How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
  1. Display the article in your Web browser and scroll to the end of the article.
  2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an e-mail form appears.
  3. Fill out the e-mail form as instructed, and click on **Submit feedback** .
- To send comments on PDF books, you can e-mail your comments to: **wasdoc@us.ibm.com** or fax them to 919-254-0206.

  Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

Chapter 1. Overview and new features for administering applications and their environments

What is new for administrators

This topic provides an overview of new and changed features of system administration.

"Introduction: System administration" on page 3

This topic describes the administration of WebSphere Application Server, Version 6 products and the applications that run on them.

Presentations from IBM Education Assistant

The following presentations provide a quick overview:

- System management architecture
- Administrative security
- Administrative clients overview
  - Start, stop, and monitor processes
  - Other commands
  - Browser-based administrative console
  - Scripting - wsadmin
- Topologies and logical administrative domains
  - Resource scoping
  - Cells, deployment managers, and node agents
  - Build cells - Add and remove nodes
  - Manage node groups
- Applications and application resources
  - Application management overview
  - JDBC
  - Installing and uninstalling applications
  - Managed application resources - Enhanced EAR files
  - Fine grained application updates
- Servers
  - Manage Web server nodes
- Configuration management
  - Configuration repository
  - Configuration archives
  - File synchronization

Contents of this section: Administering applications and their environments

Setting up the application serving environment

This section is for the administrator who is responsible for integrating application serving capabilities into an existing network environment. It looks at the product as part of a larger system, typically a production environment or realistic test environment. This section reiterates some installation and customization activities, including topology planning and creating product configurations. It carries the focus into the administrative realm, discussing port configuration and other network concerns. See also ″Overview and new features for installing an application serving environment.

This information expands the topology planning discussion by describing how to set up and maintain logical administrative domains of cells and nodes, and how to balance workload through clustering and high availability configurations.

Using the administrative clients
This section describes the many options available for administering your applications and the servers to which the applications are deployed. Options include the graphical administrative console; scripting with the wsadmin tool; programmatic administration using Java Management Extensions (JMX) and MBeans; and a wide array of command-line tools, including ANT.

Chapter 3, "Starting and stopping quick reference," on page 23
This section summarizes what can be started and stopped, including applications and the application servers on which these applications are deployed.

Chapter 4, "Class loading," on page 25
This section describes how to configure class loaders. It includes both configuration that is performed during application assembly (packaging) and configuration performed at the server. The product run-time environment uses class loaders to find and load new classes for an application. Class loaders are part of the Java virtual machine (JVM) code and are responsible for finding and loading class files.

Chapter 5, "Deploying and administering applications," on page 37
This section describes how to deploy applications onto application servers, and then how to administer the deployed applications. It includes installing applications, starting applications, exporting application files, updating applications, removing applications, and other common tasks.

Administer WebSphere applications
This section provides administrative instructions that are specific to the various types of applications. For example, you can focus on administering your Web applications in their Web container; or aspects of Web services support; or the messaging or security subsystems.

Chapter 7, "Troubleshooting deployment," on page 1539
This section describes how to identify and handle a variety of problems encountered during development, assembly, and deployment activities.

Chapter 8, "Troubleshooting administration," on page 1551
This section describes how to identify and handle a variety of problems encountered during administrative activities.

Getting started with WebSphere Application Server

Note: If you prefer to browse PDF versions of this documentation using Adobe Reader, see the **Getting Started** PDF files that are available from www.ibm.com/software/webservers/appserv/infocenter.html.

Installing

See ″Task overview: installing″ for a description of installing the WebSphere Application Server product and other installable components.

Configuring

See ″Configuring the product after installation″ in the information center for a description of what to do after installing the product.

Migrating

See ″Migrating and coexisting″ for a description of how to migrate applications and configuration data from a previous version of WebSphere Application Server.

Using the Samples Gallery

See ″Accessing the Samples (Samples Gallery)″ in the information center for a description of the set of Samples that ship with each product. The Samples demonstrate common Web application tasks.

Deploying applications

The information center describes how to deploy Web components, such as servlets and JSP files.

Introduction: System administration

Note: If you would prefer to browse PDF versions of this documentation using your Adobe Reader, see the **System Administration** PDF files available from www.ibm.com/software/webservers/appserv/infocenter.html.

A variety of tools are provided for administering the WebSphere Application Server product:

- **Console**

  The administrative console is a graphical interface that provides many features to guide you through deployment and systems administration tasks. Use it to explore available management options.

  For more information, refer to “Introduction: Administrative console” on page 4.

- **Administrative agents**

  Servers, nodes and node agents, cells and the deployment manager are fundamental concepts in the administrative universe of the product. It is also important to understand the various processes in the administrative topology and the operating environment in which they apply.

  For more information, refer to “Welcome to basic administrative architecture” on page 9.

- **Scripting**

  The WebSphere administrative (wsadmin) scripting program is a powerful, non-graphical command interpreter environment enabling you to run administrative operations in a scripting language. You can also submit scripting language programs to run. The wsadmin tool is intended for production environments and unattended operations.

  For more information, refer to “Introduction: Administrative scripting (wsadmin)” on page 7.

- **Commands**

  Command-line tools are simple programs that you run from an operating system command-line prompt to perform specific tasks, as opposed to general purpose administration. Using the tools, you can start and stop application servers, check server status, add or remove nodes, and complete similar tasks.

  For more information, refer to “Introduction: Administrative commands” on page 8.

- **Programming**

  The product supports a Java programming interface for developing administrative programs. All of the administrative tools supplied with the product are written according to the API, which is based on the industry standard Java Management Extensions (JMX) specification.

  For more information, refer to “Introduction: Administrative programs” on page 8.

- **Data**

  Product configuration data resides in XML files that are manipulated by the previously-mentioned administrative tools.

  For more information, refer to “Introduction: Administrative configuration data” on page 9.

Introduction: Administrative console

The administrative console is a graphical interface for performing deployment and system administration tasks. It runs in your Web browser. Your actions in the console modify a set of XML configuration files.

You can use the console to perform tasks such as:

- Add, delete, start, and stop application servers
- Deploy new applications to a server
- Start and stop existing applications, and modify certain configurations
- Add and delete Java 2 Platform, Enterprise Edition (J2EE) resource providers for applications that require data access, mail, URLs, and so on
- Manage variables, shared libraries, and other configurations that can span multiple application servers
- Configure product security, including access to the administrative console
- Collect data for performance and troubleshooting purposes
- Find the product version information. It is located on the front page of the console.

The information center topic, ″Starting and logging off the administrative console″, helps you begin using the console so that you can explore the available options. See also the **Reference > Administrator > Settings** section of the information center navigation. It lists the settings or properties you can configure.

Use both the MVS console and the ″Application Server administrative console″ to administer the Application Server. For example:

- Use MVS commands that are issued from the MVS console to start the base application server controller region, and the node agent and deployment manager.
- In an application server configuration, you must start the first server with an MVS operator command. After the first server is started, you can use the administrative console, if it has this application, to start other application servers in the node. After the deployment manager and node agent are active (in an ND configuration), you can use the administrative console to start and stop application servers.
- Workload management starts all servant regions using Address Space Create (ASCRE) with the administrative console, you can display and modify Application Server applications and the environments in which they run.

Identifying where to perform WebSphere Application Server operations

Administering WebSphere Application Server involves the use of both the MVS console and the WebSphere Application Server administrative console. For example:

- Use MVS commands issued from the MVS console to start the base Application Server control region, the network deployment node agent, and the deployment manager.
- In a base Application Server configuration, you must start the first server with an MVS operator command. Once the first server starts, you can then use the administrative console, if it has this application, to start other Application Servers in the node. Once the deployment manager and node agent are active (in a network deployment configuration), you can use the administrative console to start and stop application servers.
- Workload management starts all servant regions using Address Space Create (ASCRE).

The following table lists the main Application Server operations tasks and directs you to information that helps you to perform these tasks. The Application Server activities and operations can be performed from:

- A z/OS or OS/390 MVS console (most operations)
- The Application Server administrative console (some operations)
- TSO or resource recovery services (RRS) panels (some operations).

Table 1. Application Server operations tasks

Task	MVS console	Application Server administrative console	TSO panel	Reference to associated procedure
Start operations				
Starting the Application Server environment and location service daemon	Yes	No	No	See ″Starting servers″ in the information center.
Starting a cluster or application server	Yes	Application server only	No	See ″Starting clusters″, ″Starting servers″, and Using the administrative console in the information center.
Stop operations				
Stopping the location service daemon	Yes	No	No	See Steps for stopping or canceling the location service daemon from the MVS console .
Stopping a cluster	Yes	Yes	No	See ″Stopping clusters″ in the information center.
Stopping an application server	Yes	Yes	No	See ″Stopping servers″ in the information center.
Cancel operations				
Canceling the location service daemon	Yes	No	No	See Steps for stopping or canceling the location service daemon from the MVS console.
Canceling a cluster	Yes	Yes	No	See ″Stopping clusters″ in the information center.
Canceling an application server	Yes	Yes	No	See ″Stopping servers″ in the information center.
Display operations				
Displaying the status of ARM-registered address spaces including clusters and servants	Yes	No	No	See ″Displaying the status of ARM-registered address spaces including WebSphere Application Server for z/OS and server instances″ in the information center.
Displaying units of work (threads) for DB2	Yes	No	No	See *DB2 Universal Database for OS/390 and z/OS Command Reference* athttp://www.elink.ibmlink.ibm.com/public/applications/publications/cgibin/pbi.cgi.
Displaying indoubt units of work (threads) for DB2	Yes	No	No	See *DB2 Universal Database for OS/390 and z/OS Command Reference* athttp://www.elink.ibmlink.ibm.com/public/applications/publications/cgibin/pbi.cgi.
Displaying units of work for RRS	No	No	Yes	See *z/OS MVS Programming: Resource Recovery* at http://www.elink.ibmlink.ibm.com/public/applications/publications/cgibin/pbi.cgi.
Displaying units of work for CICS	Yes	No	Yes	See *CICS Operations and Utilities Guide* at http://www.elink.ibmlink.ibm.com/public/applications/publications/cgibin/pbi.cgi

