internet access to retrieve the feature from the Liberty Repository.

3. **8.5.5.2** If you are installing this feature on to Liberty version 8.5.5.2, set the required file permissions by issuing the following commands from the WebSphere Liberty installation directory:  
`chmod ugo+rx bin/zosConnect/bbgls2js` and `chmod ugo+rx bin/zosConnect/bbgjs21s`
4. You are now ready to add the z/OS Connect feature to the feature manager list in the `server.xml` file of the Liberty server where you want to enable this support.

```
<server description="z/OS Connect Liberty Server">
  <featureManager>
    <feature> zosConnect-1.0 </feature>
  </featureManager>
</server>
```

5. (Optional)

- a. If you are using WebSphere optimized local adapters (WOLA), use the **featureManager** command to install the Optimized Local Adapters feature:

```
featureManager install zosLocalAdapters-1.0
```

For more information, see “Installing Liberty Repository assets” on page 1391.

The feature is downloaded from the Liberty Repository and installed. You must have Internet access to retrieve the feature from the Liberty Repository.

- b. Update the `server.xml` file to enable WOLA for outbound calls from your Liberty server to your applications with an external address space.
  - Add a `zosLocalAdapters` element that defines the three-part WOLA group name that is used by clients to connect to the Liberty server.
  - Add a connection factory element and provide a JNDI name. For more information, see the documentation on enabling the Liberty server environment to use optimized local adapters.

```
<server>
  <featureManager>
    <feature>zosConnect-1.0</feature>
    <feature>zosLocalAdapters-1.0</feature>
  </featureManager>

  <!-- Local adapters connection factory definition -->
  <authData id="cauth1" user="user1" password="{xor}LDo8Ki02KyY="/>
  <connectionFactory id="wolaCF" jndiName="eis/ola" containerAuthDataRef="cauth1" >
    <properties.ola/>
  </connectionFactory>

  <!-- Provide WOLA server identity -->
  <zosLocalAdapters wolaGroup="LIB1" wolaName2="LIB2" wolaName3="LIB3" />
</server>
```

## Results

You are now ready to add z/OS Connect service elements to your `server.xml` configuration.

## Defining z/OS Connect services

z/OS<sup>®</sup> Connect service definitions provide the mechanism for reaching z/OS application assets using REST calls. To enable z/OS Connect services, you must add a z/OS Connect service definition to the Liberty `server.xml` file with the element name `zosConnectService` along with a name and service provider reference element name.

### About this task

z/OS Connect services are defined by the `zosConnectService` configuration element. This element contains attribute definitions that may have globally defined counterparts. Attributes can be defined

globally through the `zosConnectManager` element. These attributes, if defined, apply to all services. If both global and service level attributes are configured, the values defined at the `zosConnectService` level are used.

z/OS Connect provides a service implementation that allows z/OS Connect requests to interact with z/OS assets through WebSphere Optimized Local Adapters (WOLA). The service is automatically enabled when both `zosConnect-1.0` and the `zosLocalAdapters-1.0` features are configured. Instances of this service can be defined through the `localAdaptersConnectService` configuration element.

z/OS Connect also provides a service implementation that allows z/OS Connect requests to contact a remote REST endpoints. The service is available when the `zosConnect-1.2` feature is configured. Instances of this service can be defined through the `zosConnectServiceRestClient` configuration element. For more information, see the documentation for the z/OS Connect REST Client Service.

## Procedure

1. Add a `zosConnectService` element for each service in your `server.xml` configuration. You must configure the `serviceRef` and `serviceName` attributes at minimum. The `serviceRef` element points to the service provider configuration element. The `serviceName` attribute is how the service provider identifies itself with z/OS Connect and is also the name to use as part of the URL for z/OS Connect requests that are targeted to a specific service. The service name must be unique. The following is a sample `server.xml` file that shows what is required to add a z/OS Connect service called `recordOpsCreate`:

```
<!-- z/OS Connect service definitions -->
<zosConnectService id="zcs1"
  serviceName="recordOpsCreate"
  serviceRef="wolaCreateService"/>
```

For more information about the configurable attribute definitions associated with the `zosConnectService` element, see the documentation for the z/OS Connect feature.

2. (Optional) Add the `zosConnectManager` configuration element to the `server.xml` file. This element is a singleton in the `server.xml` configuration and it contains global values that apply to all z/OS Connect services that are defined for the server. The element can contain the names of z/OS Connect interceptors or data transformation provider configuration elements that apply to all services in the server.

The following example describes a `zosConnectManager` element that defines an operations group name of `Operator1` under the item `globalOperationsGroup`. This is the name of the security (SAF or LDAP) group that the requesting client `userid` needs to be in before z/OS Connect operations requests are permitted, such as `action=start|stop|status`. This group applies to all services in the z/OS Connect configurations. The item `dataxform` defines the element name where z/OS Connect will find a data transformation provider. Supplying the `dataxform` in the `zosConnect` element means this is the transformation provider implementation for all services in the configuration that do not already have their own data transformation element reference. The `interceptors` item is the name of the element in the configuration that describes the set of z/OS Connect interceptors that apply to all services in the configuration.

```
<zosConnectManager id="zosConnectGlobals"
  globalOperationsGroup="Operator1"
  globalDataxformRef="XformJSON2Byte"
  globalInterceptorsRef="GlobalInterceptors"/>
```

For more information about the configurable attribute definitions associated with the `zosConnectManager` element, see the documentation for the z/OS Connect feature. For more information on each attribute, see the Liberty features documentation.

3. If WOLA is configured in Liberty, the configuration for a request requires a `localAdaptersConnectService` element in the `server.xml` file. This configuration consists minimally of the target WOLA Connection Factory name, Register name and Service name. Configuration of z/OS Connect follows the Liberty conventions by only requiring the minimum parameters to be specified.

Note, when you configure a WOLA connection factory for z/OS Connect interaction, you must use container as the authentication mechanism. WOLA connection factories that do not specify a containerAuthDataRef attribute are not supported. The following is an example:

```
<!-- Local adapters connection factory definition -->
<authData id="cauth1" user="user1" password="{xor}LDo8Ki02KyY="/>
<connectionFactory id="wolaCF" jndiName="eis/ola"
  containerAuthDataRef="cauth1" >
  <properties.ola/>
</connectionFactory>

<!-- Local adapters config -->
<zosLocalAdapters wolaGroup="LIBERTY" wolaName2="LIBERTY"
  wolaName3="LIBERTY" />

<!-- WOLA Connect service and z/OS Connect service definitions -->
<localAdaptersConnectService id="wolaOpsCreate"
  registerName="BATCH01"
  serviceName="COBLPGM1"
  connectionFactoryRef="wolaCF"/>

<zosConnectService id="zcs1" serviceName="recordOpsCreate"
  serviceRef="wolaOpsCreate"
  runGlobalInterceptors="true"
  interceptorsRef="serviceInterceptorList"/>
```

The z/OS Connect service implementation that allows z/OS Connect requests to interact with z/OS assets through WebSphere Optimized Local Adapters (WOLA) might require a data transformer. If a data transformer is configured, globally or at the service level, input and output payloads are converted using the configured data transformer. If a data transformer is not configured, and the request contains a JSON payload, the service assumes that the backend program will handle the data conversion. The service converts the JSON payload, as is, to a byte array using the encoding specified in the request header or the default JSON encoding of UTF-8. Similarly, if the asset returns a payload and no data transformer is configured, the WOLA service implementation expects to receive a JSON payload in byte array form, which is converted to a JSON response payload following the same encoding rules used for transforming a JSON request payload to a byte array.

The WOLA service provider implementation allows for a number of other WOLA connection factory definitions to be specified in its localAdaptersConnectService configuration element. The following table is a list of localAdaptersConnectService attribute definitions and a description of each.

Attribute Definition	Description
serviceName required="true" type="String"	Name of the WOLA target service. This service name must match the name an external address space application is using for the service name on a WOLA Receive Request or Host Service API call, or the program name used for SVC with a WOLA CICS Link Server.
registerName required="true" type="String"	Name of the WOLA target registration. This target registration must match the name an external address space application is using for the register name on a WOLA Register API call, or the name used for RGN with a WOLA CICS Link Server.
connectionFactoryRef required="true" type="String"	Name of the connection factory element with the JNDI name of the WOLA resource adapter connection factory to be used. Refer to the Liberty WOLA resource adapter documentation for more information.

Attribute Definition	Description
connectionWaitTimeout required="false" type="Integer" min="0" max="2147483647"	Number of seconds to wait for an external address space application that matches the registration name to issue a WOLA Receive Request or Host Service API and become active. Refer to the Liberty WOLA resource adapter documentation for more information.
linkTaskTranID required="false" type="String"	Specifies the name of the WOLA CICS Link Server link invocation task transaction ID. Refer to the Liberty WOLA resource adapter documentation for more information.
useCICSContainer required="false" type="Boolean" default="false"	When using the WOLA CICS Link Server, indicates whether the payload is passed in a single CICS container or a COMMAREA to the target CICS application program. Refer to the Liberty WOLA resource adapter documentation for more information.
linkTaskReqContID required="false" type="String"	When using the WOLA CICS Link Server and the useCICSContainer flag is set to true, specifies the name of the target CICS request container. Refer to the Liberty WOLA resource adapter documentation for more information.
linkTaskReqContType type="Integer" min="0" default="0"	When using the WOLA CICS Link Server and the useCICSContainer flag is set to true, specifies the type of the target CICS request container (0=CHAR, 1=BIT). Refer to the Liberty WOLA resource adapter documentation for more information.
linkTaskRspContID required="false" type="String"	When using the WOLA CICS Link Server and the useCICSContainer flag is set to true, specifies the name of the target CICS response container. Refer to the Liberty WOLA resource adapter documentation for more information.
linkTaskRspContType type="Integer" min="0" default="0"	When using the WOLA CICS Link Server and the useCICSContainer flag is set to true, specifies the type of the target CICS response container (0=CHAR, 1=BIT). Refer to the Liberty WOLA resource adapter documentation for more information.
linkTaskChanID required="false" type="String"	When using the WOLA CICS Link Server, specifies the CICS channel name to use for delivering messages and received response messages using CICS containers. Refer to the Liberty WOLA resource adapter documentation for more information.
linkTaskChanType required="false" type="Integer" min="0" default="0"	When using the WOLA CICS Link Server and specifying the linkTaskChanID channel name, specifies the type of the target CICS containers that are associated with that channel (0=CHAR, 1=BIT). Refer to the Liberty WOLA resource adapter documentation for more information.

## Setting up the z/OS Connect REST client service

8.5.5.7

The z/OS Connect REST Client support enables z/OS Connect users to route requests to remote REST applications through z/OS Connect, thereby taking advantage of the existing interceptor infrastructure.

### About this task

This function is available when you configure the `zosConnect-1.2` feature. The z/OS Connect REST Client service is a z/OS Connect service SPI implementation. Requests that invoke this service are made in two ways:

- Use the `?action=invoke` query parameter mechanism as follows: `https://hostName:port/zosConnect/services/serviceY?action=invoke` where `serviceY` is the service name that is associated with the configured `zosConnectServiceRestClient` element.
- Use the `zosConnectService` attribute definition that is called `invokeURI`. You can use this attribute to define a custom URI that is associated with a service name and any of the following HTTP verbs: GET, POST, PUT, DELETE; for example:

```
<zosConnectService serviceName="serviceY" serviceRef="restClientServiceY" invokeURI="/my/custom/uri" />
```

An example of a service invocation for the defined service is: `https://host:port/my/custom/uri` (HTTP verb: GET/POST/PUT/DELETE). z/OS Connect understands the association between the `invokeURI` attribute and the `serviceName` attribute defined in the example. z/OS Connect calls the `invoke` method on the implementation of the z/OS Connect associated service (`restClientServiceY`).

For more information on the capability and flexibility that the `invokeURI` attribute offers, see the documentation for z/OS Connect

### Procedure

1. Configure the `zosConnectServiceRestClient` element and associate it with a `zosConnectService` element.

```
<featureManager>
  <feature>zosConnect-1.2</feature>
</featureManager>

<!-- Global interceptor definition to run for all service requests -->
<zosConnectInterceptors interceptorRef="auth,audit,fileSystemLogger" id="globalInterceptorList1"/>
<fileSystemLoggerInterceptor id="fileSystemLogger" logName="service1Log_%SERVERNAME%" sequence="1"/>
<authorizationInterceptor id="auth" sequence="2"/>
<auditInterceptor id="audit" sequence="3"/>

<!-- ZosConnectManager definition -->
<zosConnectManager globalAdminGroup="ADMIN"
  globalOperationsGroup="OPS"
  globalInvokeGroup="INVOKE"
  globalInterceptorsRef="globalInterceptorList1"/>

<zosConnectServiceRestClient id="restClientServiceY"
  host="remoteHostName"
  port="8800"
  uri="/remote/endpoint"
  httpMethod="DELETE"/>
<zosConnectService serviceName="serviceY" serviceRef="restClientServiceY" invokeURI="/my/custom/uri" />
```

In the example, requests that target the `serviceY` service are routed to the remote host and port that is configured under the associated `restClientServiceY` service and that uses the configured URI and DELETE HTTP method. The JSON payload is automatically sent with the remote request. When you configure the `zosConnectServiceRestClient` element, specify the host name and port number

attributes. If you do not specify the uri or httpMethod attributes, the values that are used are the ones from the original client request that is targeting the serviceY service. The example also shows that because interceptors are configured to run globally, every request that targets the serviceY service is logged, authorized, and audited before it is routed to the remote endpoint. The interceptors also log and audit the responses on the return from the remote endpoint. Because an invokeURI attribute is configured for the serviceY service, the requester can start the implementation of the serviceY invoke method by using the following URL: https://host:port/my/custom/uri and using either the GET, POST, PUT, or DELETE HTTP method. In this case, because the serviceY service refers to an instance of the z/OS Connect REST client service, the invoke() method on this instance is called. For more information about available configuration attributes and default values see the documentation for z/OS Connect 1.0 and z/OS Connect 1.2.

2. (Optional) Configure basic authentication. Add the appSecurity-2.0 feature to the server.xml file.

```
<featureManager>
  <feature>zosConnect-1.2</feature>
  <feature>appSecurity-2.0</feature>
</featureManager>

<zosConnectServiceRestClientBasicAuth id="fredBasicAuth" userName="Fred" password="{xor}0S060y8o0w==" />

<zosConnectServiceRestClient id="restClientServiceY"
  host="remoteHostName"
  port="8800"
  uri="/remote/endpoint"
  httpMethod="POST"
  basicAuthRef="bobBasicAuth"/>

<zosConnectService serviceName="serviceY" serviceRef="restClientServiceY" />
```

The configuration enables the user name and password that is configured for the zosConnectServiceRestClientBasicAuth element to be propagated when the request to the remote REST application endpoint is made.

3. (Optional) Configure certificate authentication. Add the appSecurity-2.0 feature to the server.xml file.

The example shows how to configure the client keystore and client truststore and associate them with the zosConnectServiceRestClient configuration.

```
<featureManager>
  <feature>zosConnect-1.2</feature>
  <feature>appSecurity-2.0</feature>
</featureManager>

<keyStore id="clientKeyStore" password="zosConnect"
  location="{server.config.dir}/resources/security/clientKey.jks" />

<keyStore id="clientTrustStore" password="zosConnect"
  location="{server.config.dir}/resources/security/clientTrust.jks" />

<ssl id="sslCertificates" keyStoreRef="clientKeyStore" trustStoreRef="clientTrustStore"/>

<zosConnectServiceRestClient id="restClientServiceY"
  host="remoteHostName"
  port="8800"
  uri="/remote/endpoint"
  httpMethod="PUT"
  sslCertsRef="sslCertificates"/>

<zosConnectService serviceName="serviceY" serviceRef="restClientServiceY" />
```

## Defining z/OS Connect interceptors

8.5.5.2

z/OS® Connect provides a framework that enables interceptors, or methods, to work with operations such as service invoke, status, start, or stop. Interceptors are OSGi services that implement the `com.ibm.wsspi.zos.connect.Interceptor Service Provider Interface (SPI)` that is provided by z/OS Connect.

## About this task

You can use interceptors for various purposes. z/OS Connect has no visibility into what an interceptor is used for. For example, an interceptor might be written to perform some infrastructure setup that is based on the message payload before the request is processed. z/OS Connect provides a copy of the input request payload to all interceptors.

z/OS Connect provides the `<zosConnectService>` configuration element that enables the administrator to configure a set of attributes that apply to a particular service. One of these attributes is `interceptorsRef`, which points to a configuration element that lists one or more interceptors to run for a specific service.

This task describes how to define a z/OS Connect interceptor and a list of interceptors and also explains how to associate the interceptors with one or more services in the configuration for a server. This task also includes a description of how to enable the z/OS Connect-provided audit and authorization interceptors for services.

## Procedure

1. Update the `<zosConnectService>` element for each service in your `server.xml` configuration for which you want to enable an interceptor or list of interceptors for.

```
<!--z/OS Connect service definitions -->
<zosConnectService id="zcs1"
  serviceName="recordOpsCreate"
  serviceRef="wola0psCreateService"
  interceptorsRef="opsCreateInterceptorList"/>
```

2. Create the associated `<zosConnectInterceptors>` element.

```
<!-- User Interceptor definitions -->
<usr_userInterceptorOne id="userI1" sequence="1"/>
<usr_userInterceptorTwo id="userI2" sequence="2"/>

<zosConnectInterceptors id="opsCreateInterceptorList" interceptorRef="userI1, userI2"/>
```

The name of the interceptor list in this example is `greetingsInterceptorList`. There are two interceptors referred to here, `userI1` and `userI2`. Interceptor implementations use the Liberty SPI extensions. These interceptors must define their metatypes to the Liberty server and create an implementation of the `com.ibm.wsspi.zos.connect.Interceptor` class. In this example, an implementation of this class was created with a metatype that defines the elements `usr_userInterceptorOne` and `usr_userInterceptorTwo`. The name of the configuration element where the list of interceptors is provided is called `interceptorsRef`. It is not a required attribute.

3. Optional: Create a global interceptor list and enable it in the `<zosConnectManager>` element. The `globalInterceptorsRef` item is the name of the element in the configuration that describes the set of z/OS Connect interceptors that apply to all of the services in the configuration.

```
<zosConnectManager id="zosConnectGlobals" globalInterceptorsRef="GlobalInterceptors"/>

<!-- User Interceptor definitions -->
<usr_userInterceptorOne id="userI1" sequence="1"/>
<usr_userInterceptorTwo id="userI2" sequence="2"/>
<zosConnectInterceptors id="globalInterceptors" interceptorRef="userI1, userI2"/>
```

4. Optional: Enable the z/OS Connect-provided audit, authorization, or logging interceptors for a service or set of services. The z/OS Connect-supplied audit interceptor implements the `com.ibm.wsspi.zos.connect.Interceptor` SPI to store audit or tracking information in the z/OS System Management Facility (SMF) data sets. The authorization interceptor provides the ability to verify that the current authenticated user has the authority to perform the requested action. Examples

of actions checked include service action=invoke, start, or stop. You enable these interceptors for one or more services in the z/OS Connect server configuration. The following example shows how to enable both the audit and authorization interceptors for a single service:

```
<!-- z/OS Connect service definition -->
<zosConnectService id="zcs1"
  serviceName="recordOpsCreate"
  serviceRef="wo1a0psCreateService"
  interceptorsRef="opsCreateInterceptorList1"/>

<!-- Audit and authorization interceptor definitions -->
<authorizationInterceptor id="authInterceptor1" sequence="1"/>
<auditInterceptor id="auditInterceptor1" sequence="2"/>

<zosConnectInterceptors id="opsCreateInterceptorList1" interceptorRef="auditInterceptor1, authInterceptor1"/>
```

## Setting up the z/OS Connect file system logger interceptor

8.5.5.7

The file system logger interceptor enables z/OS Connect users to log request information in a file system file.

### About this task

This function is available when you configure the zosConnect-1.0 or zosConnect-1.2 features and it requires configuration.

Table 113. Descriptions of the entries that are in the generated log file

Entry	Description
DateTime	The date and time that is calculated by the logger interceptor before the service invocation
ThreadID	The ID of the thread under which the service request is being processed
UserName	The user name for which the request is being processed
RequestID	The request tracking ID that is generated by z/OS Connect
RemoteAddress	The Internet Protocol (IP) address of the client who originated the request or last proxy that sent the request
LocalAddress	The Internet Protocol (IP) address of the interface on which the request was received
MessageType	Identifies whether the payload is from a request or a response
MessageSize	The character size of the payload
MessageData	A request or response payload

```
*****
ServerName: com.ibm.ws.zos.connect.interceptor.logger.fs
*****
DateTime:2015-07-19_12-14-02 | ThreadId:47 | UserName:Fred | RequestID:0000000000000001000000000000000000000000 |
RemoteAddress:127.0.0.1 | LocalAddress:127.0.0.1
MessageType:REQUEST
MessageSize:27
MessageData:{"payload":"HELLO_SERVICE"}

DateTime:2015-07-19_12-14-02 | ThreadId:47 | UserName:Fred | RequestID:0000000000000001000000000000000000000000 |
```

RemoteAddress:127.0.0.1 | LocalAddress:127.0.0.1  
MessageType:RESPONSE  
MessageSize:26  
MessageData:{"payload":"HELLO\_CALLER"}

## Procedure

1. Configure the `fileSystemLoggerInterceptor` element globally.

```
<fileSystemLoggerInterceptor id="globalFileSystemLogger" logName="globalLog_%SERVERNAME%"/>  
<zOsConnectInterceptors id="globalInterceptorList" interceptorRef="globalFileSystemLogger" />  
<zOsConnectManager globalInterceptorsRef="globalInterceptorList"/>
```

In the example, all z/OS Connect service requests are logged in a file that is called `globalLog_myServer1_yyyy-MM-dd_HH_mm_ss_SSS.log` where `myServer1` is the name of the server. The only required configuration element is the `logName` attribute definition. The configuration element accepts a `%SERVERNAME%` string that is replaced with the name of the server when the log is created. The default log file location is `${server.output.dir}/logs/zosConnect`. For more information on the available configuration attributes and default values see the documentation for z/OS Connect 1.0 and z/OS Connect 1.2.

You can also configure the `fileSystemLoggerInterceptor` element for specific services.

```
<fileSystemLoggerInterceptor id="serviceYFileSystemLogger"  
    logName="service1Log"  
    logPath="/zosConnect/logs"  
    logOption="RESPONSE"  
    maxPayloadSize="30720"/>  
<zOsConnectInterceptors id="serviceYInterceptorList" interceptorRef="serviceYFileSystemLogger" />  
<zOsConnectService serviceName="serviceY" serviceRef="serviceY" interceptorsRef="serviceYInterceptorList"/>  
<usr_myService id="serviceY"/>
```

In the example, all z/OS Connect service requests are logged in a file that is called `service1Log_yyyy-MM-dd_HH_mm_ss_SSS.log` and in the `/zosConnect/logs` path. The log path is a fully qualified path. Only response data is logged for all incoming requests that target the `serviceY` service. Because the maximum JSON payload is configured to be 30,720 characters, any JSON (response) payload that is greater than 30,720 characters is truncated to the configured maximum payload size.

2. (Optional) Configure the `bufferedLogging` and the `bufferSize` attribute definitions to enable buffered logging. The default buffer size is 8 kilobytes. All records in the buffer are flushed to the disk when the buffer becomes full. Using buffered logging is appropriate when performance is a concern and when loss of unflushed records during a failure condition is acceptable.

```
<fileSystemLoggerInterceptor id="globalFileSystemLogger"  
    logName="globalLog_%SERVERNAME%"  
    bufferedLogging="true"  
    bufferSize="16384"/>
```

3. (Optional) Configure the `rolloffLogPolicy` attribute. This policy states that when the active log file reaches the specified or default file size of 50 megabytes, a new file is created. A new file can also be created when the specified or default time of 24 hours expires since the active log file was created. In the following example, a file is created when the file reaches 16 kilobytes in size. The naming schema is the same: `globalLog_myServer1_yyyy-MM-dd_HH_mm_ss_SSS.log`. The difference between the names of the created log files is the time stamp that is used when a given file is created:

```
<fileSystemLoggerInterceptor id="globalFileSystemLogger"  
    logName="globalLog_%SERVERNAME%"  
    rolloffLogPolicy="SIZE"  
    rolloffLogPolicySize="16384"/>
```

## Defining z/OS Connect message payload transformations

8.5.5.2

IBM® z/OS® Connect provides the ability to optionally transform request and response payloads that are used for calling a business asset on z/OS operating systems. You can create message payload

transformers can be created to satisfy specific needs by implementing the `com.ibm.wsspi.zos.connect.DataXform` Service Provider Interface (SPI), which is included with z/OS Connect.

## About this task

z/OS Connect provides an implementation that requires the request and response message format be JSON. This feature supports the conversion of the request to a byte array, which can be mapped by a native language Cobol, PL/I, or C structure. This language structure of the target program, or copy book, which includes a description of the **in** and **out** parameters, is used to generate a binding file, and JSON request and response schema files by using a z/OS Connect-provided utility. The binding file that is generated by this utility is used by z/OS Connect to complete the data conversion to and from JSON and native data formats as requests arrive and responses are returned. You can retrieve the JSON schemas for the request and response message with a REST API call that is provided by z/OS Connect.

z/OS Connect provides the `zosConnectService` configuration element that enables the administrator to configure a set of attributes that apply to a particular service. One of these attributes is `dataXformRef`, which points to a data transformation configuration that is to be used for a specific service. This task describes how to request that the z/OS Connect-supplied data transformer be used.

## Procedure

1. Update the `zosConnectService` element for each service in your `server.xml` configuration for which you want to enable the z/OS Connect-supplied data transformation.

```
<!-- z/OS Connect service definition -->
<zosConnectService id="zcs1"
  serviceName="recordOpsCreate"
  serviceRef="wola0psCreateService"
  dataXformRef="xformJSON2btye"/>
```

2. Create the associated `zosConnectDataXform` element.

```
<!-- z/OS Connect data transformation provider -->
<zosConnectDataXform id="xformJSON2Byte"
  bindFileLoc="/u/bindfiles" bindFileSuffix=".bnd"
  requestSchemaLoc="/u/json" responseSchemaLoc="/u/json"
  requestSchemaSuffix=".json" responseSchemaSuffix=".json"/>
```

For more information about the configurable attribute definitions associated with the `zosConnectDataXform` element, see the documentation for the “z/OS Connect” on page 959 feature.

3. Optional: Configure a data transformer that applies to all services. Set the `globalDataXformRef` of the `<zosConnectManager>` element to the configured data transformer's ID that is intended for global use. If both global and service data transformers are defined and requests come in for a service with a configured data transformer, z/OS Connect will use the data transformer configured specifically for the service.

```
<zosConnectManager id="zosConnectGlobals" globalDataXformRef="globalDataXform"/>
```

```
<!-- z/OS Connect data transformation provider -->
<zosConnectDataXform id="globalDataXform"
  bindFileLoc="/u/bindfiles" bindFileSuffix=".bnd"
  requestSchemaLoc="/u/json" responseSchemaLoc="/u/json"
  requestSchemaSuffix=".json" responseSchemaSuffix=".json"/>
```

4. 8.5.5.8 Optional: Configure settings such as `pollingRate` and `updateTrigger` to fine tune the monitoring actions. By default, the directories associated with a data transformation definition are monitored for new files and file updates. For more information about these configuration attributes see the `zosConnectDataXform` element section under `zosConnect-1.0` and `zosConnect 1.2`.

```
<zosConnectDataXform id="ibmDataXform2"
  bindFileLoc="/zosConnect/banking/bind/" bindFileSuffix=".bnd"
  requestSchemaLoc="/zosConnect/banking/reqSchema" requestSchemaSuffix=".json"
  responseSchemaLoc="/zosConnect/banking/respSchema" responseSchemaSuffix=".json" pollingRate="500ms">
</zosConnectDataXform>
```

In the example, directories /zosConnect/banking/bind,/zosConnect/banking/reqSchema, and /zosConnect/banking/respSchema are polled for file updates every 500 milliseconds. If the pollingRate and updateTrigger configuration attributes are not configured, the default values of polled and 2 seconds are used, respectively. If you do not need file monitoring, you can disable it by setting the updateTrigger attribute to disabled. If you prefer to trigger a manual refresh of certain files, set the updateTrigger attribute to mbean and use file notification mbean:

com.ibm.ws.kernel.filemonitor.FileNotificationMBean to trigger the updates; for example:

```
String[] MBEAN_METHOD_SIGNATURE = new String[] {Collection.class.getName(),Collection.class.getName(),Collection.class.getName()};
JMXConnector jmxConnector = ...;
MBeanServerConnection mbsc = jmxConnector.getMBeanServerConnection();
ObjectName fileMonitorMBeanName = new ObjectName("WebSphere:service=com.ibm.ws.kernel.filemonitor.FileNotificationMBean");
```

```
List<String> paths = new ArrayList<String>();
paths.add("/zosConnect/banking/bind/customer.bnd");
paths.add("/zosConnect/banking/reqSchema/customer_request.json");
paths.add("/zosConnect/banking/respSchema/customer_response.json");
```

```
Object[] params = new Object[] { null, paths, null };
mbsc.invoke(fileMonitorMBeanName, "notifyFileChanges", params, MBEAN_METHOD_SIGNATURE);
```

The example uses the restConnector-1.0 feature to trigger the update of files customer.bnd, customer\_request.json, and customer\_response.json. For more information about how to create a secure JMX connection see the documentation on “Configuring secure JMX connection to Liberty” on page 1642

## Creating binding and schema files for use with z/OS Connect

0.5.5.2

z/OS Connect provides the ability to optionally transform request and response payloads that are used for calling a business asset on z/OS operating systems. z/OS Connect supplies two new utilities called BBGLS2JS and BBGJS2LS.

### Before you begin

Before you create your binding and schema files, make sure that your setup complies with these preconditions:

- Your high-level language data structures must meet the following criteria:
  - The data structures must be defined separately from the source program; for example, in a COBOL copybook.
  - If your PL/I or COBOL application program uses different data structures for input and output, the data structures must be defined in two different members in a partitioned data set. If the same structure is used for input and output, the structure must be defined in a single member.
  - For C and C++, your data structures can be in the same member in a partitioned data set.
- The language structures must be available in a partitioned data set.
- You must define to Open Multiple Virtual Storage (OMVS) the user ID that BBGLS2JS or BBGJS2LS uses to run.
- The user ID must have read permission to z/OS® UNIX and PDS libraries, and write permission to the directories that are specified on the LOGFILE, WSBIND, and JSON-SCHEMA-REQUEST and JSON-SCHEMA-RESPONSE output parameters.
- The user ID must have a sufficiently large storage allocation to run Java™. You can use any supported version of Java. The BBGLS2JS/BBGJS2LS utilities use the Java version that is specified by JAVA\_HOME in the USS environment by default. Otherwise, the ID uses the Java version specified on the PATH statement.

## About this task

The BBGLS2JS utility reads a COBOL copybook or PLI, or C structure file and generates a binding file and JSON schema files. The BBGJS2LS utility reads a JSON schema and generates the corresponding binding file and language structure file (COBOL copybook or PL/I, or C structure header file). The utilities are similar to the existing DFHLS2JS and DFHJS2LS tools, which are part of the CICS Transaction Server Mobile Extensions feature pack. While the input parameters are the same, the symbolic parameters are different.

## Procedure

1. Obtain the BBGLS2JS JCL procedure. The BBGLS2JS and BBGJS2LS JCL procedures are available on GitHub. For information about how to use the JCL, see the readme file on GitHub. You will need to copy the JCL procedure from this location into a member named BBGLS2JS in a JCL procedure library on your z/OS system.
2. Use the BBGLS2JS procedure to generate a z/OS Connect service binding file from a language structure. You will need to provide JCL to invoke the BBGLS2JS procedure with the input parameters. Refer to the BBGLS2JS reference documentation for information on the input parameters and an example job to help you use the procedure. When you submit the BBGLS2JS procedure, the utility generates the service binding file to the location that you specified with the WSBIND parameter. The generated JSON schemas are placed in the location that you specified with the JSON-SCHEMA-REQUEST and JSON-SCHEMA-RESPONSE parameters.
3. Review the generated JSON schema. These schemas are used to define the input and output data formats for interacting with the z/OS Connect service. The application developer must use these schemas when creating an application to call the service and pass the JSON request payload.

**Note:** Changing the generated schema invalidates the generated binding file at WSBIND. If you want to change the schema, for example, to rename the fields within the schema, you must use BBGJS2LS to generate a new binding file, and a new set of language structures. The application program must be re-compiled to use the new language structures.

## Auditing and tracking with z/OS Connect

Audit and track requests with z/OS<sup>®</sup> Connect, which includes an interceptor that records data to the z/OS SMF data store.

## About this task

You can enable the interceptor in z/OS Connect on a single or group of z/OS Connect services. The z/OS Connect audit interceptor records request activity to the SMF data store on z/OS operating systems. SMF type 120, subtype 11 records are generated.

The SMF data in the 120-11 record contains the standard header for SMF records. Then, there are two triplets. The first triplet points to the server identification section of which there is one instance. The second triplet points to the user data section of which there can be multiple instances.

**The server data section consists of the following parameters: (values in decimal)**

- Offset Length Data
- 0 4 Version (1)
- 4 8 System name
- 12 8 Sysplex name
- 20 8 Job id(jsabjbid)
- 28 8 Job name (jsabjbnm)

- 36 8 SToken (assbstkn)

**The user data consists of the following parameters (values in decimal):**

- Offset Length Data
- 0 4 Version (1)
- 4 4 Type
- 8 4 Length of data (user data sections are 2 K, this field indicates how much of that is used)
- 12 ? Data

**The user data consists of the following parameters (values in decimal):**

For z/OS Connect the user data type is 102 (decimal). The data contains the following parameters:

- Offset length Data
- 0 4 Version (3)
- 4 8 Arrival time (STCK format)
- 12 8 Completion time (STCK format)
- 20 64 Target URI (EBCDIC, right-padded with blanks)
- 84 4 Input payload length in bytes
- 88 64 Service name (EBCDIC, right-padded with blanks)
- 152 8 Method (EBCDIC)
- 160 4 Respond length in bytes
- 164 64 User name (EBCDIC, right-padded with blanks)
- 228 23 Request id (bytes, right-padded with zeros)
- 251 1 Boundary padding (zero)
- 252 64 Service grouping name (EBCDIC, right-padded with blanks)
- 316 8 Mapped user name (EBCDIC, right-padded with blanks) Only valid on version 3 or later.

## Procedure

1. Enable the z/OS Connect-provided audit interceptor for a service or set of services. The z/OS Connect-supplied audit interceptor implements the `com.ibm.wsspi.zos.connect.Interceptor` SPI to store auditing/tracking information in the z/OS System Management Facility (SMF) data sets. The following is an example that shows how to enable the audit interceptor for a single service:

```
<!-- Audit interceptor configuration -->
<auditInterceptor id="auditInterceptor" sequence="1"/>

<!-- Interceptor list configuration -->
<zosConnectInterceptors id="interceptorList1" interceptorRef="auditInterceptor"/>

<!-- z/OS Connect service definitions -->
<zosConnectService id="zcs1" serviceName="recordOpsCreate" serviceRef="wola0psCreateService"
  interceptorsRef="interceptorList1"/>
```

2. Retrieve live statistic data. Feature start time, total number of service requests and the distribution of requests are available by using this operational capability. Valid authenticated clients are able to use a HTTP GET for one of the following URLs to retrieve statistics about the z/OS Connect server:
  - Get statistics for a single service:
 

```
https://<hostname:port>/zosConnect/services/HelloWorld?action=getStatistics
```
  - Get statistics for all services in the server:
 

```
https://<hostname:port>/zosConnect/operations/getStatistics
```
  - Get statistics for all services under a single service provider by specifying the `provider=<service provider name>` query parameter. For example to retrieve statistics for all services associated with the provider name of **WOLA-1.0** use the following URL:

https://<hostname:port>/zosConnect/operations/getStatistics?provider=WOLA-1.0"

- The response data is returned in JSON object format.

## z/OS Connect high availability

8.5.5.2

The z/OS® Connect file contains the list of service definitions, interceptors, and data transformation configuration that you can use for high availability and failover. You can include the z/OS Connect file in your `server.xml` file, and share the configuration across multiple servers that run on the same LPAR or span multiple z/OS logical partitions (LPARs). The z/OS Connect `action=start`, `stop`, and `status` operations are not supported for WOLA-based services when you share the `server.xml` file between servers.

Additionally, the IBM HTTP Server Apache web server with the WebSphere Application Server plug-in can be placed in front of these servers to spread requests across them. You might also include Sysplex Distributor, or Distributed Virtual IP (DVIPA) in your topologies and z/OS Connect.

## Configuring security for z/OS Connect

8.5.5.2

The z/OS connect application can be accessed by authenticated users that are also authorized under the `zosConnectAccess` role. You can configure group authorization at the service definition level. Group authorization is supported for SAF and LDAP group types.

### About this task

Users must be authenticated before the z/OS Connect application can be accessed.

The default authentication mechanism required by z/OS Connect is `CLIENT_CERT`. Users must be authorized under the `zosConnectAccess` role to be able to access the z/OS Connect application. The required transport mechanism is HTTPS.

8.5.5.7

You can configure z/OS Connect to run without any security constraints by setting the `requireSecure` and `requireAuth` attribute definitions. These attributes are defined under the `zosConnectManager` element, which applies to all configured services, or it is defined under the `zosConnectService` element for a specific service. If the attributes are defined under both the `zosConnectService` element and globally under the `zosConnectManager` element, the value defined under `zosConnectService` is used. See `zosConnectManager` and `zosConnectService` for more information on those attributes.

In order to provide a finer level of security, z/OS Connect offers the ability to constrain access based on group authorization that can be configured through SAF or LDAP. For this, z/OS Connect defines three levels of authority:

- Administrator - IUsers with administrator authority have the authority to query services, perform operational tasks on them, and invoke them.
- Operations - Users with operations authority are able to perform tasks on services such as stop, start, etc. but they do not have authority to invoke services.
- Invoke - Users with invoke authority are able to invoke services, but have no other authority.

z/OS Connect supplies an authorization interceptor that implements the `com.ibm.wsspi.zos.connect.Interceptor()` SPI. This interceptor supports both SAF and LDAP. This

interceptor uses the `getGroupsForUser()` security API internally to determine which groups the current user is in, and then compares these groups to the groups provided on the service definition or in the global definition.

When the z/OS Connect supplied authorization interceptor is enabled, the RACF or LDAP group names that are associated with users can also be associated with any of the groups that are mentioned previously at the global or service definition levels. At the global level, they can be defined under the `<zosConnectManager>` configuration element. The attributes that are defined at this level include: `globalAdminGroup`, `globalOperationsGroup`, and `globalInvokeGroup`. If configured, they apply to all configured services. If more granularity is wanted, the groups can also be configured at the service level under the `<zosConnectService>` configuration element. The attributes that are defined at that level are: `adminGroup`, `operationsGroup`, and `invokeGroup`. These values, if specified, override the values that are defined globally.

When an authorization interceptor is defined at the global level, authorization checks are done one time for all services. When you use `/zosConnect/operations/getStatistics` request for more than one service and service discovery, then the user gets information on all services that are registered with z/OS Connect when the following conditions exist:

- The user passes the authorization check
- No other conditions prevent service information from being returned

If the authorization interceptor is placed in a service level definition, access to information for those services are limited to users that are in that service definition.

For example, given the following configuration with the authorization interceptor defined at the service level:

User "USR1" Groups: ADMINS1, ADMINS2

User "USR2" Groups: OPERATS1

User "USR3" Groups: ADMINS2, OPERATS1

z/OS Connect configuration:

```
<!-- z/OS Connect global configuration. It applies to all services. -->
<zosConnectManager globalAdminGroup="ADMINS1" globalOperationsGroup="OPERATS1" globalInvokeGroup="INVOKES1"/>

<!-- Interceptor configuration -->
<zosConnectInterceptors id="interceptorList1" interceptorRef="zosConnectAuthorizationInterceptor"/>
<authorizationInterceptor id="zosConnectAuthorizationInterceptor"/>

<!--Service 1-->
<zosConnectService serviceName="service1" serviceRef="service1Ref" adminGroup="ADMINS2" operationsGroup="OPERATS2" int

<!--Service 2-->
<zosConnectService serviceName="service2" serviceRef="service2Ref" operationsGroup="OPERATS2" interceptorsRef="intercep

<!--Service 3-->
<zosConnectService serviceName="service3" serviceRef="service3Ref" adminGroup="ADMINS1" interceptorsRef="interceptorLis
```

Table 114. . User data access

	service1	service2	service3
USR1	X	X	X
USR2	--	--	X
USR3	X	--	X

## Procedure

1. Setup user authentication to access the z/OS Connect application. To setup client certificate authentication, see the documentation on configuring your web application and server for client certificate authentication. To setup authentication through a registry, see the documentation on authenticating users in Liberty.

Sample 1: Basic registry configuration using steps outlined in the documentation for configuring a basic user registry for Liberty.

Server.xml:

```
<featureManager>
  <feature>zosConnect-1.0</feature>
  <feature>ssl-1.0</feature>
  <feature>appSecurity-2.0</feature>
</featureManager>
```

```
<!-- Define a keystore. -->
<keyStore id="defaultKeyStore" password="Liberty"/>
```

```
<!-- Fail over to basic authentication -->
<webAppSecurity allowFailOverToBasicAuth="true"/>
```

```
<!-- Basic registry definition -->
<basicRegistry id="basic1" realm="zosConnect">
  <user name="Fred" password="fredpwd"/>
</basicRegistry>
```

Sample 2: SAF registry configuration using steps outlined in the documentation for activating and configuring the SAF registry on z/OS.

Server.xml:

```
<featureManager>
  <feature>zosConnect-1.0</feature>
  <feature>ssl-1.0</feature>
  <feature>appSecurity-2.0</feature>
  <feature>zosSecurity-1.0</feature>
</featureManager>
```

```
<!-- Saf registry definition -->
<safRegistry id="saf" realm="zosConnect"/>
```

RACF setup. For more details follow the documentation on Liberty: Accessing z/OS security resources using WZSSAD:

```
# Define the APPL class based on the default security prefix called BBGZDFLT.
RDEFINE APPL BBGZDFLT UACC(NONE)
```

```
# Activate the APPL class.
SETROPTS CLASSACT(APPL)
```

```
# For FRED to be authenticated by the server, assign FRED READ access to the APPLID in the APPL class.
PERMIT BBGZDFLT ID(FRED) ACCESS(READ) CLASS(APPL)
```

```
# The unauthenticated user ID (i.e. WSGUEST by default) requires READ access to the APPLID in the APPL class
PERMIT BBGZDFLT CLASS(APPL) ACCESS(READ) ID(unauthenticatedUserId)
```

```
# Grant the server permission to make authentication calls.
RDEFINE SERVER BBG.SECPFY.BBGZDFLT UACC(NONE)
PERMIT BBG.SECPFY.BBGZDFLT ID(serverId) ACCESS(READ) CLASS(SERVER)
```

Note that the server needs to be granted permission to use the SAFCREDAUTH authorized service routines. See the documentation on enabling z/OS authorized services on Liberty for z/OS for more details.

2. Setup user authorization to access the z/OS Connect application by assigning users the `zosConnectAccess` role. To do so, see the documentation on configuring authorization for applications on Liberty.

Add the following to the `server.xml` file configuration outlined in step 1 of sample1:

```
<authorization-roles id="zos.connect.access.roles">
  <security-role name="zosConnectAccess">
    <user name="Fred"/>
  </security-role>
</authorization-roles>
```

Sample2: Authorization configuration using SAF/RACF:

- a. Add the following to the configuration outlined in step 1 of sample2.

```
<safAuthorization id="saf2" />
```

- b. RACF setup. Commands to assigning FRED the `zosConnectAccess` role:

```
RDEFINE EJBROLE BBGZDFLT.zos.connect.access.roles.zosConnectAccess
UACC(NONE)
PERMIT BBGZDFLT.zos.connect.access.roles.zosConnectAccess
CLASS(EJBROLE) ID(FRED) ACCESS(READ)
```

3. (Optional) Define groups for authorization when using z/OS Connect's authorization interceptor.

Sample 1: RACF Group definition when using SAF:

```
ADDGROUP OPERATS1 OMVS(GID(xxx)) OWNER(yyyy)
```

```
# Add user FRED under the OPERATS1 group
```

```
ADDUSER FRED DFLTGRP(OPERATS1) OMVS(UID(xxx) HOME(/xxxx) PROGRAM(/bin/sh)) NAME('USER FRED') NOPASSWORD
ALTUSER FRED PASSWORD(xxxxxxxx) NOEXPIRED
```

```
# Connect user Fred to the OPERATS1 group
```

```
CONNECT FRED GROUP(OPERATS1)
```

Note that the "OPERATS1" group can then be used when defining authorization groups to be used by

z/OS Connect's authorization interceptor. For example: `<zosConnectManager globalOperationsGroup="OPERATS1"/>` or `<zosConnectService serviceRef="service1" operationsGroup="OPERATS1"/>`

---

## Platform-as-a-service environment considerations for setting up Liberty

Platform-as-a-service (PaaS) environments, such as IBM Bluemix, Pivotal Cloud Foundry, and OpenShift Enterprise, provide management and monitoring of application instances, but they also have some restrictions. Because of the inherent characteristics of PaaS environments, some Liberty features are redundant or behave differently, and they are therefore not supported.

### Liberty server management restrictions

Features related to Liberty collectives do not apply to a PaaS environment because all Liberty server JVM instances are started, stopped, and managed by the PaaS infrastructure. The Liberty Admin Center feature is not designed to be used in a PaaS environment, where an application can be scaled to use multiple JVM instances without a collective controller. In this topology, a request to Admin Center could be directed to any of the running instances and have visibility only to the server on which the request runs.

The following administrative features are not supported in a PaaS environment:

- `adminCenter-1.0`
- `clusterMember-1.0`
- `collectiveController-1.0`
- `collectiveMember-1.0`

- dynamicRouting-1.0
- healthAnalyzer-1.0
- healthManager-1.0
- scalingController-1.0
- scalingMember-1.0

## File system restrictions

Most PaaS environments do not provide a persistent local file system to their applications. For Liberty, this impacts both the applications and the components within the server that write data locally and expect it to persist across a server JVM restart.

The Liberty transaction manager writes log files to the local file system when multiple resource managers are involved in the transaction. If the logs are not available after a JVM failure and restart, then transactions cannot be automatically completed and must be manually resolved to unlock data and to make it consistent across resource managers. To avoid this scenario, the Liberty buildpack or cartridge prevents transaction log records from being written and raises an exception to the application to prevent the second resource from enlisting. As a result, although you can still use transactions with a single XA resource, a second transactional resource cannot be enlisted in a transaction. Additionally, Web Services Atomic Transactions cannot be used because they always write log records.

If your PaaS environment provides persistent storage, then you can modify the Liberty buildpack or cartridge to enable two-phase transactions by removing the following Java property from the JVM configuration:

```
-Dcom.ibm.tx.jta.disable2PC=true
```

The following features depend on persistent local storage:

- wsAtomicTransaction-1.2
- Other features that use transactions, depending on the application behavior

## Network restrictions

In general, PaaS routers do not support Internet Inter-ORB Protocol (IIOP) traffic, so remote requests to Enterprise JavaBeans (EJB) components cannot be used. The following features depend on IIOP transport:

- appClientSupport-1.0
- appSecurityClient-1.0
- ejbRemote-3.2

In some situations, such as SSL termination at the router, Liberty relies on HTTP headers to describe aspects of the original client request. When you use SSL in a PaaS environment, the headers must be set by the PaaS router. On IBM Bluemix, these headers are already set, so you can use the `ssl-1.0` feature and any features that depend on it without changes. To get the expected behavior in other PaaS environments, you might need to configure the router to set these headers as described in NGINX and WebSphere Application Server.

The following features require the router to set HTTP headers:

- `ssl-1.0`
- Other features that depend on `ssl-1.0`, as listed in the *Features that enable this feature* section of “Secure Socket Layer” on page 951

---

## Chapter 6. Administering Liberty

A server configuration consists of a `server.xml` file, a `bootstrap.properties` file, and any optional files that are included by the two main configuration files. You can use WebSphere Application Server Developer Tools for Eclipse or a text editor to edit the configuration files. There is no administrative console for Liberty, but you can use Admin Center to administer Liberty servers and applications and other resources from a web browser on a smartphone, tablet, or computer.

### About this task

Liberty is configured by exception. The runtime environment operates from a set of built-in configuration default settings, and you only need to specify configuration that overrides those default settings. You do this by editing either the `server.xml` file or another XML file that is included in `server.xml` at run time.

Features are the units of functionality by which you control the pieces of the runtime environment that are loaded into a particular server. They are the primary mechanism that makes the server composable. The list of features that you specify in the server configuration provides a functional server.

When you first install and start the server, a feature manager and a default server configuration are available:

- By default, a server contains the `jsp-2.2` feature, to support servlet and JSP applications. You can use the feature manager to add the features that you need.
- Server configuration is by exception. When you specify the features that you need, the default configuration of those features provides a rich environment that is designed to cover most common requirements, therefore you only need to specify changes from the default configuration.

**8.5.5.0** You can organize Liberty servers into collectives to administer multiple Liberty servers at a time efficiently and accurately. For information about collectives, see “Setting up the server-management environment for Liberty by using collectives” on page 1134.

### Procedure

- 
- “Administering Liberty by using developer tools” on page 1556
- “Administering Liberty manually” on page 1564
- **8.5.5.0** Chapter 7, “Extending Liberty,” on page 1771

---

## XML escape characters

You need to escape specific XML characters in Liberty configuration files, such as the `server.xml` file because Liberty does not automatically escape these characters. If you use the Rational Application Developer tool, you do not need to manually escape these characters.

*Table 115. XML characters.* For more information, see Extensible Markup Language (XML) .

Original character	Escaped character
"	&quot;
'	&apos;
<	&lt;
>	&gt;

Table 115. XML characters (continued). For more information, see Extensible Markup Language (XML) .

Original character	Escaped character
&	&amp;

---

## Administering Liberty by using developer tools

### Distributed operating systems

You can modify how the workbench interacts with Liberty by using the server editor.

#### Procedure

1. In the Servers view, right-click the server and select **Open**.
2. The server editor opens.

#### What to do next

You can modify the publishing, timeout, and other settings regarding the interaction between the workbench and the server.

## Editing the Liberty configuration by using developer tools

### Distributed operating systems

You can modify the behavior of Liberty by editing the configuration. For example, you can configure which HTTP ports to use, what features are enabled, and logging and tracing settings.

#### Before you begin

For a description of the underlying process of configuring a server, and detailed information about specific aspects of server configuration, see “Administering Liberty manually” on page 1564.

#### About this task

The server configuration editor consists of two views: the Source view and the Design view. The Design view is a structured view of the file whereas the Source view is a text view. But both of them are views of the same server configuration file. The Design view has many features that help with the construction of some of the more complex elements in the server configuration such as data sources.

The following steps are demonstrated in the Design view.

#### Procedure

1. To open the Server Configuration editor, select any of the following options:
  - In the **Servers** view, right-click the server configuration and select **Open**.
  - In the **Enterprise Explorer** view, expand your server project and the server folder. Right-click the `server.xml` file and select **Open**.
2. Under the **Configuration Structure** section, the elements in the configuration are displayed.
3. Under the **Feature Manager** section, the details for the currently selected element are displayed. The details can also be modified here.
4. To add new elements, select **Server Configuration** under the **Configuration Structure** section then click **Add**.

5. To add child elements, select the parent element under the **Configuration Structure** section and then click **Add**.
6. You can remove or move elements by selecting the element and using the **Remove**, **Up**, and **Down** buttons.

## What to do next

You can use the key combinations from Table 116 in both the Source view and the Design view.

Table 116. Keyboard shortcuts

Key combination	Function
Ctrl+Space	Content assistance. It displays variables that have the correct type for the current field (int, string, and other code) or ids of the correct type for a reference field.
F3	Hyperlink to variable references and id references.

## Specifying the Liberty configuration with dropins files by using developer tools

8.5.5.6

You can specify the server configuration for Liberty by creating configuration dropins files and placing these files in the `configDropins` directory.

### About this task

You can use the dropins files to set a default configuration, or override configurations that are set in the `server.xml` file or included files. The server configuration validator includes configuration dropins files as part of the overall server configuration validation. The server configuration editor shows variables and references that are defined in dropins files in the appropriate content assistance and drop-down lists.

You can place configuration dropins files in either the `${server.config.dir}/configDropins/defaults` directory or in the `${server.config.dir}/configDropins/overrides` directory.

- If you place these files in the `defaults` directory, then the configuration is applied before the server configuration. In this case, the files provide default values, which you can override in the main `server.xml` file or the included files.
- If you place the configuration dropins files in the `overrides` directory, then the configuration is applied after the server configuration. In this case, the files override the main `server.xml` or included files.

For more information about configuration dropins files, see: “Using the configuration dropins folder to specify server configuration” on page 1593.

### Procedure

1. To create a configuration dropins file, right-click your server in the Servers view.
2. Complete one of the following options:
  - a. To create a configuration dropins file in the `defaults` directory, select **New > Configuration Dropins File > Defaults**
  - b. To create a configuration dropins file in the `overrides` directory, select **New > Configuration Dropins File > Overrides**.
3. Enter the name of the file that you want to create.
4. Click **OK**.

The new file is displayed.

5. To see the merged configuration, complete one of the following options:
  - a. Right-click the `server.xml` file in the Enterprise Explorer or Project Explorer view, and then select **Liberty > Open Merged View**.
  - b. In the Servers view, right-click on **Server Configuration** and select **Open Merged View**.The merged view of the server configuration shows the defaults at the beginning of the merged configuration. It also shows the overrides at the end of the merged configuration.

## Starting and stopping a server by using developer tools

You can start and stop a server by using the Liberty developer tools.

### Procedure

- To start a server:

In the Servers view, right-click the server and click **Start** to start the server or click **Debug** to start the server in the debug mode. Alternatively, click  to start the server, or click  to start the server in the debug mode.

**Tip:**  8.5.5.4 When you start a remote Liberty server, you can specify which debug port to use in the **Remote Start Settings** section of the server editor. The default port is 7777.

- To stop the server:

In the Servers view, right-click the server and click **Stop**. Alternatively, click  to stop the server.

**Tip:** In the Servers view, you must select the server entry to perform these tasks. Do not select the server configuration entry, for example Server Configuration [server.xml], to perform these tasks.

### What to do next

You can configure the server elements by using the tools.

## Switching a Liberty Docker server between run and debug mode by using developer tools

8.5.5.9

For your Liberty Docker server, you can use WebSphere Developer Tools to switch your server between run and debug mode. When you switch between these modes, the tools create a Docker image and a Docker container, which you can save.

### Before you begin

You must create a Liberty Docker server by using WebSphere Developer Tools. For more information about using WebSphere Developers Tools to create a Liberty server in a Docker container, see “Creating a workbench Liberty server in a Docker container by using developer tools” on page 1430.

### About this task

When you create a Liberty server in a Docker container, the run command and host mapped ports are fixed. As a result, when you switch a Liberty Docker server between run and debug modes, WebSphere Developer Tools commit a new Docker image based on your Docker container. This action preserves all of your changes to the container at that point. Then, the tools create a new container from the new image, but modify the run command to either run or debug the server. When you switch to debug mode, the tools map the debug port to the host.

The tools do not delete the original image and container. However, the tools remove any temporary images and containers when you switch modes. To avoid losing changes that you made to your server in debug mode, you can save the last temporary image and container when you delete a Liberty Docker server.

## Procedure

1. Switch your server from run mode to debug mode:
  - a. Open the Servers view in WebSphere Developer Tools by clicking **Window > Show view > Servers**.
  - b. Start your server in debug mode by right-clicking *your\_server* and selecting **Debug**.  
The tools go through the following steps:
    - 1) Disconnect from the *your\_server* container and stop the container.
    - 2) Commit the *your\_server* container to a new image that is named *your\_server\_debug\_websphere-liberty*
    - 3) Create a new container that is named *your\_server\_debug* from the *your\_server\_debug\_websphere-liberty* image.
    - 4) Connect to the *your\_server\_debug* container.
  - c. If the tools display the Server Execution Mode Switch window, click **OK** to continue.  
The tools display the Server Execution Mode Switch window only the first time that you switch the mode for your server.
2. Switch your server back to run mode from debug mode by right-clicking *your\_server* and selecting **Run**.  
The tools go through the following steps:
  - a. Disconnect from the *your\_server\_debug* container and stop the container.
  - b. Commit the *your\_server\_debug* container to a new image that is named *your\_server\_run\_websphere-liberty*
  - c. Create a new container that is named *your\_server\_run* from the *your\_server\_run\_websphere-liberty* image.
  - d. Connect to the *your\_server\_run* container.
3. Delete the *your\_server* server by right-clicking *your\_server* and selecting **Delete**.
4. Click **Yes** to save the *your\_server\_run* container and the *your\_server\_run\_websphere-liberty* image.

## Results

You switched your server from run mode to debug mode and back to run mode. When you switched back to run mode, you saved any changes that you made to the container and image when you were in debug mode.

## Defining a utility project as a shared library

### Distributed operating systems

You can define a utility project as a shared library and associate defined shared libraries with an application or web project.

### Before you begin

To use the shared library function in the workbench, you must create a utility project and define it as a shared library. The utility project is the only project type that can be used as a shared library.

## About this task

A shared library is an external Java archive (JAR) file that is used by one or more applications. Using shared libraries enables multiple application published on a server to use a single library, rather than use multiple copies of the same library. After you associate shared libraries with an application or project, the application or module class loader loads classes in the shared libraries and makes those classes available to the application or module.

## Procedure

To define a utility project as a shared library:

1. Create a utility project:
  - a. In the toolbar, select **File > New > Project**.
  - b. Expand **Java EE** and select **Utility Project**. Click **Next**.
  - c. In the **Project name** field, specify a name for the utility project.
  - d. Under the **Ear membership** section, clear the **Add project to an EAR** check box.
  - e. Under the **Target runtime** section, verify the WebSphere Application Server Liberty is selected.
  - f. Click **Finish**.
2. Define the artifacts in the newly created utility project. For example, you can add Java classes to the utility project.
3. Define the utility project as a shared library:
  - a. In the **Project Explorer** view, right-click the utility project and select **Properties > Liberty > Shared Library**.
  - b. In the **Shared library ID** field, type a string as an identifier for the shared library.
  - c. In the **Archive directory** field, type or browse to a directory where you want to place the compressed copy of your utility project as a JAR file. The file name convention of the JAR file is *utilityProjectName.jar*, where *utilityProjectName* is the name of the utility project.
  - d. In the **Liberty Shared Library** page, click **Apply** to confirm your changes. Click **OK** to close the Properties window.
4. Add the utility project to the server. **Distributed operating systems** For more details see “Adding and running an application on Liberty by using developer tools” on page 2141 topic.

## Results

Here is an example entry added to the server configuration (server.xml) file:

```
<library id="libid">
  <fileset dir="C:\temp" includes="Util.jar"/>
</library>
```

In addition, the JAR file is added in the specified archive directory. In the previous example, the `Util.jar` file is added in the `C:\temp` directory.

## Setting a web project to use shared libraries

### Distributed operating systems

If you have a utility project defined as a shared library, you can associate defined shared libraries with a web project.

## Before you begin

- **8.5.5.0** Define a utility project as a shared library.

## About this task

A shared library is an external Java archive (JAR) file that is used by one or more applications. Using shared libraries enables multiple application published on a server to use a single library, rather than use multiple copies of the same library. After you associate shared libraries with an application or project, the application or module class loader loads classes in the shared libraries and make those classes available to the application or module.

## Procedure

1. To set a web project to use shared libraries:
  - a. In the **Project Explorer** view, right-click your web project that you want to associate shared libraries.
  - b. Select **Properties > Liberty > Shared Libraries**.
  - c. When you click the **Add** button, a list of shared library **IDs** will appear. In the **IDs** field, specify one or more shared library identifiers that you want the project to reference. To specify multiple identifiers, use a comma-separated list. For example: ID1, ID2, ID3

**Tip:** The shared library identifier is the value specified in the **Shared Library ID** field from the Defining a utility project as a shared library task.

2. You might want to add its associating utility projects to the class path for compilation-purpose:
  - a. In the **Project Explorer** view, right-click your project that you are associating shared libraries.
  - b. Select **Properties > Java Build Path**.
  - c. Select the **Projects** tab.
  - d. Click **Add**.
  - e. Select the utility projects that the project references.
3. Develop the artifacts in the web project. For example, you can add a servlet in a web project that references classes in the shared libraries.
4. Add the web project to the server. **Distributed operating systems** For more details see “Adding and running an application on Liberty by using developer tools” on page 2141 topic.

## Results

Here is an example entry added to the server configuration (server.xml) file:

```
<application type="war" id="web" name="web" location="web.war">
  <classloader commonLibraryRef="libid"/>
</application>
```

## Exploring the runtime environment by using developer tools

### Distributed operating systems

You can use the **Runtime Explorer** view to browse the available servers. This view shows all of the available servers for the runtime environment as opposed to the **Servers** view, which shows only those servers that are configured in the workspace. In both the Runtime Explorer and Servers view, you can expand each server to show the configuration for that server.

## Before you begin

The application server that the Runtime Explorer view supports is the WebSphere Application Server Liberty.

## About this task

You can use the Runtime Explorer view to complete the following tasks:

- View the servers that are defined in a runtime environment.
- View the shared configurations files that are defined in a runtime environment.
- Create a server in a runtime environment.
-  **8.5.5.2** Create a runtime environment and optionally install add-ons from the Liberty Repository on the Downloads page on WASdev.net.
-  **8.5.5.6** Configure additional repositories.

## Procedure

To open the Runtime Explorer view:

1. In the toolbar of the workbench, select **Window > Show View > Other**.
2. In the **Show View** window, expand **Server** and select **Runtime Explorer**. Click **OK**.

## Displaying the server configuration in a merged view

### Distributed operating systems

You can use the **Merged Configuration** view to see a flattened view of the server configuration and any included configuration files.

## About this task

In the Server Configuration editor, under the **Configuration Structure** section, you can use the **Include** element to import files that contain additional configuration settings. The **Include** element can embed multiple layers of configuration files within the `server.xml` file, which can make the configuration difficult to read without tools. The **Merged Configuration** view provides a flattened view of the server configuration and any included configuration files. This is a read-only view and cannot be edited.

## Procedure

To display the server configuration in a merged view:

In the Servers view, right-click the server configuration and select **Open Merged View**.

## Example

Here is an example of the source code for the `server.xml` file. Look at the **include** tag which imports the `common.xml` file:

```
<server>
  <featureManager>
    <feature>jsp-2.2</feature>
    <feature>servlet-3.0</feature>
  </featureManager>
  <application id="Web2.5" location="Web2.5.war" name="Web2.5" type="war"/>
  <include location="common.xml"/>
</server>
```

Here is an example of the source code for the `common.xml` file:

```
<server>
  <application id="Setup" location="Setup.war" name="Setup" type="war"/>
</server>
```

Look under the **Configuration Structure** sections to see the difference between the Server Configuration editor and Merged Configuration view. The Merged Configuration view replaces the **Include: common.xml** element from the Server Configuration editor with **Application: Setup** element.

## Viewing the schema documentation for the server configuration

### Distributed operating systems

You can view the schema documentation for the server configuration (server.xml file) within the workbench. The documentation provides information about the configuration elements that are available, the default settings, and details for each of the elements.

### Procedure

In the **Servers** view, right-click on the server configuration and select **Open Schema Reference**.

## Generating a Liberty server dump using developer tools

Using the Liberty Utilities menu, you can generate a server dump for support.

### About this task

You can use the Utilities menu of your Liberty server to generate a server dump to capture all service-related information for support.

### Procedure

1. In the **Servers** view, right-click your Liberty server, and select **Utilities > Generate dump for Support...**
2. In the **Generate Dump** page, enter a location for the dump archive or use the **Browse** button. Then, click **Finish** to create the server dump file.
3. In the **Console** view, the path to the server dump is indicated:

```
Server TestServer dump complete in
D:\LibertyUnzip\wlp\usr\servers\TestServer\TestServer.dump-12.03.22_15.00.11.zip.
```

## Packaging a Liberty server by using developer tools

You can create a compressed file containing a server runtime environment, server configuration, and applications using the packaging wizard.

### About this task

Because a Liberty server is lightweight, you might find it useful to package up your applications and server in a compressed file. You can then store this package, distribute it to colleagues, use it to deploy the application to a different location or to another machine, or even embed it in your product distribution.

### Procedure

1. In the **Servers** view, stop the server.
2. Right-click your Liberty server, and select **Utilities > Package Server...**

3. In the Package Server page, in the **Archive** field, type a filename and path for your archive package, or click **Browse** to locate a filename and path. This filename can include a full path name. If the full path is omitted, a compressed file called *package\_file\_name.zip* is created in the `${server.output.dir}` directory.
4. In the **Include** field, select whether to include:
  - **Full runtime (all)**
  - **Minimal runtime (minify)**
  - **No runtime (usr)**

For details on these include options, see Packaging a Liberty server from the command prompt topic.

5. Click **Finish**.

## Adding a data source by using developer tools

You can add a data source to your application using the developer tools.

### Procedure

1. In the Project Explorer view, expand *liberty\_name* > **servers** > *server\_name* > **server.xml**, and select **Open**.
2. In the design view, select **Server Configuration**, and click **Add**.
3. On the Select item to add to Server Configuration: page, select **Data Source** and fill in the JNDI name.
4. On the Data Source Details panel, alongside **JDBC Driver**, click **Add**.
5. On the Configure a JDBC driver page,
  - In the **Library ref:** field, select an option from the drop-down list, or click **Add** to create a new one.
    - In the **Fileset ref:** field, select an option from the drop-down list, or click **Add** to create a new one.
      - In the **Base directory** field, type a path for your base directory or click **Browse** to locate a library location path. Use the drop-down arrow next to Browse to choose between browsing for a relative path or browsing for an absolute path.
      - In the **Includes** field, type the name of your data source, for example *derby.jar*, or click **Browse** to locate the data source archive file that you want to include.
      - In the **Excludes** field, type the archives that you want to exclude, or click **Browse** to locate the data source archive file that you want to exclude.
6. Your JDBC data source has been added to your application.

---

## Administering Liberty manually

You can administer Liberty from the command prompt, configure it with web server plug-ins, and capture its status. You can package a Liberty server configuration along with the applications that it runs, for distribution to colleagues, or installation on other systems. If available, you can use the Equinox OSGi console to aid with debugging.

### About this task

The *server.xml* file is the primary configuration file for the server. You can edit this file, and the files it includes, in a text editor. You can also change the location of the *server.xml* file. However, for most configurations you do not need to do this.

The *bootstrap.properties* file is used to specify properties that need to be available before the main configuration is processed. If you update the *bootstrap.properties* file, you must restart the server for the changes to take effect.

## Example

All the elements that can be configured in the `server.xml` file, and the files it includes, are described in “Liberty features” on page 826. However, the only required element is a server definition:

```
<server/>
```

Beyond this server definition, you only specify overrides and additions to the default configuration values. For example, to change the transaction timeout value, you specify:

```
<transactions timeout="30" />
```

Some attributes can have multiple values. For example, you use a list of values to define the features that are to be provided by the server:

```
<server>
  <featureManager>
    <feature>servlet-3.0</feature>
    <feature>localConnector-1.0</feature>
  </featureManager>
</server>
```

See also “Adding and removing Liberty features” on page 1587.

Where multiple instances of a resource type can be configured, for example applications or data sources, you need only provide the attributes that are unique for the resource. You can let the other attributes use the default values, or override them as needed. Therefore the contents of the `server.xml` file can be brief. For example, here is a complete server configuration to run a web application:

```
<server>
  <featureManager>
    <feature>servlet_3.0</feature>
  </featureManager>
  <application name="snoop" location="/mywebapps/snoop" id="snoop" type="war"/>
</server>
```

For detailed information about specific aspects of server configuration, see the subtopics.

## Customizing the Liberty environment

You can customize the Liberty environment by using certain specific variables to support the placement of product binary files and shared resources in read-only file systems.

### About this task

The Liberty specific environment variables in the following list can be configured in the `server.env` file to customize the Liberty environment. The `${wlp.install.dir}` configuration variable has an inferred location that is always set to the parent of the directory that contains the launch script.

- `WLP_USER_DIR`

This environment variable can be used to specify an alternative location for `${wlp.user.dir}`. This variable must be an absolute path. If this variable is specified, the runtime environment looks for shared resources and server definitions in the specified directory. The `${server.config.dir}` is equivalent to `${wlp.user.dir}/servers/serverName`. If this environment variable is not specified, `${wlp.user.dir}` is set to `${wlp.install.dir}/usr`.

- `WLP_OUTPUT_DIR`

This environment variable can be used to specify an alternative location for server generated output such as logs, the workarea directory, and generated files. Files in the logs directory can include `console.log`, `messages.log`, and any generated FFDC files. Generated files can include server dumps that are created with the `server dump` or `server javadump` command. This variable must be an absolute

path. If this environment variable is specified, `${server.output.dir}` is set to the equivalent of `WLP_OUTPUT_DIR/serverName`. If this environment variable is not specified, `${server.output.dir}` is the same as `${server.config.dir}`.

When the server command is used, the server process uses the output directory as its current working directory.

- **z/OS** WLP\_ZOS\_PROCEDURE

This environment variable can be used to specify the name of an STC procedure to be used to start the server as a z/OS started task rather than as a USS background process. By default, the command port remains enabled to allow continued administration of the server from the server script. Optionally, the command port can be manually disabled restricting server administration to just the z/OS operator console, see *Specifying Liberty bootstrap properties*.

- **8.5.5.0** WLP\_DEBUG\_ADDRESS

This environment variable can be used to specify an alternative port when you run the server in debug mode. The default value is 7777. When Liberty is run in debug mode from the server command, the following values are set `JAVA_DEBUG="-Dwas.debug.mode=true -Dcom.ibm.websphere.ras.inject.at.transform=true -agentlib:jdwp=transport=dt_socket,server=y,suspend=y,address=${WLP_DEBUG_ADDRESS}"`. However, if you run Liberty from the **ws-server.jar** executable JAR file, or the embedded Liberty server SPI, then you must use the same settings to enable debug mode for Liberty.

You can specify `WLP_OUTPUT_DIR`, `WLP_USER_DIR`, and **8.5.5.0** `WLP_DEBUG_ADDRESS` environment variables in `server.env` files. You can also specify JVM options in `jvm.options` files. Both `server.env` and `jvm.options` files work only when you use the server management script. If you use the **ws-server.jar** executable JAR file to launch your server, these files are not supported.

## Procedure

- Specify environment variables by using `server.env` files.

You can use `server.env` files at the installation and server levels to specify environment variables such as `JAVA_HOME`, `WLP_USER_DIR`, and `WLP_OUTPUT_DIR`. For example:

```
# Use a specific Java binary
JAVA_HOME=/opt/ibm/java-i386-60/jre
# JAVA_HOME=c:\Java
```

### Note:

- The `server.env` files support only key=value pairs.
- Empty lines and lines that start with the # character are ignored.
- There are no escape characters; all characters are literal, including backslashes and leading and trailing white space.
- There should be no white space surrounding the equals "=" sign.
- Shell and variable expansion are not supported.
- `WLP_USER_DIR` can be specified only in the `${wlp.install.dir}/etc/server.env` file because the purpose of this variable is to specify where the remaining configuration is located. After the remaining configuration is found and merged, no further configuration in a different location is expected, or supported.

The server management script searches for `server.env` files in two locations: `${wlp.install.dir}/etc/server.env` and `${server.config.dir}/server.env`. If both files are present, the contents of the two files are merged; values in the server-level file take precedence over values in the runtime-level file.

You can also specify these environment variables in the shell environment, but the `server.env` files take precedence over those variables.

- Customize JVM options by using `jvm.options` files.

You can use `jvm.options` files at the runtime and server levels to specify more server startup options, for example, `-X` arguments. The options are applied when the start, run, and debug actions are started through the server management script. Be sure to specify only one option per line. For example:

```
# Set the maximum heap size to 1024m.
-Xmx1024m

# Set a system property.
-Dcom.ibm.example.system.property=ExampleValue

# Enable verbose output for class loading.
-verbose:class

# Enable verbose garbage collection.
-verbose:gc

# Specify an alternate verbose garbage collection log on IBM Java Virtual Machines only.
-Xverbosegclog:verbosegc.log

# Specify additional verbose garbage collection options on HotSpot Java Virtual Machines only.
-Xloggc:verbosegc.log
-XX:+PrintGCDetails
-XX:+PrintGCTimeStamps
-XX:+PrintHeapAtGC
```

The server management script searches for `jvm.options` in two locations: `${wlp.install.dir}/etc/jvm.options` and `${server.config.dir}/jvm.options`. If both files are present, the options in the `${server.config.dir}/jvm.options` file are used.

**Note:**

- Do not put property values in quotes.
- Empty lines and lines that start with the `#` character are ignored.
- There are no escape characters; all characters are literal, including back-slashes and leading and trailing white space.
- There should be no white space surrounding the equals `=` sign.
- Shell and variable expansion are not supported.

## What to do next

If you start the Liberty server by using the server script, all of the operating system environment variables from the current session are available. If you start the server by using either the MBean or the Admin Center, the only available environment variables are those variables that are available to a remote command that is running on that system.

## Administering Liberty from the command line

You can use the server command and `ws-server.jar` executable JAR file to create a server, to start, or stop a server, to check if it is running, or debug a server.

### About this task

The `wlp/bin` directory contains a script called `server` to help with controlling the server process. The syntax of this script is as follows:

```
server <action> [server] [options]
```

For available values of the **options**, see “Liberty:server command options” on page 1569.

**Avoid trouble:** The administrative console allows a start and a stop of a Liberty server that is a cluster member of an auto-scalable cluster, but only when the server is in maintenance mode. Starting or

stopping a Liberty server from the command line when the Liberty server is a cluster member of an auto-scalable cluster can lead to unpredictable results.

This script supports the following actions:

**create** A command that creates a new server.

**run** A command that launches the server in the foreground.

**debug** A command that runs the named server in the console foreground after a debugger connects to the debug port. The default port is 7777. **0.5.5.0** You can use the `WLP_DEBUG_ADDRESS` variable to specify an alternative port.

**dump** A command that creates a snapshot of a server and saves the result into an archive file for further tuning and diagnosis.

### **0.5.0.1** **javadump**

A command that creates a snapshot of the server Java virtual machine (JVM) and saves the result into files. Each dump type creates a file, but not all dump types are supported by all virtual machines. The default directory for dump files is `${server.output.dir}`. To set a different default directory, you must use an IBM JVM and set the following environment variables:

- **IBM\_HEAPDUMPDIR**
- **IBM\_COREDIR**
- **IBM\_JAVACOREDIR**

### **package**

A command that packages a server.

**start** A command that launches the server as a background process.

**z/OS** You can use the `WLP_ZOS_PROCEDURE` environment variable to specify the name of an STC procedure to be used to start the server as a z/OS started task rather than as a USS background process, see Customizing the Liberty environment.

**stop** A command that stops a running server.

**status** A command that checks to see whether a specified server is running.

### **version**

A command that displays the version information of current server and Java runtime environment.

**help** A command that gets command-line script help, including details of additional options.

**Note:** If a server is not specified on the command line, the action is performed against the default server instance, `defaultServer`, if it exists.

You can also carry out similar actions by using the executable JAR file `ws-server.jar` that is in the `${wlp.install.dir}/bin/tools` directory.

## **Example**

To run the server script on Windows systems:

```
server.bat create server_name
server.bat package server_name
server.bat run server_name
server.bat help server_name
```

To run the server script on other systems:

```
server create server_name
server package server_name
server run server_name
server help server_name
```

To run the executable JAR file `ws-server.jar` without using the `server` script:

```
java -javaagent:bin/tools/ws-javaagent.jar -jar bin/tools/ws-server.jar server_name --create
java -javaagent:bin/tools/ws-javaagent.jar -jar bin/tools/ws-server.jar server_name
java -javaagent:bin/tools/ws-javaagent.jar -jar bin/tools/ws-server.jar --help
```

The `--help` option provides information about additional command-line parameters for the executable JAR file `ws-server.jar`, such as `--stop`, `--version`, `--clean`, `--include`.

## Liberty:server command options

The **server** command supports starting, stopping, creating, packaging, and dumping a Liberty server. This topic describes all available options and exit codes that you can use with the **server** command and the equivalent executable jar file `ws-server.jar`.

### Syntax

The command syntax is as follows:  
`server action serverName [options]`

where the value of **action** represents the operation that you can perform on a Liberty server. See available administration operations for Liberty from the command prompt.

**Note:** If a server is not specified on the command line, the action is performed against the default server instance, `defaultServer`, if it exists.

### Options

The following options are available for the **server** command:

**--archive**="*path\_to\_the\_target\_archive\_file*"

Specifies a target file for the *package* **8.5.0.1** or *dump* operation. This path can be either a relative path, which is relative to the installation root directory of Liberty, or an absolute path. The default archive target is a compressed file with the server name, which is stored in the installation root directory. Use quotation marks if the value contains spaces. You can use this option for both *package* and *dump* operations.

**Distributed operating systems** **IBM i** **8.5.5.0** If you specify a `.jar` extension for your archive file name, the **server** command creates a new self-extracting archive file from which the Liberty server can be installed by using the **java** command; for more information, see "Installing Liberty by extracting a Java archive file" on page 1374. The `.jar` extension facility is not available on the z/OS platform.

**--clean**

Cleans all persistent cached information that is related to the specified server instance, which includes OSGi resolver metadata and persistent OSGi bundle data. If you use this option, the server will be required to recompute any cached data at the next startup, which might take more time than a restart that can reuse cached data.

**Note:** This option is not necessary for normal operation. IBM service might request that you use this option when you provide an interim fix, or if there is a suspected problem with the cached

data. **8.5.5.0** This option might also be necessary if you are developing a product extension, and you are either updating OSGi manifests or planning to clear persistent OSGi bundle data.

**--include=package\_option**

Specifies the files that you want to package, where *package\_option* can take one of the following values:

- `all` specifies to package all the files in the Liberty installation directory. If the `${WLP_USER_DIR}` and `${WLP_OUTPUT_DIR}` are defined in the `server.env` file, the files under them are packaged. This value applies only to the *package* operation.
- `usr` specifies to package the files in the `${WLP_USER_DIR}` directory. This value applies only to the *package* operation.
- **8.5.5.0** `minify` specifies to package only those parts of the runtime environment, and files in the `${WLP_USER_DIR}` directory, that are required to run the server, which minimizes the size of the resulting archive. This value applies only to the *package* operation.

**--include=diagnose\_option,diagnose\_option,...**

Specifies the type of diagnostic information to be captured. The value of **--include** is a comma-delimited list, which can contain any of the following values:

- `heap` is used to help diagnose the excessive memory consumption and memory leaks, which shows live objects in the memory and references between them. On IBM J9 virtual machines, the resulting file is named `heapdump.date.time.processID.sequenceNumber.phd`. On HotSpot virtual machines, the resulting file is named `java.date.time.processID.sequenceNumber.hprof`. This value applies to both the *dump* and *javadump* operations
- `system` is also used to help diagnose the excessive memory consumption and memory leaks, but they are also useful for finding defects in the virtual machine. These dumps are only supported on IBM J9 virtual machines. The resulting file is named `core.date.time.processID.sequenceNumber.dmp`. This value applies to both the *dump* and *javadump* operations.
- `thread` is used to help diagnose hung threads, deadlocks, and can sometimes be used for diagnose excessive CPU issues. These dumps are always created with the `server javadump` command. On IBM J9 virtual machines, the resulting file is named `javacore.date.time.processID.sequenceNumber.txt`. On HotSpot virtual machines, the resulting file is named `javadump.date.time.processID.sequenceNumber.txt`. This value can also be applied to the *dump* operation.

**Note:** The thread dump type is supported only when the server is running on the Java SDK. If the server is started with a JRE, an error is reported indicating that the server does not support the dump type. This restriction applies to HotSpot virtual machines only; the thread Java dump type is supported on any IBM JVM (JRE or SDK).

**8.5.5.0** **--os=os\_value,os\_value,...**

Specifies the operating systems that you want the packaged server to support. Supply a comma-separated list. The default value is `any`, indicating that the server is to be deployable to any operating system supported by the source.

To specify that an operating system is not to be supported, prefix it with a minus sign ("`-`"). For a list of operating system values, refer to the OSGi Alliance web site at the following URL: <http://www.osgi.org/Specifications/Reference#os>.

This option applies only to the *package* operation, and can be used only with the **--include=minify** option. If you exclude an operating system, you cannot later include it if you repeat the *minify* operation on the archive.

## Server Process

The server process is created by using the environment variables that are specified in the `server.env` file. The following JVM options are added by default:

- **8.5.5.0** The `-javaagent:wlp/bin/tools/ws-javaagent.jar` option is required for trace, monitoring, and other server capabilities.
- The `-Xshareclasses` and related options enable the shared class cache on supported IBM J9 virtual machines. The cache directory is set to `WLP_OUTPUT_DIR/.classCache`.
- The `-XX:MaxPermSize` option increases the size of the permanent generation for HotSpot virtual machines prior to Java 8. You can set the `WLP_SKIP_MAXPERMSIZE` environment variable to `true` to avoid this default option, which avoids warnings such as:

Java HotSpot(TM) Client VM warning: ignoring option MaxPermSize=256m; support was removed in 8.0

You can use the `jvm.options` file to override these default JVM options or add additional JVM options. For more information about the `server.env` and `jvm.options` file, see “Customizing the Liberty environment” on page 1565.

**UNIX** **z/OS** **IBM i** **8.5.5.1** By default, the `server` command sets the `umask` value to deny all permissions to “Other” users before running the action. However, you can set the `WLP_SKIP_UMASK` environment variable to `true` to avoid setting the `umask` value.

The current working directory of the server process is set to the server output directory.

**UNIX** **z/OS** **IBM i** The `server` command creates a process ID (PID) file when you start the server and deletes the PID file when you stop the server. By default, the PID file is set to `WLP_OUTPUT_DIR/.pid/serverName.pid`. The absolute path of the PID file can be changed by setting the `PID_FILE` environment variable, or the absolute path of the PID directory can be changed by setting the `PID_DIR` environment variable.

The standard output and error from the server process is output to the foreground console when you use the `run` and `debug` actions and is redirected to the `WLP_OUTPUT_DIR/serverName/logs/console.log` file by default when you use the `start` action. The log name can be changed by setting the `LOG_FILE` environment variable, and the log directory can be changed by setting the `LOG_DIR` environment variable. For more information about the logging configuration, see “Liberty:Logging and Trace” on page 2313.

The `stop` action prevents new application requests from entering the server, which allows existing requests some time to complete. After that time, the remaining server components are stopped and the server process exits. Application requests that do not complete in the allowed time fail, but their exact behavior depends on their activity when the server components stopped.

## Exit codes

The following exit codes are available for the `server` command and the equivalent executable JAR file `ws-server.jar`:

- 0 OK. 0 indicates successful completion of the requested operation. For server status, 0 indicates that the server is running.
- 1 For server status, 1 indicates that the server is not running. For other operations, it indicates invocation of a redundant operation. For example, starting a started server or stopping a stopped server. This code might also be returned by JVM if invalid Java options are used.
- 2 The server does not exist.
- 3 An unsupported action was called on a running server. For example, the server is running when the package action is called.

- 4 An unsupported action was called on a stopped server. For example, the server is not running when the dump action is called
- 5 Unknown server status. For example, the workarea directory is missing, or the Attach API fails to work.
- >=20 Return codes greater than or equal to 20 indicates that an error occurred while performing the requested . Messages are printed and captured in log files with more information about the error.

## Usage

The following examples demonstrate the correct syntax:

```
server run
server start myserver --clean
server package myserver --archive="archivefile.zip" --include=all
server dump myserver --archive="c:\mybackup\myserver.zip" --include=thread
```

8.5.0.1

server javadump myserver

8.5.0.1

server javadump myserver --include=heap,system

## Liberty: iAdmin command

IBM i

The command supports operating a Liberty server on the IBM i platform. The command file is in the wlp/lib/native/os400/bin directory. The command file is a script named iAdmin.

## Syntax

The command syntax is as follows:

```
iAdmin task [options]
```

where the value of **task** can be one of the following options:

- **POSTINSTALL**
- **PREUNINSTALL**
- **GRANTAUTH**

The **POSTINSTALL** task configures the server start command to launch servers as jobs in the QWAS85 subsystem. Additionally, the task:

- Configures Liberty to run servers under the QEJBSVR user profile.
- Configures the default JDK location by setting WLP\_DEFAULT\_JAVA\_HOME in file wlp/etc/default.env to the location of the 32 bit version of the minimum supported Java level.
- Adds an entry for the product in the IBM i native product registry.
- Creates IBM i native libraries and objects such as the QWAS85 subsystem and the QEJBSVR user profile.

Call the iAdmin POSTINSTALL command only after Installing Liberty by extracting an archive file.

The **GRANTAUTH** task grants the QEJBSVR user profile the necessary file permission and ownership for the server role. The **POSTINSTALL** sets the file ownership and authorities correctly for the QEJBSVR user profile. However, if you create files manually, or if you modify the authorities on files used by the Liberty server, you can call the iAdmin GRANTAUTH command to ensure that QEJBSVR has the correct authorities.

The **PREUNINSTALL** task removes the native libraries and objects created by the **POSTINSTALL** task. Call the iAdmin PREUNINSTALL command before removing the Liberty application-serving environment from your system, but you only need do so if Liberty was installed by executing a JAR file.

## Note:

- You must have \*ALLOBJ and \*SECADM special authority to use the **POSTINSTALL** and **PREUNINSTALL** commands.
- You must have \*ALLOBJ special permission, own, or have \*OBJMGT authority to all objects in the specified directory subtrees to use the **GRANTAUTH** command.
- After running the **POSTINSTALL** task, you must also have \*ALLOBJ and \*SECADM special authority to start and stop the Liberty server.

## Options

The following options are available for the **iAdmin** command:

### **--outputdir wlp\_user\_dir**

The directory for server generated files. This option must only be an absolute path, is optional for the **GRANTAUTH** task, and is ignored for all other tasks. When not specified, the default location for server generated output is used.

### **--rolename role\_name**

The role that the user profile is assigned. The server role is the only currently supported role. This option is required for the **GRANTAUTH** task and is ignored for all other tasks.

### **--userdir wlp\_user\_dir**

The directory containing shared resources and server definitions. This option can only be an absolute path, is optional for the **GRANTAUTH** task, and is ignored for all other tasks. When not specified, the default location for shared resources and server definitions is used.

### **--userprofilename user\_profile\_name**

The user profile to grant authority to. **QEJBSVR** is the only currently supported user profile name for the server role. This option is required for the **GRANTAUTH** task and is ignored for all other tasks.

## Usage scenarios

The following examples demonstrate correct syntax. Run the command in any of the following examples on one line.

- Configuring Liberty to start as a job in the QWAS85 subsystem and to swap to the QEJBSVR user profile when running.  
`wlp/lib/native/os400/bin/iAdmin POSTINSTALL`
- Granting the server role to the QEJBSVR user profile for the shared resources, server definitions, and output locations configured for this Liberty runtime environment.  
`wlp/lib/native/os400/bin/iAdmin GRANTAUTH --rolename server --userprofilename QEJBSVR`
- Removing the native libraries and objects created by the **POSTINSTALL** task.  
`wlp/lib/native/os400/bin/iAdmin PREUNINSTALL`

## Liberty:application client commands

8.5.5.6

The **client** command supports create, run, debug, package and help actions.

## Syntax

The `wlp/bin` directory contains scripts that are called `client` and `client.bat` to help with running client applications. The syntax of these scripts are as follows:

```
client <action> client_name [options]
```

where the value of **action** represents the operation that you can perform on an application client.

**Attention:** If an application client name is not specified on the command line, the task is taken against the default application client instance, `defaultClient`.

## Actions

The client script supports the following actions:

**create** A command that creates a new application client.

**run** A command that launches the application client in the foreground.

**debug** A command that runs the named application client in the console foreground after a debugger connects to the debug port. The default port is 7778.

**package** A command that packages an application client.

**help** A command that gets command-line script help, including details of more options.

## Options

The client script supports the following options:

**--archive="path to the target archive file"**

Specify the archive target to be generated by the package action. You can specify the target as an absolute path or as a relative path. If this option is omitted, the archive file is created in the client output directory. The target file name extension might influence the format of the generated archive. The default archive format for the package action is pax on z/OS and zip on all other platforms. The jar archive format produces a self-extracting jar file that similar to the original installer archive.

**--clean**

Clean all cached information related to this client instance.

**--include=value,value,...**

A comma-delimited list of values. The valid values vary depending on the action.

**template="templateName"**

Specify the name of the template to use when creating a new client.

**--autoAcceptSigner**

Automatically accept and store the signer certificate in the client truststore without being prompted to examine the server certificate.

## Example

The following examples show the application client command actions that you can run on Windows systems: 

```
client.bat create client_name
client.bat run client_name
client.bat help
```

The following examples show the application client command actions that you can run on other systems:

```
client create client_name
client run client_name
client help
```

## Running an application client from the command line: 8.5.5.6

You can use the client run task to run an application client.

### Before you begin

Before you can run an application client, you must create a client and add a configuration for your client application in the `client.xml` file. See the [Creating a Liberty client manually](#) topic for examples of how you would create the application client.

### About this task

The `wlp/bin` directory contains scripts that are called `client` and `client.bat` to run client applications. The syntax of these scripts is as follows:

```
client action <client_name> [options]
```

### Procedure

Use the following command to run the client:

```
client run client_name
```

#### Windows

```
client.bat run client_name
```

where *client\_name* is the name of the client.

**Attention:** If a default client exists, it runs `defaultClient`. If a default client does not exist, `defaultClient` is created, then runs (and likely fails because there is no application that is configured).

## Liberty:configUtility command

8.5.5.5

The **configUtility** command enables you to download configuration snippets from the IBM WebSphere Liberty Repository. The command also enables you to replace configuration snippet variables with your input values. The Liberty repository *config snippets* are samples of Liberty server configurations for specific tasks.

For information about accessing and using the Liberty repository, see “[Liberty: Liberty Repository](#)” on page 965.

### Syntax

The command syntax is as follows:

```
configUtility action | configUtility configSnippet [options]
```

where *action* can take one of the following values:

**find** Display a list of all configuration snippets in the repository.

 Specify a string to filter the list to configuration snippets that have the specified string in the description. Enclose strings that contain spaces in double-quotation marks.

**help** Display help information for a specified action.

**install** Download the configuration snippet from the repository or use a local configuration snippet for variable substitution.

The *configSnippet* variable is the name of the configuration snippet. Run the **configUtility find** command to get the names of configuration snippets in the repository.

## Options

The following options are available for the **configUtility install configSnippet** command:

**--info** List all variable options in the configuration snippet. Return an empty list if the configuration snippet has no variables for substitution.

**--v[variable]=value**

Replace configuration snippet variables found by the **--info** option with your input values. The utility identifies these variable using **--v[variable]**. Do not include the brackets ([]) in the command.

**--createConfigFile=path**

Optional. The utility writes the code snippet to the file specified by *path* instead of to the console screen. Add the provided code snippet to the server.xml configuration to include the specified file.

**--encoding=[xor|aes]**

Optional. Specify the keystore password encoding. Supported encodings are xor and aes. The default encoding is xor.

**--key=key**

Optional. Specify a key to be used when encoding using AES. This string is hashed to produce an encryption key which is used to encrypt and decrypt the password. Optionally, provide the key to the server by defining the variable wlp.password.encryption.key whose value is the key. If this option is not provided, a default key is used.

**--useLocalFile=file**

Use a configuration snippet from a local file system. You must specify the file path. This option replaces specifying a configuration snippet name.

## Usage

The following examples demonstrate correct syntax:

```
configUtility find
configUtility find filter_string
configUtility find "filter string"
configUtility help
configUtility install configSnippet
configUtility install configSnippet --info
configUtility install configSnippet --vvariable=value
configUtility install configSnippet --createConfigFile=C:/wlp/usr/servers/server1/snippet-include.xml
configUtility install configSnippet --encoding=aes --key=myAESkey
configUtility install --useLocalFile=C:/wlp_temp/mySnippet.xml
```

**Tip:** If your option value has spaces, you must enclose it in double quotation marks ("). For example, if the file path for the **--createConfigFile** option is C:\Program Files\mySnippets\snippet-include.xml, specify **--createConfigFile="C:/Program Files/mySnippets/snippet-include.xml"** in the command.

## CAUTION:

Different operating system might treat some characters differently. For the Windows environment, if you have ! in your input string, it needs to be escaped by the ^ character. For example,

```
D:\Liberty\images\855\Liberty855\wlp\bin>configUtility createConfigFile="a^!"
```

## Downloading and customizing configuration snippets from the command line: 8.5.5.5

You can use the **configUtility** command to download configuration snippets from the IBM WebSphere Liberty Repository. You can also use the command to replace configuration snippet variables with your input values. The Liberty repository *config snippets* are samples of Liberty server configurations for specific tasks.

### Procedure

1. Open a command line, then change directory to the wlp/bin directory.
2. Generate a list of configuration snippets in the Liberty repository.

Run the following command to write a list of configuration snippets to your console screen:

```
configUtility find
```

From this generated list, you can determine the name of a configuration snippet to download and, optionally, modify.

8.5.5.6 You can specify a string to filter the list to configuration snippets that have the specified string in the description. For example, for a list of security-related configuration snippets, run:

```
configUtility find security
```

Enclose strings that contain spaces in double-quotations marks; for example:

```
configUtility find "ejb security"
```

3. Optional: Generate a list of all variable options for a configuration snippet.  
Using the name of configuration snippet obtained in step 2, run the following command to write a list of variable options for the snippet to your console screen. For *configSnippet*, specify the name of the snippet:

```
configUtility install configSnippet --info
```

The command returns an empty list if the configuration snippet has no variables for substitution.

4. Download a configuration snippet.

Using the name of the configuration snippet obtained in step 2, run the following command to write the configuration snippet to your console screen. For *configSnippet*, specify the name of the snippet:

```
configUtility install configSnippet
```

To write the configuration snippet to a file instead of to your console screen, add the **--createConfigFile** option and specify a file path. You can include the generated file in a server.xml configuration file using an include statement. For example, to write the configuration snippet to the C:\wlp\usr\servers\server1\snippet-include.xml file on your local file system, run the following command:

```
configUtility install configSnippet --createConfigFile=C:\wlp\usr\servers\server1\snippet-include.xml
```

**Tip:** If the file path has spaces, you must enclose it in double quotation marks ("). For example, if the file path is C:\Program Files\mySnippets\snippet-include.xml, specify **--createConfigFile="C:/Program Files/mySnippets/snippet-include.xml"** in the command.

To download and replace configuration snippet variables found by the **--info** option with your input values, use the **--v[variable]=value** option:

```
configUtility install configSnippet --v[variable]=value
```

For example, to specify a value of user1 for the \$[adminUser] variable in the remoteAdministration snippet, run:

```
configUtility install remoteAdministration --vadminUser=user1
```

This command writes a configuration for Remote Administration to a console screen, with user1 replacing the `[$adminUser]` variable:

```
<quickStartSecurity userName="user1" userPassword="{adminPassword}"/>
```

For more information about command options, see “Liberty:configUtility command” on page 1575.

## Running the ddlGen utility

8.5.5.6

You can generate data definition language (DDL) if there are features in the server configuration that require access to a database.

### Before you begin

You must start the server before running the ddlGen utility.

### About this task

The utility generates data definition language (DDL) for each feature that is configured in the server that requires access to a database. You can change the path that the ddlGen utility uses to search for the server by exporting the environment variable, `WLP_USER_DIR`, in the command line where the utility is run.

### Procedure

1. In the `server.xml` file, add the `localConnector-1.0` feature under the `featureManager` tag.

```
<featureManager>  
  <feature>localConnector-1.0</feature>  
</featureManager>
```

2. In a command line, run the `wlp/bin/ddlGen {generate|help} <server_name>` command, where `<server_name>` is the name of the server that you want to generate DDL for.

### Results

The following table shows the nonzero codes that might be returned:

Table 117. Return codes and explanations for the ddlGen utility

Return Code	Explanation
0	Success. The DDL is generated to <code>/\${server.output.dir}/ddl</code> .
20	The action provided is not valid.
21	The server was not found. Message CWWKD0100E shows the file system directory where the utility looked for the server. This location can be changed by exporting the variable, <code>WLP_USER_DIR</code> , in the command line where the utility is run.
22	The <code>localConnector</code> feature is not present in the server configuration or the server was not started.
23	The MBean that generates DDL was not found.
24	The MBean that generates DDL reported an error. The server logs contain more details about the error.
255	An unexpected error occurred.

## Liberty:Generating Liberty configurations schema from the command line

8.5.5.0

Use the `ws-schemagen.jar` tool that is in the installation's `bin/tools` directory to generate the schema for Liberty core and other installed products extensions in a single output file.

## Syntax

The command syntax is as follows:

```
java [JVM options] -jar ws-schemagen.jar [options] outputFile
```

## Options

The following options are available:

### **--encoding=charset**

Where *charset* is the character set to use when you are creating the output file.

### **--ignorePidsFile=fileName**

Where *fileName* is the name of the file name that contains a list of pids to ignore.

### **--locale=language**

Where *language* specifies the language to use when you are creating the output file. This string consists of the ISO-639 two-letter lowercase language code, optionally followed by and underscores and the ISO-3166 uppercase two-letter country code.

## Usage examples

The following example generates the installed products' schema and stores in a file called `schema.xml`:

```
java -jar ws-schemagen.jar schema.xml
```

The following example generates the installed products' schema and stores in a file that is called `schema.xml` using the Brazilian Portuguese language:

```
java -jar ws-schemagen.jar schema.xml --locale=pt_BR
```

The following example displays help information:

```
java -jar ws-schemagen.jar --help
```

## Generating a Liberty server dump from the command line

From the command line, you can use the `server dump` **8.5.0.1** or `server javadump` command to capture status information for a Liberty server.

### About this task

The `server dump` command is useful for problem diagnosis of a Liberty server because the result file contains server configuration, log information, and details of the deployed applications in the `workarea` directory. The command can be applied to either a running or a stopped server.

For a running server, the following information is also included:

- State of each OSGi bundle in the server
- Wiring information for each OSGi bundle in the server
- Component list that is managed by the Service Component Runtime (SCR) environment
- Detailed information of each component from SCR
- Configuration administration data of each OSGi bundle
- Information about registered OSGi services
- Runtime environment settings such as Java virtual machine (JVM), heap size, operating system, thread information, and network status

**8.5.0.1** The server `jvaddump` command is useful for diagnosing problems at the JVM level, such as hung threads, deadlocks, excessive processing, excessive memory consumption, memory leaks, and defects in the virtual machine. The command can be used only on a running server. Each dump type creates a file, but not all dump types are supported by all virtual machines. See “Liberty:server command options” on page 1569. The default directory for dump files is `${server.output.dir}`. To set a different default directory, you must use an IBM JVM and set the following environment variables:

- **IBM\_HEAPDUMPDIR**
- **IBM\_COREDIR**
- **IBM\_JAVACOREDIR**

## Procedure

1. Open a command line, then change directory to the `wlp/bin` directory.
2. **8.5.0.1** Capture the status information by using one of the following command-line tools. If you do not specify a server name, `defaultServer` is used.
  - To create a snapshot of the server status, use `server dump` command.

**Distributed operating systems** **IBM i**

```
server dump server_name --archive=package_file_name.dump.zip
```

**8.5.0.1** `--include=heap` where `package_file_name.dump.zip` is a file name that you choose. This file name can include a full path name. If the full path is omitted, a compressed file called `package_file_name.dump.zip` is created in default directory `${server.output.dir}`.

**z/OS**

```
server dump server_name --archive=package_file_name.dump.pax
```

**8.5.0.1** `--include=heap` where `package_file_name.dump.pax` is a file name that you choose. This file name can also include a full path. If the full path is omitted, a compressed file called `package_file_name.dump.pax` is created in default directory `${server.output.dir}`.

**8.5.0.1** The `--include` parameter is optional. You can request additional memory dump types. For example, `--include=heap` option requests a heap dump; `--include=thread,heap,system` option requests a thread dump, a heap dump, and a system dump.

- **8.5.0.1** To create a snapshot of the JVM status, use `server jvaddump` command.

**Distributed operating systems** **IBM i**

```
server jvaddump server_name --include=heap
```

**z/OS**

```
server jvaddump server_name --include=heap
```

The `--include` parameter is optional. You can request additional memory dump types. For example, `--include=heap` option requests a heap dump; `--include=heap,system` option requests a heap dump and a system dump. The output files are created in the default directory `${server.output.dir}`. To set a different default directory, you must use an IBM JVM and set the **IBM\_HEAPDUMPDIR**, **IBM\_COREDIR**, and **IBM\_JAVACOREDIR** environment variables.

**Note:** The resulting file is created by using UTF-8 encoding for entry names, so the tool that you use to open the file must be able to use UTF-8 encoding for entry names. The `jar` command in a Java SDK uses this format.

## Results

If the specified server does not exist, the command does not succeed. If the specified server exists, a result file is created that contains the status information of the server.

## Packaging a Liberty server from the command line

From the command line, you can create a compressed file that contains a Liberty runtime environment, the files in the shared resources directory, a specific server, and the applications that are embedded in the server. You can also choose to exclude the runtime binary files from the compressed file.

### About this task

The Liberty server is lightweight, and therefore you can easily package a server installation in a compressed file. You can store this package, distribute it to colleagues, and then use it to deploy the installation to a different location or to another machine, or even embed the installation in a product distribution.

The server installation that you want to package cannot already be joined to a collective. You can only package a stand-alone server.

**Note:** **Distributed operating systems** The resulting file is created by using UTF-8 encoding for entry names, so the tool that you use to open the file must be able to use UTF-8 encoding for entry names. The `jar` command in a Java SDK uses this format.

### Procedure

To package a Liberty server from the command line, complete the following steps:

1. Open a command line, then change directory to the `wlp/bin` directory.
2. Stop the server.
3. Run the **package** command to create a package.

**8.5.5.5** You can package the Liberty profile server or the runtime.

- Package the Liberty server.

The default archive format is `.zip` on all platforms apart from z/OS where it is `.pax`. You can also generate a `.jar` archive.

If you do not specify a server name, `defaultServer` is used. If you do not specify the **--archive** parameter, the value of `server_name` is used for `package_file_name`, and the compressed file is created in the `${server.output.dir}` directory.

Choose the correct command for your environment.

– **Distributed operating systems** **IBM i**

Use this command to generate a `.zip` archive.

```
server package server_name --archive=package_file_name.zip --include=all
```

where `package_file_name.zip` is a file name that you choose. This file name can include a full path name. If the full path is omitted, a compressed file called `package_file_name.zip` is created in the `${server.output.dir}` directory.

– **Distributed operating systems** **IBM i**

Use this command to generate a `.jar` archive. The advantage of a `.jar` archive is that the scripts in the `bin` directory keep their permissions, so they are executable when the package is installed.

```
server package server_name --archive=package_file_name.jar --include=all
```

where `package_file_name.jar` is a file name that you choose.

For more information about extraction options with this archive file, see “Java archive file extraction options” on page 1376.

– **z/OS**

Use this command to generate a `.pax` archive.

```
server package server_name --archive=package_file_name.pax --include=all
```

where *package\_file\_name.pax* is a file name that you choose. This file name can also include a full path. If the full path is omitted, a compressed file called *package\_file\_name.pax* is created in the `${server.output.dir}` directory.

The pax archive format saves the extended attributes that are required for the Liberty to work as designed in all supported scenarios. If a compressed file in ZIP format is required, specify the target archive name and include the `.zip` extension. If the specified name ends with `.zip`, then a compressed file in ZIP format is generated, instead of the z/OS default PAX format.

An archive format of `.jar` is not valid on z/OS.

You can also use the `--include` option with this command. For example, the `--include=all` option packages the runtime binaries and the relevant files in the `${WLP_USER_DIR}` directory; the `--include=usr` option packages only relevant files in the `${WLP_USER_DIR}` directory, effectively excluding the runtime binaries from the compressed file.

The `--include=usr` option is not valid with an archive format of `.jar`.

**8.5.5.0** If you use the `--include=minify` option, the **server** command packages only those parts of the runtime environment, and files in the `${WLP_USER_DIR}` directory, that are required to run the server. This option significantly reduces the size of the resulting archive.

The parts of the runtime environment that are retained by the `minify` operation depend on the features that are configured in the server that you are packaging. Only those features that are required to run the server are retained, and the remaining features are removed. Therefore, you cannot later enable a feature that has been removed. For example, if only the `servlet-3.0` feature is retained, you cannot later enable the `jpa-2.0` feature.

You can repeat the `minify` operation to further reduce the size of the archive if the configuration is changed. There is, however, no reverse operation for the `minify` operation, so if you later require one or more features that have been removed, you must begin again with a complete Liberty server.

While the `minify` operation is running, the server is temporarily started, and you see the associated messages. For this reason, you cannot use the `--include=minify` option with a server that is not able to be started, but you can package it with the `--include=all` or `--include=usr` options.

You can specify the operating systems that you want the packaged server to support by using the `--os` option with the `--include=minify` option.

For example, to package a server with z/OS support removed, use the following command:

```
server package --archive="nozoz.zip" --include=minify --os=-z/OS
```

To package a server with OS/400 support retained, but z/OS support removed, use the following command:

```
server package --archive="small.zip" --include=minify --os=OS/400,-z/OS
```

To package a server that supports only Linux, use the following command:

```
server package --archive="linux.zip" --include=minify --os=Linux
```

**Note:** **z/OS** To unpackage a file on z/OS, go to the location where you want to unpackage the file and then run the following command. The `-ppx` option is used to preserve the extended attributes.

```
pax -ppx -rf location filename.pax
```

Where *location* is the path where the file exists and *filename.pax* is the name of the file.

- **8.5.5.5** Package the Liberty runtime.

Create a runtime archive that contains the `wlp` directory, but does not contain the `usr` directory. The naming convention for a server package is *package\_name.zip*; for example, `CustomerPortalApp.zip`. To create a runtime archive, run the **package** command without a server name and with the `--include=wlp` option:

```
server package --include=wlp
```

To specify a package file name and target location, add the `--archive=package_path_name` option; for example:

```
server package --include=wlp --archive=c:\temp\myPackage.zip
```

If you do not specify a valid package name or target location with the `--archive` option, then the command creates the `wlp.zip` runtime archive in the `$WLP_OUTPUT_DIR` location, which is the `${wlp.install.dir}/usr/servers` directory by default. The target location must exist before running the command. Thus, if the target location is `c:\temp`, the `C:\temp` directory must exist and have write permission for the command to write the archive to the `C:\temp` directory.

## Running a Liberty server from a JAR file

8.5.5.9

You can start a Liberty server from a Java archive (JAR) file. This method provides a compact, portable way of starting a Liberty server. You create the JAR file by using the Liberty server command and then run as an executable JAR file by using the `java -jar` command.

### Create the runnable JAR file

You can specify `minify` to get the smallest archive possible. You must specify a JAR type archive to get a runnable JAR file. The default archive type is `.zip` on all platforms except `z/OS`, where the only supported type is `pax`. For example:

```
server package <server name> --include=[minify,]runnable --archive=<jar file name>.jar
```

### Run the JAR file

Run the JAR file by using the standard `java` command with the `-jar` option, for example:

```
java -jar <jar file name>.jar
```

### Operation

When the JAR file runs, it gets extracted to a temporary location and then the server runs in the foreground, started by the Liberty server run command. All output is written to `stdout` or `stderr`. By default, files are extracted to temporary locations:

- For Windows: `%HOMEPATH%/wlpExtract/<jar file name>_nnnnnnnnnnnnnnnnnn`
- For all other platforms: `$HOME/wlpExtract/<jar file name>_nnnnnnnnnnnnnnnnnn`

You can control the output location by using the `WLP_JAR_EXTRACT_ROOT` or `WLP_JAR_EXTRACT_DIR` environment variable.

### Stopping the server

To stop the Liberty server press **Ctrl-C**. When the Liberty server stops, the extraction directory is automatically deleted. If you stop the active shell in any other way, the extraction directory is not cleaned up automatically, you must clean it up manually.

### Run in debug mode

You can run the Liberty server in debug mode if you set the environment variable `WLP_JAR_DEBUG` before you start the server.

### Controlling output

By default, server output is written to the extraction directory, which is deleted when the server stops. If you want to save the output, specify a durable output location by using the `WLP_OUTPUT_DIR` environment variable before you start the server.

## Two-phase commit transactions

By default, two-phase commit transactions are disabled because the transaction logs are in the expansion directory and are deleted when the Liberty server is stopped. Therefore, transaction recovery is not possible.

To enable two-phase commit, configure the transaction log to be in a durable location in the file system or an RDBMS and set the `WLP_JAR_ENABLE_2PC` environment variable.

To configure the transaction log, use either the `transactionLogDirectory` or `dataSourceRef` attribute on the transaction element in your `server.xml` configuration.

## Running under CYGWIN

Running a Liberty server JAR file in a CYGWIN shell has two requirements:

1. Specify the `WLP_JAR_CYGWIN` environment variable.

This variable causes the Liberty server JAR runner to do UNIX-style file and process handling when it is running in the CYGWIN environment.

2. Run under the bash shell, not mintty.

Automatic extraction file deletion occurs only when you run under the bash shell. You can run under mintty, but you must delete the extraction files manually. Mintty does not forward the necessary signal that is required to trigger Java shutdown hooks.

## Environment variable reference

Table 118. The environment variable names and their definitions

Environment variable name	Description
<code>WLP_JAR_EXTRACT_ROOT</code>	Extracts JAR file to directory <code>\${WLP_JAR_EXTRACT_ROOT}/&lt;jar file name&gt;_nnnnnnnnnnnnnnnnnnnn</code>
<code>WLP_JAR_EXTRACT_DIR</code>	Extracts JAR file to directory <code>\${WLP_JAR_EXTRACT_DIR}</code> .
<code>WLP_OUTPUT_DIR</code>	Writes Liberty server output files to directory <code>\${WLP_OUTPUT_DIR}</code> .
<code>WLP_JAR_DEBUG</code>	Runs Liberty server by using server debug <code>&lt;server name&gt;</code> instead of server run <code>&lt;server name&gt;</code> .
<code>WLP_JAR_ENABLE_2PC</code>	Set to value true to enable 2PC when the runnable JAR file runs.
<code>WLP_JAR_CYGWIN</code>	Set to value true if you are running the JAR file under CYGWIN.

## Starting and stopping a server from the command line

You can use the server tasks to start or stop a server.

### About this task

The `wlp/bin` directory contains a script called `server` to help with controlling the server process. The syntax of this script is as follows:

```
server action serverName [options]
```

For available values of `[options]`, see “Liberty:server command options” on page 1569.

**Note:** If a server is not specified on the command line, the action is performed against the default server instance, `defaultServer`, if it exists.

**Tip:** Do not use the command line to start or stop a server that is managed by auto scaling with an enabled scaling policy.

## Procedure

- Use the following command to start the server:

```
server start serverName
```

where *serverName* is the name of the server.

- Use the following command to stop the server:

```
server stop serverName
```

where *serverName* is the name of the server.

**Note:** Normal server stop includes a quiesce stage before the server is shutdown. The quiesce stage, a period of 30 seconds, allows for services to perform pre-shutdown work, for example, stopping inbound listeners while allowing existing requests to complete. Applying the `--force` option to the stop command will skip the quiesce stage. The `--force` option will have no effect if **server stop** was already invoked. If you use the `--force` option, you may see unexpected exceptions in the `messages.log` file that occur after the **server stop** command was received by the server.

## Example

To start or stop a server by using the server script on Windows systems:

```
server.bat start serverName
```

```
server.bat stop serverName
```

To start or stop a server by using the server script on other systems:

```
server start serverName
```

```
server stop serverName
```

## Starting and stopping a Liberty server as a Windows service

### Windows

You can optionally register the Liberty server as a Microsoft Windows Service program when you run on Windows operating systems. You can manually start, stop, and unregister the Liberty server as a Windows service. You can also use the Microsoft Windows Services program to change Liberty to start automatically as a Windows service when the Windows server starts.

## Before you begin

Set the `JAVA_HOME` environment variable before you run the following commands. You can use the `server.env` file path to set the `JAVA_HOME` value reliably. For more information about using the `server.env` file, see “Customizing the Liberty environment” on page 1565.

## About this task

The commands to register, start, stop, and unregister Liberty as a Windows service use the same `server.bat` file that is used when you start the Liberty server from the command line. For available values of `[options]`, see “Liberty:server command options” on page 1569.

## Procedure

- Use the following command to register the server:

```
server registerWinService serverName
```

where *serverName* is the name of the server.

The Windows service name and Windows service display name is the *serverName*. After you register, you can find and administer the Liberty server as a service by using **regedit** from the Windows Registry program. Entries for the service in the registry are in the following locations:

```
HKEY_LOCAL_MACHINE->SOFTWARE->Wow6432Node->Apache Software Foundation->Procrun 2.0->serverName
HKEY_LOCAL_MACHINE->SYSTEM->CurrentControlSet->services->serverName
```

- Use the following command to start the server:

```
server startWinService serverName [options]
```

where *serverName* is the name of the server.

- Use the following command to stop the server:

```
server stopWinService serverName
```

where *serverName* is the name of the server.

- Use the following command to unregister the server:

```
server unregisterWinService serverName
```

where *serverName* is the name of the server.

## What to do next

When you install a fix pack by using archives, the directory under which the fix pack is installed can change from the directory where the Liberty server was running before you installed the fix pack. If you are running a Liberty server as a Windows service, then unregister that Liberty server as a Windows service before you install the fix pack. After you install the fix pack, register the Liberty server as a Windows service again.

If you need to manually remove Liberty as a Windows service, then update the Windows registry by using the Windows **regedit** program. The two entries that need to be removed from the Windows Registry are in the following locations:

```
HKEY_LOCAL_MACHINE->SOFTWARE->Wow6432Node->Apache Software Foundation->Procrun 2.0->serverName
HKEY_LOCAL_MACHINE->SYSTEM->CurrentControlSet->services->serverName
```

## Using Ant to automate tasks for Liberty

Apache Ant is a Java library tool for automating the build process. You can use Ant tasks that are provided by Liberty to manage the server and applications.

### Before you begin

**Important:** The `wlp-anttasks.jar` file that is included with Liberty is planned to be removed. For more information, see Removal notices. An open source Ant plug-in with more tasks for Liberty is available. The more recent Ant plug-in has a different antlib namespace, `xmlns:wlp="antlib:net.wasdev.wlp.ant"`. For more information about the open source Ant plug-in for Liberty, see the GitHub repository.

The Liberty Ant plug-in `wlp-anttasks.jar` files are located in Maven Central. If you want to use these tasks in your build script, you must make sure the plug-in is available on the Ant class path. Copy the plug-in file `wlp-anttasks.jar` to the `/lib` directory of the Ant installation, and declare the `antlib` namespace in the `build.xml` file. See the following example:

```
<project .... xmlns:wlp="antlib:net.wasdev.wlp.ant">
  ...
</project>
```

The namespace can be any string, provided you avoid name conflicts. After that, you must use the namespace as a prefix of the Ant tasks for Liberty. For example, you must use `wlp:server` when calling the server task.

## About this task

You can create build scripts that use these Ant tasks to package, install, and test your application on Liberty.

## Using an OSGi console

Eclipse Equinox currently provides an OSGi console that you can use to aid with debugging. This console is not available by default. You can enable this console in the OSGi framework that is running within Liberty by using the `osgiConsole-1.0` feature and by specifying a port to attach to.

## About this task

Liberty uses the Eclipse Equinox implementation of the OSGi core specification. Equinox currently provides an OSGi console. To enable this console, you first allocate a specific port to it by setting the `osgi.console` property in the `bootstrap.properties` file. Then you can use Telnet to connect to the console on that port, and explore the OSGi framework.

## Procedure

- **8.5.5.0** Add the `osgiConsole-1.0` Liberty feature to your `server.xml` file.  

```
<feature>osgiConsole-1.0</feature>
```
- Allocate a specific port to the OSGi console.  
You set the OSGi console port by specifying the `osgi.console` property. You set this property as a bootstrap property in the `bootstrap.properties` file. See “Specifying Liberty bootstrap properties” on page 1437.  

```
osgi.console=5471
```

The OSGi console is disabled when the `osgi.console` property is not set.
- Use Telnet to connect to the OSGi console port.  

```
telnet localhost 5471
```
- Use the console to explore the framework.  
The available commands vary, depending on the OSGi framework being used. Command-line help provides enough information to get started.

## Adding and removing Liberty features

Features are the units of functionality by which you control the pieces of the runtime environment that are loaded into a particular server. To add or remove a Liberty feature, you add or remove an XML snippet in the `<feature>` subelement of the `server.xml` configuration file. When you add or remove Liberty features, the changes are applied dynamically.

### Distributed operating systems

## Before you begin

You can add and remove Liberty features as described in this topic, or as described in “Editing the Liberty configuration by using developer tools” on page 1556.

## About this task

For a list of the main Liberty features, including the XML snippets that enable them, see “Liberty features” on page 826.

## Procedure

To add or remove Liberty features, complete the following steps:

1. Open the `server.xml` configuration file for editing.

Where *path\_to\_liberty* is the location you installed Liberty on your operating system, and *server\_name* is the name of your server.

You can do this using a text editor. By default, the path and file name for the configuration root document file is *path\_to\_liberty/wlp/usr/servers/server\_name/server.xml*. However, you can change the path. See **8.5.0.1** “Customizing the Liberty environment” on page 1565.

2. Add or remove features in the configuration file.

The set of features is enclosed within the `<featureManager>` element, and each feature within the `<feature>` subelement. For example:

```
<server>
  <featureManager>
    <feature>servlet-3.0</feature>
    <feature>localConnector-1.0</feature>
  </featureManager>
</server>
```

The matching of feature names is not case-sensitive; the following example is also a valid server configuration:

```
<featureManager>
  <feature>Servlet-3.0</feature>
  <feature>localConnector-1.0</feature>
</featureManager>
```

3. Save the changes to the configuration file.

## Results

Your changes are applied. If the server is running, the changes are applied dynamically.

## Using include elements, variables, and Ref tags in configuration files

You can keep all your configuration settings in a single `server.xml` file, or you can use include elements to consolidate configuration settings from separate files. You can use variables in the configuration to avoid hardcoding values that might not be appropriate when the configuration is reused in different environments. You can use Ref tags to refer to (and thereby reuse) existing code blocks that are defined elsewhere in the configuration.

## Procedure

- “Using include elements in configuration files”
- “Using variables in configuration files” on page 1590
- “Using Ref tags in configuration files” on page 1592

## Using include elements in configuration files

You can keep all your configuration in a single `server.xml` file, or you can use include elements to consolidate configurations from separate files to create the structure that is most useful to you.

## About this task

It can be easier to maintain a complex configuration by splitting it across a set of files. For example:

- You might want to include a file that contains variables that are specific to the local host, so that your main configuration can be used on multiple hosts.

- You might want to keep all of the configuration for a particular application in a separate file that can be versioned with the application itself.

## Example

This is the syntax for including a configuration file. You can set the **optional** attribute as true if you want to skip the include file when it cannot be found :

```
<include optional="true" location="pathname/filename" />
or
<include optional="true" location="url" />
```

The following list shows the possible locations; they are searched in the order shown.

1. in a location specified relative to the parent file
2. in the server configuration directory
3. in a location specified as an absolute path
4. on a web server

To ensure that your include configuration behaves predictably, you need to be aware of the following processing rules for included configuration files:

- For singleton services such as logging, or application monitoring, entries are processed in the order they appear in the file and later entries add to or override previous ones. This is also true for configuration instances, for example an application or data source, where the configuration instances have the same ID.
- Include statements can be placed anywhere within the `<server />` element.
- Each included file must contain a `<server />` element that matches the one in the parent configuration file.
- Included files can nest other included files.
- Each included file is logically merged into the main configuration at the position that the `<include />` statement occurs in the parent file.

In the following example, the primary server configuration file `server.xml` includes the contents of the `blogDS.xml` configuration file, which is located in the shared configuration directory. The `blogDS.xml` file contains a data source definition. This definition has been put in a separate configuration file so that it can be included in several different `server.xml` files, and thereby used across multiple server instances.

Here is example code from the `server.xml` file:

```
<server>
  <featureManager>
    <feature>servlet-3.0</feature>
    <feature>jdbc-4.0</feature>
  </featureManager>
  <application id="blog" location="blog.war" name="blog" type="war"/>
  <include optional="true" location="{shared.config.dir}/blogDS.xml"/>
</server>
```

Here is the example code from the `blogDS.xml` file:

```
<server>
  <dataSource id="blogDS" jndiName="jdbc/blogDS" jdbcDriverRef="derbyEmbedded">
    <properties createDatabase="create" databaseName="C:/liberty/basics/derby/data/blogDB" />
  </dataSource>
  <jdbcDriver id="derbyEmbedded"/>
  <library>
```

```

        <fileset dir="C:/liberty/basics/derby" includes="derby.jar" />
    </library>
</jdbcDriver>
</server>

```

## Using variables in configuration files

You can use variables in the configuration to avoid hardcoding values that might not be appropriate when the configuration is reused in different environments.

### About this task

Variables can be defined by setting a property in any of the following places:

- in the server configuration file, or an included file
- in the `bootstrap.properties` file

The following predefined variables can be referenced:

- directory properties, see “Liberty:Directory locations and properties” on page 1434
- JVM system properties
- **8.5.5.0** process environment variables

If the same variable is specified in multiple places, the precedence is as follows:

- variables in `bootstrap.properties` override the process environment variables
- variables in `server.xml`, or included XML files, override the variables in `bootstrap.properties` and process environment variables

**Best practice:** Variables that are specific to a particular server, for example port numbers, are specified in the `bootstrap.properties` file, allowing the `server.xml` to be shared across multiple servers while you keep those values different in each server. Variables that are shared across a group of servers, for example database configuration for a particular host, is better specified in an xml file that is included into the parent configuration file.

**Best practice:** Variable names must begin with an alphabetic character, and must contain the following characters only: alphabetic characters, numeric characters, and the “\_” and “.” characters.

### Procedure

- Specify a variable in a configuration file.

The variable definition syntax is `variable_name=value`. If the value contains a path, it is normalized during configuration processing by replacing repeated forward and backward slashes with a single forward slash, unless the value starts with double forward or backward slashes, which remain unchanged.

**Best practice:** If you need to set the value of a variable to contain repeated forward slashes, as are sometimes used for JDBC driver connection URLs, break the value into two parts at the double slashes. By placing the double forward slashes as the initial characters, normalization is avoided. For example, to store the value “jdbc:db2://host\_name.com”, use two variables:

```

URL_PART_1="jdbc:db2:"
URL_PART_2="//host_name.com"

```

Variables that are defined in the configuration files are scoped to the configuration elements by which they are used. For example, the following code fragment creates a variable that is called `updateTrigger_var` to be used in **applicationMonitor** configuration elements:

```

<applicationMonitor updateTrigger_var="mbean" />

```

To create a variable that is used in a particular configuration instance (such as an application or resource entry), you must also specify the instance identifier. For example: `<httpEndpoint id="defaultHttpEndpoint" HTTP_default_var="8889" />`

- Specify a variable in the `bootstrap.properties` file.

Variables that are defined in the `bootstrap.properties` file are not scoped to particular configuration elements. You enter the variables as key-value pairs. For example:

```
HTTP_default_var=8006
```

- Use a defined variable in the configuration.

The variable substitution syntax is `${variable_name}`. Multiple variable values may be concatenated by specifying `${variable_name1}${variable_name2}`. For example, to use the `HTTP_default_var` variable, add the following code fragment to the configuration file:

```
<httpEndpoint id="defaultHttpEndpoint"
httpPort="${HTTP_default_var}">
</httpEndpoint>
```

- Use variable element in the configuration

You can use the variable element to define a variable globally in the server configuration. If the same variable is defined in an included file, it is overridden by the one in the `server.xml` file. For example, to use the variable element, add the following code fragment to the configuration file:

```
<variable name="HTTP_default_var" value="8889" />
```

- **8.5.5.0** Use process environment variables in the configuration

Process environment variables are available if you use the `env.` configuration variable prefix, for example:

```
<fileset dir="${env.LIBRARY_DIR}" includes="*.jar"/>
```

For more information about specifying environment variables, see “Customizing the Liberty environment” on page 1565.

- **8.5.5.4** Use variable expressions in configuration

For configuration variables, you can use a limited variable expression syntax with the format `${<operand><operator><operand>}`. The description of the variable is as follows:

#### operand

Operands can either be long integer literals or the name of a variable that contains a long integer value. Variable names must begin with an alphabetic character, and must contain the following characters only: alphabetic characters, numeric characters, and the “\_” and “.” characters.

#### operator

The available operators are as follows:

- + for addition
- - for subtraction
- \* for multiplication
- / for division

If the expression cannot be parsed, a non-integer value is used, or an arithmetic error occurs, then the behavior is undefined.

For example, if the `HTTP_port_base` variable is defined, a variable expression might be used to define multiple `httpEndpoints`:

```
<httpEndpoint id="defaultHttpEndpoint" httpPort="${HTTP_port_base+0}"/>
<httpEndpoint id="httpEndpoint2" httpPort="${HTTP_port_base+1}"/>
```

- Override inheritable attributes in the configuration

You can override the default values of inheritable attributes in the configuration. The inheritable attributes are listed on the page with an `Inherits` type. For example, the **onError** attribute is one of

inheritable attributes. You can define a variable name for the **onError** attribute globally by either setting it in the `bootstrap.properties` or `server.xml` file with a variable element. If the same variable name is specified in both files, the value in the `server.xml` file is used. If the attribute is not explicitly set in either of two files, it uses the default value. If an invalid value is set to the inheritable attribute, the attribute value falls back to the global value defined in `bootstrap.properties` or `server.xml` file or the default value if not defined at the global level.

Another example is logging properties in Liberty. See “Liberty:Logging and Trace” on page 2313.

## Using Ref tags in configuration files

You can define a common configuration element, then reuse that definition by referring to it (using a Ref tag) from elsewhere in the configuration. Ref tags can be used in the same configuration file that contains the element definition, or in an included configuration file.

### About this task

Different approaches are used to specify relationships between the required configuration elements. For example, the following data source definitions are all valid. The first uses no Ref tags, the second uses a combination of direct element definition and Ref tags, and the third uses Ref tags only.

### Example

Example 1: Using no Ref tags.

```
<dataSource id="blogDS" jndiName="jdbc/blogDS">
  <properties createDatabase="create" databaseName="C:/liberty/basics/derby/data/blogDB"/>
  <jdbcDriver>
    <library>
      <fileset dir="C:/liberty/basics/derby" includes="derby.jar"/>
    </library>
  </jdbcDriver>
  <connectionManager maxPoolSize="10"/>
</dataSource>
```

Example 2: Combining direct element definition and Ref tags.

```
<dataSource id="blogDS" jndiName="jdbc/blogDS" connectionManagerRef="derbyPool">
  <properties createDatabase="create" databaseName="C:/liberty/basics/derby/data/blogDB"/>
  <jdbcDriver libraryRef="derbyLib"/>
</dataSource>

<connectionManager id="derbyPool" maxPoolSize="10"/>

<library id="derbyLib"/>
  <fileset dir="C:/liberty/basics/derby" includes="derby.jar"/>
</library>
```

Example 3: Using Ref tags only (except for the properties element, which is only permitted as nested).

```
<dataSource id="blogDS" jndiName="jdbc/blogDS"
  connectionManagerRef="derbyPool" jdbcDriverRef="derbyEmbedded">
  <properties createDatabase="create" databaseName="C:/liberty/basics/derby/data/blogDB"/>
</dataSource>

<connectionManager id="derbyPool" maxPoolSize="10"/>

<jdbcDriver id="derbyEmbedded" libraryRef="derbyLib"/>

<library id="derbyLib" filesetRef="derbyFileset"/>

<fileset id="derbyFileset" dir="C:/liberty/basics/derby" includes="derby.jar"/>
```

## Using the configuration dropins folder to specify server configuration

8.5.5.5

You can specify additional configuration files in the `configDropins` directory without specifying include elements in the `server.xml` file.

### Procedure

1. Create a `configDropins` directory under the `usr/servers/server_name` directory.
  - `usr/servers/server_name/configDropins/overrides`  
If you want to add configuration files to replace anything in the `server.xml` file of the server, create a `configDropins/overrides` directory. For example, to change ports that are defined in the `server.xml`, use a `configDropins/overrides` directory.
  - `usr/servers/server_name/configDropins/defaults`  
If you want the `server.xml` file to be the master configuration, but want to specify defaults for elements that the `server.xml` does not define, create a `configDropins/defaults` directory. For example, if you want developers to be able to provide configuration, but you want the `server.xml` to be the master configuration and you do not want the `server.xml` changed, use a `configDropins/defaults` directory.
2. Place the server configuration files in either the `configDropins/overrides` or `configDropins/defaults` directory.  
Both directories are monitored for updates so that when you add, remove, or update configuration files, the runtime configuration is updated dynamically.  
If there are any conflicts, the following rules determine precedence:
  - The configuration that is specified in the `configDropins/overrides` directory takes precedence over the configuration in the `server.xml` file. Configuration specified in `server.xml` file takes precedence over configuration that is specified in the `configDropins/defaults` directory.
  - Configuration from files in both the `configDropins/defaults` and `configDropins/overrides` directories take precedence over any default configuration that is specified by a feature.
  - The configuration files in the dropins directory are processed in alphabetical order. A later configuration overrides an earlier one. As an example, if `configDropins/defaults` contains `a.xml`, `b.xml` and `c.xml`, the configuration from `c.xml` takes precedence over `b.xml`, and `b.xml` takes precedence over `a.xml`.

**Note:** To maintain consistency across platforms, file names are converted to lower case before sorting alphabetically. This means that if two files are specified in the same dropins directory that have the same name except for case variations (such as `extraConfig.xml` and `ExtraConfig.xml`), the ordering behavior is indeterminate.

3. Optional: Turn off configuration monitoring. See “Controlling dynamic updates” on page 1594.

### ID variables that refer to configuration files

8.5.5.6

The Liberty run time occasionally needs to refer to a configuration element from the `server.xml` file. This action can occur in several ways, such as in the text of a message or in a file name.

The Liberty run time uses an xpath-style syntax to refer to configuration elements. The element type is printed first, followed by brackets that contain the ID of the configuration element. If the configuration element is nested inside another configuration element, the inner configuration element is preceded with a forward slash separating the inner and outer elements.

- For example, the following `databaseStore` configuration element is referred to as `databaseStore[DBTaskStore]` because the `databaseStore` is not nested and has an ID value of `DBTaskStore`.

```
<server>
  <databaseStore id="DBTaskStore">
    ...
  </databaseStore>
</server>
```

- The following data source configuration element is referred to as `databaseStore[DBTaskStore]/dataSource[DataSource0]` because the data source is nested underneath `databaseStore`, `databaseStore` has an ID value of `DBTaskStore`, and data source has an ID value of `DataSource0`.

```
<server>
  <databaseStore id="DBTaskStore">
    <dataSource id="DataSource0">
      ...
    </dataSource>
  </databaseStore>
</server>
```

- In some cases, a configuration element does not have an ID. In this case, an ID is generated. For example, the following data source configuration element might be referred to as `databaseStore[default-0]/dataSource[DataSource0]` because the `databaseStore` does not define an ID.

```
<server>
  <databaseStore>
    <dataSource id="DataSource0">
      ...
    </dataSource>
  </databaseStore>
</server>
```

## Controlling dynamic updates

There are three types of dynamic update that can be controlled through configuration: changing the server configuration; adding and removing applications; updating installed applications. For all deployed applications, you can configure whether application monitoring is enabled and how often to check for updates to applications. For the “dropins” directory, you can also configure the name and location of the directory and choose whether to deploy the applications that are in the directory.

### About this task

By default, deployed applications are monitored for updates, and the updates are dynamically applied to the running application. This applies both to applications that are deployed through configuration entries, and those deployed from the “dropins” directory. You can change these default behaviors by setting the **config** and **applicationMonitor** elements in the `server.xml` configuration file. You can use a text editor to do this, or you can use the developer tools and select **Configuration Admin Service** or **Application Monitor** in the server configuration design view.

See also the descriptions of the **config** and **applicationMonitor** elements in .

The default settings for application monitoring are as follows:

```
<applicationMonitor updateTrigger="polled" pollingRate="500ms"
  dropins="dropins" dropinsEnabled="true"/>
```

The default settings for configuration monitoring are as follows:

```
<config updateTrigger="polled" monitorInterval="500ms"/>
```

#### Notes:

- The **updateTrigger** property has three possible values:
  - polled** The runtime environment scans the `server.xml` file for changes using the timing interval specified by the **monitorInterval** property.

## **mbean**

The runtime environment only looks for updates when prompted to do so through a call to an MBean. This is the mode that is used by the developer tools to update the `server.xml` file, unless you override it.

## **disabled**

The updates are not dynamically applied.

- When you specify the **pollingRate** property or the **monitorInterval** property, you include the unit of time after the number:
  - ms (milliseconds)
  - s (seconds)
  - m (minutes)
  - h (hours)
- The **dropins** property specifies the name of the directory used as the “dropins” directory.
- The **dropinsEnabled** property is a boolean property that determines whether the applications in the “dropins” directory are deployed.

## **Procedure**

- Configure dynamic changes to the server configuration.

Changes to the `server.xml` file, or any files it includes, are detected by the runtime environment and applied to the active configuration. You can disable this behavior by setting the **config** element in the `server.xml` file:

```
<config updateTrigger="disabled"/>
```

You can also control dynamic updates to the server configuration through a provided mbean by setting the **config** element in the `server.xml` file:

```
<config updateTrigger="mbean"/>
```

You can then use the `FileNotificationMbean` to notify the server which configuration file or files you want to be dynamically reprocessed.

- Configure dynamic addition and removal of applications.

As described in Chapter 10, “Deploying applications in Liberty,” on page 2139, applications can be dynamically added to and removed from the server runtime environment through two mechanisms:

- By adding or removing application entries in the `server.xml` file.

If you disable dynamic changes to the server configuration as described in the previous step, then adding or removing application entries has no effect on a running server. Your changes are only applied at the next server restart. The changes are picked up immediately, if you update application entries using the developer tools.

- By moving application files into and out of the “dropins” directory.

This behavior can be controlled by setting the **applicationMonitor** element in the `server.xml` file. For example, to disable dynamic installation of applications from the “dropins” location, create an entry as follows:

```
<applicationMonitor dropinsEnabled="false"/>
```

- Configure dynamic updates to installed applications.

By default, if you add, remove or modify any files within a deployed application, or you replace the whole application with an updated version, the previous version is automatically stopped and the new version is started. This process applies for any deployed application, whether the application is in the “dropins” directory or at a location defined in the `server.xml` file. You can control this behavior by setting the **applicationMonitor** element in the `server.xml` file. For example, to disable dynamic update of all applications, create an entry as follows:

```
<applicationMonitor updateTrigger="disabled"/>
```

- Configure the name and location of the “dropins” directory.

By default, the “dropins” directory is `${server.config.dir}/dropins`. You can change this by setting the **applicationMonitor** element in the `server.xml` file. For the location, you can use any known variable, or a property in the `bootstrap.properties` file, or an absolute path, or a path relative to the server directory. For example, both the following settings point to the same location:

```
<applicationMonitor dropins="${server.config.dir}/applications" />
<applicationMonitor dropins="applications" />
```

**Restriction:** For web service applications, if the service client and service provider are not in the same application and the WSDL file in the service provider application is changed, you need to restart the web service client application manually to avoid the WSDL definition cache issue.

## Configuring class loaders and libraries for Java EE applications

By default, each application can access a set of provided APIs and its own internal classes and libraries. You can override the default settings, and configure class loading for each application.

### About this task

Each Java EE application has its own class loader in a running Liberty server. Liberty assumes some default settings for all Java EE applications, so that they can access the supported specification APIs (for example the servlet APIs if the servlet feature is enabled), and the IBM APIs. By default, each application can access these provided APIs and access its own internal classes and libraries. If you have to override the default settings and configure class loading for your application, complete one or more of the following tasks.

**Note:** If you use configuration to override the default settings, you cannot deploy the application by dropping it into the “dropins” directory.

### Procedure

- “Using a Java library with a Java EE application”
- “Sharing a library across multiple Java EE applications” on page 1597
- “Accessing third-party APIs from a Java EE application” on page 1598
- “Removing access to third-party APIs for a Java EE application” on page 1599
- “Overriding a provided API with an alternative version” on page 1600
- “Providing global libraries for all Java EE applications” on page 1598

### Using a Java library with a Java EE application

One way of using Java libraries with an application is to include them in the application itself. This might not always be desirable or appropriate, especially if the application is already packaged and does not include the library.

### About this task

In the following example, a library called Alexandria consists of two files:

- `alexandria-scrolls.jar` and
- `commons-lang.jar`

An application called Scholar, running on a server called Academy, needs access to this library.

### Procedure

1. Create a `mylib/Alexandria` directory in the `servers/Academy` directory under the `${WLP_USER_DIR}` directory.  
For example: `wlp/usr/servers/Academy/mylib/Alexandria`.
2. Copy the `alexandria-scrolls.jar` and `commons-lang.jar` files into the new folder.

3. Configure class loading for the application, so that the Alexandria library is loaded.

In the `server.xml` file, or an included file, add the following code:

```
<application id="scholar" name="Scholar" type="ear" location="scholar.ear">
  <classloader>
    <privateLibrary>
      <fileset dir="{server.config.dir}/mylib/Alexandria" includes="*.jar" scanInterval="5s" />
    </privateLibrary>
  </classloader>
</application>
```

**Note:** The `<privateLibrary>` element can also take a `filesetRef` attribute with a comma-separated list of `<fileset>` element IDs.

## Sharing a library across multiple Java EE applications

Libraries can be shared across multiple Java EE applications. All the applications can use the same classes at run time, or each application can use its own separate copy of those classes loaded from the same location.

### About this task

In the following example, a library called Alexandria consists of two files:

- `alexandria-scrolls.jar` and
- `commons-lang.jar`

An application called Scholar and an application called Student are running on a server called Academy, and both need access to this library.

### Procedure

1. Create a `mylib/Alexandria` directory in the `servers/Academy` directory under the `{WLP_USER_DIR}` directory.

For example: `wlp/usr/servers/Academy/mylib/Alexandria`.

2. Copy the `alexandria-scrolls.jar` and `commons-lang.jar` files into the new folder.
3. Configure class loading for the application, so that the Alexandria library is loaded.

In the `server.xml` file, or an included file, define the library by adding the following code:

```
<library id="Alexandria">
  <fileset dir="{server.config.dir}/mylib/Alexandria" includes="*.jar" scanInterval="5s" />
</library>
```

**Note:** The `<library>` element can also take a `filesetRef` attribute with a comma-separated list of `<fileset>` element IDs.

4. Reference the library from the applications, so that both these applications share a single copy of the library.

In the `server.xml` file, or an included file, add the following code:

```
<application id="scholar" name="Scholar" type="ear" location="scholar.ear">
  <classloader commonLibraryRef="Alexandria" />
</application>

<application id="student" name="Student" type="ear" location="student.ear">
  <classloader commonLibraryRef="Alexandria" />
</application>
```

**Note:** The `<commonLibraryRef>` element can take a comma-separated list of library IDs.

5. Optional: Configure another application to have its own set of classes loaded from the same JAR files. For example, if another application called Spy needs its own copy of the classes, the same physical files on disk can be used. In the `server.xml` file, or an included file, add the following code:

```
<application id="spy" name="Spy" type="war" location="spy.war">
  <classloader privateLibraryRef="Alexandria" />
</application>
```

**Note:** The `<privateLibraryRef>` element can take a comma-separated list of library IDs.

## Providing global libraries for all Java EE applications

You can provide global libraries that can be used by any Java EE application. You do this by putting the JAR files for those libraries in a global library directory, then specifying use of global libraries in the class loader configuration for each application. However, the global libraries cannot be used by other applications, for example, by OSGi applications.

### About this task

Under the user directory specified by using the environment variable `WLP_USER_DIR`, there are the following locations in which you can place global libraries:

- `${shared.config.dir}/lib/global`
- `${server.config.dir}/lib/global`

If there are files present in these locations at the time an application is started, and that application does not have a `<classloader>` element configured, the application uses these libraries. If a class loader configuration is present, these libraries are not used unless the global library is explicitly referenced.

**Attention:** If you use global libraries, you are advised also to configure a `<classloader>` element for every application. The servlet specification requires applications to share the global library class loader in their class loader parent chain. This breaks the separation of class loaders for each application that is otherwise possible. So, applications are more likely to have long-lasting effects on classes loaded in Liberty and on each other, and class space consistency issues are more likely to arise between applications, especially as features are added and removed from a running server. None of these considerations apply for applications that specify a `<classloader>` element in their configuration, because they maintain this separation.

### Example

In the following example, an application called `Scholar` is configured to use a common library called `Alexandria`, and also to use the global library.

In the `server.xml` file, or an included file, enable the global library for an application by adding the following code:

```
<application id="" name="Scholar" type="ear" location="scholar.ear">
  <classloader apiTypeVisibility="spec" commonLibraryRef="Alexandria, global" />
</application>
```

The settings for the global library can also be configured explicitly, as a library element with the special ID `global`. For example:

```
<library id="global">
  <fileset dir="/path/to/folder" includes="*.jar" />
</library>
```

## Accessing third-party APIs from a Java EE application

By default, Java EE applications do not have access to the third-party APIs available in Liberty. To enable this access, the application must be configured in the `server.xml` file, or an included file.

## About this task

In the following example, an application that is called Scholar needs access to the third-party APIs that are available in Liberty.

The application also uses a common library called Alexandria. This library is located in the `${server.config.dir}/mylib/Alexandria` directory.

**Avoid trouble:** Third party APIs might not remain compatible after an upgrade. For more information, see “Liberty externals support” on page 19.

## Procedure

1. Configure class loading for the application, so that the application can access the third-party APIs.

The default value for the `apiTypeVisibility` attribute of the `classloader` element is `spec,ibm-api,api`. Where `spec` represents public specification APIs available for both compile and run time, `ibm-api` represents APIs available in Liberty, and `api` represents public APIs available for both compile and run time. Including `third-party` in the `apiTypeVisibility` attribute of the `classloader` element makes third party APIs available.

In the `server.xml` file, or an included file, configure the API type visibility by adding the following code:

```
<application id="scholar" name="Scholar" type="ear" location="scholar.ear">
  <classloader apiTypeVisibility="spec, ibm-api, third-party" commonLibraryRef="Alexandria" />
</application>
```

2. Optional: If the application uses any common libraries, set those libraries to use the same API type visibility setting.

In the `server.xml` file, or an included file, add the following code:

```
<library id="Alexandria" apiTypeVisibility="spec, ibm-api, third-party">
  <fileset dir="${server.config.dir}/mylib/Alexandria" includes="*.jar" scanInterval="5s" />
</library>
```

## Removing access to third-party APIs for a Java EE application

By default, Java EE applications do not have access to the third-party APIs available in Liberty. You can also remove access explicitly in the `server.xml` file, or an included file.

## About this task

In the following example, an application called Scholar has previously been configured to access third-party APIs, as described in “Accessing third-party APIs from a Java EE application” on page 1598. You want to remove this access, and to make it explicit in the configuration that the application now uses the default access setting.

The application also uses a common library called Alexandria. This library is in the `${server.config.dir}/mylib/Alexandria` directory.

## Procedure

1. Configure class loading for the application, to show that the application can no longer access the third-party APIs.

In the `server.xml` file, or an included file, remove `third-party` from the set of values included for the `apiTypeVisibility` attribute:

```
<application id="scholar" name="Scholar" type="ear" location="scholar.ear">
  <classloader apiTypeVisibility="spec, ibm-api" commonLibraryRef="Alexandria" />
</application>
```

2. Optional: If the application uses any common libraries, set those libraries to use the same API type visibility setting.

In the `server.xml` file, or an included file, add the following code:

```
<library id="Alexandria" apiTypeVisibility="spec, ibm-api">
  <fileset dir="${server.config.dir}/mylib/Alexandria" includes="*.jar" scanInterval="5s" />
</library>
```

## Overriding a provided API with an alternative version

If an application provides (or uses a library that provides) classes that are also available in Liberty, by default the classes from Liberty are used. To change this so that the application uses the alternative versions of these classes, the application must be configured in the `server.xml` file, or an included file.

### About this task

If a web application includes classes that are also present in the server runtime environment, you might want to control which copy of each of those classes is used by the application. For example, if different versions of the classes are present in both the application and the server runtime environment, you must ensure that the version packaged in the application is used.

By default, classes from the Liberty runtime environment are used by all Java EE applications. You can override this behavior by using the class loader configuration **delegation** attribute. This configuration is specific to a particular application, or to a shared library that can be selected for use by an application.

### Example

In the following example, an application called `Scholar` needs to use classes that it provides (or that are provided in a library that it uses), rather than using the copies of the classes that are available in Liberty.

- When the classes are packaged within the application, override the default `parentFirst` delegation behavior with a `classloader` element in the `server.xml` configuration file or a file that it includes:

```
<application id="" name="Scholar" type="ear" location="scholar.ear">
  <classloader delegation="parentLast" />
</application>
```

This tells the application class loader to look at the Liberty classes only after looking in the application and its associated libraries for a class.

- When the classes are packaged in a shared library, add the **delegation** attribute to the `classloader` element that configures the use of the shared library as follows:

```
<application id="" name="Scholar" type="ear" location="scholar.ear">
  <classloader delegation="parentLast" commonLibraryRef="mySharedLib"/>
</application>
```

```
<library id="mySharedLib">
  <fileset dir="${server.config.dir}/myLib" includes="*.jar" />
</library>
```

You can also use the **privateLibraryRef** attribute for private libraries in an application. See “Sharing a library across multiple Java EE applications” on page 1597.

## Configuring libraries for OSGi applications

8.5.5.6

Each OSGi application can access a set of provided APIs and its own internal classes. Shared libraries can also be configured to provide access to extra packages from shared libraries.

### About this task

Each OSGi application has its own set of OSGi bundles in a running Liberty server. Each OSGi bundle specifies the packages that it needs and the packages it provides for use by other OSGi bundles. Bundles

within an OSGi application can access any packages that are provided by other bundles within the same OSGi application. Additionally, OSGi bundles within an OSGi application can access API packages provided by the Liberty server. Shared libraries can also be used to provide API packages for use by OSGi applications.

Libraries can be shared across multiple OSGi applications. All the applications, including Java EE applications, can use the same classes at runtime that are provided by shared libraries.

## Procedure

1. Create a `mylib/osgi` directory in the `servers/defaultServer` directory under `${WLP_USER_DIR}` directory. For example: `wlp/usr/servers/defaultServer/mylib/osgi`.
2. Copy the `osgi-lib.jar` and `commons-lang.jar` files into the new folder.
3. Configure the shared library for the application so that the library is loaded. In the `server.xml` file, or an included file, define the library by adding the following code:

```
<library id="mylib">
  <fileset dir="${server.config.dir}/mylib/osgi" includes="*.jar" scanInterval="5s">
</library>
```

**Note:** The `library` element can also take a `filesetRef` attribute with a comma-separated list of `fileset` element IDs.

4. Reference the library as an OSGi library so that OSGi applications can access the packages provided by the library and share a single copy of the library. In the `server.xml` file, or an included file, add the following code:

```
<osgiLibrary libraryRef="myLib"/>
```

5. Optional: Configure the list of packages to make them available for access from OSGi applications. Packages that are contained in the shared library can be accessed by OSGi applications when the library is configured by using the `osgiLibrary` element. Packages can also be listed to give more control over what packages are accessible by OSGi applications. The package syntax uses the OSGi `Export-Package` header syntax to define each package. To list the packages in the `server.xml` file, or an included file, add the following code:

```
<osgiLibrary libraryRef="myLib">
  <package>org.example.osgi.lib.pkg1; version=1.0</package>
  <package>org.example.osgi.lib.pkg2; version=1.1</package>
</osgiLibrary>
```

**Note:** When no package elements are used, the library is scanned to find the packages that the library provides. Each package that is discovered gets the default version of 0.0.0.

## Configuring JPA for Liberty

8.5.5.6

### About this task

Java Persistence API (JPA) 2.0 for WebSphere Application Server is built on the Apache OpenJPA 2.2.x open source project.

Apache OpenJPA is a compliant implementation of the JPA 1.0 and 2.0 specifications. Using OpenJPA as a base implementation, WebSphere Application Server employs extensions to provide more features and utilities for WebSphere Application Server customers. Because JPA for WebSphere Application Server is built from OpenJPA, all OpenJPA function, extensions, and configurations are unaffected by the WebSphere Application Server extensions. You do not need to make changes to OpenJPA applications to use these applications in WebSphere Application Server.

Java Persistence API (JPA) 2.1 for WebSphere Application Server is built on the EclipseLink open source project. EclipseLink is the reference implementation for all version of the JPA specification. The provider

of JPA for this product is `org.eclipse.persistence.jpa.PersistenceProvider`.

## Configuring JPA logging

8.5.5.6

Logging supports viewing, tracing, and troubleshooting the runtime behavior of an application. Each of the JPA features provides different levels of logging for you to specify how detailed you want the logging to be.

### About this task

When using either the `jpa-2.0` or `jpa-2.1` features, you can configure logging to aid in troubleshooting. Become familiar with the logging capabilities of these two features.

#### **jpa-2.0**

There are many supported `jpa-2.0` trace specifications that can be configured through the Liberty configuration. These trace strings can be used in conjunction with any other trace specifications.

##### Container-managed JPA applications

- `JPA=all`  
Enables all JPA container trace and all OpenJPA tracing
- `openjpa=all`  
Enables all OpenJPA tracing
- OpenJPA specific log channels

```
openjpa.jdbc.SQL=all
```

```
<server>
```

```
...
```

```
<logging traceSpecification="openjpa.jdbc.SQL=all"  
  traceFileName="trace.log"  
  maxFileSize="20"  
  maxFiles="10"  
  traceFormat="BASIC" />  
</server>
```

##### Application managed JPA applications

When running a JPA application that is application managed, logging and tracing is controlled by the OpenJPA runtime. All JPA tracing and logging must be configured through OpenJPA persistence properties.

```
<persistence version="2.0">  
<persistence-unit>  
  <properties>  
    <property name="openjpa.Log" value="openjpa.jdbc.SQL=trace"/>  
  </properties>  
</persistence-unit>  
</persistence>
```

##### Notable OpenJPA logging persistence properties

`openjpa.ConnectionFactoryProperties=PrintParameters=true`-- If true, SQL bind parameters are included in exceptions and logs.

#### **jpa-2.1**

When the `jpa-2.1` feature is enabled, all JPA logging and tracing is routed through the Liberty loggers.

##### Supported trace strings

- `JPA=all`  
Enables JPA container trace and all EclipseLink categories
- `eclipselink=all`

Enables all EclipseLink trace

- EclipseLink specific log categories
  - sql, transaction, event, connection, query, cache, propagation, sequencing, ejb, dms, metadata, weaver, properties, server
  - ie: eclipselink.sql=All -- Enables EclipseLink SQL trace

```
<server>
...
<logging traceSpecification="eclipselink.sql=all"
  traceFileName="trace.log"
  maxFileSize="20"
  maxFiles="10"
  traceFormat="BASIC" />
</server>
```

### Notable EclipseLink logging persistence properties

eclipselink.logging.parameters -- If true, SQL bind parameters are included in exceptions and logs.

### Procedure

In the persistence unit definition in the persistence.xml file, specify the logging level depending on the desired level of logging details that you want. Specify the eclipselink.logging.level property where the value is the logging level. For the list of logging levels available, refer to the EclipseLink logging wiki page. The following example will turn on all logging that is available.

```
<persistence-unit name="pu">
  <properties>
    <property name="eclipselink.logging.level" value="ALL"/>
  ...
  </properties>
</persistence-unit>
```

## Configuring the JPA 2.1 schema generator

8.5.5.6

In the jpa-2.0 feature, which is built on OpenJPA, you can generate data definition language (DDL) or interact directly with the database to define table schemas based on the JPA entity definition by using the SchemaMapper tool. In the jpa-2.1 feature, which is built on EclipseLink, you can use the new Schema Generator feature added to the JPA 2.1 specification, which has similar functions to the OpenJPA SchemaMapper.

### About this task

If you need functions similar to the OpenJPA SchemaMapper, you can configure the Schema Generator feature that is in the JPA 2.1 specification.

### Procedure

1. In the persistence unit definition, within the persistence.xml file, specify the database action property with the possible values of: none, create, drop, drop-and-create. Each value corresponds to the action that is taken against the database. The following example causes the tables that correspond to the entities specified in the persistence unit to be dropped and new tables are created in their place.

```
<persistence-unit name="pu">
  <properties>
    <property name="javax.persistence.schema-generation.database.action"
  value="drop-and-create" />
  ...
  </properties>
</persistence-unit>
```

2. Specify the script action property with the possible values of: none, create, drop, drop-and-create. If any value other than none is specified, you must specify a target property as well. This means that if the script action is create, which generates the create statements for the entity definition, you must specify a corresponding create target property with a target file where the statements are written to.

```
<persistence-unit name="pu">
  <properties>
    <property name="javax.persistence.schema-generation.scripts.action"
value="drop-and-create" />
    <property name="javax.persistence.schema-generation.scripts.create-target"
value="createTargetFile.ddl"/>
    <property name="javax.persistence.schema-generation.scripts.drop-target"
value="sampleDrop.ddl"/>
  ...
  </properties>
</persistence-unit>
```

## Disabling the EclipseLink shared object cache

8.5.5.6

The EclipseLink shared object cache contains a subset of all objects that are read and persisted for the persistence unit. The EclipseLink shared cache differs from the local EntityManager/L1/persistence context cache. The shared cache exists during the persistence unit and is shared by all EntityManagers and users of the persistence unit.

### About this task

If you are migrating an existing application or running an environment where your application spans multiple Java Virtual Machines (JVMs), you can disable the EclipseLink shared object cache.

Choose one of the following ways to disable the EclipseLink shared object cache.

### Procedure

- Set the `<shared-cache-mode>NONE</shared-cache-mode>` property in the `persistence.xml` file.

```
<persistence-unit name="pu">
  <shared-cache-mode>NONE</shared-cache-mode>
  <properties>
  ...
  </properties>
</persistence-unit>
```

- Set the `eclipselink.cache.shared.default` property to `false` in the persistence unit definition that is found in the `persistence.xml` file.

```
<persistence-unit name="pu">
  <properties>
    <property name="eclipselink.cache.shared.default" value="false" />
  ...
  </properties>
</persistence-unit>
```

## Configuring a web server plug-in for Liberty

You can configure a web server plug-in to receive an HTTP request for dynamic resources. You can forward the request to the Liberty server, which provides high-availability and workload balancing through the web server plug-in.

### Before you begin

1. Install a supported web server, such as the IBM HTTP Server that is included with IBM WebSphere Application Server. See [Installing IBM HTTP server](#) for more information. The web server that is provided with IBM i is already installed with product 5761-DG1 for IBM i V6R1, or 5770-DG1 for IBM i V7R1. The IBM i web server is referred to as the IBM HTTP Server for IBM i. The HTTP Server that

is provided with WebSphere Application Server does not run on IBM i and is included for z/OS, V7 and V8.0. To download the V8.5 HTTP server, see IBM Ported Tools for z/OS .

2. Install the web server plug-ins and the WebSphere Customization Toolbox (WCT). To install the web server plug-in, see Installing and configuring web server plug-ins .

**IBM i** For IBM i, see Installing and configuring web server plug-ins .

**z/OS** For IBM z/OS, see Installing Web Server Plug-ins for IBM WebSphere Application Server for z/OS .To install the WCT, see Installing and using the WebSphere Customization Toolbox.

**IBM i** **z/OS** For IBM i and z/OS, install the WCT on your workstation. You do not need to install any of the WCT tools. The Java SDK installed with the WCT is used to run the JConsole Java utility in a later step.

## About this task

A web server plug-in is used to forward HTTP requests from a supported web server to one or more application servers. The plug-in checks the request against configuration data in the `plugin-cfg.xml` file. The configuration data maps the URI for the HTTP request to the host name of an application server. The web server plug-in then uses this information to forward the request to the application server.

The procedure applies to Liberty servers not in a collective.

## Procedure

1. Configure the web server plug-in for your chosen web server by using the WCT.
  - When prompted in WCT, choose the **remote** scenario and specify the host name that Liberty is accessible on.
  - Do not copy or run the generated `configureWebserver` script. This script is not required with Liberty.

**z/OS** This step is not necessary for z/OS platforms.

2. **IBM i** **z/OS** Configure your HTTP server to use the `plugin-cfg.xml` file.

Find the location of your current `plugin-cfg.xml` by finding the value that is specified for the `WebSpherePluginConfig` directive at the end of the configuration file of the HTTP server. For example, `<IHS_ROOT>/conf/httpd.conf`.

Enable the plug-in within the `httpd.conf` file of the web server by using the `LoadModule` phrase, and specify the location of `plugin-cfg.xml` file by using the `WebSpherePluginConfig` phrase. For example:

- On Windows systems: **Windows**

```
LoadModule was_ap22_module "path/to/mod_was_ap22_http.dll"  
WebSpherePluginConfig "C:\Program Files\IBM\HTTPServer\conf\plugin-cfg.xml"
```

- On other distributed systems: **AIX** **Linux** **UNIX** **HP-UX** **Solaris**

```
LoadModule was_ap22_module "path/to/mod_was_ap22_http.so"  
WebSpherePluginConfig "/opt/IBM/HTTPServer/conf/plugin-cfg.xml"
```

**IBM i** **z/OS** For IBM i and z/OS, see [http://www14.software.ibm.com/webapp/wsbroker/redirect?version=phil&product=was-nd-mp&topic=tins\\_manualWebIHS80](http://www14.software.ibm.com/webapp/wsbroker/redirect?version=phil&product=was-nd-mp&topic=tins_manualWebIHS80) for instructions about enabling the plug-in within the `httpd.conf` file.