Table 1. Application Server operations tasks (continued)

Task	MVS console	Application Server administrative console	TSO panel	Reference to associated procedure
Displaying units of work (transactions) for IMS	Yes	No	No	See *IMS/ESA Summary of Operator Commands* at hhttp://www.elink.ibmlink.ibm.com/public /applications/publications/cgibin/pbi.cgi.
Displaying the status of a cluster	Yes	Yes	No	See ″Example: Displaying status of clusters″ in the information center.
Displaying the status of a server	Yes	Yes	No	See ″Example: Displaying status of a server″ in the information center.
Displaying active address spaces	Yes	No	No	See ″Example: Displaying active address spaces″ in the information center.
Displaying active replies	Yes	No	No	See ″Example: Displaying active replies″ in the information center.
Modify operations				
Getting help for the modify command	Yes	No	No	See ″Example: Getting help for the modify command″ in the information center.
Canceling application clusters and servers	Yes	No	No	See ″Example: Canceling application clusters and servers with the modify command″ in the information center.
Modifying the Java trace string	Yes	No	No	See ″Example: Modifying the Java trace string″ in the information center.
Displaying status	Yes	No	No	See ″Modify command″ in the information center.
Other Application Server operations				
ARM and restart	Yes	No	No	See ″Automatic restart management″ in the information center.
Setting up error log streams for different clusters and servants	No	You can associate a log stream with a cluster from the administrative console	No	See ″Setting up the error log″
Setting up System Management Facilities recording	Yes	Enable it from here, but initiate it from the MVS console.	No	See ″Collecting job-related information with Systems Management Facility (SMF)″
Shutting down the WebSphere Application Server for z/OS environment	Yes	Application server only	No	See ″Stopping clusters″, Stopping servers″, and Steps for stopping or canceling the location service daemon from the MVS console in the information center.

Table 1. Application Server operations tasks (continued)

Task	MVS console	Application Server administrative console	TSO panel	Reference to associated procedure
Taking a WebSphere Application Server for z/OS system cluster out of service	Yes	Application server only; You cannot take a WebSphere Application Server for z/OS system cluster out of service from the administrative console	No	
Workload Management				
Displaying the status of a WLM application environment	Yes	No	No	See ″Handling workload management and server failures″ in the information center.
Handling workload management and server failures	Yes	No	No	See ″Handling workload management and server failures″ in the information center.
Getting out of the stopped state and back to the available state for an application environment	Yes	No	No	See ″Handling workload management and server failures″ in the information center.
Checking and managing the workload management application environment (display, stop/quiesce, restart/resume)	Yes	No	No	See ″Handling workload management and server failures″ and ″WLM dynamic application environment operator commands″ in the information center.

Introduction: Administrative scripting (wsadmin)

The WebSphere administrative (wsadmin) scripting program is a powerful, non-graphical command interpreter environment enabling you to run administrative operations in a scripting language. The wsadmin tool is intended for production environments and unattended operations. You can use the wsadmin tool to perform the same tasks that you can perform using the administrative console.

The following list highlights the topics and tasks available with scripting:

- ″Getting started with scripting″ Provides an introduction to WebSphere Application Server scripting and information about using the wsadmin tool. Topics include information about the scripting languages and the scripting objects, and instructions for starting the wsadmin tool.

- ″Deploying applications″ Provides instructions for deploying and uninstalling applications. For example, stand-alone Java archive files and Web archive files, the administrative console, remote enterprise archive (EAR) files, file transfer applications, and so on.
- ″Managing deployed applications″ Includes tasks that you perform after the application is deployed. For example, starting and stopping applications, checking status, modifying listener address ports, querying application state, configuring a shared library, and so on.
- ″Configuring servers″ Provides instructions for configuring servers, such as creating a server, modifying and restarting the server, configuring the Java virtual machine, disabling a component, disabling a service, and so on.
- ″Configuring connections to Web servers″ Includes topics such as regenerating the plug-in, creating new virtual host templates, modifying virtual hosts, and so on.
- ″Managing servers″ Includes tasks that you use to manage servers. For example, stopping nodes, starting and stopping servers, querying a server state, starting a listener port, and so on.
- ″Clustering servers″ Includes topics about clusters, such as creating clusters, creating cluster members, querying a cluster state, removing clusters, and so on.
- Configuring security Includes security tasks, for example, enabling and disabling global security, enabling and disabling Java 2 security, and so on.
- Configuring data access Includes topics such as configuring a Java DataBase Connectivity (JDBC) provider, defining a data source, configuring connection pools, and so on.
- Configuring messaging Includes topics about messaging, such as Java Message Service (JMS) connection, JMS provider, WebSphere queue connection factory, MQ topics, and so on.
- Configuring mail, URLs, and resource environment entries Includes topics such as mail providers, mail sessions, protocols, resource environment providers, referenceables, URL providers, URLs, and so on.
- ″Dynamic caching″ Includes caching topics, for example, creating, viewing and modifying a cache instance.
- ″Troubleshooting with scripting″ Provides information about how to troubleshoot using scripting. For example, tracing, thread dumps, profiles, and so on.
- ″Obtaining product information″ Includes tasks such as querying the product identification.
- ″Scripting reference material″ Includes all of the reference material related to scripting. Topics include the syntax for the wsadmin tool and for the administrative command framework, explanations and examples for all of the scripting object commands, the scripting properties, and so on.

Introduction: Administrative commands

Command-line tools are simple programs that you run from an operating system command-line prompt to perform specific tasks, as opposed to general purpose administration. For additional information, see ″Using command line tools″ in the information center. Using the tools, you can start and stop application servers, check server status, add or remove nodes, and complete similar tasks.

See **Reference > Commands** in the information center navigation for the names and syntax of all the commands that are available with the product. A subset of these commands are particular to system administration purposes.

Introduction: Administrative programs

The product supports a Java programming interface for developing administrative programs. See ″Using administrative programs (JMX)″ in the information center. All of the administrative tools supplied with the product are written according to the API, which is based on the industry standard Java Management Extensions (JMX) specification. You can write a Java program that performs any of the administrative features of the WebSphere Application Server administrative tools. You can also extend the basic WebSphere Application Server administrative system to include your own managed resources.

Introduction: Administrative configuration data

Administrative tasks typically involve defining new configurations of the product or performing operations on managed resources within the environment. IBM WebSphere Application Server configuration data is kept in files. Because all product configuration involves changing the content of those files, it is useful to know the structure and content of the configuration files. See ″Configuration documents″ in the information center.

The WebSphere Application Server product includes an implementation of the Java Management Extension (JMX) specification. All operations on managed resources in the product go through JMX functions. This setup means a more standard framework underlying your administrative operations as well as the ability to tap into the systems management infrastructure programmatically.

Welcome to basic administrative architecture

This article discusses basic concepts in the administrative architecture to help you understand system administration in a WebSphere Application Server environment. The fundamental concepts for WebSphere Application Server administration include software processes called servers, topological units referenced as nodes and cells, and the configuration repository used for storing configuration information.

Servers perform the actual running of the code. Several types of servers exist depending on the configuration. Each server runs in its own Java virtual machine (JVM). The application server is the primary run-time component in all WebSphere Application Server configurations. All WebSphere Application Server configurations can have one or more application servers. In some configurations, each application server functions as a separate entity. No workload distribution or common administration among application servers exists. In other configurations, workload can be distributed between servers and administration can be done from a central point.

A node is a logical group of WebSphere Application Server-managed server processes that share a common configuration repository. A node is associated with a single WebSphere Application Server profile. A WebSphere Application Server node does not necessarily have a one-to-one association with a system. One computer can host arbitrarily many nodes, but a node cannot span multiple computer systems. A node can contain zero or more application servers.

The configuration repository holds copies of the individual component configuration documents that define the configuration of a WebSphere Application Server environment. All configuration information is stored in .xml files.

A cell is a grouping of nodes into a single administrative domain. A cell can consist of multiple nodes, all administered from a deployment manager server. When a node becomes part of a cell (a federated node), a node agent server is installed on the node to work with the deployment manager server to manage the WebSphere Application Server environment on that node.

When a node is a standalone node, not part of a cell, the configuration repository is fully contained on the node. When a node is part of a cell, the configuration and application files for all nodes in the cell are centralized into a cell master configuration repository. This centralized repository is managed by the deployment manager server and synchronized to local copies that are held on each node. The local copy of the repository that is given to each node contains just the configuration information needed by that node, not the full configuration that is maintained by the deployment manager.

WebSphere Application Server types

This section discusses the three server types that interact to perform system administration.

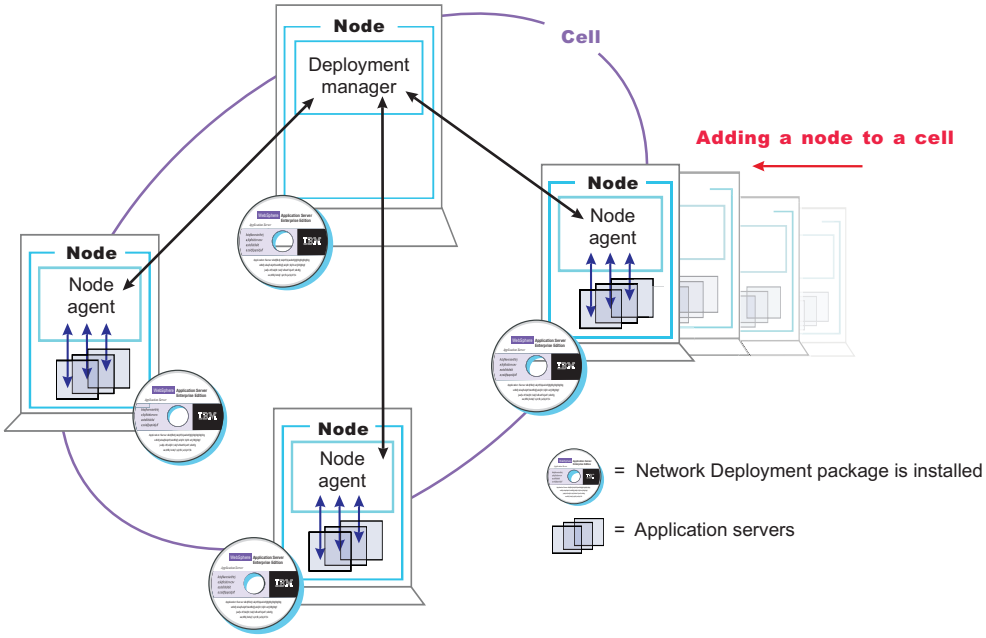
Application Server: A WebSphere Application Server provides the functions that are required to support and host user applications. An application server runs on only one node, but one node can support many application servers.