3. Optional: If you want the web server plug-in to forward HTTP requests to more than one Liberty server, repeat the previous steps for each additional server. Make sure that you consolidate all the plug-in configurations into one `plugin-cfg.xml` file.
  - You can use a `pluginCfgMerge` utility in the traditional server to merge multiple `plugin-cfg.xml` files. See Configuring simple load balancing across multiple application server profiles .
  - You can use a Plugin Merge command-line tool available on GitHub to merge individual configuration files into a single `merged-plugin-cfg.xml` file.

- If you are using the job manager to merge multiple `plugin-cfg.xml` files, see [Generating a merged plug-in configuration for Liberty servers using the job manager](#).

## Generating a merged plug-in configuration for Liberty servers

### 8.5.5.0

You can call the `ClusterManager` MBean `generateClusterPluginConfig` operation to create a single, merged `plugin-cfg.xml` file that instructs a web server plug-in to redirect requests to multiple application servers residing on multiple hosts.

### About this task

The operation first generates server-specific `plugin-cfg.xml` files on each started cluster member. The operation then merges the server-specific `plugin-cfg.xml` files into one `plugin-cfg.xml` file on the cluster manager.

This operation works only if the cluster has at least two started cluster members. The path to the merged `plugin-cfg.xml` file on the cluster manager is returned to the client. Therefore, it can be downloaded using the `fileTransfer` MBean.

The merged `plugin-cfg.xml` file name is `<clusterName>-plugin-cfg.xml`. It is saved in the following directory on the cluster manager by default:

```

${server.output.dir}/pluginConfig

```

This directory can be changed by providing the `clusterPluginConfig` element in the `server.xml` file:

```

<clusterPluginConfig>
  <outputDir>new output directory</outputDir>
</clusterPluginConfig>

```

**Note:** Make sure that the new output directory is writable and accessible by the `fileTransfer` MBean. Refer to the `fileTransfer` MBean documentation for details.

### Example:

```

// call the generateClusterPluginConfig operation on the ClusterManager MBean to generate
// a merged plugin-cfg.xml file for all started cluster members.
String clusterName = "myCluster";
ObjectName rmObjectName = new ObjectName("WebSphere:feature=collectiveController,type=ClusterManager,name=ClusterManager");

// rcObj contains the absolute path to the merged plugin-cfg.xml file.
Object rcObj = connection.invoke(rmObjectName, "generateClusterPluginConfig",
    new Object[] { clusterName },
    new String[] { "java.lang.String" });

// invoke the downloadFile operation on fileTransfer MBean to download the merged plugin-cfg.xml to the client.
String sourceFilePath = (String) rcObj;
String targetFilePath = "<my target directory>";
ObjectName objectName = new ObjectName("WebSphere:feature=restConnector,type=FileTransfer,name=FileTransfer");

connection.invoke(objectName, "downloadFile",
    new String[] { sourceFilePath, targetFilePath },
    new String[] { "java.lang.String", "java.lang.String" });

```

Refer to the `ClusterManager` MBean documentation for additional information on cluster management.

## Generating the plugin-cfg.xml file

This information can be used to generate the `plugin-cfg.xml` file for the web server, which is used to forward HTTP requests from a supported web server to one or more application servers. The plug-in takes a request and checks the request against configuration data in the `plugin-cfg.xml` file.

## Before you begin

If an application programmatically modifies the session cookie configuration by using Servlet 3.0 APIs, then the application must be initialized before you generate the `plugin-cfg.xml` file. Otherwise, the **AffinityCookie** attribute that is defined for that application might be wrong. To avoid this problem, you can set **deferServletLoad** to false, start the server, generate the plug-in, and then remove the **deferServletLoad** attribute.

## About this task

A web server plug-in is used to forward HTTP requests from a supported web server to one or more application servers. The plug-in takes a request and checks the request against configuration data in the `plugin-cfg.xml` file. The configuration data maps the URI for the HTTP request to the host name of an application server. The web server plug-in then uses this information to forward the request to the application server.

## Procedure

1. Start the server that hosts your applications, and ensure that the `localConnector-1.0` feature for IBM i and z/OS platforms, or the `restConnector-1.0` feature if you are configuring a plug-in for IBM i or z/OS, and any other required features are included in the server configuration.

In the `pluginConfiguration` element of the server configuration file, you can specify the **webserverPort** and **webserverSecurePort** attributes to forward requests from the web server. By default, the value of **webserverPort** is 80 and the value of **webserverSecurePort** is 443. However, you might want to change these settings. For example, for Linux and similar platforms, if you are a non-root user, you must use port numbers greater than 1024.

For all configurable attributes of the `pluginConfiguration` element, see “Java Servlets 3.1” on page 917.

Here is an example of a `server.xml` server configuration file:

```
<server description="new server">
  <featureManager>
    <feature>localConnector-1.0</feature>
    <feature>jsp-2.2</feature>
  </featureManager>

  <keyStore id="defaultKeyStore" password="{xor}PGY6bW4w0yw+" />

  <httpEndpoint id="defaultHttpEndpoint"
    host="*"
    httpPort="9080">
    <tcpOptions soReuseAddr="true" />
  </httpEndpoint>

  <pluginConfiguration webserverPort="80"
    webserverSecurePort="443"
    sslKeyringLocation="path/to/sslkeyring"
    sslStashfileLocation="path/to/stashfile"
    sslCertlabel="definedbyuser"/>

  <application type="war" id="myapp" name="myapp" location="${server.config.dir}/apps/myapp.war" />
  <application type="war" id="snoop" name="snoop" location="${server.config.dir}/apps/snoop.war" />
</server>
```

**IBM i** **z/OS** For IBM i and z/OS, include the `restConnector-1.0` feature instead of the `localConnector-1.0` feature. For details, see [Configuring secure JMX connection to Liberty](#).

**IBM i** **z/OS** Here is an example of a `server.xml` server configuration file for IBM i and z/OS:

```
<server description="new server">
<!-- Enable features -->
```

```

<featureManager>
  <feature>jsp-2.2</feature>
  <feature>restConnector-1.0</feature>
</featureManager>

<keyStore id="defaultKeyStore" password="{xor}PGY6bW4w0yw+" />

<httpEndpoint id="defaultHttpEndpoint"
  host="*"
  httpPort="9080"
  httpsPort="9443">
  <tcpOptions soReuseAddr="true" />
</httpEndpoint>

<quickStartSecurity userName="testuser"
  userPassword="security" />

<pluginConfiguration webserverPort="80"
  webserverSecurePort="443"
  sslKeyringLocation="path/to/sslkeyring"
  sslStashfileLocation="path/to/stashfile"
  sslCertlabel="definedbyuser"/>

<application type="war" id="myapp" name="myapp" location="${server.config.dir}/apps/myapp.war" />
<application type="war" id="snoop" name="snoop" location="${server.config.dir}/apps/snoop.war" />
</server>

```

**Note:**

- If you configure the web server plug-in to use SSL, you must enable the ssl-1.0 Liberty feature of Liberty.
  - If the web server is using the default ports, you do not have to include the pluginConfiguration element in the server.xml file.
  - The keystore that is used by the web server plug-in must be a CMS keystore, which can be created by using the Key Management (iKeyman) utility. You cannot use the JKS keystore that is created by Liberty or traditional for the web server plug-in, though you must exchange signer certificates between the web server plug-in keystore and the Liberty keystore.
  - To configure the location of the plug-in log file, add the following code snippet to the server.xml file within the pluginConfiguration element:
 

```
logDirLocation="/path/to/log/file/"
```
2. Generate the plugin-cfg.xml file for your Liberty server and applications by calling the WebSphere:name=com.ibm.ws.jmx.mbeans.generatePluginConfig MBean.
- a. Using the same Java SDK as the server, run the **jconsole** Java utility in a command window. For example, run the following command:
- ```
c:\java\bin\jconsole
```

The server process is listed in the choices that are waiting for connection.

**IBM i** **z/OS** For IBM i and z/OS, run the jconsole Java utility from a command window by using the Java SDK installed with the WCT on your workstation. For example, complete the following steps:

- 1) Create directory C:\restClient on your workstation.
- 2) Copy \${wlp.install.dir}/clients/restConnector.jar to the C:\restClient directory on your workstation.
- 3) Copy \${server.output.dir}/resources/security/key.jks to the C:\restClient directory on your workstation.
- 4) In a command window, type SET JAVA\_HOME=wct\_root\java.

**Note:** Ensure that you temporarily modify `wct_root\java\jre\lib\security\java.security` by commenting out the two lines that set the SSL socket factories to the WebSphere Application Server SSL socket factories. This modification is documented in the Troubleshooting SSL section of the troubleshooting tips topic.

- 5) From the same command window, run the **jconsole** Java utility.

For example, run the following command:

```
"%JAVA_HOME%\bin\jconsole -J-Djava.class.path=%JAVA_HOME%\lib\jconsole.jar;%JAVA_HOME%\lib\tools.jar;
C:\restClient\restConnector.jar -J-Djavax.net.ssl.trustStore=C:\restClient\key.jks
-J-Djavax.net.ssl.trustStorePassword=Liberty -J-Djavax.net.ssl.trustStoreType=jks
```

You might also need the following parameter:

```
-J-Dcom.ibm.ws.jmx.connector.client.disableURLHostnameVerification=true
```

- b. Connect to your server then click the **MBeans** tab.  After the jConsole starts, select **Remote Process**, and enter the JMX service URL: `service:jmx:rest://<host>:<port>/IBMJMXConnectorREST`. The port number is the HTTPS port. You must also provide the user name and password.
- c. Locate the `com.ibm.ws.jmx.mbeans.generatePluginConfig` MBean under the **WebSphere** domain.
- d. Call the `generateDefaultPluginConfig` operation to generate the `plugin-cfg.xml` file, or call the `generatePluginConfig` operation to customize installation root directory and server name before you generate the `plugin-cfg.xml` file.

Here is an example of a `plugin-cfg.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<Config ASDisableNagle="false" AcceptAllContent="false" AppServerPortPreference="HostHeader"
  ChunkedResponse="false" FIPSEnable="false" IISDisableNagle="false"
  IISPluginPriority="High" IgnoreDNSFailures="false" RefreshInterval="60"
  ResponseChunkSize="64" SSLConsolidate="false" SSLPKCSDriver="REPLACE"
  SSLPKCSPassword="REPLACE" TrustedProxyEnable="false" VHostMatchingCompat="false">
  <Log LogLevel="Error" Name=".\\logs\defaultServer\http_plugin.log"/>
  <Property Name="ESIEnable" Value="true"/>
  <Property Name="ESIMaxCacheSize" Value="1024"/>
  <Property Name="ESIInvalidationMonitor" Value="false"/>
  <Property Name="ESIEnableToPassCookies" Value="false"/>
  <Property Name="PluginInstallRoot" Value="."/>
  <VirtualHostGroup Name="default_host">
    <VirtualHost Name="*:80"/>
    <VirtualHost Name="*:443"/>
    <VirtualHost Name="*:9080"/>
  </VirtualHostGroup>
  <ServerCluster CloneSeparatorChange="false" GetDWLMTTable="false" IgnoreAffinityRequests="true"
    LoadBalance="Round Robin" Name="defaultServer_default_node_Cluster"
    PostBufferSize="64" PostSizeLimit="-1" RemoveSpecialHeaders="true"
    RetryInterval="60">
    <Server CloneID="b564bdc7-2c27-4a4b-ad37-9213c66e60d1" ConnectTimeout="0"
      ExtendedHandshake="false" MaxConnections="-1" Name="default_node_defaultServer0"
      ServerIOTimeout="900" WaitForContinue="false">
      <Transport Hostname="somehost.example.com" Port="9080" Protocol="http"/>
    </Server>
    <PrimaryServers>
      <Server Name="default_node_defaultServer0"/>
    </PrimaryServers>
  </ServerCluster>
  <UriGroup Name="default_host_defaultServer_default_node_Cluster_URIs">
    <Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/myapp/*"/>
    <Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/snoop/*"/>
  </UriGroup>
  <Route ServerCluster="defaultServer_default_node_Cluster"
    UriGroup="default_host_defaultServer_default_node_Cluster_URIs"
    VirtualHostGroup="default_host"/>
</Config>
```

The plugin-cfg.xml file is generated in the `${server.output.dir}` directory.

**Note:**

- You can use the **jConsole** utility with Liberty. However, any issues with the utility itself must be reported to your Java SDK provider.
  - The management interface for the `WebSphere:name=com.ibm.ws.jmx.mbeans.generatePluginConfigMBean` is `com.ibm.websphere.webcontainer.GeneratePluginConfigMBean`.
3. Copy the plugin-cfg.xml file to the machine that hosts the web server. **IBM i** For IBM i, complete the following steps:
- a. Run the **manageprofiles** Qshell command to create an http profile. For example, `plugins_root/bin/manageprofiles -create -profileName http -templatePath http`.
  - b. Copy the plugin-cfg.xml file to the config directory of the http profile that was created in substep a, for example, `plugin_profile_root/config/plugin-cfg.xml`, and set the file permissions.
  - c. Run the following command from a system command line to change the file authorities to the required settings:  

```
CHGAUT USER(QEJBSVR QTMHHTTP QNOTES) OBJ('plugin_profile_root/config/plugin-cfg.xml') DTAAUT(*RWX)
```

## Configuring session persistence for Liberty

When session data must be maintained across a server restart or an unexpected server failure, you can configure Liberty to persist the session data to a database. This configuration allows multiple servers to share the same session data, and session data can be recovered in the event of a failover.

### About this task

To configure one or more servers in Liberty to persist session data to a database, complete the following steps.

### Procedure

1. Define a shared session management configuration that you can reuse among all of your servers. You must complete the following steps, as a minimum requirement:
  - a. Enable the `sessionDatabase-1.0` feature.
  - b. Define a data source:

```
<dataSource id="SessionDS" ... />
```
  - c. Refer to the data source from the session database configuration.

```
<httpSessionDatabase id="SessionDB" dataSourceRef="SessionDS" ... />
```
  - d. Refer to the persistent storage location from the session management configuration.

```
<httpSession storageRef="SessionDB" ... />
```

**Note:** **8.5.5.0** The `storageRef` attribute of the `httpSession` element and the `id` attribute of the `httpSessionDatabase` element are not mandatory. If the `sessionDatabase-1.0` feature is enabled and the `httpSessionDatabase` element references a valid data source, session persistence is enabled even if the `storageRef` attribute is not set.

See for details about the `httpSession` and `httpSessionDatabase` elements.

For example, you can create a file named `${shared.config.dir}/httpSessionPersistence.xml` as follows:

```
<server description="Demonstrates HTTP Session Persistence Configuration">
  <featureManager>
    <feature>sessionDatabase-1.0</feature>
    <feature>servlet-3.0</feature>
  </featureManager>
```

```

<httpEndpoint id="defaultHttpEndpoint" host="*" httpPort="${httpPort}">
  <tcpOptions soReuseAddr="true"/>
</httpEndpoint>

<fileset id="DerbyFiles" includes="*.jar" dir="${shared.resource.dir}/derby/client"/>
<library id="DerbyLib" filesetRef="DerbyFiles"/>
<jdbcDriver id="DerbyDriver" libraryRef="DerbyLib"/>
<dataSource id="SessionDS" jdbcDriverRef="DerbyDriver">
  <properties.derby.client user="user1" password="password1"
    databaseName="${shared.resource.dir}/databases/SessionDB"
    createDatabase="create"/>
</dataSource>

<httpSessionDatabase id="SessionDB" dataSourceRef="SessionDS"/>
<httpSession storageRef="SessionDB" cloneId="${cloneId}"/>

<application id="test" name="test" type="ear" location="${shared.app.dir}/test.ear"/>
</server>

```

**Note:** When multiple servers are configured to persist session data to the same database, those servers must share the same session management configuration. Any other configuration is not supported. For example, it is not possible for one server to use a multi-row schema while another server uses a single-row schema.

The HTTP server plugin uses the clone ID that is inserted into the response/request header to maintain session affinity between requests. While the clone ID is normally unchanging, in Liberty, the clone ID is generated when you start a server for the first time and it is regenerated if you start the server with the `--clean` option. For production use, manually assigning a clone ID will ensure that the ID is stable and that request affinity is correctly maintained. The clone ID must be unique for each server and can be 8 to 9 alphanumeric characters in length and is specified in step 3.

2. Include the shared session management configuration in each of your servers. For example, create two `server.xml` files for server instances named `s1` and `s2`, as follows:

```

• ${wlp.user.dir}/servers/s1/server.xml
• ${wlp.user.dir}/servers/s2/server.xml
<server description="Example Server">
  <include location="${shared.config.dir}/httpSessionPersistence.xml"/>
</server>

```

See “Using include elements in configuration files” on page 1588.

3. Specify unique variables in the `bootstrap.properties` file of each server.

```

• ${wlp.user.dir}/servers/s1/bootstrap.properties
  httpPort=9081
  cloneId=s1
• ${wlp.user.dir}/servers/s2/bootstrap.properties
  httpPort=9082
  cloneId=s2

```

4. Create a table for session persistence before you start the servers.

- If you want to change the default row size, table name, or table space name, see for details about the `httpSessionDatabase` element.

- **Distributed operating systems** No additional action is required if your server is installed on one of the distributed operating systems. The server automatically creates the table.

- **z/OS** If your server is installed on z/OS, you have to create the table manually. If your server is using z/OS DB2 for session persistence, you have to follow different steps to create the table manually.

- If your server is using DB2 for session persistence, you can increase the page size to optimize performance for writing large amounts of data to the database.
5. Synchronize the system clocks of all machines that host Liberty servers. If the system clocks are not synchronized, session invalidation can occur prematurely
  6. Optional: If required, integrate HTTP sessions and security in Liberty. By default, after a session is created and accessed within a protected resource with security enabled, only the originating owner of that session can access it. Session security (security integration) is enabled by default.
  7. Optional: If required, Install and configure the web server plug-in to route requests to each of the servers you configured. The session affinity is only maintained if your plug-in configuration specifies clone IDs that match the clone IDs defined in the server configuration.

## Configuring and deploying a basic JCA ResourceAdapter

8.5.5.2

You can configure and deploy a basic Java™ EE Connector Architecture (JCA) ConnectionFactory and Resource Adapter.

### About this task

You can install a resource adapter and configure instances of the resources it provides. This task uses an example resource adapter called ExampleRA.rar, which provides 3 types of resources: a connection factory and two types of administered objects.

### Procedure

1. Enable the JCA feature in your server.xml file. The server.xml file is found at [path\_to\_liberty\wlp\usr\servers\server\_name]

```
<server>
  <featureManager>
    <feature>jca-1.6</feature>
    <feature>servlet-3.0</feature>
  </featureManager>
</server>
```

2. Place the resource adapter RAR file (ExampleRA.rar) into the dropins folder of your server. If your server is running, you will see the following message in your console log indicating that the resource adapter has been installed:

```
[AUDIT ] J2CA7001I: Resource adapter ExampleRA installed in 1.306 seconds.
```

3. Inspect the deployment descriptor, annotations, and other documentation from the resource adapter to identify which types of resources the adapter provides and the configuration properties that each adapter accepts. The example resource adapter, ExampleRA.rar, has this information in the ra.xml deployment descriptor. The ra.xml file is found at [path\_to\_ExampleRA\ExampleRA\META-INF.] The deployment descriptor identifies 3 types of resources you can configure.

```
<connection-definition>
  <managedconnectionfactory-class>com.ibm.example.jca.adapter.ManagedConnectionFactoryImpl</managedconnectionfactory-class>
  <config-property>
    <config-property-name>tableName</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
  </config-property>
  <connectionfactory-interface>javax.resource.cci.ConnectionFactory</connectionfactory-interface>
  ...
</connection-definition>

  <adminobject>
    <adminobject-interface>javax.resource.cci.ConnectionSpec</adminobject-interface>
    <adminobject-class>com.ibm.example.jca.adapter.ConnectionSpecImpl</adminobject-class>
    <config-property>
      <config-property-name>readOnly</config-property-name>
```

```

    <config-property-type>java.lang.Boolean</config-property-type>
    <config-property-value>>false</config-property-value>
  </config-property>
</adminobject>

<adminobject>
  <adminobject-interface>javax.resource.cci.InteractionSpec</adminobject-interface>
  <adminobject-class>com.ibm.example.jca.adapter.InteractionSpecImpl</adminobject-class>
  <config-property>
    <description>Function name. Supported values are: ADD, FIND, REMOVE</description>
    <config-property-name>functionName</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
  </config-property>
</adminobject>

```

4. In the server.xml file, configure instances of the available resource types.

```

<server>
  <featureManager>
    <feature>jca-1.6</feature>
    <feature>servlet-3.0</feature>
  </featureManager>

  <connectionFactory jndiName="eis/conFactory">
    <properties.ExampleRA tableName="TABLE1"/>
  </connectionFactory>

  <adminObject jndiName="eis/conSpec">
    <properties.ExampleRA.ConnectionSpec/>
  </adminObject>

  <adminObject jndiName="eis/iSpec_ADD">
    <properties.ExampleRA.InteractionSpec functionName="ADD"/>
  </adminObject>

  <adminObject jndiName="eis/iSpec_FIND">
    <properties.ExampleRA.InteractionSpec functionName="FIND"/>
  </adminObject>

</server>

```

5. Use resource injection to access the resources in your servlet; for example:

```

@Resource(lookup = "eis/conFactory")
private ConnectionFactory conFactory;

@Resource(lookup = "eis/conSpec")
private ConnectionSpec conSpec;

@Resource(lookup = "eis/iSpec_ADD")
private InteractionSpec iSpec_ADD;

@Resource(lookup = "eis/iSpec_FIND")
private InteractionSpec iSpec_FIND;

...

MappedRecord input = conFactory.getRecordFactory().createMappedRecord("input");
input.put("city", "Rochester");
input.put("state", "Minnesota");
input.put("population", 106769);

Connection con = conFactory.getConnection(conSpec);
try {
  Interaction interaction = con.createInteraction();
  interaction.execute(iSpec_ADD, input);
}

```

```

        interaction.close();
    } finally {
        con.close();
    }
}

```

**Note:** You must enable the JNDI feature in the `server.xml` file if you want to look up the resources from the namespace rather than using injection.

## Overview of JCA configuration elements

8.5.5.2

The Java Platform, Enterprise Edition Connector Architecture (JCA) feature provides configuration elements to define instances of connection factories, administered objects, and activation specifications, and to associate these instances with an installed resource adapter. Each of the JCA configuration elements consists of two basic parts, a top-level element and a subelement, both of which are required for the configured instance.

A *top-level element* configures general capabilities that are provided by the Liberty server, such as JNDI name, connection management, and container authentication. A *subelement* ties the instance to an installed resource adapter and enables you to specify vendor-defined configuration properties.

Generic JCA pre-defined top-level configuration elements:

- `connectionFactory`
- `adminObject`
- `activationSpec`

If the JMS feature is enabled, there are also pre-defined generic configuration elements for JMS:

- `jmsConnectionFactory`
- `jmsQueueConnectionFactory`
- `jmsTopicConnectionFactory`
- `jmsDestination`
- `jmsQueue`
- `jmsTopic`
- `jmsActivationSpec`

Subelements are generated from the resource adapter deployment descriptor and annotations when your resource adapter is installed. You will not see any documentation of the available subelements in the static documentation for available server configuration elements.

Use the following rules to generate the names of the server configuration subelements:

- If a resource adapter provides exactly one interface within one of the listed categories, such as `connectionFactory` or `adminObject`, the subelement is: `properties.<rar_identifier>`
- If the interface name is unique without the package name, the subelement is: `properties.<rar_identifier>.<InterfaceName>`
- If the implementation name is unique without the package name, the subelement is: `properties.<rar_identifier>.<ImplementationName>`
- In other cases, the subelement name is `properties.<rar_identifier>.<fully.qualified.InterfaceName>` or `properties.<rar_identifier>.<fully.qualified.ImplementationName>`

The following examples illustrate the case where only one interface within each category is provided by a resource adapter with identifier `MyAdapter`:

```

<connectionFactory jndiName="eis/cf1" containerAuthDataRef="auth1">
  <properties.MyAdapter portNumber="1234" someVendorProperty="100"/>
</connectionFactory>

<connectionFactory jndiName="eis/cf2" containerAuthDataRef="auth2">
  <properties.MyAdapter portNumber="1234" someVendorProperty="200"/>
</connectionFactory>

<jmsConnectionFactory jndiName="jms/cf">
  <properties.MyAdapter serverName="localhost" anotherProperty="40"/>
</jmsConnectionFactory>

<jmsQueueConnectionFactory jndiName="jms/qcf">
  <properties.MyAdapter serverName="localhost" vendorProp1="1"/>
</jmsQueueConnectionFactory>

<jmsTopicConnectionFactory jndiName="jms/tcf">
  <properties.MyAdapter serverName="localhost" prop1="A" prop2="B"/>
</jmsTopicConnectionFactory>

<adminObject jndiName="eis/interactionSpec">
  <properties.MyAdapter functionName="find" executionTimeout="5000"/>
</adminObject>

<jmsDestination jndiName="jms/destination1">
  <properties.MyAdapter name="DEST1"/>
</jmsDestination>

<jmsQueue jndiName="jms/queue1">
  <properties.MyAdapter queueName="QUEUE1"/>
</jmsQueue>

<jmsTopic id="topic1" jndiName="jms/topic1">
  <properties.MyAdapter topicName="TOPIC1"/>
</jmsTopic>

<activationSpec id="app1/module1/MyMessageDrivenBean">
  <properties.MyAdapter prop1="a" prop2="b" prop3="c"/>
</activationSpec>

<jmsActivationSpec id="app1/module1/MyJMSMessageDrivenBean">
  <properties.MyAdapter destinationRef="topic1"/>
</jmsActivationSpec>

```

## Configuring resource adapters: 8.5.5.2

You can configure resource adapters that comply with the Java EE Connector Architecture (JCA) specification versions 1.6, 1.5, or 1.0.

### About this task

You can install and configure a resource adapter and the various connection factories, administered objects, and activation specifications as defined in the JCA specification.

### Procedure

1. Update the `server.xml` file to add the `jca-1.6` feature under the `featureManager` tag. The `server.xml` file is found at `[path_to_liberty\wlp\usr\servers\server_name]`

```

<featureManager>
  <feature>jca-1.6</feature>
</featureManager>

```

2. (Optional) Enable the following additional features based on the needs of your system:

- If your resource adapter provides JMS specification interfaces, enable the `jms-1.1` feature.

```
<feature>jms-1.1</feature>
```
- If you want to look up connection factories and administered objects from your application, enable the `jndi-1.0` feature.

```
<feature>jndi-1.0</feature>
```

- If your resource adapter provides activation specifications for message driven beans, enable the mdb-3.1 feature.  
`<feature>mdb-3.1</feature>`
  - If your resource adapter supports inbound security, enable the jcaInboundSecurity-1.0 feature.  
`<feature>jcaInboundSecurity-1.0</feature>`
  - If your resource adapter supports bean validation and you want your beans to be validated, you can enable the beanValidation-1.0 feature.  
`<feature>beanValidation-1.0</feature>`
3. Configure one or more resource adapters in the server. You can use one of the following methods to configure the resource adapter.
- Configure a standalone resource adapter by editing the `theserver.xml` file.  
`<resourceAdapter location="C:/adapters/MyAdapter.rar"/>`
  - Configure an embedded resource adapter by editing the `server.xml` file to install an application that embeds one or more resource adapter modules. The following example assumes that the `app1.ear` file contains one or more embedded RAR files:  
`<application location="C:/applications/app1.ear"/>`
  - Allow the server to automatically configure a standalone resource adapter by dropping the RAR file in the server drop-ins folder.  
`wlp/usr/servers/your-server-name/dropins/MyDropinAdapter.rar`
  - Allow the server to automatically configure an application containing one or more embedded resource adapters by dropping the EAR file in the server drop-ins folder. The following example assumes that the `app2.ear` file contains one or more embedded RAR files:  
`wlp/usr/servers/your-server-name/dropins/app2.ear`
4. Start the application server. After the server is started, messages such as the following are displayed in the `console.log` file:
- ```
[AUDIT ] J2CA7001I: Resource adapter MyAdapter installed in 0.495 seconds.
[AUDIT ] J2CA7001I: Resource adapter MyDropinAdapter installed in 0.311 seconds.
[AUDIT ] J2CA7001I: Resource adapter app1.MyEmbeddedAdapter installed in 0.247 seconds.
[AUDIT ] J2CA7001I: Resource adapter app2.anotherEmbeddedAdapter installed in 0.518 seconds.
```

## Example

A unique identifier for a resource adapter is necessary to identify configured instances of connection factories, administered objects, and activation specifications as being associated with an installed resource adapter. For stand-alone resource adapters, the module name is used as the identifier. For resource adapters embedded in applications, the combination of the application name plus the module name (delimited by the period character) are used as the identifier.

- To specify properties for a stand-alone resource adapter using a `properties.MyAdapter` subelement that includes the resource adapter identifier, `MyAdapter`:  
`<resourceAdapter location="C:/adapters/MyAdapter.rar">`  
`<properties.MyAdapter logFile="${server.output.dir}/logs/myAdapter.log"/>`  
`</resourceAdapter>`
- To associate a connection factory with a stand-alone resource adapter using a `properties.MyAdapter` subelement that includes the resource adapter identifier, `MyAdapter`:  
`<resourceAdapter location="C:/adapters/MyAdapter.rar"/>`  
`<connectionFactory jndiName="eis/cf">`  
`<properties.MyAdapter serverName="localhost" portNumber="1234"/>`  
`</connectionFactory>`
- To associate a connection factory with a resource adapter `MyEmbeddedAdapter`, which is enabled in the `app1` application, using a `properties.app1.MyEmbeddedAdapter` subelement:

```

<application location="C:/applications/app1.ear"/>
<connectionFactory jndiName="eis/cf">
  <properties.appl.MyEmbeddedAdapter serverName="localhost" portNumber="1234"/>
</connectionFactory>

```

- In some cases, the module name is not sufficiently unique to serve as the identifier. This might happen, for example, if you install two different versions of the same resource adapter. Alternately, the module name might be unique, but undesirable for use in configuration because it is lengthy or contains non-alphanumeric characters. You can override the resource adapter identifier by specifying the id attribute.

The following example demonstrates how to override the identifier for stand-alone resource adapters:

```

<resourceAdapter id="MyAdapterV1" location="C:/adapters/version-1.0/MyAdapter.rar"/>
<resourceAdapter id="MyAdapterV2" location="C:/adapters/version-2.0/MyAdapter.rar"/>
<connectionFactory jndiName="eis/cf1">
  <properties.MyAdapterV1 serverName="localhost" portNumber="1234"/>
</connectionFactory>
<connectionFactory jndiName="eis/cf2">
  <properties.MyAdapterV2 serverName="localhost" portNumber="1234"/>
</connectionFactory>

```

- The following example demonstrates how to override the identifier for a resource adapter that is embedded in an application. The example changes the identifier to MyEmbeddedRA:

```

<application location="C:/applications/app1.ear">
  <resourceAdapter id="MyEmbeddedAdapter" alias="MyEmbeddedRA"/>
</application>
<connectionFactory jndiName="eis/cf">
  <properties.appl.MyEmbeddedRA serverName="localhost" portNumber="1234"/>
</connectionFactory>

```

- To compute the module name for embedded resource adapters, the <module-name> entry in the resource adapter deployment descriptor (ra.xml) takes precedence as the module name. For example, given the following definition in ra.xml:

```

<connector ...>
  <module-name>MyRARModule</module-name>
</connector>

```

the module name would be set to "MyRARModule".

If the module name is absent from the connector deployment descriptor, the short form of the URI referring to the resource adapter module in the application deployment descriptor (application.xml) is used. For example, given the following module definition in application.xml:

```

<module>
  <connector>connectors/MyRARModule.rar</connector>
</module>

```

the module name would be computed as "MyRARModule".

If multiple resource adapters are embedded in an application and define the same <module-name> value, the first one listed in application.xml uses that module name. The module names of the other connectors with that same conflicting name are calculated from the full form of the URI with all / (forward slash) characters converted to a period (.). For example, if two connectors were embedded in an application both containing the following definition in ra.xml:

```

<connector ...>
  <module-name>MyRARModule</module-name>
</connector>

```

and the following definitions in application.xml:

```

<module>
  <connector>subfolder1/connector1.rar</connector>
</module>
<module>
  <connector>subfolder2/connector2.rar</connector>
</module>

```

The module name for the first connector would be "MyRARModule" and the module name for the second would be "subfolder2.connector2.rar"

You can configure connection factories that comply with Java EE Connector Architecture (JCA) specification.

### About this task

You can configure one or more connection factory instances for connection factory types that are provided by an installed resource adapter.

**Note:** To configure JCA support for the Liberty profile, you must edit the `server.xml` file using either the Source view of the Server configuration editor of the WebSphere® Application Server Developer Tools for Eclipse, or some other text editor. This topic assumes that a resource adapter with a unique identifier of `MyAdapter` has already been configured in the server, see the documentation on configuring resource adapters for further details. An end-to-end example of configuring a basic scenario is provided in the following steps.

**Note:** Editing the properties sub-elements of the server configuration for connection factories, administrative objects, activation specifications, and resource adapters in the Design view of WebSphere® Development Tools (WDT) is not supported.

### Procedure

1. Update the `server.xml` file to add the `jca-1.6` feature under the `featureManager` tag.

```
<featureManager>
  <feature>jca-1.6</feature>
  <feature>jndi-1.0</feature> <!-- Add the jndi feature to enable look up of connection factories and administered objects -->
  ...
</featureManager>
```

2. Install a resource adapter. For example, update the `server.xml` file as follows:

```
<resourceAdapter location="C:/adapters/MyAdapter.rar"/>
```

3. Configure one or more connection factory instances. When you configure the connection factory instances, you must supply a `properties` subelement, even if you do not want to override any configuration properties, in order to associate the `connectionFactory` element with a connection factory interface that is provided by a particular resource adapter. In the following example, the `MyAdapter` resource adapter provides only one type of connection factory:

```
<connectionFactory jndiName="eis/cf1">
  <properties.MyAdapter portNumber="1234" someVendorProperty="100"/>
</connectionFactory>
```

```
<connectionFactory jndiName="eis/cf2" containerAuthDataRef="auth2">
  <connectionManager maxPoolSize="20" connectionTimeout="0"/>
  <properties.MyAdapter portNumber="1234" someVendorProperty="200"/>
</connectionFactory>
<authData id="auth2" user="user2" password="{xor}Lz4sLCgwLTtt"/>
```

4. (Optional) If required, identify the available connection factory property subelement names.
  - If a resource adapter provides exactly one connection factory interface, excluding any JMS connection factories, the subelement is: `properties.<rar_identifier>`
  - If the interface name is unique without the package name, the subelement name is: `properties.<rar_identifier>.<InterfaceName>`
  - If the implementation name is unique without the package name, the subelement name is: `properties.<rar_identifier>.<ImplementationName>`
  - In other cases, the subelement name is: `properties.<rar_identifier>.<fully.qualified.InterfaceName>`

## Example

Use the following example to learn how to configure resource adapters with two connection factories with unique interface class names.

In the following snippet from a ra.xml file, the MyAdapter resource adapter provides two connection factories with unique interface class names:

```
<connection-definition>
  <config-property>
    <config-property-name>ServerName</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
  </config-property>
  <connectionfactory-interface>javax.resource.cci.ConnectionFactory</connectionfactory-interface>
  <connectionfactory-impl-class>com.vendor.adapter.ConnectionFactoryImpl</connectionfactory-impl-class>
</connection-definition>
<connection-definition>
  <config-property>
    <config-property-name>ServerName</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
  </config-property>
  <connectionfactory-interface>javax.sql.DataSource</connectionfactory-interface>
  <connectionfactory-impl-class>com.vendor.adapter.DataSourceImpl</connectionfactory-impl-class>
</connection-definition>
```

The following is an example of a server configuration for this scenario:

```
<connectionFactory jndiName="eis/cf">
  <properties.MyAdapter.ConnectionFactory serverName="localhost"/>
</connectionFactory>

<connectionFactory jndiName="jdbc/ds">
  <properties.MyAdapter.DataSource serverName="localhost"/>
</connectionFactory>
```

Use the following example to learn how to configure resource adapters with two connection factories with unique implementation class names.

In the following snippet from a ra.xml file, the MyAdapter resource adapter provides two connection factories with unique implementation class names:

```
<connection-definition>
  <config-property>
    <config-property-name>ServerName</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
  </config-property>
  <connectionfactory-interface>javax.resource.cci.ConnectionFactory</connectionfactory-interface>
  <connectionfactory-impl-class>com.vendor.adapter.ConnectionFactoryImpl</connectionfactory-impl-class>
</connection-definition>
<connection-definition>
  <config-property>
    <config-property-name>ServerName</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
  </config-property>
  <connectionfactory-interface>com.vendor.adapter.ConnectionFactory</connectionfactory-interface>
  <connectionfactory-impl-class>com.vendor.adapter.MyConnectionFactoryImpl</connectionfactory-impl-class>
</connection-definition>
```

The following is an example of a server configuration for this scenario:

```
<connectionFactory jndiName="eis/cf1">
  <properties.MyAdapter.ConnectionFactoryImpl serverName="localhost"/>
</connectionFactory>
```

```
<connectionFactory jndiName="eis/cf2">
  <properties.MyAdapter.MyConnectionFactoryImpl serverName="localhost"/>
</connectionFactory>
```

Use the following example to learn how to configure resource adapters with two connection factories where neither the simple interface nor implementation class names are unique.

In the following snippet from a ra.xml file, the MyAdapter resource adapter provides two connection factories where neither the simple interface nor the implementation class names are unique:

```
<connection-definition>
  <config-property>
    <config-property-name>ServerName</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
  </config-property>
  <connectionfactory-interface>javax.resource.cci.ConnectionFactory</connectionfactory-interface>
  <connectionfactory-impl-class>com.vendor.adapter.ConnectionFactoryImpl</connectionfactory-impl-class>
</connection-defintion>

<connection-definition>
  <config-property>
    <config-property-name>HostName</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
  </config-property>
  <connectionfactory-interface>com.vendor.adapter.custom.ConnectionFactory</connectionfactory-interface>
  <connectionfactory-impl-class>com.vendor.adapter.custom.ConnectionFactoryImpl</connectionfactory-impl-class>
</connection-defintion>
```

The following is an example of a server configuration for this scenario:

```
<connectionFactory jndiName="eis/cci-cf">
  <properties.MyAdapter.javax.resource.cci.ConnectionFactory serverName="localhost"/>
</connectionFactory>

<connectionFactory jndiName="eis/custom-cf">
  <properties.MyAdapter.com.vendor.adapter.custom.ConnectionFactory hostName="localhost"/>
</connectionFactory>
```

It is possible to override the suffixes of configuration element names. See the information about customizing JCA configuration elements to learn how to override the suffixes of configuration element names.

## Configuring JCA administered objects: 8.5.5.2

You can configure administered objects that comply with the Java EE Connector Architecture (JCA) specification.

### About this task

You can configure one or more instances of administered objects that are provided by an installed resource adapter.

**Note:** To configure JCA support for Liberty, you must edit the server.xml file using either the Source view of the Server configuration editor of the WebSphere® Application Server Developer Tools for Eclipse, or some other text editor. This topic assumes that a resource adapter with a unique identifier of MyAdapter has already been configured in the server, see the documentation on configuring resource adapters for further details. An end-to-end example of configuring a basic scenario is provided in the following steps.

**Note:** Editing the properties sub-elements of the server configuration for connection factories, administrative objects, activation specifications, and resource adapters in the Design view of WebSphere® Development Tools (WDT) is not supported.

### Procedure

1. Update the server.xml file to add the jca-1.6 feature under the featureManager tag.

```
<featureManager>
  <feature>jca-1.6</feature>
  <feature>jndi-1.0</feature>  <!-- Add the jndi feature to enable look up of connection factories and administered ob
  ...
</featureManager>
```

2. Install a resource adapter. For example, update the server.xml file as follows:

```
<resourceAdapter location="C:/adapters/MyAdapter.rar"/>
```

3. Configure one or more administered object instances. When you configure administered object instances, you must supply a properties subelement, even if you do not want to override any configuration properties, to associate the adminObject element with an administered object type that is provided by a particular resource adapter. In the following example, the MyAdapter resource adapter provides only one type of administered object:

```
<adminObject jndiName="eis/interactionSpec">
  <properties.MyAdapter functionName="find" executionTimeout="5000"/>
</adminObject>
```

4. (Optional) If required, identify the available administered object property subelement names.

- If a resource adapter provides exactly one administered object interface excluding any JMS destinations, queues and topics, the subelement name is: properties.<rar\_identifier>
- If the interface name is unique without the package name, the subelement name is: properties.<rar\_identifier>.<InterfaceName>
- If the implementation name is unique without the package name, the subelement name is: properties.<rar\_identifier>.<ImplementationName>
- If the combination of interface name and implementation name are unique without the package name, the subelement name is: properties.<rar\_identifier>.<InterfaceName>-<ImplementationName>
- In other cases, the subelement name is: properties.<rar\_identifier>.<fully.qualified.InterfaceName>-<fully.qualified.ImplementationName>

### Example

Use the following example to learn how to configure resource adapters with two administered objects with unique interface class names.

In the following snippet from a ra.xml file, the MyAdapter resource adapter provides two administered objects with unique interface class names:

```
<adminobject>
<adminobject-interface>javax.resource.cci.ConnectionSpec</adminobject-interface>
<adminobject-class>com.vendor.adapter.ConnectionSpecImpl</adminobject-class>
<config-property>
  <config-property-name>isolationLevel</config-property-name>
  <config-property-type>java.lang.Integer</config-property-type>
</config-property>
...
</adminobject>
```

```
<adminobject>
<adminobject-interface>javax.resource.cci.InteractionSpec</adminobject-interface>
<adminobject-class>com.vendor.adapter.InteractionSpecImpl</adminobject-class>
<config-property>
```

```

    <config-property-name>FunctionName</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
</config-property>
...
</adminobject>

```

The following is an example of a server configuration for this scenario:

```

<adminObject jndiName="eis/connectionSpec">
  <properties.MyAdapter.ConnectionSpec isolationLevel="4"/>
</adminObject>

<adminObject jndiName="eis/interactionSpec">
  <properties.MyAdapter.InteractionSpec functionName="find"/>
</adminObject>

```

Use the following example to learn how to configure resource adapters with two administered objects with unique implementation class names.

In the following snippet from a ra.xml file, the MyAdapter resource adapter provides two administered objects with unique implementation class names:

```

<adminobject>
<adminobject-interface>javax.resource.cci.InteractionSpec</adminobject-interface>
<adminobject-class>com.vendor.adapter.FinderInteractionSpec</adminobject-class>
<config-property>
  <config-property-name>ResultSetType</config-property-name>
  <config-property-type>java.lang.Integer</config-property-type>
</config-property>
...
</adminobject>

<adminobject>
<adminobject-interface>javax.resource.cci.InteractionSpec</adminobject-interface>
<adminobject-class>com.vendor.adapter.UpdaterInteractionSpec</adminobject-class>
<config-property>
  <config-property-name>ExecutionTimeout</config-property-name>
  <config-property-type>java.lang.Long</config-property-type>
</config-property>
...
</adminobject>

```

The following is an example of a server configuration for this scenario:

```

<adminObject jndiName="eis/finder">
  <properties.MyAdapter.FinderInteractionSpec resultSetType="1003"/>
</adminObject>

<adminObject jndiName="eis/updater">
  <properties.MyAdapter.UpdaterInteractionSpec executionTimeout="3000"/>
</adminObject>

```

Use the following example to learn how to configure resource adapters with two administered objects where neither the simple interface nor implementation class names are unique.

In the following snippet from a ra.xml file, the MyAdapter resource adapter provides two administered objects where neither the simple interface nor the implementation class names are unique:

```

<adminobject>
<adminobject-interface>javax.resource.cci.InteractionSpec</adminobject-interface>
<adminobject-class>com.vendor.adapter.finder.InteractionSpecImpl</adminobject-class>
<config-property>
  <config-property-name>ResultSetType</config-property-name>
  <config-property-type>java.lang.Integer</config-property-type>
</config-property>
...

```

```

</adminobject>

<adminobject>
<adminobject-interface>javax.resource.cci.InteractionSpec</adminobject-interface>
<adminobject-class>com.vendor.adapter.updater.InteractionSpecImpl</adminobject-class>
<config-property>
  <config-property-name>ExecutionTimeout</config-property-name>
  <config-property-type>java.lang.Long</config-property-type>
</config-property>
...
</adminobject>

```

The following is an example of a server configuration for this scenario:

```

<adminObject jndiName="eis/finder">
  <properties.MyAdapter.javax.resource.cci.InteractionSpec-com.vendor.adapter.finder.InteractionSpecImpl resultSetType="1" />
</adminObject>

<adminObject jndiName="eis/updater">
  <properties.MyAdapter.javax.resource.cci.InteractionSpec-com.vendor.adapter.updater.InteractionSpecImpl executionTimeout="1" />
</adminObject>

```

It is possible to override the suffixes of configuration element names. See the information about customizing JCA configuration elements to learn how to override the suffixes of configuration element names.

### Configuring JCA activation specifications: 8.5.5.2

You can configure activation specifications that comply with the Java EE Connector Architecture (JCA) specification.

#### About this task

You can configure one or more instances of activation specifications that are provided by an installed resource adapter.

**Note:** To configure JCA support for Liberty, you must edit the `server.xml` file using either the Source view of the Server configuration editor of the WebSphere® Application Server Developer Tools for Eclipse, or some other text editor. This topic assumes that a resource adapter with a unique identifier of `MyAdapter` has already been configured in the server, see the documentation on configuring resource adapters for further details. An end-to-end example of configuring a basic scenario is provided in the following steps.

**Note:** Editing the properties sub-elements of the server configuration for connection factories, administrative objects, activation specifications, and resource adapters in the Design view of WebSphere® Development Tools (WDT) is not supported.

#### Procedure

1. Update the `server.xml` file to add the `jca-1.6` feature under the `featureManager` tag.

```

<featureManager>
  <feature>jca-1.6</feature>
  <feature>jndi-1.0</feature> <!-- Add the jndi feature to enable look up of connection factories and administered ob
  ...
</featureManager>

```

2. Install a resource adapter. For example, update the `server.xml` file as follows:

```

<resourceAdapter location="C:/adapters/MyAdapter.rar"/>

```

3. Configure one or more activation specifications. When you configure activation specifications, you must supply a `properties` subelement, even if you do not want to override any configuration

properties, to associate the activationSpec element with a message listener type that is provided by a particular resource adapter. In the following example, the MyAdapter resource adapter provides only one type of message listener:

```
<activationSpec id="app1/module1/MyMessageDrivenBean">
  <properties.MyAdapter messageFilter="ALL"/>
</activationSpec>
```

4. If required, identify the available activation specification property subelement names.
  - If a resource adapter provides exactly one message listener interface, excluding any JMS connection factories, the subelement name is: `properties.<rar_identifier>`
  - If the message listener interface name is unique without the package name, the subelement name is: `properties.<rar_identifier>.<MessageListenerInterfaceName>`
  - If the activation specification implementation name is unique without the package name, the subelement name is: `properties.<rar_identifier>.<ActivationSpecificationImplementationName>`
  - If the activation specification implementation name is unique without the package name, the subelement name is: `properties.<rar_identifier>.<ActivationSpecificationImplementationName>`
  - In other cases, the subelement name is: `properties.<rar_identifier>.<fully.qualified.MessageListenerInterfaceName>`
5. See the documentation on deploying message-driven beans for information about how to associate the activation specification with a message-driven bean.

### Example

Use the following example to learn how to configure resource adapters with two message listener types with unique interface class names.

In the following snippet from a `ra.xml` file, the MyAdapter resource adapter provides two message listener types with unique interface class names:

```
<messageListener>
<messageListener-type>javax.resource.cci.MessageListener</messageListener-type>
<activationSpec>
  <activationSpec-class>com.vendor.adapter.CCIActivationSpec</activationSpec-class>
  <config-property>
    <config-property-name>maxSize</config-property-name>
    <config-property-type>java.lang.Long</config-property-type>
  </config-property>
  ...
</activationSpec>
...
</messageListener>

<messageListener>
<messageListener-type>com.vendor.adapter.MyMessageListener</messageListener-type>
<activationSpec>
  <activationSpec-class>com.vendor.adapter.MyActivationSpec</activationSpec-class>
  <config-property>
    <config-property-name>messageFilter</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
  </config-property>
  ...
</activationSpec>
...
</messageListener>
```

The following is an example of a server configuration for this scenario:

```
<activationSpec id="app1/module1/CCIMessageDrivenBean">
  <properties.MyAdapter.MessageListener maxSize="1024"/>
</activationSpec>
```

```
<activationSpec id="app1/module1/MyMessageDrivenBean">
  <properties.MyAdapter.MyMessageListener messageFilter="ALL"/>
</activationSpec>
```

Use the following example to learn how to configure resource adapters with two message listener types with unique implementation class names

In the following snippet from a ra.xml file, the MyAdapter resource adapter provides two message listener types with unique implementation class names:

```
<messageListener>
<messageListener-type>javax.resource.cci.MessageListener</messageListener-type>
<activationSpec>
  <activationSpec-class>com.vendor.adapter.CCIActivationSpec</activationSpec-class>
  <config-property>
    <config-property-name>maxSize</config-property-name>
    <config-property-type>java.lang.Long</config-property-type>
  </config-property>
  ...
</activationSpec>
...
</messageListener>

<messageListener>
<messageListener-type>com.vendor.adapter.MessageListener</messageListener-type>
<activationSpec>
  <activationSpec-class>com.vendor.adapter.MyActivationSpec</activationSpec-class>
  <config-property>
    <config-property-name>messageFilter</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
  </config-property>
  ...
</activationSpec>
...
</messageListener>
```

The following is an example of a server configuration for this scenario:

```
<activationSpec id="app1/module1/CCIMessageDrivenBean">
  <properties.MyAdapter.CCIActivationSpec maxSize="1024"/>
</activationSpec>

<activationSpec id="app1/module1/MyMessageDrivenBean">
  <properties.MyAdapter.MyActivationSpec messageFilter="ALL"/>
</activationSpec>
```

Use the following example to learn how to configure resource adapters with two message listener types where neither the simple interface nor implementation class names are unique.

In the following snippet from a ra.xml file, the MyAdapter resource adapter provides two message listener types where neither the simple interface nor the implementation class names are unique:

```
<messageListener>
<messageListener-type>javax.resource.cci.MessageListener</messageListener-type>
<activationSpec>
  <activationSpec-class>com.vendor.adapter.cci.ActivationSpec</activationSpec-class>
  <config-property>
    <config-property-name>maxSize</config-property-name>
    <config-property-type>java.lang.Long</config-property-type>
  </config-property>
  ...
</activationSpec>
...
</messageListener>
```

```

<messageListener>
<messageListener-type>com.vendor.adapter.MessageListener</messageListener-type>
<activationSpec>
  <activationSpec-class>com.vendor.adapter.ActivationSpec</activationSpec-class>
  <config-property>
    <config-property-name>messageFilter</config-property-name>
    <config-property-type>java.lang.String</config-property-type>
  </config-property>
  ...
</activationSpec>
  ...
</messageListener>

```

The following is an example of a server configuration for this scenario:

```

<activationSpec id="app1/module1/CCIMessageDrivenBean">
  <properties.MyAdapter.javax.resource.cci.MessageListener maxSize="1024"/>
</activationSpec>

<activationSpec id="app1/module1/MyMessageDrivenBean">
  <properties.MyAdapter.com.vendor.adapter.MessageListener messageFilter="ALL"/>
</activationSpec>

```

It is possible to override the suffixes of configuration element names. See the information about customizing JCA configuration elements to learn how to override the suffixes of configuration element names.

## Configuring JMS connection factories: 8.5.5.2

You can configure JMS connection factories that are provided by resource adapters that comply with the Java EE Connector Architecture (JCA) specification.

### About this task

You can configure one or more JMS connection factory instances for JMS connection factory types that are provided by an installed resource adapter.

Configuration elements are provided for the following types of JMS connection factories:

- javax.jms.ConnectionFactory: jmsConnectionFactory
- javax.jms.QueueConnectionFactory: jmsQueueConnectionFactory
- javax.jms.TopicConnectionFactory: jmsTopicConnectionFactory

### Note:

To add JCA support for Liberty, you must edit the `server.xml` file using either the Source view of the Server configuration editor of the WebSphere® Application Server Developer Tools for Eclipse, or some other text editor. Editing portions of the configuration for connection factories, administrative objects, activation specifications, and resource adapters in the Design view is not supported in the Beta.

### Procedure

Configure one or more JMS connection factory instances. When you configure the connection factory instances, you must supply a `properties` subelement, even if you do not want to override any configuration properties, to associate the `jmsConnectionFactory`, `jmsQueueConnectionFactory`, or `jmsTopicConnectionFactory` element with a connection factory interface that is provided by a particular resource adapter. The `properties` subelement always follows the pattern `properties.<rar_identifier>` for JMS connection factories. In the following example, the `MyAdapter` resource adapter provides only one type of connection factory:

```

<jmsConnectionFactory jndiName="jms/cf" containerAuthDataRef="auth1">
  <properties.MyAdapter serverName="localhost" anotherProperty="40"/>
</jmsConnectionFactory>
<authData id="auth1" user="user1" password="{xor}Lz4sLCgwLTtu"/>

<jmsQueueConnectionFactory jndiName="jms/qcf">
  <connectionManager maxPoolSize="20" connectionTimeout="0"/>
  <properties.MyAdapter serverName="localhost" vendorProp1="1"/>
</jmsQueueConnectionFactory>

<jmsTopicConnectionFactory jndiName="jms/tcf">
  <properties.MyAdapter serverName="localhost" prop1="A" prop2="B"/>
</jmsTopicConnectionFactory>

```

**Note:** This topic assumes that a resource adapter with a unique identifier of MyAdapter has already been configured in the server and that the `jms-1.1` feature has been enabled. See topic “Configuring resource adapters” on page 1615 for further details.

Limitation: Editing the properties of the resource adapter configuration for connection factories, administrative objects, activation specifications, and resource adapters in the Design view of WebSphere Development Tools (WDT) is not supported.

## Configuring JMS destinations: 8.5.5.2

You can configure JMS destinations that are provided by resource adapters that comply with the Java EE Connector Architecture (JCA) specification.

### About this task

You can configure one or more instances of JMS destination, queue, or topic types that are provided by an installed resource adapter.

Configuration elements are provided for the following types of JMS destinations:

- `javax.jms.Destination`: `jmsDestination`
- `javax.jms.Queue`: `jmsQueue`
- `javax.jms.Topic`: `jmsTopic`

### Note:

To add JCA support for Liberty, you must edit the `server.xml` file using either the Source view of the Server configuration editor of the WebSphere® Application Server Developer Tools for Eclipse, or some other text editor. Editing portions of the configuration for connection factories, administrative objects, activation specifications, and resource adapters in the Design view is not supported in the Beta.

### Procedure

1. Configure one or more JMS destination, queue, or topic instances. When you configure the destination instances, you must supply a `properties` subelement, even if you do not want to override any configuration properties, to associate the `jmsDestination`, `jmsQueue`, or `jmsTopic` element with a JMS destination interface that is provided by a particular resource adapter. In the following example, the MyAdapter resource adapter provides only one type of JMS destination, one type of JMS queue, and one type of JMS topic:

```

<jmsDestination jndiName="jms/destination1">
  <properties.MyAdapter name="DEST1"/>
</jmsDestination>

<jmsQueue jndiName="jms/queue1">
  <properties.MyAdapter queueName="QUEUE1"/>

```

```

</jmsQueue>

<jmsTopic id="topic1" jndiName="jms/topic1">
  <properties.MyAdapter topicName="TOPIC1"/>
</jmsTopic>

```

- (Optional) If required, identify the available destination, queue, and topic property subelement names.

**Note:** This topic assumes that a resource adapter with a unique identifier of MyAdapter has already been configured in the server. See topic “Configuring resource adapters” on page 1615 for further details.

Limitation: Editing the properties of the resource adapter configuration for connection factories, administrative objects, activation specifications, and resource adapters in the Design view of WebSphere Development Tools (WDT) is not supported.

- If a resource adapter provides exactly one type of administered object with the `javax.jms.Destination` interface, the subelement name is: `properties.<rar_identifier>`
- If the implementation name is unique without the package name the subelement name is: `properties.<rar_identifier>.<ImplementationName>`
- In other cases, the subelement name is: `properties.<rar_identifier>.<fully.qualified.InterfaceName>`
- If a resource adapter provides exactly one type of administered object with the `javax.jms.Queue` interface, the subelement name is: `properties.<rar_identifier>`
- If the implementation name is unique without the package name, the subelement name is: `properties.<rar_identifier>.<ImplementationName>`
- In other cases, the subelement name is: `properties.<rar_identifier>.<fully.qualified.InterfaceName>`
- If a resource adapter provides exactly one type of administered object with the `javax.jms.Topic` interface, the subelement name is: `properties.<rar_identifier>`
- If the implementation name is unique without the package name, the subelement name is: `properties.<rar_identifier>.<ImplementationName>`
- In other cases, the subelement name is: `properties.<rar_identifier>.<fully.qualified.InterfaceName>`

## Example

Use the following example to learn how to configure resource adapters with two JMS destinations with unique implementation class names

In the following snippet from a `ra.xml` file the MyAdapter resource adapter provides two JMS destinations with unique implementation class names:

```

<adminobject>
<adminobject-interface>javax.jms.Destination</adminobject-interface>
<adminobject-class>com.vendor.adapter.QueueImpl</adminobject-class>
<config-property>
  <config-property-name>queueName</config-property-name>
  <config-property-type>java.lang.String</config-property-type>
</config-property>
  ...
</adminobject>

<adminobject>
<adminobject-interface>javax.jms.Destination</adminobject-interface>
<adminobject-class>com.vendor.adapter.TopicImpl</adminobject-class>
<config-property>
  <config-property-name>topicName</config-property-name>

```

```

    <config-property-type>java.lang.String</config-property-type>
  </config-property>
  ...
</adminobject>

```

The following is an example of a server configuration for this scenario:

```

<jmsDestination jndiName="jms/destination1">
  <properties.MyAdapter.QueueImpl queueName="D1"/>
</adminObject>

<jmsDestination jndiName="jms/destination2">
  <properties.MyAdapter.TopicImpl topicName="D2"/>
</jmsDestination>

```

Use the following example to learn how to configure resource adapters with two administered objects without implementation class names that are unique.

In the following snippet from a ra.xml file the MyAdapter resource adapter provides two administered objects with non-unique implementation class names:

```

<adminobject>
<adminobject-interface>javax.jms.Queue</adminobject-interface>
<adminobject-class>com.vendor.adapter.QueueImpl</adminobject-class>
<config-property>
  <config-property-name>queueName</config-property-name>
  <config-property-type>java.lang.String</config-property-type>
</config-property>
...
</adminobject>

<adminobject>
<adminobject-interface>javax.jms.Queue</adminobject-interface>
<adminobject-class>com.vendor.adapter.advanced.QueueImpl</adminobject-class>
<config-property>
  <config-property-name>name</config-property-name>
  <config-property-type>java.lang.String</config-property-type>
</config-property>
...
</adminobject>

```

The following is an example of a server configuration for this scenario:

```

<jmsQueue jndiName="jms/myQueue">
  <properties.MyAdapter.com.vendor.adapter.QueueImpl queueName="Q1"/>
</jmsQueue>

<jmsQueue jndiName="jms/myAdvancedQueue">
  <properties.MyAdapter.com.vendor.adapter.advanced.QueueImpl name="Q1"/>
</jmsQueue>

```

In some scenarios, lengthy configuration element names might be undesirable. See the information about customizing JCA configuration elements to learn how to override the suffixes of configuration element names.

### Configuring JMS activation specifications: 8.5.5.2

You can configure JMS activation specifications that are provided by resource adapters that comply with the Java EE Connector Architecture (JCA) specification.

#### About this task

You can configure one or more JMS activation specification instances for JMS message listeners that are provided by an installed resource adapter.

**Note:**

To add JCA support for Liberty, you must edit the `server.xml` file using either the Source view of the Server configuration editor of the WebSphere® Application Server Developer Tools for Eclipse, or some other text editor. Editing portions of the configuration for connection factories, administrative objects, activation specifications, and resource adapters in the Design view is not supported in the Beta.

**Procedure**

Configure one or more JMS activation specification instances. When you configure the activation specification instances, you must supply a `properties` subelement, even if you do not want to override any configuration properties, to associate the `jmsActivationSpec` element with a JMS message listener that is provided by a particular resource adapter. The `properties` subelement always follows the pattern `properties`, `<rar_identifier>` for JMS activation specifications. The following example configures two instances of JMS activation specifications:

```
<jmsActivationSpec id="app1/module1/MyJMSMessageDrivenBean">
  <properties.MyAdapter destinationRef="topic1"/>
</jmsActivationSpec>

<jmsActivationSpec id="app1/module1/AnotherJMSMessageDrivenBean">
  <containerAuthData user="user1" password="{xor}Lz4sLCgwLTtu"/>
  <properties.MyAdapter destinationRef="queue1"/>
</jmsActivationSpec>
```

**Note:** This topic assumes that a resource adapter with a unique identifier of `MyAdapter` has already been configured in the server and that the `jms-1.1` and `mdb-3.1` features have been enabled. See topic “Configuring resource adapters” on page 1615 for further details.

Limitation: Editing the properties of the resource adapter configuration for connection factories, administrative objects, activation specifications, and resource adapters in the Design view of WebSphere Development Tools (WDT) is not supported.

**Customizing JCA configuration elements:** 8.5.5.2 

You can customize how JCA properties subelements are generated when installing a resource adapter.

**About this task**

When you install a stand-alone resource adapter or a resource adapter that is embedded in an application, you can add one or more `<customize>` subelements under the `<resourceAdapter>` element to choose the suffix that is used for the `properties` subelement for the specified interface or implementation class. Customizing subelement enables you to avoid lengthy `properties` subelement names that might otherwise be required for the configuration elements to have unique names.

**Note:**

To add JCA support for Liberty, you must edit the `server.xml` file using either the Source view of the Server configuration editor of the WebSphere® Application Server Developer Tools for Eclipse, or some other text editor. Editing portions of the configuration for connection factories, administrative objects, activation specifications, and resource adapters in the Design view is not supported in the Beta.

**Procedure**

1. For a stand-alone resource adapter, start with the existing configuration that you want to customize. For example, if a resource adapter `MyAdapter` provides two connection factories, where neither the simple interface nor implementation class names are unique:

```

<featureManager>
  <feature>jca-1.6</feature>
  <feature>jndi-1.0</feature> <!-- Add the jndi feature to enable look up of connection factories and administered ob
  ...
</featureManager>
<resourceAdapter location="C:/adapters/MyAdapter.rar"/>

<connectionFactory jndiName="eis/cci-cf">
  <properties.MyAdapter.javax.resource.cci.ConnectionFactory serverName="localhost"/>
</connectionFactory>

<connectionFactory jndiName="eis/custom-cf">
  <properties.MyAdapter.com.vendor.adapter.custom.ConnectionFactory hostName="localhost"/>
</connectionFactory>

```

2. Add customize subelements to the resourceAdapter to choose the suffixes for both of the connection factory interfaces.

```

<featureManager>
  <feature>jca-1.6</feature>
  <feature>jndi-1.0</feature> <!-- Add the jndi feature to enable look up of connection factories and administered ob
  ...
</featureManager>

<resourceAdapter location="C:/adapters/MyAdapter.rar">
  <customize interface="javax.resource.cci.ConnectionFactory" suffix="cci"/>
  <customize interface="com.vendor.adapter.custom.ConnectionFactory" suffix="custom"/>
</resourceAdapter>

<connectionFactory jndiName="eis/cci-cf">
  <properties.MyAdapter.cci serverName="localhost"/>
</connectionFactory>

<connectionFactory jndiName="eis/custom-cf">
  <properties.MyAdapter.custom hostName="localhost"/>
</connectionFactory>

```

3. For a resource adapter that is embedded in an application, start with the existing configuration that you want to customize. For example, assume that you have an application app1 with an embedded resource adapter named MyAdapter as follows:

```

<featureManager>
  <feature>jca-1.6</feature>
  <feature>jndi-1.0</feature> <!-- Add the jndi feature to enable look up of connection factories and administered ob
  ...
</featureManager>

<application name="app1" type="ear" location="C:/applications/app1.ear"/>

<adminObject jndiName="eis/interactionSpec-find">
  <properties.app1.MyAdapter.javax.resource.cci.InteractionSpec-com.vendor.adapter.finder.InteractionSpecImpl resultSe
</adminObject>

<adminObject jndiName="eis/interactionSpec-update">
  <properties.app1.MyAdapter.com.vendor.adapter.InteractionSpec-com.vendor.adapter.updater.InteractionSpecImpl executi
</adminObject>

```

4. Specify a resourceAdapter element for the Resource Adapter Archive (RAR) module in the application. Specify the id attribute to be the module name of the RAR module. Add customize subelements to choose the suffixes for both of the administered objects that are based on the interface or implementation class. In this example, only the implementation class is specified, which is sufficient to identify the administered objects:

```

<featureManager>
  <feature>jca-1.6</feature>
  <feature>jndi-1.0</feature> <!-- Add the jndi feature to enable look up of connection factories and administered ob
  ...
</featureManager>

```

```

<application name="app1" type="ear" location="C:/applications/app1.ear">
  <resourceAdapter id="MyAdapter">
    <customize implementation="com.vendor.adapter.finder.InteractionSpecImpl" suffix="finder"/>
    <customize implementation="com.vendor.adapter.updater.InteractionSpecImpl" suffix="updater"/>
  </resourceAdapter>
</application>

<adminObject jndiName="eis/interactionSpec-find">
  <properties.app1.MyAdapter.finder resultSetType="1003"/>
</adminObject>

<adminObject jndiName="eis/interactionSpec-update">
  <properties.app1.MyAdapter.updater executionTimeout="3000"/>
</adminObject>

```

## Accessing stand-alone resource adapters from Java EE applications:

8.5.5.2

You can access stand-alone resource adapters from Java EE applications.

### About this task

Stand-alone resource adapter classes and resources can be shared across multiple Java EE applications. By default, Java EE applications have access to JCA spec API but do not have access to the vendor classes and resources of stand-alone resource adapters. A prerequisite of enabling this access is that both the resource adapter and the application must be configured in the server configuration.

In the following example, an application called Scholar and an application called Student are running on a server called Academy. Both applications need access to a resource adapter called Socrates16, which is provided in the socrates.rar file that is located in the C:/adapters/version-1.6 directory.

### Procedure

1. Configure the stand-alone resource adapter.

In the server.xml file, configure the stand-alone resource adapter by adding the following code:

```
<resourceAdapter id="Socrates16" location="C:/adapters/version-1.6/socrates.rar" />
```

2. Reference the resource adapter from the applications so that both applications can access the classes and resources that are provided in the resource adapter module.

In the server.xml file, set the classProviderRef attribute to the ID of the resource adapter within the class loading configurations of the applications by adding the following code:

```

<application id="scholar" name="Scholar" type="ear" location="scholar.ear">
  <classloader classProviderRef="Socrates16" />
</application>

```

```

<application id="student" name="Student" type="ear" location="student.ear">
  <classloader classProviderRef="Socrates16" />
</application>

```

3. Optional: Configure the class loading of the stand-alone resource adapter to access third-party APIs. By default, neither resource adapters nor Java applications can access third-party APIs. Whenever the class loading configuration of an application requires access to third-party APIs and the application requires access to a stand-alone resource adapter, configure the class loading of the resource adapter to also access third-party APIs.

In the server.xml file, configure the apiTypeVisibility attribute of the class loading configuration of the resource adapter to access third-party APIs by adding the following code:

```

<resourceAdapter id="Socrates16" location="C:/adapters/version-1.6/socrates.rar">
  <classloader apiTypeVisibility="spec, ibm-api, api, third-party" />
</resourceAdapter/>

```

```
<application id="scholar" name="Scholar" type="ear" location="scholar.ear">
```

```

    <classloader classProviderRef="Socrates16" apiTypeVisibility="spec, ibm-api, api, third-party" />
</application>

<application id="student" name="Student" type="ear" location="student.ear">
  <classloader classProviderRef="Socrates16" apiTypeVisibility="spec, ibm-api, api, third-party" />
</application>

```

## Configuring ManagedExecutorService instances

You can configure `ManagedExecutorService` instances to run asynchronous tasks with the specified thread context. It is a best practice for Java EE applications to avoid directly managing their own threads; therefore, the `ManagedExecutorService` extends the JSE `ExecutorService` to provide a way to launch asynchronous tasks within an application server environment. You might also configure the `ManagedExecutorService` to propagate various thread contexts that are relevant to Java EE applications to the thread of the asynchronous task.

### 8.5.5.0

#### About this task

The `ManagedExecutorService` is available under the `<concurrent-1.0>` feature and enabled in the `server.xml` file as follows:

```

<featureManager>
  <feature>concurrent-1.0</feature>
</featureManager>

```

Propagation of context to the thread of a task that is executed by the `ManagedExecutorService` is managed by the context service. A default instance of the context service (`DefaultContextService`) is created by the server and configured to propagate at least `classloaderContext`, `jeeMetadataContext` and `securityContext`. This default context service instance is used if a `ManagedExecutorService` is created without referring to a specific context service instance or configuring a context service instance directly within. Refer to the [Configuring thread context service instances](#) topic for more information.

A default managed executor instance (`DefaultManagedExecutorService`) is available as `java:comp/DefaultManagedExecutorService` and uses the default context service instance for thread context capture and propagation.

#### Procedure

Example configuration in the `server.xml` file:

- Managed executor service instance that is registered in JNDI with the name `concurrent/execSvc`, and that uses the default context service instance:

```

<managedExecutorService jndiName="concurrent/execSvc"/>

```

- Managed executor service instance with context service configured to propagate `jeeMetadataContext` only:

```

<managedExecutorService jndiName="concurrent/execSvc1">
  <contextService>
    <jeeMetadataContext/>
  </contextService>
</managedExecutorService>

```

- Managed executor service instance with `classloaderContext` and `securityContext`:

```

<managedExecutorService jndiName="concurrent/execSvc2">
  <contextService>
    <classloaderContext/>
    <securityContext/>
  </contextService>
</managedExecutorService>

```

- Thread context service that is shared by multiple managed executor service instances:

```
<contextService id="contextSvc1">
  <jeeMetadataContext/>
</contextService>
```

```
<managedExecutorService jndiName="concurrent/execSvc3" contextServiceRef="contextSvc1"/>
```

```
<managedExecutorService jndiName="concurrent/execSvc4" contextServiceRef="contextSvc1"/>
```

- Thread context service that inherits from the previous example and is used by a managed executor service instance:

```
<contextService id="contextSvc2" baseContextRef="contextSvc1">
  <classloaderContext/>
</contextService>
```

```
<managedExecutorService jndiName="concurrent/execSvc5" contextServiceRef="contextSvc2"/>
```

- Managed executor service instance with `zosWLMContext` plus thread context propagation inherited from the default context service instance:

```
<managedExecutorService jndiName="concurrent/execSvc6">
  <contextService baseContextRef="DefaultContextService">
    <zosWLMContext defaultTransactionClass="TRAN1"/>
  </contextService>
</managedExecutorService>
```

## Example

Managed executor serviced instances can be injected into application components (by using `@Resource`) or looked up with resource environment references (`resource-env-ref`). Regardless of how the instance is obtained, you can use it interchangeably as `javax.enterprise.concurrent.ManagedExecutorService` or its `java.util.concurrent.ExecutorService` superclass.

- Example that looks up the default managed executor:

```
ManagedExecutorService executor =
    (ManagedExecutorService) new InitialContext().lookup(
        "java:comp/DefaultManagedExecutorService");
executor.submit(doSomethingInParallel);
```

- Example that uses `@Resource` to inject as `java.util.concurrent.ExecutorService`:

```
@Resource(lookup="concurrent/execSvc1")
ExecutorService execSvc1;
```

```
...
```

```
// submit task to run
Future<Integer> future1 = execSvc1.submit(new Callable<Integer>() {
    public Integer call() throws Exception {
        // java:comp lookup is possible because <jeeMetadataContext> is configured
        DataSource ds = (DataSource) new InitialContext().lookup("java:comp/env/jdbc/ds1");
        ... make updates to the database
        return updateCount;
    }
});
Future<Integer> future2 = execSvc1.submit(anotherTaskThatUpdatesADatabase);
```

```
numUpdatesCompleted = future1.get() + future2.get();
```

- Example that uses `@Resource` to inject as `javax.enterprise.concurrent.ManagedExecutorService`:

```
@Resource(lookup="concurrent/execSvc1")
ManagedExecutorService execSvc1;
```

```
...
```

```
// submit task to run
Future<Integer> future1 = execSvc1.submit(new Callable<Integer>() {
```

```

public Integer call() throws Exception {
    // java:comp lookup is possible because <jeeMetadataContext> is configured
    DataSource ds = (DataSource) new InitialContext().lookup("java:comp/env/jdbc/ds1");
    ... make updates to the database
    return updateCount;
}
});
Future<Integer> future2 = execSvc1.submit(anotherTaskThatUpdatesADatabase);

```

```
numUpdatesCompleted = future1.get() + future2.get();
```

- Example <resource-env-ref> for java.util.concurrent.ExecutorService in the web.xml file:

```

<resource-env-ref>
  <resource-env-ref-name>concurrent/execSvc2</resource-env-ref-name>
  <resource-env-ref-type>java.util.concurrent.ExecutorService</resource-env-ref-type>
</resource-env-ref>

```

- Example <resource-env-ref> for javax.enterprise.concurrent.ManagedExecutorService in the web.xml file:

```

<resource-env-ref>
  <resource-env-ref-name>concurrent/execSvc2</resource-env-ref-name>
  <resource-env-ref-type>javax.enterprise.concurrent.ManagedExecutorService</resource-env-ref-type>
</resource-env-ref>

```

- Example lookup that uses a resource environment reference:

```

ExecutorService execSvc2 =
    (ExecutorService) new InitialContext().lookup("java:comp/env/concurrent/execSvc2");

futures = execSvc2.invokeAll(Arrays.asList(task1, task2, task3));

```

- Example lookup that uses a resource environment reference and casts to ManagedExecutorService:

```

ManagedExecutorService execSvc2 =
    (ManagedExecutorService) new InitialContext().lookup("java:comp/env/concurrent/execSvc2");

futures = execSvc2.invokeAll(Arrays.asList(task1, task2, task3));

```

## Configuring thread context service instances

8.5.5.4

You can configure ContextService instances to capture a managed thread context and apply it to invocations of specified interface methods on any thread.

### About this task

It is a best practice for Java EE applications to avoid directly managing their own threads; therefore, the ContextService provides a way to establish a previously captured thread context onto unmanaged threads, as well as managed threads, overlaying any thread context that is in place.

A default thread context service instance (DefaultContextService) is created by the server and configured to capture and propagate at least classloaderContext, jeeMetadataContext and securityContext. You can configure thread context propagation to include the following types of thread context:

#### classloaderContext

Makes the thread context classloader of the submitter of the task available to the task.    
8.5.5.4 If the context classloader is serialized, the classloader must be a thread context classloader from the application. Classloader serialization for Web Application Bundles is not currently supported.

#### jeeMetadataContext

Makes the namespace of the application component that submitted the task available to the task.

## securityContext

**8.5.5.4** You must enable the appSecurity-2.0 feature in the server.xml file to use this type of thread context. Makes the caller subject and invocation subject of the submitter of the task available to the task, and this is accomplished by logging in with the submitter's WSPincipal using JAAS login. For details on what information in the submitter's subject is not in the security context, see the concurrent-1.0 feature restrictions.

z/OS

## syncToOSThreadContext

Synchronizes the identity of the runAs Subject for the unit of work with the operating system identity.

z/OS

## zosWLMContext

Used to classify work.

**Important:** Additional thread context providers might be made available by features in stack products. The optional baseContextRef attribute allows a context service instance to inherit from the context configuration of another context service instance.

## Procedure

Enable the thread context service in the server.xml file. The thread context service is available under the <concurrent-1.0> feature.

```
<featureManager>
  <feature>concurrent-1.0</feature>
</featureManager>
```

## Example

Configure thread context service instances in the server.xml file:

- Thread context service that is registered in JNDI with the name, concurrent/threadContextSvc1, that captures and propagates jeeMetadataContext only:

```
<contextService id="threadContextSvc1" jndiName="concurrent/${id}">
  <jeeMetadataContext/>
</contextService>
```

- Thread context service with classloaderContext and securityContext:

```
<contextService jndiName="concurrent/threadContextSvc2">
  <classloaderContext/>
  <securityContext/>
</securityContext/>
```

- Thread context service that inherits jeeMetadataContext from threadContextSvc1 and adds securityContext:

```
<contextService jndiName="concurrent/threadContextSvc3"
baseContextRef="threadContextSvc1">
  <securityContext>
</contextService>
```

Example that looks up the default context service:

```
ContextService threadContextSvc =
  (ContextService) new InitialContext().lookup(
    "java:comp/DefaultContextService");
myContextualAsyncCallback = threadContextSvc.createContextualProxy(
  myAsyncCallback, MyAsyncCallback.class);
doSomethingAsync(arg1, arg2, myContextualAsyncCallback);
```

Examples to inject thread context service instances into application components (by using @Resource) or look up with resource environment references (resource-env-ref).

- Example that uses @Resource:

```
@Resource(lookup="concurrent/threadContextSvc1")
ContextService threadContextSvc1;

...