Node agent: When a node is federated, a node agent is created and installed on that node. The node agent works with the deployment manager to perform administrative activities on the node.

Deployment manager: With the deployment manager, you can administer multiple application servers from one centralized manager. The deployment manager works with the node agent on each node to manage all the servers in a distributed topology.

The following diagram depicts the concepts that are discussed in this article.

IBM WebSphere Application Server Network Deployment package



The concepts that are discussed in this article form the basis of WebSphere Application Server administration. More detailed descriptions can be found in other sections.

Introduction: Servers

Application servers

Application servers provide the core functionality of the WebSphere Application Server product family. They extend the ability of a Web server to handle Web application requests, and much more. An application server enables a server to generate a dynamic, customized response to a client request.

For additional overview, refer to “Introduction: Application servers” on page 11.

Clusters

Workload management optimizes the distribution of client processing tasks. Incoming work requests are distributed to the application servers that can most effectively process the requests. Workload management also provides failover when servers are not available, improving application availability.

Clusters are sets of application servers that are managed together and participate in workload management. The servers that are members of a cluster can be on different host machines, as opposed to the servers that are part of the same node and must be located on the same host machine.

For additional overview, refer to “Introduction: Clusters” on page 12.

Introduction: Application servers

Overview

An application server is a Java Virtual Machine (JVM) that is running user applications. The application server collaborates with the Web server to return a dynamic, customized response to a client request. Application code, including servlets, JavaServer Pages (JSP) files, enterprise beans and their supporting classes, runs in an application server. Conforming to the Java 2 platform, Enterprise Edition (J2EE) component architecture, servlets and JSP files run in a Web container, and enterprise beans run in an Enterprise JavaBeans (EJB) container.

To begin creating and managing an application server, see ″Administering application servers″ in the information center.

You can define multiple application servers, each running its own JVM. Enhance the operation of an application server by using the following options:

- Configure transport chains to provide networking services to such functions as the service integration bus component of IBM service integration technologies, WebSphere Secure Caching Proxy, and the high availability manager core group bridge service. See ″Configuring transport chains″ in the information center for more information.
- Plug into an application server to define a hook point that runs when the server starts and shuts down. See ″Custom services″ for more information.
- Define command-line information that passes to a server when it starts or initializes. See ″startServer command″ for more information.
- Tuning application servers
- Enhance the performance of the application server JVM. See ″Using the JVM″ in the information center for more information.
- Use an Object Request Broker (ORB) for RMI/IIOP communication. See “Managing Object Request Brokers” on page 1289 for more information.

Asynchronous messaging

The product supports asynchronous messaging based on the Java Message Service (JMS) of a JMS provider that conforms to the JMS specification version 1.1.

The JMS functions of the default message service in WebSphere Application Server are served by one or more messaging engines (in a service integration bus) that runs within application servers.

In a deployment manager cell, there can be WebSphere Application Server version 5 nodes. If a version 5 node is configured to use V5 default messaging (the version 5 embedded messaging), there can be at most one JMS server on that node.

Generic Servers

A generic server is a server that is managed in the WebSphere administrative domain, although it is not a server that is supplied by the WebSphere Application Server product. The generic server can be any server or process that is necessary to support the Application Server environment.

Introduction: Web servers

The application server and Web server communicate using Web server plug-ins. ″Communicating with Web servers″ escribes how to set up your Web server and Web server plug-in environment and how to create a Web server definition. The Web server definition associates a Web server with a previously defined managed or unmanaged n6de. After you define the Web server to a node, you can use the administrative console to perform the following functions for that Web server.

If the Web server is defined to a managed node, you can:

- Check the status of the Web server
- Generate a plug-in configuration file for that Web server.
- Propagate the plug-in configuration file after it is generated.

If the Web server it is defined to an unmanaged node, you can:
- Check the status of the Web server
- Generate a plug-in configuration file for that Web server.

After you set up your Web server and Web server plug-in, whenever you deploy a Web application, you must specify a Web server as the deployment target that serves as a router for requests to the Web application. The configuration settings in the plug-in configuration file (plugin-cfg.xml) for each Web server are based on the applications that are routed through that Web server. If the Web server plug-in configuration service is enabled, a Web server plug-in's configuration file is automatically regenerated whenever a new application is associated with that Web server.

Note: Before starting the Web server, make sure you are authorized to run any Application Response Measurement (ARM) agent associated with that Web server.

Refer to your Web server documentation for information on how to administer that Web server. For tips on tuning your Web server plug-in, see ″Web server plug-in tuning tips″ in the information center.

Introduction: Clusters

Clusters are groups of servers that are managed together and participate in workload management. A cluster can contain nodes or individual application servers. A node is usually a physical computer system with a distinct host IP address that is running one or more application servers. Clusters can be grouped under the configuration of a cell, which logically associates many servers and clusters with different configurations and applications with one another depending on the discretion of the administrator and what makes sense in their organizational environments.

Clusters are responsible for balancing workload among servers. Servers that are a part of a cluster are called cluster *members*. When you install an application on a cluster, the application is automatically installed on each cluster member.

Node groups bound clusters. All cluster members of a given cluster must be members of the same node group. For more information about clusters and node groups, see ″Clusters and node groups″ in the information center.

To learn more about clusters, see ″Clusters and workload management″ and ″Balancing workloads with clusters″ for more information.

Core groups

A group of clusters can be defined as a *core group*. All of the application servers defined as a member of one of the clusters included in a core group are automatically members of that core group. Individual application servers that are not members of a cluster can also be defined as a member of a core group. The use of core groups enables WebSphere Application Server to provide high availability for applications that must always be available to end users. You can also configure core groups to communicate with each other using the *core group bridge*. The core groups can communicate within the same cell or across cells.

To learn more about core groups, see ″Setting up a high availability environment″ in the information center.

Introduction: Environment

The environment of the product applies to the configuring of Web server plug-ins, variables, and objects that you want consistent throughout a cell.

Cell-wide settings

Cell-wide settings are sets of configuration data that are stored in files in the cell directory. These configuration files are replicated to every node in the cell. Several different configuration settings apply to the entire cell. These settings include the definition of virtual hosts, shared libraries, and any variables that must be consistent throughout the entire cell.

For more information, refer to “Introduction: Cell-wide settings.”

Variables

A variable is a configuration property that can be used to provide a parameter for any value in the system. A variable has a name and a value to use in place of that name wherever the variable name is located within the system.

For more information, refer to ″Setting up a high availability environment″ in the information center.

Introduction: Cell-wide settings

The configuration data for WebSphere Application Server is stored in XML files. The XML files exist in one of several directories in the configuration repository tree.

The directory in which a configuration file exists determines its scope, or how broadly or narrowly that data applies. Files in an individual server directory apply to that specific server only. Files in a node-level directory apply to every server on that node. Files in the cell directory apply to every server on every node within the entire cell.

Cell-wide settings are configuration files in the cell directory. The files are replicated to every node in the cell. Several different configuration settings apply to the entire cell. These settings include the definition of virtual hosts, shared libraries, and any variables that you want consistent throughout the entire cell.

Introduction: Variables

Variables in the WebSphere environment come in many varieties. Variables are used to control settings and properties relating to the server environment. Three main variable options that are important for a WebSphere Application Server user to know and understand are custom properties, environment variables, and WebSphere-specific variables.

Environment variables

Environment variables, also called *native environment variables*, are not specific to the WebSphere Application Server and are defined by other elements, such as UNIX, Language Environment (LE), or third-party vendors, among others. Some of the UNIX-specific native variables are LIBPATH and STEPLIB. These variables tend to be operating system-specific.

Environment variables are specified in the administrative console. Click **Application Server >***server_name***> Process Definition > Servant Process > Environment Entries**.

This path is also used to set environment variables that control the collection of application server and Web container information in z/OS System Management Facility (SMF) records.

WebSphere variables

WebSphere variables are used for three purposes:

- Configuring WebSphere Application Server path names, such as JAVA_HOME, and APP_INSTALL_ROOT.
- Configuring certain cell-wide customization values.
- Configuring the WebSphere Application Server for z/OS location service.

WebSphere variables are specified in the administrative console by clicking **Environment > Manage WebSphere variables**. How the WebSphere variable is set determines its scope. A variable can apply to a cell, a node, or a server. If the variable is set:

- At the server level, it applies to the entire server.
- At the node level, it applies to all servers in the node, unless you set the same variable at the server level. In that case, for that server, the setting that is specified at the server level overrides the setting that is specified at the node level.
- At the cell level, it applies to all nodes in that cell, unless you set the same variable at the node or server level.
  - If you set the same variable at the server level, for that server, the setting that is specified at the server level overrides the setting that is specified at the cell level.
  - If you set the same variable at the node level, for all servers in that node, the setting that is specified at the node level overrides the setting that is specified at the cell level.

Custom properties

Custom properties are property settings meant for a specific functional component. Any configuration element can have a custom property. Common configuration elements are cell, node, server, Web container, and transaction service. A limited number of supported custom properties are available and these properties can be set in the administrative console using the custom properties link that is associated with the functional component.

For example, to set HTTP transport custom properties, follow one of the following paths:

- **Servers > Application Servers >** *server_name* **> Web Container > HTTP Transport > Additional Properties > Custom Properties**
- **Servers > Application Servers >** *server_name* **> Web Container > Additional Properties > Custom Properties**

Custom properties set from the Web container custom properties page apply to all transports that are associated with that Web container; custom properties set from the HTTP transport custom properties page apply only to that specific transport. If the same properties are set on both pages, the settings on the transport page override the settings that are defined on the Web container page for that specific transport.

Chapter 2. How do I administer applications and their environments?

- Establish the application serving environment
- Secure the application serving environment - see Security
- Set up Web access for applications
- Set up resources for applications to use
- Configure class loaders - see development and deployment
- Deploy and administer applications
- Use the administrative clients
- Troubleshoot deployment and administration

Establish the application serving environment

The following tasks involve establishing application serving capability in your network environment, whether you use single or clustered application servers. Servers can be grouped into administrative domains known as nodes and cells.

See also the overview:

- Version 6 topology and terminology

Administer nodes

A node is a grouping of managed servers. Use this task to view information about and manage nodes.

Documentation: ″Managing nodes″

Show me

Tell me:

- Add and remove nodes
- Manage node groups
- Cell, deployment managers, nodes, and node agents

Administer node agents

Node agents are administrative agents that represent a node to your system and manage the servers on that node. Node agents monitor application servers on a host system and route administrative requests to servers. A node agent is created automatically when a node is added to a cell.

Documentation: See	Show me	Tell me
″Managing node agents″ in the information center.		

Administer cells

When you installed the WebSphere Application Server Network Deployment product, a cell was created. A cell provides a way to group one or more nodes of your Network Deployment product. You probably will not need to reconfigure the cell. Use this task to view information about and manage a cell.

Documentation: See	Show me	Tell me
″Configuring cells″ in the information center.		

Administer configurations

Application server configuration files define the available application servers, their configurations, and their contents. You should periodically save changes to your administrative configuration. You can change the default locations of configuration files, as needed.

Documentation: See	Tell me:
″Working with server configuration files″ in the information center.	• Repository • Archives

---

Configure remote file services

Configuration data for the WebSphere Application Server product resides in files. Two services help you reconfigure and otherwise manage these files: the file transfer service and file synchronization service. By default, the file transfer service is always configured and enabled at a node agent, so you do not need to take additional steps to configure this service. However, you might need to configure the file synchronization service.

Documentation:	Tell me
″Configuring remote file services″	

Administer application servers

Create, configure, and operate application server processes. An application server configuration provides settings that control how an application server provides services for running enterprise applications and their components.

Documentation:

- ″Administering application servers″
- ″Configuring servers with scripting″
- ″Managing servers with scripting″

Show me

Tell me

Administer other server types

One step in the process of creating an application server is to specify a template. A server template is used to define the configuration settings of the new server. You have the option of specifying the default server template or choosing a template that is based on a server that already exists. The default template will be used if you do not specify a different template when you create the server.

You can create other types of servers, to represent Web servers in your topology, or for other purposes. There are two types of *generic* servers: (1) Non-Java applications or processes, or (2) Java applications or processes. A *custom service* provides the ability to plug into a WebSphere application server to define a hook point that runs when the server starts and shuts down.

Documentation:

- ″Creating generic servers″
- ″Custom services″

Tell me:

- Generic servers

Guide me (Web servers)

Balance workloads by clustering application servers

To monitor application servers and manage the workloads of servers, use server clusters and cluster members provided by the Network Deployment product.

Documentation:

- ″Clustering servers with scripting″

Show me

Tell me:

- WLM details
- Data replication service

Establishing high availability (HA) for failover

Planning ahead for high availability support is important in order to avoid the risk of a failure without failover coverage. The application server runtime of the infrastructure managed by a high availability manager includes such entities as cells and clusters. These components relate closely to core groups, high availability groups, and the policy that defines the high availability infrastructure. In a properly configured high availability environment, a high availability manager can reassess the environment it is managing and accept new components as they are added to the environment.

Deploy and administer applications

These tasks involve deploying applications onto the application server, then administering the applications.

Install applications

Installable modules include enterprise archive (EAR), enterprise bean (EJB), Web archive (WAR), resource adapter (connector or RAR), and application client files.

Documentation	Show me	Tell me
• Console:Installing application files • Scripting: ″Deploying applications using scripting″		

Start and stop applications

You can start an application that is not running (has a status of Stopped) or stop an application that is running (has a status of Started).

Documentation:	Show me	Tell me
• Starting and stopping applications • Starting applications with scripting		

Update applications

Update deployed applications or modules using the administrative console or **wsadmin** scripting. Learn which changes are candidates for hot deployment and dynamic reloading, in which you can make various changes to applications and their modules without having to stop the server and start it again.

Documentation:	Tell me	Teach me
• Updating applications • ″Updating installed applications with the wsadmin tool″		

Deploy applications rapidly (WebSphere Rapid Deployment)

Take advantage of new rapid deployment capabilities. WebSphere rapid deployment offers the following advantages: You do not need to assemble your J2EE application files prior to deployment. You do not need to use other installation tools mentioned in this table to deploy the files. Refer to the **Rapid deployment tools** documentation in the information center.

Enhanced EAR files

	Tell me	Teach me

Deploy and administer Web services applications

To deploy Web services that are based on the Web Services for Java 2 platform, Enterprise Edition (J2EE) specification, you need an enterprise application, also known as an enterprise archive (EAR) file that has been configured and enabled for Web services. You can use either the administrative console or the wsadmin scripting interface to deploy an EAR file.

Documentation	Show me	Tell me

Use the administrative clients

A variety of tools are provided for administering the product.

Choose an administrative client

Learn about and decide among the available administrative clients, including a graphical console, scripting (wsadmin), command line tools, and Java Management Extensions (JMX) programs.

Documentation:	Tell me
″Using the administrative clients″	

Use the administrative console

The administrative console is a Web-based tool that you use to administer the product. The administrative console supports a full range of product administrative activities.

Documentation	Show me	Tell me

Use scripting (wsadmin)

Scripting is a non-graphical alternative that you can use to configure and manage WebSphere Application Server. The WebSphere Application Server **wsadmin** tool provides the ability to run scripts. The tool supports a full range of product administrative activities.

Documentation

Chapter 3. Starting and stopping quick reference

This topic describes how to start and stop the main operations in your application serving environment. It also provides a quick guide to accessing the main tools that are provided with this product.

- Use commands to start and stop servers.

Quick reference: Issuing commands to start and stop servers
These examples are for starting and stopping the default profile on a server. Otherwise, you might need to be in the `install_root/profiles/profile_name/bin`directory to start and stop the server.
Deployment manager Go to the *install_root* `/bin`directory of a Network Deployment installation and run the following command. See ″startManager command″ in the information center for details and variations. `startManager`
Application server Go to the *install_root* /bin directory of a WebSphere Application Server or Network Deployment installation and run the following command. See ″startServer command″ in the information center for details and variations `startServer server` where *server* is the application server that you want to start. Issuing START *appserver_proc_name* and STOP *appserver_proc_name* in the Using the MVS console is an additional option on z/OS systems.
Stopping the servers Use the same command as to start, except substitute stop for start. For example, to stop an application server, issue the command: `stopServer server` To start and stop application server clusters, see ″Starting clusters″.

- Use administrative clients and tools.

Quick reference: Opening the administrative console
To open the console, enter this Web address in your Web browser: `http://your_fully_qualified_server_name:9060/ibm/console` Depending on your configuration, your Web address might differ. Other factors can affect your ability to access the console. See ″Starting and logging off the administrative console″ for details, as needed.

  - You also can :Use the MVS console″ on z/OS systems.
  - To launch a scripting client, see ″Starting the wsadmin scripting client″ in the information center.
  - To learn about all available administrative clients, see ″Using the administrative clients″ .
  - For performance monitoring, see “Monitoring performance with Tivoli Performance Viewer (TPV)” on page 1674.

  See the administrator commands that are listed in the **Reference** section of the information center.
- Use development and deployment tools. Use the following tools to edit deployment descriptors. A deployment descriptor is an Extensible Markup Language (XML) file that describes how to deploy a module or application by specifying configuration and container options. The tools are available for use on distributed operating systems.

  Assembly tools

  The assembly tools and Rational Web Developer provide a graphical interface for developing

code artifacts, assembling the code artifacts into various archives (modules), and configuring related Java 2 Platform, Enterprise Edition (J2EE) Version 1.2, 1.3 or 1.4-compliant deployment descriptors.

See ″Starting an assembly tool″ in the information center.

Application Client Resource Configuration Tool (ACRCT)
Use the ACRCT to configure deployment descriptors for client applications. See “Deploying J2EE application clients on workstation platforms” on page 244.

Text editor
It is not recommended because it has no built-in error checking or validation, but you can edit deployment descriptors with any text editor with which you can edit XML files.

- Use installation and customization tools. Use the following tools to find planning information, start the product installation, and perform customization and other activities after installation.

  Customization dialog
  After ″Installing the product and additional software″, use the customization dialog to configure the product. See ″Starting the Customization Dialog″ in the information center.
- Use troubleshooting tools - see ″Working with diagnostic tools and controls″ in the information center.

Chapter 4. Class loading

Class loaders are part of the Java virtual machine (JVM) code and are responsible for finding and loading class files. Class loaders enable applications that are deployed on servers to access repositories of available classes and resources. Application developers and deployers must consider the location of class and resource files, and the class loaders used to access those files, to make the files available to deployed applications. Class loaders affect the packaging of applications and the run-time behavior of packaged applications of deployed applications.

This article describes how to configure class loaders for application files or modules that are installed on an application server.