Callable<Integer> processSalesOrderCompletion = new Callable<Integer>() {
    public Integer call() throws Exception {
        DataSource ds = (DataSource) new InitialContext().lookup("java:comp/env/jdbc/ds1");
        ...update various database tables
        return isSuccessful;
    }
};
// capture thread context of current application component
execProps = Collections.singletonMap(ManagedTask.TRANSACTION,
ManagedTask.USE_TRANSACTION_OF_EXECUTION_THREAD);
processSalesOrderCompletion = (Callable<Boolean>)
    threadContextSvc1.createContextualProxy(processSaleCompletion, execProps,
Callable.class);

//later from a different application component
tran.begin();
...
successful = processSalesOrderCompletion.call();
if (successful)
    tran.commit();
else
    tran.rollback();
```

- Example that specifies resource-env-ref in the web.xml file:

```
<resource-env-ref>
  <resource-env-ref-name>concurrent/threadContextSvc3</resource-env-ref-name>
  <resource-env-ref-type>javax.enterprise.concurrent.ContextService</resource-
env-ref-type>
</resource-env-ref>
```

- Example lookup that uses the resource environment reference:

```
ContextService threadContextSvc3 =
(ContextService) new InitialContext().lookup("java:comp/env/concurrent/threadContextSvc3");
Runnable updateAndGetNextFromDatabase = threadContextSvc3.createContextualProxy
(new Runnable() {
    public void run() {
        DataSource ds = (DataSource) new InitialContext().lookup("java:comp/env/jdbc/ds1");
        ... update the database and get next item to process
    }
}, Runnable.class);
barrier = new CyclicBarrier(3, updateAndGetNextFromDatabase);
...
```

## Configuring managed scheduled executors

8.5.5.4

You can configure `ManagedScheduledExecutorService` instances to schedule asynchronous tasks to run with the thread context of the thread from which the task is scheduled. It is a best practice for Java EE applications to avoid directly managing their own threads; therefore, the `ManagedScheduledExecutorService` extends the JSE `ExecutorService` to provide a way to schedule asynchronous tasks within an application server environment. You might also configure the `ManagedScheduledExecutorService` to capture a thread context that is relevant to Java EE applications and propagate it to the thread of the scheduled task.

## About this task

**Important:** In Liberty, managed scheduled executors do not have their own thread pools. Tasks submitted to managed scheduled executor instances run on the common Liberty executor thread pool.

The managed scheduled executor `<concurrent-1.0>` feature is enabled in the `server.xml` file as follows:

```
<featureManager>
  <feature>concurrent-1.0</feature>
</featureManager>
```

Thread context capture and propagation is managed by the context service. A default instance of the context service (`DefaultContextService`) is created by the server and configured to propagate at least `classloaderContext`, `jeeMetadataContext` and `securityContext`. This default context service instance is used if a `ManagedScheduledExecutorService` is created without referring to a specific context service instance or configuring a context service instance directly within. For more information about context service instances, refer to the [Configuring thread context service instances](#) topic.

A default managed scheduled executor instance (`DefaultManagedScheduledExecutorService`) is available as `java:comp/DefaultManagedScheduledExecutorService` and uses the default context service instance for thread context capture and propagation.

## Procedure

Example configuration in the `server.xml` file:

- Managed scheduled executor that is registered in JNDI with the name `concurrent/scheduledExecutor`, and that uses the default context service instance:

```
<managedScheduledExecutorService jndiName="concurrent/scheduledExecutor"/>
```

- Managed scheduled executor with context service configured to capture and propagate `classloaderContext` only:

```
<managedScheduledExecutorService jndiName="concurrent/scheduledExecutor1">
  <contextService>
    <classloaderContext/>
  </contextService>
</managedScheduledExecutorService>
```

- Managed scheduled executor with `jeeMetadataContext` and `securityContext`:

```
<managedScheduledExecutorService jndiName="concurrent/scheduledExecutor2">
  <contextService>
    <jeeMetadataContext/>
    <securityContext/>
  </contextService>
</managedScheduledExecutorService>
```

- Thread context service that is shared by multiple managed scheduled executors:

```
<contextService id="contextSvc1">
  <jeeMetadataContext/>
</contextService>
```

```
<managedScheduledExecutorService jndiName="concurrent/scheduledExecutor3"
contextServiceRef="contextSvc1"/>
```

```
<managedScheduledExecutorService jndiName="concurrent/scheduledExecutor4" contextServiceRef="contextSvc1"/>
```

## Example

Inject managed scheduled executors into application components (by using `@Resource`) or look up with resource environment references (`resource-env-ref`). Regardless of how the instance is obtained, it can be

used interchangeably as `javax.enterprise.concurrent.ManagedScheduledExecutorService` or any of the following superclasses: `java.util.concurrent.ScheduledExecutorService`, `java.util.concurrent.ExecutorService`, `javax.enterprise.concurrent.ManagedExecutorService`

- Example that looks up the default managed scheduled executor:

```
ManagedScheduledExecutorService executor =
    (ManagedScheduledExecutorService) new InitialContext().lookup(
        "java:comp/DefaultManagedScheduledExecutorService");
executor.schedule(beginSalePrices, 12, TimeUnit.HOURS);
executor.schedule(restoreNormalPrices, 60, TimeUnit.HOURS);
```

- Example that uses `@Resource` to inject as `java.util.concurrent.ScheduledExecutorService`:

```
@Resource(lookup="concurrent/scheduledExecutor2")
ScheduledExecutorService executor;
...

// schedule a task to run every half hour from now
Runnable updateSalesReport = new Runnable() {
    public void run() throws Exception {
        // java:comp lookup is possible because <jeeMetadataContext> is configured
        DataSource ds = (DataSource) new InitialContext().lookup("java:comp/env/jdbc/ds1");
        ... query and update various database tables
    }
};
ScheduledFuture<?> future = executor.scheduleAtFixedRate(updateSalesReport, 0, 30, TimeUnit.MINUTES);
```

- Example that uses `@Resource` to inject as `javax.enterprise.concurrent.ManagedScheduledExecutorService`:

```
@Resource(lookup="concurrent/scheduledExecutor2")
ManagedScheduledExecutorService executor;
```

... usage is same as previous example

- Example `<resource-env-ref>` for `java.util.concurrent.ScheduledExecutorService` in the `web.xml` file:

```
<resource-env-ref>
  <resource-env-ref-name>concurrent/scheduledExecutor1</resource-env-ref-name>
  <resource-env-ref-type>java.util.concurrent.ScheduledExecutorService</resource-env-ref-type>
</resource-env-ref>
```

- Example `<resource-env-ref>` for `javax.enterprise.concurrent.ManagedScheduledExecutorService` in the `web.xml` file:

```
<resource-env-ref>
  <resource-env-ref-name>concurrent/scheduledExecutor2</resource-env-ref-name>
  <resource-env-ref-type>javax.enterprise.concurrent.ManagedScheduledExecutorService</resource-env-ref-type>
</resource-env-ref>
```

- Example lookup that uses a resource environment reference:

```
ManagedScheduledExecutorService executor =
    (ManagedScheduledExecutorService) new InitialContext().lookup("java:comp/env/concurrent/scheduledExecutor2");
executor.schedule(payrollTask, fridaysAtMidnightTrigger);
```

## Configuring managed thread factories

8.5.5.4

You can configure `ManagedThreadFactory` instances to create new threads that run with a thread context of the thread from which the managed thread factory is looked up or injected. It is a best practice for Java EE applications to avoid directly managing their own threads; therefore, the `ManagedThreadFactory` extends the JSE `ThreadFactory` to provide a way to create managed threads within an application server environment. You might also configure the `ManagedThreadFactory` to capture a thread context that is relevant to Java EE applications and propagate it to the new thread.

### About this task

The managed thread factory is available under the `<concurrent-1.0>` feature and enabled in the `server.xml` file as follows:

```
<featureManager>
  <feature>concurrent-1.0</feature>
</featureManager>
```

Thread context capture and propagation is managed by the context service. A default instance of the context service (`DefaultContextService`) is created by the server and configured to propagate at least `classloaderContext`, `jeeMetadataContext` and `securityContext`. This default context service instance is used if a `ManagedThreadFactory` does not specify a context service. For more information about context service instances, refer to the [Configuring thread context service instances](#) topic.

A default instance of `ManagedThreadFactory` (`DefaultManagedThreadFactory`) is available as `java:comp/DefaultManagedThreadFactory` and uses the default context service instance for thread context capture and propagation.

## Procedure

Example configuration in the `server.xml` file:

- Managed thread factory that is registered in JNDI with the name `concurrent/threadFactory`, and that uses the default context service instance:

```
<managedThreadFactory jndiName="concurrent/threadFactory" maxPriority="5"/>
```

- Managed thread factory with context service configured to capture and propagate `securityContext` only:

```
<managedThreadFactory jndiName="concurrent/threadFactory1">
  <contextService>
    <securityContext/>
  </contextService>
</managedThreadFactory>
```

- Managed thread factory with `classloaderContext` and `jeeMetadataContext`:

```
<managedThreadFactory jndiName="concurrent/threadFactory2">
  <contextService>
    <classloaderContext/>
    <jeeMetadataContext/>
  </contextService>
</managedThreadFactory>
```

- Thread context service that is shared by multiple managed thread factories:

```
<contextService id="contextSvc1">
  <jeeMetadataContext/>
</contextService>
```

```
<managedThreadFactory jndiName="concurrent/threadFactory3"
contextServiceRef="contextSvc1"/>
```

```
<managedThreadFactory jndiName="concurrent/threadFactory4"
contextServiceRef="contextSvc1"/>
```

## Example

Managed thread factories can be injected into application components (by using `@Resource`) or looked up with resource environment references (`resource-env-ref`). Regardless of how the instance is obtained, it can be used interchangeably as `javax.enterprise.concurrent.ManagedThreadFactory` or `java.util.concurrent.ThreadFactory`.

- Example that looks up the default managed thread factory:

```
ManagedThreadFactory threadFactory =
    (ManagedThreadFactory) new InitialContext().lookup(
        "java:comp/DefaultManagedThreadFactory");
```

```
// Create an executor that always runs tasks with the thread context of the managed thread factory
ExecutorService executor = new ThreadPoolExecutor(
    coreThreads, maxThreads, keepAliveTime, TimeUnit.MINUTES,
    new ArrayBlockingQueue<Runnable>(workRequestQueueSize),
    threadFactory, new ThreadPoolExecutor.AbortPolicy());
```

- Example that uses `@Resource` to inject `asjava.util.concurrent.ThreadFactory`:

```
@Resource(lookup="concurrent/threadFactory2")
ThreadFactory threadFactory
...
```

```
// create a new thread
Thread dailySalesAnalysisTask = threadFactory.newThread(new Runnable() {
    public void run() {
        // java:comp lookup is possible because <jeeMetadataContext> is configured
        DataSource ds = (DataSource) new InitialContext().lookup("java:comp/env/jdbc/ds1");
        ... analyze the data
    }
});
dailySalesAnalysisTask.start();
```

- Example that uses `@Resource` to inject as `javax.enterprise.concurrent.ManagedThreadFactory`:

```
@Resource(lookup="concurrent/threadFactory2")
ManagedThreadFactory threadFactory;
```

... usage is same as previous example

- Example `<resource-env-ref>` for `java.util.concurrent.ThreadFactory` in the `web.xml` file:

```
<resource-env-ref>
  <resource-env-ref-name>concurrent/threadFactory1</resource-env-ref-name>
  <resource-env-ref-type>java.util.concurrent.ThreadFactory</resource-env-ref-type>
</resource-env-ref>
```

- Example `<resource-env-ref>` for `javax.enterprise.concurrent.ManagedThreadFactory` in the `web.xml` file:

```
<resource-env-ref>
  <resource-env-ref-name>concurrent/threadFactory2</resource-env-ref-name>
  <resource-env-ref-type>javax.enterprise.concurrent.ManagedThreadFactory</resource-
env-ref-type>
</resource-env-ref>
```

- Example lookup that uses a resource environment reference:

```
ManagedThreadFactory threadFactory =
    (ManagedThreadFactory) new InitialContext().lookup("java:comp/env/concurrent/threadFactory");
// Create a scheduled executor that always runs tasks with the thread context of the managed thread factory
ScheduledExecutorService executor = Executors.newScheduledThreadPool(5, threadFactory);
... use executor to schedule tasks from any thread
```

## Connecting to Liberty by using JMX

Use this information to access Java Management Extensions (JMX) connectors on Liberty. You can also access the secured JMX connector remotely by using SSL.

### About this task

There are two JMX connectors supported on Liberty, each connector is enabled through a different Liberty feature: `localConnector-1.0` and `restConnector-1.0`.

- The local connector is enabled through the Liberty feature `localConnector-1.0`. Access through the local connector is protected by the policy implemented by the SDK in use. Currently the SDKs require that the client runs on the same host as Liberty, and under the same user ID.
- The REST connector is enabled through the Liberty feature `restConnector-1.0`. Remote access through the REST connector is protected by a single administrator role. In addition, SSL is required to keep the communication confidential. The `restConnector-1.0` feature already includes the `ssl-1.0` feature.

An application deployed on Liberty has unrestricted access to its MBeanServer directory.

A JMX connection to the collective controller enables JMX access to multiple Liberty servers through the same connection. See “Setting up the server-management environment for Liberty by using collectives” on page 1134 for more information.

**Restriction:** Do not use JDK options that start with `com.sun.management.jmxremote`, which are described in <http://docs.oracle.com/javase/7/docs/technotes/guides/management/agent.html>, with the Liberty JMX support. Those JDK options adversely affect the Liberty MBean registration framework.

## Procedure

- Connect to the local JMX connector
- Connect to the REST connector
- **8.5.0.1** Work with JMX MBeans

## Configuring local JMX connection to Liberty

You can access the local Java Management Extensions (JMX) connector on Liberty. The local connector is enabled through the Liberty feature `localConnector-1.0`.

### About this task

The local connector is enabled through the Liberty feature `localConnector-1.0`. Access through the local connector is protected by the policy implemented by the SDK in use. Currently the SDKs require that the client runs on the same host as Liberty, and under the same user ID.

**Note:** An application deployed on Liberty has unrestricted access to its MBeanServer directory.

The following section describes how to configure and access the local connector on Liberty.

## Procedure

1. Enable the local connector by using the following code in the `server.xml` file.

```
<featureManager>
  <feature>localConnector-1.0</feature>
</featureManager>
```
2. **8.5.0.1** Access the local connector by using the JConsole tool or JMX client that is installed on the same host.
  - For the JConsole tool, select the local process `ws-server.jar defaultServer` from the connection panel then click **Connect**.
  - **8.5.0.1** For the JMX client, see “Working with JMX MBeans on Liberty” on page 1646.

## Configuring secure JMX connection to Liberty

You can access the secured Java Management Extensions (JMX) connectors on Liberty by using SSL. The secured JMX connection is enabled by the Liberty feature `restConnector-1.0`.

### About this task

The REST connector is enabled through the Liberty feature `restConnector-1.0`. Remote access through the REST connector is protected by a single administrator role. In addition, SSL is required to keep the communication confidential. The `restConnector-1.0` feature already includes the `ssl-1.0` feature.

**Note:** An application deployed on Liberty has unrestricted access to its MBeanServer directory.

The following section describes how to configure and access the REST connector on Liberty.

## Procedure

1. Enable the REST connector using the following code in the `server.xml` file.

```
<featureManager>
  <feature>restConnector-1.0</feature>
</featureManager>
```

2. Configure SSL certificates in the `server.xml` file.

Ensure that the CN value of the certificate's subjectDN is the host name of the machine where the server is running, and that the truststore contains the certificate of the server in the jConsole connection.

3. Configure a user or group to the administrator role in the `server.xml` file.

- Map to the administrator role for Liberty
- **z/OS** Map to the administrator role for Liberty on z/OS

4. Access the REST connector.

**8.5.5.4** You can access a Liberty REST connector from a Java client or directly through an HTTPS call. A Java client uses the client-side of the connector, which is in `wlp/clients/restConnector.jar` and implements the `javax.management.MBeanServerConnection` interface. HTTPS calls use the server-side of the connector. As to HTTPS calls on the server-side, any programming language that can make HTTPS calls, such as C++, JavaScript, curl, Ruby, and Perl, can use the REST APIs. The REST APIs contain endpoints for management (JMX), file transfer, collective routing and collective deployment.

- Access the REST connector from a JMX client application or by using the jConsole tool provided in the Java SDK. Use `-J` flags to pass the system properties as Java options and set the class path to include the connector class files. The connector class files are packed in the `clients/restConnector.jar` file.

- Use the following properties for SSL certificates:

```
-J-Djavax.net.ssl.trustStore=<location of your client trust store>
-J-Djavax.net.ssl.trustStorePassword=<password for the trust store>
-J-Djavax.net.ssl.trustStoreType=<type of trust store>
```

The following example shows the jConsole tool being used with SSL configurations:

```
jconsole -J-Djava.class.path=%JAVA_HOME%/lib/jconsole.jar;
          %JAVA_HOME%/lib/tools.jar;
          %WLP_HOME%/clients/restConnector.jar
          -J-Djavax.net.ssl.trustStore=key.jks
          -J-Djavax.net.ssl.trustStorePassword=Liberty
          -J-Djavax.net.ssl.trustStoreType=jks
```

After the jConsole starts, select **Remote Process**, and enter the JMX service URL: `service:jmx:rest://<host>:<port>/IBMJMXConnectorREST`. The port number is the HTTPS port. You must also provide the user name and password.

- **z/OS** For z/OS, use the following system properties:

```
-J-Djava.protocol.handler.pkgs=com.ibm.crypto.provider
-J-Djavax.net.ssl.trustStore=<SAF keyring>
-J-Djavax.net.ssl.trustStorePassword=<password to SAF>
-J-Djavax.net.ssl.trustStoreType=JCERACFKS
```

- **8.5.5.4** Access the REST connector directly using an HTTPS call.

To use HTTPS calls to access REST connectors, you need WebSphere Application Server Liberty 8.5.5.4 or later.

- a. Open a browser at `https://<host>:<port>/IBMJMXConnectorREST/api`, and enter the administrative credentials you specified in step 3.
- b. Examine the available REST APIs. Each item has a description of its behavior, input, output, query parameters, and header.

**Note:** You can specify some JMX REST connection options as system properties. See the Liberty API - WebSphere JMX REST Connector API.

## Mapping the administrator role for Liberty:

You can use `quickStartSecurity` element or any supported user registries for the administrator role mapping in Liberty.

### About this task

All the JMX methods and MBeans accessed through the REST connector are currently protected by a single role named "administrator". To get started quickly, use `quickStartSecurity` element to configure a single user with administrator role and configure the default SSL configuration.

You can also use any supported user registry. You cannot use `quickStartSecurity` element if you have already configured another user registry. In this case, you have to map users or roles from the registry to the administrator role.

### Procedure

- Use `quickStartSecurity` element for a single user mapping.

Here is an example showing the minimal required configuration:

```
<featureManager>
  <feature>restConnector-1.0</feature>
</featureManager>
<quickStartSecurity userName="bob" userPassword="bobpassword" />
<keyStore id="defaultKeyStore" password="keystorePassword"/>
```

- Or use the basic registry for administrator role mapping.

Here is an example of the basic registry that gives the user "bob" or the group "group1" administrator role:

```
<basicRegistry>
  <user name="bob" password="bobpassword"/>
  <user name="joe" password="joepassword"/>
  <group name="group1" ...>
  </group>
</basicRegistry>

<administrator-role>
  <user>bob</user>
  <group>group1</group>
</administrator-role>
```

- Or use the LDAP registry for administrator role mapping **8.5.5.0** (you will need to add the `ldapRegistry-3.0` feature to your `server.xml` file).

Here is an example of the LDAP registry that gives the user "bob" administrator role.

```
<ldapRegistry id="basic" host="" port="">
  <tds.properties ... />
</ldapRegistry>

<administrator-role>
  <user>cn=bob,o=ibm,c=us</user>
</administrator-role>
```

## Mapping the administrator role for Liberty on z/OS: **z/OS**

You must configure SAF keyring and RACF authorization to map a z/OS user to an administrator role for Liberty on z/OS.

## About this task

For z/OS users using SAF keyring and RACF authorization, the SSL definition must point to SAF, and the administrator role is defined in RACF.

## Procedure

- Configure SSL definitions with SAF. Here is a sample configuration:

```
<featureManager>
  <feature>zosSecurity-1.0</feature>
  <feature>restConnector-1.0</feature>
</featureManager>

<sslDefault sslRef="defaultSSLSettings" />
<ssl id="defaultSSLSettings" keyStoreRef="CellDefaultKeyStore"
  trustStoreRef="CellDefaultTrustStore" />
<keyStore id="CellDefaultKeyStore" location="safkeyring:///WASKeyring2048" type="JCERACFKS"
  password="keystorepassword" fileBased="false" readOnly="true" />
<keyStore id="CellDefaultTrustStore" location="safkeyring:///WASKeyring2048" type="JCERACFKS"
  password="truststorepassword" fileBased="false" readOnly="true" />
```

- Configure administrator role by using RACF authorization.

To assign a user to the administrator role, you must grant the user access to the SAF profile associated with the role. See “Liberty: Controlling how roles are mapped to SAF Profiles” on page 1941 for more details.

By default, the SAF profile name for the administrator role is `BBGZDFLT.com.ibm.ws.management.security.resource.Administrator`. That profile must exist in the `EJBROLE` SAF class, and the admin user must be granted `READ` access to it.

Here is the example RACF commands for user `mstone1`:

```
RDEFINE EJBROLE BBGZDFLT.com.ibm.ws.management.security.resource.Administrator UACC(NONE)
PERMIT BBGZDFLT.com.ibm.ws.management.security.resource.Administrator ID(MSTONE1) ACCESS(READ) CLASS(EJBROLE)
```

## Developing a JMX Java client for Liberty:

You can develop a Java Management Extensions (JMX) client application to access the secured REST connector of the Liberty server.

## About this task

Using a JMX remote client application, you can administer the Liberty server through JMX programming.

## Procedure

- Develop a sample JMX client as follows. The REST connector supports the standard JMX API.

```
import javax.management.remote.JMXServiceURL;
import javax.management.MBeanServerConnection;
import javax.management.remote.JMXConnector;
import javax.management.remote.JMXConnectorFactory;
import java.util.HashMap;

public class Test {

    public static void main(String[] args) {
        System.setProperty("javax.net.ssl.trustStore", <truststore location>);
        System.setProperty("javax.net.ssl.trustStorePassword", <truststore password>);

        //If the type of the trustStore is not jks, which is default,
        //set the type by using the following line.
        System.setProperty("javax.net.ssl.trustStoreType", <truststore type>);
```

```

try {
    HashMap<String, Object> environment = new HashMap<String, Object>();
    environment.put("jmx.remote.protocol.provider.pkgs", "com.ibm.ws.jmx.connector.client");
    environment.put(JMXConnector.CREDENTIALS, new String[] { "bob", "bobpassword" });

    JMXServiceURL url = new JMXServiceURL("service:jmx:rest://<host>:<port>/IBMJMXConnectorREST");
    JMXConnector connector = JMXConnectorFactory.newJMXConnector(url, environment);
    connector.connect();
    MBeanServerConnection mbsc = connector.getMBeanServerConnection();
} catch(Throwable t) {
    ...
}
}
}

```

- Optional: Disable host name verification for SSL certificates. The certificates that are installed with the Liberty profile might not contain the host name of where the server is actually running. If you want to disable host name verification of SSL certificates, you can set the system property `com.ibm.ws.jmx.connector.client.disableURLHostnameVerification` to `true`, which disables host name verification for all connections. To disable host name verification on a per-connection basis, pass the property as a new environment when you create the JMX connection:

```

HashMap<String, Object> environment = new HashMap<String, Object>();
environment.put("jmx.remote.protocol.provider.pkgs", "com.ibm.ws.jmx.connector.client");
environment.put("com.ibm.ws.jmx.connector.client.disableURLHostnameVerification", Boolean.TRUE);
environment.put(JMXConnector.CREDENTIALS, new String[] { "bob", "bobpassword" });
...

```

- Optional: Configure JMX REST connector settings by using the environment Map.

```

...
HashMap<String, Object> environment = new HashMap<String, Object>();
environment.put("com.ibm.ws.jmx.connector.client.rest.maxServerWaitTime", 0);
environment.put("com.ibm.ws.jmx.connector.client.rest.notificationDeliveryInterval", 65000);
...

```

- **8.5.5.0** Optional: The Liberty REST connector allows you to specify a custom SSL socket factory that can be used to obtain sockets. If the `javax.net.ssl.SSLHandshakeException`: `com.ibm.jsse2.util.j: PKIX path building failed: java.security.cert.CertPathBuilderException: unable to find valid certification path to requested target` exception is displayed, you can create your own `SSLContext` from your own `KeyStores` and then use the `SocketFactory` from that context with the REST connector.

```

KeyStore trustStore = KeyStore.getInstance(KeyStore.getDefaultType());
InputStream inputStream = new FileInputStream("myTrustStore.jks");
trustStore.load(inputStream, "password".toCharArray());
TrustManagerFactory trustManagerFactory = TrustManagerFactory.getInstance(TrustManagerFactory.getDefaultAlgorithm());
trustManagerFactory.init(trustStore);
TrustManager[] trustManagers = trustManagerFactory.getTrustManagers();
SSLContext sslContext = SSLContext.getInstance("SSL");
sslContext.init(null, trustManagers, null);

```

```

Map<String, Object> environment = new HashMap<String, Object>();
environment.put(ConnectorSettings.CUSTOM_SSLSOCKETFACTORY, sslContext.getSocketFactory());
environment.put(ConnectorSettings.DISABLE_HOSTNAME_VERIFICATION, true);
environment.put("jmx.remote.protocol.provider.pkgs", "com.ibm.ws.jmx.connector.client");
environment.put(JMXConnector.CREDENTIALS, new String[] { "admin", "password" });
JMXServiceURL url = new JMXServiceURL("REST", "myhost", 9443, "/IBMJMXConnectorREST");
jmxConn = JMXConnectorFactory.connect(url, environment);

```

## Working with JMX MBeans on Liberty

### 8.5.0.1

You can access the attributes and call the operations of Java Management Extensions (JMX) management beans (MBeans) on Liberty. In addition, you can register your own MBeans from an application running on Liberty.

## About this task

The primary interfaces for interacting with MBeans on Liberty are as follows:

- `javax.management.MBeanServer`, which is for application code running on Liberty.
- `javax.management.MBeanServerConnection`, which is for external code running in a separate Java virtual machine.

You can use an instance of either of these interfaces to access the attributes and call the operations of MBeans.

## Procedure

- For application code running on Liberty, you can use a `javax.management.MBeanServer` instance by using the following code:

```
import java.lang.management.ManagementFactory;
import javax.management.MBeanServer;

...

MBeanServer mbs = ManagementFactory.getPlatformMBeanServer();
...
```

- For external code running in a separate Java virtual machine, you can use a `javax.management.MBeanServerConnection` instance. See “Developing a JMX Java client for Liberty” on page 1645.

## Liberty: List of provided MBeans: **8.5.0.1**

Liberty provides a list of MBeans and corresponding management interfaces that you can use to manipulate and monitor the server.

For each MBean or MXBean in the list:

- The name is the `javax.management.ObjectName` value that uniquely identifies the MBean or MXBean. When there are multiple instances of an MBean or MXBean, the `ObjectName` value can contain a wildcard (\*), which is described in the **Comments** entries in this topic.
- The **Management interface** entries specify the name of the Java interface that can be used to construct a proxy object for the MBean or MXBean as described in “Liberty:Examples of accessing MBean attributes and operations” on page 1654. For more information about the management interface, see the Java API document for Liberty. The Java API documentation for each Liberty API is available in a separate .zip file in one of the javadoc subdirectories of the `${wlp.install.dir}/dev` directory.

### **8.5.5.0**

**WebSphere: feature=channel fw, type=endpoint, name=\***

- **Management interface:** `com.ibm.websphere.endpoint.EndPointInfoMBean`
- **Comments:** One instance is available for each endpoint in the system, where \* is a unique endpoint name.

### **8.5.5.0**

**WebSphere: feature=clusterMember, type=ClusterMember, name=ClusterMember**

- **Management interface:** `com.ibm.websphere.cluster.member.ClusterMemberMBean`

- **Comments:** This MBean is available when the `clusterMember` feature is enabled on a collective member. To join a cluster, add `<clusterMember name=<clusterName> />` into the server configuration. The name of the cluster can be retrieved by this MBean.

#### 8.5.5.0

**WebSphere: feature=collectiveController, type=ClusterManager, name=ClusterManager**

- **Management interface:** `com.ibm.websphere.collective.controller.ClusterManagerMBean`
- **Comments:** This MBean is available when the `collectiveController` feature is enabled. It provides operations that can be used to query and manipulate Liberty servers that have enabled the `collectiveMember` and `clusterMember` features.

#### 8.5.5.5

**WebSphere: feature=collectiveController, type=AdminMetadataManager, name=AdminMetadataManager**

- **Management interface:** `com.ibm.websphere.collective.repository.AdminMetadataManagerMBean`
- **Comments:** This MBean provides the administrative metadata MBean operations to add, retrieve and remove metadata. The metadata includes tags, owner, contact, and note data. The metadata information is stored in the collective repository. You can find the MBean class and API documentation in the following locations:
  - `${wlp.install.dir}/dev/api/ibm/com.ibm.websphere.appserver.api.collectiveController_version.jar`
  - `${wlp.install.dir}/dev/api/ibm/javadoc/com.ibm.websphere.appserver.api.collectiveController_version-javadoc.zip`

#### 8.5.5.0

**WebSphere: feature=collectiveController, type=CollectiveRegistration, name=CollectiveRegistration**

- **Management interface:** `com.ibm.websphere.collective.controller.CollectiveRegistrationMBean`
- **Comments:** This MBean is available when the `collectiveController` feature is enabled. It provides operations that enable registration of hosts, Liberty servers to be joined as members, replication of new controllers, and controller access authentication of members to the collective controller.

#### 8.5.5.0

**WebSphere: feature=collectiveController, type=CollectiveRepository, name=CollectiveRepository**

- **Management interface:** `com.ibm.websphere.collective.repository.CollectiveRepositoryMBean`
- **Comments:** This MBean is available when the `collectiveController` feature is enabled. It provides operations that enable reading and writing of data into the collective repository.

#### 8.5.5.0

**WebSphere: feature=collectiveController, type=RepositoryConfiguration, name=RepositoryConfiguration**

- **Management interface:** `com.ibm.websphere.collective.repository.RepositoryConfigurationMBean`
- **Comments:** This MBean is available when the `collectiveController` feature is enabled. It provides operations that enable adding and removing collective controller replicas to scale out the replica set and provide high availability capabilities.

#### 8.5.5.0

**WebSphere: feature=collectiveController, type=RepositoryPathUtility, name=RepositoryPathUtility**

- **Management interface:** `com.ibm.websphere.collective.repository.RepositoryPathUtilityMBean`
- **Comments:** This MBean is available when the `collectiveController` feature is enabled. It provides utility operations that enable easier construction of paths for use with the `RepositoryConfiguration` MBean.

### 8.5.5.0

**WebSphere: feature=collectiveController, type=RoutingContext, name=RoutingContext**

- **Management interface:**com.ibm.websphere.collective.controller.RoutingContextMBean
- **Comments:** This MBean is for setting up the JMX routing context - to call MBeans on a collective member server through a collective controller for example.

**Note:** **Distributed operating systems** **IBM i** The collectiveController-1.0 feature and its capabilities are available only in WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. The feature is not available in WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a WebSphere Application Server Liberty Network Deployment installation, you can use its collectiveController-1.0 feature to work with collective members from WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core installations.

See “Liberty: Example of setting up a JMX routing environment” on page 1657 for more information.

### 8.5.5.0

**WebSphere: feature=collectiveController, type=ServerCommands, name=ServerCommands**

- **Management interface:**com.ibm.websphere.collective.controller.ServerCommandsMBean
- **Comments:** This MBean runs in the collective controller and can remotely invoke the Liberty **server** command on a target host. It has three operations: `getServerStatus`, `startServer`, and `stopServer`. The `getServerStatus` operation allows you to get the status of a member server in a collective by providing its hostname, server's user directory, and server name. You can subscribe for server up or down changes by calling `addNotificationListener`. An `AttributeChangeNotification` is sent to all listeners when any server in the collective changes its state. The hostname, server's user directory, and server name are stored as a comma-separated string in the message for identification purposes.

You can find the MBean class and API documentation in the following locations:

- `${wlp.install.dir}/dev/api/ibm/com.ibm.websphere.appserver.api.collectiveController_version.jar`
- `${wlp.install.dir}/dev/api/ibm/javadoc/com.ibm.websphere.appserver.api.collectiveController_version-javadoc.zip`

**Note:** **Distributed operating systems** **IBM i** The collectiveController-1.0 feature and its capabilities are available only in WebSphere Application Server Liberty Network Deployment and WebSphere Application Server Liberty for z/OS. **8.5.5.0** The feature is not available in WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a WebSphere Application Server Liberty Network Deployment installation, you can use its collectiveController-1.0 feature to work with collective members from WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core installations.

### 8.5.5.0

**WebSphere: feature=restConnector, type=FileService, name=FileService**

- **Management interface:**com.ibm.websphere.filetransfer.FileServiceMXBean
- **Comments:** This MXBean enables you to perform various file-related operations on the host where Liberty resides.

You can find its class and API documentation in the following locations:

- `liberty_home/dev/api/ibm/com.ibm.websphere.appserver.api.restConnector_version.jar`
- `liberty_home/dev/api/ibm/javadoc/com.ibm.websphere.appserver.api.restConnector_version-javadoc.zip`

The exposed operations include the ability to query certain metadata (last modified date, size, and so on) for a given file or directory and also to query all child files (and corresponding metadata) for a given directory. Support for archive creation and expansion is also provided, which can be useful to compress Liberty log files or to extract an application before deploying it.

This MBean contains two attributes: the read list and the write list. They represent the lists of locations that users can read or write to when using the FileService or FileTransfer capabilities provided by Liberty. Through the MBean, these attributes can only be read, but they can be configured or customized through the following elements in the `server.xml` file:

```
<remoteFileAccess>
  <readDir>${server.output.dir}/logs</readDir>
  <readDir>${server.output.dir}/apps</readDir>
  <writeDir>${server.output.dir}/dropins</writeDir>
</remoteFileAccess>
```

If the `readDir` element is not specified, the default is the combination of: `${wlp.install.dir}`, `${wlp.user.dir}`, and `${server.output.dir}`. If a `writeDir` element is not specified, the default is the empty set.

The `restConnector-1.0` feature must be included in the `server.xml` file in order for this MBean to be loaded and to honor its configuration elements

Using Liberty-defined variables is allowed with all the server-side parameters that take a string representing a file path. Such variables are defined on the `liberty_home/README.TXT` file.

#### 8.5.5.0

##### **WebSphere: feature=restConnector, type=FileTransfer, name=FileTransfer**

- **Management interface:** `com.ibm.websphere.filetransfer.FileTransferMBean`
- **Comments:** This MBean allows you to perform various file-transfer operations on the host where Liberty resides.

You can find its class and API documentation in the following locations:

```
liberty_home/dev/api/ibm/com.ibm.websphere.appserver.api.restConnector_version.jar
liberty_home/dev/api/ibm/javadoc/com.ibm.websphere.appserver.api.restConnector_version-javadoc.zip
```

This MBean is registered on the PlatformMBeanServer from the same JVM that its corresponding Liberty process is running, but it can be accessed only by using the IBM JMX REST Connector. The connection can be local or remote, but the REST Connector must be used.

The exposed operations include the ability to download, upload, and delete a file. Each read and write request on the server is bound to the configurable read and write lists that are accessed through the FileServiceMBean. The FileTransferMBean can also be fully accessed and operated from the built-in Java JConsole, provided that the JConsole is connected through the IBM JMX REST Connector.

Using Liberty-defined variables is allowed with all the server-side parameters that take a string representing a file path. Such variables are defined on the `liberty_home/README.TXT` file.

#### 8.5.5.5

##### **WebSphere: name=com.ibm.websphere.config.mbeans.ServerXMLConfigurationMBean**

- **Management interface:** `com.ibm.websphere.config.mbeans.ServerXMLConfigurationMBean`
- **Comments:** The ServerXMLConfigurationMBean provides an interface for retrieving the file paths of all server configuration files known to the server. The MBean is available from the Kernel, so you do not need to enable a special feature. You can find the MBean class and API documentation in the following locations:
  - `${wlp.install.dir}/dev/api/ibm/com.ibm.websphere.appserver.api.config_version.jar`
  - `${wlp.install.dir}/dev/api/ibm/javadoc/com.ibm.websphere.appserver.api.config_version-javadoc.zip`

#### 8.5.5.4

**WebSphere:name=com.ibm.websphere.runtime.update.RuntimeUpdateNotificationMBean**

- **Management interface:**com.ibm.websphere.runtime.update.RuntimeUpdateNotificationMBean
- **Comments:** The RuntimeUpdateNotificationMBean provides notifications for server runtime updates. The user data object attached to the notification is a java.util.Map. The notification type for runtime update notifications emitted by this MBean is com.ibm.websphere.runtime.update.notification.

8.5.5.5

**WebSphere:name=com.ibm.ws.config.mbeans.FeatureListMBean**

- **Management interface:**com.ibm.websphere.config.mbeans.FeatureListMBean
- **Comments:** The FeatureListMBean exposes a single method to generate an XML report on all the features installed at run time. The MBean is available from the Kernel, so you do not need to enable a special feature. You can find the MBean class and API documentation in the following locations:
  - `${wlp.install.dir}/dev/api/ibm/com.ibm.websphere.appserver.api.config_version.jar`
  - `${wlp.install.dir}/dev/api/ibm/javadoc/com.ibm.websphere.appserver.api.config_version-javadoc.zip`

8.5.5.5

**WebSphere:name=com.ibm.ws.config.serverSchemaGenerator**

- **Management interface:**com.ibm.websphere.config.mbeans.ServerSchemaGenerator
- **Comments:** The ServerSchemaGenerator MBean exposes methods to generate schema from the installed image, the most used way, or from a current runtime. The MBean is available from the Kernel, so you do not need to enable a special feature. You can find the MBean class and API documentation in the following locations:
  - `${wlp.install.dir}/dev/api/ibm/com.ibm.websphere.appserver.api.config_version.jar`
  - `${wlp.install.dir}/dev/api/ibm/javadoc/com.ibm.websphere.appserver.api.config_version-javadoc.zip`

**WebSphere:name=com.ibm.ws.jmx.mbeans.generatePluginConfig**

- **Management interface:**com.ibm.websphere.webcontainer.GeneratePluginConfigMBean
- **Comments:** See “Configuring a web server plug-in for Liberty” on page 1604.

**WebSphere:service=com.ibm.ws.kernel.filemonitor.FileNotificationMBean**

- **Management interface:**com.ibm.websphere.filemonitor.FileNotificationMBean

**WebSphere:service=com.ibm.websphere.application.ApplicationMBean,name=\***

- **Management interface:**com.ibm.websphere.application.ApplicationMBean
- **Comments:** One instance is available for each application in the system, where \* is a unique application name.

8.5.5.6

**WebSphere:service=com.ibm.ws.jca.cm.mbean.ConnectionManagerMBean,\***

- **Management interface:**com.ibm.ws.jca.cm.mbean.ConnectionManagerMBean
- **Comments:** One instance is available for each Connection Manager in the system, including those created in the following contexts:
  - When explicitly configured in the server configuration
  - When implicitly created because of @DataSourceDefinition or @ConnectionFactoryDefinition annotations
  - When created as a result of a connection factory or data source in the server configuration

The mbean instance is not available until the corresponding connection factory or data source is first used.

To narrow the connection manager instance, you can specify additional attributes, such as those shown in the following examples:

```
WebSphere:service=com.ibm.ws.jca.cm.mbean.ConnectionManagerMBean,jndiName=jdbc/db2,*
```

```
WebSphere:service=com.ibm.ws.jca.cm.mbean.ConnectionManagerMBean,name=jmsConnectionFactory[cf1]/connectionManager[default]
```

```
WebSphere:service=com.ibm.ws.jca.cm.mbean.ConnectionManagerMBean,name=databaseStore[dbstore1]/dataSource[default-0]/conn
```

```
WebSphere:service=com.ibm.ws.jca.cm.mbean.ConnectionManagerMBean,jndiName=java.module/env/jdbc/ds3,application=MyApp,modu
```

#### **WebSphere:type=JvmStats**

- **Management interface:** com.ibm.websphere.monitor.jmx.JvmMXBean
- **Comments:** Available when the monitor-1.0 feature is enabled. See “Liberty:JVM monitoring” on page 2267.

#### **WebSphere:type=ServletStats,name=\***

- **Management interface:**com.ibm.websphere.webcontainer.ServletStatsMXBean
- **Comments:** When the monitor-1.0 feature is enabled, one instance is available for each servlet that has been served, where \* is of the form <AppName>.<ServletName>. See “Liberty:Web application monitoring” on page 2268.

#### **WebSphere:type=ThreadPoolStats,name=Default Executor**

- **Management interface:**com.ibm.websphere.monitor.jmx.ThreadPoolMXBean
- **Comments:** Available when the monitor-1.0 feature is enabled. See “Liberty:ThreadPool monitoring” on page 2269.

#### **8.5.5.0**

#### **WebSphere:feature=jaxws,type=WebServiceStats,service=\*,port=\***

- **Management interface:**org.apache.cxf.management.counters.ResponseTimeCounterMBean
- **Comments:** Available when the monitor-1.0 feature is enabled. The WebServiceStats can be either Performance.Counter.Server or Performance.Counter.client, where **service=\*** is the qualified name of a service endpoint, **port=\*** is the port name of the service endpoint. See “Liberty:JAX-WS monitoring” on page 2270.

**Note:** This is a Dynamic Model Mbean.

#### **8.5.5.0**

**8.5.5.0** WebSphere:feature=jaxws,type=Bus.Service.Endpoint,bus.id=\*,service=\*,port=\*,name=\*

- **Management interface:** org.apache.cxf.endpoint.ManagedEndpoint
- **Comments:** Available when the localConnector-1.0 or restConnector-1.0 feature is enabled and the JAX-WS application is accessed at least once. The **bus.id=\*** is the name of the bus, where \* is of the form <AppName>-Server-Bus. The **service=\*** is the qualified name of the endpoint, where \* is of the form {ServiceNamespace}ServiceName. The **port=\*** is the port name of the endpoint, where the \* is the

current port name. **8.5.5.0** The format of the MBean is as follows:

<BUS>@<SERVICE>@<PORT>@<URL\_PATTERN>, where:

- <BUS> is the same value as the field **bus.id**;
- <SERVICE> is the same value as the field **service**;
- <PORT> is the same value as the field **port**;
- <URL\_PATTERN> might be the following values in different scenarios;
  - If the url-pattern element is defined in the web.xml file of your application, the value of url-pattern element is used. For example, the url-pattern element is /SayHelloURL in the web.xml file:

```

<servlet-mapping>
  <servlet-name>com.ibm.ws.jaxws.test.jmx.service.WSTestEndpointService</servlet-name>
  <url-pattern>/SayHelloURL</url-pattern>
</servlet-mapping>

```

For example, the MBean might be as follows:

```

WebSphere:feature=jaxws,bus.id=EJBWSBasic-Server-Bus,type=Bus.Service.Endpoint,
service="{http://ejbbasic.jaxws.ws.ibm.com/}SayHelloService",port="SayHelloPort",
name="EJBWSBasic-Server-Bus@{http://ejbbasic.jaxws.ws.ibm.com/}SayHelloService@SayHelloPort@SayHelloURL"

```

- If the URL pattern is not specified, the service name is used as the default value. For example, the MBean might be as follows:

```

WebSphere:feature=jaxws,bus.id=EJBWSBasic-Server-Bus,type=Bus.Service.Endpoint,
service="{http://ejbbasic.jaxws.ws.ibm.com/}SayHelloService",port="SayHelloPort",
name="EJBWSBasic-Server-Bus@{http://ejbbasic.jaxws.ws.ibm.com/}SayHelloService@SayHelloPort@SayHelloService"

```

- If the URL pattern cannot be retrieved by the web services engine when the endpoint MBean is registered, a random unique number is used to ensure that the MBean is unique. For example, the MBean might be as follows:

```

WebSphere:feature=jaxws,bus.id=EJBWSBasic-Server-Bus,type=Bus.Service.Endpoint,
service="{http://ejbbasic.jaxws.ws.ibm.com/}SayHelloService",port="SayHelloPort",
name="EJBWSBasic-Server-Bus@{http://ejbbasic.jaxws.ws.ibm.com/}SayHelloService@SayHelloPort@261689241"

```

**Note:**

- This is a Dynamic Model Mbean.
- The destroy operation on this MBean is not supported.

**8.5.5.3**

**WebSphere:feature=kernel,name=ServerInfo**

- **Management interface:** com.ibm.websphere.kernel.server.ServerInfoMBean
- **Comments:** The ServerInfoMbean interface is used to retrieve information about the running server. Search the following directories for the class and API documentation:

```

liberty_home/dev/api/ibm/com.ibm.websphere.appserver.api.kernel.service_version-javadoc.zip
liberty_home/dev/api/ibm/com.ibm.websphere.appserver.api.kernel.service_version.jar

```

The exposed operations include a method to retrieve the product install and user directory locations, the default host name, the server name, the product version, the Java specification version, and the Java Runtime version.

**8.5.5.0**

**WebSphere:feature=wasJmsServer, type=MessagingEngine,name=\***

- **Management interface:** com.ibm.websphere.messaging.mbean.MessagingEngineMBean
- **Comments:** Available when the wasJmsServer-1.0 feature is enabled. One messaging engine instance is available for each Liberty. The **name=\*** is the name of the MBean, where \* is the unique name of the messaging engine MBean. See “Liberty:JMS messaging” on page 1010.

**8.5.5.0**

**WebSphere:feature=wasJmsServer, type=Queue,name=\***

- **Management interface:** com.ibm.websphere.messaging.mbean.QueueMBean
- **Comments:** The MBean is available when the wasJmsServer-1.0 feature is enabled and the MBean of the messaging engine is available. The **name=\*** is the name of the MBean, where \* is the name of the queue MBean. See “Liberty:JMS messaging” on page 1010.

**8.5.5.0**

**WebSphere:feature=wasJmsServer, type=Topic,name=\***

- **Management interface:**com.ibm.websphere.messaging.mbean.TopicMBean
- **Comments:** The MBean is available when the wasJmsServer-1.0 feature is enabled and the MBean of the messaging engine is available. The **name=\*** is the name of the MBean, where \* is the name of the topic MBean. See “Liberty:JMS messaging” on page 1010.

#### 8.5.5.0

**WebSphere:feature=wasJmsServer, type=Subscriber,name=\***

- **Management interface:**com.ibm.websphere.messaging.mbean.SubscriberMBean
- **Comments:** The MBean is available when the wasJmsServer-1.0 feature is enabled and the MBean of the messaging engine is available. The **name=\*** is the name of the MBean, where \* is the name of the subscriber MBean.

**Note:** The **SubscriberMBean** is a subscriber to the existing **TopicMBean**. See “Liberty:JMS messaging” on page 1010.

**Liberty:Examples of accessing MBean attributes and operations:** **8.5.0.1**

You can use Liberty to access the attributes, and call the operations, of Java Management Extensions (JMX) management beans (MBeans).

After you obtain an MBeanServer instance (for an application running on Liberty) or an MBeanServerConnection instance (for an external client), you can access the attributes or call the operations of MBeans provided by Liberty. See “Working with JMX MBeans on Liberty” on page 1646.

The following code examples assume the variable mbs is an MBeanServer or MBeanServerConnection instance. You can use the provided methods to access the attributes and operations in a similar way to Java reflection. Alternatively, each MBean has a management interface with getter methods for the attributes and methods for the operations. You can use these interfaces by implementing one of the javax.management.JMX.newMBeanProxy methods or one of the javax.management.JMX.newMXBeanProxy methods for MXBeans to obtain a proxy object. The name of a management interface ends with “MXBean”. For the names of the management interfaces, see “Liberty: List of provided MBeans” on page 1647.

#### Example 1: Check the state of application "myApp"

```
import javax.management.ObjectName;
import javax.management.JMX;
import com.ibm.websphere.application.ApplicationMBean;
...

ObjectName myAppMBean = new ObjectName(
    "WebSphere:service=com.ibm.websphere.application.ApplicationMBean,name=myApp");
if (mbs.isRegistered(myAppMBean)) {
    String state = (String) mbs.getAttribute(myAppMBean, "State");
    // alternatively, obtain a proxy object
    ApplicationMBean app = JMX.newMBeanProxy(mbs, myAppMBean, ApplicationMBean.class);
    state = app.getState();
}
```

#### Example 2: Get response time statistics for servlet "Example Servlet" from application "myApp"

```
import javax.management.ObjectName;
import javax.management.openmbean.CompositeData;
import javax.management.JMX;
import com.ibm.websphere.webcontainer.ServletStatsMXBean;
...

```

```

ObjectName servletMBean = new ObjectName("WebSphere:type=ServletStats,name=myApp.Example Servlet");
if (mbs.isRegistered(servletMBean)) {
    CompositeData responseTimeDetails = (CompositeData) mbs.getAttribute(servletMBean, "ResponseTimeDetails");
    CompositeData responseTimeReading = (CompositeData) responseTimeDetails.get("reading");
    Double mean = (Double) responseTimeReading.get("mean");
    Double standardDeviation = (Double) responseTimeReading.get("standardDeviation");
    // alternatively, obtain a proxy object
    ServletStatsMXBean servletStats = JMX.newMXBeanProxy(mbs, servletMBean, ServletStatsMXBean.class);
    StatisticsMeter meter = servletStats.getResponseTimeDetails();
    StatisticsReading reading = meter.getReading();
    mean = reading.getMean();
    standardDeviation = reading.getStandardDeviation();
}

```

### Example 3: Create a web server plug-in configuration file

```

import com.ibm.websphere.webcontainer.GeneratePluginConfigMBean;

...

ObjectName pluginMBean = new ObjectName("WebSphere:name=com.ibm.ws.jmx.mbeans.generatePluginConfig");
if (mbs.isRegistered(pluginMBean)) {
    mbs.invoke(pluginMBean, "generatePluginConfig", new Object[] {
        "installRoot", "serverName", new String[] {
            String.class.getName(), String.class.getName()
        }
    });
    // alternatively, use a proxy object
    GeneratePluginConfigMBean plugin = JMX.newMBeanProxy(mbs, name, GeneratePluginConfigMBean.class);
    plugin.generatePluginConfig("installRoot", "serverName");
}

```

#### 8.5.5.0

### Example 4: Query status of Web Service Endpoint

```

import javax.management.ObjectName;
import javax.management.MBeanServerConnection;
import javax.management.MBeanInfo;
import javax.management.MBeanAttributeInfo;
import javax.management.MBeanOperationInfo;

...

// Init mbs as needed
MBeanServerConnection mbs;

// Get MBeanInfo for specific ObjectName
ObjectName objName = new ObjectName("WebSphere:feature=jaxws,bus.id=testCXFJMXSupport-Server-Bus,
    type=Bus.Service.Endpoint,service=\"{http://jaxws.samples.ibm.com:jmx}/TestEndpointService\",
    port=\"TestEndpoint\",instance.id=1816106538");
MBeanInfo beanInfo = mbs.getMBeanInfo(objName);

// Go through attributes to find the interested one
for (MBeanAttributeInfo attr : beanInfo.getAttributes()) {
    if (attr.getName().equals("State")) {
        String status = String.valueOf(mbs.getAttribute(objName, attr.getName()));
        break;
    }
}

```

#### 8.5.5.0

### Example 5: Shut down the CXF server bus

```

import javax.management.ObjectName;
import javax.management.MBeanServerConnection;
import javax.management.MBeanInfo;
import javax.management.MBeanAttributeInfo;
import javax.management.MBeanOperationInfo;

...

// Init mbsc as needed
MBeanServerConnection mbs;

// Get MBeanInfo for specific ObjectName
ObjectName objName = new ObjectName("WebSphere:feature=jaxws,bus.id=testCXFJMXSupport-Server-Bus,
    type=Bus,instance.id=1618108530");

```

```

MBeanInfo beanInfo = mbsc.getMBeanInfo(objName);

// Go through operation to find the interested one and invoke
for (MBeanOperationInfo operation : beanInfo.getOperations()) {
    if (operation.getName().equals("shutdown")) {
        mbs.invoke(objName, operation.getName(), new Object[] { true }, new String[] { boolean.class.getName() });
        break;
    }
}

```

## Liberty:Examples of registering MBeans: **8.5.0.1**

An application can register its own MBean instances on Liberty. That MBean instance can then be used by other applications or external administrators.

Any application can register an MBean by using an MBeanServer instance. Suppose an application contains a class called `org.example.Example` that implements the interface `org.example.ExampleMBean`, which defines some attributes and operations. As in the following example, the application might simply instantiate the `Example` class then register it using a unique `ObjectName`. If the `ObjectName` chosen is already in use, a `javax.management.InstanceAlreadyExistsException` is reported.

```

import java.lang.management.ManagementFactory;
import javax.management.MBeanServer;
import javax.management.ObjectName;
import org.example.Example;

...

MBeanServer mbs = ManagementFactory.getPlatformMBeanServer();
Object mbean = new Example();
ObjectName name = new ObjectName("org.example.MyApplication:name=Example");
mbs.registerMBean(mbean, name);

```

In addition, an application might register an MBean that extends `java.lang.ClassLoader` and provides access to any number of MBean implementation classes. Then you can use any other JMX client, local or remote, to create and register MBeans provided by the application. For example, suppose the application has an MBean class `org.example.ApplicationClassLoader` that performs the following tasks:

- Implements any empty interface `org.example.ApplicationClassLoaderMBean`
- Extends `java.lang.ClassLoader`, and
- Provides access to the `org.example.Example` MBean implementation class

The application can register an instance of `ApplicationClassLoader` to make the `Example` MBean available to other JMX clients as follows:

```

import java.lang.management.ManagementFactory;
import javax.management.MBeanServer;
import javax.management.ObjectName;
import org.example.ApplicationClassLoader;

...

MBeanServer mbs = ManagementFactory.getPlatformMBeanServer();
Object classLoader = new ApplicationClassLoader();
ObjectName name = new ObjectName("org.example.MyApplication:name=ClassLoader");
mbs.registerMBean(classLoader, name);

```

Any JMX client can create an `Example` instance. The following example assumes the variable `mbs` is an `MBeanServer` or `MBeanServerConnection` instance. See “Working with JMX MBeans on Liberty” on page 1646.

```
import javax.management.ObjectName;

...

ObjectName loaderName = new ObjectName("org.example.MyApplication:name=ClassLoader");
ObjectName exampleName = new ObjectName("org.example.MyApplication:name=Example");
mbs.createMBean("org.example.Example", exampleName, loaderName);
```

If necessary, you can use other forms of the `MBeanServer.createMBean` method to create the MBean by using non-default constructors.

For more information about the management interface, see the Java API document for Liberty. The Java API documentation for each Liberty API is available in a separate .zip file in one of the javadoc subdirectories of the `{wlp.install.dir}/dev` directory.

### Liberty: Example of setting up a JMX routing environment: **8.5.5.0**

You can use Liberty to call Java Management Extensions (JMX) management beans (MBeans) on a collective member server through a collective controller server.

**Note:** **Distributed operating systems** **IBM i** The `collectiveController-1.0` feature and its capabilities are available only in WebSphere Application Server Liberty Network Deployment and WebSphere

Application Server Liberty for z/OS. **8.5.5.0** The feature is not available in WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core. If you have a WebSphere Application Server Liberty Network Deployment installation, you can use its `collectiveController-1.0` feature to work with collective members from WebSphere Application Server Liberty, WebSphere Application Server Liberty - Express, or WebSphere Application Server Liberty Core installations.

The `collectiveMember-1.0` feature enables a server to be managed by a collective controller (the `collectiveController-1.0` feature). After a server is configured to be managed by a collective controller, you can directly call any MBeans on the collective member through the collective controller server.

The following is an example of how to call MBeans on a collective member through a collective controller server.

```
// Set up the trust store to the collective controller server.

System.setProperty("javax.net.ssl.trustStore", "<trustStore for https connection to collective controller>");
System.setProperty("javax.net.ssl.trustStorePassword", "<trustStore password>");

Map<String, Object> environment = new HashMap<String, Object>();
environment.put("jmx.remote.protocol.provider.pkgs", "com.ibm.ws.jmx.connector.client");
environment.put(JMXConnector.CREDENTIALS, new String[] { "<username>", "<password>" });
environment.put(ClientProvider.DISABLE_HOSTNAME_VERIFICATION, true);
environment.put(ClientProvider.READ_TIMEOUT, 2 * 60 * 1000);

JMXServiceURL url = new JMXServiceURL(
    "REST", "<hostname of collective controller server>", "<https port>", "/IBMJMXConnectorREST");
jmxConnector = JMXConnectorFactory.connect(url, environment);
MBeanServerConnection exmbsc = jmxConnector.getMBeanServerConnection();

// You have a MBeanServerConnection now; at this point, however, all of your MBean calls
// are on the collective controller server.

// The next few lines of code are to set up the routing context so that all calls
// can be routed to a collective member.

ObjectName rmObjectName = new ObjectName(
    "WebSphere:feature=collectiveController,type=RoutingContext,name=RoutingContext");

// Call the MBeanRoutingContext MBean to set up the routing context.

Object rcObj = connection.invoke(rmObjectName, "assignServerContext",
    new Object[] {
```

```

    "<hostname of the collective member>", "<collective member server usr dir>", "<collective member server name>"
  },
// With the collective-member server usr dir and collective-member server name,
// the managed server can be uniquely identified on a host.

  new String[] { "java.lang.String", "java.lang.String", "java.lang.String" });

  if (rcObj instanceof Boolean) {
    Boolean result = (Boolean) rcObj;
    if (result.booleanValue()) {
      System.out.println("routing context is configured correctly");
    }
    Or if (!result.booleanValue()) {
      System.out.println("routing context result is false");
    }
  } else {
    System.out.println("failed to configure routing context");
  }
}

```

If the routing context is configured correctly, all future calls to this MBeanServerConnection will be routed to target collective member server.

## Establishing a JMX MBean Liberty server connection

8.5.5.0

You can use Jython-based scripts to establish a Java Management Extensions (JMX) MBean Liberty server connection.

### Before you begin

You must obtain and install the Jython version of your choice before you can perform this procedure. Without a Jython runtime, the instructions will fail.

### Procedure

1. Set up the environment.

The files that you need are located in *liberty\_home/clients/jython*.

- a. Copy the `lib/restConnector.py` file to *jython\_home/Lib*.
- b. Set the classpath for `restConnector.jar` in *liberty\_home/clients*.
 

```
set CLASSPATH=%CLASSPATH%;c:\wlp\clients\restConnector.jar
```

2. Run the utility.

**Example 1:** Getting a simple connection using `connector.connect(host,port,user,password)`

```

from restConnector import JMXRESTConnector
JMXRESTConnector.trustStore = "c:/key.jks"
JMXRESTConnector.trustStorePassword = "Liberty"

```

```

connector = JMXRESTConnector()
connector.connect("foo.bar.com",9443,"theUser","thePassword")
mconnection = connector.getMBeanServerConnection()
# mconnection.invoke(...)
connector.disconnect()

```

**Example 2:** Getting an advanced connection using `connector.connect(host,port,map)` with user-provided properties

```

import java
import javax
import jarray
import com.ibm.websphere.jmx.connector.rest
import com.ibm.ws.jmx.connector.client.rest

map=java.util.HashMap()
map.put("jmx.remote.provider.pkgs","com.ibm.ws.jmx.connector.client")
map.put(javax.management.remote.JMXConnector.CREDENTIALS,jarray.array(["theUser","thePassword"],java.lang.String))

```

```

map.put(com.ibm.ws.jmx.connector.client.rest.ClientProvider.READ_TIMEOUT,2*60*1000)
map.put(com.ibm.websphere.jmx.connector.rest.ConnectorSettings.DISABLE_HOSTNAME_VERIFICATION, True)

connector = JMXRESTConnector()
connector.connect("foo.bar.com",9443,map)
mconnection = connector.getMBeanServerConnection()
# mconnection.invoke(...)
connector.disconnect()

```

### Example 3: Registering a notification listener

```

import java
import javax

from restConnector import JMXRESTConnector
from restConnector import BaseNotificationListener

class SampleNotificationListener(BaseNotificationListener):
    def __init__(self):
        pass

    def handleNotification(self,notification,handback):
        print "Notification received:"
        print " Source: " + notification.getSource().toString()
        print " Type: " + notification.getType()
        print " Message: " + notification.getMessage()

# main starts here

JMXRESTConnector.trustStore = "c:/key.jks"
JMXRESTConnector.trustStorePassword = "Liberty"

connector=JMXRESTConnector()
connector.connect("foo.bar.com",9443,"theUser","thePassword")
mconnection=connector.getMBeanServerConnection()

listener=SampleNotificationListener()
handback=java.lang.Object()

notifier1=javax.management.ObjectName("web:name=Notifier1")
mconnection.addNotificationListener(notifier1,listener,None,handback)

```

#### **JMXRESTConnector.trustStore**

Sets the path to where the SSL key file is stored

#### **JMXRESTConnector.trustStorePassword**

Sets the password for the key

#### **JMXRESTConnector.connect(host,port,user,password)**

Creates a connector to the server

#### **JMXRESTConnector.connect(host,port,map)**

Creates a connector with user properties

#### **JMXRESTConnector.getMBeanServerConnection**

Gets a connection to the MBean server

#### **JMXRESTConnector.disconnect()**

Closes the connection

## What to do next

After a connection to the MBean server is established, you can make calls to the MBean server by using the `invoke(...)` method.

**Note:** A library of Jython scripts is available for you to download from the Liberty Repository.

## Liberty: File transfer

The restConnector-1.0 feature includes the FileTransfer and FileService MBeans. The FileTransfer MBean supports delete, upload, and download operations to and from a running Liberty server. The FileService MBean provides access to directory lists and file metadata, and it also provides archive operations such as **create** and **expand**.

The FileTransfer and FileService MBeans are useful for carrying out remote operations on a Liberty, such as updating the configuration or installing an application. A configuration update can be performed remotely by uploading an updated server.xml file for the target Liberty server. An application can be installed by uploading both the application archive and an updated server.xml file or simply by uploading the application archive to the monitored dropins folder.

The FileTransfer MBean includes configurable read and write lists so that you can control the directories that can be read or written when using the FileTransfer MBean.

**8.5.0.1** See the section on the FileTransfer MBean in “Liberty: List of provided MBeans” on page 1647 for information on how to configure the restConnector-1.0 feature and control the FileTransfer MBean read and write lists.

The uploadFile method from FileTransfer contains a boolean called "expandOnCompletion" that allows a user to upload and expand the archive with a single MBean invocation. A directory is created with the same name as the archive on the target path and the FileService MBean is automatically invoked to expand the archive.

**Example:** A call to uploadFile with parameters {"C:/temp/myArchive.zip", "\${server.output.dir}/myArchive.zip", true} will result in a myArchive.zip directory under \${server.output.dir} that contains the extracted contents of the archive being created.

## Transferring files in a Liberty collective

### 8.5.5.0

A Liberty controller enables special file transfer capabilities within a Liberty collective. The most advanced such functionality is file transfer for multiple hosts within a single REST call. You can use the FileTransfer and FileService MBeans in a Liberty collective to perform file actions on any Liberty server in the collective. This includes both Liberty servers configured as collective controllers and as collective members.

### About this task

When you establish a remote JMX connection to a collective controller, you can use the RoutingContext MBean to direct your FileTransfer and FileService MBean calls to execute on any Liberty server in the collective. The collective controller takes care of routing the request and creating authorized connections between the collective controller and the target collective member.

By routing file operations to specific collective members, you can perform configuration-file updates and install applications on any Liberty server in the collective.

The FileTransfer MBean additionally can perform operations on a host computer in a collective whether or not there is a collective member on that host. By registering the host computer with the Liberty collective and specifying a RoutingContext that specifies that host, the FileTransfer command can be used to upload or download files to or from that host system. For example, you can upload and expand a Liberty archive to push out Liberty to new hosts.

The upload and extract operation in a routing environment has a more complex logic than that in the non-routing environment:

- If the target host machine has access to an **unzip** command on its path, that command is invoked to extract the archive.
- If an **unzip** command is not found, the process uses a Java-based archive extraction.
  1. A small Liberty-built jar file is temporarily pushed into the target host.
  2. A path to Java is found by checking the following:
    - Configured Java-home value that was setup during host registration
    - Configured JAVA\_HOME variable visible to RXA
    - Configured JRE\_HOME variable visible to RXA
    - Java home found on the path
  3. The custom Java jar file is invoked to extract the original archive.
  4. The custom Java jar file is deleted from the target host.
  5. If the archive being expanded by the custom Java jar file is a Liberty archive, the process recursively sets the permissions of its wlp/bin folder to 755 to allow for remote management of that Liberty instance.

The FileTransfer MBean uses authorization information stored in the collective controller for either the target host computer or collective member. This information was stored when the host computer or collective member was registered. See “Registering host computers with a Liberty collective” on page 1142 for more information on setting up this information for the host computer.

File-transfer operations directed at the host computer use the authorization information stored for the host computer. File-transfer operations directed at a collective member use the authorization overridden by the collective member, if any, or use the information stored for the host computer by default. See “Overriding Liberty server host information” on page 1144 for more information on overriding host information.

The FileService MBean operates on Liberty (not only on host computers) and uses the authorization configurations from Liberty. It does not use host-computer authorization information.

## Transferring files to and from a collective member or registered host with REST calls

8.5.5.6

You can perform routed file transfer operations from a collective controller to a collective member or to a registered host of a collective by invoking REST APIs. The operations include downloading files from a remote location, uploading files to a remote location, and deleting files in a remote location. Use the **GET**, **POST**, or **DELETE** REST APIs. The file transfer operations occur within an IBM JMX REST Connector.

### Before you begin

To perform file transfer operations from a collective controller to a member server, the server must be joined as a member to the collective. See “Configuring a Liberty collective” on page 1136.

To perform file transfer operations to a host computer, the host must be registered with the collective controller. See “Registering host computers with a Liberty collective” on page 1142.

### Procedure

1. Optional: To read about the REST APIs, point a browser at `https://controller_host_name:controller_port_name/IBMJMXConnectorREST/api` and enter the controller administrative user ID and password to log in. The controller must be running to view the REST API documentation. Alternatively, you can use a collective member host, port, login user ID and password to view the REST API documentation.

The **File Transfer** and **Routing** sections describe the APIs used to transfer files between the collective controller and a member server or a registered host.

The `collectiveController-1.0` and `collectiveMember-1.0` features enable the `restConnector-1.0` feature, which provides file transfer capability. Thus, collective controllers and members do not need to specify `restConnector-1.0` in a feature manager to view the REST APIs or perform file transfer operations. A stand-alone server configuration might need the `restConnector-1.0` feature to view the REST APIs.

2. Unless you work directly with a Liberty instance, set the routing context as HTTP headers.

- Member server routing

```
com.ibm.websphere.jmx.connector.rest.routing.hostName=string
com.ibm.websphere.jmx.connector.rest.routing.serverName=string
com.ibm.websphere.jmx.connector.rest.routing.serverUserDir=string
```

- Registered host routing

```
com.ibm.websphere.jmx.connector.rest.routing.hostName=string
```

3. Ensure the target file is within the configurable read/write directories of the server for file transfer operations with a member server, or within configurable read/write directories of the host for file transfer operations with a registered host.

4. Invoke REST APIs that download, upload, or delete files.

`{filePath}` must be URL-encoded. For routing operations with registered hosts, `{filePath}` must be an absolute path and cannot contain Liberty variables.

- Download one file from a member server or registered host using the **GET** operation.

```
GET https://controller_host:controller_port/IBMJMXConnectorREST/file/{filePath}
```

- Upload one file to a member server or registered host using the **POST** operation.

```
POST https://controller_host:controller_port/IBMJMXConnectorREST/file/{filePath}
```

- Delete one file from a member server or registered host using the **DELETE** operation.

```
DELETE https://controller_host:controller_port/IBMJMXConnectorREST/file/{filePath}
```

- Delete multiple files from a member server or registered host using the **POST** operation.

```
POST https://controller_host:controller_port/IBMJMXConnectorREST/file/collection
```

## Example

To download the `myFile.txt` file from the member server `myServerA` on the host `myTarget.com` with a user directory of `C:/server/wlp`:

1. Set the member server routing context as HTTP headers.

```
com.ibm.websphere.jmx.connector.rest.routing.hostName=myTarget.com
com.ibm.websphere.jmx.connector.rest.routing.serverName=myServerA
com.ibm.websphere.jmx.connector.rest.routing.serverUserDir=C:/server/wlp
```

2. Invoke a **GET** call to download the file.

```
GET https://myTarget.com:9443//IBMJMXConnectorREST/file/C%3A%2Ftemp%2FmyFile.txt
```

To download the `myFile.txt` file from the registered host `myTarget.com`:

1. Set the registered host routing context as an HTTP header.

```
com.ibm.websphere.jmx.connector.rest.routing.hostName=myTarget.com
```

2. Invoke a **GET** call to download the file.

```
GET https://myTarget.com:9443//IBMJMXConnectorREST/file/C%3A%2Ftemp%2FmyFile.txt
```

To download the `server.xml` file from the member server `myServerA` on the host `myTarget.com` with a user directory of `C:/server/wlp`:

1. Set the member server routing context as HTTP headers.

```
com.ibm.websphere.jmx.connector.rest.routing.hostName=myTarget.com
com.ibm.websphere.jmx.connector.rest.routing.serverName=myServerA
com.ibm.websphere.jmx.connector.rest.routing.serverUserDir=C:/server/wlp
```

2. Invoke a **GET** call to download the `${server.config.dir}/server.xml` file.

```
GET https://myTarget.com:9443//IBMJMXConnectorREST/file/%24{server.config.dir}%2Fserver.xml
```

## What to do next

Get status or details on the REST call. See “Getting status on a REST call for multiple registered hosts” on page 1665.

## Uploading files to multiple registered hosts with a single REST call

8.5.5.6

You can upload files from a collective controller to multiple registered hosts of a collective by invoking the **POST** REST API. The file transfer operations occur within an IBM JMX REST Connector.

### Before you begin

Create a collective controller. See “Configuring a Liberty collective” on page 1136.

Register each remote host computer with the collective controller. See “Registering host computers with a Liberty collective” on page 1142.

### Procedure

1. Optional: To read about the REST APIs, point a browser at `https://controller_host_name:controller_port_name/IBMJMXConnectorREST/api` and enter the controller administrative user ID and password to log in. The controller must be running to view the REST API documentation.

The **File Transfer** and **Routing** sections describe the APIs used to transfer files between the collective controller and a member server or a registered host.

The `collectiveController-1.0` feature enables the `restConnector-1.0` feature, which provides file transfer capability. Thus, collective controllers do not need to specify `restConnector-1.0` in a feature manager to view the REST APIs or perform file transfer operations. A stand-alone server configuration might need the `restConnector-1.0` feature to view the REST APIs.

2. List the target hosts in an HTTP header for the collective controller.

```
com.ibm.websphere.collective.hostNames=comma-separated_list_of_target_hosts
```

Optionally, set other HTTP headers:

- Specify whether to perform the file uploads and the action asynchronously. Default is `false`. To change the default, specify `true` for *boolean*.

```
com.ibm.websphere.jmx.connector.rest.asyncExecution=boolean
```

- Specify a set of actions to perform after the file uploads. An existing built-in action is `com.ibm.websphere.jmx.connector.rest.postTransferAction.join`, which joins the Liberty servers inside the incoming Liberty archive to the collective. Use the header to list other custom actions. If you list more than one custom action, delimit the action with a URL-encoded comma character.

```
com.ibm.websphere.jmx.connector.rest.postTransferAction=comma-separated_list_of_actions
```

To enable the custom actions, add the following configuration to the collective controller `server.xml`:

```
<hostAccess enableCustomActions="true" />
```

- Specify a list of options to pass into the post-transfer actions. This list of options must be either null or contain the same number of list items as the `postTransferAction` header list, where the item index of each option must match the index of its corresponding action. If you list more than one option, delimit the action with a URL-encoded comma character.

```
com.ibm.websphere.jmx.connector.rest.postTransferAction.options=comma-separated_list_of_options
```

If you specify the built-in action `com.ibm.websphere.jmx.connector.rest.postTransferAction.join`, the corresponding option must be:

```
--user=adminUser --password=adminPw --keystorePassword=keystorePw [--rpcUser=rpcUser --rpcPassword=rpcPw]
```

- Specify environment variables to set before the transfer actions run. The payload of the header is a JSON object where each JSON key is an environment variable and each JSON value is its corresponding value. If you specify system paths, use forward slashes (/).

```
com.ibm.websphere.jmx.connector.rest.transferEnvVars=list_of_environment_variables
```

### 3. Upload a file to multiple registered hosts by using the **POST** operation.

- a. Ensure that the target location is within a configurable write directory of the hosts.
- b. Invoke the **POST** operation.

```
POST https://controller_host:controller_port/IBMJMXConnectorREST/file/{filePath}[?expandOnCompletion=boolean&local=boolean]
```

- `{filePath}` is a UTF-8 URL-encoded absolute path that specifies the target location. For example, if the file is `C:/temp/myFile.txt`, the path is `C%3A%2Ftemp%2FmyFile.txt`.
- `expandOnCompletion` is an optional query parameter that toggles an automatic expansion of the uploaded archive. The default value is `false`.
- `local` is an optional query parameter that specifies whether the file to upload is already in the controller. If true, then the payload of this **POST** request is a string that represents the source file location inside the controller. The default value is `false`.
- If the `local` query parameter is not used, or explicitly set to `false`, the **POST** payload is the binary content of the source file itself.

## What to do next

Get status or details on the REST call. See “Getting status on a REST call for multiple registered hosts” on page 1665.

## Deleting files from multiple registered hosts with a single REST call

8.5.5.6

You can delete files on multiple registered hosts of a collective from a collective controller by invoking the **DELETE** REST API. The file deletions occur within an IBM JMX REST Connector.

### Before you begin

Create a collective controller. See “Configuring a Liberty collective” on page 1136.

Register each remote host computer with the collective controller. See “Registering host computers with a Liberty collective” on page 1142.

### Procedure

1. Optional: To read about the REST APIs, point a browser at `https://controller_host_name:controller_port_name/IBMJMXConnectorREST/api` and enter the controller administrative user ID and password to log in. The controller must be running to view the REST API documentation.

The **File Transfer** and **Routing** sections describe the APIs used to transfer files between the collective controller and a member server or a registered host.

The `collectiveController-1.0` feature enables the `restConnector-1.0` feature, which provides file transfer capability. Thus, collective controllers do not need to specify `restConnector-1.0` in a feature manager to view the REST APIs or perform file transfer operations. A stand-alone server configuration might need the `restConnector-1.0` feature to view the REST APIs.

2. List the target hosts in an HTTP header for the collective controller.

```
com.ibm.websphere.collective.hostNames=comma-separated_list_of_target_hosts
```

Optionally, set other HTTP headers:

- Specify whether to perform the file deletion and the action asynchronously. Default is `false`. To change the default, specify `true` for `boolean`.

```
com.ibm.websphere.jmx.connector.rest.asyncExecution=boolean
```

- Specify a set of actions to perform before the file deletion. An existing built-in action is `com.ibm.websphere.jmx.connector.rest.preTransferAction.remove`, which removes the Liberty servers inside the Liberty directory to be deleted from the collection. Use the header to list other custom actions. If you list more than one custom action, delimit the action with a URL-encoded comma character.

```
com.ibm.websphere.jmx.connector.rest.preTransferAction=comma-separated_list_of_actions
```

To enable the custom actions, add the following configuration to the collective controller `server.xml`:

```
<hostAccess enableCustomActions="true" />
```

- Specify a list of options to pass into the pre-transfer actions. This list of options must be either null or contain the same number of list items as the `preTransferAction` header list, where the item index of each option must match the index of its corresponding action. If you list more than one option, delimit the action with a URL-encoded comma character.

```
com.ibm.websphere.jmx.connector.rest.preTransferAction.options=comma-separated_list_of_options
```

If you specify the built-in action

`com.ibm.websphere.jmx.connector.rest.preTransferAction.remove`, the corresponding option must be:

```
--user=adminUser --password=adminPw --keystorePassword=keystorePw [--rpcUser=rpcUser --rpcPassword=rpcPw]
```

- Specify credentials to use for the delete action. The payload of the header is a JSON object where each JSON key is an environment variable and each JSON value is its corresponding value. If you specify system paths, use forward slashes (/).

```
com.ibm.websphere.jmx.connector.rest.transferCredentials=list_of_environment_variables
```

- Specify environment variables to set before the actions run. The payload of the header is a JSON object where each JSON key is an environment variable and each JSON value is its corresponding value. If you specify system paths, use forward slashes (/).

```
com.ibm.websphere.jmx.connector.rest.transferEnvVars=list_of_environment_variables
```

### 3. Delete a file from multiple registered hosts using the **DELETE** operation.

- a. Ensure the target location is within a configurable write directory of the hosts.
- b. Invoke the **DELETE** operation.

```
DELETE https://controller_host:controller_port/IBMJMXConnectorREST/file/{filePath}[?recursiveDelete=boolean]
```

- `{filePath}` is a UTF-8 URL-encoded absolute path that specifies the target location. For example, if the file is `C:/temp/myFile.txt`, the path is `C%3A%2Ftemp%2FmyFile.txt`.
- `recursiveDelete` is an optional query parameter that deletes non-empty directories. The default value is `false`.

## What to do next

Get status or details on the REST call. See “Getting status on a REST call for multiple registered hosts.”

## Getting status on a REST call for multiple registered hosts

8.5.5.6

You can get status or details about a call to upload or delete files on multiple registered hosts of a collective by invoking the **GET REST** API.

## Before you begin

Call a REST API to upload or delete files on multiple registered hosts. See “Uploading files to multiple registered hosts with a single REST call” on page 1663 or “Deleting files from multiple registered hosts with a single REST call” on page 1664.

## Procedure

- Get overall multiple task status, with the option of filtering the results.

```
GET https://controller_host:controller_port/IBMJMXConnectorREST/file/status/[?key=value]
```

The *key* variable is a task property filtered with the *value* variable. You can specify multiple *key=value* pairs to use as query filters.

- Get status about a specific task.

```
GET https://controller_host:controller_port/IBMJMXConnectorREST/file/status/{taskID}
```

*{taskID}* represents a task; for example, c8a2b96b-5a6a-493c-ad0c-140df87d61cf.

- Get a list of available properties from a specific task.

```
GET https://controller_host:controller_port/IBMJMXConnectorREST/file/status/{taskID}/properties
```

*{taskID}* represents a task; for example, c8a2b96b-5a6a-493c-ad0c-140df87d61cf.

- Get the value of a property in a specific task.

```
GET https://controller_host:controller_port/IBMJMXConnectorREST/file/status/{taskID}/properties/{property}
```

– *{taskID}* represents a task; for example, c8a2b96b-5a6a-493c-ad0c-140df87d61cf.

– *{property}* represents the property to get.

- Get status about the hosts of a specific task.

```
GET https://controller_host:controller_port/IBMJMXConnectorREST/file/status/{taskID}/hosts
```

*{taskID}* represents a task; for example, c8a2b96b-5a6a-493c-ad0c-140df87d61cf.

- Get details about steps that were taken within a specific host of a specific task.