To better understand class loaders in WebSphere Application Server, read “Class loaders.” The article “Class loading: Resources for learning” on page 35 refers to additional sources.

Configure class loaders for application files or modules that are installed on an application server using the administrative console. You configure class loaders to ensure that deployed application files and modules can access the classes and resources that they need to run successfully.

1. If an installed application module uses a resource, create a resource provider (See ″Introduction: Mail, URLs, and other J2EE resources″ in the information center) that specifies the directory name of the resource drivers. Do not specify the resource Java archive (JAR) file names. All JAR files in the specified directory are added into the class path of the WebSphere Application Server extensions class loader. If a resource driver requires a native library (.DLL or .so file), specify the name of the directory that contains the library in the native path of the resource configuration.
2. Specify class-loader values for an application server.
3. Specify class-loader values for an installed enterprise application.
4. Specify the class-loader mode for an installed Web module.
5. If your deployed application uses shared library files, associate the shared library files with your application. Use a library reference to associate a shared library file with your application.
   a. If you have not done so already, define a shard library for each library file that your applications need. See ″Creating a shared library″ in the information center
   b. Define a library reference instance for each shared library that your application uses. See, ″Associating shared libraries with applications″ in the information center.
6. **Optional:** Configure class preloading.

Class loaders

Class loaders find and load class files. Class loaders enable applications that are deployed on servers to access repositories of available classes and resources. Application developers and deployers must consider the location of class and resource files, and the class loaders used to access those files, to make the files available to deployed applications.

The run-time environment of WebSphere Application Server uses the following class loaders to find and load new classes for an application in the following order:

1. The bootstrap, extensions, and CLASSPATH class loaders created by the Java virtual machine

   The bootstrap class loader uses the boot class path (typically classes in `jre/lib`) to find and load classes. The extensions class loader uses the system property java.ext.dirs (typically `jre/lib/ext`) to find and load classes. The CLASSPATH class loader uses the CLASSPATH environment variable to find and load classes.

   The CLASSPATH class loader loads the Java 2 Platform, Enterprise Edition (J2EE) application programming interfaces (APIs) provided by the WebSphere Application Server product in the `j2ee.jar` file. Because this class loader loads the J2EE APIs, you can add libraries that depend on the J2EE

APIs to the class path system property to extend a server class path. However, a preferred method of extending a server class path is to add a shared library. See ″Managing shared libraries″ in the information center.

2. A WebSphere-specific extensions class loader

   The WebSphere Application Server extensions class loader loads the WebSphere Application Server classes that are required at run time. The extensions class loader uses a ws.ext.dirs system property to determine the path that is used to load classes. Each directory in the `ws.ext.dirs` class path and every Java archive (JAR) file or ZIP file in these directories is added to the class path used by this class loader.

   The WebSphere Application Server extensions class loader also loads resource provider classes into a server if an application module installed on the server refers to a resource that is associated with the provider and if the provider specifies the directory name of the resource drivers.

3. One or more application module class loaders that load elements of enterprise applications running in the server

   The application elements can be Web modules, enterprise bean (EJB) modules, resource adapters archives (RAR files), and dependency JAR files. Application class loaders follow J2EE class-loading rules to load classes and JAR files from an enterprise application. WebSphere Application Server enables you to associate shared libraries with an application.

4. Zero or more Web module class loaders

   By default, Web module class loaders load the contents of the `WEB-INF/classes` and `WEB-INF/lib` directories. Web module class loaders are children of application class loaders. You can specify that an application class loader load the contents of a Web module rather than the Web module class loader.

Each class loader is a child of the previous class loader. That is, the application module class loaders are children of the WebSphere-specific extensions class loader, which is a child of the CLASSPATH Java class loader. Whenever a class needs to be loaded, the class loader usually delegates the request to its parent class loader. If none of the parent class loaders can find the class, the original class loader attempts to load the class. Requests can only go to a parent class loader; they cannot go to a child class loader. If the WebSphere Application Server class loader is requested to find a class in a J2EE module, it cannot go to the application module class loader to find that class and a ClassNotFoundException error occurs. After a class is loaded by a class loader, any new classes that it tries to load reuse the same class loader or go up the precedence list until the class is found.

Class preloading

The first time that a WebSphere Application Server process starts, the name of each run-time class that is loaded and the name of the JAR file that contains the class are written to a preload file. The names of non-runtime classes such as custom services, resource classes such as `db2java.zip`, classes on the JVM class path, and application classes are not written to the preload file. Subsequent startups of the process use the preload file to start the process more quickly.

Preload files have the `.preload` extension. WebSphere Application Server processes that have preload files include the following:

Process	Preload file name
Application server	*cell_name.node_name.server_name*.preload
`startserver`	`WsServerLauncher.preload`
`launchClient`	`launchClient.preload`

Running the `startserver server1` command causes the `startserver` command to use a `WsServerLauncher.preload` file and the server to use a *cell_name.node_name*`.server1.preload` file. Later, running a command such as `startserver server1 -script`, where the -script option creates a new script, uses the *cell_name.node_name*`.server1.preload` file only.

Preload files, by default, are installed in the *install_root* directory.

New classes required during the startup of a process are added to the preload file. Any classes that are removed from a process are ignored during subsequent startups. Although it is not necessary, an administrator can delete the preload file and force a refresh that removes the ignored classes from the file.

Class-loader isolation policies

The number and function of the application module class loaders depend on the class-loader policies that are specified in the server configuration. Class loaders provide multiple options for isolating applications and modules to enable different application packaging schemes to run on an application server.

Two class-loader policies control the isolation of applications and modules:

Application class-loader policy

Application class loaders load EJB modules, dependency JAR files, embedded resource adapters, and application-scoped shared libraries. Depending on the application class-loader policy, an application class loader can be shared by multiple applications (Single) or unique for each application (Multiple). The application class-loader policy controls the isolation of applications that are running in the system. When set to `Single`, applications are not isolated. When set to `Multiple`, applications are isolated from each other.

WAR class-loader policy

By default, Web module class loaders load the contents of the `WEB-INF/classes` and `WEB-INF/lib` directories. The application class loader is the parent of the Web module class loader. You can change the default behavior by changing the Web application archive (WAR) class-loader policy of the application.

The WAR class-loader policy controls the isolation of Web modules. If this policy is set to `Application`, then the Web module contents also are loaded by the application class loader (in addition to the EJB files, RAR files, dependency JAR files, and shared libraries). If the policy is set to `Module`, then each Web module receives its own class loader whose parent is the application class loader.

Note: WebSphere Application Server class loaders never load application client modules.

For each application server in the system, you can set the application class-loader policy to `Single` or `Multiple`. When the application class-loader policy is set to `Single`, then a single application class loader loads all EJB modules, dependency JAR files, and shared libraries in the system. When the application class-loader policy is set to `Multiple`, then each application receives its own class loader that is used for loading the EJB modules, dependency JAR files, and shared libraries for that application.

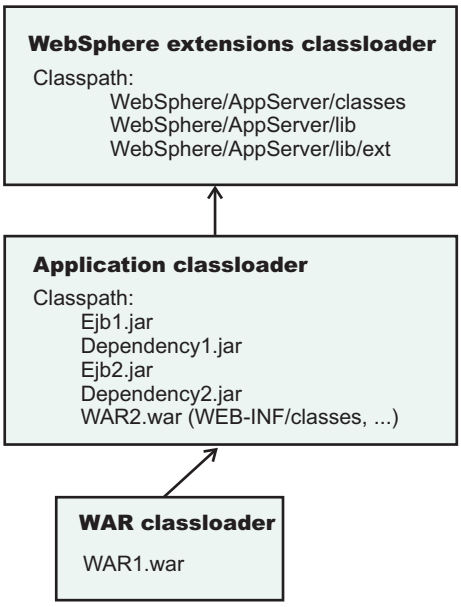
An application class loader loads classes from Web modules if the application's WAR class-loader policy is set to `Application`. If the application's WAR class-loader policy is set to `Module`, then each WAR module receives its own class loader.

The following example shows that when the application class-loader policy is set to `Single`, a single application class loader loads all of the EJB modules, dependency JAR files, and shared libraries of all applications on the server. The single application class loader can also load Web modules if an application has its WAR class-loader policy set to `Application`. Applications that have a WAR class-loader policy set to `Module` use a separate class loader for Web modules.

```
Server's application class-loader policy: Single
Application's WAR class-loader policy: Module

Application 1
 Module:  EJB1.jar
 Module: WAR1.war
   MANIFEST Class-Path: Dependency1.jar
  WAR Classloader Policy = Module
Application 2
```

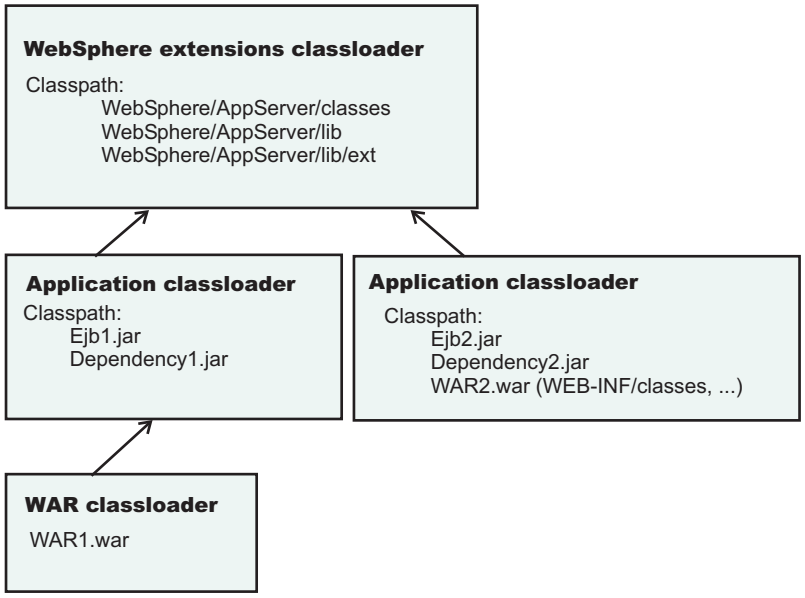
```
Module:   EJB2.jar
 MANIFEST Class-Path: Dependency2.jar
Module: WAR2.war
 WAR Classloader Policy = Application
```



The following example shows that when the application class-loader policy of an application server is set to `Multiple`, each application on the server has its own class loader. An application class loader also loads its Web modules if the application WAR class-loader policy is set to `Application`. If the policy is set to `Module`, then a Web module uses its own class loader.

```
Server's application class-loader policy: Multiple
Application's WAR class-loader policy: Module

Application 1
 Module:  EJB1.jar
 Module: WAR1.war
  MANIFEST Class-Path: Dependency1.jar
  WAR Classloader Policy = Module
Application 2
 Module:   EJB2.jar
  MANIFEST Class-Path: Dependency2.jar
 Module: WAR2.war
  WAR Classloader Policy = Application
```



Class-loader modes

Two values for a class-loader mode are supported:

Parent First

The `Parent First` class-loader mode causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. This value is the default for the class-loader policy and for standard JVM class loaders.

Parent Last

The `Parent Last` class-loader mode causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent. Using this policy, an application class loader can override and provide its own version of a class that exists in the parent class loader.

The following settings determine the mode of a class loader:

- If the application class-loader policy of an application server is `Single`, the server-level mode value defines the mode for an application class-loader.
- If the application class-loader policy of an application server is `Multiple`, the application-level mode value defines the mode for an application class loader.
- If the WAR class-loader policy of an application is `Module`, the module-level mode value defines the mode for a WAR class-loader.

Configuring class loaders of a server

You can configure the application class loaders for an application server. Class loaders enable applications that are deployed on the application server to access repositories of available classes and resources.

This article assumes that an administrator created an application server on a WebSphere Application Server product. See ″Creating application servers″.

Configure the class loaders of an application server to set class-loader policy and mode values which affect all applications that are deployed on the server. Use the administrative console to configure the class loaders.

1. Click **Servers** > **Application Servers** >*server_name* to access the settings page for an application server. See ″Application server settings″ for more information.

2. Specify the application class-loader policy for the application server. The application class-loader policy controls the isolation of applications that run in the system (on the server). An application class loader groups enterprise bean (EJB) modules, shared libraries, resource adapter archives (RAR files), and dependency Java archive (JAR) files associated to an application. Dependency JAR files are JAR files that contain code which can be used by both enterprise beans and servlets. The application class-loader policy controls whether an application class loader can be shared by multiple applications or is unique for each application. Use the settings page for the application server to specify the application class-loader policy for the server: See ″Application server settings″ in the information center.

Option	Description
Single	Applications are not isolated from each other. Uses a single application class loader to load all of the EJB modules, shared libraries, and dependency JAR files in the system.
Multiple	Applications are isolated from each other. Gives each application its own class loader to load the EJB modules, shared libraries, and dependency JAR files of that application.

3. Specify the application class-loader mode for the application server. The application class loading mode specifies the class-loader mode when the application class-loader policy is `Single`. On the settings page for the application server, select either of the following values:

Option	Description
Parent first	Causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. `Parent first` is the default value for class loading mode.
Parent last	Causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent. Using this policy, an application class loader can override and provide its own version of a class that exists in the parent class loader.

4. Specify the class-loader mode for the class loader.
   a. On the settings page for the application server, click **Java and Process Management > Class loader** to access the Class loader page.
   b. On the Class loader page, click **New** to access the settings page for a class loader.
   c. On the settings page for a class loader, specify the class-loader mode. The `Parent First` value causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. The `Parent Last` value causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent.
   d. Click **OK**.

   An identifier is assigned to a class-loader instance. The instance is added to the collection of class loaders shown on the Class loader page.

Save the changes to the administrative configuration.

Class loader collection

Use this page to manage class-loader instances on an application server. A class loader determines whether an application class loader or a parent class loader finds and loads Java class files for an application.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Java and Process Management > Class loader**.

Class loader ID

Provides a string that is unique to the server identifying the class-loader instance. The product assigns the identifier.

Class loader mode

Specifies the class-loader mode when the application class-loader policy for the application server is `Single`.

You specify a policy of `Single` on the settings page for the application server, accessed by clicking **Servers > Application Servers >***server_name*. When the policy is `Single`, applications are not isolated from each other. A single application class loader contains all of the EJB modules, dependency JAR files, and shared libraries in the system.

The `Parent First` value causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. The `Parent Last` value causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent. Specifying the `Parent Last` value enables an application class loader to override and provide its own version of a class that exists in the parent class loader.

Class loader settings

Use this page to configure a class loader for applications that reside on an application server.

To view this administrative console page, click **Servers > Application Servers >***server_name* **> Java and Process Management > Class loader >***class_loader_ID*.

Class loader ID

Provides a string that is unique to the server identifying the class-loader instance. The product assigns the identifier.

Data type String

Class loader mode

Specifies the class-loader mode when the application class-loader policy for the application server is `Single`.

You specify a policy of `Single` on the settings page for the application server, accessed by clicking **Servers > Application Servers >***server_name*. When the policy is `Single`, applications are not isolated from each other. A single application class loader contains all of the EJB modules, dependency JAR files, and shared libraries in the system.

The `Parent First` value causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path.

The `Parent Last` value causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent. Specifying the `Parent Last` value enables an application class

loader to override and provide its own version of a class that exists in the parent class loader.

Data type	String
Default	Parent First

Configuring application class loaders

You can set values that control the class-loading behavior of an installed enterprise application. Class loaders enable an application to access repositories of available classes and resources.

This article assumes that you installed an application on an application server.

Configure the class loaders of an enterprise application to set class-loader policy and mode values for this application.

An application class loader groups enterprise bean (EJB) modules, shared libraries, resource adapter archives (RAR files), and dependency Java archive (JAR) files associated to an application. Dependency JAR files are JAR files that contain code which can be used by both enterprise beans and servlets.

An application class loader is the parent of a Web application archive (WAR) class loader. By default, a Web module has its own WAR class loader to load the contents of the Web module. The WAR class-loader policy value of an application class loader determines whether the WAR class loader or the application class loader is used to load the contents of the Web module.

Use the administrative console to configure the class loaders.

1. Click **Applications > Enterprise Applications >***application_name* to access the settings page for an enterprise application.
2. Specify the class-loader mode for the application. The application class-loader mode specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The default is to search in the parent class loader before searching in the application class loader to load a class. Select either of the following values for **Class loader mode**:

Option	Description
Parent First	Causes the class loader to search in the parent class loader first to load a class. This value is the standard for Development Kit class loaders and WebSphere Application Server class loaders.
Parent Last	Causes the class loader to search in the application class loader first to load a class. By specifying `Parent Last`, your application can override classes contained in the parent class loader. **Tip:** Specifying the `Parent Last` value might result in LinkageErrors or ClassCastException messages if you have mixed use of overridden classes and non-overridden classes.

3. Specify whether to use a single or multiple class loaders to load Web application archives (WAR files) of your application. By default, Web modules have their own WAR class loader to load the contents of the `WEB-INF/classes` and `WEB-INF/lib` directories. The default WAR class loader value is `Module`, which uses a separate class loader to load each WAR file. Setting the value to `Application` causes the application class loader to load the Web module contents as well as the EJB modules, shared libraries, RAR files, and dependency JAR files associated to the application. The application class loader is the parent of the WAR class loader. Select either of the following values for **WAR class loader policy**:

Option	Description
Module	Uses a different class loader for each WAR file.
Application	Uses a single class loader to load all of the WAR files in your application.

4. Specify whether to enable class reloading when application files are updated. By default, class reloading is not enabled. See the description for **Enable class reloading** in “Enterprise application settings” on page 56 for details on enabling and disabling reloading. You might specify different values for EJB modules and for Web modules such as servlets and JavaServer page (JSP) files.
5. Specify the number of seconds to scan the application’s file system for updated files. The value specified for **Reloading interval** takes effect only if class reloading is enabled. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-application-ext.xmi`) file of the enterprise application (EAR file). You might specify different values for EJB modules and for Web modules such as servlets and JSP files.

   To enable reloading, specify an integer value that is greater than zero (for example, 1 to 2147483647).

   To disable reloading, specify zero (0).
6. Click **OK**.

Save the changes to the administrative configuration.

Configuring Web module class loaders

You can set values that control the class-loading behavior of an installed Web module.

This article assumes that you installed a Web module on an application server.

Configure the class-loader mode value of an installed Web module. By default, a Web module has its own Web application archive (WAR) class loader to load the contents of the Web module, which are in the `WEB-INF/classes` and `WEB-INF/lib` directories.

An application class loader is the parent of a WAR class loader. The WAR class-loader policy value of an application class loader determines whether the WAR class loader or the application class loader is used to load the contents of the Web module. The default WAR class loader policy value is `Module`. If the policy is set to `Module`, then each Web module receives its own class loader whose parent is the application class loader. If the policy is set to `Application` on the settings page of an enterprise application, then the application class loader loads the Web module contents as well as the enterprise bean (EJB) modules, shared libraries, resource adapter archives (RAR files), and dependency Java archive (JAR) files associated to an application. Thus, the configuration of the parent application class loader affects the WAR class loader.

Use the administrative console to configure the application and WAR class loaders.