```
GET https://controller_host:controller_port/IBMJMXConnectorREST/file/status/{taskID}/hosts/{hostName}
```

– *{taskID}* represents a task; for example, c8a2b96b-5a6a-493c-ad0c-140df87d61cf.

– *{hostName}* represents a host; for example, machineA.xyz.com.

## Example

Get overall multiple task status, with the option of filtering the results. If the JSON response is:

```
[
  {
    "taskID" : String ,
    "taskStatus" : String,
    "taskURL" : URL
  }*
]
```

For the following **GET** call:

```
GET https://myTarget.com:9443/IBMJMXConnectorREST/file/status
```

Typical status is:

```
[
  {
    "taskID" : "c8a2b96b-5a6a-493c-ad0c-140df87d61cf" ,
    "taskStatus" : "succeeded",
    "taskURL" : "/IBMJMXConnectorREST/file/status/c8a2b96b-5a6a-493c-ad0c-140df87d61cf"
  },
  {
    "taskID" : "18c807ff-e7bb-4584-a988-278039d0aabd" ,
    "taskStatus" : "failed",
    "taskURL" : "/IBMJMXConnectorREST/file/status/18c807ff-e7bb-4584-a988-278039d0aabd"
  }
]
```

For the following **GET** call with two *key=value* pairs:

```
GET https://myTarget.com:9443/IBMJMXConnectorREST/file/status?user=bob&status=succeeded
```

Typical status is:

```
[
  {
    "taskId" : "c8a2b96b-5a6a-493c-ad0c-140df87d61cf" ,
    "taskStatus" : "succeeded",
    "taskURL" : "/IBMJMXConnectorREST/file/status/c8a2b96b-5a6a-493c-ad0c-140df87d61cf"
  }
]
```

## Configuring binary logging in Liberty

**8.5.5.0**

Use this information as a guide for configuring binary logging in your Liberty.

### About this task

Binary logging provides faster log and trace handling capabilities and more flexible ways to use log and trace content than the default Liberty log and trace framework.

A server configuration consists of a `bootstrap.properties` file, a `server.xml` file, and any (optional) files that are included with those files. The `bootstrap.properties` file specifies properties that need to be available before the main configuration is processed, and are kept to a minimum. The `server.xml` file is the primary configuration file for the server.

The `server.xml` file and its associated files use a simple xml format that is suitable for most text editors.

**Distributed operating systems** A richer editing experience is provided by the eclipse server adapter for Liberty (WAS4D+ adapter), which uses a generated schema to provide drop-down lists of available choices, auto-completion, and other editing tools. For a description of the eclipse server adapter for Liberty, see “Editing the Liberty configuration by using developer tools” on page 1556.

The `bootstrap.properties` file specifies whether the server uses binary logging as the log and trace framework, or the default log and trace framework. A server restart is required to switch between binary logging and the default log and trace framework.

You can modify the configuration of binary logging through the server configuration or the `bootstrap.properties` file.

- **Server configuration:** To get logging from your own code, which is loaded after server configuration processing, use the server configuration to configure binary logging.
- **bootstrap.properties file:** You might need to set logging properties to take effect before the server configuration files are processed. For example, if you need to analyze problems that occur early in server start or configuration processing. In this case, you can configure binary logging in the `bootstrap.properties` file.

You can set Logging properties in either the `bootstrap.properties` or the `server.xml` file. Use attributes in the `server.xml` file, or use equivalent properties in the `bootstrap.properties` file. Any settings in the `bootstrap.properties` file are used from the time the server reads the `bootstrap.properties` file until the time the `server.xml` file is processed. If the logging properties in the `bootstrap.properties` file are not replaced or reset in the `server.xml` file, the property values in the `bootstrap.properties` file continue to be used.

When binary logging is enabled, the `maxFileSize`, `maxFiles`, `messageFileName`, `traceFileName`, and `traceFormat` logging element attributes are ignored (since binary logging runs without `trace.log` and `messages.log` files). The `traceSpecification`, `consoleLogLevel`, and `logDirectory` attributes continue to be used to set the trace specification, the level for the console log, and the placement of the log and trace files.

If you set logging or binary logging attributes in the `server.xml` file, you can avoid changes in configuration between startup time and runtime by setting the corresponding properties in the `bootstrap.properties` file to the same value. If no logging or binary logging properties are set in the `bootstrap.properties` file, the server uses the default logging settings.

## Procedure

- Enable binary logging for the server by updating the `bootstrap.properties` file. In the `bootstrap.properties` file, add the following text on a line by itself:  
`websphere.log.provider=binaryLogging-1.0`
- Use the following parameters to configure binary logging. All subelements that are listed are subelements of the logging element in the `server.xml` file. The following table lists the attributes that are configurable in the `server.xml` file and the equivalent properties that can be set in the `bootstrap.properties` file:

*Table 119. Binary logging attributes that are configurable in `server.xml` and the equivalent properties that can be set in `bootstrap.properties`*

Logging subelement	Attribute	Equivalent <code>bootstrap.properties</code> property
binaryLog	purgeMaxSize	<code>com.ibm.hpel.log.purgeMaxSize</code>
	purgeMinTime	<code>com.ibm.hpel.log.purgeMinTime</code>
	fileSwitchTime	<code>com.ibm.hpel.log.fileSwitchTime</code>
	bufferingEnabled	<code>com.ibm.hpel.log.bufferingEnabled</code>
	outOfSpaceAction	<code>com.ibm.hpel.log.outOfSpaceAction</code>
binaryTrace	purgeMaxSize	<code>com.ibm.hpel.trace.purgeMaxSize</code>
	purgeMinTime	<code>com.ibm.hpel.trace.purgeMinTime</code>
	fileSwitchTime	<code>com.ibm.hpel.trace.fileSwitchTime</code>
	bufferingEnabled	<code>com.ibm.hpel.trace.bufferingEnabled</code>
	outOfSpaceAction	<code>com.ibm.hpel.trace.outOfSpaceAction</code>

The following example shows a `bootstrap.properties` file that is configured to enable binary logging:

```
websphere.log.provider=binaryLogging-1.0
```

The following example shows a `server.xml` file with the binary logging subelements. The log content is set to expire after 96 hours and the trace content is set to retain a maximum of 1024MB:

```
<server description="new server">
  <logging>
    <binaryLog purgeMinTime="96"/>
    <binaryTrace purgeMaxSize="1024"/>
  </logging>
</server>
```

For the full logging configuration reference, see the logging, binaryLog, and binaryTrace elements in the .

## Results

After you restart the server, binary logging is enabled and configured.

## Administering the transaction service on Liberty

**8.5.5.0**

Liberty provides many of the same transaction services that are provided in the WebSphere Application Server traditional. If an application uses two or more resources, the Liberty transaction manager coordinates the updates to all the resource managers under the control of a global transaction. In Liberty, transaction services are implicitly activated when you specify features that require the use of transactions; for example, jpa-2.0, jdbc-4.0, and wasJmsServer-1.0.

## About this task

You can control when database transaction recovery occurs, you can specify configuration settings that determine how database transactions are recovered, and you can choose whether to store your transaction logs as operating system files or in a relational database.

## Liberty: Configuring the startup of the transaction service

8.5.5.0

Database transaction recovery can occur either when the transaction service is first used, or at server startup.

## About this task

By default, transaction recovery after a server failure happens when the transaction service is first used rather than at server startup. You can alter this behavior by specifying transaction service attributes that control when recovery happens, and whether the system waits for recovery to finish before allowing transactional work to proceed.

## Procedure

To configure transaction service startup, specify the following attributes in the transaction element in the server.xml file:

- recoverOnStartup

This attribute can take the following values:

- true: Transaction recovery occurs at server startup.
- false: Transaction recovery occurs when the transaction service is first used.

- waitForRecovery

This attribute can take the following values:

- true: The server waits for transaction recovery to finish before allowing transactional work to proceed.
- false: The server allows transactional work to proceed without waiting for transaction recovery to finish.

## Example

With the following transaction element configuration, transaction recovery occurs at server startup, and the server waits for transaction recovery to finish before allowing transactional work to proceed.

```
<transaction
  recoverOnStartup="true"
  waitForRecovery="true"
/>
```

## Liberty:How database transactions are recovered

When the Liberty transaction manager recovers indoubt database transactions, it uses either the unique identifier or the JNDI name to locate the current dataSource element, and then determines the user ID and password to use for recovery.

Configure a data source by specifying the attributes of the `dataSource` element in the `server.xml` configuration file. You can assign a unique identifier or a **jndiName** attribute for the data source as follows:

```
<dataSource id="ds1" jndiName="jdbc/ds1"... />
```

You must not change the value of the **id** or **jndiName** attribute when a recovery is pending for a transaction in which the data source participated. If you change any other attributes of the `dataSource` element, those changes are retained for the recovery. Therefore, you can, for example, add a **recoveryAuthDataRef** attribute that specifies a database user ID and password to use for recovery.

The database user ID and password to use for recovery are determined according to the following order of precedence:

1. If the `dataSource` element has the **recoveryAuthDataRef** attribute defined, then the user ID and password from the `authData` element are used. For example:

```
<authData id="recoveryAuth" user="dbuser1" password="{xor}0z0vKDtu"/>
<dataSource id="ds1" jndiName="jdbc/ds1" jdbcDriverRef="DB2"
  recoveryAuthDataRef="recoveryAuth" .../>
```

2. If container-managed authentication is used, then the user ID and password from the container-managed authentication alias are used. For example:

- In the `ibm-web-bnd.xml` file, you have the following code:

```
<resource-ref name="jdbc/ds1ref" binding-name="jdbc/ds1">
  <authentication-alias name="user1Auth"/>
</resource-ref>
```

- In the `server.xml` file, you must define the following code:

```
<authData id="user1Auth" user="dbuser1" password="{xor}0z0vKDtu"/>
<dataSource id="ds1" jndiName="jdbc/ds1" jdbcDriverRef="DB2" .../>
```

3. The user ID and password from the `dataSource` element are used. For example:

```
<dataSource id="ds1" jndiName="jdbc/ds1" jdbcDriverRef="DB2" ...>
  <properties.db2.jcc databaseName="testdb" user="dbuser1" password="{xor}0z0vKDtu"/>
</dataSource>
```

4. If none of the previous conditions are satisfied, and the recovery is attempted without any user ID and password, then the behavior is determined by the JDBC driver and database.

**Note:** If the transaction recovery is performed by an application-defined data source, such as an `@DataSourceDefinition` annotation or a `<data-source>` element in the deployment descriptor, you must ensure that the associated application is running when the recovery is taking place. You cannot use configuration settings in the `server.xml` file to recover application-defined data sources.

## Liberty: Storing transaction logs in a relational database

### 8.5.5.0

You can choose to store your Liberty transaction logs in a relational database rather than as operating system files. In WebSphere Application Server traditional, this feature provides high availability (HA) support without having to use a shared file system. The feature is provided in Liberty for compatibility and for evaluation and testing purposes.

### About this task

The WebSphere Application Server transaction service writes information to a transaction log for every global transaction that involves two or more resources, or that is distributed across multiple servers. These transactions are started or stopped either by applications or by the container in which they are deployed. The transaction service maintains transaction logs to ensure the integrity of transactions. Information is written to the transaction logs in the prepare phase of a distributed transaction, so that if a

WebSphere Application Server with active transactions restarts after a failure, the transaction service is able to use the logs to replay any indoubt transactions. This allows the overall system to be brought back to a consistent state.

In previous releases of WebSphere Application Server, the transaction logs were stored as operating system files. In WebSphere Application Server Version 8.5.5 and later, this remains the default configuration but you can choose to store the transaction logs in a relational database management system (RDBMS). This configuration option is aimed at customers working in an HA environment. In previous releases of WebSphere Application Server, HA transaction support required the use of a shared file system to host the transaction logs, such as an NFSv4-mounted network attached storage (NAS) or a storage area network (SAN). This new feature allows customers, particularly those with an investment in HA database technology, to use their HA database as a shared repository for the transaction logs, as an alternative to using a shared file system.

By default, Liberty transaction logs are stored in operating system files. However, for compatibility with WebSphere Application Server traditional, and for evaluation and testing purposes, you can configure the transaction logs to be stored in an RDBMS. You can use any database type that is supported by Liberty.

## Procedure

To configure the Liberty transaction logs to be stored in an RDBMS, complete the following steps:

1. Configure a dedicated, non-transactional data source in the Liberty `server.xml` file.

The following example extract from the `server.xml` file shows how to configure Liberty to store its transaction logs in a DB2 database:

```
<transaction>
  <dataSource transactional="false">
    <jdbcDriver libraryRef="DB2JCC4LIB"/>
    <properties.db2.jcc currentSchema="CBIVP"
      databaseName="SAMPLE" driverType="4"
      portNumber="50000" serverName="localhost"
      user="db2admin" password="{xor}0z1tPjsyNjE=" />
    </dataSource>
  </transaction>

<library id="DB2JCC4LIB">
  <fileset dir="C:/SQLLIB/java" includes="db2jcc4.jar db2jcc_license_cu.jar"/>
</library>
```

2. (optional) Create the database tables.

Liberty attempts to create the necessary database tables when the server first starts. When this is not possible, due to insufficient permission for example, the server fails to start. Under these circumstances, you must create the two required database tables manually.

The following DDL structures show how to create the tables on DB2:

```
CREATE TABLE WAS_TRAN_LOG(
  SERVER_NAME VARCHAR(128),
  SERVICE_ID SMALLINT,
  RU_ID BIGINT,
  RUSECTION_ID BIGINT,
  RUSECTION_DATA_INDEX SMALLINT,
  DATA LONG VARCHAR FOR BIT DATA)

CREATE TABLE WAS_PARTNER_LOG(
  SERVER_NAME VARCHAR(128),
  SERVICE_ID SMALLINT,
  RU_ID BIGINT,
  RUSECTION_ID BIGINT,
  RUSECTION_DATA_INDEX SMALLINT,
  DATA LONG VARCHAR FOR BIT DATA)
```

The following DDL structures shows how to create the database table on Oracle:

```

CREATE TABLE WAS_TRAN_LOG(
  SERVER_NAME VARCHAR(128),
  SERVICE_ID SMALLINT,
  RU_ID NUMBER(19),
  RUSECTION_ID NUMBER(19),
  RUSECTION_DATA_INDEX SMALLINT,
  DATA BLOB)

CREATE TABLE WAS_PARTNER_LOG(
  SERVER_NAME VARCHAR(128),
  SERVICE_ID SMALLINT,
  RU_ID NUMBER(19),
  RUSECTION_ID NUMBER(19),
  RUSECTION_DATA_INDEX SMALLINT,
  DATA BLOB)

```

## Administering data access resources on Liberty

Administer data access resources using the Liberty features for JDBC, MongoDB, and more.

### Administering data access applications on Liberty

With Liberty, applications can access data in both relational and NoSQL databases.

#### Procedure

- Configuring relational database connectivity in Liberty.
- Configure connection pooling for database connections
- Configure database transaction recovery

#### Configuring relational database connectivity in Liberty:

You can configure a data source associated with different JDBC providers for database connectivity. The JDBC providers supply the driver implementation classes that are required for JDBC connectivity with your specific vendor database.

#### About this task

To access a database from your application, you must use a data source. Data sources are provided by JDBC drivers and come in the following varieties:

- `javax.sql.DataSource`  
This is the basic form of a data source. It does not provide interoperability that enhances connection pooling, and cannot participate as a two-phase capable resource in transactions involving multiple resources.
- `javax.sql.ConnectionPoolDataSource`  
This type of data source is enabled for connection pooling. It cannot participate as a two-phase capable resource in transactions involving multiple resources.
- `javax.sql.XADataSource`  
This type of data source is both enabled for connection pooling and is able to participate as a two-phase capable resource in transactions involving multiple resources.

In order to be usable in the Liberty, your JDBC driver must provide at least one of these types of data sources. For the commonly used JDBC drivers, Liberty is already aware of the implementation class names for the various data source types. You only need to tell Liberty where to find the JDBC driver.

#### Procedure

1. In the `server.xml` file, define a shared library pointing to the location of your JDBC driver JAR or compressed files. For example:

```
<library id="DB2JCC4Lib">
  <fileset dir="C:/DB2/java" includes="db2jcc4.jar db2jcc_license_cisuz.jar"/>
</library>
```

2. Define a data source using the JDBC driver. If you don't specify the type of data source, Liberty chooses the data source in the following order depending on which is available.

- javax.sql.ConnectionPoolDataSource
- javax.sql.DataSource
- javax.sql.XADataSource

Here is an example that accepts the default for data source type:

```
<dataSource id="db2" jndiName="jdbc/db2">
  <jdbcDriver libraryRef="DB2JCC4Lib"/>
  <properties.db2.jcc databaseName="SAMPLEDB" serverName="localhost" portNumber="50000"/>
</dataSource>
```

Here is an example that uses javax.sql.XADataSource type:

```
<dataSource id="db2xa" jndiName="jdbc/db2xa" type="javax.sql.XADataSource">
  <jdbcDriver libraryRef="DB2JCC4Lib"/>
  <properties.db2.jcc databaseName="SAMPLEDB" serverName="localhost" portNumber="50000"/>
</dataSource>
```

A default data source is available when at least one Java EE 7 feature is enabled. This data source uses a different priority to determine the type if none is specified.

- javax.sql.XADataSource
- javax.sql.ConnectionPoolDataSource
- javax.sql.DataSource

This data source is available as java:comp/DefaultDataSource. A jndiName does not need to be specified for it. To configure the default data source, specify a data source with the id set to DefaultDataSource. Here is an example that configures the default data source to point at a DB2 database:

```
<dataSource id="DefaultDataSource">
  <jdbcDriver libraryRef="DB2JCC4Lib"/>
  <properties.db2.jcc databaseName="SAMPLEDB" serverName="localhost" portNumber="50000"/>
</dataSource>
```

3. Optional: Configure attributes for the data source, such as JDBC vendor properties and connection pooling properties.

For example:

```
<dataSource id="DefaultDataSource" jndiName="jdbc/db2" connectionSharing="MatchCurrentState"
  isolationLevel="TRANSACTION_READ_COMMITTED" statementCacheSize="20">
  <connectionManager maxPoolSize="20" minPoolSize="5"
    connectionTimeout="10s" agedTimeout="30m"/>
  <jdbcDriver libraryRef="DB2JCC4Lib"/>
  <properties.db2.jcc databaseName="SAMPLEDB" serverName="localhost" portNumber="50000"
    currentLockTimeout="30s" user="user1" password="pwd1"/>
</dataSource>
```

For a full list of configuration attributes for the dataSource element, connectionManager element and some commonly used JDBC vendors, see “Data Source (dataSource)” on page 191.

4. Optional: Configure data sources for commonly used databases according to the following examples.

#### For DB2

```
<dataSource id="DefaultDataSource" jndiName="jdbc/db2">
  <jdbcDriver libraryRef="DB2JCC4Lib"/>
  <properties.db2.jcc databaseName="SAMPLEDB" serverName="localhost" portNumber="50000"/>
</dataSource>

<library id="DB2JCC4Lib">
  <fileset dir="C:/DB2/java" includes="db2jcc4.jar db2jcc_license_cisuz.jar"/>
</library>
```

### For DB2 on iSeries (Native)

```
<dataSource id="DefaultDataSource" jndiName="jdbc/db2iNative">
  <jdbcDriver libraryRef="DB2iNativeLib"/>
  <properties.db2.i.native databaseName="*LOCAL"/>
</dataSource>

<library id="DB2iNativeLib">
  <fileset dir="/QIBM/Proddata/java400/jdk6/lib/ext" includes="db2_classes16.jar"/>
</library>
```

### For DB2 on iSeries (Toolbox)

```
<dataSource id="DefaultDataSource" jndiName="jdbc/db2iToolbox">
  <jdbcDriver libraryRef="DB2iToolboxLib"/>
  <properties.db2.i.toolbox databaseName="SAMPLEDB" serverName="localhost"/>
</dataSource>

<library id="DB2iToolboxLib">
  <fileset dir="/QIBM/ProdData/Http/Public/jt400/lib" includes="jt400.jar"/>
</library>
```

### For Derby Embedded

```
<dataSource id="DefaultDataSource" jndiName="jdbc/derbyEmbedded">
  <jdbcDriver libraryRef="DerbyLib"/>
  <properties.derby.embedded databaseName="C:/databases/SAMPLEDB" createDatabase="create"/>
</dataSource>

<library id="DerbyLib">
  <fileset dir="C:/db-derby-10.8.1.2-bin/lib"/>
</library>
```

### For Derby Network Client

```
<dataSource id="DefaultDataSource" jndiName="jdbc/derbyClient">
  <jdbcDriver libraryRef="DerbyLib"/>
  <properties.derby.client databaseName="C:/databases/SAMPLEDB" createDatabase="create"
    serverName="localhost" portNumber="1527"/>
</dataSource>

<library id="DerbyLib">
  <fileset dir="C:/db-derby-10.8.1.2-bin/lib"/>
</library>
```

### For Informix® JCC

```
<dataSource id="DefaultDataSource" jndiName="jdbc/informixjcc">
  <jdbcDriver libraryRef="DB2JCC4Lib"/>
  <properties.informix.jcc databaseName="SAMPLEDB" serverName="localhost" portNumber="1526"/>
</dataSource>

<library id="DB2JCC4Lib">
  <fileset dir="C:/Drivers/jcc/4.8" includes="db2jcc4.jar db2jcc_license_cisuz.jar"/>
</library>
```

### For Informix JDBC

```
<dataSource id="DefaultDataSource" jndiName="jdbc/informix">
  <jdbcDriver libraryRef="InformixLib"/>
  <properties.informix databaseName="SAMPLEDB" ifxIFXHOST="localhost"
    serverName="ol_machinename" portNumber="1526"/>
</dataSource>

<library id="InformixLib">
  <fileset dir="C:/Drivers/informix" includes="ifxjdbc.jar ifxjdbcx.jar"/>
</library>
```

### For Microsoft SQL Server (Microsoft JDBC driver)

```
<dataSource id="DefaultDataSource" jndiName="jdbc/mssqlserver">
  <jdbcDriver libraryRef="MSJDBClib"/>
  <properties.microsoft.sqlserver databaseName="SAMPLEDB"
    serverName="localhost" portNumber="1433"/>
</dataSource>
```

```

<library id="MSJDBClib">
  <fileset dir="C:/sqljdbc_6.0/enu/sqljdbc41.jar"/>
</library>

```

#### For Microsoft SQL Server (DataDirect Connect for JDBC driver)

```

<dataSource id="DefaultDataSource" jndiName="jdbc/ddsqserver">
  <jdbcDriver libraryRef="DataDirectLib"/>
  <properties.datadirect.sqlserver databaseName="SAMPLEDB"
    serverName="localhost" portNumber="1433"/>
</dataSource>

<library id="DataDirectLib">
  <fileset dir="C:/DataDirect/Connect-4.2/lib/sqlserver.jar"/>
</library>

```

#### For MySQL

```

<dataSource id="DefaultDataSource" jndiName="jdbc/mysql">
  <jdbcDriver libraryRef="MySQLLib"/>
  <properties databaseName="SAMPLEDB" serverName="localhost" portNumber="3306"/>
</dataSource>

<library id="MySQLLib">
  <fileset dir="C:/mysql-connector-java-x.x.xx/mysql-connector-java-x.x.xx.jar"/>
</library>

```

#### For Oracle

```

<dataSource id="DefaultDataSource" jndiName="jdbc/oracle">
  <jdbcDriver libraryRef="OracleLib"/>
  <properties.oracle URL="jdbc:oracle:thin:@//localhost:1521/SAMPLEDB"/>
</dataSource>

<library id="OracleLib">
  <fileset dir="C:/Oracle/lib/ojdbc6.jar"/>
</library>

```

#### For Sybase

```

<dataSource id="DefaultDataSource" jndiName="jdbc/sybase">
  <jdbcDriver libraryRef="SybaseLib"/>
  <properties.sybase databaseName="SAMPLEDB" serverName="localhost" portNumber="5000"/>
</dataSource>

<library id="SybaseLib">
  <fileset dir="C:/Drivers/sybase/jconn4.jar"/>
</library>

```

#### For solidDB

```

<dataSource id="DefaultDataSource" jndiName="jdbc/solidDB">
  <jdbcDriver libraryRef="solidLib"/>
  <properties databaseName="SAMPLEDB" URL="jdbc:solid://localhost:2315"/>
</dataSource>

<library id="solidLib">
  <fileset dir="C:/Drivers/solidDB/SolidDriver2.0.jar"/>
</library>

```

#### For a JDBC driver that is not known to Liberty

```

<dataSource id="DefaultDataSource" jndiName="jdbc/sample" type="javax.sql.XADataSource">
  <jdbcDriver libraryRef="SampleJDBClib"
    javax.sql.XADataSource="com.ibm.sample.SampleXADataSource"/>
  <properties databaseName="SAMPLEDB" hostName="localhost" port="12345"/>
</dataSource>

<library id="SampleJDBClib">
  <fileset dir="C:/Drivers/SampleJDBC/sampleDriver.jar"/>
</library>

```

In the example, the JDBC driver is located at C:/Drivers/SampleJDBC/sampleDriver.jar and provides an implementation of javax.sql.XADataSource named

com.ibm.sample.SampleXADDataSource. The JDBC driver also provides vendor-specific data source properties such as **databaseName**, **hostName** and **port**.

Configuring a default data source: 8.5.5.6

You can configure a default data source that is associated with different JDBC providers for database connectivity. The JDBC providers supply the driver implementation classes that are required for JDBC connectivity with your specific vendor database.

### About this task

To access a database from your application, you must configure a data source.

### Procedure

1. Configure the `datasource` element with the ID `DefaultDataSource` in the `server.xml` file.

```
<dataSource id="DefaultDataSource">
  <jdbcDriver libraryRef="MyJDBCLib"/>
  <properties.derby.embedded databaseName="myDB" createDatabase="create"/>
  <containerAuthData user="user1" password="{xor}0z0vKDtu" />
</dataSource>
<library id="MyJDBCLib">
  <file name="C:/derby/derby.jar"/>
</library>
```

**Note:** The server must be running at the Java Enterprise Edition 7 platform level. This platform level is enabled when one or more Java Enterprise Edition 7 features are enabled in the `server.xml` file.

2. To use the `DefaultDataSource` in a web application, a reference can be obtained with dependency injection:

```
@Resource
DataSource defaultDataSource;
```

or through JNDI lookup:

```
DataSource defaultDataSource = (DataSource) new InitialContext().lookup("java:comp/DefaultDataSource");
```

*Liberty:How data source configuration updates are applied:*

If you change the attributes of the **dataSource** element while a server is running, the updates to different attributes are applied at different times and in different ways.

You configure a data source by specifying the attributes of the **dataSource** element in the `server.xml` configuration file. If you change these attributes for a running server, the updates are applied at different times and in different ways, depending on which attribute is changed. The following table describes, for each attribute of the **dataSource** element, how a configuration change is applied at run time.

*Table 120. How data source configuration updates are applied at run time.* The first column of the table lists the attributes of the **dataSource** element. The second column describes, for each attribute, how the configuration update is applied at run time.

Attribute name	How the configuration update is applied
<b>beginTranForResultSetScrollingAPIs</b>	The update is effective immediately.
<b>beginTranForVendorAPIs</b>	The update is effective immediately.
<b>commitOrRollbackOnCleanup</b>	The update is effective immediately.
<b>connectionManagerRef</b>	All connections and the connection pool are destroyed. The data source is then managed by the new connection manager.
<b>connectionSharing</b>	The update is applied with each first connection handle in a transaction.

Table 120. How data source configuration updates are applied at run time (continued). The first column of the table lists the attributes of the `dataSource` element. The second column describes, for each attribute, how the configuration update is applied at run time.

Attribute name	How the configuration update is applied
<code>isolationLevel</code>	The update is applied with new connection requests; current connections retain their isolation level.
<code>jdbcDriverRef</code>	All connections and the connection pool are destroyed. The new JDBC driver is then used.
<code>jndiName</code>	All connections and the connection pool are destroyed. The new JNDI name is then used.
<code>propertiesRef</code>	If the data source is Derby Embedded, all connections and the connection pool are destroyed before new properties go into effect. For other JDBC drivers, the new properties go into effect with new connection requests.
<code>queryTimeout</code>	The update is effective immediately.
<code>recoveryAuthDataRef</code>	Authentication data for transaction recovery. All connections and the connection pool are destroyed. The new recovery authentication data is then used.
<code>statementCacheSize</code>	The statement cache is resized upon next use.
<code>supplementalJDBCTrace</code>	All connections and the connection pool are destroyed. The new setting is then used.
<code>syncQueryTimeoutWithTransactionTimeout</code>	The update is effective immediately.
<code>transactional</code>	The update is applied to new connections and existing connections not in use from the connection pool.
<code>type</code>	All connections and the connection pool are destroyed. The new setting is then used.

*Liberty:Application-defined data sources:*

You can define a data source within your application, through annotations or in the deployment descriptor, as defined by the Java EE specification.

**Note:** **8.5.5.0** The `commonLibraryRef` class loader attribute is recommended for application defined data sources. The `privateLibraryRef` attribute cannot be used for the `java:global` namespace and is discouraged for the other scopes. If multiple applications declare the same `java:global` namespace to specify the data source, the `server.xml` files of the applications must all specify a `commonLibraryRef` attribute to the same shared library.

When defining a data source in an application, the JDBC driver must be made available to the application. This is accomplished by configuring a shared library in the `server.xml` for your application.

For example:

```
<application id="myApp" name="myApp" location="myApp.war" type="war">
  <classloader commonLibraryRef="DB2Lib"/>
</application>

<library id="DB2Lib">
  <fileset dir="C:/DB2/java" includes="db2jcc4.jar db2jcc_license_cisuz.jar"/>
</library>
```

Then, you can define a data source in your application either through annotations or in the deployment descriptor.

- Use annotations as in the following example:

```

@DataSourceDefinition(
    name           = "java:comp/env/jdbc/db2",
    className      = "com.ibm.db2.jcc.DB2DataSource",
    databaseName   = "SAMPLEDB",
    serverName     = "localhost",
    portNumber     = 50000,
    properties     = { "driverType=4" },
    user           = "user1",
    password       = "pwd1"
)

```

```

public class MyServlet extends HttpServlet {

    @Resource(lookup="java:comp/env/jdbc/db2")
    DataSource ds;

```

- Use the deployment descriptor as in the following example, for example, in a web.xml file:

```

<data-source>
  <name>java:comp/env/jdbc/db2</name>
  <class-name>com.ibm.db2.jcc.DB2DataSource</class-name>
  <server-name>localhost</server-name>
  <port-number>50000</port-number>
  <database-name>SAMPLEDB</database-name>
  <user>user1</user>
  <password>pwd1</password>
  <property><name>driverType</name><value>4</value></property>
</data-source>

```

In general, properties that can be defined on `dataSource` or `connectionManager` in the `server.xml` files can also be specified on application defined data sources. Two exceptions to this are `connectionManagerRef` and `jdbcDriverRef`, which you cannot specify because the application defined data source implicitly defines the connection manager and JDBC driver. When using application defined data sources for two-phase commit, you can specify the `recoveryAuthDataRef` property to select the authentication data that is used for transaction recovery. However, it is important to be aware that recovery of transactions is only possible while the application is running. You can use variables, encoded passwords, and duration syntax in application defined data sources.

**Note:** The duration syntax does not apply to properties that are explicitly defined in the annotation, such as `loginTimeout` or `maxIdleTime`.

Here is an example of two data sources using connection manager properties, variables, encoded passwords, and duration syntax.

```

@DataSourceDefinitions(value = {
    @DataSourceDefinition(
        name           = "java:comp/env/jdbc/derby",
        className      = "org.apache.derby.jdbc.EmbeddedDataSource40",
        databaseName   = "${shared.resource.dir}/data/SAMPLEDB",
        minPoolSize    = 1,
        maxPoolSize    = 10,
        maxIdleTime    = 180,
        properties     = { "agedTimeout=10m", "connectionTimeout=30s", "createDatabase=create" }
    ),
    @DataSourceDefinition(
        name           = "java:comp/env/jdbc/oracle",
        className      = "oracle.jdbc.pool.OracleDataSource",
        url            = "jdbc:oracle:thin:@//localhost:1521/SAMPLEDB",
        user           = "user1",
        password       = "{xor}0z0vKDtt"
    )
})

```

You can use the client reroute feature to configure your enterprise applications for a DB2 database to recover from a communication loss, and the applications can continue to work with minimal interruption. Rerouting is central to the support of continuous operations, but rerouting is only possible when there is an alternative location that is identified to the application server connection.

### Before you begin

This task assumes that:

- The DB2 data source to which your application connects is running:
  - DB2 for z/OS Version 10.1 or later or
  - DB2 Database for Linux, UNIX, and Windows Version 9.7 or later
- You configured the DB2 database with a redundant setup or the ability to fail the DB2 server to a standby node.

### About this task

You can use client reroute for DB2 to provide information about alternative servers in case the connection to the primary database server fails.

Without any configuration on the client side, the Java Common Connectivity (JCC) Java Database Connectivity (JDBC) driver for DB2 supports the client reroute capability, if it is enabled on the DB2 server, when the driver makes an initial connection to the DB2 server. When the JCC JDBC driver connects to a DB2 server that has one or more alternative servers that are configured, the primary server sends information about the alternative servers to the JCC JDBC driver. If the connection to the primary server fails, the JCC JDBC driver is able to reroute connections to an alternative server. If the application server process crashes, however, the alternative server information is lost and the client needs to connect to the primary server again. If the client cannot make an initial connection to the primary server, the client has no knowledge of the alternative servers and cannot reroute.

To overcome this problem, you can configure a DB2 data source in the application server with the **Alternate server name** and **Alternate port number** fields, or with the `clientRerouteAlternateServerName` and `clientRerouteAlternatePortNumber` data source custom properties, to support client reroute even on the initial connection attempt. If the JDBC driver is not able to connect to the primary DB2 server, the information that is necessary for a client reroute is already present, and the JDBC driver can reroute the connection to an alternate server.

**Attention:** The data source custom property, `enableClientAffinitiesList`, changes the semantics of the `clientRerouteAlternateServerName` and `clientRerouteAlternatePortNumber` properties.

When a connection is rerouted and the JCC JDBC driver is connected to the alternative DB2 server, the alternative server sends information about its own alternative server to the JCC JDBC driver. The JCC JDBC driver then has the information that is required to reroute the connection again if the alternative DB2 server is not available. The server that was originally the alternative server is now the primary server, and a new alternative server is established. However, this new state of the primary and alternative servers is no longer kept by the JCC JDBC driver. If the application server fails and is restarted, the JCC JDBC driver must start from the original server configuration and attempt to connect to the server that was originally considered the primary server.

You can use the automatic client rerouting feature within the following DB2 configurable environments:

- Enterprise Server Edition (ESE) with the data partitioning feature (DPF)
- Data Propagator (DPROPR)-style replication
- High availability cluster multiprocessor (HACMP<sup>™™</sup>)

- High availability disaster recovery (HADR)

## Procedure

1. Define your DB2 data source in the `server.xml` file with the following properties:

- `clientRerouteAlternateServerName`
  - Type of valid values:
    - Domain name; for example: `www.ibm.com`
    - IP address (IPv4 and IPv6); for example: `23.72.11.219`
  - Format of multiple values:
    - Comma separated; for example: `host1, host2, host3`
    - Space separated; for example: `host1 host2 host3`
  - Order significance:
    - The order of the provided host names is the order that the JCC JDBC driver uses to try to find the next available server to connect to.
- `clientRerouteAlternatePortNumber`
  - Type of valid values:
    - Integer representing the port number; for example: `50000`
  - Format of multiple values:
    - Comma separated; for example: `port1, port2, port3`
    - Space separated; for example: `port1 port2 port3`
  - Order significance:
    - The order of the provided ports must match the order of their associated servers.

2. (Optional) You can add one or both of the following properties:

- `retryIntervalForClientReroute`

This property defines the number of seconds the JCC JDBC driver waits between each attempt to establish a connection.

If no value is assigned, the default behavior is used. To learn more, see [JDBC and SQL support](#).
- `maxRetriesForClientReroute`

This property defines the number of retries the JCC JDBC driver attempts to connect the server before it decides to move on to the next server. This property is only used when `RetryIntervalForClientReroute` property is set.

If no value is assigned, the default behavior is used. To learn more, see [JDBC and SQL support](#).

## Example

```
<dataSource id="DefaultDataSource"jndiName="jdbc/db2">
  <properties.db2.jcc
    databaseName="sampleDatabase"
    driverType="4"
    serverName="host"
    portNumber="50000"
    clientRerouteAlternateServerName="host01, host02, host03"
    clientRerouteAlternatePortNumber="50000, 50005, 50000"
    retryIntervalForClientReroute="2"
    maxRetriesForClientReroute="3" />
  ...
</dataSource>
```

**Note:** Ensure that an equal number of entries is specified for both ports and hosts. Otherwise, a warning is displayed and client reroute is not enabled.

The Liberty server can be enabled to interact with DB2 by using the JDBC Type 2 driver implementation on z/OS.

## Before you begin

The angel process must be started before you enable this support. For more information, see “Administering Liberty on z/OS” on page 1731. You can configure a Liberty Profile server to run as a z/OS started task. For more information, see [Configuring a Liberty Profile server as a z/OS started task](#).

## About this task

When you use an RRS capable resource such as DB2, you have the following optional configurations:

- You can enable the server to automatically delete resource manager names from the Resource and Recovery Services (RRS) RM.DATA logstream when the server is stopped. This configuration is optional, but if enabled it prevents resource manager names from accumulating in the logstream. To enable automatic RM name deletion, configure Resource Access Control Facility (RACF) to allow the server to call the ATRSRV macro. To enable automatic RM name deletion, the user ID that the Liberty server runs under must have ALTER access in the FACILITY class to either:
  - MVSADMIN.RRS.COMMANDS.gname.sysname resource to access to a specific logging group name (gname) and system (sysname)
  - MVSADMIN.RRS.COMMANDS.\* resource to allow access to all systems and logging group names
- You can define the RM.METADATA logstream to log data that assists debugging. The user ID that the Liberty server runs under must have ALTER access in the FACILITY class as described.

**Note:** For more information about the ATRSRV macro, setting the appropriate RACF permission, and how to define the RM.METADATA logstream, refer to the *MVS Programming: Resource Recovery* publication relevant to your system's z/OS level.

- You can control the time to wait for transactions actively by using native contexts to complete when the server is stopped or the `zosTransaction-1.0` feature is no longer needed. This can be done by using `nativeTransactionManager` configuration element and the `shutdownTimeout` attribute.
- You can restrict user authority for performing any transactional work that involves RRS capable resources, for example DB2 T2, on a particular server. This can be done by using `nativeTransactionManager` configuration element, and the `resourceManagerNamePrefix` attribute.

**Note:** The `resourceManagerNamePrefix` attribute specifies a 1-8 alphanumeric (A-Z, a-z, 0-9) and national (@,#,\$) only character prefix to be used as part of the server generated resource manager name that is registered with RRS. The prefix "DEFAULT" is a reserved prefix that identifies a default server configuration and should not be used for securing server access. If the configured prefix does not follow the name, length, and character requirements, the DEFAULT prefix name is used. The prefix is intended for system administrators to enable only authorized users to perform transactional work (normal and recovery) involving RRS capable resources. For example DB2 T2, on the server where the prefix was configured. System administrators must define a `BBG.RMNAME.<PREFIX>.RRS` resource under the SERVER class, and give the required users READ authority.

These examples describe the optional configuration:

Server.xml element and attribute definition:

```
<nativeTransactionManager shutdownTimeout="20s" resourceManagerNamePrefix="PROD1"/>
```

RACF resource definition and user authorization:

```
RDEF SERVER BBG.RMNAME.PROD1.RRS UACC(NONE)
PERMIT BBG.RMNAME.PROD1.RRS CLASS(SERVER) ACCESS(READ) ID(PROD1USR)
SETR RACLIST(SERVER) GENERIC(SERVER) REFR
```

## Procedure

1. Update the Liberty server's `server.xml` configuration file. Add the `zosTransaction-1.0` feature subelement to the `featureManager` element:

```
<featureManager>
  <feature>zosTransaction-1.0</feature>
</featureManager>
```

Specifying this feature enables the application server to synchronize and appropriately manage transactional activity between the Resource Recovery Services (RRS), the transaction manager of the application server, and the resource manager. So, work without configuring the `zosTransaction-1.0` feature is not allowed.

2. Add the resource's (DB2) native libraries to the resource's `<library>` configuration element: The `<library>` element in the example shows:

```
<library id="DB2T2LibRef">
  <fileset dir="<YOUR DB2 T2 LIBRARY PATHS>" />
  <fileset dir="<YOUR DB2 T2 NATIVE LIBRARY PATHS>" />
</library>
```

3. Configure the `jdbcDriver` and `datasource` elements.

When you define the `datasource` element, you can skip configuring the `type` attribute because the value `javax.sql.ConnectionPoolDataSource` is used by default. If you choose to explicitly configure the `type` attribute, you must use the value: `javax.sql.ConnectionPoolDataSource`.

The `datasource` element can include a child element named `properties.db2.jcc`. Attributes that are supplied in the `properties.db2.jcc` element are passed directly to the DB2 JCC Driver. The `driverType` attribute is required and must be set to 2. The `databaseName` attribute is also required. The `ssid` attribute is not required, but can be used to control which DB2 for z/OS subsystem this data source connects to if there are multiple DB2 subsystems on the LPAR.

## Example

This example describes how to configure your application, jdbc driver, library, fileset, and data source elements, in the `server.xml` configuration file.

```
<application type="war" id="db2T2TxWar" name="db2T2TxWar"
  location="/u/user1/wlp/usr/servers/defaultServer/dropins/db2T2Tx.war" />
<jdbcDriver id="DB2T2" libraryRef="DB2T2LibRef"/>

<library id="DB2T2LibRef">
  <fileset dir="/db2v10/jcc/classes" />
  <fileset dir="/db2v10/jcc/lib" />
</library>

<dataSource id="jdbc/DB2T2" jndiName="jdbc/DB2T2" jdbcDriverRef="DB2T2">
  <properties.db2.jcc driverType="2" databaseName="LOC1" />
</dataSource>
```

*Configuring connection pooling for database connections:*

You can configure connection pooling for your data source by defining a connection manager for it.

## Example

The following example code uses the `connectionManager` element in the `server.xml` file to define a connection pool for a data source:

```
<dataSource id="DefaultDataSource" jndiName="jdbc/example" jdbcDriverRef="DB2" >
  <connectionManager maxPoolSize="10" minPoolSize="2"/>
  <properties.db2.jcc databaseName="TESTDB"/>
</dataSource>
```

The server uses default values for any connection management settings that are not defined on the connection manager element. If a connection manager is not defined at all for a data source, the server uses default values for all of the settings.

Using thread local storage for connections can increase performance for applications on multi-threaded systems. See Chapter 12, “Tuning Liberty,” on page 2291.

You can define multiple data sources and associate each with a different connection manager. However, you cannot associate multiple data sources with a single connection manager.

For more information about the `connectionManager` element, see .

*Liberty:How connection pooling configuration updates are applied:*

If you change the attributes of the **connectionManager** element while a server is running, the updates to different attributes are applied at different times and in different ways.

You configure a connection pool by specifying the attributes of the **connectionManager** element in the `server.xml` configuration file. If you change these attributes for a running server, the updates are applied at different times and in different ways, depending on which attribute is changed. The following table describes, for each attribute of the **connectionManager** element, how a configuration change is applied at run time.

*Table 121. How connection manager configuration updates are applied at run time.* The first column of the table lists the attributes of the **connectionManager** element. The second column describes, for each attribute, how the configuration update is applied at run time.

Attribute name	How the configuration update is applied
<b>agedTimeout</b>	The update is effective immediately.
<b>connectionTimeout</b>	The update is effective immediately.
<b>maxIdleTime</b>	The update is effective immediately.
<b>maxNumberOfMCsAllowableInThread</b>	The update is effective immediately.
<b>maxPoolSize</b>	The update is effective immediately.
<b>minPoolSize</b>	The update is effective immediately.
<b>numConnectionsPerThreadLocal</b>	The update is effective immediately.
<b>reapTime</b>	The update is effective immediately.
<b>purgePolicy</b>	The update is effective immediately.

**Note:** The attributes **agedTimeout** and **maxIdleTime** are updated immediately. However, they are not used fully unless the value of **reapTime** attribute is greater than zero.

Because updates to the connection manager are effective immediately, errors might occur if you make changes with active connections; including the potential risks for the connections to be ended prematurely.

### Configuring MongoDB connectivity in Liberty: **8.5.5.0**

Applications that use MongoDB can run on Liberty. For access to a MongoDB instance, the applications use the MongoDB Java driver and data sources that you configure for the server.

#### Before you begin

**Note:** **8.5.5.0** The Liberty provides configuration support for MongoDB. MongoDB (from “humongous”) is a scalable, high-performance, open source NoSQL database.

Only MongoDB Java driver versions 2.10.0 to 2.12.5 are supported.

## About this task

To enable an application to use MongoDB, you configure a shared library for the MongoDB Java driver and a library reference to the shared library in the `server.xml` file of Liberty. An application can access MongoDB directly from the application or through the `mongodb-2.0` feature and MongoDB instance configurations in the `server.xml` file.

## Procedure

1. Install the MongoDB Java driver in a location that your application and the Liberty runtime can access.

For example, place the MongoDB driver `.jar` file in the `Liberty_profile_root/usr/servers/server_name/lib` directory.

2. Configure a shared library for the MongoDB driver `.jar` file in the `server.xml` file of the Liberty server.

```
<library id="MongoLib">
  <file name="{server.config.dir}/lib/mongo.jar" />
</library>
```

3. Enable your application to access MongoDB, either by direct access from the application or by using the `mongodb-2.0` feature.

- Enable direct access to MongoDB from the application.
  - a. Configure a library reference for the shared library in an application element in the `server.xml` file.

```
<application ...>
  <classloader commonLibraryRef="MongoLib"/>
</application>
```

The application can now access the MongoDB APIs directly. If you want the application to use the runtime injection engine, continue with the next steps.

- Configure the `mongodb-2.0` feature, `mongo`, and `mongoDB` elements in the `server.xml` file.
  - a. Add the `mongodb-2.0` feature to the `server.xml` file.

```
<featureManager>
  <feature>mongodb-2.0</feature>
  <feature>jndi-1.0</feature>
</featureManager>
```

The JNDI feature is only required when you use `jndi` to look up resources. It is not required if you use resource injection.

- b. Configure a `mongo` element that has a reference to the shared library created in a previous step.

```
<mongo id="mongo" libraryRef="MongoLib" />
```

- c. Configure the `mongoDB` element.

```
<mongoDB jndiName="mongo/testdb" mongoRef="mongo" databaseName="db-test" />
```

Configuring a JNDI name enables an application or the Liberty runtime to look up the MongoDB instance.

- d. Enable your application to access MongoDB.

The following example shows both JNDI lookup and resource injection:

```
public class TestServlet extends HttpServlet {
    @Resource(name = "mongo/testdb")
    protected DB db;
    ...
    protected void doGet(HttpServletRequest request,
        HttpServletResponse response) throws ServletException, IOException {
        // Alternatively use InitialContext lookup
        DB lookup = (DB) new InitialContext().lookup("java:comp/env/mongo/testdb");
        ...
    }
}
```

- e. If you are using JNDI lookup, add a resource environment reference to the `web.xml` file of your application:

```
<resource-env-ref>
  <resource-env-ref-name>mongo/testdb</resource-env-ref-name>
  <resource-env-ref-type>com.mongodb.DB</resource-env-ref-type>
</resource-env-ref>
```

## What to do next

Test use of the MongoDB from your application.

Optionally, review additional configuration properties in the `mongo` and `mongoDB` sections of .

*Configuring secure MongoDB connections in Liberty:* **8.5.5.0**

You can configure application-managed or container-managed security for MongoDB connections in Liberty.

## Before you begin

Enable your application to use MongoDB. See [Creating Liberty applications that use MongoDB](#).

## About this task

You can secure MongoDB applications by using application-managed security or container-managed security. For both types of security, the MongoDB server must be running with authentication explicitly enabled to secure MongoDB connections.

## Procedure

- Configure application-managed security for MongoDB.

If the `mongo` configuration element does not specify user and password attributes, the product assumes that an application is either using application-managed security or is not using security. To enable application-managed security, the application must authenticate using the MongoDB APIs; for example:

```
<mongo id="mongo1" libraryRef="MongoLib" />
<mongoDB jndiName="mongo/testdb" mongoRef="mongo1" databaseName="db-test-1"/>
```

```
{ ...
// Java snippet
@Resource(name = "mongo/testdb")
protected DB db;

private void auth() {
  if (!db.isAuthenticated())
    db.authenticate("user", "password".toCharArray());
}
```

- Configure container-managed security for MongoDB.

To use container-managed security, the `mongo` configuration element must specify a user and password. Only one user is allowed for each `mongo` configuration. All MongoDB instances use the specified user and password. For example, all MongoDB instances that reference `mongo1` in the following example use `mongoUserName` and `pw`:

```
<mongo id="mongo1" libraryRef="MongoLib" user="mongoUserName" password="pw"/>
<mongoDB jndiName="mongo/testdb" mongoRef="mongo1" databaseName="db-test-1"/>
<mongoDB jndiName="mongo/testdb2" mongoRef="mongo1" databaseName="db-test-2"/>
```

Applications that use container-managed security must not call `com.mongodb.DB.authenticate(user, pass)`.

## What to do next

Ensure that the MongoDB server is running, and then test the MongoDB security from your application.

Connecting to a distributed set of MongoDB instances: **8.5.5.0**

Accessing data that is stored in a distributed set of MongoDB instances is nearly the same procedure as connecting to a single MongoDB instance.

## Before you begin

Enable your application to use MongoDB. See [Creating Liberty applications that use MongoDB](#).

## About this task

When you configure the mongo feature in your `server.xml` file, you can pass a collection of `hostNames` and ports that are either replica set members or sharded mongos servers.

If the `host:port` combinations are replica set members, the client finds all members and uses the master by default. If the combinations are sharded mongos servers, the client sends all requests to the closest member with the lowest ping time. If the closest member is down, the client automatically fails over to the next server.

## Procedure

Configure the `hostNames` and ports in your `server.xml` file.

```
<mongo id="mongo1" libraryRef="MongoLib" hostNames="localhost,localhost,localhost" ports="9991,9992,9993"/>
```

## Results

You configured a sharded MongoDB configuration.

Configuring CouchDB connectivity with the ektorp client library in Liberty: **8.5.5.4**

Applications that run on Liberty can use CouchDB. For access to a CouchDB instance, applications can configure a connector for the NoSQL database with the ektorp client library.

## Before you begin

Liberty provides configuration support for CouchDB. CouchDB is a scalable, high-performance, open source NoSQL database.

You must use Version 1.4.1 or later of the ektorp Java driver. Use the Maven plug-in to obtain the ektorp driver and its dependencies.

```
<dependency>
  <groupId>org.ektorp</groupId>
  <artifactId>org.ektorp</artifactId>
  <version>1.4.1</version>
</dependency>
```

## About this task

To enable an application to use CouchDB, you must configure a shared library for the CouchDB Java driver and a library reference to the shared library in the `server.xml` file. An application can access CouchDB either directly from the application, or through the `couchdb-1.0` feature and CouchDB instance configurations in the `server.xml` file.

## Procedure

1. Install the CouchDB Java driver in a location that your application and the Liberty runtime can access. For example, place the ektorp driver file and its dependencies in the `Liberty_profile_root/usr/servers/server_name/lib` directory.
2. Configure a shared library for the ektorp driver files in the `server.xml` file of the Liberty server.

```
<library id="couchdb-lib">
  <fileset
    dir='${server.config.dir}/lib'
    includes='org.ektorp-1.4.1.jar
    commons-codec-1.6.jar
    commons-io-2.0.1.jar
    commons-logging-1.1.1.jar
    httpclient-4.2.5.jar
    httpclient-cache-4.2.5.jar
    httpcore-4.2.4.jar
    jackson-annotations-2.2.2.jar
    jackson-core-2.2.2.jar
    jackson-databind-2.2.2.jar
    slf4j-api-1.6.4.jar
    slf4j-simple-1.6.4.jar' />
</library>
```

3. Enable your application to access CouchDB, either by direct access from the application or by using the `couchdb-1.0` feature.

- Enable direct access to CouchDB from the application.
  - a. Configure a library reference for the shared library in an application element in the `server.xml` file.

```
<application ...>
  <classloader commonLibraryRef="couchdb-lib"/>
</application>
```

The application can now access the CouchDB APIs directly. If you want the application to use the runtime injection engine, continue with the next steps.

- Configure the `couchdb-1.0` feature, and the `couchdb` elements in the `server.xml` file.
  - a. Add the `couchdb-1.0` feature to the `server.xml` file.

```
<featureManager>
  <feature>couchdb-1.0</feature>
  <feature>jndi-1.0</feature>
</featureManager>
```

The JNDI feature is only required when you use JNDI to look up resources. This feature is not required if you use resource injection.

- b. Configure a `couchdb` element that has a reference to the shared library created in a previous step.

```
<couchdb id="couchdb" jndiName="couchdb/connector"
  libraryRef="couchdb-lib" url="http://example.com:5984" username="username"
  password="password"/>
```

Configuring a JNDI name enables an application or the Liberty runtime to look up the CouchDB instance.

- c. Enable your application to access CouchDB.

The following example shows both JNDI lookup and resource injection:

```
public class TestServlet extends HttpServlet {
    @Resource(name = "couchdb/connector")
    protected CouchDbInstance db;
    ...
    protected void doGet(HttpServletRequest request,
        HttpServletResponse response) throws ServletException, IOException {
```

```
// Alternatively use InitialContext lookup
    CouchDbInstance lookup = (CouchDbInstance) new
InitialContext().lookup("java:comp/env/couchdb/connector");
...

```

- d. If you are using JNDI lookup, add a resource environment reference to the `web.xml` file of your application:

```
<resource-env-ref>
  <resource-env-ref-name>couchdb/connector</resource-env-ref-name>
  <resource-env-ref-type>org.ektorp.CouchDbInstance</resource-env-ref-type>
</resource-env-ref>

```

You can use the `couchdb-1.0` feature to configure a connection to an online Cloudant service. Specify the URL, `userid`, and password of your existing Cloudant account in the `couchdb` configuration element. For example:

```
<couchdb id='couchdb' jndiName='couchdb/connector' libraryRef='couchdb-lib' url='https://mylink.cloudant.com/' userna

```

See the documentation for “Liberty:The limits to protection through password encryption” on page 1009 to learn about how to secure passwords in configuration files.

## What to do next

Now that you have configured your application to enable the use of CouchDB, you are ready to test the use of CouchDB from your application.

## Planning to use optimized local adapters in Liberty for z/OS

Plan how to implement WebSphere optimized local adapters (WOLA) in your Liberty server environment.

### Before you begin

For CICS Transaction Server for z/OS to communicate with optimized local adapters, the minimum required version of CICS Transaction Server for z/OS is version 4.1.

### About this task

If you have applications that are written in native languages, such as Cobol, PL/I, C/C++, and high-level assembly languages, that run under z/OS batch, Customer Information Control System (CICS), or UNIX System Services environments, you can use optimized local adapters to directly call between the native-language application and Java-based business logic on a Liberty server. You can use optimized local adapters to make the following calls:

- Inbound calls from an external address space to Enterprise JavaBeans (EJB) applications that are deployed on a local Liberty server
- Outbound calls from an application that is running under the Liberty server on z/OS to a server program that is running in an external address space

If you have a large number of native-language applications that you want to use on Liberty, implementing optimized local adapters provides the following benefits:

- Performance improvement
- Identity context propagation
- Local binding support
- Gateway or proxy for legacy assets on z/OS systems

## Procedure

1. Review the existing business and middleware applications in your environment to determine which application processes would benefit from using optimized local adapters. Choose processes that you can remove and replace with calls to the optimized local adapter native API callable services.  
For more information about when to use optimized local adapters, see “Optimized local adapters on Liberty for z/OS” on page 1690 and “Optimized local adapters usage scenarios for Liberty for z/OS” on page 1693.
2. If you plan to propagate a System Authorization Facility (SAF) user ID from Liberty for z/OS to the enterprise information system (EIS), verify that the Liberty server is using a SAF-based user registry. For more information, see “Activating and configuring the SAF registry on z/OS” on page 1857.
3. Review the optimized local adapters samples. There are several examples that are included when you install Liberty for z/OS. For information about using the samples, see “Optimized local adapters samples for Liberty” on page 1691.
4. Decide how to use optimized local adapters. You can use the optimized local adapters to make inbound or outbound calls.
  - a. Use the optimized local adapters to call inbound to Liberty server EJB applications.

The following image shows the flow of an inbound CICS call to a Liberty server EJB application.

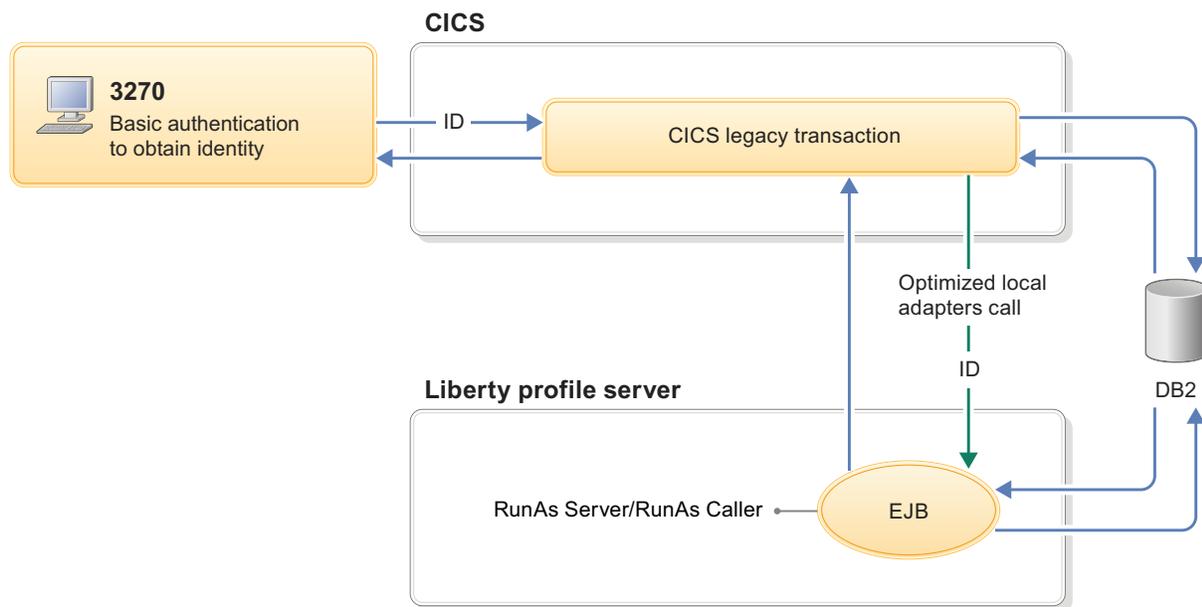

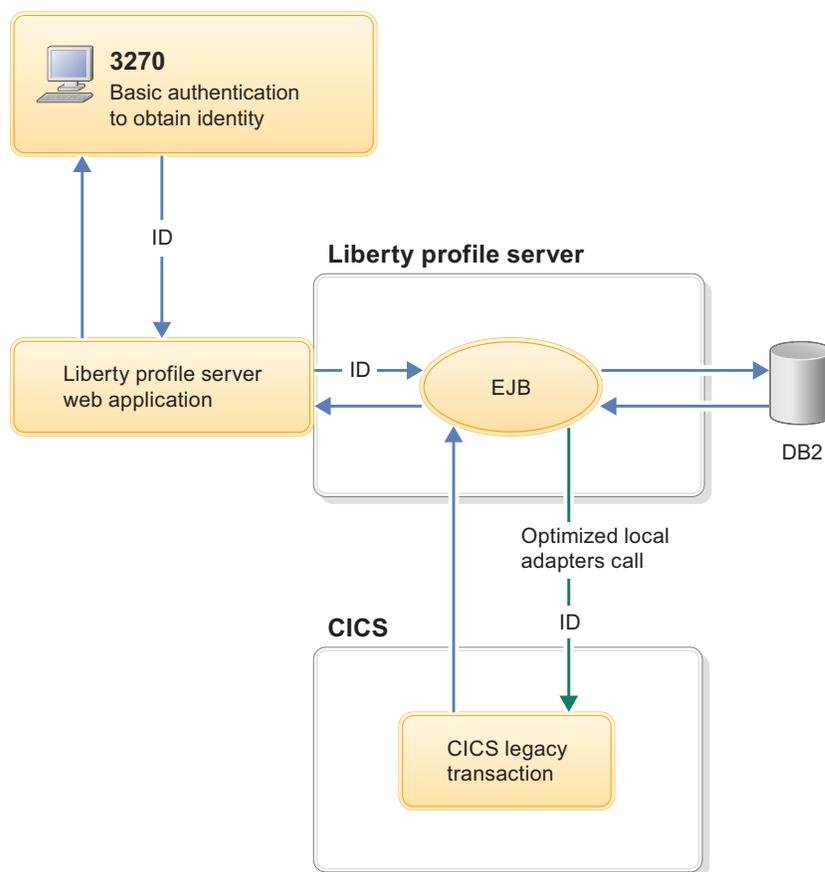

Figure 28. Using CICS

- b. Use the optimized local adapters to call programs in external address spaces from Liberty server applications.

The following figure shows the flow of an outbound Liberty server call to a CICS transaction.

For more information about using optimized local adapters, see “Enabling the Liberty server environment to use optimized local adapters” on page 1697 and “Optimized local adapters APIs on Liberty for z/OS” on page 2079

**Optimized local adapters on Liberty for z/OS:** z/OS 8.5.5.2

Optimized local adapters support on Liberty for z/OS consists of a set of callable services and a Java EE Connector Architecture (JCA) 1.5 resource adapter. The services and adapter work together to provide high-performance calling between native-language applications on z/OS and business logic in a Liberty server environment.

You can use WebSphere optimized local adapters (WOLA) to make inbound calls to applications that are deployed on Liberty from an external address space. You can also use optimized local adapters to make outbound calls from Liberty applications to applications that are running in an external address space on the same z/OS system.

With this support, existing z/OS applications that are written in Cobol, PL/I, C, C++, and assembly language can achieve high performance and efficient integration with Java applications that are deployed on the Liberty server on the same z/OS system.

Optimized local adapters also provide close integration of qualities of service (QoS), including support for fast thread-level security propagation and assertion between the API-exploiting external address spaces and the Liberty server. Support is provided for using the adapters APIs in the following environments:

- Customer Information Control System (CICS)
- UNIX System Services
- Batch processing

A task-related user exit (TRUE) program is provided to support the optimized local adapters under CICS.

## Benefits of using optimized local adapters

### Performance improvement

You can achieve significant performance characteristics when you use the optimized local adapters APIs to call into applications that are deployed on a Liberty server from local batch and UNIX System Services, and CICS applications. The ability to pass parameter data using binary techniques provides a large part of the performance improvement. The transport-level support that the adapters provide uses z/OS cross-memory services to optimize the performance of calls to applications that are deployed on a locally accessible Liberty server.

### Identity context propagation

For inbound requests to the Liberty server using the optimized local adapters APIs, the user ID on the existing z/OS thread is always propagated and asserted in the Liberty EJB container. For calls from CICS, you can extend this propagation by specifying a registration option that propagates and asserts the identity of the CICS task-level user. For calls from Liberty applications, you can propagate and assert identity under CICS using the optimized local adapters CICS link server. You can control this behavior by specifying a flag on the Register API.

### Local binding support

Optimized local adapters can provide a high-performance local binding for existing applications, middleware, and subsystems on z/OS platforms. If there is a local Liberty server available, these local bindings are used with current programming interfaces.

### Gateway or proxy for legacy assets on z/OS systems

Optimized local adapters provide the basis for you to use the Liberty stack as an easily accessible set of capabilities. These capabilities extend the life of application assets that might be difficult to replace. When you use an enterprise bean as a proxy, any Cobol, assembly language, or C/C++ application that is deployed on a z/OS system can easily become a web services client or a Web 2.0 application requester that reaches a set of web applications that are within reach of your locally running application server.

Using the Liberty outbound APIs, any Cobol, assembly language, or C/C++ application can be presented to the Liberty server as a callable service. You can then deploy a provider web services application in the local Liberty server that accepts requests as a gateway for this backend service. In this scenario, the JCA 1.5 programming model sends requests to the application, receives responses from it, and sends back responses to the web-based caller.

## Optimized local adapters samples for Liberty:

z/OS

8.5.5.2

Use the WebSphere optimized local adapters (WOLA) sample files to quickly get started using the optimized local adapters on Liberty.

The sample files for optimized local adapters on Liberty are available on GitHub. For information about how to install the samples, see the readme file on GitHub.

- “Job Control Language (JCL) samples”
- “Program List Table (PLT) samples” on page 1692
- “Link server samples” on page 1692
- “Samples for inbound calls” on page 1692
- “Samples for outbound calls” on page 1693

### Job Control Language (JCL) samples

- CSDUPDAT.jclsamp - The CSDUPDAT program is a Customer Information Control System (CICS) DFHCSDUP utility job that defines all resource definitions that are needed to use optimized local adapters under CICS.

- DFHPLTOL.jclsamp - The DFHPLTOL program contains JCL source code for assembling a sample Program List Table (PLT) with the sample program to enable the task-related user exit (TRUE), BBOACPLT, and the sample BBOC command processor PLT, BBOACPL2.
- OLABATCH.jclsamp - The OLABATCH program contains JCL source code to run one of the samples in z/OS batch. This sample must run on the same logical partition (LPAR) as the Liberty server.

### Program List Table (PLT) samples

- BBOACPLT.cicsasm - The BBOACPLT program contains assembly language sample source code for a CICS PLT initialization routine that shows how to enable the optimized local adapter TRUE during CICS startup.
- BBOACPL2.cicsasm - The BBOACPL2 program contains assembly language sample source code for a CICS PLT initialization routine that shows how to get optimized local adapter INITPARMS from CICS startup parameters and issue the BBOC STRT\_SRVR command during CICS startup.
- BBOACPL3.cicsasm - The BBOACPL3 program contains assembly language sample source for a CICS PLT initialization routine that shows how to pass multiple BBOC commands to the BBOACNTL program during CICS startup.

### Link server samples

- OLACB01.jclsamp - The OLACB01 program contains JCL source code for a CICS program that can be called from the link server. The program uses a COMMAREA object to pass its parameters. Use this sample target program with the optimized local adapter CICS link server. The program echoes back the sent message.
- OLACB02.jclsamp - The OLACB02 program contains JCL source code for a CICS program that can be called from the link server. The program uses a CONTAINER object to pass its parameters. Use this sample target program with the optimized local adapter CICS link server. The program echoes back the sent message.
- OLACB10.jclsamp - The OLACB10 program contains JCL source code for a CICS program that can be called from the link server. The program uses multiple containers to pass data to CICS from an EJB bean. Use this sample target program with the optimized local adapter CICS link server.
- OLACB11.jclsamp - The OLACB11 program contains JCL source code for a CICS program that can be called from the link server. The program uses multiple containers to pass data to CICS from an EJB bean, and modifies that data within the program. Use this sample target program with the optimized local adapter CICS link server. The data is modified inside the target program.
- OLACB12.jclsamp - The OLACB12 program contains JCL source code for a CICS program that can be called from the link server. The program uses multiple containers to pass data to CICS from an EJB bean, and shows how objects can be removed from the request container so that they are not sent in the response container. Use this sample target program with the optimized local adapter CICS link server. The data is deleted inside the target program.

### Samples for inbound calls

- OLACB05.jclsamp - The OLACB05 program contains JCL source code for a CICS sample Cobol program that demonstrates how to use the APIs to register, get a connection, call an EJB bean with the Send Request API, get the response, and release the connection, and unregister.
- OLACB06.jclsamp - The OLACB06 program contains JCL source code for a CICS sample Cobol program that demonstrates how to use the APIs to register, call an EJB bean with the Invoke API, and unregister.
- OLACC01.jclsamp - The OLACC01 program contains JCL source code for a C program that demonstrates how to use the APIs to register, call an EJB with the Invoke API, and unregister. You can run this sample under batch, UNIX System Services, or CICS.

## Samples for outbound calls

- OLACB03.jclsamp - The OLACB03 program contains JCL source code for a CICS sample Cobol program that demonstrates how to make a CICS task into an optimized local adapter server by using the Host Service API.
- OLACB04.jclsamp - The OLACB04 program contains JCL source code for CICS sample Cobol program that demonstrates how to make a CICS task into an optimized local adapter server by using the Receive Request and Get Data APIs.
- OLACC02.jclsamp - The OLACC02 program contains JCL source code for C program that calls the Host Service, Send Request, Send Response, and Get Data APIs. This program essentially invokes itself, calling in to an EJB that then calls back to this program. You can run this sample under batch, UNIX System Services, or CICS.

## Optimized local adapters usage scenarios for Liberty for z/OS:

z/OS

8.5.5.2

Real-world scenarios illustrate how optimized local adapters and the supporting native API callable services provide can benefit enterprise architecture and application development on the z/OS platform.

WebSphere optimized local adapters (WOLA) provide existing native-language business and middleware applications in z/OS batch, Customer Information Control System (CICS), and UNIX System Services environments an alternative way to call Java applications that are implemented as Enterprise JavaBeans (EJB) applications on Liberty. Using optimized local adapters, you can also call from Liberty applications to an external server program that is running locally or on the same logical partition (LPAR) using Java EE Connect Architecture (JCA) Version 1.5.

A scenario where the optimized local adapters can provide increased performance is CICS support for the use of server and client web services. The targeted backend applications can call business logic that is located elsewhere more efficiently when using the optimized local adapters instead of XML and SOAP messaging technology.

The following hypothetical real-world scenarios describe how optimized local adapters are useful to achieve various business goals.

### Financial services company scenario

An IBM z/OS financial services customer that is running business applications under z/OS batch must decide about purchasing a financial processing application, which provides new support for stock trade real-time reporting to the exchanges. The ability to do this style of real-time reporting can result in increasing revenue for the customer.

The application that does real-time reporting is a Java Enterprise Edition (Java EE) application on a Liberty server that runs on Windows 8. The application offers a set of enterprise beans and associated web services interfaces that can be called for various kinds of interactions.

A test scenario is developed and successfully implemented to call the Java EE application from a batch Cobol program. Therefore, the customer decides to move forward and do more rigorous testing. Further testing shows that when this mechanism is pressed by more than 50-100 requests per second, it begins to slow to the point where the response times do not meet the customer requirements. The effort is abandoned until a more realistic approach is available for exchanging information in real time between the batch business application and the new vendor application.

The optimized local adapters can provide this batch customer with an option to deploy Liberty for z/OS and update the batch application to use the optimized local adapters Invoke or Send Request API. These APIs provide a way to call EJB applications that are deployed on a local Liberty server, which calls the business logic for the web service.

## Insurance company scenario

An IBM z/OS insurance industry customer that is running a business application under CICS wants to provide customers with the ability to retrieve and update policy information in real time. This information must be gathered in various ways and from several places, including:

- Information that is directly gathered from DB2
- Information that is gathered by calling a program in CICS
- Information that is gathered by starting a web service to communicate with a remote service provided by another company

The customer chooses to use a Java application for several reasons, but most importantly because most of their programming skills are based in Java. When the new application is tested, the customer experiences long response times when retrieving information. The slow response time is a result of the Liberty server running on a distributed server and the latency that is involved with communicating remotely with DB2 while it calls CICS using web services and SOAP messages.

To fix the problem, the customer deploys multiple Liberty servers in the same configuration to reduce the number of requests per second on any one of the servers and to spread the requests across separate network paths.

Using optimized local adapters gives the customer an alternative other than deploying multiple servers. The customer could install the application on a Liberty server on z/OS, closer to the DB2 and CICS environments. Using the optimized local adapters APIs for the calls to CICS from the Liberty server provides a significant improvement over the web services and SOAP solution. Consolidating on z/OS platforms reduces the need for more distributed servers that consume floor space, power, and resources to maintain. In this scenario, because the location of the data and applications is the gating factor, increasing the size of the remote server to the most robust one available does not necessarily solve the problem.

## Migrating business logic to Liberty for z/OS

A customer has years of application logic with Cobol running inside of CICS. They want to migrate some of these applications to Liberty to take advantage of Java and Java EE technologies and use other capabilities in the WebSphere stack.

One of the applications is too large to migrate in one piece, and they want to gradually move portions of it to a Liberty server. The transactional and security qualities of service that CICS provides must be maintained during the migration, and the performance impact of the migration must be minimal. Using optimized local adapters, portions of the application can be migrated to Liberty and wrapped in a stateless session bean. The Cobol application logic can be modified to use the optimized local adapter to call the stateless session beans. These calls to the Liberty server run under the same transaction and security contexts that are used by the Cobol programs in the CICS region. There is a significant performance gain when compared to making similar calls using a web service. The customer can continue to relocate portions of the application to the Liberty server until the application is migrated.

## Optimized local adapters performance considerations for Liberty: 8.5.5.2

The WebSphere optimized local adapter (WOLA) APIs are designed to provide optimal performance for calling between an external address space and applications on Liberty for z/OS. The APIs establish new kinds of application patterns by supporting fine-grained interactions between applications in these environments. By choosing the best configuration options for your system, you can maximize the performance benefits of using the optimized local adapters.

## Selecting minimum and maximum connection values for the Register API call

Selecting a minimum connections value for the Register API call that is too large can degrade performance. Because each established connection remains until the Unregister API is called, a minimum connection value that is too large consumes more memory and increases the time that is needed to complete each Register and Unregister API call. Select the smallest minimum connections value that suits your needs; for example, if hundreds of simultaneous threads can potentially share a registration, then it might make sense to dedicate more memory and time to registration with a large minimum connections value. If you expect fewer concurrent threads, set a smaller minimum connections value.

Selecting a value that is too small for the maximum number of connections can also degrade performance if the client must wait for a connection when it requests one. When the maximum connections value is exceeded, the calling thread waits the number of seconds specified on the wait time parameter for Connection Get, Invoke, Receive Request Any, or Host Service APIs for a connection to become available. When this time expires, return and reason codes are passed back that indicate that a connection handle could not be acquired for the request before the wait time expired. Select a maximum connections value that best fits the anticipated needs of your environment.

## Selecting maximum connection values when you start a CICS link server

When you start a link server task under Customer Information Control System (CICS) without specifying the minimum connections (MNC) and maximum connections (MXC) parameters, MNC defaults to 1 and MXC defaults to 10. The value of the MXC parameter specifies the number of link invocation tasks (BBO#) that can be started and concurrently run by the link server task (BBO\$). As a result, the value also limits the number of concurrent threads on the Liberty server that can run and start CICS target programs.

Select an MXC value that reflects the expected duration of the typical target CICS programs that are started under this instance of the link server. For example, if the target CICS programs are mostly long-running, a larger MXC value is appropriate to keep requests flowing efficiently from the Liberty server into CICS. If the target programs are short-lived, a smaller MXC value is more efficient.

## Shared 64-bit memory

When the optimized local adapters feature is enabled in a Liberty server, the server obtains 32 MB of shared memory that is located above the 2 GB bar in z/OS. This memory is shared by all Liberty servers with the same wolaGroup name and stores the shared optimized local adapter control structures.

Additional shared memory that is located above the 2 GB bar is allocated to store messages passed between a client and a Liberty server. The amount of storage that is required to pass messages depends on the average size of the messages that are passed, and there must be enough shared memory to hold all of the message data that exists at any one time. Additional memory is allocated as required.

If an application continues to call the Register API and loop without calling the Unregister API and without terminating, which automatically cleans up these registrations, it can overflow the optimized local adapters shared memory buffer for the WOLA group. If this occurs, API calls are returned with out-of-memory reason codes.

You can calculate a rough estimate of the amount of WOLA shared memory that your application needs. Each client registration consumes 384 bytes of shared memory plus 192 bytes of shared memory for each connection. A registration with a maximum of 100 connections consumes about 20 KB of shared memory. Each client thread, which must wait for a connection to become available if all connections are in use, consumes an additional 80 bytes. Each service that the registration hosts consumes an additional 384 bytes.

For example, suppose you have 200 registrations in your WOLA group. Each registration contains 200 connections, and has a maximum of 1,000 threads waiting for a connection at any time. The total memory consumed by this configuration is about 24 MB, which leaves enough shared memory to host about 25,500 services concurrently or 125 concurrent services per registration.

200 Registrations x 384 bytes =	76,800 bytes
200 Registrations x 200 connections x 192 bytes =	7,680,000 bytes
200 Registrations x 1000 waiters x 80 bytes =	16,000,000 bytes
-----	
	23,756,800 bytes
33,554,432 bytes - 23,756,800 bytes =	9,797,632 bytes remaining
	/ 384 bytes per service
-----	
	25,514 services

### Optimized local adapters CICS link server performance considerations

You can use optimized local adapters for a CICS link server as a simple way to invoke existing CICS application programs from applications that are running on the Liberty server. When you start the link server, the optimized local adapters link server task (BBO\$) starts and receives program link requests from the Liberty server. When a link request is received, the link server task (BBO\$) initiates the program link task (BBO#), which in turn issues an EXEC CICS LINK command to the target program, receives a response, and sends it to the Liberty server caller. To perform these actions, the thread-level identity of the application on the Liberty server is propagated and asserted onto the target CICS task by setting the SEC=Y parameter on the BBOC **START\_SRVR** command.

You can improve performance by running a link server with SEC=N and using the identity of the user ID that initiated the link server, but this approach might not meet the security and auditing requirements of your organization. If you decide to run the link server with SEC=N, you can further improve performance by also specifying REU=Y on the BBOC **START\_SRVR** command. When you set REU=Y, the link server reuses the program link invocation tasks (BBO#) between program invocation requests.

**Important:** If you run the link server with SEC=N and REU=Y, the optimized local adapter JCA no longer supports passing a separate link transaction ID. Requests for a separate transaction ID result in a ResourceException in the application. If you attempt to run the link server with SEC=Y and REU=Y, the reuse option is forced to No because the link server must start a new program link task for each request and assert the propagated identity.

If you run a link server with REU=Y, program link tasks (BBO#) remain active until a BBOC **STOP\_SRVR** or **UNREGISTER** command is entered for the registration. If you are also running with a high maximum connections (MXC) value and a large number of requests arrive concurrently, the number of active program link tasks (BBO#) might reach the CICS maximum concurrent task threshold. For more information about setting the CICS maximum concurrent task threshold, see the documentation for your version of CICS.

To achieve the fastest performance when you call into an application under CICS from the Liberty server, code the Host Service, Receive Request Any, or Receive Request Specific APIs directly in your application program. However, coding the APIs directly does not provide the built-in support for identity propagation that the link server provides.

### Considerations for using the JCA resource adapter

When you use the optimized local adapter JCA resource adapter, each connection that is obtained from the ConnectionFactory object requires additional memory overhead. If your application makes several

calls to an external address space or CICS in the same application method, you can achieve better performance by using the same connection for each interaction and using the same JCA interaction object within an application method.

When you create the JCA ConnectionFactory object for optimized local adapters, you can modify the minimum and maximum size of the JCA connection pool for that ConnectionFactory. The connection pool represents logical connections that are bound to physical connections that are specified when you call the Register API during an interaction. For optimal performance, set the size of the JCA connection pool to be the same size of the physical connection pool that you set during the Register API call. If your JCA connection pool is too small, your application might have to wait for a JCA connection object, even though there are physical connections available.

## Administering optimized local adapters on Liberty for z/OS

Enable optimized local adapters and register an external address space with a local Liberty server.

### Enabling the Liberty server environment to use optimized local adapters:

You must enable the Liberty server to receive inbound and outbound requests using the optimized local adapters support. WebSphere optimized local adapters (WOLA) for z/OS are a set of callable services (APIs) that give native z/OS applications the ability to make inbound calls to application server enterprise beans and enable native programs to act as a server and accept requests from applications running in the WebSphere Liberty server.

#### Before you begin

 Use IBM Installation Manager to install Liberty for WebSphere Application Server Version 8.5.5.2, along with the following interim fixes:

- 8.5.5.2-WS-WLP-OS390-IFPI18279
- 8.5.5.2-WS-WLP-OS390-IFPI18379

Download the interim fixes from IBM Fix Central, or install the interim fixes directly from the service repository. After you install the interim fixes, use the featureManager command to install the zosLocalAdapters-1.0 feature in your Liberty environment. For more information, see “Installing assets using the featureManager command” on page 1403.

 Use IBM Installation Manager to install Liberty for WebSphere Application Server Version 8.5.5.3 or later. Install the zosLocalAdapters-1.0 feature in your Liberty environment. For more information, see “Installing Liberty Repository assets” on page 1391.

#### Procedure

1. Allocate or select a load module library to contain the optimized local adapter load modules. This library is used by applications that are running outside the Liberty server. The library must be a PDS-E and requires approximately 40 tracks (3390) to hold the optimized local adapter modules.
2. Copy the optimized local adapter load modules from wlp/clients/zos/\* to the load module library. The following example shows how to copy load modules into the \$DSNAME data set:  

```
cp -Xv wlp/clients/zos/* "'/'$DSNAME'"
```
3. To enable optimized local adapters support on the Liberty server, configure the zosLocalAdapters-1.0 feature in the server.xml file.
  - a. To enable the feature, add the zosLocalAdapters-1.0 feature to the server.xml file as shown in the following example.