1. If you have not done so already, configure the application class loader. Settings such as **WAR class loader policy**, **Enable class reloading**, and **Reloading interval** can affect Web module class loading. If **WAR class loader policy** is set to `Module`, then the Web module receives its own class loader and the WAR class-loader policy of the Web module defines the mode for a WAR class loader. If the policy is set to `Application`, then the application class loader loads the Web module contents.
2. Click **Applications > Enterprise Application >***application_name* **> Web modules >***Web_module_name* to access the settings page for a deployed Web module.
3. Specify the class-loader mode for the installed Web module. The Web module class-loader mode specifies whether the class loader searches in the parent application class loader or in the WAR class loader first to load a class. The default is to search in the parent application class loader before searching in the WAR class loader to load a class. Select either of the following values for **Class loader mode**:

Option	Description
Parent first	Causes the class loader to search in the parent application class loader first to load a class. This is the standard for Development Kit class loaders and WebSphere Application Server class loaders. **Tip:** If classes and resources needed by the Web module cannot be accessed by the application class loader, but can be accessed by the WAR class loader, specify `Parent last`. If the application class loader cannot find a class, the class loader delegates the request to find the class to its parent, the WebSphere Application Server extensions class loader. If the WebSphere Application Server extensions class loader cannot find the class, the class loader delegates the request to its parent, the bootstrap, extensions, and CLASSPATH class loaders created by the Java virtual machine. Requests can only go to a parent class loader; they cannot go to a child class loader. Thus, if `Parent first` is specified, the WAR class loader never receives a request to load a class.
Parent last	Causes the class loader to search in the WAR class loader first to load a class. By specifying `Parent last`, your WAR class loader can override classes contained in the parent application class loader. **Tip:** Specifying the `Parent last` value might result in LinkageErrors or ClassCastException messages if you have mixed use of overridden classes and non-overridden classes.

4. Click **OK**.

Save the changes to the administrative configuration.

Configuring class preloading

Class preloading affects how quickly a WebSphere Application Server process starts.

The first time that a WebSphere Application Server process starts up, the name of each class that is loaded and the name of the JAR file that contains the class are written to a preload file. Subsequent startups of the process use the preload file to start the process more quickly.

No configuring of class preloading is necessary.

However, an administrator can disable or enable preloading explicitly. By default, class preloading is enabled for WebSphere Application Server processes. To change the configuration for class preloading, an administrator sets new values for system properties.

- Disable class preloading. Set the Java virtual machine (JVM) system property ibm.websphere.preload.classes to `false`.
  1. In the administrative console, click **Servers > Application Servers >***server_name* **> Java and Process Management > Process Definition > Java Virtual Machine** to access the Java Virtual Machine page. See ″Java virtual machine settings″ in the information center
  2. On the Java Virtual Machine page, specify `-Dibm.websphere.preload.classes=false` for **Generic JVM arguments**.
  3. Click **OK**.
  4. Save your administrative configuration.

5. Stop the application server and then restart the application server. See ″Stopping servers″ and ″Starting servers″ in the information center.

- Enable class preloading again. If you disabled class preloading, you can enable it again by doing either of the following:
  - Set the JVM system property to `true`. On the Java Virtual Machine page, specify `-Dibm.websphere.preload.classes=true` for **Generic JVM arguments**. See ″Java virtual machine settings″ in the information center.
  - Remove the JVM system property that was created to disable class preloading. On the Java Virtual Machine page, remove the value `-Dibm.websphere.preload.classes=false` specified for **Generic JVM arguments**. See ″Java virtual machine settings″ in the information center.

  After you change the JVM system property, click **OK**, save your administrative configuration, stop the application server, and then restart the application server. See ″Stopping servers″ and ″Starting servers″ in the information center.
- Regenerate a class preload file. Delete the `.preload` file for the WebSphere Application Server process. When the process next starts up, a new class preload file is generated for the process.

Class loading: Resources for learning

Use the following links to find relevant supplemental information about class loaders. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Refer to ″Web resources for learning″ for links to information applicable to WebSphere Application Server generally, such as lists of IBM technical papers, Redbooks and samples.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page. IBM Support has documents that can save you time gathering information that is needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Chapter 5. Deploying and administering applications

Deploying an application file consists of installing the application file on a server configured to hold installable modules.

Before installing an enterprise application or other installable module on an application server, you must develop and assemble the module and configure the target server. Before choosing a server as a target for the module, ensure that the node version for the server is compatible with your module. See ″Assembling applications″ and ″Administering application servers″ in the information center.

During installation, you can configure the module enough to enable it to run on the server. After installation, you can configure the module further, start or stop the application, and otherwise manage its activity.

- Install application files on an application server.
- Edit the administrative configuration for an application.
- Start and stop the application.
- Export applications.
- Export DDL files.
- Update an application or module.
- Uninstall applications.
- Remove a file from an application or module.

After making changes to administrative configurations of your applications in the administrative console, ensure that you save the changes.

If a changed application or module is deployed on a cluster, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Enterprise (J2EE) applications

Enterprise applications (or J2EE applications) are applications that conform to the Java 2 Platform, Enterprise Edition, specification.

Enterprise applications can consist of the following:

- Zero or more EJB modules
- Zero or more Web modules
- Zero or more connector modules (packaged in RAR files)
- Zero or more application client modules
- Additional JAR files containing dependent classes or other components required by the application
- Any combination of the above

A J2EE application is represented by, and packaged in, an enterprise archive (EAR) file.

System applications

A *system application* is a J2EE enterprise application that is central to a WebSphere Application Server product.

Examples of system applications include *adminconsole* and *filetransfer*.

Because a system application is an important part of a WebSphere Application Server product, a system application is deployed when the product is installed and is updated only through a product fix or upgrade. Users cannot change the metadata for a system application such as its J2EE bindings or J2EE extensions, unless the metadata assigns users and groups for security purposes. Non-security related metadata requiring a change must be updated through a product fix or upgrade.

System applications are not shown in the list of installed applications on the console Enterprise Applications page, or through wsadmin and Java application programming interfaces, to prevent users from accidentally stopping, updating or removing the system applications.

Note that J2EE Samples are not system applications even though they are provided as part of a WebSphere Application Server product. Similarly, applications that support changes to their metadata are not system applications.

Installing application files

As part of deploying an application, you install application files on a server configured to hold installable modules.

Before you can install your application files on an application server, you must configure the target application server. As part of configuring the server, determine whether your application files can be installed to your deployment targets.

Also, before you install the files, assemble modules as needed.

Installable modules include enterprise archive (EAR), enterprise bean (EJB), Web archive (WAR), and resource adapter (connector or RAR) files. Complete the following steps to install your files.

1. Determine which method to use to install your application files. WebSphere Application Server provides several ways to install modules.
2. Install the application files using
   - Administrative console
   - wsadmin scripts - See ″Getting started with scripting″ in the information center.
   - Java administrative programs - See ″Using administrative programs (JMX)″ that use JMX APIs
   - Java programs that define a J2EE DeploymentManager object in accordance with J2EE Deployment API Specification (JSR-88)
3. Start the deployed application files using
   - Administrative console
   - wsadmin startApplication
   - Java programs that use ApplicationManager or AppManagement MBeans
   - Java programs that define a J2EE DeploymentManager object in accordance with J2EE Deployment API Specification (JSR-88)

Save the changes to your administrative configuration.

When saving the configuration, synchronize the configuration with the nodes where the application is expected to run.

Next, test the application. For example, point a Web browser at the URL for a deployed application and examine the performance of the application. If the application does not perform as desired, update the application, then save and test it again.

Installable module versions

The contents of a module affect whether you can install the module on a WebSphere Application Server Version 6.0 and later (6.x) deployment target, or must install the module on a Version 5.0 and later (5.x) deployment target.

Installable application modules

You can install an application, enterprise bean (EJB) module or Web module developed for a Version 5.x product on a 5.x or 6.x deployment target, provided the module--

- Does not support Java 2 Platform, Enterprise Edition (J2EE) 1.4;
- Does not call any 6.x runtime application programming interfaces (APIs); and
- Does not use any 6.x product features.

If the module supports J2EE 1.4, calls a 6.x API or uses a 6.x feature, then you must install the module on a 6.x deployment target.

Selecting options such as **Pre-compile JSP**, **Use Binary Configuration**, **Deploy Web services** or **Deploy enterprise beans** during application installation to a 6.x server or a 6.x deployment manager indicates that the application uses 6.x product features. You cannot deploy such applications on a 5.x deployment target. You must deploy such applications on a 6.x deployment target.

Similarly, you must deploy an application that uses J2EE 1.4 features such as Java Authorization Contract for Containers (JACC) provided by an application server on a 6.x deployment target.

Installable RAR files

You can install a standalone resource adapter (connector) module, or RAR file, developed for a Version 5.x product to a 5.x or 6.x deployment target, provided the module does not call any 6.x runtime APIs. If the module calls a 6.x API, then you must install the module on a 6.x deployment target.

Deployment targets

A *5.x deployment target* is a server or a cluster with at least one member on a WebSphere Application Server Version 5 product.

A *6.x deployment target* is a server or cluster with all members on a WebSphere Application Server Version 6 product.

Table 2. Compatible deployment target versions for 5.x and 6.x modules

Module type	Module Java support	Module calls 6.x runtime APIs or uses 6.x features?	Client versions that can install module	Deployment target versions
Application, EJB, Web, or client	J2EE 1.3	No	5.x or 6.x	5.x or 6.x
Application, EJB, Web, or client	J2EE 1.3	Yes	6.x	6.x
Application, EJB, Web, or client	J2EE 1.4	Yes or No	6.x	6.x
Resource adapter	JCA 1.0	No	5.x or 6.x	5.x or 6.x
Resource adapter	JCA 1.0	Yes	6.x	6.x
Resource adapter	JCA 1.5	Yes or No	6.x	6.x

Ways to install applications or modules

WebSphere Application Server provides several ways to install application files on a server or cluster.

Installable files include enterprise archive (EAR), enterprise bean (EJB), Web archive (WAR), resource adapter (connector or RAR), and application client modules.