```
<featureManager>
  <feature>zosLocalAdapters-1.0</feature>
</featureManager>
```

- b. Create a WOLA group by configuring a `zosLocalAdapters` element with a three-part WOLA group name in the `server.xml` file. The three-part WOLA group name is used by clients to connect to the Liberty server. Each part of the group name must be 1 to 8 alphanumeric characters.

**Note:** Do not use lowercase characters in the WOLA group name. The z/OS security subsystem converts lowercase characters to uppercase, which can cause a mismatch with your configuration.

```
<zosLocalAdapters wolaGroup="LIB1" wolaName2="LIB2" wolaName3="LIB3"/>
```

4. Configure a connection factory by adding a `connectionFactory` element to the `server.xml` file and specifying its properties in a `properties.ola` element.

```
<connectionFactory jndiName="eis/ola">
  <properties.ola RegisterName="OLASERVER"/>
</connectionFactory>
```

For information about WOLA connection factory properties, see “Connection factory properties for optimized local adapters on Liberty” on page 1699.

5. Create SERVER profiles for z/OS.
  - a. Create SERVER profiles for the optimized local adapter authorized service. Use the following Time Sharing Option (TSO) commands:

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.LOCALCOM UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.LOCALCOM CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.WOLA UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.WOLA CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

- b. Create a SERVER profile for the authorized client module BBGZSCFM and permit the Started Task user ID of the Liberty server to the profile. This action enables a Liberty server to load the z/OS Authorized client services. To enable a server that is running as WLPUSER1 to access the authorized client module:

```
RDEF SERVER BBG.AUTHMOD.BBGZSCFM UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSCFM CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

- c. Create SERVER profiles for optimized local adapter authorized client service. Use the following TSO commands:

```
RDEF SERVER BBG.AUTHMOD.BBGZSCFM.WOLA UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSCFM.WOLA CLASS(SERVER) ACCESS(READ) ID(WLPUSER1)
```

For more information, see “Enabling z/OS authorized services in Liberty for z/OS” on page 1942.

6. If you have CBIND enabled in System Authorization Facility (SAF), grant access to the clients that will use optimized local adapters.

- a. Define a profile for the Liberty server in the CBIND class. The profile name is `BBG.WOLA.<WOLA1>.<WOLA2>.<WOLA3>`, where `WOLA1`, `WOLA2`, and `WOLA3` are the three parts of the optimized adapter group name that are specified in the `<zosLocalAdapters>` element in the `server.xml` file. You can define a profile by using the SAF **RDEFINE** TSO command. For example, the following command creates a profile in the CBIND class for a WOLA group named `LIB1.LIB2.LIB3`:

```
RDEF CBIND BBG.WOLA.LIB1.LIB2.LIB3 UACC(NONE)
```

- b. Permit READ access to the profile. For example, the following command permits read access for the `username` user name on the `bbg.wola.lib1.lib2.lib3` profile:

```
PERMIT BBG.WOLA.LIB1.LIB2.LIB3 CLASS(CBIND) ACCESS(READ) ID(USERNAME)
```

You can use asterisks to permit a user access to multiple profiles. The following example permits READ access to the `username` user for all profiles that start with `bbg.wola` in the CBIND class:

```
RDEF CBIND BBG.WOLA.* UACC(NONE)
PERMIT BBG.WOLA.* CLASS(CBIND) ACCESS(READ) ID(USERNAME)
```

For more information about SAF commands and syntax, see the documentation for your version of z/OS.

## Results

You can now deploy and start applications that use optimized local adapters on the Liberty server.

## What to do next

Ensure that all external connections that use the optimized local adapters are running the latest version of the optimized local adapters load module library.

1. Ensure that the load module library is at the latest level.
2. Ensure that the library is made available to all of the external address spaces that use the optimized local adapters. For example, make sure the library is available in the STEPLIB for batch jobs, or in the DFHRPL concatenation for Customer Information Control System (CICS).

If you want to use the optimized local adapters with CICS, you must enable support for the adapters in CICS. For more information, see “Enabling support for Liberty optimized local adapters in CICS” on page 1703.

If you want to create a connection, begin by registering the external address space to the Liberty server. For more information, see “Registering an external address space with a local Liberty server using optimized local adapters” on page 1711.

Connection factory properties for optimized local adapters on Liberty:

z/OS

8.5.5.2

Use the properties for the WebSphere optimized local adapters (WOLA) to configure a connection factory when you enable WOLA on your Liberty server.

One or more connection factories must be configured to enable the optimized local adapters on z/OS for inbound and outbound support, even though the connection factory is only used directly for outbound. For information about configuring a connection factory, see “Enabling the Liberty server environment to use optimized local adapters” on page 1697.

Property	Values	Description
RegisterName	Any alphanumeric string of 1 to 12 characters	This property defines the WOLA register name to use for connections that are obtained from this connection factory.
Username	String; further restrictions on supported values depend on the associated user registry	This property defines a user ID that overrides the user ID that is sent from the connection factory. The <b>Username</b> property is used together with the <b>Password</b> property to authenticate the user and obtain the corresponding MVS user ID.
Password	Any string	This property defines the password that is used together with the <b>Username</b> property to authenticate the user.

Property	Values	Description
LinkTaskTranID	Any 4-character string	When you are using a Customer Information Control System (CICS) link server, this property defines the name of the CICS transaction that starts the link task that processes requests that are issued from the connection factory. This property overrides the link task transaction ID specified by the control transaction (BBOC) when the CICS link server was started.
UseCICSContainer	true, false	When you are using a CICS link server, this property defines whether the input and output messages are passed to the target CICS program in a COMMAREA object or in a CONTAINER object. If this property is set to true, the messages are passed in a CONTAINER object. If this property is set to false, the messages are passed in a COMMAREA object. <b>Note:</b> If the input and output messages are specified using a javax.resource.cci.MappedRecord interface, the messages are always passed in a CONTAINER object.
LinkTaskReqContID	A string of 1 to 16 characters that matches the container name defined to CICS	When you are using a CICS link server, this property defines the name of the CONTAINER object that contains input messages sent to the CICS program. <b>Note:</b> To use this property, the <b>UseCICSContainer</b> property must be set to true.
LinkTaskReqContType	0, 1	When you are using a CICS link server, this property defines whether the input CONTAINER object is defined as a CHAR or a BIT container. If this property is set to 0, the target program expects a CHAR container. If this property is set to 1, the target program expects a BIT container. When a CHAR container is requested, the input data is assumed to be in the ASCII code page, and the data is converted to EBCDIC when the container is created.
LinkTaskRspContID	A string of 1 to 16 characters that matches the container name defined to CICS	When you are using a CICS link server, this property defines the name of the CONTAINER that contains the output message from the CICS program. <b>Note:</b> To use this property, the <b>UseCICSContainer</b> property must be set to true.

Property	Values	Description
LinkTaskRspContType	0, 1	When you are using a CICS link server, this property defines whether the output CONTAINER is defined as a CHAR or a BIT container. If this property is set to 0, the target program sends a CHAR CONTAINER. If this property is set to 1, the target program sends a BIT CONTAINER. When a CHAR CONTAINER is requested, the data from the CICS program is assumed to be in the EBCDIC code page, and the data is converted to ASCII when data is retrieved from the CONTAINER.
LinkTaskChanID	A string of 1 to 16 characters that matches the channel name defined to CICS	When you are using a CICS link server, this property defines the name of the CHANNEL that contains the input and output CONTAINER objects. <b>Note:</b> To use this property, the <b>UseCICSContainer</b> property must be set to true.
LinkTaskChanType	0, 1	When you are using a CICS link server, this property defines whether the input and output CONTAINER objects are defined as CHAR or BIT containers. If this property is set to 0, the target program sends and receives CHAR containers. If this property is set to 1, the target program sends and receives BIT containers. When a CHAR container is requested, the input data is assumed to be in the ASCII code page, and the data is converted to EBCDIC when the containers are created. Similarly, the data from the CICS program is assumed to be in the EBCDIC code page, and the data is converted to ASCII when data is retrieved from the containers. <b>Note:</b> Use this property only when the input and output messages are specified using a <code>javax.resource.cci.MappedRecord</code> interface.

Property	Values	Description
ConnectionWaitTimeout	Any integer between 0 and 2147483647	<p>This property defines the maximum number of seconds that a request waits for a service name to become available. The service name is specified on Interaction objects in connections that are obtained from the connection factory. If the service name is not available after the specified number of seconds elapse, a <code>javax.resource.ResourceException</code> is thrown.</p> <p>Setting this property to 0 disables the timer. The default value for this property is 30.</p>
OTMAGroupID	String of 1 to 8 characters that matches the IMS XCF group name that is defined to IMS.	When you use IBM Information Management System (IMS), this property defines the group name that the IMS region uses to connect to the cross-system coupling facility (XCF). The value should match what is declared in the <code>IMSPBxxx PROCLIB</code> member for the parameter named <code>GRNAME</code> .
OTMAServerName	String of 1 to 16 characters that matches the IMS XCF system name that is defined to IMS.	When you use IBM Information Management System (IMS), this property defines the system name that the IMS region uses to connect to the cross-system coupling facility (XCF). The value should match what is declared in the <code>IMSPBxxx PROCLIB</code> member for the parameter named <code>OTMANM</code> .
OTMAClientName	String of 1 to 16 characters, alphanumeric including national characters, defaulting to the string <code>DEFAULT</code> .	When you use IBM Information Management System (IMS), this property defines the system name that the Liberty server uses to connect to the cross-system coupling facility (XCF). The value should be unique within the XCF group that is used by the IMS region that you connect to.
OTMASyncLevel	0,1	When you use IBM Information Management System (IMS), this property controls the sync level that is used to send messages to and from IMS. A value of 0 uses sync level <code>NONE</code> , and a value of 1 uses sync level <code>CONFIRM</code> .
OTMAMaxSegments	Any integer between 0 and 2147483647	When you use IBM Information Management System (IMS), this property controls the maximum number of segments that a reply message is allowed to contain. The default value is 1.

Property	Values	Description
OTMAMaxRecvSize	Any integer between 0 and 2147483647	When you use IBM Information Management System (IMS), this property controls the maximum number of bytes that a reply message is allowed to contain. The default value is 32768.
OTMARRequestLLZZ	0,1	When you use IBM Information Management System (IMS), this property controls the format of the request message that is sent to IMS. A value of 1, the default, indicates that the request starts with an LLZZ format header. A value of 0 indicates that the request starts with an LLLLZZ header.
OTMARResponseLLZZ	0,1	When you use IBM Information Management System (IMS), this property controls the format of the response message that is received from IMS. A value of 1 indicates that the response starts with an LLZZ format header. A value of 0, the default, indicates that the request starts with an LLLLZZ header.

## Enabling support for Liberty optimized local adapters in CICS:

You must enable your Customer Information Control System (CICS) environment to receive inbound and outbound requests using WebSphere optimized local adapters (WOLA).

### Before you begin

Enable your Liberty server environment to use optimized local adapters. For more information, see “Enabling the Liberty server environment to use optimized local adapters” on page 1697.

### Procedure

1. Add the CICS resource definitions for the optimized local adapters to the primary CICS system definition (CSD) file, DFHCSD. You can either manually add the definitions in CICS or download and run the CSUPDAT sample.
  - In CICS, use the CEDA transaction or an equivalent transaction to add the definitions to the DFHCSD. See “Optimized local adapter definitions for CICS” on page 1705 for the required definitions.
  - Use the CICS offline CSD update program, DFHCSDUP, to add the definitions to the DFHCSD. For more information about the DFHCSDUP program, see the documentation for your version of CICS. See “Optimized local adapter definitions for CICS” on page 1705 for the required definitions.
  - Update the definitions by running the CSDUPDAT.jc1samp sample job.
    - a. Download the optimized local adapter samples. For more information about downloading and installing the samples, see “Optimized local adapters samples for Liberty” on page 1691.
    - b. Copy the samples and CSDUPDAT member to a data set.
    - c. Customize the CSDUPDAT.jc1samp sample job for your environment. For example, in the sample job, enter the name of the dataset where the CSD is located.
    - d. Run the CSDUPDAT.jc1samp sample job.

- Copy the load modules and DLLs that are required for CICS from the Liberty server hierarchical file system (HFS) or zSeries file system (zFS) to a partitioned data set for use under CICS. The following example shows how to copy load modules into the \$DSNAME data set:

```
cp -Xv wlp/clients/zos/* "'/$DSNAME'"
```

- Place the data set in the CICS DFHRPL concatenation.
- Set up the Liberty message catalog in the CICS region. The optimized local adapters programs issue messages from a message catalog that ships with Liberty. For the programs to issue messages, the NLSPATH environment variable in the CICS region must point to the directory that contains the message catalog. This directory is wlp/lib/native/zos/s390x/nls/%N.cat, where wlp is the directory in which the Liberty server is installed.

To set the environment variable, use the Language Environment ENVAR option, which you can set by editing the CEEROPT CSECT that the CICS region uses. After you edit the CSECT, you can build, compile, link, and copy the CSECT into the DFHRPL data set. For more information about other ways to set Language Environment options, see the documentation for your version of CICS.

**Note:** Ways of setting Language Environment options that involve editing the application source code or relinking the application are not supported because the optimized local adapter programs cannot be recompiled or relinked.

The following example shows a CEEROPT CSECT that defines the NLSPATH environment variable for a Liberty server that is installed in /u/MSTONE1/wlp. Note that the definition spans two lines and includes a continuation character, X, in column 72.

```
CEEROPT CSECT
CEEROPT AMODE ANY
CEEROPT RMODE ANY
*****
*
* Utility: CEEROPT
* Purpose: Set default LE runtime options for CICS region.
*
*****
      CEEXOPT ENVAR=(('NLSPATH=/u/MSTONE1/wlp/lib/native/zos/s390x/nlX
                    s/%N.cat'),OVR)
      END
```

- Secure your optimized local adapter connections by performing the following actions:
  - Create SERVER profiles for z/OS.
  - If you have CBIND enabled in System Authorization Facility (SAF), grant access to the clients that will use optimized local adapters.

For more information, see “Securing optimized local adapters for inbound support in Liberty for z/OS” on page 1949.

- Start the optimized local adapters task-related user exit (TRUE) program.

You can start the TRUE program with BBOC, an optimized local adapters transaction for CICS. You can use this transaction to start, stop, enable, and disable tracing for the TRUE module. The TRUE program name is BBOATRUE, which you activate using the BBOC transaction with the START\_TRUE parameter.

When CICS security is enabled, the user ID where the BBOC START\_TRUE and STOP\_TRUE parameters run must have authority to issue the EXEC CICS ENABLE PROGRAM(BBOATRUE) and DISABLE PROGRAM(BBOATRUE) EXITALL commands. Messages that are issued by the Liberty server under CICS are routed to the BBOQ extra partition transient data queue (TDQ) that is allocated under DD BBOOUT in the CICS region.

For more information, see “Liberty server transactions for CICS: BBOC, BBO\$, and BBO#” on page 1705.

- Optional: If you want to use the CICS link server, start the optimized local adapters CICS link server task by issuing the BBOC\_START\_SRVR command on a CICS workstation. For more information, see “Liberty server transactions for CICS: BBOC, BBO\$, and BBO#” on page 1705.

## What to do next

If you want to create a connection, begin by registering the external address space to the Liberty server. For more information, see “Registering an external address space with a local Liberty server using optimized local adapters” on page 1711.

Optimized local adapter definitions for CICS:

z/OS

8.5.5.2

You must define the WebSphere optimized local adapter (WOLA) transactions, programs, task-related user exits (TRUE), and transient data queues (TDQs) in CICS to enable WOLA support.

You must add the definitions that enable WOLA support in CICS to the primary CICS system definition (CSD) file, DFHCSD. For information about how to add the definitions, see “Enabling support for Liberty optimized local adapters in CICS” on page 1703.

When you add the definitions, you can specify the suggested GROUP name, BBOACSD, or you can specify a different name. You must specify all other values as shown in the following example.

```
DEFINE PROGRAM(BBOACNTL) GROUP(BBOACSD) LANGUAGE(C)
    DATALOCATION(ANY) EXECKEY(CICS)
    CONCURRENCY(THREADSAFE) API(OPENAPI)
DEFINE PROGRAM(BBOATRUE) GROUP(BBOACSD) LANGUAGE(ASSEMBLER)
    DATALOCATION(ANY) EXECKEY(CICS)
    CONCURRENCY(THREADSAFE) API(OPENAPI)
DEFINE PROGRAM(BBOACSRV) GROUP(BBOACSD) LANGUAGE(C)
    DATALOCATION(ANY) EXECKEY(CICS)
    CONCURRENCY(THREADSAFE) API(OPENAPI)
DEFINE PROGRAM(BBOACLNK) GROUP(BBOACSD) LANGUAGE(C)
    DATALOCATION(ANY) EXECKEY(USER)
    CONCURRENCY(THREADSAFE) API(OPENAPI)
DEFINE TRANSACTION(BBOC) PROGRAM(BBOACNTL) GROUP(BBOACSD)
    TASKDATALOC(ANY) TASKDATAKEY(CICS)
DEFINE TRANSACTION(BBO$) PROGRAM(BBOACSRV) GROUP(BBOACSD)
    TASKDATALOC(ANY) TASKDATAKEY(CICS)
DEFINE TRANSACTION(BBO#) PROGRAM(BBOACLNK) GROUP(BBOACSD)
    TASKDATALOC(ANY) TASKDATAKEY(USER)
DEFINE TDQUEUE(BBOQ) TYPE(EXTRA) DDNAME(BBOOUT) GROUP(BBOACSD)
    DATABUFFERS(1) BLOCKFORMAT(UNBLOCKED) RECORDF(V)
    TYPEFILE(OUTPUT) DISPOSITION(SHR) OPENTIME(INITIAL)
    BLOCKSIZE(224) RECORDSIZE(220)
```

Liberty server transactions for CICS: BBOC, BBO\$, and BBO#:

z/OS

8.5.5.2

WebSphere optimized local adapters (WOLA) are supported in the CICS product through the BBOC, BBO\$, and BBO# transactions.

The optimized local adapters run in a CICS region as a *resource manager*. In CICS, the Task Related User Exit (TRUE) is the primary vehicle that is used by resource providers. TRUE support provides the boundary between the CICS application threads and the external resource manager threads. Currently, DB2, WebSphere MQ, and TCPIP sockets run in CICS using the TRUE support.

Applications that run under CICS use the optimized local adapter APIs according to the following workflow:

1. The application runs the provided stub routines.
2. The stub routines start the CICS resource manager interface module, passing it the name of the optimized local adapter TRUE routine, BBOATRUE, and the parameters specific to each API.
3. CICS dispatches the TRUE on one of the OPENAPI task control blocks (TCBs) and runs until the API call is completed.
4. The call goes back to CICS with the output parameters.

See the following sections for more information about the Liberty server transactions for CICS:

- “Control transaction for CICS: BBOC”
  - “Sample BBOC commands” on page 1709
  - “Automatically running a BBOC command during CICS startup” on page 1710
- “Link server transaction for CICS: BBO\$” on page 1711
- “Program link invocation transaction for CICS: BBO#” on page 1711

### Control transaction for CICS: BBOC

The BBOC transaction is the WebSphere control, or operations transaction, for the adapters support under CICS. You can use the transaction to enable and start the Liberty server TRUE and to set tracing levels for debugging the APIs and code that interfaces with the Liberty server. BBOC also sets registrations and unregistrations, and starts and stops link server tasks in CICS. These server tasks provide support for starting existing CICS programs and passing data with COMMAREA objects or containers with the input parameters over the adapters. BBOC is a CICS workstation-based transaction that you can run on a 3270 workstation or from a sequential, or SDSCI-type, workstation.

The syntax for the BBOC transaction is BBOC operation\_name **parameters**, where multiple parameters are separated by one or more spaces.

#### RGN

The 12-character register name

#### DGN

The first eight-character name of the WOLA group to join

#### NDN

The second eight-character name of the WOLA group to join

#### SVN

The third eight-character name of the WOLA group to join

#### LSYNC

LSYNC controls whether CICS passes the SYNCONRETURN option when it links to the target program. If you specify LSYNC=Y, the CICS link server passes the SYNCONRETURN option on the EXEC CICS LINK command. You might need to specify this option when the target program is in another CICS region. The default value is LSYNC=N.

#### SVC

The service name of a maximum of 8 characters. The parameter supports masking with asterisks (\*); for example, you can specify \*, abc\*, \*abc, abc\*xyz, abc\*xy\*z, and so on.

#### MNC

The number of minimum connections. The minimum value is 0, and the default value is 1.

#### MXC

The maximum number of connections. The maximum value is 9999, and the default value is 10.

#### SEC

The SEC parameter controls which user ID is propagated. The default value is SEC=N.

If you specify SEC=N and are calling from CICS to the Liberty server, the CICS region user ID is propagated. If you specify SEC=N and are calling from the Liberty server to CICS under the link server task (BBO\$), the link task runs under the user ID of the started link server.

If you specify SEC=Y and are calling from CICS to the Liberty server, the task-level user ID is propagated to the Liberty server. If you specify SEC=Y and are calling from the Liberty server to CICS, the link server attempts to start the link task (BBO#) with the propagated user ID from the Liberty

server. The propagation works only if you created a System Authorization Facility (SAF) SURROGAT class definition to permit the user ID of the link server to issue the EXEC CICS START TRAN('BBO#') USERID(<propagated\_id>) command.

#### STX

The four-character name of the link server CICS transaction ID to use. The default value is BBO\$.

**Note:** If you define a transaction name that is different from the default, you must also define the transaction in the primary CICS system definition (CSD) file, DFHCSD, with the same program name and attributes as BBO\$.

#### LTX

The four-character name of the link-to-program CICS transaction ID to use. The default value is BBO#.

**Note:** If you define a transaction name that is different from the default, you must also define the transaction in the primary CICS system definition (CSD) file, DFHCSD, with the same program name and attributes as BBO#.

#### TRC

Defining a value for this parameter enables tracing at the following levels:

- When set to 0: No tracing; error messages only
- When set to 1: Basic tracing
- When set to 2: Detailed tracing

#### TDQ

The four-character name of the CICS extra-partition transient data queue (TDQ) where adapter messages are written. If you do not specify this parameter, the default is BBOQ and DD BBOOUT. If messages cannot be written to the specified TDQ, they are written to the CICS region stdout, tdq CESO dd CEEOUT.

#### REU

REU controls whether the link server reuses the program link invocation tasks (BBO# transactions) between program invocation requests. The default value is N.

**Important:** If you run the link server with SEC=N and REU=Y, the optimized local adapter JCA no longer supports passing a separate link transaction ID. Requests for a separate transaction ID result in a ResourceException in the application. If you attempt to run the link server with SEC=Y and REU=Y, the reuse option is forced to No because the link server must start a new program link task for each request and assert the propagated identity.

#### REUC

The number of requests for which the CICS link task (BBO#) remains active and is reused. When this count is reached, the link task ends. The maximum value is 2147483648.

**Important:** For a transactional scenario, the link task ends after the count is reached and the next commit is received from the Liberty server.

#### REUT

The number of seconds that the CICS Link task (BBO#) remains active and is reused. When this time interval expires, after the next request is received and processed, the link task ends. The maximum value is 2147483648.

**Important:** For a transactional scenario, the link task ends after the requested time is reached and the next commit is received from the Liberty server.

#### 0.5.5.2 TXN

TXN describes the transactional behavior of the registration that is generated by the BBOC transaction. This option is only supported by registrations to WebSphere Traditional server instances.

When BBOC creates a WOLA registration by using the REGISTER operation, TXN=Y signifies that any Java Platform, Enterprise Edition applications started in the WebSphere Application Server that use this registration joins the current CICS unit of work. When TXN=Y, a global transaction is created between CICS and WebSphere Application Server, which completes by using the two-phase commit protocol when the CICS application issues an EXEC CICS SYNCPOINT, or when a sync point is implied, such as when the CICS task ends.

When BBOC is used to create a link server by using the START\_SRVR function, TXN=Y signifies that the CICS link server task joins the current WebSphere Application Server transaction when a service is started. For example, if a Java Platform, Enterprise Edition application starts a resource manager local transaction (RMLT) and starts a CICS program by using the optimized local adapters JCA connector, the link task joins the local transaction and then starts the target CICS program. Updates that are made in the CICS program are not committed or backed out until the Java Platform, Enterprise Edition application completes the RMLT by using the commit or rollback API.

**Table 122. BBOC.** The following table summarizes BBOC operation names, descriptions, and parameters.

Operation name	Abbreviation	Description	Parameters
START_TRUE	STR	Start the Liberty server TRUE	TRC=<0 1 2> TDQ=<tdqname>
STOP_TRUE	PTR	Stop the Liberty server TRUE	TRC=<0 1 2> TDQ=<tdqname>
REGISTER	REG	Register with the Liberty server WOLA group	RGN=<name> DGN=<name> NDN=<name> SVN=<name> MNC=<minimum_number_of_connections> MXC=<maximum_number_of_connections> SEC=<Y N> TRC=<0 1 2> TDQ=<tdqname> TXN=<Y N>
UNREGISTER		Unregister with the Liberty server optimized local adapters	RGN=<name>

Table 122. BBOC (continued). The following table summarizes BBOC operation names, descriptions, and parameters.

Operation name	Abbreviation	Description	Parameters
START_SRVR	STA	Start the Liberty server task for the passed register name.	RGN=<name> DGN=<name> NDN=<name> SVC=<name> SVN=<name> MNC=<minimum_number_of_connections> MXC=<maximum_number_of_connections> SEC=<Y N> STX=<CICS_link_server_transaction_ID> LTX=<CICS_link_server_transaction_ID> TRC=<0 1 2> TDQ=<tdqname> REU=<Y N> REUC=<number_of_requests> REUT=<number_of_seconds> TXN=<Y N>
STOP_SRVR	STP	Stop the Liberty server task for the register name.	RGN=<name> TRC=<0 1 2> TDQ=<tdqname>

### Sample BBOC commands

The following are samples of BBOC invocations that demonstrate how various tasks and configurations can be accomplished with the CICS adapters program link support.

- Start the adapters CICS TRUE program.  
`bboc start_true`
- Stop the adapters CICS TRUE program.  
`bboc stop_true`
- Register with the name, CICS-HR1, in the WOLA group with names LIB1, LIB2, and LIB3, with 10 maximum connections, 5 minimum connections, and security propagation.  
`bboc register rgn=CICS-HR1 dgn=LIB1 ndn=LIB2 svn=LIB3 mnc=5 mxc=10 sec=y`
- Unregister with the name, CICS-HR1.  
`bboc unregister rgn=CICS-HR1`
- Start a server transaction as BBO\$ for all service and program names under the registration name, CICS PAYR, with a WOLA group with 10 maximum connections, 5 minimum connections, and security propagation.  
`bboc start_srvr rgn=CICSPAYR dgn=LIB1 ndn=LIB2 svn=LIB3 mnc=5 mxc=10 sec=y`
- Stop the BBO\$ server transaction that is running under the registration name, CICS PAYR.

```
bboc stop_srvr rgn=CICSPAYR
```

- Start a server transaction as BBO\$ for the service and program names that start with PAYR under the register name, CICSPAY1, with a WOLA group with 10 maximum connections, 5 minimum connections, and security propagation.

```
bboc start_srvr rgn=CICSPAY1 dgn=LIB1 ndn=LIB2 svn=LIB3 mnc=5 mxc=10 sec=y svc=PAYR*
```

- Start a server transaction under the transaction ID, PAY2, and register with the name, PAYROLL2, for all service and program names in a WOLA group with 10 maximum connections, 5 minimum connections, basic tracing, and security propagation.

```
bboc start_srvr rgn=PAYROLL2 dgn=LIB1 ndn=LIB2 svn=LIB3 mnc=5 mxc=10 sec=y stx=PAY2 trc=1
```

- Start a server transaction under the transaction ID, PAY3, and the link transaction ID of PY3L. Register with the name, PAYROLL3, for service and program names that start with PAYRL3 in a WOLA group with 10 maximum connections, 5 minimum connections, basic tracing, and security propagation.

```
bboc start_srvr rgn=PAYROLL3 dgn=LIB1 ndn=LIB2 svn=LIB3 mnc=5 mxc=10 sec=y svc=PAYRL3*  
stx=PAY3 ltx=PY3L trc=1
```

### Automatically running a BBOC command during CICS startup

Two CICS Program List Table Post-Initialization (PLTPI) programs, BBOACPLT and BBOACPL2, are provided as samples on GitHub. For more information, see “Optimized local adapters samples for Liberty” on page 1691.

- To start the optimized local adapters TRUE when CICS starts, add BBOACLPT as phase 2 or phase 3 entries in your CICS PLT.
- To issue a BBOC command using INITPARM data when CICS starts, add BBOACPL2 as phase 2 or phase 3 entries in your CICS PLT.

You can pass a string of commands up to the CICS limit of 60 characters inside the INITPARM. The following sample INITPARM string calls BBOACPL2 and passes a request to start a link server under the register name PAYROLL, with WOLA group names of LIB1, LIB2, and LIB3. By specifying SVC=\*, this link server receives requests for all service names.

```
INITPARM=(BBOACPL2='STA RGN=PAYROLL DGN=LIB1 NDN=LIB2 SVN=LIB3 SVC=*')
```

The command string can be any BBOC command, such as REG in the following sample INITPARM string. When CICS starts, the string creates a registration under the name LIBAPP that consists of 10 minimum connections and 100 maximum connections.

```
INITPARM=(BBOACPL2='REG RGN=LIBAPP DGN=LIB1 NDN=LIB2 SVN=LIB3 MNC=10 MXC=100')
```

If you create a registration when CICS starts, do not use the Register API in your applications. Instead, immediately use the other APIs, such as Invoke or Connection Get.

**Important:** You can use only one INITPARM string per BBOACPL2 program.

If you use the PLT programs to automatically create a registration or a link server, be sure to unregister or stop the server before you shut down CICS to avoid a delay while CICS cancels any remaining optimized local adapters transactions. You can remove the optimized local adapters resources in the following ways:

- Run BBOC STOP\_SERVER for all CICS link servers or run BBOC URG for all registrations.
- Purge the BBO\$ tasks.
- Write a Program List Table (PLT) shutdown program that runs the EXEC CICS LINK command to BBOACNTL for each link server that passes the STOP\_SERVER string.
- Issue the following command: CEMT P SHUT, IMMED

## Link server transaction for CICS: BBO\$

The BBO\$ CICS transaction supports calls from the Liberty server to CICS. The BBO\$ transaction is a non-workstation transaction that represents an instance of a server task that is started with the BBOC START\_SRVR operation for a certain register name and service name. This server task provides program link invocation capability, which is the ability to start an existing CICS program from the Liberty server over the optimized local adapter APIs.

You can override the name of the transaction, BBO\$, by specifying `STX=name` on the BBOC START\_SRVR command. The new transaction name must be defined to CICS with the same program name and attributes as BBO\$. For more information, see “Optimized local adapter definitions for CICS” on page 1705.

## Program link invocation transaction for CICS: BBO#

The BBO# CICS transaction supports calls from the Liberty server to CICS. The BBO# transaction is a non-workstation transaction that represents an instance of a task that the link server task, BBO\$, starts to invoke a program link. The BBO\$ transaction initiates a BBO# for each CICS program link request from a Liberty server application.

You can override the name of the transaction, BBO#, by specifying `LTX=name` on the BBOC START\_SRVR command. The new transaction name must be defined to CICS with the same program name and attributes as BBO#. For more information, see “Optimized local adapter definitions for CICS” on page 1705. Alternatively, the Liberty server application can pass the new transaction name to CICS using the JCA `setLinkTaskTransid` method.

## Registering an external address space with a local Liberty server using optimized local adapters:

For WebSphere optimized local adapters (WOLA) to make an outbound call to your local optimized local adapter group or an inbound call to a Liberty server, you must bind the current address space to the Liberty server and establish connection attributes using the Register API.

### Before you begin

Enable the Liberty server environment to use WOLA. For more information, see “Enabling the Liberty server environment to use optimized local adapters” on page 1697.

The Liberty server must be active on the same z/OS image that the register request originates from.

If you are using the Customer Information Control System (CICS), enable optimized local adapters support in CICS. For more information, see “Enabling support for Liberty optimized local adapters in CICS” on page 1703. Activate the task-related user exit (TRUE) program before you make a connection between CICS and the Liberty server.

### Procedure

1. Decide which parameters to use when you register the address space using the Register API, BBOA1REG.

The API accepts parameters for the following items:

- The three parts of the WOLA group name that you specified when you added the feature to the `server.xml` file
- The register name
- The minimum number of initial connections
- The maximum number of connections

- Registration flag words to specify tracing behavior

For inbound calls to the Liberty server, a security context that contains the user ID of the address space that makes the request is always propagated to the Liberty server. For CICS, the `reg_flag_C2Wprop` registration flag propagates the user ID of the CICS task rather than the user ID from the address space.

For outbound calls from the Liberty server, the `reg_flag_W2Cprop` registration flag tells the Liberty server to propagate the user ID to CICS. CICS then attempts to start the target program with that user ID.

For more information about API parameters, see “Optimized local adapters APIs on Liberty for z/OS” on page 2079 and “Securing optimized local adapters on Liberty for z/OS” on page 1949.

2. Verify that another optimized local adapter group that this address space is connected to is not already using the selected register name. If the register name is used by another optimized local adapter group, an error return code is passed back, and the register request fails.
3. Call the Register API for your caller from the native-language application in the client address space using the parameters that you selected.  
A 0 return and reason code indicates that the client address space is now bound to the Liberty server.

## Results

The passed register name string is reserved in the current address space. No other register calls can be made with this token until an Unregister API call is received for it.

**Important:** If you use the minimum connections setting on this call, the result is a pool of connections that are pre-established with the target server and wait for requests.

A registration entry context or control block is also created and associated with the register name string. Each unique register name has a register context. Multiple register names with the same address space and thread can bind with one or more Liberty optimized local adapter groups.

## What to do next

You can use the registration to make inbound and outbound calls between the Liberty environment and the external address space. For more information, see “Developing applications that use optimized local adapters on Liberty” on page 2073.

## Administering web applications on Liberty

Liberty provides support to the web applications using Liberty features such as `servlet-3.0`, `servlet-3.1`, `jsp-2.2`, and other features.

### Procedure

Specify when servlets are loaded and initialized.

#### Specifying when servlets are loaded and initialized

By default, Liberty defers servlet loading until a request is received for the associated web application. You can override this default behavior by specifying the web container `deferServletLoad` attribute to `false`.

#### About this task

The servlet specification defines the **load-on-startup** servlet attribute, which is specified in the `web.xml` file of a web application. If a servlet has a non-negative value for the **load-on-startup** attribute, the servlet must be loaded and initialized when the web application is deployed. Liberty optimizes server start time and memory use by not starting a servlet until a request is received for the web application.

You can override this deferral so that your servlets are loaded and initialized when the web application is installed, rather than waiting for the first request for the application.

## Example

To configure the server to load servlets when a web application is installed, add the following line to the `server.xml` configuration file or a file that it includes:

```
<webContainer deferServletLoad="false"/>
```

This setting applies to all web applications installed in the server.

## Configuring Cross Origin Request Sharing on a Liberty server

8.5.5.9

You can enable Cross Origin Request Sharing (CORS) for your web applications on a Liberty server.

### About this task

Enabling CORS will allow JavaScript clients to make requests against your application on the Liberty server even if the client and the server are on two different domains. Web browsers prevent these requests due to same-origin policy.

### Procedure

1. Ensure the server configuration has all features needed for your deployed application, such as `servlet-3.0`, `jaxrs-1.1`, and so on. Also ensure the ports and user registry settings are correct for the deployed application.
2. Add the CORS service setting to the `server.xml` file. The `cors` element defines the CORS settings for the URL being setup in the domain.

### Example

Here is an example of a CORS configuration for a web application at the `sampleApp/path` context root.

```
<cors domain="/sampleApp/path"
  allowedOrigins="https://alice.com:8090"
  allowedMethods="GET, DELETE, POST"
  allowedHeaders="accept, MyRequestHeader1"
  exposeHeaders="MyResponseHeader1"
  allowCredentials="true"
  maxAge="3600" />
```

Here is an example of a CORS configuration for the RESTful endpoint `/ibm/api/collective`. This setting will apply to all the endpoint paths which start with `/ibm/api/collective` including `ibm/api/collective/docs`.

```
<cors domain="/ibm/api/collective"
  allowedOrigins="https://alice.com:8090"
  allowedMethods="GET, DELETE, POST"
  allowedHeaders="accept, MyRequestHeader1"
  exposeHeaders="MyResponseHeader1"
  allowCredentials="true"
  maxAge="3600" />
```

## Configuring Liberty for Servlet 3.1

You can configure Liberty for the Servlet 3.1 feature, which provides full support for the Servlet 3.1 specification.

## About this task

To configure a Liberty server to run an application that is enabled for Servlet 3.1, you must set the `<servlet-3.1>` feature.

## Procedure

Update the `server.xml` file to add the `<servlet-3.1>` feature. For example:

```
<featureManager>
  <feature>servlet-3.1</feature>
</featureManager>
```

### Important:

- The `websocket-1.0` and `websocket-1.1` features require the `servlet-3.1` feature and as a result, configuring the `websocket-1.0` or `websocket-1.1` feature causes the `servlet-3.1` feature to load.
- You can use Java EE 6 features, such as `jsp-2.2` and `jsf-2.0`, with the `servlet-3.1` feature. However, you cannot use a Java EE 6 feature to exploit Servlet 3.1 features.
- You can choose between the Servlet 3.0 and Servlet 3.1 feature implementations for each server instance, but you must consider any behavior changes. If required behavior is contained only in the Servlet 3.1 feature, then you must use the Servlet 3.1 feature. If an existing application would be adversely impacted by behavior changes in the Servlet 3.1 feature, then use the Servlet 3.0 feature to preserve the existing behavior for that application.
- It is not possible to use both the Servlet 3.0 and Servlet 3.1 features in the same Liberty server. If both features are configured, it will produce an error. Read the Servlet 3.1 behavior changes topic to learn about changes from Servlet 3.0 and Servlet 3.1.

## Results

The Servlet-3.1 feature is enabled and loads in the Liberty server at run time.

### Servlet 3.1 behavior changes:

The Servlet 3.1 implementation contains behavior changes that might cause an application that was written for Servlet 3.0 to behave differently or fail when you use the Servlet 3.1 feature.

You can choose between the Servlet 3.0 and Servlet 3.1 feature implementations for each server instance, with consideration for behavior changes. If the required behavior is contained in the Servlet 3.1 feature only, then you must use the Servlet 3.1 feature. If an existing application would be adversely impacted by behavior changes in the Servlet 3.1 feature, then using the Servlet 3.0 feature preserves the existing behavior for that application. It is not possible to use both the Servlet 3.0 and Servlet 3.1 features in the same server. It is an error to configure both features. If you configure both features, neither servlet feature is loaded.

The behavior changes are introduced for three reasons:

- Changes that are required by clarifications in the Servlet 3.1 specification.
- Changes that are required for the Servlet 3.1 implementation to pass the Servlet 3.1 Technology Compatibility Kit (TCK).
- Changes to improve the servlet implementation.

### Programmatically added servlets, filters, and listeners

A clarification from the Servlet 3.1 specification now makes it illegal for a `ServletContextListener` to programmatically configure servlets, filters, or listeners if the `ServletContextListener` was not declared in the `web.xml` file or `web-fragment.xml` file or was not annotated with `@WebListener`. As a result, any call

on the ServletContext to perform such programmatic configuration results in an UnsupportedOperationException.

### **Forward after asynchronous processing is started**

In the Servlet 3.0 implementation, a response is always closed before the forward method of the RequestDispatcher interface returns. However, due to a clarification in the Servlet 3.1 specification, the Servlet 3.1 implementation does not close or flush the response before the forward method of the RequestDispatcher interface returns, if the request is put into the asynchronous mode. This change might affect existing 3.0 applications, which add response output on return from forward because such response data is now sent, whereas in Servlet 3.0, it was not.

### **URL pattern clashes**

In Servlet 3.0, an application would start successfully even when a URL pattern was mapped to multiple servlets. However, due to a clarification in the Servlet 3.1 specification, the application must fail to start. In the Liberty Servlet 3.1 implementation, a message is output and the application fails to start:

```
SRVE9016E: Unable to insert mapping [{0}] for servlet named [{1}]. The URL pattern is already defined for servlet named
```

Explanation: There is an application error. A servlet mapping URL pattern should not map to multiple servlets.

User action: Change the URL pattern for the servlet mapping.

### **ServletContext.getMinorVersion()**

In the Servlet 3.0 feature implementation, this API returns 0.

In the Servlet 3.1 feature this API now returns 1.

### **ServletContext.getServerInfo()**

In the Servlet 3.0 feature implementation, this API returns SMF WebContainer.

In the Servlet 3.1 feature this API now returns IBM WebSphere Liberty/8.5.5.<x>, where <x> is the WebSphere Application Server fix pack number.

### **ServletResponse.reset()**

You can use ServletResponse.reset() to clear any buffered response data, the status code, and response headers when a response is not already committed. If the Servlet 3.1 feature is being used, this method also clears any record of ServletResponse.getWriter() or ServletResponse.getOutputStream() that were previously called.

### **X-Powered-By header**

In the Servlet 3.0 feature implementation, the X-Powered-By header is set to Servlet/3.0. In the Servlet 3.1 feature implementation, the X-Powered-By header is set to Servlet/3.1.

### **Resource reference injection target merging**

In the Servlet 3.0 specification, the <injection-target> elements of a resource reference that is defined in a web-fragment.xml file are added only to the parent web.xml file if the web.xml resource reference definition with the same name has no <injection-target> elements. In the Servlet 3.1 specification, it is clarified that all <injection-target> elements in web-fragment.xml descriptors are added to the parent web.xml descriptors list of <injection-target> elements for a resource reference of the same name. When the Servlet 3.1 feature is in use, this feature might change existing application function by activating

injection targets that were previously excluded from the web.xml file.

### **Tolerance of duplicate elements in web descriptors**

In the Servlet 3.1 specification, it was clarified that a web.xml file cannot contain two <absolute-ordering> elements. Deployment of an application with multiple <absolute-ordering> elements fails. Additionally, web-fragment.xml descriptors cannot contain two <ordering> elements. Deployment of an application with multiple <ordering> elements fails. Previously, the deployment would not fail, but the function of the elements might be indeterminate.

### **Web fragment ordering change in metadata - complete cases**

The processing of the <absolute-ordering> element is changed in cases where a web.xml descriptor is marked metadata-complete="true". Previously in metadata-complete="true" cases, all web fragment archives would be used. When the Servlet-3.1 feature is in use, the <absolute-ordering> element in metadata-complete cases is considered to be complete. This change results in fragments that are not listed in the <absolute-ordering> element to be excluded from processing.

### **AsyncContext.dispatch()**

When AsyncContext.dispatch() is used (for example, with no parameters), the request is dispatched to the original URL. With the Servlet-3.0 feature in use, if a query string was included with the original request, this is made available to the dispatched resource. However, when the Servlet 3.1 feature in use, if a query string was provided to the dispatching resource, it is this query string that is made available to the dispatched resource. For example:

Request for /FirstResource?param=One

First Resource:

```
getParameter("param") returns "One"
forward request to /SecondResource?param=Two
```

SecondResource

```
getParameter(param) returns "Two"
ac.start()
ac.dispatch() dispatches to /FirstResource
```

First Resource

```
Servlet-3.0 feature : getParamter("param") returns "One"
Servlet-3.1 feature : getParameter("param") returns "Two"
```

This change was required by the Servlet 3.1 TCK.

Obtaining the request or response object after an AsyncContext.dispatch() or AsyncContext.complete() is not permitted and results in the following exception being thrown:

```
java.lang.IllegalStateException: SRVE9015E: Cannot obtain the request or response object after an AsyncContext.dispatch() o
at com.ibm.ws.webcontainer31.async.AsyncContext31Impl.getRequest(AsyncContext31Impl.java:72)
[...]
```

### **SessionCookieConfig.setComment()**

According to the Java Servlet 3.1 Specification, this API returns an illegalStateException if it is called after the ServletContext completes initialization, and the Servlet 3.1 feature follows this required behavior. However, the Servlet 3.0 feature does not prevent use of this API after the context is initialized and as a result, applications that depend on the Servlet 3.0 feature behavior will not work with the Servlet 3.1 feature.

### **sendRedirect(java.lang.String location) API**

The sendRedirect(java.lang.String location) API accepts relative URLs; however, the servlet container must convert the relative URL to an absolute URL before it can send the response to the client. If the

location is relative without a leading '/' (folder/default.jsp), the container interprets it as relative to the current request URI. If the location is relative with a leading '/', the container interprets it as relative to the servlet container root.

For example, if the redirection location that is provided by application is folder/default.jsp, with no leading '/', and the inbound request URL is http://host:port/context\_root/folder or http://host:port/context\_root/folder/, the request is redirected to http://host:port/context\_root/folder/folder/default.jsp, which is relative to the current request URI.

This behavior is found in the Servlet 3.0 feature when the `com.ibm.ws.webcontainer.redirectwithpathinfo` property is set to **true**. This property is ignored in the Servlet 3.1 feature and the behavior defaults, as described.

## Default error pages

The IBM extended function is the ability to specify a default error page with a web extension, such as `ibm-web-ext.xml`.

As a function of Servlet 3.0 and higher, default error pages are a modification of the ability to specify error pages. As with normal (non-default) error pages, default error pages are specified in web module descriptors (`web.xml`), and in web fragment descriptors (`web-fragment.xml`).

Normal (non-default) error pages specify either an exception-type or an error-code. A default error page omits both exception-type and error-code. A default error page is used when a servlet throws an exception or sets an error-code result and no configured error page matches the type of the exception or matches the set error code.

The ability to define default error pages is provided by the Servlet 3.0 specification, and is supported by the Servlet 3.0 schemas. Default error pages are error pages that do not contain an **exception-type** or an **error-code** element, according to the Servlet 3.1 specification.

Examples of error pages and default error pages follow.

### Default error page precedence rules

Three rules apply for determining precedence for default error pages in the `web.xml`, `web-fragment.xml`, and `ibm-web-ext.xml` files.

- Rule 1: `web.xml` and `web-fragment.xml` files.

When a default error page is specified in the `web.xml` file, it overrides (masks) any default error page that is specified in a `web-fragment.xml` file. Also, there is no error if, in addition, multiple `web-fragment.xml` files specify default error pages.

- Rule 2: `web-fragment.xml` and `web-fragment.xml`.

When a default error page is not specified in the `web.xml` file, an error condition exists if different default error pages are specified by two or more `web-fragment.xml` files.

- Rule 3: `ibm-web-ext.xml` and `web.xml` or `web-fragment.xml` files.

The rule of precedence between the `ibm-web-ext.xml` file and either the `web.xml` or `web-fragment.xml` files depends on the web container feature level.

When the web container feature level is 3.0, a default error page that is defined by an `ibm-web-ext.xml` file has precedence over a default error page that is defined in `web.xml` or `web-fragment.xml` files.

**Note:** When the web container uses feature level 3.0, you cannot use Servlet 3.1 schemas. Refer to the rule on using default error pages for servlet 3.0 schemas.

When the web container feature level is 3.1 or higher, a default error page that is specified by `web.xml` or `web-fragment.xml` file has precedence over a default error page that is specified in the `ibm-web-ext.xml` file.

## Schema rules

Two rules apply for whether default error pages are processed in `web.xml` or `web-fragment.xml` files. The rules depend on the web container feature version, which Servlet schema is in use, and the setting of a Java custom property.

These rules arose because IBM WebSphere Application Server traditional V8.0, did not support default error pages in the V8.0 general availability release. Support for default error pages was added to WebSphere Application Server traditional, in a service pack, by APAR PM94199.

Support for default error pages was added to WebSphere Application Server Liberty, in a service pack, by APAR PI05845. Because these updates are a change of externally visible function, the new function is disabled by default and must be enabled by a Java system property.

- Rule 1: Default error pages using Servlet 3.0 schema and using web container feature version 3.0.

When the web container feature version is 3.0 and a default error page is specified in `web.xml` or `web-fragment.xml` files that use a Servlet 3.0 schema, the default error pages are processed only if `com.ibm.ws.webcontainer.allowdefaulterrorpage` Java system property is set to **true**. When the Java system property is not set, or is not set to **true**, the default error page is ignored. A default error page that is specified by the `ibm-web-ext.xml` file is used.

- Case 2: Default error pages by using web container feature version 3.1.

When the web container feature version is 3.1 or higher, a default error page that is specified in the `web.xml` file or the `web-fragment.xml` file is always processed, regardless of what servlet schema version is used, and regardless of whether the Java custom property is set.

This case occurs when a descriptor uses a Servlet 3.1 schema, since the processing of a descriptor that uses a Servlet 3.1 schema requires web container feature version 3.1.

**Attention:** Web fragments were not added until Servlet 3.0. The `web-fragment.xml` file has no schema from Servlet 2.5.

## Error page and default error page examples

A default error page that is defined in an `ibm-web-ext.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext xmlns="http://websphere.ibm.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1
  version="1.0">

  <default-error-page uri="/ExtErrorPage.html"/>
</web-ext>
```

An error-code error page element, which is defined in either the `web.xml` file or `web-fragment.xml` file:

```
<error-page>
  <error-code>404</error-code>
  <location>/ErrorCodeErrorPage.html</location>
</error-page>
```

An exception-type error page element, which is defined in either the `web.xml` file or `web-fragment.xml` file:

```
<error-page>
  <exception-type>javax.servlet.ServletException</exception-type>
  <location>/ExceptionTypeErrorPage.html</location>
</error-page>
```

A default error page element, which is defined in either the `web.xml` file or `web-fragment.xml` file:

```

<error-page>
  <location>/DefaultErrorPage.html</location>
</error-page>

```

### Schema examples

Example header of a web.xml file that uses a Servlet 2.5 schema:

```

<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/web-app_2_5.xsd"
  version="2.5">

```

Example header of a web.xml file that uses a Servlet 3.0 schema:

```

<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/web-app_3_0.xsd"
  version="3.0">

```

Example header of a web.xml file that uses a Servlet 3.1 schema:

```

<?xml version="1.0" encoding="UTF-8"?>
<web-app
  xmlns="http://xmlns.jcp.org/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://xmlns.jcp.org/xml/ns/javaee http://xmlns.jcp.org/xml/ns/javaee/web-app_3_1.xsd"
  version="3.1">

```

Example header of a web-fragment.xml file that uses a Servlet 3.0 schema:

```

<?xml version="1.0" encoding="utf-8"?>
<web-fragment xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/web-fragment_3_0.xsd"
  version="3.0">

```

Example header of a web-fragment.xml file that uses a Servlet 3.1 schema:

```

<?xml version="1.0" encoding="utf-8"?>
<web-fragment xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns="http://xmlns.jcp.org/xml/ns/javaee"
  xsi:schemaLocation="http://xmlns.jcp.org/xml/ns/javaee http://xmlns.jcp.org/xml/ns/javaee/web-fragment_3_1.xsd"
  version="3.1">

```

### Servlet 3.1 feature functions:

The product supports a subset of Servlet 3.1 functions. View the clarifications and descriptions of some of the functions available.

Descriptions of the new Servlet 3.1 functions are provided in the specification and are not described here. However, additional considerations for the Servlet 3.1 feature are as follows:

#### Asynchronous I/O

A new feature of the Servlet 3.1 feature specifies that when the non-blocking read is started, any resource during the remaining request lifetime cannot call APIs, which can result in a blocking read. For example, for a POST request after the read listener is set by the resource, any subsequent call to `getParameter()` and `getPart()` API results in an `IllegalStateException`.

You must consider setting timeout with the `AsyncContext.setTimeout` API when you work with async servlets, otherwise the container default value (for example, 30 seconds) is used. The timeout resets each time async starts using the `ServletRequest.startAsync` API is called and expires when the `AsyncContext.complete` API is not called within the timeout period that follows the last time async started. When you use the async I/O support that is provided by the Servlet 3.1 feature, set the timeout

value with the `AsyncContext.setTimeout` API to also allow for async I/O to complete. Completion depends on other external factors, such as environment or network speed.

## Upgrade processing

| **Important:** Use the `ServletOutputStream` class with the `WriteListener` interface and the  
| `ServletInputStream` class with the `ReadListener` interface. Do not use these classes with the  
| `ObjectInputStream` class or the `ObjectOutputStream` class. These classes circumvent some of the required  
| checks for the `ReadListener` and `WriteListener` interfaces, mainly the `isReady` checks, and can cause  
| unexpected behavior.

| Upgrade processing is a Servlet 3.1 feature that has non-blocking read and write capability. When the read or write operations are async, there are no limits on how much time the server waits for the operation to complete. You can set the timeouts with the web container custom properties in the `server.xml` file, such as `upgradereadtimeout` and `upgradewritetimeout`. See the following example of a timeout of 5 seconds:

```
<webContainer upgradereadtimeout="5000" />  
<webContainer upgradewritetimeout="5000" />
```

The request must not be upgraded by using the upgrade feature for Servlet 3.1 when the request is being handled by async servlet.

The application that supports the Servlet 3.1 feature for upgrade requires that the connection on the request remains open between the client and the application that hosts the upgrade. If the application does not initiate the `WebConnection.close()` when the upgrade processing is complete from its handler or any other resources, such as `ReadListener` or `WriteListener`, the TCP connection remains open until the server recycles.

When you use an `UpgradeHandler` and a `ReadListener` from the Servlet 3.1 feature, the `ReadListener.onAllDataRead` method is invoked only when the client closes the connection to the server that hosts the upgraded application. The Javadoc for `onReadListener.onAllDataRead` returns the following message:

Invoked when all data for the current request is read.

In the Upgrade case, the server does not know the end of the data because upgraded data is not delimited the way that HTTP request body data is. Aside from when the client connection closes, there is no determination for the end of the data.

## Form based authentication

After successful authentication, a client is redirected to the resource of the original request. The Servlet 3.1 specification specifies: To improve the predictability of the HTTP method of the redirected request, containers should redirect using the 303 (SC\_SEE\_OTHER) status code, except where interoperability with HTTP 1.0 user agents is required; in which cases the 302 status code should be used. The Servlet-3.1 feature maintains interoperability with HTTP 1.0 user agents and always uses the 302 status code. For more information on configuring Servlet 3.1 for security, read the [Configuring Liberty for Servlet 3.1](#) topic.

## Large post data

The addition of the `ServletRequest.getContentLengthLong()` API requires support for receiving post data of a length greater than `Integer.MAX_VALUE` and cannot be fully accommodated in a single-byte array or string.

This addition has implications when you obtain post data content that use APIs that return content in a string or `byte[]`. For example, the `javax.servlet.ServletRequest` methods for accessing parameters:

```
String getParameter(String name)
String[] getParameterValues()
Map<String,String> getParameterMap()
```

It is possible to send post data that contains multiple parameters, which when combined, have a length of greater than `Integer.MAX_VALUE`. However, each individual parameter name and parameter value must be less than `Integer.MAX_VALUE` in length.

Sending a large amount of post data include these additional considerations:

- You must send post data in chunks of less than `Integer.MAX-VALUE` in length.
- Post data that is processed by the web container, such as parameters or parts, must be fully read before processing starts. The post data might impose significant memory requirements for large post data because it might require as much memory as double the size of the post data in order for web container processing to be successful.

## Configuring Liberty for Expression Language 3.0

8.5.5.5

You can configure Liberty for the Expression Language (EL) 3.0 feature, which provides full support for the EL 3.0 specification.

### About this task

To configure a Liberty server to run an application that is enabled for EL 3.0, you must set the `<el-3.0>` feature.

### Procedure

Update the `server.xml` file to add the `<el-3.0>` feature. For example:

```
<featureManager>
  <feature>el-3.0</feature>
</featureManager>
```

### Important:

- The EL 3.0 feature does not require any additional features. You can configure it independently of JavaServer Pages (JSP) 2.3.
- The JSP 2.3 feature requires the EL 3.0 feature. When you configure the JSP 2.3 feature, the EL 3.0 feature also loads into the server run time.
- You can use other Java EE 6 features, such as JSF 2.0 and CDI 1.0, with the EL 3.0 feature.
- You can choose between EL 3.0 and EL 2.2 (included in the JSP 2.2 feature) for each server instance, but you must consider any behavior changes. If the required behavior is contained only in the EL 3.0 feature, then you must use the EL 3.0 feature. If an existing application would be adversely impacted by behavior changes in the EL 3.0 feature, then use the EL 2.2 feature (included in JSP 2.2) to preserve the existing behavior for that application.
- It is not possible to use both the EL 3.0 feature and JSP 2.2 (includes EL 2.2) features in the same Liberty server. If both features are configured, it produces an error:  
CWWKF0033E: The singleton features com.ibm.websphere.appserver.javax.el-2.2 and com.ibm.websphere.appserver.javax.el-3

See  [8.5.5.5](#) “Expression Language 3.0 feature functions” on page 1722 to learn about changes in the EL 3.0 feature, compared to the EL 2.2 feature.

### Results

The EL 3.0 feature is enabled and loads in the Liberty server at run time.

## Expression Language 3.0 feature functions: 8.5.5.5

The Expression Language (EL) 3.0 feature provides full support for the EL 3.0 specification.

Descriptions of EL 3.0 functions are provided in the EL 3.0 specification and are not fully described here. However, some of the key enhancements include the following:

- EL 3.0 is now available as a separate feature and you can configure it independently of JavaServer Pages (JSP) 2.3.
- Add support for Lambda expressions (value expression with parameters). For more information, see Section 1.20 of the EL 3.0 specification.
- Addition of operations on collections objects. For more information, see Chapter 2.0 of the EL 3.0 specification.
- New operators:
  - String concatenation. For more information, see section 1.8 of the EL 3.0 specification.
  - Assignment. For more information, see section 1.13 of the EL 3.0 specification.
  - Semi-colon. For more information, see section 1.14 of the EL 3.0 specification.
  - Field and Methods. For more information, see Section 1.22 of the EL 3.0 specification.

**Important:** There is a change in the EL 3.0 feature that might break existing applications. The default coercion for nulls to non-primitive types (except String) returns nulls. For example, a null that is coerced to a Double now returns a null value, whereas before it returned 0.0. The following code example describes this scenario:

```
Integer number=null;  
factory.coerceToType(number, java.lang.Double.class)
```

## Configuring Liberty for JavaServer Faces 2.2

8.5.5.6

You can configure Liberty for the JavaServer Faces (JSF) 2.2 feature, which provides full support for the JSF 2.2 specification.

### About this task

The Liberty JSF implementation is based on the MyFaces open source implementation. To configure a Liberty server to run an application that is enabled for JSF 2.2, you must set the <jsf-2.2> feature.

### Procedure

Update the `server.xml` file to add the <jsf-2.2> feature. For example:

```
<featureManager>  
  <feature>jsf-2.2</feature>  
</featureManager>
```

### Important:

Consider the following points when you use JavaServer Faces 2.2:

- JSF 2.2 feature does not implicitly load the bean validation feature like the JSF 2.0 feature does. When you migrate your application from JSF 2.0 to JSF 2.2, and your application uses bean validation, you must also enable the `beanValidation-1.1` feature.
- The JSF 2.2 feature requires the `servlet-3.1`, `jsp-2.3`, `timedexit-1.0`, and `el-3.0` features. When the JSF 2.2 feature is enabled in the `server.xml` file, each of these features is also enabled.
- You cannot run the JSF 2.2 feature with Java EE 6 features; for example, `servlet-3.0`, `jsp-2.2` and `cdi-1.0`.

- You can choose between the JSF 2.0 and JSF 2.2 feature implementations for each server instance, but you must consider any behavior changes. If the required behavior is contained only in the JSF 2.2 feature, then you must use the JSF 2.2 feature. If an existing application would be adversely impacted by behavior changes in the JSF 2.2 feature, then use the JSF 2.0 feature to preserve the existing behavior for that application.
- It is not possible to use both the JSF 2.0 and JSF 2.2 features in the same Liberty server. If both features are configured, it produces an error:  
CWWKF0033E: The singleton features jsf-2.0 and jsf-2.2 cannot be loaded at the same time. The configured features jsf-2.0 and jsf-2.2 cannot be loaded at the same time.
- JSF 2.2 is compatible with earlier releases, such as JSF 2.1 and JSF 2.0; however, consider the following exceptions:
  - An error in previous versions of the JSF specification caused exceptions to be swallowed that now are propagated to the exception handler. Read Backward Compatibility with Previous Versions in the overview section of the JSF 2.2 specification.
  - Changes made to the specification for Composite Component Attribute ELResolver and Composite Component Metadata. Read Backward Compatibility with Previous Versions in the overview section of the JSF 2.2 specification.

## Results

The JSF 2.2 feature is enabled and loads in the Liberty server at run time.

## What to do next

To use the FlowBuilder API to create Flows with FlowBuilder annotations, it is required that the relevant CDI producer method is declared within a managed bean or a session bean class. To ensure that the class is managed correctly by CDI, define the producer method class as a managed bean (by giving it a scope), or set CDI bean-discovery-mode to all. You can set the CDI bean-discovery-mode to all in the beans.xml file in your web archive:

```
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://xmlns.jcp.org/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://xmlns.jcp.org/xml/ns/javaee http://xmlns.jcp.org/xml/ns/javaee/beans_1_1.xsd"
  bean-discovery-mode="all">
</beans>
```

## JavaServer Faces 2.2 feature functions: 8.5.5.6

The JavaServer Faces (JSF) 2.2 feature provides full support for the JSF 2.2 specification.

Descriptions of JSF 2.2 functions are provided in the JSF 2.2 specification and are not fully described here. However, some of the key enhancements are as follows:

- Faces Flows enables developers to logically group JSF views to represent modules of functions. Each module has a well-defined set of entry and exit points. Combining modules creates a flow of functions. An example of a flow of functions is an order checkout process. Read section 7.5 of the JSF 2.2 specification.
- Resource Library Contracts enable resource libraries to reside in the contracts directory of the web-app root directory, or in the META-INF/contracts entry name in the JAR file. Read section 10.1.3 of the JSF 2.2 specification.
- JSF 2.2 introduced the ability for applications to use stateless views. Read section 7.8.1.1 of the JSF 2.2 specification.
- JSF 2.2 can handle HTML5 attributes through pass-through elements and pass-through attributes. Read section 10.1.4 of the JSF 2.2 specification.

## Configuring Liberty for JavaServer Pages 2.3

8.5.5.5

You can configure Liberty for the JavaServer Pages (JSP) 2.3 feature, which provides full support for the JSP 2.3 specification.

### About this task

To configure a Liberty server to run an application that is enabled for JSP 2.3, you must set the `<jsp-2.3>` feature.

### Procedure

Update the `server.xml` file to add the `<jsp-2.3>` feature. For example:

```
<featureManager>
  <feature>jsp-2.3</feature>
</featureManager>
```

### Important:

- The `jsp-2.3` feature requires both the `servlet-3.1` and `el-3.0` features and when configured, causes these features to load.
- You cannot use `jsp-2.3` with the `servlet-3.0` feature.
- You can use other Java EE 6 features, such as JSF 2.0 and CDI 1.0, with the JSP 2.3 feature.
- You can choose between the JSP 2.2 and JSP 2.3 feature implementations for each server instance, but you must consider any behavior changes. If the required behavior is contained only in the JSP 2.3 feature, then you must use the JSP 2.3 feature. If an existing application would be adversely impacted by behavior changes in the JSP 2.3 feature, then use the JSP 2.2 feature to preserve the existing behavior for that application.
- It is not possible to use both the JSP 2.2 and JSP 2.3 features in the same Liberty server. If both features are configured, it produces an error:

CWWKF0033E: The singleton features jsp-2.3 and jsp-2.2 cannot be loaded at the same time. The configured features jsp-2.3

8.5.5.5

“JavaServer Pages 2.3 feature functions” to learn about changes in the JSP 2.3 feature.

### Results

The JSP 2.3 feature is enabled and loads in the Liberty server at run time.

### JavaServer Pages 2.3 feature functions: 8.5.5.5

The JavaServer Pages (JSP) 2.3 feature provides full support for the JSP 2.3 specification.

Descriptions of the new JSP 2.3 functions are provided in the JSP 2.3 specification and are not described here. However, the new specification additions are minor, as compared to the JSP 2.2 feature:

- Support for Expression Language (EL) 3.0
- Availability of Servlet 3.1 APIs to a JSP.
- There are no known behavior differences between JSP 2.2 and JSP 2.3 that directly prevent a JSP that runs with JSP 2.2 from successfully running with JSP 2.3. However, if a JSP uses Expression Language (EL) or Servlet API functions, you must consider the changes between Servlet 3.1 and Servlet 3.0, and between EL 3.0 and EL 2.2.

# Administering Contexts and Dependency Injection applications on Liberty

8.5.5.6

Liberty provides support for contexts and dependency injection in applications using the Liberty features `cdi-1.0` and `cdi-1.2`.

## Procedure

-  [8.5.5.6](#) “Configuring Liberty for Contexts and Dependency Injection 1.2”
-  [8.5.5.6](#) “Contexts and Dependency Injection 1.2 overview”
-  [8.5.5.6](#) “Contexts and Dependency Injection 1.2 behavior changes” on page 1726

## Configuring Liberty for Contexts and Dependency Injection 1.2

8.5.5.6

You can configure Liberty for the Contexts and Dependency Injection (CDI) 1.2 feature, which provides full support for the Contexts and Dependency Injection 1.2 specification.

### About this task

To configure the Liberty server to run an application that is enabled for CDI 1.2, you must set the `<cdi-1.2>` feature.

## Procedure

Update the `server.xml` file to add the `<cdi-1.2>` feature. For example:

```
<featureManger>
  <feature>cdi-1.2</feature>
</featureManger>
```

### Note:

- You can use other Java EE 7 features, such as `jsp-2.3` and `jsf-2.2` with the `cdi-1.2` feature. However, you cannot use Java EE 6 features such as `jsp-2.2` and `jsf-2.0` with the `cdi-1.2` feature.
- You can choose between the CDI 1.0 and CDI 1.2 feature implementations for each server instance, but you must consider the behavior changes. If the behavior is only contained in the CDI 1.2 feature, then you must use the CDI 1.2 feature. If an existing application might be adversely impacted by behavior changes in the CDI 1.2 feature, then use the CDI 1.0 feature to preserve the existing behavior for that application.
- It is not possible to use both the CDI 1.0 and CDI 1.2 features in the same Liberty server. If both features are configured, it produces an error. Read the CDI 1.2 behavior changes topic to learn about changes from CDI 1.0 to CDI 1.2.

## Results

The CDI 1.2 feature is enabled and loads in the Liberty server at run time.

## Contexts and Dependency Injection 1.2 overview

8.5.5.6

Liberty provides support for contexts and dependency injection in applications by using the Liberty features `cdi-1.0` and `cdi-1.2`.

The Contexts and Dependency Injection (CDI) 1.2 feature provides full support for the CDI 1.2 specification. Full descriptions of the CDI 1.2 functions are provided in the CDI 1.2 specification, see Contexts and Dependency Injection for the Java EE platform.

The set of services that are provided by the CDI 1.2 feature includes a well-defined lifecycle for stateful objects that are bound to lifecycle contexts and a typesafe dependency injection mechanism.

### **Using Contexts and Dependency Injection 1.2 with JavaServer Faces applications**

You can use the CDI 1.2 feature with the JavaServer Faces (JSF) 2.2 feature to enable JSF applications to take advantage of the sophisticated context and dependency injection model that is provided in the CDI 1.2 feature. This service is provided through integration with the Unified Expression Language (EL) which enables any contextual object to be used directly within a JSF or JavaServer Pages (JSP) page.

### **Using Contexts and Dependency Injection 1.2 with Enterprise JavaBeans (EJB)**

You can use the CDI 1.2 feature with the Enterprise JavaBeans (EJB) 3.2 feature to enhance the EJB component model with contextual lifecycle management. The services that are provided by the CDI 1.2 feature integrate the Java EE web tier with Java EE enterprise services. In particular, this enables EJB components to be used as JSF managed beans, thus integrating the programming models of EJB and JSF.

### **Using Contexts and Dependency Injection 1.2 with Servlet 3.1**

You can use the CDI 1.2 feature with the Servlet 3.1 feature to enable servlet applications to take full advantage of the services that are provided by the CDI 1.2 feature. Using both features enables contextual managed beans to be injected into servlet applications by using field, method or constructor injection. The CDI 1.2 feature also provides automatic registration of servlet listeners, filters, and interceptors.

### **Java Interceptors in Contexts and Dependency Injection 1.2 Applications**

The CDI 1.2 feature extends the Java model for interceptors. The CDI 1.2 feature provides the ability to associate interceptors with beans. The interceptors are bound by using typesafe interceptor bindings. This model can be extended to EJB beans when both the CDI 1.2 and EJB 3.2 features are loaded onto the Liberty server.

### **Contexts and Dependency Injection 1.2 behavior changes**

8.5.5.6

The Contexts and Dependency Injection (CDI) 1.2 implementation contains some behavior changes that might cause an application that was migrated from CDI 1.0 to behave differently or fail on CDI 1.2.

You can choose between the CDI 1.0 and CDI 1.2 feature implementations for each server instance, with consideration for behavior changes. If the required behavior is contained in the CDI 1.2 feature only, then you must use the CDI 1.2 feature. If an existing application might be adversely impacted by behavior changes in the CDI 1.2 feature, then by using the CDI 1.0 feature the existing behavior is preserved for that application. It is not possible to use both the CDI 1.0 and CDI 1.2 features in the same server as the features are not compatible. If you configure both features, the server produces a configuration error.

The CDI 1.0 feature is built on Apache OpenWebBeans implementation of CDI. The CDI 1.2 feature is built on the Weld implementation of CDI. The behavior changes introduced are due to the differences in the two implementations.

## The conversation ID CID

In the CDI 1.0 implementation, the CID is globally unique. In CDI 1.2, it is unique per HTTP session. This behavior is in line with the CDI specification and is a convention that is chosen by the Weld. To get a globally unique CID, the CID must be specified at conversation start by calling `Conversation.begin`.

## Referencing schemas in the beans.xml file

In a CDI 1.2 implementation, here is an example of a schema that is referenced in the beans.xml file:

```
xmlns="http://xmlns.jcp.org/xml/ns/javaee"  
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"  
xsi:schemaLocation="http://xmlns.jcp.org/xml/ns/javaee http://xmlns.jcp.org/xml/ns/javaee/beans_1_1.xsd"
```

If you use an invalid schema, the server gives an exception error. You can turn off the validation of the beans.xml file by setting the `org.jboss.weld.xml.disableValidating=true` JVM property, which also prevents the error from being produced. If the beans.xml file specifies decorators or interceptors, a valid schema must be used, otherwise the decorators and interceptors are not correctly instantiated.

## Implicit bean archives

The CDI 1.2 implementation defines two different types of bean archives: explicit and implicit.

An explicit bean archive is an archive that contains a beans.xml file:

- with a version number of 1.1 (or later), and with the bean-discovery-mode of all
- with no version number
- that is an empty file

An implicit bean archive is any other archive, which contains one or more bean classes with a bean defining annotation as defined in the specification in Section 2.5.1, "Bean defining annotations", or one or more session beans. See the specification, Contexts and Dependency Injection for the Java EE platform.

When you update the schema to a CDI 1.2 implementation, to keep the bean archive as explicit the bean discovery mode must be set to all:

```
<beans xmlns="http://xmlns.jcp.org/xml/ns/javaee"  
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"  
xsi:schemaLocation="http://xmlns.jcp.org/xml/ns/javaee  
http://xmlns.jcp.org/xml/ns/javaee/beans_1_1.xsd"  
bean-discovery-mode="all"  
version="1.1">
```

**Note:** An implicit bean archive discovers only beans that have a bean defining annotation.

This new type of bean archive can result in an archive that is not intended to be a CDI bean archive but it becomes an implicit bean archive in the CDI 1.2 implementation. To stop this behavior, you can add a beans.xml file with the bean discovery mode set to none, preventing the archive from being a bean archive. An alternative solution is to add the following property to the server.xml file for your Liberty server:

```
<cdi12 enableImplicitBeanArchives="false"/>
```

Setting this property to false prevents the archives without beans.xml files from becoming implicit bean archives.

Setting this property to false gives an improved performance at startup time.

# Administering Session Initiation Protocol (SIP) on Liberty

8.5.5.7

You can configure SIP on Liberty by adding and configuring elements in the `server.xml` file.

## Before you begin

Install the `sipServlet-1.1` feature in your Liberty server. For more information, see “Adding and removing Liberty features” on page 1587.

## About this task

8.5.5.7 This task describes how to manually configure SIP for Liberty in your `server.xml` file. Alternatively, you can configure SIP by using the developer tools, which automatically enable all configurations in the `server.xml` file. For more information, see [WebSphere Developer Tools > Developing > Developing SIP applications](#).

For information about the elements and attributes that you can use to configure SIP on Liberty, see the documentation for `SipServlet-1.1`.

## Procedure

1. In the `server.xml` file, configure the SIP container by adding a `sipContainer` element. For a full list of attributes and their descriptions, see `sipContainer` element.

```
<sipContainer invalidateSessionOnShutdown="true" msgArrivalTimeAttr="true" markInternalResponse="true"></sipContainer>
```

2. Configure the SIP stack by adding a `sipStack` element. You can configure behavior such as automatic responses, message information, and connection reuse.

For a full list of attributes and their descriptions, see `sipStack` element.

```
<sipStack hideMessageBody="true" hideMessageReqUri="true"
  auto100nInvite="false" auto4820nMergedRequests="true"
  forceConnectionReuse="false" acceptNonUtf8Bytes="true"
  pathMtu="1600" compactHeaders="API">
  <commaSeparatedHeaders>Comma separated headers</commaSeparatedHeaders>
  <hideMessageHeaders>iup</hideMessageHeaders>
  <sipQuotedParameters>Require</sipQuotedParameters>
</sipStack>
```

SIP timers provide a mechanism for session expiration. You can set values for the SIP timers that are different from default values that are specified in RFC 3261 by specifying the timer attributes on the `sipStack` element.

```
<sipStack timerT1="500" timerT2="4000" timerT4="5000" timerA="500" timerB="32000" timerD="32000"
  timerE="500" timerF="32000" timerG="500" timerH="32000" timerI="5000" timerJ="32000" timerK="5000"></sipStack>
```

3. Configure the SIP application router by adding a `sipApplicationRouter` element. When you configure a SIP application router, you can either use the default application router (DAR) or create a custom application router. The DAR component uses a configuration text file that is modeled as a Java properties file to define the order in which the application router sends SIP requests to applications.

If you do not configure an application router and are manually deploying your applications, applications are triggered in the order that the applications were deployed. If you deploy multiple applications through the `server.xml` file, you cannot define the application order.

- To use the DAR component with a DAR configuration file, specify the location of the DAR .properties file on the `sipDarConfiguration` attribute of the `sipApplicationRouter` element.

```
<sipApplicationRouter sipDarConfiguration="pathToDar.properties"></sipApplicationRouter>
```

- To use a custom application router, configure the router in the `server.xml` file:
  - a. Add the `bells-1.0` feature to the `server.xml` file.

```
<featureManager>
  <feature>bells-1.0</feature>
</featureManager>
```

For more information, see the documentation for bells-1.0.

- b. In the server.xml file, add your custom application router JAR file as a shared library and add the bell configuration for the javax.servlet.sip.ar.spi.SipApplicationRouterProvider service.

```
<library id="carLib" name="carLib" description="Custom App Router Library">
  <file name="pathToJar.jar"></file>
</library>
<bell libraryRef="carLib">
  <service>javax.servlet.sip.ar.spi.SipApplicationRouterProvider</service>
</bell>
```

For more information about shared libraries, see “Liberty: Shared libraries” on page 2254

- c. On the sipApplicationRouter element, set the carProvider attribute to the full name of the custom application router provider class.

```
<sipApplicationRouter carProvider="example.example"></sipApplicationRouter>
```

You can specify the error response code that the SIP container sends if no active servlet can be mapped to an incoming initial request by adding the sipNoRouteErrorCode attribute to the sipApplicationRouter element.

```
<sipApplicationRouter carProvider="example.example" sipNoRouteErrorCode="403"></sipApplicationRouter>
```

For a full list of attributes and their descriptions, see sipApplicationRouter element.

4. Configure the SIP endpoints by adding a sipEndpoint element. You can configure custom ports, hosts, and binding behavior. Any SIP endpoint that you configure overrides the default endpoint. For a full list of attributes and their descriptions, see sipEndpoint element.

```
<sipEndpoint host="localhost" sipTCPPort="5060" bindRetries="60" bindRetriesDelay="5000"></sipEndpoint>
```

**Note:** Transport Layer Security (TLS) is disabled by default. To enable TLS for your SIP container, enable and configure SSL communication for your Liberty server. For more information, see “Enabling SSL communication in Liberty” on page 1834.

5. Configure SIP performance by adding a sipTasksDispatcher element. You can configure the number of SIP tasks that can be run concurrently. A SIP application task is a sequence of application code that is serially executed on the SIP container on a single thread. For example, the application implementation of a SipServlet.doInvite() method or a SipTimerListener.timeout() method are each considered a single task if the application code that is called from these methods is executed serially on a managed Liberty thread that is provided by the container. The actual maximum number of concurrent SIP tasks is limited by the maximum number of managed Liberty threads.

For a full list of attributes and their descriptions, see sipTasksDispatcher element.

```
<sipContainer>
  <sipTasksDispatcher concurrentContainerTasks="15"/>
</sipContainer>
```

6. If you want to resolve SIP URIs by using Domain Name System (DNS) Naming Authority Pointer (NAPTR) records, configure a domain resolver.
  - a. Add and configure a domainResolver element. If you configure this element, SIP URIs are resolved through DNS into the IP address, port, and transport protocol of the next hop to contact.

**Note:** SIP does not support use of DNS procedures for a server to send a response to a back-up client if the primary client fails.

For a full list of attributes and their descriptions, see domainResolver element.

```
<domainResolver dnsAutoResolve="true">
  <dnsServers>dns.server.com</dnsServers>
</domainResolver>
```

- b. Configure your DNS server to work with the SIP container. The following example is a BIND db file for configuring RFC 3263 support on a DNS server.

```

**8.5.7** For information about performing DNS lookups in your SIP applications, see “Performing DNS lookups in Session Initiation Protocol (SIP) applications on the Liberty profile” on page 2131.

## Administering JavaMail on Liberty

**8.5.6**

You can configure JavaMail on Liberty by adding and configuring elements in the `server.xml` file.

### About this task

If you have an external mail server, you can use the JavaMail API to send and receive email on applications that are running on a Liberty server. The API allows applications to interact with the external mail server by providing common store and transport protocols, such as POP3, IMAP, and SMTP.

Liberty supports JavaMail 1.5. For more information about JavaMail 1.5, see the JavaMail API documentation.

For information about the elements and attributes that you can use to configure JavaMail on Liberty, see “JavaMail 1.5” on page 923.

## Procedure

1. In the `server.xml` file, add the `javaMail-1.5` feature. After you add the feature, you can call the JavaMail libraries in any application that runs on the server.  

```
<featureManager>
  <feature>javaMail-1.5</feature>
</featureManager>
```
2. Optional: If you want to create a `javax.mail.Session` object, add and configure a `mailSession` element. After the mail session is configured, the session is created and injected by using the Java Naming and Directory Interface (JNDI).

**Note:** If you use the standard JNDI context, `java:comp/env/mail/exampleMailSession`, configure the `jndiName` attribute as `jndiName="mail/exampleMailSession"`.

```
<mailSession mailSessionID="examplePop3MailSession"
  jndiName="ExampleApp/POP3Servlet/exampleMailSession"
  description="POP3 javax.mail.Session"
  storeProtocol="pop3"
  transportProtocol="smtp"
  host="exampleserver.com"
  user="iamaexample@example.com"
  password="example"
  from="smtp@testserver.com">
  <property name="mail.pop3.host" value="pop3.example.com" />
  <property name="mail.pop3.port" value="3110" />
</mailSession>
```

## Administering Liberty on z/OS

z/OS

On the z/OS platform you can start, stop, or modify Liberty by using MVS operator commands.

### Before you begin

Ensure that the following security profiles are set up as described in “Enabling z/OS authorized services in Liberty for z/OS” on page 1942.

- STARTED profiles for the server process, and the angel process
- SERVER profiles to allow access to authorized z/OS services

**Attention:** Each LPAR has one angel process. An angel started at service level 8.5.5.2 or later can coexist with other Liberty for z/OS servers that also use an angel at service level 8.5.5.2 or later. For multiple Liberty for z/OS servers that are running on the same LPAR with service levels before and after 8.5.5.2 that require an angel process, an angel at 8.5.5.2 or later will need to be started first to ensure proper operation of the angel process.

### About this task

This topic describes how to start, modify, and stop Liberty by using the MVS console. You can also start and stop the server from a shell, or use a shell to start the server as a started task, see “Starting and stopping a server from the command line” on page 1584.

A started task is JCL that is run immediately in response to an operator START command. Two JCL procedure templates (PROCs) are available in the `wlp/templates/zos/procs` directory. One template is for the server process, and the other is for the angel process:

- `bbgzsrv` for Liberty.

- bbgzangl for the angel process that is required for controlling access to system authorized services on the z/OS platform.

Administrators can copy the templates to a user location, and then customize them to start Liberty servers from the MVS console.

**Note:** Files in the /templates directories might be modified when product updates are applied. The examples section provides further information about the two PROC templates.

The target of an operator STOP command is a job or a started task.

After the JCL procedure templates are customized, they must be placed into the system procedure library concatenation. The name of the procedure member becomes the argument to the START command.

## Procedure

- To start a process, use the START (s) command for the appropriate proc:
  - START bbgzsrv to start the bbgzsrv proc for the server process
  - START bbgzangl to start the bbgzangl proc for the angel process
- To modify Liberty, use the MODIFY command. See the following topics:
  - “Liberty: Modify Commands on z/OS” on page 1734
  - “Liberty profile: Process types on z/OS” on page 1019
- To stop a process, use the STOP (p) command for the appropriate proc:
  - STOP bbgzsrv to stop the bbgzsrv proc
  - STOP bbgzangl to stop the bbgzangl proc

## Example

The following example shows the procedure template for the server process (bbgzsrv). This PROC is in a data set in the z/OS proclib concatenation.

```
//BBGZSRV PROC PARMS='defaultServer'
/*-----
/* INSTDIR - the path to the WebSphere Liberty install.
/*          This path is used to find the product code and is
/*          equivalent to the WLP_INSTALL_DIR environment variable
/*          in the Unix shell.
/* USERDIR - the path to the WebSphere Liberty user area.
/*          This path is used to store shared and server specific
/*          configuration information and is equivalent to the
/*          WLP_USER_DIR environment variable in the Unix shell.
/*-----
// SET INSTDIR='/u/MSTONE1/wlp'
// SET USERDIR='/u/MSTONE1/wlp/usr'
/*-----
/* Start the Liberty server
/*
/* WLPUDIR - PATH DD that points to Liberty's "user"
/*          directory. If the DD is not allocated, the user
/*          directory location defaults to the wlp/usr directory
/*          in the install tree.
/* STDOUT - Destination for stdout (System.out)
/* STDERR - Destination for stderr (System.err)
/* MSGLOG - Destination for messages.log (optional)
/* STDENV - Initial Unix environment - read by the system. The
/*          installation default and server specific server
/*          environment files will be merged into this environment
/*          before the JVM is launched.
/*-----
```

```

//STEP1 EXEC PGM=BPXBATSL,REGION=0M,
// PARM='PGM &INSTDIR./lib/native/zos/s390x/bbgzsrv &PARMS'
//WLPUDIR DD PATH='&USERDIR.'
//STDOUT DD SYSOUT=*
//STDERR DD SYSOUT=*
//*MSGLOG DD SYSOUT=*
//*STDENV DD PATH='/etc/system.env',PATHOPTS=(ORDONLY)
//*STDOUT DD PATH='&ROOT/std.out',
//* PATHOPTS=(OWRONLY,OCREAT,OTRUNC),
//* PATHMODE=SIRWXU
//*STDERR DD PATH='&ROOT/std.err',
//* PATHOPTS=(OWRONLY,OCREAT,OTRUNC),
//* PATHMODE=SIRWXU

```

### Notes:

- The launcher uses the STDENV DD as the initial environment, but this DD is optional. The initial environment to the process is defined in the PROC. It can point to any type of data set that LE supports, but the format must be compatible with what is expected. For example, EBCDIC, simple key=value with no expansion.
- A PATH DD that points to an existing directory (not a file) is allowed. If that DD is opened, the FILE stream that is returned is valid for fldata so the HFS path that is associated with the DD can be used. The PROC template defines a WLPUDIR PATH DD that represents the equivalent of WLP\_USER\_DIR.
- The WLP\_USER\_DIR is determined by the following logic:
  - If the WLPUDIR DD is defined, the associated path is used as WLP\_USER\_DIR
  - If WLPUDIR is not defined but WLP\_USER\_DIR is set in the initial environment (from STDENV), it is used
  - If WLPUDIR is not defined and WLP\_USER\_DIR is not set in the initial environment, the default value of \$WLP\_INSTALL\_DIR/usr is used
- The environment is determined by the following logic:
  - If the STDENV DD is defined, it is read by LE as the initial environment. If you want to set the \_BPX\_BATCH\_UMASK environment variable, it must be set here in the STDENV DD.
  - If \$WLP\_INSTALL\_DIR/etc/server.env exists and is readable, its key=value contents are read and set into the environment. The file can be in ASCII or EBCDIC. Comments start with a '#' and go to the end of the line. Values that contain white space can be placed in double quotation marks. Any environment entries that are specified in this file overrides entries from the initial environment
  - If \$WLP\_USER\_DIR/servers/{serverName}/server.env exists and is readable, its key=value contents are read and set into the environment. This file can also be in ASCII or EBCDIC and supports comments. Any entries that are specified here override entries from the initial environment and the etc/server.env.
  - Regardless of the user specified environment, the following entries are explicitly set: \_BPXK\_WLM\_PROPAGATE=NO, JAVA\_THREAD\_MODEL=HEAVY, and JAVA\_PROPAGATE=NO. If \_EDC\_PTHREAD\_YIELD is not set, it is set to -2.
- After the environment is set, the JAVA\_HOME is determined by the following logic:
  - If JAVA\_HOME is set in the environment, its location is used as JAVA\_HOME
  - If JAVA\_HOME is not set in the environment but \$WLP\_INSTALL\_DIR/./java64 exists, \$WLP\_INSTALL\_DIR/./java64 is used as JAVA\_HOME
  - If JAVA\_HOME is not set in the environment and \$WLP\_INSTALL\_DIR/./java64 does not exist, \$WLP\_INSTALL\_DIR/./java is used as JAVA\_HOME
- After JAVA\_HOME is determined, JVM command line options are determined by the following logic:
  - If \$WLP\_USER\_DIR/servers/{serverName}/jvm.options exists and is readable, its contents are read. The file can be in ASCII or EBCDIC and each line of the file should be a single java command line argument. Comments start at a '#' and go to the end of the line

- If \$WLP\_USER\_DIR/servers/{serverName}/jvm.options does not exist but \$WLP\_INSTALL\_DIR/etc/jvm.options exists and is readable, its contents are read. The file can be in ASCII or EBCDIC and must have one java command line argument per line. Comments are supported
- Regardless of the contents of any jvm.options, -Dfile.encoding=iso8859-1, -javaagent:\$WLP\_INSTALL\_DIR/lib/bootstrap-agent.jar, and -classpath \$WLP\_INSTALL\_DIR/lib/server-launcher.jar are on the command line
- If you want to pass arguments to the JVM, define the JAVA\_OPTS DD statement so that Java command line arguments are then read from this DD. The following example shows a sample input file:
 

```
-Xmx512m
-Xms256m
-Daaa.bbb.ccc=something.forsomeone
```
- When a Liberty server is started from a proc, the server validates that it is not running with a umask of 000. If it detects that the umask is 000, it overrides it with a value of 022.

The following example shows the command that you would use to start Liberty by using the sample bbgzsrv proc for a configured "defaultServer":

```
start bbgzsrv,parms='defaultServer'
```

The following example shows the procedure template for the angel process (bbgzangl):

```
//BBGZANGL PROC PARMS='',COLD=N
/*-----
// SET ROOT='/u/MSTONE1/wlp'
/*-----
/* Start the Liberty angel process
/*-----
//STEP1 EXEC PGM=BPXBATA2,REGION=0M,
// PARM='PGM &ROOT./lib/native/zos/s390x/bbgzangl COLD=&COLD &PARMS'
//STDOUT DD SYSOUT=*
//STDERR DD SYSOUT=*
```

## Liberty: Modify Commands on z/OS

z/OS

On the z/OS platform, you can modify Liberty by using MVS operator commands that are supported by a Liberty server process or that are supported by the Angel process.

### MODIFY commands that are supported by a Liberty server process

#### Trace enablement

The following example shows the **MODIFY** command to enable tracing for the specified Liberty server:

```
MODIFY [jobname.]identifier,LOGGING='<trace_specification>'
```

Substitute the value *trace\_specification* for a valid trace specification. For more information, see *Liberty: Logging and Trace*.

#### SVC dumps

To start an SVC dump, the server must be authorized with read access to the BBG.AUTHMOD.BBGZSAFM.ZOSDUMP resource profile in the SERVER class. The following example shows sample RACF commands for authorizing the server, where <userid> is the user ID assigned to the server:

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.ZOSDUMP UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.ZOSDUMP CLASS(SERVER) ACCESS(READ) ID(<USERID>)
SETR RACLIST(SERVER) GENERIC(SERVER) REFR
```

The following example shows the **MODIFY** command to request an SVC dump from the specified Liberty server:

```
MODIFY [jobname.]identifier,svcdump
```

### 8.5.5.2 Java heap dumps

The following example shows the **MODIFY** command to request a Java virtual machine (JVM) heap dump from the specified Liberty server:

```
MODIFY [jobname.]identifier,HEAPDUMP
```

### 8.5.5.2 Java core dumps

The following example shows the **MODIFY** command to request a JVM core dump from the specified Liberty server:

```
MODIFY [jobname.]identifier,JAVACORE
```

### 8.5.5.2 Server dumps

The following example shows the **MODIFY** command to request a server dump from the specified Liberty server:

```
MODIFY [jobname.]identifier,DUMP[,INCLUDE=<JAVA_DUMP_1>,<JAVA_DUMP_2>,...]
```

The **INCLUDE** parameter is optional. If the **INCLUDE** parameter is specified, any Java dumps that are listed on the **INCLUDE** parameter are requested and included in the server dump package. The following Java dump types are valid:

- THREAD for a Java core dump
- HEAP for a Java heap dump

## MODIFY commands that are supported by the Angel process

### Code version

The following example shows the **MODIFY** command to display the version of Angel code that is loaded:

```
MODIFY [jobname.]identifier,VERSION
```

### Enable or disable tracing

The following example shows the **MODIFY** command to enable or disable tracing for the Angel code:

```
MODIFY [jobname.]identifier,TRACE=[Y|N]
```

Select Y to enable tracing, or select N to disable tracing.

### Display servers

The following example shows the **MODIFY** command to display a list of servers that are currently connected to the Angel code:

```
MODIFY [jobname.]identifier,DISPLAY,SERVERS
```

## Liberty: APIs for z/OS command processing support

z/OS

The CommandHandler and ModifyResults application programming interfaces (APIs) are available for z/OS command processing support.

### com.ibm.ws.zos.command.processing.CommandHandler.java

The CommandHandler interface is the service that the command processing component looks for (by using the OSGi Whiteboard pattern). The command processing code will deliver any z/OS command string that matches its filter.

A z/OS modify command has the following format:

```
MODIFY <jobname.>identifier,command
```

The command value is matched against the **modify.filter.regex** property. The property value is treated as a regular expression.

For example, commands can be directed to the started job by issuing a z/OS modify command:

```
"MODIFY <jobname.>identifier,<cmdverb1>,<parm1>,<parm2>,( <moreInfo1>)
```

The **modify.filter.regex** property matches the value for the `<cmdverb1>,<parm1>,<parm2>,( <moreInfo1>)` command string. When the server receives the command, all currently registered CommandHandler's are matched, and the command is delivered according to the defined interface.

### **com.ibm.ws.zos.command.processing.ModifyResults.java**

The ModifyResults interface wraps the results of processing the command. It contains the command response messages and other information.

## **Enabling workload management for Liberty on z/OS**

z/OS

To enable access to z/OS native workload management (WLM) services for your applications running on Liberty, you use the zosWlm-1.0 feature with additional configuration.

### **About this task**

z/OS

For code examples, and for information about configuration syntax, classification rules, and the attributes of the `httpClassification` element, see “Liberty: WLM classification for z/OS” on page 1737.

### **Procedure**

- “Accessing authorized z/OS native WLM services on Liberty”
- “Accessing unauthorized z/OS native WLM services on Liberty” on page 1737

### **Accessing authorized z/OS native WLM services on Liberty:**

z/OS

To enable access to authorized z/OS native workload management (WLM) services, you use the Liberty zosWlm-1.0 feature, and define the security setup to permit the Authorized WLM Service (ZOSWLM).

### **Before you begin**

Start the Angel process using `<START bbgzang1>`. For more information, see “Administering Liberty on z/OS” on page 1731

z/OS

For code examples, and for information about configuration syntax, classification rules, and the attributes of the `httpClassification` element, see “Liberty: WLM classification for z/OS” on page 1737.

### **Procedure**

1. Enable the Liberty zosWlm-1.0 feature.
2. Define the security setup to permit the Authorized WLM Service (ZOSWLM).

### **Example**

```
RDEF SERVER BBG.AUTHMOD.BBGZSAFM.ZOSWLM UACC(NONE)
PERMIT BBG.AUTHMOD.BBGZSAFM.ZOSWLM CLASS(SERVER) ACCESS(READ) ID(<USERID>)
```

The "subsystem name" used for classifying work requests is *BBGZSRV*, and it is specified on the WLM Connect Service `ConnectWorkMgr`.

The `collectionName` is supplied as the "COLLECTION" value on the `Classify` work (`__server_classify`). This example shows how the value used for the `collectionName` can be specified:

```
<zosWorkloadManager collectionName="AbcDef1234"/>
```

**Note:** The `collectionName` supports mixed case.

**Note:** The `collectionName` only uses the first 18 characters.

**Note:** If no value is specified, the value `/${wlp.server.name}` is used. This is the directory name of the server.

### Accessing unauthorized z/OS native WLM services on Liberty: z/OS

To enable access to unauthorized z/OS native WLM services, you use the Liberty `zosWlm-1.0` feature, and enable Liberty to use the native LE WLM services, such as `ConnectWorkMgr`, `createWorkUnit`, `deleteWorkUnit`, `extractWorkUnit`, `joinWorkUnit` and `leaveWorkUnit`.

#### Before you begin

z/OS For code examples, and for information about configuration syntax, classification rules, and the attributes of the `httpClassification` element, see "Liberty: WLM classification for z/OS."

#### Procedure

1. Enable the Liberty `zosWlm-1.0` feature.
2. Define a security profile for the FACILITY class and profile "BPX.WLMSEVER" that allows the user associated with the server READ access. This enables the Liberty server to use the native LE WLM services, such as `ConnectWorkMgr`, `createWorkUnit`, `deleteWorkUnit`, `extractWorkUnit`, `joinWorkUnit` and `leaveWorkUnit`.

#### Example

The "subsystem name" used for classifying work requests is *BBGZSRV*, and it is specified on the WLM Connect Service `ConnectWorkMgr`.

The `collectionName` is supplied as the "COLLECTION" value on the `Classify` work (`__server_classify`). This example shows how the value used for the `collectionName` can be specified:

```
<zosWorkloadManager collectionName="AbcDef1234"/>
```

**Note:** The `collectionName` supports mixed case.

**Note:** The `collectionName` only uses the first 18 characters.

**Note:** If no value is specified, the value `/${wlp.server.name}` is used. This is the directory name of the server.

### Liberty: WLM classification for z/OS: z/OS

Syntax and support notes about Liberty for z/OS workload management (WLM) feature.

A WLM enclave is associated with the thread that the request is dispatched on. It is also associated with a WLM Service Class. A WLM Service Class is assigned to the WLM enclave by WLM, based on rules

that you define in the WLM configuration. The WLM Service Class indicates the WLM goals for each class of client work, for example, 95% complete in 1 second or less. The WLM Service Class also indicates the importance of the goals relative to other work on the system. WLM uses information that is provided by the Liberty server during classification to assign a WLM Service Class. The following three properties help WLM to classify the work:

**Subsystem Type**

For WebSphere, Subsystem Type is CB.

**Collection Name**

Name of the server that is running the work. You can create WLM classification rules that are based on the server that is running the work.

**Transaction Class**

Name that is determined from classification of the work within the Liberty code. Transaction Class is based on the Liberty configuration that you provide for the request that is being dispatched. You can assign different Transaction Classes to different applications within the same server, and thus different WLM Service Classes.

Syntax for configuration in the server.xml file:

```
<featureManager>
  <feature>zosWlm-1.0</feature>
</featureManager>

<wlmClassification>
  <httpClassification transactionClass="CLASS001" host="127.0.0.1" port="9080" method="GET"
    resource="/testResource" />
</wlmClassification>
```

Table 123. Default Values

Attributes	Default values
transactionClass=""	Empty string
host="*"	Wildcard
port="*"	Wildcard
method="*"	Wildcard
resource="*"	Wildcard

**Important:**

- All attributes of <httpClassification ... /> are optional.
- If you turn on WLM, but do not specify a minimum of one rule, WLM is active but no enclaves are created.
- Classification rules have a top-down ordering, that is, each rule takes precedence over all rules below it.
- Transaction Classes can be mixed case.
- Ports can be specified as ranges. For example, port="9080-9085".
- Ports and methods can be specified as a comma-separated list. For example, port="9043,9080" or method="GET,PUT".
- Resources can be specified by using wildcards. One asterisk represents any number of characters, and is used as a wildcard for the string between two path separator (/) characters. Two consecutive asterisks represent any number of characters that include the path separator. Double asterisks cannot appear with other characters within a pair of path separators.
  - resource="/test\*/\*" matches /testaa/bb.html, but does not match /testaa/bb/cc.html
  - resource="\*.html" matches /aaa.html but does not match/aaa/bbb.html

- resource="/go/set\*/\*\*/archive.jsp" matches /go/seta/bb/2/archive.jsp, /go/setaa/bb/2/archive.jsp, and /go/set/archive.jsp
- The default, if resource= is not specified, matches ALL strings, which is equivalent to resource="\*\*/\*", which matches /aaa, /aaa/bbb, and /aaa/bbb/cc.html

Example configuration:

```
<wlmClassification>
  <httpClassification transactionClass="CLASS004" resource="/res2"/>
  <httpClassification transactionClass="CLASS003" resource="/res1"/>
  <httpClassification transactionClass="CLASS002" port="9043" />
  <httpClassification transactionClass="CLASS001" />
</wlmClassification>
```

#### Notes:

- Rules 1 and 2 catch all incoming requests to their respective resources
- Rule 3 catches any incoming request not to either listed resource but on port 9043
- Rule 4 is a "catch-all" rule, which matches any request that comes in that was not matched by Rule 1, Rule 2, or Rule 3

## Enabling syncToOSthread for applications

To enable **syncToOSthread** on Liberty, you use the **appSecurity-1.0** and **zosSecurity-1.0** features with additional configuration.

### Before you begin

Enabling **syncToOSthread** support requires the **appSecurity-1.0** and **zosSecurity-1.0** features. You must also define the **syncToOSthread** configuration element. In addition, you must use the SAF registry for authentication, and authorized SAF services must be available.

Because **syncToOSthread** support requires authorized SAF services, the angel process must be up and running and the server must be connected to it. For more information about the angel process, see “Liberty profile: Process types on z/OS” on page 1019.

### Procedure

1. Configure the application to use **syncToOSthread** by adding the following **env-entry** to the application's deployment descriptor:

```
<env-entry>
  <env-entry-name>com.ibm.websphere.security.SyncToOSthread</env-entry-name>
  <env-entry-type>java.lang.Boolean</env-entry-type>
  <env-entry-value>true</env-entry-value>
</env-entry>
```

2. Configure the server to enable **syncToOSthread** for applications by adding the **appSecurity-1.0** and **zosSecurity-1.0** features, and defining the **syncToOSthread** configuration element with attribute appEnabled="true". Additionally, ensure the SAF registry must be used for authentication:

```
<featureManager>
  <feature>appSecurity-1.0</feature>
  <feature>zosSecurity-1.0</feature>
</featureManager>

<safRegistry id="saf" />
<syncToOSthread appEnabled="true" />
```

3. Grant the server permission to perform **syncToOSthread** operations by configuring your SAF product with either of the following profiles:

- Grant the userid of the server CONTROL access to the BBG.SYNC.<profilePrefix> profile in the FACILITY class. This allows the server to sync any RunAs identity with the OS identity:  
`PERMIT BBG.SYNC.<profilePrefix> ID(<serverUserId>) ACCESS(CONTROL) CLASS(FACILITY)`
- Grant the userid of the server READ access to the BBG.SYNC.<profilePrefix> profile in the FACILITY class. Additionally, grant the userid of the server READ access to one or more BBG.SYNC.<runAsUserId> profiles in the SURROGATE class, one for each RunAs identity to be synchronized with the OS identity:  
`PERMIT BBG.SYNC.<profilePrefix> ID(<serverUserId>) ACCESS(READ) CLASS(FACILITY)`  
`PERMIT BBG.SYNC.<runAsUserId> ID(<serverUserId>) ACCESS(READ) CLASS(SURROGAT)`

**Note:** The <profilePrefix> is by default “BBGZDFLT” and can be configured by using the <safCredentials profilePrefix="xx"> element in your configuration file.

For more information about **syncTo0SThread**, see Java thread identity and an operating system thread identity

## Enabling syncTo0SThread for J2C connections

z/OS

8.5.0.2

To enable **syncTo0SThread** for J2C connections on Liberty, you use the **appSecurity-1.0** and **zosSecurity-1.0** features with additional configuration.

### Before you begin

Enabling **syncTo0SThread** support for J2C connections requires the **appSecurity-1.0** and **zosSecurity-1.0** features. You must also define the **syncTo0SThread** configuration element. In addition, you must use the SAF registry for authentication, and authorized SAF services must be available.

Because **syncTo0SThread** support requires authorized SAF services the angel process must be up and running and the server must be connected to it. For more information about the angel process, see “Liberty profile: Process types on z/OS” on page 1019.

### Procedure

1. Configure the server to enable **syncTo0SThread** for J2C connections by adding the **appSecurity-1.0** and **zosSecurity-1.0** features and defining the **syncTo0SThread** configuration element with attribute `j2cEnabled="true"`. Additionally, ensure the SAF registry must be used for authentication:

```
<featureManager>
  <feature>appSecurity-1.0</feature>
  <feature>zosSecurity-1.0</feature>
</featureManager>

<safRegistry id="saf" />
<syncTo0SThread j2cEnabled="true" />
```

#### Note:

- For connections that use a resource that specifies `res-auth=container`, setting `j2cEnabled=true` enables **syncTo0SThread** for type-2 J2C connections. Enablement of **syncTo0SThread** synchronizes the Java RunAs identity with the OS identity during the establishment of the connection. The connection is thereby associated with the OS identity and is assigned the same permissions and privileges as the OS identity.
  - Do not specify a JAAS alias for the data source if you wish to use **syncTo0SThread**. The JAAS alias, if defined, will override the OS identity.
2. Grant the server permission to perform **syncTo0SThread** operations by configuring your SAF product with either of the following profiles:
    - Grant the userid of the server CONTROL access to the BBG.SYNC.<profilePrefix> profile in the FACILITY class. This allows the server to sync any RunAs identity with the OS identity:

```
PERMIT BBG.SYNC.<profilePrefix> ID(<serverUserId>) ACCESS(CONTROL) CLASS(FACILITY)
```

- Grant the userid of the server READ access to the BBG.SYNC.<profilePrefix> profile in the FACILITY class. Additionally, grant the userid of the server READ access to one or more BBG.SYNC.<runAsUserId> profiles in the SURROGATE class, one for each RunAs identity to be synchronized with the OS identity:

```
PERMIT BBG.SYNC.<profilePrefix> ID(<serverUserId>) ACCESS(READ) CLASS(FACILITY)
PERMIT BBG.SYNC.<runAsUserId> ID(<serverUserId>) ACCESS(READ) CLASS(SURROGAT)
```

**Note:** The <profilePrefix> is by default “BBGZDFLT” and can be configured by using the <safCredentials profilePrefix="xx"> in your configuration file.

For more information about **syncToOSThread**, see Java thread identity and an operating system thread identity

---

## Administering Liberty using Admin Center

8.5.5.2

You can use WebSphere Liberty Administrative Center ("Admin Center") to administer Liberty servers and applications and other resources from a web browser on a smartphone, tablet, or computer.

### About this task

Use the Admin Center with a Liberty server or Liberty Core installation. An installation of the WebSphere Application Server full profile is not required.

Admin Center offers the ability to start, stop, and view details about Liberty servers and applications. It also offers the ability to edit server configuration files, to view bookmarked information, to add tools, to monitor server resources, and to deploy server packages on hosts within a collective. Advantages of the Admin Center design include:

- A user interface with a mobile look-and-feel for web browsers on a smartphone or tablet
- Support for multiple lightweight, task-oriented tools
- A toolbox that you can customize by selecting tools from a catalog, specifying bookmarks, or specifying user preferences

 **Watch:** The Touring Admin Center video shows the user interface and briefly describes Admin Center features. [Transcript]

### Procedure

1. Set up Admin Center.
  - Install Liberty with Admin Center.
  - Configure the server.xml file to enable Admin Center and secure login.
  - If the server is not running, start the server.
2. Log in to Admin Center.
  - Point a web browser at Admin Center.
  - On the Welcome page, specify an authorized user name and password to log in.
3. Use the Toolbox.
  - Select a tool or bookmark.
  - Add a tool.
  - Remove a tool.
  - Add or remove a bookmark.
  -  Rearrange tool and bookmark icons.
  - Filter toolbox contents.
  - Edit user preferences such as text direction.

- **8.5.5.6** Uninstall an Admin Center tool.
4. **8.5.5.7** Use the Server Config tool to view and edit server configuration files in the Liberty topology.
    - Enable editing of files to change `server.xml` or any other files in the server configuration directory.
    - View or edit a configuration file in the Server Config tool.
    - Customize a default setting for Design or Source mode.
  5. Use the Explore tool to explore and manage resources in the Liberty topology.
    - View a summary of all resources on the Explore tool Dashboard.
    - View a summary of all applications, clusters, servers, or hosts.
    - View details about a resource.
    - **8.5.5.4** View details about all servers on a Liberty runtime.
    - Start, stop, or restart a resource.
    - Deploy a server package on a host from the Explore tool.
    - **8.5.5.5** Search for resources.
  6. **8.5.5.5** Optional: View charts of server or application metrics in the Monitor view of the Explore tool.
    - Open the Monitor view on a server or application.
    - Show or hide charts.
    - Show or hide chart legends.
    - **8.5.5.6** View chart data in a table.
  7. **8.5.5.5** Optional: Set and view administrative metadata for server, cluster, or application resources in the Explore tool.
    - **8.5.5.6** Set and view administrative metadata for resources in the Tags and Metadata dialog of the Explore tool.
    - View administrative metadata defined in an `admin-metadata.xml` file in the Explore tool.
  8. **8.5.5.7** Optional: Enable maintenance mode for a server or host in the Explore tool.
  9. Optional: Use the Deploy tool to install Liberty server package (archive) files on hosts within a collective.
  10. Optional: After using the Deploy tool, use the Background Tasks page to check the status of Deploy Installation tasks.
  11. After completing work in Admin Center, log out.

## Setting up Admin Center

**8.5.5.2**

Admin Center is a web user interface that runs on Liberty V8.5.5.2 and later servers. After installing Liberty and creating a server, configure the `server.xml` file.

### Before you begin

Install WebSphere Application Server Liberty with Liberty Administrative Center ("Admin Center"). The Installing Liberty Repository assets topic lists the ways to install assets such as Admin Center. The quickest way to install Admin Center is to run the **installUtility** command or the **featureManager** command:

1. If you have not done so already, install WebSphere Application Server Liberty V8.5.5.2 or later.

**Restriction:** Ensure that you use a Java virtual machine (JVM) that supports Liberty products and Secure Sockets Layer (SSL). Do not use an IBM JVM available with a WebSphere Application Server traditional product, such as Network Deployment, for your Liberty installation with Admin Center. By default, the IBM JVM available with a traditional product points to security classes that are available only with a traditional product, and not to security classes needed by Admin Center. Using an IBM JVM available with a traditional product can cause Admin Center to not display in a browser.

2. Open a command window at the main directory of the Liberty installation. For example, open a command window at `c:\wlp`.
3. Run a command to install the `adminCenter-1.0` feature.

**8.5.5.6** For Version 8.5.5.6 or later, run the **installUtility** command:

```
bin/installUtility install adminCenter-1.0
```

For Version 8.5.5.5 or earlier, run the **featureManager** command:

```
bin/featureManager install adminCenter-1.0 --when-file-exists=ignore
```

4. For the Liberty Developers edition, run a command to install the `collectiveController-1.0` feature.

**8.5.5.6** For Version 8.5.5.6 or later, run the **installUtility** command:

```
bin/installUtility install collectiveController-1.0
```

For Version 8.5.5.5 or earlier, run the **featureManager** command:

```
bin/featureManager install collectiveController-1.0 --when-file-exists=ignore
```

This step applies only to the Developers edition and not to the Network Deployment, z/OS or Core editions of Liberty. Optionally, you can install the `collectiveController-1.0` feature before installing the `adminCenter-1.0` feature.

For more information, go to the WASdev website, select the **Downloads** tab, and search the Liberty repository for the Admin Center asset.

To install Admin Center on hosts that cannot access the internet-based Liberty repository, first install Liberty and the Admin Center feature on a host that can access the internet. Then transfer the installation to the target hosts. For information about packaging Liberty servers and runtimes for deployment to other hosts, see Packaging a Liberty server by using developer tools and Packaging a Liberty server from the command line.

## About this task

You can set up Admin Center on stand-alone servers and on collective controllers. This topic focuses on setting up a stand-alone Liberty server.

To enable Admin Center on a collective controller, see Configuring a Liberty collective and the example in Deploying resources with Admin Center. Ensure the `server.xml` file of the collective controller includes `<feature>adminCenter-1.0</feature>` in the feature manager configuration and sets a host value in the `httpEndpoint` element, such as `host="*"` so all hosts can access the collective controller.

## Procedure

1. If your Liberty installation does not have a server, create a Liberty server.

For example, in a command window at the `wlp/bin` directory, create a server named `myServer`.

```
server create myServer
```

The example command adds server files to the `wlp/usr/servers/myServer` directory.

2. Open an editor on the `server.xml` file of the Liberty server, and configure the server for Admin Center.

- a. Add the `adminCenter-1.0` feature to the feature manager.

```
<featureManager>
  <feature>adminCenter-1.0</feature>
</featureManager>
```

For more timely updates to server and application status in the Explore tool, also add the `websocket-1.1` or `websocket-1.0` feature to the server configuration.

```
<featureManager>
  <feature>adminCenter-1.0</feature>
  <feature>websocket-1.1</feature>
</featureManager>
```

WebSocket provides a live view of the topology regardless of size. Without the WebSocket feature, Admin Center periodically and frequently polls for changes.

- b. Add one or more users to configure a secure login. For example:

```
<quickStartSecurity userName="admin" userPassword="adminpwd" />
```

If user names or passwords include non-English characters, create the `jvm.options` file for the server and define the default client encoding as UTF-8:

```
-Ddefault.client.encoding=UTF-8
```

For information about the `jvm.options` file, see “Customizing the Liberty environment” on page 1565.

- c. To protect keystore files that have server authentication credentials, define a keystore and assign it a password.

```
<keyStore id="defaultKeyStore" password="Liberty" />
```

For an example `server.xml` file that defines an Administrator and a non-Administrator and that defines a keystore, see the Example in this topic. For information about defining multiple administrative users, see “Setting up BasicRegistry and role mapping on Liberty” on page 1832.

- d. To access Admin Center from a smartphone, tablet, or remote computer, ensure that the `server.xml` file sets the host attribute of the `httpEndpoint` element to \* (asterisk) or to a defined host name. By default, the host attribute is set to `localhost`.

```
<httpEndpoint id="defaultHttpEndpoint"
  host="*"
  httpPort="9080"
  httpsPort="9443" />
```

- e. Save your changes to the `server.xml` file.

If you defined the default client encoding as UTF-8 for non-English characters in the `jvm.options` file and the user registry is in `quickStartSecurity` or `basicRegistry` elements, which store user names and passwords in the `server.xml` file, then save the `server.xml` file in UTF-8 encoding.

3. If the server is not running, start the server.

For example, in a command window at the `wlp/bin` directory, enter a **run** or **start** command.

```
server run myServer
```

Look for server messages that show the `adminCenter` web application is running. After Admin Center is running, you can point a web browser at the application and log in. See “Logging in to Admin Center” on page 1745.

 **Watch:** The Setting up Admin Center video demonstrates the procedure. [Transcript]

## Example: server.xml file that defines two authorized users

```
<server description="new server">

  <!-- Enable features -->
  <featureManager>
    <feature>adminCenter-1.0</feature>
  </featureManager>

  <!-- Define the host name for use by the collective.
  If the host name needs to be changed, the server should be
  removed from the collective and re-joined. -->
  <variable name="defaultHostName" value="localhost" />

  <!-- Define an Administrator and non-Administrator -->
  <basicRegistry id="basic">
    <user name="admin" password="adminpwd" />
    <user name="nonadmin" password="nonadminpwd" />
  </basicRegistry>

  <!-- Assign 'admin' to Administrator -->
  <administrator-role>
    <user>admin</user>
  </administrator-role>
```

```
<keyStore id="defaultKeyStore" password="Liberty" />

<httpEndpoint id="defaultHttpEndpoint"
  host="*"
  httpPort="9080"
  httpsPort="9443" />

</server>
```

## Logging in to Admin Center

After the Admin Center web application starts, you can point a web browser at Admin Center and log in. After logging in, the first page shown is the Toolbox.

### Before you begin

Ensure that you have a browser that supports Admin Center.

- For browsing the Admin Center on a computer: Firefox ESR 24, Firefox 29, Chrome 35, Safari 7, or Internet Explorer 11 browser (for best experience, use Chrome or Firefox browser)
- For browsing the Admin Center on an iPhone or iPad: Safari browser on iOS 6.x or 7.x
- For browsing the Admin Center on an Android mobile device: Chrome browser on Android 4.2 or 4.3

### Procedure

1. Point a web browser at Admin Center.

```
https://host_name:port_number/adminCenter/
```

For *host\_name*, specify the IP address or domain name server (DNS) host name of the computer on which the Liberty server is running. Specify localhost only if the browser is running on the same computer as the server.

For *port\_number*, specify the httpsPort value in the server.xml file. For example:

```
https://localhost:9443/adminCenter/
```

```
https://myhost.xyz.com:9443/adminCenter/
```

```
https://9.65.234.567:9443/adminCenter/
```

2. If your browser prompts you to confirm that the connection is trusted, specify an exception or otherwise enable the connection to continue to Admin Center.
3. Log in to Admin Center.

When you configured the server.xml file of the server to enable Admin Center, you defined one or more user names and passwords authorized to access the Admin Center. To log in to Admin Center, specify an authorized user name and password.

For example, specify the user name admin and the password adminpwd.

### What to do next

When you first access the Toolbox, it has the Server Config and Explore tools and a bookmark to WASdev.net. The Toolbox also has the Deploy tool if Admin Center is run on a collective controller. The Deploy tool is not available if Admin Center is run on a stand-alone server.

To add or remove tools and bookmarks, select  and use the Tool Catalog to customize your user-specific Toolbox.

**8.5.5.4** To view a tool, select its Toolbox icon or directly launch the tool using the URL that is shown in the browser when viewing the tool. For example, to directly launch the Explore tool, use a URL such as `https://localhost:9443/adminCenter/#explore`.

Later, to log out of Admin Center, select  > **Log out *user\_name***.

## Customizing the Toolbox

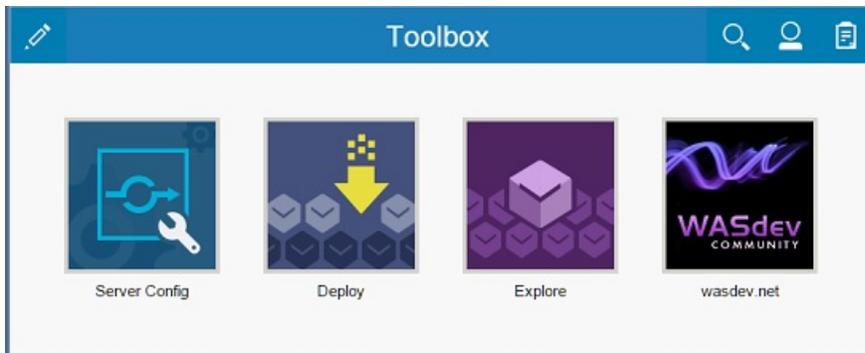

When you first log in to Admin Center, the Toolbox contains the Server Config and Explore tools and a bookmark to WASdev.net. The Toolbox also has the Deploy tool if the server hosting Admin Center is a collective controller. You can edit the Toolbox contents by adding tools from the Tool Catalog or by adding bookmarks. A *tool* is a web application that performs a particular task and is typically provided by the product. A *bookmark* is a user-added link to any site. You can further customize your Toolbox by rearranging icons, filtering Toolbox contents, or editing preferences.

### About this task

Select tools, bookmarks, and menu choices in the Toolbox to use Admin Center. The Toolbox offers the following options:

- Select a tool or bookmark.
- Add a tool.
- Remove a tool.
- Add or remove a bookmark.
- Rearrange tool and bookmark icons.
- Filter toolbox contents.
- Edit user preferences such as text direction.
- **8.5.5.6** Uninstall an Admin Center tool.

## Procedure

- To work with an existing tool or to open a browser on a bookmarked URL, select the icon for the tool or bookmark.
- Add tools.
  1. Select  >  > **Add Tool**.
  2. Select  on the tool to add.
  3. Confirm that you want to add the tool.
  4. Select  to return to the Toolbox.

**8.5.5.4** After you add a tool, use the Toolbox to first launch the tool. To directly launch the tool at a later time, you can use the URL that is shown in the browser when viewing the tool.
- Remove tools.
  1. Select .
  2. Select  on the tool to remove.
  3. Confirm that you want to remove the tool.
  4. Select  to return to the Toolbox.
- Add or remove bookmarks.
  1. Select  >  > **Add Bookmark**.
  2. Enter the bookmark name and URL, and then select **Add** to add the bookmark to your Toolbox. To later remove the bookmark, select the bookmark and then .
  3. Select  to return to the Toolbox.
- **8.5.5.4** Rearrange tool and bookmark icons.
  1. Select .
  2. Drag and drop the icons into the order that you prefer.
  3. Select  to return to the Toolbox.
- Filter toolbox contents.
  1. Select .
  2. Type the tool or bookmark name in the text field. Filtered search results are shown if the characters typed match the names of Toolbox contents.
  3. After searching, select  to close the text field.
- Edit your preferences.

1. Select  > **Preferences**.
2. For **Enable bidirectional support**, specify whether text displays left to right, the default, or displays right to left. Select **Contextual** for the first typed character to determine the direction. When the first character is in a language such as Arabic or Hebrew, control orientation and typing direction become right to left, with right alignment for text.
3. Select  to return to the Toolbox.

- **8.5.5.6** Uninstall an Admin Center tool.

By default, the Toolbox contains Admin Center tools such as the Explore tool and, if the server hosting Admin Center is a collective controller, the Deploy tool. You can use the feature manager to uninstall Admin Center tools to fully customize your Toolbox. Run the **uninstall** command for featureManager. For example, if you use DevOps you might want to uninstall the Deploy tool. To do so, run:

```
wlp/bin/featureManager uninstall com.ibm.websphere.appserver.adminCenter.tool.deploy-1.0
```

Admin Center tools use the `com.ibm.websphere.appserver.adminCenter.tool.*` naming format:

- `com.ibm.websphere.appserver.adminCenter.tool.explore-1.0.mf`
- `com.ibm.websphere.appserver.adminCenter.tool.deploy-1.0`

## What to do next

Your selections are saved for the user name that was specified when logging in. If you later log in under the same user name, the Toolbox shows the same tool, bookmark, and preference selections as when you last logged out. If you log in under a different user name, the Toolbox shows the selections for that other user name.

## Editing server configuration files in Admin Center

**8.5.5.7**

You can use the Server Config tool to view and edit server configuration files in the Liberty topology. The Server Config tool displays configuration files such as a `server.xml` file in two modes. The Design mode displays the content of configuration files using graphical controls with inline documentation. The Source mode provides direct access to the file text and has content assist capabilities. You can customize the modes, for example, to add or remove parameter descriptions on the Design mode or to add or remove line numbers on the Source mode. Before you can edit files, you must add a `remoteFileAccess` element to the server configuration file; otherwise, files are shown in read-only mode.

**8.5.5.8**

### About this task

 **Watch:** The Getting started with the Server Configuration Tool for WebSphere Liberty video shows how to enable and use the tool.

### Procedure

1. Enable editing of files in the server configuration directory.

- a. Open an editor on the server configuration file.

The configuration file for a server typically has a path name such as `wlp/usr/servers/server_name/server.xml`.

- b. Add the following `remoteFileAccess` element to the server configuration file.

```
<remoteFileAccess>
  <writeDir>${server.config.dir}</writeDir>
</remoteFileAccess>
```

- c. Save the file changes.

Server configuration files such as the `server.xml` and any included files no longer are read-only in the Server Config tool. You can change element and parameter settings, and otherwise edit the files.

2. View or edit a configuration file in the Server Config tool.

- a. From the Toolbox, select .
- b. If Admin Center is run on a collective controller, select the server that has the configuration file you want to view or edit.
- c. After a file is open for editing, you can switch between **Design** and **Source** modes.

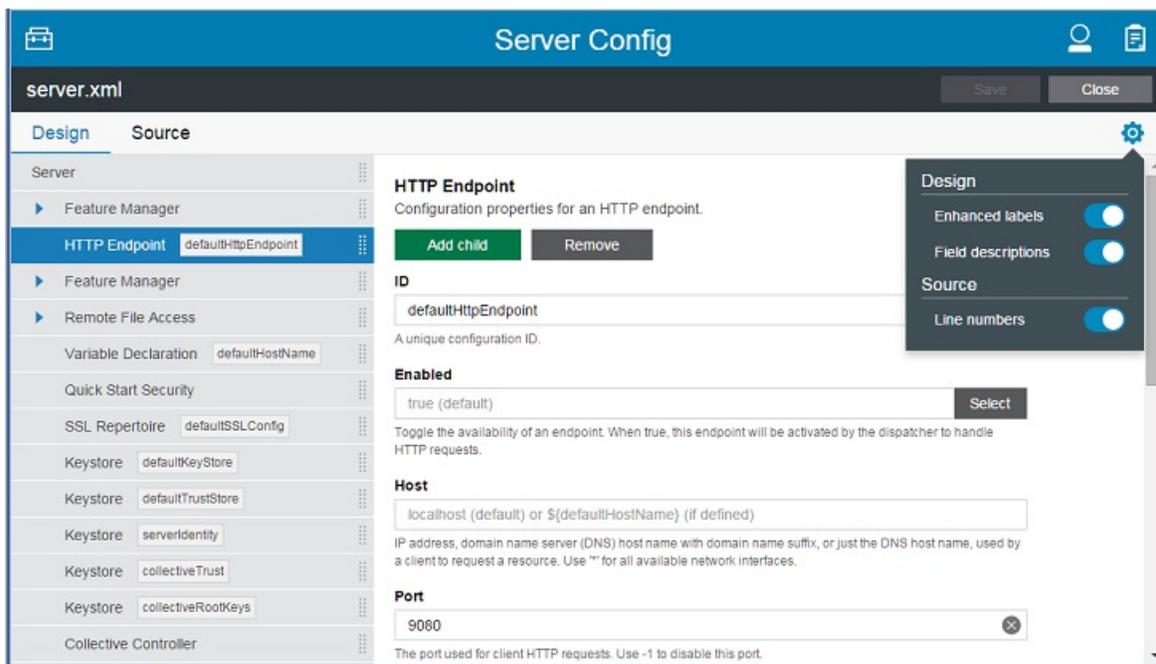

In the Design mode, select elements in the configuration to see enabled features and parameter settings.

In the Source mode, hover on elements and parameters to view their documentation. You can press Ctrl+Space to use content assist, which helps you add new elements, parameters, and values.

- d. After you finish working with a file, select **Save** to save the file changes and then **Close** to return to the main page of the tool. To discard file changes, select **Close** and then confirm to not save the changes.
3. Optional: Customize the default settings for Design or Source mode.

By default, the Design mode uses enhanced labels for file elements. Enhanced labels display element names such as featureManager as Feature Manager. Also, the Design mode displays parameter descriptions by default. The Source mode displays line numbers by default. To change a default setting:

- a. Select .
- b. Enable or disable one or more default settings.
- c. Select **Close**.

## What to do next

To return to the Toolbox, select .

## Exploring and managing resources with Admin Center

You can use the Explore tool to view and manage resources in the Liberty topology.

## About this task

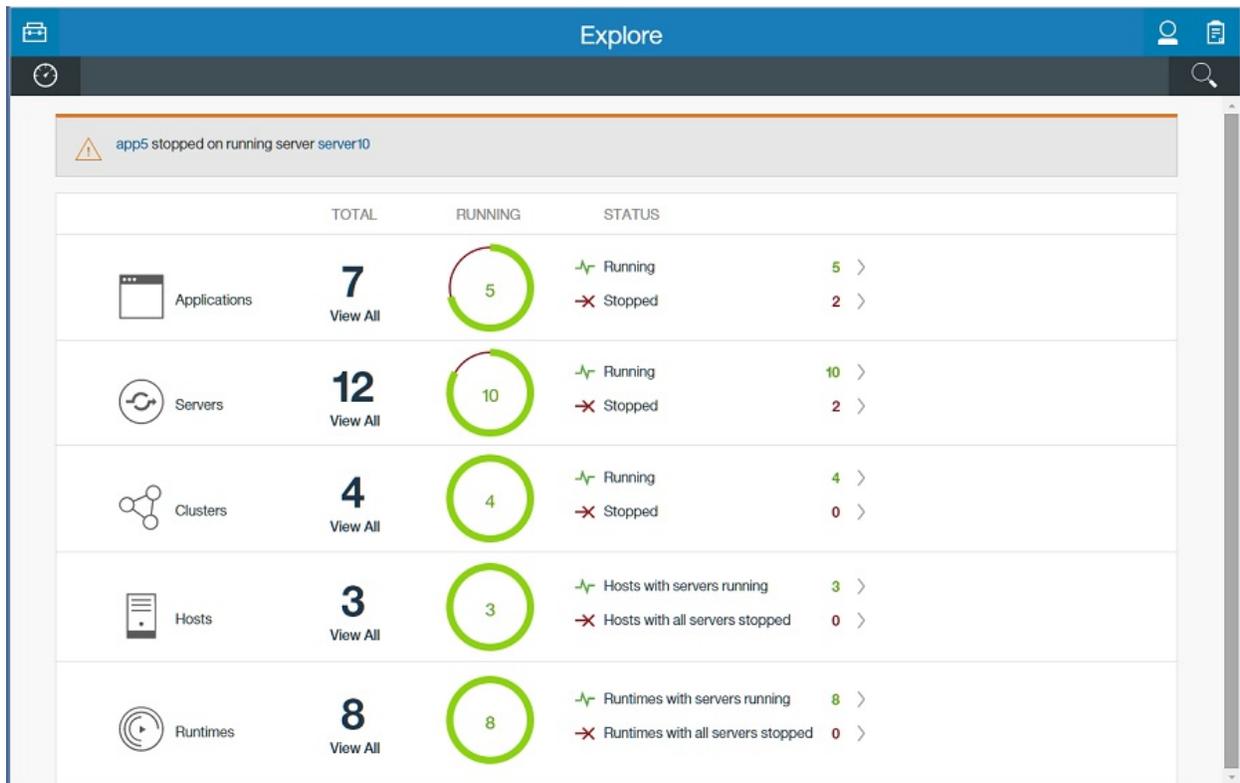

The Explore tool offers the following options to work with application, server, cluster, host, and runtime resources:

- View a summary of all resources on the Dashboard.
- View a summary of all applications, servers, clusters, hosts, or runtimes.
- View details about a resource.
- [8.5.5.4](#) View details about all servers on a Liberty runtime.
- Start, stop, or restart a resource.
- Deploy a server package on a host from the Explore tool.
- [8.5.5.5](#) Search for resources.

## Procedure

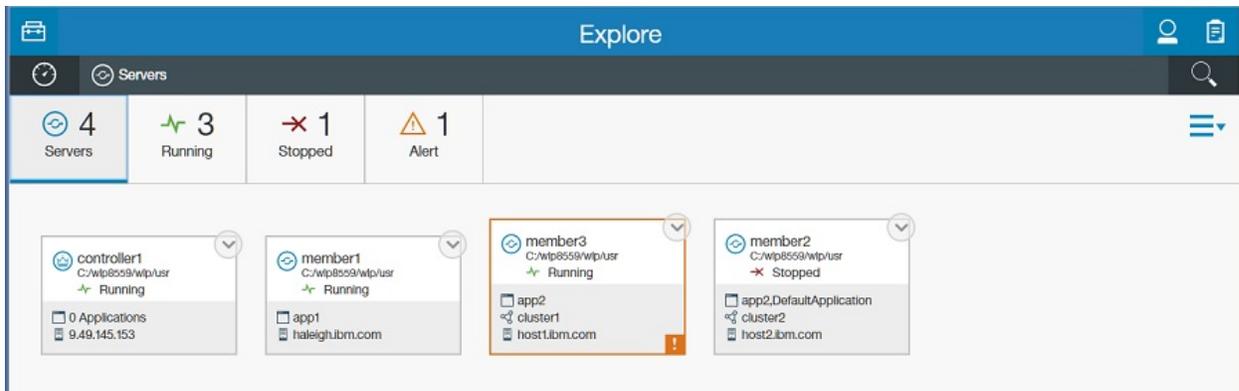

- View a summary of all resources on the Explore tool Dashboard.

From the Toolbox, select . The Explore page, or "Dashboard," shows the number of applications, servers, clusters, hosts, and runtimes that Admin Center is managing. The Dashboard also shows the number of resources that are running, stopped, or in an unknown state. If an alert condition is met, the alert is shown on the Dashboard with a link to the appropriate resource page. The resource name, total, and status also have links to the appropriate resource pages.

- View a summary of all applications, servers, clusters, hosts, or runtimes.

From the Dashboard, select a link on the **Applications**, **Servers**, **Clusters**, **Hosts**, or **Runtimes** panel. For example, to see a summary of all servers, select the **View All** link on the **Servers** panel. The state of all servers is shown. Whether a server is a collective controller or stand-alone server is also shown.

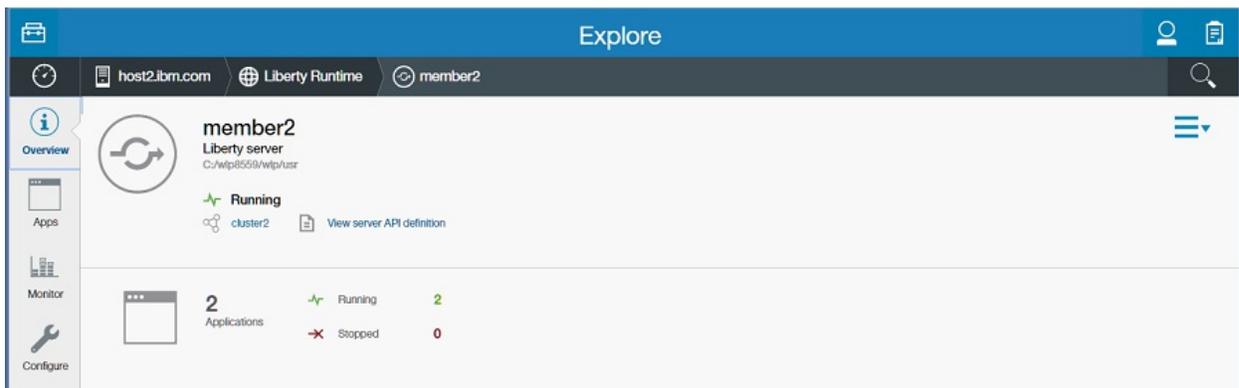

If an alert condition is met, an exclamation mark  is shown on the resource card. Select  for details on the alert condition.

To filter the view, select an icon that shows the number of resources in a specific state. For example, select the **1 Alert** icon to display the one server with an alert condition.

For more timely updates to server and application status, add the websocket-1.1 or websocket-1.0 feature to the server configuration for your servers that use the adminCenter-1.0 feature.

- View details about a resource.

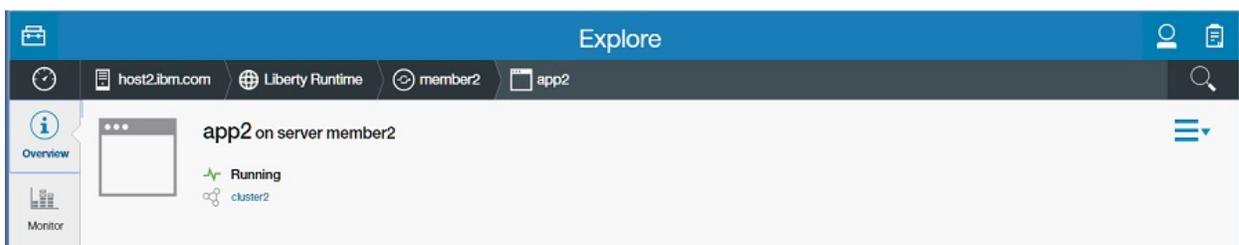

From the Explore page, select a link on the **Applications**, **Servers**, **Clusters**, **Hosts**, or **Runtimes** panel and then a specific resource. For example, to see details about a server, select a link on the **Servers** panel and then one of the servers.

If an alert condition is met, the alert is described with a link to the appropriate resource page.

**8.5.5.9** If the apiDiscovery-1.0 feature is in the configuration file for a server, the  icon with the **View server API definition** link is shown in details about the server. When the server is stopped, the **View server API definition** link is unavailable. For information about the apiDiscovery-1.0 feature, see “Discovering REST API documentation on a Liberty server” on page 2260.

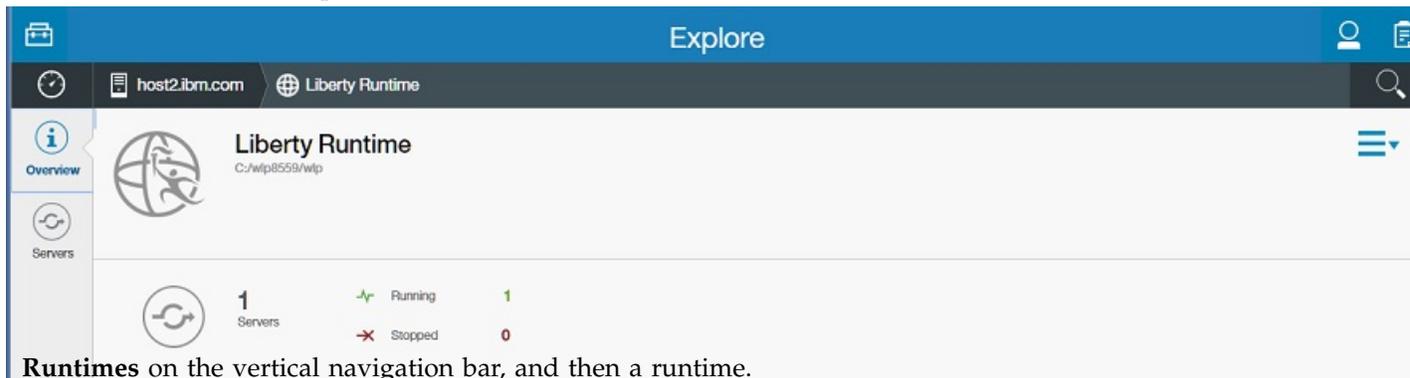

For resources on Liberty servers, select a resource to see more details. For example, select **Apps** and then an application to display details about the application on one of the servers. From the application details page you also can access the Monitor view for each application.

- 8.5.5.4 View details about all servers on a Liberty runtime.

From the Dashboard:

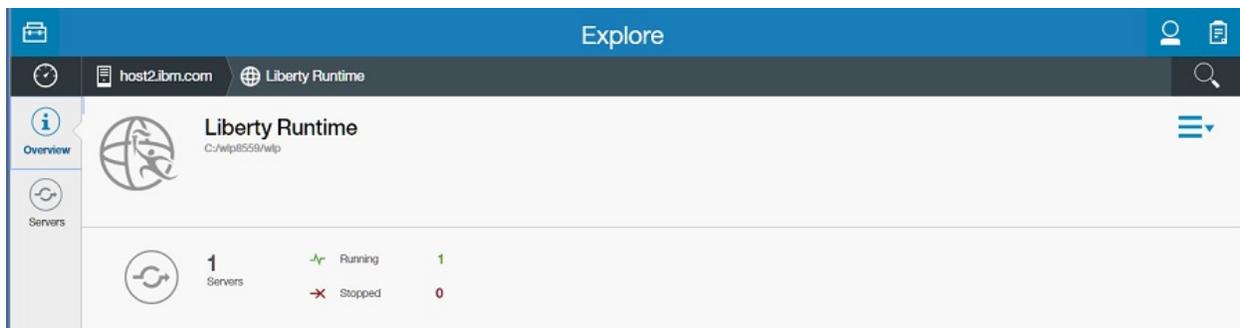

- Select a link on the **Hosts** panel, a host,

**Runtimes** on the vertical navigation bar, and then a runtime.

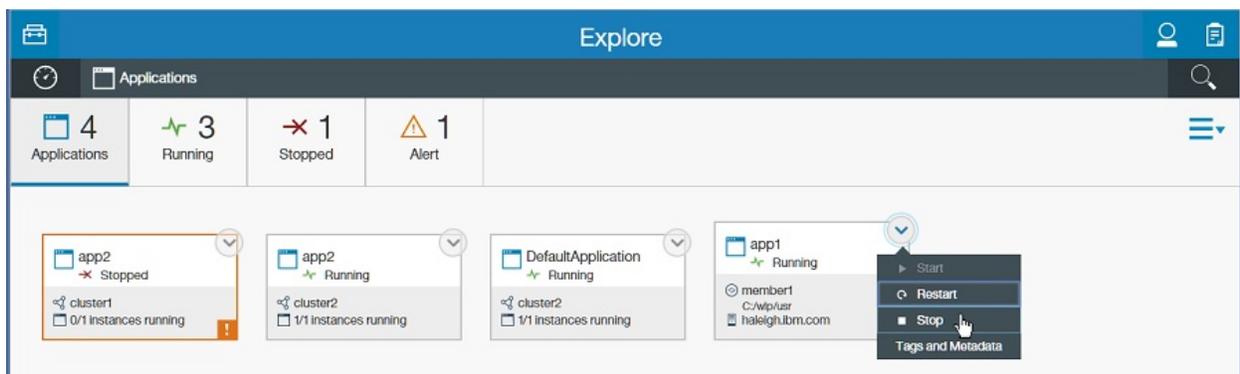

- Select a link on the **Servers** panel, a server, and then **Liberty Runtime** on the horizontal navigation bar.

The Runtime view displays details about the runtime, such as the number and states of servers on the runtime. The runtime details are useful for distinguishing among servers with the same name on the same host.

- Start, stop, or restart a resource.

To start, stop, or restart one resource, select  for the resource, select the available action from the popup dialog, and then confirm the selection.

Alternatively, select  > *one\_or\_more\_resources* > *action\_button*. You can start, stop, or restart multiple resources with this option. For example, to start two stopped servers:

1. When viewing Servers, select .
2. Select two servers in a stopped, partially started, or unknown state.

3. Select the **Start** button.
4. 8.5.5.7 Confirm the selection.

The screenshot shows the VMware vSphere 'Explore' interface. At the top, a summary bar indicates 4 Servers, 2 Running, 2 Stopped, and 1 Alert. Below this, a search filter is applied to 'Type' with 'Alert' selected. The main table displays application instances:

Alert	Name	Location	State	Instances	Tags	Actions
⚠	app2	cluster1	⏹ Stopped	0/1 instances running		⌵
	app2	cluster2	🟢 Running	1/1 instances running		⌵
	DefaultApplication	cluster2	🟢 Running	1/1 instances running	default_app	⌵
	app1	member1 on hale...	⏹ Stopped			⌵

Below the application instances, there are sections for '4 Servers' and '2 Clusters'. The '4 Servers' table shows:

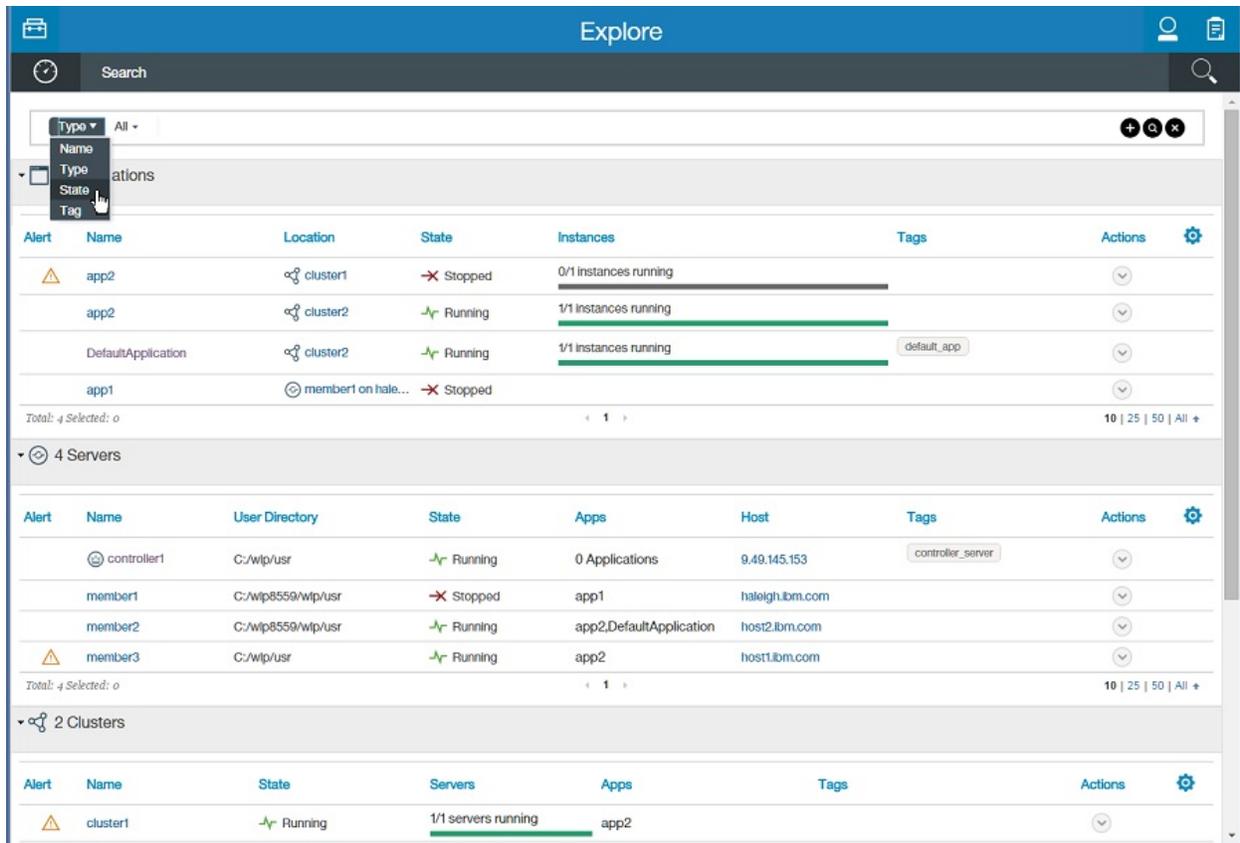

Alert	Name	User Directory	State	Apps	Host	Tags	Actions
	controller1	C:\wlp\usr	🟢 Running	0 Applications	9.49.145.153	controller_server	⌵
	member1	C:\wlp8559\wlp\usr	⏹ Stopped	app1	haleigh.ibm.com		⌵
	member2	C:\wlp8559\wlp\usr	🟢 Running	app2,DefaultApplication	host2.ibm.com		⌵
⚠	member3	C:\wlp\usr	🟢 Running	app2	host1.ibm.com		⌵

The '2 Clusters' table shows:

Alert	Name	State	Servers	Apps	Tags	Actions
⚠	cluster1	🟢 Running	1/1 servers running	app2		⌵

, specify the search criteria, and then select . To add search criteria, select and then specify additional values. To clear the entire search field, select .

The search results list details about resources that fit the search criteria. You can select and then select an available action from the popup dialog to change the resource status or, for hosts, to deploy a server package. To see more details about a resource, select the resource name.

**8.5.5.6** You can filter the search results by entering a string in the search field. For example, enter `er` to show resources that contain the "er" string.

**8.5.5.9** To show or hide columns, select  and the columns to display.

## What to do next

Select  to return to the Explore tool Dashboard. Select a previously viewed resource page on an Explore tool navigation bar to return to that page.

**8.5.5.4** To directly launch the Explore tool in the future, you can use the URL that is shown in the browser when viewing the Explore tool. For example, to directly view information about a particular resource in the future, you can use the URL that is shown in the browser when viewing information about the resource in the Explore tool. Each resource in the Explore tool has a unique URL that you can bookmark and use to directly launch the same resource page.

To return to the Toolbox, select .

## Monitoring metrics in Admin Center

**8.5.5.5**

You can use the Monitor view of the Admin Center Explore tool to track used heap memory, loaded classes, active Java virtual machine (JVM) threads, central processing unit (CPU) usage, and other metrics depending on the resource. The Monitor view shows the metrics graphically in charts. You can customize the Monitor view by selecting the charts to show or hide.

## Procedure

- Open the Monitor view on a server or application.
  1. From the Toolbox, select .
  2. Select a server or application to monitor.
    - To monitor a server, select the **Servers** panel and then a server.
    - To monitor an application, select the **Applications** panel and then an application instance. Or, to monitor an application on a server, select the **Servers** panel, a server, and then an application.
  3. Select  **Monitor** on the vertical navigation bar.

When first displayed, the Monitor view shows the following charts:

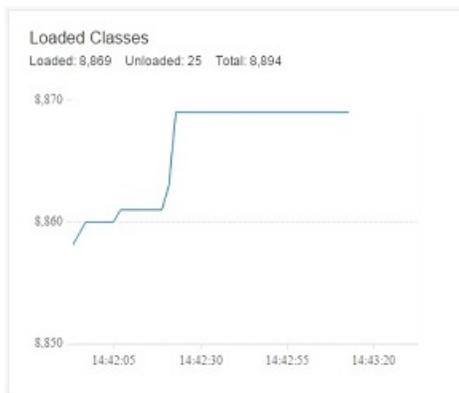

### Used Heap Memory

The Used Heap Memory chart shows the heap memory used by the server in megabytes (MB) every two seconds. The chart also shows the used, committed and maximum megabytes.

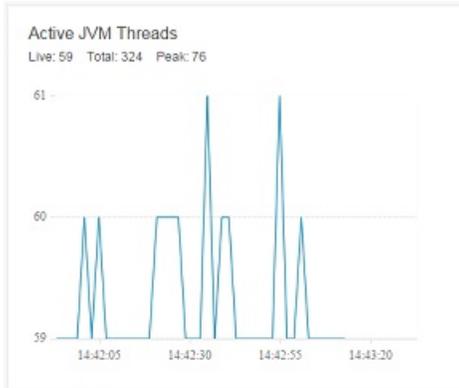

### Loaded Classes

The Loaded Classes chart shows the number of classes loaded every two seconds. The chart also shows the number of loaded and unloaded classes, as well as the total number of classes.

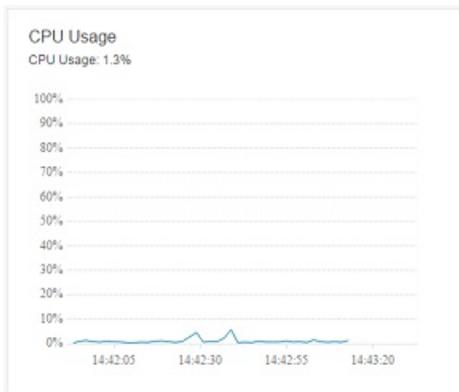

### Active JVM Threads

The Active JVM Threads chart shows the number of JVM threads every two seconds. The chart also shows the number of live, total, and peak threads.

### CPU Usage

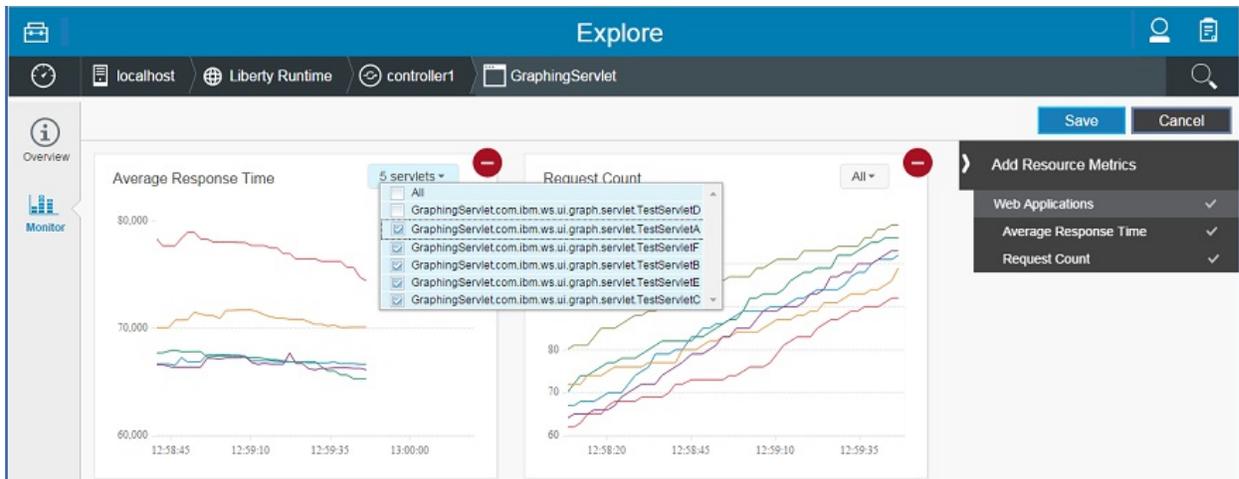

The CPU Usage chart shows the percentage of CPU used every two seconds.

If a server has the `monitor-1.0` feature enabled, the Monitor view also has other charts, depending on the resource:

- Active Sessions
- Active Liberty Threads
- Average Response Time
- Average Wait Time
- Request Count
- Used Connections

**8.5.5.6** The charts available if a server enables the `monitor-1.0` feature have additional configuration options. For example, charts for web applications with multiple servlets, servers with active sessions, or servers with data sources display a drop-down list from which you can select resources to show in the chart.

Select , the resources to show in the chart, and then **Save**.

- Show or hide charts.

Select , the charts to show or hide, and then **Save**. The Monitor view shows or hides the selected charts, depending on whether the chart is shown or hidden when you make the selection.

**8.5.5.6** Your selections are saved for the resource and login user name. When the user opens the Monitor view on the resource in the future, the same chart selections are shown.

- Show or hide chart legends.

If a chart has multiple grid lines, you can choose whether to show or hide the chart legend depending on whether a legend is shown or hidden when you make a selection.

For example, to view a chart legend, select  for the chart and then **Show legend**.

To then hide the legend, select  for the chart and then **Hide legend**.

- **8.5.5.6** View chart data.

In addition to viewing chart data graphically, you can view chart data in a table. Select  for the chart and then **View chart data**.

## Setting and viewing administrative metadata in Admin Center

**8.5.5.5**

You can use the Tags and Metadata dialog of the Explore tool to set and view administrative metadata for server, cluster, host, runtime, and application resources in a Liberty collective. Also, you can view administrative metadata for server, cluster, runtime, and application resources defined in an admin-metadata.xml file in the Explore tool. If a resource has administrative metadata defined in both the Tags and Metadata dialog and an admin-metadata.xml file, the Explore tool displays the resource metadata from both the dialog and the admin-metadata.xml file.

### About this task

The following steps describe how to set or view resource metadata in the Explore tool:

- Set and view administrative metadata in the Tags and Metadata dialog.
- View administrative metadata that is set in an admin-metadata.xml file.

**8.5.5.6** The product stores changes that you save in the Tags and Metadata dialog directly to the collective repository, and not to an admin-metadata.xml file. Changes made to metadata settings in the admin-metadata.xml file are shown in the Tags and Metadata dialog and on the Explore tool resource page when the server to which the admin-metadata.xml file belongs is restarted. Metadata deleted using the Tags and Metadata dialog redisplay in the Explore tool after the server restarts if the deleted

metadata is still defined in the admin-metadata.xml file.

## Procedure

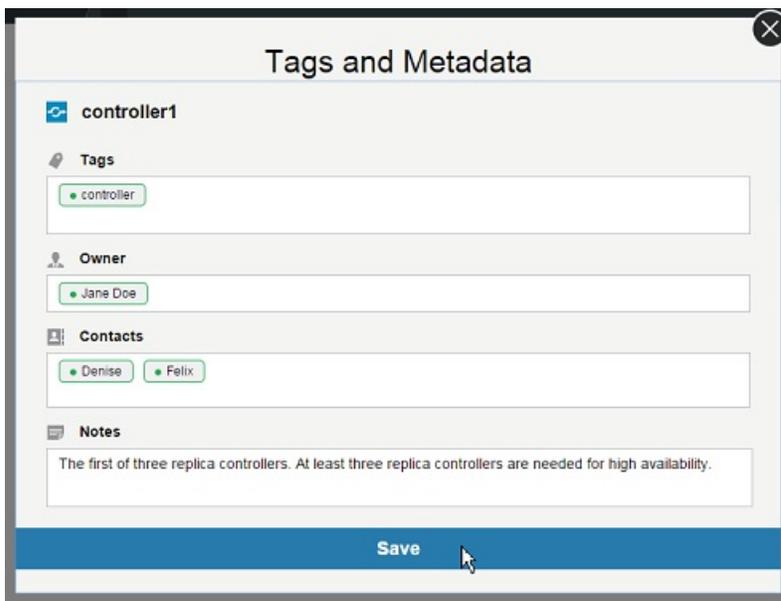

- **8.5.5.6** Set and view administrative metadata for server, cluster, host, runtime, and application resources in the Tags and Metadata dialog of the Explore tool.
  1. From the Toolbox, select .
  2. Select a resource for which to set administrative metadata.
    - For server metadata, select the **Servers** panel and then a server.
    - For cluster metadata, select the **Clusters** panel and then a cluster.
    - **8.5.5.8** For host metadata, select the **Hosts** panel and then a host.
    - **8.5.5.8** For runtime metadata, select the **Servers** panel, a server, and then **Liberty Runtime** or select the **Hosts** panel, a host, **Runtimes**, and then a runtime instance.
    - For application metadata, view application details on a particular server. For example, if app1 is deployed to server1, view the **app1 on server1** details to see the application metadata. If server1 is a member of a cluster, view the **app1 on cluster cluster\_name** details.
      - 8.5.5.8** Each instance of app1 in members of the cluster inherits the app1 application metadata.
  3. Select  or  and then select **Tags and Metadata**.
  4. In the Tags and Metadata dialog, add metadata values to the **Tags**, **Owner**, **Contacts** or **Notes** fields and then select **Save**.

**Tags** A tag is a word that you can use to search for resources. Specify no tags or as many tags as you want. Tags that contain uppercase characters convert to lowercase; thus, MyTag converts to mytag.

**Owner** An owner is typically a person or entity responsible for the metadata. The owner can provide a key for the metadata. Specify no more than one owner.

**Contacts** A contact is a person or entity who can provide information about the resource object. Specify zero or many contacts.

**Notes** A note is arbitrary text. Specify no more than one note.

The metadata is shown in details about the resource after you expand the **Tags and Metadata** link.

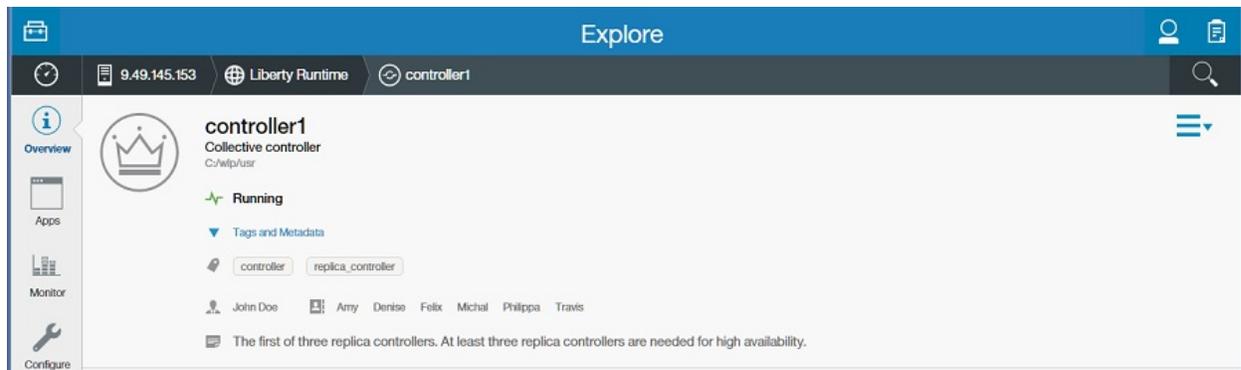

- View administrative metadata for server, cluster, runtime, and application resources defined in an admin-metadata.xml file.

You can see administrative metadata that is set in an `admin-metadata.xml` file in a details or runtime view. “Setting administrative metadata for Liberty resources” on page 1476 describes how to enable an `admin-metadata.xml` file.

For example, suppose a collective controller named `controller1` has the following `admin-metadata.xml` file in its server configuration directory, `$WLP_USER_DIR/servers/controller1`:

```
<admin-metadata>
  <server owner="John Doe">
    <tag>controller</tag>
    <tag>replica_controller</tag>
    <contact>Michal</contact>
    <contact>Felix</contact>
    <contact>Travis</contact>
    <contact>Philippa</contact>
    <contact>Amy</contact>
    <note>The first of three replica controllers. At least three replica controllers are needed for high availability.</note>
  </server>
</admin-metadata>
```

The metadata is shown in details about the `controller1` server after you expand the **Tags and Metadata** link:

Select the expanded **Tags and Metadata** link to hide the metadata.

## Enabling maintenance mode in Admin Center

8.5.5.7

You can use the Explore tool to enable maintenance mode for a server or host. Enable maintenance mode before you perform diagnostic tests, maintenance, or tuning on a server joined to a collective or on a host registered to a collective. Maintenance mode can prevent the disruption of client requests by routing client traffic targeted for a server that is in maintenance mode to another server. Enabling maintenance mode is a persistent change; a server or host remains in maintenance mode until the mode is disabled.

### About this task

The following steps describe how to enable or disable maintenance mode:

- Enable maintenance mode for a server or host.
- Disable maintenance mode for a server or host.

For more information about maintenance mode, see “Entering maintenance mode for Liberty collectives” on page 1516.

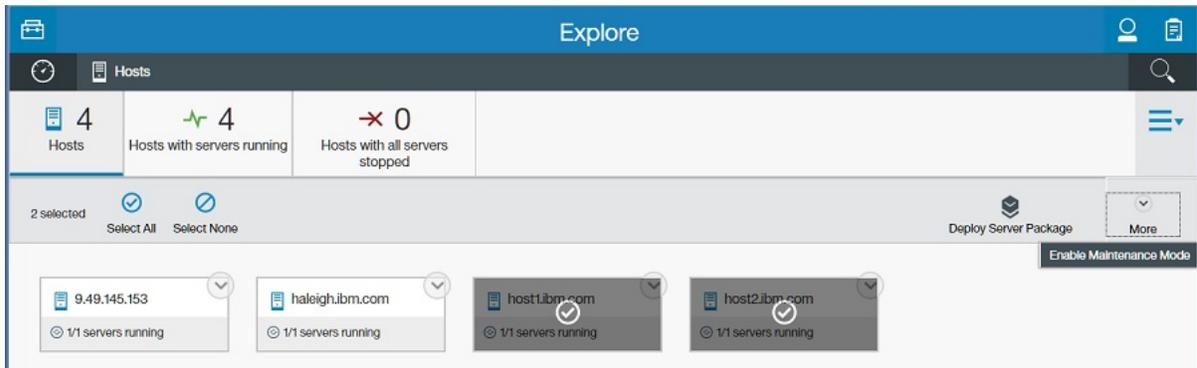

### Procedure

- Enable maintenance mode for a server or host.
  1. Open the Explore tool on Servers or Hosts.
    - a. From the Toolbox, select .
    - b. From the Dashboard, select the **Servers** or **Hosts** panel.

- When viewing Servers or Hosts, select  for a resource and then select **Enable Maintenance Mode** from the popup dialog.

Or, select  > *one\_or\_more\_servers\_or\_hosts* > **Enable Maintenance Mode**. For example, to enable maintenance mode on two hosts:

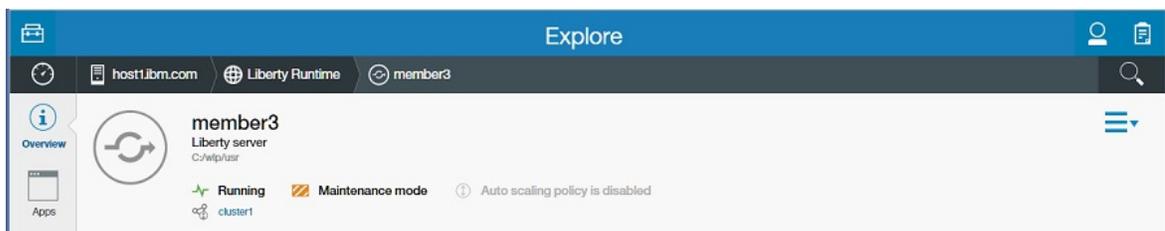

- When viewing Hosts, select .
- Select two registered hosts that are not in maintenance mode.
- Select the **More** button.
- Select the **Enable Maintenance Mode** button.

Enabling maintenance mode on a server might require additional selections:

- If an **Enable maintenance mode** prompt is displayed, select whether to break affinity with active sessions and then select **Enable**. By default, a web server continues to send requests with affinity to a server in maintenance mode. Selecting the **Break affinity with active sessions** toggle causes requests with affinity to a server to be routed to other servers.
- If a server has an enabled scaling policy  and a **Maintenance mode cannot be enabled** prompt is displayed, select **Force** or **Cancel**. When a scaling member is placed into maintenance mode, the scaling controller starts another server to replace the scaling member that is in maintenance mode if another server is needed to meet the scaling policy minimum or to meet current workload demand. If the scaling controller cannot find a server to replace the scaling member, the **Maintenance mode cannot be enabled** prompt is displayed. Selecting **Force** enables maintenance mode for the scaling member without starting alternate servers, which can break auto scaling policies. Selecting **Cancel** does not enable maintenance mode for the scaling member.

When the maintenance mode is enabled on a scaling member, the scaling policy is disabled automatically:

When maintenance mode is enabled on a host, the product attempts to place all servers on the host into maintenance mode, with the host entering maintenance mode regardless of whether its servers do. After a host is in maintenance mode, a scaling controller cannot provision new servers on the host.

- Disable maintenance mode for a server or host.

When viewing Servers or Hosts in the Explore tool, select  for a resource in maintenance mode and then select **Disable Maintenance Mode** from the popup dialog.

Or, select  > *one\_or\_more\_servers\_or\_hosts* > **Disable Maintenance Mode**.

## Deploying resources with Admin Center

8.5.5.2

You can use the Deploy tool to install Liberty server package (archive) files on hosts within a collective. Then, use the Explore tool to manage the servers.

### Before you begin

- The Admin Center feature must be installed and configured on a Liberty server that also includes the collective controller feature and all required security configuration.

To create a Liberty collective that includes the hosts to which you plan to deploy the Liberty installation, see the following topics:

- Configuring a Liberty collective -- To enable Admin Center on the collective controller, the `server.xml` file of the collective controller must include `<feature>adminCenter-1.0</feature>` in the feature manager configuration. Also, the `server.xml` file must set a `host` value in the `httpEndpoint` element; for example, add `host="*"` so all hosts can access the collective controller.
- Registering host computers with a Liberty collective -- The **registerHost** command must include a `hostWritePath` parameter that sets the path to which you want to deploy a server package. You specify this same path for **Target Directory** when using the Deploy tool. If a host is already registered, you can use the **updateHost** command to reset the `hostWritePath` information.

Each host must include Java support for the `jar` utility, and optionally an `unzip` utility, in the environment (path) of the Remote Procedure Call (RPC) user specified during registration of the host.

- The Liberty environment that you want to deploy must be compressed into a server package in the ZIP, JAR, or PAX format. The server package must meet the following requirements:
  - The server package includes, at minimum, a Liberty run time and a server. The server package can include other resources, such as a web application that runs on the server.
  - The top-level directory in the server package must be `wlp`, and it must contain the standard Liberty directories (`bin`, `clients`, `dev`, `lafiles`, `lib`, `templates`, `usr`). The `usr` directory must reside in the default location, and all servers must use the default output directory.
  - Included servers must not contain any collective membership configuration settings or keystore files.

Available tools for packaging archives include:

- The Liberty server **package** command. Sample command syntax is:

```
wlp/bin/server package myServer --include=all | minify --archive=myServer.zip | jar | pax
```
- The **package** action in the WebSphere Developer Tools for Eclipse product.

You might need to customize the installation, for example, by changing port numbers, database connections, or messaging system connections.

### About this task

After you define the Liberty collective and create the server package, use the Deploy tool to install the server package on hosts within the collective.

See “Example: Configuring a collective controller, registering a host, creating a server package, and deploying the server package” on page 1763 for an example of deploying a server package to a localhost Windows computer.

### Procedure

1. Go to the Deploy tool.
  - From the Toolbox, select .

- From details on hosts in the Explore tool, select  > *one\_or\_more\_host\_names* > **Deploy Server Package**.

**8.5.5.4** To directly launch the Deploy tool in the future, you can use the URL that is shown in the browser when viewing the Deploy tool.

2. For **Target Hosts**, select the host computers on which to install the server package. Move target hosts from **Available hosts** to **Selected hosts**.

Each target host must be registered with the collective that is managed by Admin Center. See Registering host computers with a Liberty collective.

3. For **Server Package**, select whether to upload a server package file or use a server package file on a collective controller. Then, specify the file path.
4. For **Target Directory**, specify a target directory for the Liberty installation. If the directory exists, it must be empty. If the directory does not exist, the product creates it as file system permissions permit. For server package ZIP or JAR formats, specify the installation directory. For example, specify `/home/user1/liberty` for the product to upload the server package to `/home/user1` and unzip to the `liberty` directory.

**8.5.5.4** For server package PAX formats, specify the installation directory and PAX file name. For example, specify `/home/user1/liberty/package_name.pax` for the product to expand the archive to the `/home/user1/liberty/package_name.pax` directory.

The RPC user of each target host must have read and write access to the parent of the installation directory.

5. For **KeyStore Password**, specify a password to protect newly generated keystore files containing server authentication credentials. The same password is used for all deployed servers.  
The product generates keystore files in the resources directory of each deployed server.
6. For **Remote Management Credentials**, specify how the collective controller will connect to each target host to remotely manage the deployed servers.

- **8.5.5.4** If all target hosts are registered with the collective controller, you can choose the default option, **Use the connection method and credentials configured for each target host**.

**Restriction:** You cannot use the **Use the connection method and credentials configured for each target host** option to deploy an 8.5.5.3 or earlier server package. The server package must support Liberty 8.5.5.4 or later.

- If all target hosts support SSH, you can choose **Use automatically-generated SSH keys for each server**.
  - If any target host runs on a Windows operating system or otherwise does not support SSH, or if you do not want to use SSH keys, choose **Use the following operating system user name and password on each target host** and specify the operating system login user name and password. The operating system user must possess file system privileges for operating Liberty servers in the installation. All files in a deployed installation are owned by the operating system user who registered the respective target host with the collective. Specifying a different operating system user for **Remote Management Credentials** does not change ownership of the files.
7. For **Password**, specify the password that you used to log in to Admin Center. The operation to join the deployed servers to the collective is run with your Liberty administrative user name and password.
  8. Select **Deploy**.

## Results

The Deploy action runs. Select  on a desktop or tablet, or  on a smartphone, for status on the deployment.

## Example: Configuring a collective controller, registering a host, creating a server package, and deploying the server package

This example describes how to install a Liberty server package on a Windows host within a collective using the Deploy tool.

- Create a collective controller that uses Admin Center and start the collective controller.
- Run the **registerHost** command to register a host computer with the collective controller.
- Create a server package to install using the Deploy tool.
- Install the server package using the Deploy tool.

Configure a collective controller, register a host with the collective controller, and package a server before using the Deploy tool.

- Create a collective controller that uses Admin Center and start the collective controller.

1. Create a server. This example names the server `myController`.

```
wlp/bin/server create myController
```

2. Create a collective controller.

```
wlp/bin/collective create myController --keystorePassword=myControllerPwd
```

3. Open an editor on the `myController` `server.xml` file and make the following changes:

- Add the generated collective controller configuration to the `myController` `server.xml` file. For example, copy output from the collective command and paste it after the `httpEndpoint` element and before `</server>`, the last tag of the `server.xml` file.
- Add the `adminCenter-1.0` feature to the feature manager.

```
<featureManager>  
  <feature>jsp-2.2</feature>  
  <feature>adminCenter-1.0</feature>  
</featureManager>
```

- Add a `host` value to the `httpEndpoint` element of the `myController` `server.xml` file. For example, add `host="*"` so all hosts can access the controller.

```
<!-- To access this server from a remote client add a host  
attribute to the following element, e.g. host="*" -->  
<httpEndpoint id="defaultHttpEndpoint"  
  host="*"  
  httpPort="9080"  
  httpsPort="9443" />
```

- Specify values for `userName` and `userPassword`.

```
<quickStartSecurity userName="admin" userPassword="adminpwd" />
```

**Tip:** If user names or passwords include non-English characters, create the `jvm.options` file for the server and define the default client encoding as UTF-8:

```
-Ddefault.client.encoding=UTF-8
```

If the user registry is in `quickStartSecurity` or `basicRegistry` elements, which store user names and passwords in the `server.xml` file, then save the `server.xml` file in UTF-8 encoding. For information about the `jvm.options` file, see “Customizing the Liberty environment” on page 1565.

4. Start the controller.

```
wlp/bin/server start myController
```

- Run the **registerHost** command to register a host computer with the collective controller.

For this example, the collective controller is running on the localhost computer, which has a hostname of `winHost`. The computer uses a Windows operating system, which does not support SSH, so the command must specify an RPC user and password.

```
wlp/bin/collective registerHost winHost --host=localhost --port=9443 --user=admin --password=adminpwd --rpcUser=myWindowsLoginID
```

The command does the following:

- Registers the localhost computer with the collective controller.
- For user and password, specifies the `userName` and `userPassword` values set in the `myController server.xml` file.
- Specifies the operating system login user for `rpcUser` and the operating system user password for `rpcUserPassword`.
- Sets `hostWritePath` to the path of the directory to which the Deploy tool installs the server package.

When prompted, type `y` to accept the certificate chain.

If you later want to change these settings, you can use the **collective updateHost** command.

- Create a server package to install using the Deploy tool.
  1. If you do not have an existing server to package, run the **create** command to create a new server.
 

```
wlp/bin/server create server1
```
  2. If you have an existing server to package, ensure the server that you want to package is stopped.
  3. Run the **package** command to create the server package.
 

```
wlp/bin/server package server1
```

The command creates a server package named, for example, `C:\wlp\usr\servers\server1\server1.zip`.
- Install the server package using the Deploy tool.
  1. Launch the Deploy tool from the Toolbox or from the Explore tool host page. See “Logging in to Admin Center” on page 1745.
  2. For **Target Hosts**, move the target host, `winHost`, from **Available hosts** to **Selected hosts**.
  3. For **Server Package**, select to use a server package file on a collective controller. Then, specify the file path, `C:\wlp\usr\servers\server1\server1.zip`.
  4. For **Target Directory**, specify the directory set for `hostWritePath` in the **registerHost** command, `c:\wlp_example\member`.
  5. For **KeyStore Password**, specify a password to protect newly generated keystore files containing server authentication credentials. The same password is used for all deployed servers. For example, specify `serverpwd`.
  6. For **Remote Management Credentials**, specify how the collective controller will get the host operating system login credentials to remotely manage the deployed servers. For this example that uses a Windows host computer, you have two choices. You can choose **Use the connection method and credentials configured for each target host** because the target host is registered with the collective controller. Or, you can choose **Use the following operating system user name and password on each target host** and then specify the operating system login user and login user password.
  7. For **Password**, specify the password that you used to log in to Admin Center.
  8. Select **Deploy**.

## What to do next

For details about the status of the deployment on a desktop or tablet, select  on the title bar.

To view the status on a smartphone, select .

On the Background Tasks page, you can view a summary of all running background tasks and access a detailed history of running, stopped, and completed background tasks. See “Monitoring background tasks.”

## Monitoring background tasks

8.5.5.2

You can use the Background Tasks page to check the status of Deploy Installation tasks and view task details.

## About this task

To see details about the progress of steps, errors, or warnings, select a task step in the progress bar or an icon on the Background Tasks page.

## Procedure

1. Select  on a desktop or tablet, or  on a smartphone.

A drop-down dialog opens, showing active background tasks, which have In Progress or Pending status. The dialog also has a link to **Task Details and History**.

2. To view status on all background tasks, active and completed, select **Task Details and History**.
3. Browse details on tasks in the Background Tasks page.

The Background Tasks page lists running, pending, and completed tasks. Task status is shown by progress bar colors and by icons. No icon is shown if all steps for a task are running or pending.

*Table 124. Background Tasks icon and progress bar.* View the icon and progress bar color to determine the task status.

Icon	Progress bar	Task status
		Successful
		Warning
		Error
		In Progress
		Pending

Each color segment in the progress bar indicates the percentage of each status for the task. The percentage at the end of a progress bar indicates the percentage of hosts that completed the task. Hosts are sub-tasks of a task.

Select a task row to see hosts. If you are deploying a server package to multiple hosts, a list of the hosts is shown under the task.

The icon next to a host name indicates the current status of all operations on the host. Select a host name to see details about operations on the host. If a task, host, or step failed, select the failed step and view error messages.

Background Tasks				
Deploy Installation - liberty.zip	Running	00:00:00:00		0%
 Deploy Installation - liberty.zip	Failed	00:00:00:00		66%
<ul style="list-style-type: none"> <li>^  host2</li> <li>^  host6</li> <li>^  host3</li> <li>^  host1 <ul style="list-style-type: none"> <li>CWWKX0271I: Started to upload file D:/work/liberty/liberty.zip to directory /tmp in... 4/16/2015, 11:33 AM</li> <li>CWWKX0261E: The host authentication information for the host host1 is not avai... 4/16/2015, 11:33 AM</li> </ul> </li> <li>^  host4</li> <li>^  host5</li> </ul>				

## What to do next

After you use task details to troubleshoot any errors or warnings, select  to return to the previous page.

## Configuration updates

**8.5.5.0**

You can make updates to the configuration by using the developer tools or from the command line.

### Updating the server.xml file

The server.xml file can be updated either from the developer tools or from the command line. If there are any problems with the configuration, the specific configuration element updates that have problems do not take effect, but other successful updates are implemented.

This behavior can be changed by updating the onError variable from the default value of WARN to FAIL. If the value is set to FAIL, any problem with the configuration update causes the entire update to fail.

**8.5.5.5** Updates occur if you update any files that are included from the server.xml file or configuration in the configDropins directories.

### Restarting the server with an updated configuration

The WebSphere Application Server Liberty runtime environment caches the currently used configuration so that when you restart the server, the server.xml file is not processed unless there are any changes. If the server.xml file is changed, the cached configuration is updated with the new values. If any problems are found in the new configuration, the cached configuration values remain in use. The console log displays a warning message for each configuration element that is still using an older value. For example:

CWWKG0076W: The previous configuration for `httpEndpoint` with id `defaultHttpEndpoint` is still in use.

The server can be started without using cached configuration by running the server script with the `--clean` option.

---

## Liberty and Chef

Chef software is an open source configuration management tool that you can use to create and manage the installation of an Infrastructure as a Service (IaaS). You can use Chef to provision a Liberty installation.

Chef uses cookbooks, which are reusable sets of components that are written in the Ruby programming language. A cookbook provides all the necessary components that are needed to configure an associated piece of software, for example, Apache HTTP Server. An important distinction between using Chef and writing scripts is the ability of Chef to determine the differences between the current software configuration and a new configuration and make only the changes necessary to move from one to the other. For more information, see the online Chef documentation [About Cookbooks](#).

By using Chef, you can create scalable infrastructure with minimal configuration to maintain. You can easily expand your existing infrastructure, for example, by creating and starting a new application server or web server. Chef automatically connects the new servers into the existing infrastructure as necessary.

The `wlp` cookbook installs and configures the WebSphere Application Server Liberty. It provides recipes, resources, and libraries for creating, managing, and configuring Liberty server instances. For more information, see `wlp` cookbook.

To learn more about Chef, see the online Chef documentation [How Chef works](#).

To learn more about using Chef cookbooks, see [Getting started with the Chef cookbooks for Liberty](#).

---

## Liberty: Including configuration information from external xml files in the server.xml file

8.5.5.6

You can use the **include** element to include configuration information from an external xml file in the `server.xml` file.

If you have configuration information in an external xml file, you can use the **include** element to include the configuration information in the `server.xml` file. For example, if you have an xml file, `simpleSecurity.xml`, with the following content:

```
<server>
  <quickStartSecurity userPassword="thePassword"/>
</server>
```

You can use the following method to include the configuration information in `simpleSecurity.xml` file in your `server.xml` file:

```
<server>
  <featureManager>
    <feature>servlet-3.0</feature>
  </featureManager>
  <quickStartSecurity userName="theUser"/>
  <include location="simpleSecurity.xml"/>
</server>
```

The effective configuration is as follows:

```

<server>
  <featureManager>
    <feature>servlet-3.0</feature>
  </featureManager>
  <quickStartSecurity userName="theUser"/>
  <quickStartSecurity userPassword="thePassword"/>
</server>

```

## Conflict handling

You can configure the *onConflict* attribute in the `server.xml` file to handle the value conflict between `server.xml` file and the external file. This attribute can be configured to one of the three values: *Merge*, *Replace*, and *Ignore*.

**Merge** The values are merged together. *Merge* is the default value of the *onConflict* attribute and *Merge* is equivalent to the behavior that you get if you specify all of the conflicting elements in the `server.xml` file. In the previous example, there are two **quickStartSecurity** elements, and they are effectively merged into a single element. The effective configuration is as follows:

```
<quickStartSecurity userName="theUser" userPassword="thePassword"/>
```

For more information about how configuration elements are merged, see “Liberty:Configuration element merging rules.”

### Replace

The value from the included configuration file replaces the conflicting values in the `server.xml` file. In the previous example, the included **quickStartSecurity** element replaces the one from the `server.xml` file, so the effective configuration is as follows:

```
<quickStartSecurity userPassword="thePassword"/>
```

**Ignore** The value from the included file is ignored. In the previous example, the **quickStartSecurity** element from the included file is ignored, so the effective configuration is as follows:

```
<quickStartSecurity userName="theUser"/>
```

---

## Liberty:Configuration element merging rules

8.5.5.6

If a configuration element is specified multiple times in the server configuration, the elements are merged. The following rules apply to configuration merging:

- Singleton elements are always merged. In the following example, all instances of the element in the server configuration are `featureManager` merged to form a single `featureManager` element:

```

<featureManager>
  <feature>servlet-3.0</feature>
</featureManager>
<featureManager>
  <feature>jdbc-4.0</feature>
</featureManager>

```

The effective configuration becomes:

```

<featureManager>
<feature>servlet-3.0</feature>
<feature>jdbc-4.0</feature>
</featureManager>

```

- Factory elements that are specified at the top level of the server configuration are merged if they have the same ID. In the following example, the `dataSource` element with `id= "ds1"` is merged and the `dataSource` element with `id= "ds2"` stays as it is. For example,

```

<dataSource id="ds1" jdbcDriverRef="myDriver"/>
<dataSource id="ds1" jndiName="jdbc/myDriver"/>
<dataSource id="ds2" jdbcDriverRef="myDriver2"/>

```

The effective configuration becomes:

```
<dataSource id="ds1" jdbcDriverRef="myDriver" jndiName="jdbc/myDriver"/>
<dataSource id="ds2" jdbcDriverDref="myDriver2"/>
```

- If a factory element does not have an ID value, it is considered distinct from other elements of the same type without an ID value. Multiple factory elements without ID values are not merged together. In the following example, the dataSource are not merged, so the effective configuration is the same as the specified configuration:

```
<dataSource jdbcDriverRef="myDriver"/>
<dataSource jndiName="jdbc/myDriver"/>
```

The effective configuration becomes:

```
<dataSource jdbcDriverRef="myDriver"/>
<dataSource jndiName="jdbc/myDriver"/>
```

- If the elements that are to be merged have conflicting attributes, the merged element uses the last value that is encountered by the configuration parser. In the following example, the dataSource element with id= "ds1" is merged and the jdbcDriverRef="myDriver2" is used, while jdbcDriverRef="myDriver" is removed.

```
<dataSource id="ds1" jdbcDriverRef="myDriver"/>
<dataSource id="ds1" jdbcDriverRef="myDriver2"/>
```

The effective configuration becomes:

```
<dataSource id="ds1" jdbcDriverRef="myDriver2"/>
```

- If a factory element is nested underneath another element, it is merged with other elements under the same effective parent only. In the following example, the dataSource element with id= "ds1" is merged and the properties.derby.embedded id="props1" element is merged with the other properties.derby.embedded id="props1" element whose parent is alsodataSource id="ds1".

```
<dataSource id="ds1">
  <properties.derby.embedded id="props1" databaseName="myDB"/>
</dataSource>
<dataSource id="ds2">
  <properties.derby.embedded id="props1" user="myUser"/>
</dataSource>
<dataSource id="ds1">
  <properties.derby.embedded id="props1" createDatabase="create"/>
</dataSource>
```

The effective configuration becomes:

```
<dataSource id="ds1">
  <properties.derby.embedded id="props1" databaseName="myDB" createDatabase="create"/>
</dataSource>
<dataSource id="ds2">
  <properties.derby.embedded id="props1" user="myUser"/>
</dataSource>
```

- If a factory element is nested underneath another element and the factory element does not have a specified ID value, special rules apply depending on the cardinality of the nested element. If multiple nested elements of a particular type are expected, the elements are not merged. However, if only a single nested element is expected, the nested elements are merged together. For example,

```
<topLevel>
  <multipleNested enabled="true"/>
  <multipleNested value="1"/>
  <singleNested enabled="false"/>
  <singleNested value="2"/>
</topLevel>
```

The effective configuration becomes:

```
<topLevel>
  <multipleNested enabled="true"/>
  <multipleNested value="1"/>
  <singleNested enabled="false" value="2"/>
</topLevel>
```

- If two factory elements are nested underneath another element and the ID values that do not match, the merging behavior depends on the cardinality of the nested element. If multiple nested elements are expected, the elements are not merged. If a single nested element is expected, the nested elements are merged together despite the conflicting ID values. For example,

```
<topLevel>
  <multipleNested id="1" enabled="true"/>
  <multipleNested id="2" value="1"/>
  <singleNested id="3" enabled="false"/>
  <singleNested id="4" value="2"/>
</topLevel>
```

The effective configuration becomes:

```
<topLevel>
  <multipleNested id="1" enabled="true"/>
  <multipleNested id="2" value="1"/>
  <singleNested id="4" enabled="false" value="2"/>
</topLevel>
```

---

## Chapter 7. Extending Liberty

### 8.5.5.0

You can expand the capability of Liberty by using product extensions. You can write your own Liberty features and install them onto an existing Liberty server, or you can package them for delivery to your users.

#### About this task

### 8.5.5.0

This section describes how to develop features for a product extension, how to install features to the built-in “usr” product extension, and how to use your features in an application server. Liberty provides various System Programming Interfaces (SPIs) that you can use to extend the runtime environment; you can also use more advanced features such as operating the Liberty server from your Java applications programmatically. **8.5.5.0** The Java API documentation for each Liberty SPI is available in a separate .zip file in one of the javadoc subdirectories of the `{wlp.install.dir}/dev` directory.

For an overview of writing product extensions for Liberty, see “Liberty profile: Product extension” on page 967.

For full details of how to extend Liberty, see the following subtopics:

---

### Developing a Liberty feature for Liberty

### 8.5.5.0

A Liberty feature consists of a feature manifest file, and one or more OSGi bundles. The OSGi bundles contain classes and services that provide a particular capability when the feature is installed onto a Liberty server.

#### About this task

You can develop a Liberty feature in either of the following ways:

- Develop the feature manually; see “Developing a Liberty feature manually.”
- Use the WebSphere Application Server Developer Tools; see “Creating a Liberty feature by using developer tools” on page 1782.

For full details on developing Liberty features, see the following subtopics:

### Developing a Liberty feature manually

### 8.5.5.0

You can create a Liberty feature manually and install it to Liberty.

#### About this task

A feature can consist of a single OSGi bundle and a feature manifest file. This example makes a library available to applications so that the external packages are visible on the default application class path. By

copying the feature manifest into the `${wlp.user.dir}/extension/lib/features` directory, and the OSGi bundle into the `${wlp.user.dir}/extension/lib` directory, the feature can be installed to Liberty. Then you can use the feature in your `server.xml` file.

For details about the format of a feature manifest file, see “Liberty feature manifest files” on page 1773.

This example describes how to construct a Liberty feature manually. Alternatively, you can use the WebSphere Application Server Developer Tools. See “Creating a Liberty feature by using developer tools” on page 1782.

## Procedure

To create a Liberty feature manually, complete the following steps:

1. Create an OSGi bundle containing your Java classes, and a bundle manifest file with appropriate OSGi headers, for example to export the Java packages that you want to expose to applications. `Bundle-SymbolicName` is the only required header; this entry specifies a unique identifier for a bundle, based on the reverse domain name convention. It is good practice to specify a version for the bundle, and in this example some Java packages are exported for application use:

```
Bundle-SymbolicName: com.usr.samplebundle
Bundle-Version: 1.0.1
Export-Package: com.usr.samplebundle.pkg1; version="1.0.0",
               com.usr.samplebundle.pkg2; version="1.0.1"
```

2. Use the `jar` command to package the Java classes and the feature manifest file. For example:  
`jar cfm samplebundle.jar MANIFEST.Mf *.class`
3. Create a feature manifest file named `feature-name.mf` which describes the feature to the runtime environment.
  - a. Provide the required manifest headers:
    - `Subsystem-SymbolicName` to specify the identity and visibility of the feature;
    - `Subsystem-Content` to locate the files that comprise the feature;
    - `IBM-Feature-Version` to identify which version of feature support is required by the runtime environment.
  - b. Best practice: Add the optional manifest headers to indicate the applicable version of the subsystem specification (`Subsystem-ManifestVersion`), the version of your feature (`Subsystem-Version`), and a short name of your feature (`IBM-ShortName`). Specifying these values will help you to evolve your feature in the future.
  - c. In the `IBM-API-Package` header, list the packages that are to be exposed on the default class loader for applications.
  - d. Optional: When you create your Liberty feature, you install it into the user product extension, and the packages in your feature can be accessed by any other feature that is installed to the user product extension. To make one or more SPI packages available to features in other product extensions, list the packages in the `IBM-SPI-Package` header.

```
Subsystem-ManifestVersion: 1.0
Subsystem-SymbolicName: com.example.myfeature.sample-1.0; visibility:=public
Subsystem-Version: 1.0.0.qualifier
Subsystem-Type: osgi.subsystem.feature
Subsystem-Content: samplebundle; version="[1,1.0.100]"
IBM-Feature-Version: 2
IBM-API-Package: com.usr.samplebundle.pkg1; type="api",
               com.usr.samplebundle.pkg2; type="api"
IBM-SPI-Package: com.sample.myservice.spi;
IBM-ShortName: sample-1.0
```

4. Copy the bundle into the `${wlp.user.dir}/extension/lib` directory.
5. Copy the feature manifest into the `${wlp.user.dir}/extension/lib/features` directory.

- If you have defined Subsystem-Name and Subsystem-Description headers in the feature manifest file, and have localized the values, copy the localization files specified in the Subsystem-Localization header into the `/${wlp.user.dir}/extension/lib/features/110n` directory.

## Results

After your feature is installed to Liberty, you can add the feature name to the list of configured feature in your `server.xml` file. For example:

```
<featureManager>
  <feature>usr:sample-1.0</feature>
</featureManager>
```

## Liberty feature manifest files

**8.5.5.0**

A Liberty feature consists of a feature manifest file and a collection of one or more OSGi bundles that provide classes and services corresponding to a particular capability in the Liberty profile runtime environment. You can find the introduction of the format of a feature manifest and the meaning of each header in the manifest file.

The feature manifest file in the Liberty profile uses the Subsystem Service metadata format in the OSGi Enterprise R5 specification. A feature is defined by a feature manifest file (`.mf` file) that is stored in the `lib/features` directory, and must use a custom type of Subsystem: **8.5.5.0** `osgi.subsystem.feature`. For more information on OSGi manifest syntax, see section 1.3.2 of the OSGi core specification.

**Note:** In the feature manifest file, the attributes take the form `name=value`, but directives take the form `name:=value`.

The following headers are defined:

*Table 125. Headers of a feature manifest file.*

This table shows the headers of a feature manifest file in the Liberty profile. The first column shows a list of headers. The second column shows the description of each header, and the third column states whether the header is required.

Header	Description	Required?
Subsystem-ManifestVersion	The version format for the feature manifest file. Must be set to 1.	No
Subsystem-SymbolicName	The symbolic name of the feature and any attributes or directives.	Yes
Subsystem-Version	The version of the feature. See the OSGi core specification section 3.2.5 for the details of how this is defined.	No
Subsystem-Type	The subsystem type for the feature. All features are currently of the same subsystem type: <code>osgi.subsystem.feature</code> .	Yes
Subsystem-Content	The subsystem content of the feature. This is a comma separated list of bundles and subsystems that are required to run this feature. If you want to allow the auto feature to be configured in the <code>server.xml</code> file, you must have the capability header containing the required features, and also define them in the subsystem content.	Yes
Subsystem-Localization	The location of the localization files for the feature.	No

Table 125. Headers of a feature manifest file (continued).

This table shows the headers of a feature manifest file in the Liberty profile. The first column shows a list of headers. The second column shows the description of each header, and the third column states whether the header is required.

Header	Description	Required?
Subsystem-Name	A short, human readable name for the feature. This value can be localized.	No
Subsystem-Description	A description of the feature. This value can be localized.	No
IBM-Feature-Version	The version of this subsystem type. Must be set to 2.	Yes
IBM-Provision-Capability	The capability header that describes whether a feature can be provisioned automatically.	No
IBM-API-Package	The API packages that are exposed to applications by this feature, features in other product extensions, and the Liberty kernel.	No
IBM-API-Service	The OSGi services that are exposed to OSGi applications by this feature.	No
IBM-SPI-Package	The SPI packages that are exposed by this feature to features in other product extensions, and the Liberty kernel.	No
IBM-ShortName	The short name of the feature.	No
IBM-AppliesTo	The Liberty version that this feature applies to.	No
Subsystem-License	The license type for this feature.	No
IBM-License-Agreement	The prefix of the location of the license agreement files.	No
IBM-License-Information	The prefix of the location of the license information files.	No
IBM-App-ForceRestart	Specifies that applications are to be restarted when the feature is installed to, or uninstalled from, a running server.	No

## Subsystem-SymbolicName

The syntax for this header matches the `Bundle-SymbolicName` syntax for a bundle. It has a symbolic name that follows the package names style syntax, and can optionally take a set of attributes and directives.

**8.5.5.0** The following attributes are supported:

- **superseded**. This attribute indicates whether this feature is superseded by one or more features or items of functionality. It takes one of the following values:
  - `true` - The feature is superseded.
  - `false` - The feature is not superseded.

This attribute is optional; the default value is `false`.

For more information, see [Superseded features](#).

- **superseded-by**. This attribute specifies a comma-separated list of the features that supersede this feature, if any, and is optional.

**8.5.5.0** The following directive is supported:

- **visibility**. This directive takes one of the following values:

- `public` - Feature considered to be API. The feature is supported by the developer tools, for use in the `server.xml` file, and output in messages.
- `protected` - Feature considered to be SPI. The feature is not supported by the developer tools, for use in the `server.xml` file, or output in messages. The feature is provided so extenders can use it to build higher-level features.
- `private` - (default) The feature is product internals. The feature is not supported for use in the `server.xml` file or to be referenced by extender features. The feature can be changed at any time, including between fix packs.

For example:

```
Subsystem-SymbolicName: com.ibm.example.feature-1.0;
visibility:=public; superseded=true; superseded-by="com.ibm.example.feature-2.0"
```

**8.5.5.0** If a feature name in the `superseded-by` list is surrounded by brackets, `[]`, this feature is separated from the superseding feature. In the following example, feature `appSecurity-1.0`, which contains features `servlet-3.0` and `ldapRegistry-3.0`, is superseded by feature `appSecurity-2.0`, which does not contain `servlet-3.0` and `ldapRegistry-3.0` features:

```
IBM-ShortName: appSecurity-1.0
Subsystem-SymbolicName: com.ibm.websphere.appserver.appSecurity-1.0; visibility:=public;
superseded=true; superseded-by="appSecurity-2.0, [servlet-3.0], [ldapRegistry-3.0]"
```

For more information, see `Separated features`.

**Best practice:** If the developer tools must show the feature, it must be `public`. If the feature is available only to trusted parties, it must be `protected`. If the feature is internal and subject to change at any time, it must be `private`.

- **8.5.5.6** **singleton**. This directive takes one of the following values:
  - `True`. The feature is a singleton.
  - `False`. The feature is not a singleton.

The **singleton** directive is optional. The default value is `False`.

This directive is used to declare that a particular feature is a singleton. A singleton means that only one version of a given feature can be loaded into the runtime at a time. By default, features are not singletons. If the feature is a singleton and multiple versions of a given feature are required by the server configuration, then the runtime attempts to find a common version that is tolerated by all requiring features. For more information on version toleration, see the **ibm.tolerates** directive under `Subsystem-Content`.

When a feature is a singleton, then the symbolic name value is in the form "`<singleton feature name>-<singleton version>`", where the name and version are separated by a hyphen. The singleton feature name can contain hyphens, but the characters that follow the last hyphen are interpreted as the singleton version. If the characters that follow the last hyphen are not a valid version, then a singleton version of `0.0.0` is used and the complete symbolic name is used as the singleton name. The singleton version is used when processing `ibm.tolerates` directives under `Subsystem-Content`; for example:

```
Subsystem-SymbolicName: com.ibm.example.feature-1.0;
visibility:=public; singleton=true
```

## Subsystem-Content

This header defines the content of the feature, both for run time and install. It follows the same header syntax as the `Subsystem` specification with the following syntax:

```
Subsystem-Content ::= content ( ',' content )*
content ::= unique-name ( ';' parameter )*
unique-name ::= unique-name (see OSGi core spec section 1.3.2)
```

The unique-name uses the form of the `Bundle-SymbolicName` or `Subsystem-SymbolicName` headers. The following attributes are supported:

- **version** - The range of versions to be matched when you find a bundle. Only bundles in this range are selected. A typical example of the version range is `[1,1.0.100)`.
- **type** - The type of content to be provisioned. You can specify any value to indicate the content type; some types result in bundles being installed and started in the OSGi framework of a server that uses the feature, all types cause the content to be included in an installation package that includes the feature. The following values are predefined:
  - `osgi.bundle` - This is the default value and indicates an OSGi bundle that should be provisioned both into the OSGi framework of the server and an installation package.
  - `osgi.subsystem.feature` - This value indicates that the feature should be provisioned both into the OSGi framework of the server and an installation package. These features need to use the name that is specified in `Subsystem-SymbolicName` header.
  - `jar` - This value indicates that a JAR file should be included in an installation package and is selected by using a combination of a version range, a location value, or both.
  - `file` - This value indicates that the file that is identified in the **location** attribute should be included in an installation package.

#### 8.5.5.0

The following directives are supported:

- **location** - The location of the bundle. For a bundle or JAR type, this value can be a comma-separated list of directories that represent a search path. For any type, this value might be a single entry that points directly to the resource and might be specified as a file URL. Paths might be absolute or relative. Relative paths are resolved relative to the location of the product extension that contains the feature. For a user feature, the default product extension location is used which is `${wlp.user.dir}/extension`. The location of non-default product extensions is declared by the `com.ibm.websphere.productInstall` property in its properties file in the `${wlp.install.dir}/etc/extensions` directory.

For example:

```
Subsystem-Content: com.ibm.websphere.appserver.api.basics; version="[1,1.0.100)"; type=jar; location="dev/api/ibm/,lib/",
                  com.ibm.websphere.appserver.spi.application;
                  location="dev/spi/ibm/com.ibm.websphere.appserver.spi.application_1.0.0.jar"; type="jar",
                  com.ibm.websphere.appserver.spi.application_1.0.0-javadoc.zip;
                  location="dev/spi/ibm/javadoc/com.ibm.websphere.appserver.spi.application_1.0.0-javadoc.zip"; type="file"
```

- **start-phase** - The start phase when the bundle should start during system startup. The **start-phase** directive can take one of the following values:
  - `SERVICE` - This value indicates the earliest phase. By default it maps to a start level of 9.
  - `CONTAINER` - This is the default value if no **start-phase** is provided. It indicates the container phase when application containers are started. By default it maps to a start level of 12.
  - `APPLICATION` - This value indicates the latest phase when applications are started.

Bundles can also be defined to start before or just after these phases by adding `_LATE` to be later, or `_EARLY` to be earlier than the key phase. So if you want to run immediately after the container phase, use `CONTAINER_LATE`, and if you want to run before the `APPLICATION` phase then use `APPLICATION_EARLY`.

- **8.5.5.6** **ibm.tolerates** - Specifies alternative singleton version or versions of a singleton feature, `type=osgi.subsystem.feature`, to be provisioned into the system if there are version conflicts.

The unique-name specifies the symbolic name of the preferred version of a singleton feature. If the including feature is known to work with other singleton versions of a given singleton feature, then these singleton versions can be specified by using the **ibm.tolerates** directive. This gives greater compatibility to the defining feature in the case that other features define conflicting required version values of a given singleton feature.

Singleton versions that are listed in the **ibm.tolerates** directive are only used if a version conflict. The ordering of versions that are listed in the **ibm.tolerates** directive is not significant - any version that is listed in the **ibm.tolerates** directive can be selected to satisfy dependency requirements.

The tolerated version or versions of a given singleton feature must be explicitly listed in the **ibm.tolerates** directive. Use commas to separate a list of tolerated versions. Specifying a version range is not supported.

For example:

```
Subsystem-Content: com.ibm.websphere.appserver.example.featureA-1.1; ibm.tolerates="1.2"; type="osgi.subsystem.feature",
com.ibm.websphere.appserver.example.featureB-1.1; ibm.tolerates="1.2, 1.4, 1.6"; type="osgi.subsystem.feature"
```

**Note:**

Tolerated versions are not transitive. This prevents a feature that your feature depends on from being automatically opted in to supporting a later level of a feature, without testing it.

For example: User feature featureC-1.1 includes sipServlet-1.1 in the Subsystem-Content header of its manifest file. sipServlet-1.1 includes servlet-3.0 and tolerates servlet 3.1. If featureC-1.1 was written before servlet-3.1 existed and then servlet-3.1 was added and tolerated by the feature used by it (sipServlet-1.1), featureC-1.1 should have a say on whether it also tolerated servlet-3.1.

If you configure the server.xml file to have the following two features:

```
<feature>usr:featureC-1.1</feature> // includes: sipServlet-1.1
<feature>websocket-1.0</feature> // this feature requires servlet-3.1
```

You will see an error message that resembles the following displayed:

```
CWWKF0033E: The singleton features servlet-3.0 and servlet-3.1 cannot be loaded at the same time.
The configured features usr:featureC-1.1 and websocket-1.0 include one or more features that cause the conflict.
Your configuration is not supported; update server.xml to remove incompatible features."
```

This error is reported because featureC-1.1 is not opted in to tolerating servlet-3.1, and so has to have servlet-3.0, and websocket-1.0 does not support servlet-3.0 and so has to have servlet-3.1.

The solution is for featureC-1.1 to also directly depend on servlet-3.0 and tolerate servlet-3.1.

   The following directives are supported in version 8.5.5.4 and later:

- **ibm.zos.extended.attributes** - Sets the extended attributes to the specified value for the associated file. The value can be any combination of 'a', 'l', 'p', and 's'. Summary of the value options:
  - a = APF authorized
  - p = Program controlled
  - s = Shared address space
  - l = Shared library
- **ibm.file.encoding** - Converts the associated file from ASCII encoding to the encoding type specified. The **ibm.file.encoding** directive can take the value "ebcdic", which converts the ASCII encoded file to EBCDIC encoding.

        The following directive is supported in version 8.5.5.4 and later:

- **ibm.executable** - Adds the execute permission to the associated file, according to the current umask setting, when the value is set to "true". Any other value results in no action taken. The following table shows the current umask and which class gets the execute permission.

Table 126. Examples of umask values and classes with execute permissions set by ibm.executable

Umask	Execute permissions granted to class
022	owner, group, other
023	owner, group

Table 126. Examples of umask values and classes with execute permissions set by `ibm.executable` (continued)

Umask	Execute permissions granted to class
055	owner

## Subsystem-Localization

This header specifies the location of the localization files for the feature.

For example:

```
Subsystem-Localization: OSGI-INF/110n/loc
```

## Subsystem-Name

Use this header to supply a short, human readable name for the feature. You can specify either a literal string or a property name. If you specify a property name, the value can be localized.

For example

```
Subsystem-Name: %name
```

where the value of `name` is defined in a properties file at the location that is specified by the `Subsystem-Localization` header (`loc.properties` in the previous example), in the following format:

```
name=feature_name
```

## Subsystem-Description

Use this header to supply a description for the feature. You can specify either a literal string or a property name. If you specify a property name, the value can be localized.

For example

```
Subsystem-Description: %desc
```

where the value of `desc` is defined in a properties file at the location that is specified by the `Subsystem-Localization` header (`loc.properties` in the previous example), in the following format:

```
desc=feature_description
```

## IBM-Provision-Capability

Automatically provisioned features are features that have the `IBM-Provision-Capability` header in the manifest. This header describes other features that must be provisioned for this feature to be automatically provisioned. When you list the other features, use the `Subsystem-SymbolicName` header of the feature. When any features are configured in the `server.xml` file, the runtime checks to see whether any automatically provisioned features have their capabilities satisfied, and if any have, they are automatically provisioned.

The format of the `IBM-Provision-Capability` header uses standard OSGi LDAP filters.

## IBM-API-Package

This header is used to indicate which API packages are visible to applications. It matches the `Export-Package` header syntax. This means it is a comma-separated list of API packages, but each API package can have some attributes.

**8.5.5.0** The following attribute is supported:

- **type** - The type of API package. The **type** attribute takes one of the following values:
  - `spec` - Indicates an API provided by a standard body, such as `javax.servlet` or `org.osgi.framework`.
  - `ibm-api` - Indicates a value-add API provided by IBM.
  - `api` - Indicates a user-defined API. This is the default value.
  - `third-party` - Indicates an API that is visible, but not controlled by IBM. Typically, these are open source packages.
  - `internal` - Indicates non-API packages that must be exposed to applications for them to function. This might be used if Java code is bytecode enhanced, or *weaved*, to add references to internal code at run time.

For example:

```
IBM-API-Package: javax.servlet; type="spec",
                 com.ibm.websphere.servlet.session; type="ibm-api",
                 com.ibm.wsspi.webcontainer.annotation; type="internal"
```

## IBM-API-Service

This header is used to indicate which services from the feature are visible to OSGi applications. The feature must also register the service in the OSGi service registry.

It has the following syntax

```
IBM-API-Service ::= service ( ',' service )*
                  service ::= service-name ( ';' attribute )*
                  service-name ::= unique-name
```

The `service-name` is the Java class or interface name of the service. The attributes are interpreted as the service properties for the services.

For example:

```
IBM-API-Service: com.ibm.example.service.FeatureServiceOne;
                 myServiceAttribute=myAttributeValue,
                 com.ibm.example.service.FeatureServiceTwo
```

If an OSGi application wants to use the services that are provided by the `IBM-API-Service` header, the application must include a blueprint reference to the service in order for the service to be provisioned into the application.

For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0">
  <reference id="FeatureServiceOneRef"
            interface="com.ibm.example.service.FeatureServiceOne" />
</blueprint>
```

In order for a service to be usable by a bundle in an OSGi application, the interface package must be available to that bundle, which means the interface package must be specified by an `Import-Package` header in the manifest file of the consuming bundle. The interface package must also be specified by an `Export-Package` header in a feature bundle and specified in the `IBM-API-Package` header of the feature manifest file. The service that is provided by a feature must be registered in the OSGi service registry by using the OSGi `BundleContext` interface or any other mechanism such as Declarative Services or Blueprint. For more information, see “Developing an OSGi bundle with simple activation” on page 1788 and “Composing advanced features by using OSGi Declarative Services” on page 1793.

## IBM-SPI-Package

When you create your own Liberty feature, you install it into the user product extension. All the packages in your feature can be accessed by any other feature that is installed into the user product extension. However, if you want a package in your feature to be accessed by a feature that is installed into another product extension, you must list the package name in the IBM-SPI-Package header.

Any package that is listed in the IBM-SPI-Package header must be exported by a bundle in the Liberty feature, by being listed in the Export-Package header of the bundle manifest file.

## IBM-ShortName

This header is a short name for a feature that you can use to specify a feature in the `server.xml` file. If there is no IBM-ShortName header in the manifest file, then the Subsystem-SymbolicName is used by default. The IBM-ShortName header is only valid for public features.

## IBM-AppliesTo

This header specifies the Liberty version that this feature applies to. Supply a comma-separated list of items, each in the following form:

```
product_id; productVersion=product_version; productInstallType=product_install_type; productEdition=product_editions
```

If you supply more than one item, the value of *product\_id* must be different for each one.

**8.5.5.7** The value of *productVersion* can be either an exact version, such as *8.5.5.7*, or a minimum version, denoted by the version that ends with a plus sign, +, such as *8.5.5.7+*.

The value of *productEdition* can be either a single edition or a comma-separated list of editions that are enclosed in quotation marks.

For example:

```
IBM-AppliesTo: com.ibm.websphere.appserver; productVersion=8.5.5.6; productInstallType=Archive; productEdition="BASE,DEVELOPERS,EXPRESS,ND"
```

## Subsystem-License

This header defines the license type for this feature. If you supply a value for the Subsystem-License header, and do not supply values for the IBM-License-Agreement and IBM-License-Information headers, then the Subsystem-License header value is displayed to the user for acceptance during installation.

If there is a feature that is already installed with the same Subsystem-License header value, then the license is not displayed, and license approval is not sought, during the installation. If dependencies in the Subsystem-Content header mean that there are two or more features being installed that have the same Subsystem-License header value, the user has only to accept the license once during installation.

For example:

```
Subsystem-License: L-JTHS-93TMHH
```

```
Subsystem-License: http://www.apache.org/licenses/LICENSE-2.0.html
```

## IBM-License-Agreement

This header specifies the prefix of the location of the license agreement files. Supply the file path in the subsystem archive to the *LA\_language* files, up to, but not including, the "\_" character (the language code is appended by the installation tool). If this license has not been accepted, the user must accept the license when you install the feature. The license files are copied to the Liberty installation directory.

For example:

```
IBM-License-Agreement: lafiles/LA
```

## IBM-License-Information

This header specifies the prefix of the location of the license information files. Supply the file path in the subsystem archive to the *LI\_language* files, up to, but not including, the "\_" character (the language code is appended by the installation tool). If this license has not been accepted, the user must accept the license when you install the feature. The license files are copied to the Liberty installation directory.

For example:

```
IBM-License-Information: lafiles/LI
```

## IBM-App-ForceRestart

This header causes applications to be restarted when the feature is installed to, or removed from, a running server. This header can take one of the following values:

- `install` - restart applications when the feature is installed.
- `uninstall` - restart applications when the feature is uninstalled.
- `install,uninstall` - restart applications when the feature is installed or uninstalled.

## Example feature manifest file

The following example shows the definition for the `example-1.0` feature. The public visibility attribute allows this feature to be directly specified in server configuration (`server.xml`) files; it will also be included in the drop down list of features that are displayed in **Server Configuration** view of the developer tools and will be available for inclusion in features that are in other product extensions. If this feature is installed into the `usr` product extension of a runtime install, it can be configured into a server by including the following code in the `server.xml` file:

```
<featureManager>  
  <feature>usr:example-1.0</feature>  
</featureManager>
```

Configuration of this feature in a server results in the specified bundle, `com.ibm.example.bundle1`, being installed and started in the OSGi framework of the server runtime environment. The single API package, `com.ibm.example.publicapi`, will be visible to all applications in that server, except for Java EE applications that are configured to not have visibility to the `api` package type. OSGi applications must explicitly import the package if they wish to use it. The two SPI packages, `com.ibm.example.spi.utils` and `com.acme.spi.spiservices`, will be visible to all feature code in the server, as will the API package.

```
IBM-Feature-Version: 2  
Subsystem-ManifestVersion: 1.0  
Subsystem-SymbolicName: com.ibm.example-1.0; visibility:=public  
Subsystem-Version: 1.0.0.qualifier  
Subsystem-Type: osgi.subsystem.feature  
Subsystem-Content: com.ibm.example.bundle1; version="1.0.0"  
Subsystem-Localization: OSGI-INF/l10n/loc  
Manifest-Version: 1.0  
Subsystem-Name: %name  
Subsystem-Description: %desc  
IBM-API-Package: com.ibm.example.publicapi; type="api"  
IBM-SPI-Package: com.ibm.example.spi.utils, com.ibm.example.spi.spiservices  
IBM-ShortName: example-1.0
```

## Auto-provisioning a feature

8.5.5.0

Auto-provisioning allows a feature to have dependencies on features that must be provisioned before it can be provisioned.

## About this task

An auto-provisioned feature is a feature that has dependencies on other features. Because of the dependencies, the lifecycle of the auto-provisioned feature is as follows:

- The feature is provisioned automatically when all required features are provisioned.
- The feature is de-provisioned automatically when any of the required features are de-provisioned.

## Procedure

To configure a feature to be auto-provisioned, follow these steps:

1. Determine which features must be provisioned before the runtime automatically provisions this feature.
2. Add the `IBM-Provision-Capability` to the manifest header. The format of the `IBM-Provision-Capability` header uses standard OSGi LDAP filters.
3. Deploy the feature to the server.

## Results

The feature automatically provisions when the required features are provisioned.

## Example

In the following example, if features `requiredFeature1-1.0` and `requiredFeature2-1.0` are provisioned, this feature is automatically provisioned. If either of these required features are removed from the `server.xml` file, this feature is automatically de-provisioned.

```
IBM-Provision-Capability: osgi.identity; filter="(
&(type=osgi.subsystem.feature)(osgi.identity=requiredFeature1-1.0)", osgi.identity;
filter="(amp;(type=osgi.subsystem.feature)(osgi.identity=requiredFeature2-1.0))"
```

## Automatic installation of auto-provisioned features

If all the required features are also installed, auto-provisioned features can be installed automatically.

To configure a feature to be auto-installed, the `IBM-Install-Policy` header must be added to the feature manifest. The header is optional. If the `IBM-Install-Policy` header is specified, the following values are valid:

- `manual`: The feature is not auto-installed.
- `when-satisfied`: If all required features are installed, the feature is auto-installed.

If the header is not set, then the feature is not auto-installed, which is equivalent to setting the `IBM-Install-Policy` header to `manual`.

## Creating a Liberty feature by using developer tools

8.5.5.0

You can use the WebSphere Application Server Developer Tools to write your own features and install them into an existing Liberty server, or to package them for delivery to your users.

## About this task

To develop a Liberty feature in the WebSphere Application Server Developer Tools, you create a Liberty feature project and target it to the WebSphere Application Server Liberty version 8.5.5 or later.

You add OSGi bundles that contain classes and services that implement the function provided by your Liberty feature. If your feature provides any API packages to OSGi applications, or SPI packages to features in other product extensions, you can declare those packages in the Liberty feature manifest file.

You can export your liberty feature as a compressed file that can be extracted over an existing WebSphere Application Server Liberty to extend its capabilities.

For more information on creating Liberty features, see “Liberty profile: Product extension” on page 967.

Creating a Liberty feature by using WebSphere Application Server Developer Tools is described in more detail in the following subtopics:

### Procedure

1. “Creating a Liberty feature project.”
2. “Adding OSGi bundles to a Liberty feature project” on page 1784.
3. “Specifying API and SPI packages for a Liberty feature project” on page 1784.
4. “Installing a Liberty feature to Liberty V8.5.5” on page 1785.

### Creating a Liberty feature project

**8.5.5.0**

To develop a Liberty feature by using the WebSphere Application Server developer tools, you must create a Liberty feature project in your workspace.

## About this task

A Liberty feature project contains classes and services that implement the function provided by your Liberty feature

### Procedure

To create a Liberty feature project, complete the following steps:

1. Click **File > New > Other > OSGi > Liberty Feature Project** and then click **Next**. The New Liberty Feature Project wizard opens.
2. In the **Project name** field, enter the name of your Liberty feature project.
3. Select a **Target runtime** from the drop down list. The list will include the WebSphere Application Server Liberty 8.5.5 if it is defined in your workspace as an installed runtime environment.
4. Click **Next**. The OSGi Bundles Selection dialog box opens.
5. Select one or more OSGi bundles to add to the Liberty feature project, or click **New Bundle** to create an OSGi bundle to add to the Liberty feature project. You can add further bundles after you have created the Liberty feature project; see “Adding OSGi bundles to a Liberty feature project” on page 1784.

For information on creating an OSGi bundle, see Creating OSGi bundle projects.

6. Click **Finish** to create the Liberty feature project.

### Results

The Liberty feature project is added to your workspace.

## Adding OSGi bundles to a Liberty feature project

8.5.5.0

A Liberty feature includes OSGi bundles that contain classes and services. The classes and services implement the functions that the Liberty feature provides. You can include OSGi bundles in a Liberty feature that was created with the WebSphere Application Server Developer Tools by adding the bundles to the corresponding Liberty feature project.

### Procedure

To add OSGi bundles to a Liberty feature project, complete the following steps:

1. From the Project Explorer view, open the feature manifest file for the Liberty feature project by double-clicking the **Manifest** node in the project hierarchy, indicated by the manifest icon ().
2. In the Contained Bundles pane, click **Add** to select one or more bundles to add to the Liberty feature project, or click **New** to create a new OSGi bundle to add to the Liberty feature project. For information on creating an OSGi bundle, see [Creating OSGi bundle projects](#).
3. (Optional) Specify the version range for the contained bundle by selecting the bundle, clicking **Properties**, and entering the required values in the **Minimum Version** and **Maximum Version** fields.
4. (Optional) Use the **Location** field in the Properties dialog box to specify the location where you want the bundle to be packaged when exported, relative to the product extension installation folder. If you want the bundle to be packaged in more than one location, enter the locations as a comma-separated list. By default, the bundle is packaged in the `/lib` folder.

### Results

The bundle names are added to the Subsystem-Content header in the manifest file. For more information on the headers in the feature manifest file for a Liberty feature, see “Liberty feature manifest files” on page 1773.

## Specifying API and SPI packages for a Liberty feature project

8.5.5.0

Use the Liberty feature manifest file to declare which packages you want to share as an API or SPI with other applications and features in the Liberty runtime environment.

### About this task

A package cannot be declared as an API or SPI unless it is exported by a bundle in the Liberty feature, by being listed in the Export-Package header of the bundle manifest file.

### Procedure

To specify API and SPI packages for a Liberty feature project, complete the following steps:

1. From the Project Explorer view, open the feature manifest file for the Liberty feature project by double-clicking the **Manifest** node in the project hierarchy, indicated by the manifest icon ().
2. To make one or more API packages available to OSGi applications, click **Add** in the IBM API Packages pane.
3. When you create your own Liberty feature, you install it into the user product extension, and all the packages in your feature can be accessed by any other feature that is installed into the user product extension. To make one or more SPI packages available to features in other product extensions, click **Add** in the IBM SPI Packages pane.

4. (Optional) Specify the package version by selecting the package, clicking **Properties**, and entering the required value in the **Version** field.
5. (Optional) For an API package, select the package type from the **Type** list in the Properties dialog box. The type can be one of the following values:
  - `spec` - Indicates an API provided by a standard body, such as `javax.servlet` or `org.osgi.framework`.
  - `ibm-api` - Indicates a value-add API provided by IBM.
  - `api` - Indicates a user-defined API. This is the default value.
  - `third-party` - Indicates an API that is visible, but not controlled by IBM. Typically, these are open source packages.
  - `internal` - Indicates non-API packages that must be exposed to applications for them to function. This might be used if Java code is bytecode enhanced, or *weaved*, to add references to internal code at run time.

## Results

The package names are added to the `IBM-API-Package` and `IBM-SPI-Package` headers in the feature manifest file. For more information on the headers in the feature manifest file for a Liberty feature, see “Liberty feature manifest files” on page 1773.

## Installing a Liberty feature to Liberty V8.5.5

**8.5.5.0**

When you develop a Liberty feature by using the WebSphere Application Server Developer Tools, you need to create a Liberty feature project that packages the Liberty feature. You can use the workbench to install Liberty features to Liberty runtime environments and enable installed features using the server configuration editor. Changes to features already installed on Liberty can be pushed to all respective runtime environments using the **Update Feature** menu option in the workbench.

### Before you begin

Create a Liberty feature project.

**Restriction:** This topic is supported for WebSphere Application Server Liberty V8.5.5. For versions 8.5 or earlier, see “Manually installing a Liberty feature to Liberty V8.5 or earlier” on page 1786 topic.

### Procedure

To install a Liberty feature, complete the following steps:

1. In the **Enterprise Explorer** view, right-click your Liberty feature project and select **Install Feature**.
2. In the **Feature install** wizard and under **Target Runtimes**, select the Liberty runtime environment that you want to install your feature. Click **Finish**.

**Tip:** If the feature is already installed on Liberty, the Liberty entry is no longer an available option in the list of target runtimes. Instead, you should use the **Update Features** menu option (available when you right-click the Liberty feature project in the Enterprise Explorer view) to update any changes to a feature already installed on Liberty.

3. Add the feature name to the list of configured features in your server configuration (`server.xml` file):
  - a. In the Servers view, expand your Liberty server, right-click the **Server Configuration [server.xml]** and select **Open**.
  - b. In the Server Configuration editor, under the **Configuration Structure**, expand **Server Configuration** and select **Feature Manager**.
  - c. Under the **Feature Manager**, select the **Add** button.

- d. In the **Add Features** wizard, search and select your feature with the prefix `usr:` followed by the name of your Liberty feature project, for example, `usr:MyLibertyFeatureProject`. Click **OK**.

In the **Source** tab of the Server Configuration editor, the `server.xml` file displays the newly added feature entry under the `featureManager` node:

```
<featureManager>
  <feature>usr:MyLibertyFeatureProject</feature>
</featureManager>
```

## Results

After installing the Liberty feature, you can find the following file structure in the `${wlp.user.dir}/extension` directory:

```
/lib
  /features
    manifest files
    .
    .
    .
  OSGi bundle JAR files
  .
  .
  .
```

## What to do next

To update changes to a feature already installed on the Liberty runtime environments, use the **Update Features** menu option (available when you right-click the Liberty feature project in the Enterprise Explorer view). A **Progress Information** window opens and the workbench takes a moment to perform this update action.

## Manually installing a Liberty feature to Liberty V8.5 or earlier

**8.5.0.1**

When you develop a Liberty feature by using the WebSphere Application Server Developer Tools, you create a Liberty feature project that packages the Liberty feature in a compressed file. To install the Liberty feature, you must extract the contents of the compressed file to the Liberty environment.

## Before you begin

Create a Liberty feature project.

**Restriction:** This topic is supported for WebSphere Application Server Liberty V8.5 or earlier. For versions 8.5.5, see “Installing a Liberty feature to Liberty V8.5.5” on page 1785 topic.

## About this task

The compressed file has the following structure:

```
/lib
  OSGi bundle JAR files
  .
  .
  .
/features
  manifest file
```

## Procedure

To install a Liberty feature, complete the following steps:

1. In your workspace, right-click your Liberty feature project and select **Export > Liberty Feature**.
2. In the **To ESA file** field, specify the location and name of the compressed file to which you want to export the Liberty feature project.
3. Click **Finish** to export the Liberty feature project to the specified location.
4. Extract the contents of the compressed file to the `${wlp.user.dir}/extension` directory.
5. Add the feature name to the list of configured features in your `server.xml` file; you must prefix the feature name with `usr:`.

For example:

```
<featureManager>
  <feature>usr:sample-1.0</feature>
</featureManager>
```

## Adding OSGi metatype descriptions to a Liberty feature project

You can add OSGi metatype descriptions to a Liberty feature that was created with the WebSphere Application Server Developer Tools by creating a metatype XML file. You can package that file in an OSGi bundle project.

### Procedure

1. From the Project Explorer view, add a folder in the `BundleContent` folder, and name it `OSGI-INF`.
2. Create a folder that is named `metatype` in the `OSGI-INF` folder.
3. Create the metatype XML file in the `metatype` folder.

The metatype XML file must have a `.xml` suffix. You can use any name for the file.

4. Optional: Provide translated strings for your metatype definitions.

- a. Create a folder to contain the translated properties files.

For example, you can create a subfolder that is named `I10n` in the `OSGI-INF` folder, and use the prefix `metatype` for your translated properties files.

- b. In the metatype XML file, specify the location of the folder that you created.

Use the following example as a guide:

```
<box>
<metatype:MetaData xmlns:metatype="http://www.osgi.org/xmlns/metatype/v1.1.0"
  localization="OSGI-INF/I10n/metatype">
</box>
```

## Results

You created a metatype XML file, which you can use to add OSGi metatype descriptions to a Liberty feature.

## What to do next

You can add information to the metatype XML file. For more information about what to add to the file, see “Liberty feature manifest files” on page 1773.

To describe your configuration by using the OSGi metatype service, package the metatype XML file in the `OSGI-INF/metatype` folder of one of your OSGi bundle projects, not in the Liberty feature project. For best results, put the metatype XML file in the same OSGi bundle as the code that receives and processes the configuration values, such as the associated `ManagedService` implementation. For more information, see “Describing configuration by using the OSGi Metatype service” on page 1798.

## Developing an OSGi bundle with simple activation

8.5.5.0

The most straightforward way to control the lifecycle of your OSGi bundle code is to implement the `org.osgi.framework.BundleActivator` interface in one of the classes within your bundle. When the server starts and stops the bundle, the start and stop methods of the `BundleActivator` interface are called.

### About this task

If you are using the WebSphere Application Server Developer Tools, create an OSGi bundle project, and create an OSGi `BundleActivator` class in that project. Then identify your bundle activator class to the OSGi framework by adding the `Bundle-Activator` header to the bundle `MANIFEST.MF` file. For example:  
`Bundle-Activator: com.example.bundle.Activator.`

### Example

```
package com.example.bundle;

import org.osgi.framework.BundleActivator;
import org.osgi.framework.BundleContext;

public class Activator implements BundleActivator {
    public void start(BundleContext context) throws Exception {
        System.out.println("Sample bundle starting");
        // Insert bundle activation logic here
    }

    public void stop(BundleContext context) throws Exception {
        System.out.println("Sample bundle stopping");
        // Insert bundle deactivation logic here
    }
}
```

## Receiving configuration data by using the `ManagedService` interface

8.5.5.0

Liberty configuration is managed by the OSGi Configuration Admin service and can be accessed according to the OSGi Configuration Admin service specification. Sets of configuration properties are identified by a persisted identity (PID) that is used to associate an element in the `server.xml` file, where the PID is used as the element name, with a component that registers to receive the properties.

### About this task

For an OSGi bundle whose lifecycle is managed by using the `BundleActivator` interface, a straightforward way to receive the configuration properties is to implement the `org.osgi.service.cm.ManagedService` interface, which specifies the PID as one its properties.

### Example

#### Remember:

1. In Eclipse, you must select an SPI target runtime from **Window > Preferences > Plug-In Development > Target Platform**.
2. Add the following statement to your `MANIFEST.MF` file:  
`Import-Package: org.osgi.service.cm;version="1.5.0"`
3. Press `Ctrl + Shift + O` to update your bundle activator.

In this example, the Activator class implements the ManagedService interface in addition to the BundleActivator interface, and receives configuration properties by using the updated method. You can provide default property values to simplify what must be specified in the user configuration.

```
public class Activator implements BundleActivator, ManagedService {

    public void start(BundleContext context) throws Exception {
        System.out.println("Sample bundle starting");
        // register to receive configuration
        ServiceRegistration<ManagedService> configRef = context.registerService(
            ManagedService.class,
            this,
            getDefaults()
        );
    }

    public void stop(BundleContext context) throws Exception {
        System.out.println("Sample bundle stopping");
        configRef.unregister();
    }

    Hashtable getDefaults() {
        Hashtable defaults = new Hashtable();
        defaults.put(org.osgi.framework.Constants.SERVICE_PID, "simpleBundle");
        return defaults;
    }

    public void updated(Dictionary<String, ?> properties) throws ConfigurationException {
        if (properties != null)
        {
            String configColor = (String) properties.get("color");
            String configFlavor = (String) properties.get("flavor");
        }
    }
}
```

User configuration for the bundle can optionally be provided in the `server.xml` file, or an included file, by the following entry:

```
<simpleBundle color="red" flavor="raspberry" />
```

**Note:** The element name in the user configuration, `simpleBundle` matches the value of the `org.osgi.framework.Constants.SERVICE_PID` property used in the `ManagedService` registration.

**8.5.5.0** For more advanced configuration use, see “Describing configuration by using the OSGi Metatype service” on page 1798.

## Working with the OSGi service registry

You can create an object and register it as an OSGi service for use by third-party features that are deployed to Liberty.

### About this task

Services are the OSGi lightweight and flexible component model. When you create services and wire them together with Java code, you can use mechanisms such as `ServiceTrackers` to help find the services that you want, and `Declarative Services (DS)` and `Blueprint` to specify the wiring declaratively. Liberty has standardized on using `DS` for wiring, except for a small number of cases where extra flexibility is required.

## Registering OSGi services: 8.5.5.0

You can create an object and register it as an OSGi service for use by third-party features.

### About this task

By using plain old Java code, you can create an object, and then register it as a service using the `BundleContext` class. Because the code has to run, you typically register the object in a `BundleActivator` interface. When you register the object, you can specify what interfaces it provides, and supply a property map. A `ServiceRegistration` object is returned; if necessary, you can use the `ServiceRegistration` object to change the properties at any time. When the service is completed, you use the `ServiceRegistration` object to unregister the service.

To obtain a service, you query the `BundleContext` for a service that implements a required interface and, optionally, supply an LDAP-syntax filter to match the service properties. Depending on the method you call, you can retrieve the best match or all the matches. You can then use the returned `ServiceReference` that provides the properties to do further matching in your code. You can use the `ServiceReference` to get the actual service object. When you have finished using the service, you use the `BundleContext` to release the service.

### Procedure

1. Declare the service interface by adding the following code in your bundle.

```
package com.ibm.foo.simple;

/**
 * Our multifunctional sample interface
 */
public interface Foo
{
}
```

2. Specify the implementation code of the interface.

```
package com.ibm.foo.simple;

/**
 * The implementation of the Foo interface
 */
public class FooImpl implements Foo
{
    public FooImpl()
    {
    }
    public FooImpl(String vendor)
    {
    }

    /**
     * used by the ServiceFactory implementation.
     */
    public void destroy() {
    }
}
```

3. Use the `BundleContext` to register the service, modify the service properties, and unregister the service directly in your code.

```
import java.util.Dictionary;

import org.osgi.framework.BundleContext;
import org.osgi.framework.ServiceRegistration;
```

```

/**
 * Registers and unregisters a Foo service directly,
 * and shows how to modify the service properties in code.
 */
public class FooController
{

    private final BundleContext bundleContext;
    private ServiceRegistration<Foo> sr;

    public FooController( BundleContext bundleContext )
    {
        this.bundleContext = bundleContext;
    }

    public void register(Dictionary<String, Object> serviceProperties) {
        Foo foo = new FooImpl();
        //typed service registration with one interface
        sr = bundleContext.registerService( Foo.class, foo, serviceProperties );
        //or
        //untyped service registration with one interface
        sr = (ServiceRegistration<Foo>)bundleContext.registerService(
            Foo.class.getName(), foo, serviceProperties );
        //or
        //untyped service registration with more than one interface (or class)
        sr = (ServiceRegistration<Foo>)bundleContext.registerService(new String[] {
            Foo.class.getName(), FooImpl.class.getName()}, foo, serviceProperties );
    }

    public void modifyFoo(Dictionary<String, Object> serviceProperties) {
        //with the service registration you can modify the service properties at any time
        sr.setProperties( serviceProperties );
    }

    public void unregisterFoo() {
        //when you are done unregister the service using the service registration
        sr.unregister();
    }

}

```

#### 4. Obtain and return the service from another class:

```

package com.ibm.foo.simple;

import java.util.Collection;

import org.osgi.framework.BundleContext;
import org.osgi.framework.InvalidSyntaxException;
import org.osgi.framework.ServiceReference;

/**
 * A simple Foo client that directly obtains the Foo service and returns it when done.
 */
public class FooUser
{

    private final BundleContext bundleContext;

    public FooUser( BundleContext bundleContext )
    {
        this.bundleContext = bundleContext;
    }

    /**
     * assume there's only one Foo

```

```

    */
    public void useFooSimple() {
        ServiceReference<Foo> sr = bundleContext.getServiceReference( Foo.class );
        String[] propertyKeys = sr.getPropertyKeys();
        for (String key: propertyKeys) {
            Object prop = sr.getProperty( key );
            //think about whether this is the Foo we want....
        }
        Foo foo = bundleContext.getService( sr );
        try {
            //use foo
        } finally {
            //we're done
            bundleContext.ungetService( sr );
        }
    }

    /**
     * Use a filter to select a particular Foo. Note we get a collection back and have to pick one.
     * @throws InvalidSyntaxException
     */
    public void useFooFilter() throws InvalidSyntaxException {
        Collection<ServiceReference<Foo>> srs = bundleContext.getServiceReferences(
            Foo.class, "(service.vendor=IBM)(id='myFoo')" );
        ServiceReference<Foo> sr = srs.iterator().next();
        String[] propertyKeys = sr.getPropertyKeys();
        for (String key: propertyKeys) {
            Object prop = sr.getProperty( key );
            //think about whether this is the Foo we want....
        }
        Foo foo = bundleContext.getService( sr );
        try {
            //use foo
        } finally {
            //we're done
            bundleContext.ungetService( sr );
        }
    }
}

```

## Using OSGi services: **8.5.5.0**

Services can be registered and unregistered asynchronously at any time. Therefore you should call a service for as short a time as possible. You can use the `ServiceTracker` class to track service availability concurrently.

### About this task

If you want to track services, you can create a `ServiceTracker` object by using your bundle context, the interface you want, and the properties you want to match, and then open the tracker. You can query the tracker for the best match or all matches. Make sure that you do not occupy the service after you use it. You do not have to tell the tracker you are done; the tracker caches the matching services internally, and clears them as they are unregistered. When you have finished using the tracker, use the `serviceTracker.close()` method to close it.

### Example

The following example shows how to use a `ServiceTracker` object to track a service:

```

package com.ibm.foo.tracker;

import com.ibm.foo.simple.Foo;

```

```

import org.osgi.framework.BundleContext;
import org.osgi.util.tracker.ServiceTracker;

/**
 * Simplest use of a ServiceTracker to get a service
 */
public class TrackingFooUser
{
    private ServiceTracker<Foo, Foo> serviceTracker;

    public TrackingFooUser( BundleContext bundleContext )
    {
        serviceTracker = new ServiceTracker<Foo, Foo>( bundleContext, Foo.class, null );
        serviceTracker.open();
    }

    public void doFoo() {
        Foo foo = serviceTracker.getService();
        //use foo
        //no need to return it... just don't use it for long.
    }

    public void shutdown() {
        serviceTracker.close();
    }
}

```

## Composing advanced features by using OSGi Declarative Services

**8.5.6.0**

Simple features can be controlled by using bundle activator classes and direct implementation of interfaces such as `ManagedService` and `ServiceTracker`. As relationships between bundles become more complex, it can be better to use facilities such as OSGi Declarative Services (DS) to decompose a feature into individual services. DS (sometimes known as the Service Component Runtime, or SCR) provides lifecycle and injection management of OSGi services.

### About this task

Organizing your feature logic as a set of declarative services has a number of advantages:

- Activation of the service (which includes loading the Java classes that provide the service) can be deferred until the service is used; allowing the server to start quickly and to keep resource use to a minimum.
- A reference to the service is placed into the service registry, even when the service has not been activated, so that dependencies on the service can be resolved.
- Dependencies on other services can be injected at runtime, and activation of the various services will be ordered based on such dependencies.
- A service can be deactivated and reactivated when its service properties change, if required.

Detailed information about use of OSGi Declarative Services is available from a number of online resources, including the OSGi Community Wiki.

This task provides simple descriptions of how to declare your services to DS, how to obtain references to other services, and how to manage configuration properties for each service.

## Declaring your services to OSGi Declarative Services

8.5.5.0

You can use a separate XML file to declare each service within a bundle.

### About this task

The Declarative Services (DS) support operates on declared components, each of which is defined by an XML file in the bundle. When a bundle containing component declarations is added to the framework, DS reads each component declaration and registers provided services in the service registry. DS then manages the lifecycle of the component: controlling its lifecycle based on a combination of declared attributes and satisfied dependencies.

The XML description of components allows DS to resolve service dependencies without requiring the component to be instantiated, or its implementation classes to be loaded. This facilitates late and lazy resource loading, which helps improve server startup and reduce runtime memory footprint.

The XML files that describe the components are listed in the MANIFEST.MF file of the bundle using the Service-Component header, and by convention are located in the /OSGI-INF directory of the bundle.

There are a number of tools that can be used to generate the required XML; the following examples show the XML itself.

This topic describes a simple OSGi bundle using XML to declare its components to DS.

### Procedure

1. Identify your component through its implementation class name.

```
<component>
  <implementation class="com.example.bundle.HelloComponent"/>
</component>
```

2. Declare the service by referencing the name of the interface that it provides. This is the name that will be published to the service registry by DS when the bundle is started.

```
<component>
  <implementation class="com.example.bundle.HelloComponent"/>
  <service>
    <provide interface="com.example.HelloService"/>
  </service>
</component>
```

3. Name the component. The component name also acts as the service “persisted identity”, or PID, which is used to associate configuration properties with the service. Configuration properties with a matching PID will be injected into the component on activation, and whenever the properties are updated.

```
<component name="HelloService">
  <implementation class="com.example.bundle.HelloComponent"/>
  <service>
    <provide interface="com.example.HelloService"/>
  </service>