Table 3. Ways to install application files

Option	Method	Modules	Comments	Starting after install
Administrative console install wizard See “Installing application files with the console” on page 41.	Click **Applications > Install New Application** in the console navigation tree and follow instructions in the wizard.	All EAR, EJB, WAR, RAR, and application client files	Provides one of the easier ways to install application files. See “Preparing for application installation settings” on page 46 for guidance. For applications that do not require changes to the default bindings, select the **Generate Default Bindings** option and then, on the Summary panel, click **Finish**.	Click **Start** on the Enterprise Applications page accessed by clicking **Applications > Enterprise Applications** in the console navigation tree.
wsadmin scripts	Invoke AdminApp object *install* commands in a script or at a command prompt. See ″Installing applications with the wsadmin tool″ in the information center.	All EAR, EJB, WAR, RAR, and application client files	Getting started with scripting provides an overview of wsadmin.	• Invoke the AdminApp *startApplication* command. • Invoke the *startApplication* method on an ApplicationManager MBean using AdminControl. See ″Starting an application through programming″. .
Java application programming interfaces	Install programs by completing the steps in ″Managing applications through programming″.	All EAR files	Use MBeans to install the application.	Start the application by calling the *startApplication* method on a proxy.

Table 3. Ways to install application files (continued)

WebSphere rapid deployment Refer to articles under **Rapid deployment of J2EE applications** in this information center.	Briefly, do the following: 1. Update your J2EE application files. 2. Set up the rapid deployment environment. 3. Create a free-form project. 4. Launch a rapid deployment session. 5. Drop your updated application files into the free-form project.	All J2EE modules, including EAR files and standalone EJB, WAR, RAR, and application client files	WebSphere rapid deployment offers the following advantages: • You do not need to assemble your J2EE application files prior to deployment. • You do not need to use other installation tools mentioned in this table to deploy the files.	Use any of the above options to start the application. Clicking **Start** on the Enterprise Applications page is the easiest option.
Java programs	Code programs that use J2EE DeploymentManager (JSR-88) methods.	All J2EE modules, including EAR files and standalone EJB, WAR, RAR, and application client files	• Uses J2EE Application Deployment Specification (JSR-88). • Can customize modules using DConfigBeans.	Call the J2EE DeploymentManager (JSR-88) method *start* in a program to start the deployed modules when the module's running environment initializes.

Installing application files with the console

Installing application files consists of placing assembled enterprise application, Web, enterprise bean (EJB), or other installable modules on a server or cluster configured to hold the files. Installed files that start and run properly are considered *deployed*.

Before installing enterprise application files, ensure that you are installing your application files onto a compatible deployment target. If the deployment target is not compatible, select a different target.

To install new enterprise application files to a WebSphere Application Server configuration, you can use the administrative console, the wsadmin tool, or Java programs that call J2EE DeploymentManager (JSR-88) methods. This article describes how to use the administrative console to install an application, EJB component, or Web module.

Important: After you start performing the steps below, click **Cancel** to exit if you decide not to install the application. Do not simply move to another administrative console page without first clicking **Cancel** on an application installation page.

1. Click **Applications > Install New Application** in the console navigation tree. The first of two Preparing for application installation pages is displayed.
2. On the first Preparing for application installation page:
   a. Specify the full path name of the source enterprise application file (`.ear` file otherwise known as an *EAR file*). The EAR file that you are installing can be either on the client machine (the machine that runs the Web browser) or on the server machine (the machine to which the client is connected). If you specify an EAR file on the client machine, then the administrative console uploads the EAR file to the machine on which the console is running and proceeds with application installation. You can also specify a standalone Web application archive (WAR) or Java archive (JAR) file for installation.
   b. If you are installing a standalone WAR file, specify the context root.

c. Click **Next**.

3. On the second Preparing for application installation page:
   a. Select whether to generate default bindings. Using the default bindings causes any incomplete bindings in the application to be filled in with default values. Existing bindings are not altered. You can customize default values used in generating default bindings. For example, you can specify a Java Naming and Directory Interface (JNDI) prefix for EJB files in EJB modules, default data source and connection factory settings for EJB modules, virtual host for Web modules, and so on. "Preparing for application installation settings" on page 46 describes available customizations and provides sample bindings.
   b. Click **Next**. If security warnings are displayed, click **Continue**. The Install New Application pages are displayed. If you chose to generate default bindings, you can proceed to the Summary step (last step below). "Example: Installing an EAR file using the default bindings" on page 51 provides sample steps.
4. On the **Step: Select installation options** panel, provide values for the following settings specific to WebSphere Application Server. Default values are used if you do not specify a value.
   a. For **Pre-compile JSP**, specify whether to precompile JavaServer page (JSP) files as a part of installation. The default is not to precompile JSP files. Install onto a 6.x deployment target. If you select **Pre-compile JSP** and try installing your application onto a 5.x deployment target, the installation is rejected. For this option, install only onto a 6.x deployment target.
   b. For **Directory to install application**, specify the directory to which the application EAR file will be installed. The default value is the value of APP_INSTALL_ROOT/*cell_name*, where the APP_INSTALL_ROOT variable is *install_root*/installedApps; for example, C:\WebSphere\AppServer\profiles*profile _name*\installedApps*cell_name*.

      Note: If an installation directory is not specified when an application is installed on a single-server (base) configuration, the application is installed in APP_INSTALL_ROOT/*base_cell_name*. When the base server is made a part of a Network Deployment configuration (using the addNode utility), the cell name of the new configuration becomes the cell name of the deployment manager node. If the -includeapps option is used for the addNode utility, then the applications that are installed prior to the addNode operation still use the installation directory APP_INSTALL_ROOT/*base_cell_name*. However, an application that is installed after the base server is added to the network configuration uses the default installation directory APP_INSTALL_ROOT/*network_cell_name*. To move the application to the APP_INSTALL_ROOT/*network_cell_name* location upon running the addNode operation, you should explicitly specify the installation directory as ${APP_INSTALL_ROOT}/${CELL} during installation. In such a case, the application files can always be found under APP_INSTALL_ROOT/*current_cell_name*.
   c. For **Distribute application**, specify whether WebSphere Application Server expands or deletes application binaries in the installation destination. The default is to enable application distribution. As a result, when you save changes in the console, application binaries for newly installed applications are expanded to the directory specified. The binaries are also deleted when you uninstall and save changes to the configuration. If you disable this option, then you must ensure that the application binaries are expanded appropriately in the destination directories of all nodes where the application is expected to run.

      Important: If you disable this option and you do not copy and expand the application binaries to the nodes, a later saving of the configuration or manual synchronization does not move the application binaries to the nodes for you.
   d. For **Use Binary Configuration**, specify whether the application server uses the binding, extensions, and deployment descriptors located with the application deployment document, the deployment.xml file (default), or those located in the EAR file. The default is not to use the binary configuration. If you select **Use Binary Configuration**, your application files must be installed onto a 6.x deployment target. The files cannot be installed onto a 5.x deployment target.

e. For **Deploy enterprise beans**, specify whether the EJBDeploy tool runs during application installation. The tool generates code needed to run EJB files. You must enable this setting in the following situations:
   - The EAR file was assembled using an assembly tool such as Rational Web Developer or Application Server Toolkit (AST) and the EJBDeploy tool was not run during assembly.
   - The EAR file was not assembled using an assembly tool.
   - The EAR file was assembled using versions of the Application Assembly Tool (AAT) previous to Version 5.

   Enabling this setting might cause the installation program to run for several minutes. Also, install onto a 6.x deployment target. If you select **Deploy enterprise beans** and try installing your application onto a 5.x deployment target, the installation is rejected. For this option, install only onto a 6.x deployment target.

f. For **Application name**, name the application. Application names must be unique within a cell and cannot contain characters that are not allowed in object names. See ″Object names″.

g. For **Create MBeans for resources**, specify whether to create MBeans for various resources (such as servlets or JSP files) within an application when the application is started. The default is to create MBean instances.

h. For **Enable class reloading**, specify whether to enable class reloading when application files are updated. The default is not to enable class reloading. For EJB modules or any non-Web modules, enabling class reloading sets reloadEnabled to `true` in the `deployment.xml` file for the application. If an application's class definition changes, the application server run time stops and starts the application to reload application classes.

   For Web modules such as servlets and JSP files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is set to `true`. You can set reloadingEnabled to `true` when editing the extended deployment descriptors of your Web module in an assembly tool.

   To disable reloading of a Web module, set the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file to `false`. Or, if the Web module has the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file set to `true`, enable class loading, and set the **Reload interval** property to zero (0).

i. For **Reload interval in seconds**, specify the number of seconds to scan the application's file system for updated files. The default is the value of the reload interval attribute in the IBM extension (`META-INF/ibm-application-ext.xmi`) file of the EAR file. To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). To disable reloading, specify zero (0).

   The reload interval specified here takes effect only if class reloading is enabled.

j. For **Deploy Web services**, specify whether the Web services deploy tool `wsdeploy` runs during application installation. The tool generates code needed to run applications using Web services. The default is not to run the `wsdeploy` tool. You must enable this setting if the EAR file contains modules using Web services and has not previously had the `wsdeploy` tool run on it, either from the **Deploy** menu choice of an assembly tool or from a command line. Note that if you select **Deploy** and try installing your application onto a 5.x deployment target, the installation is rejected. For this option, install only onto a 6.x deployment target.

k. For **Validate Input off/warn/fail,** specify whether WebSphere Application Server examines the application references specified during application installation or updating and, if validation is enabled, warns you of incorrect references or fails the operation. An application typically refers to resources using data sources for container managed persistence (CMP) beans or using resource references or resource environment references defined in deployment descriptors. The validation checks whether the resource referred to by the application is defined in the scope of the deployment target of that application. Select **off** for no resource validation, **warn** for warning messages about incorrect resource references, or **fail** to stop operations that fail as a result of incorrect resource references.

l. For **Process embedded configuration**, specify whether the embedded configuration should be processed. An embedded configuration consists of files such as `resource.xml` and `variables.xml`.

When selected or `true`, the embedded configuration is loaded to the application scope from the `.ear` file. If the `.ear` file does not contain an embedded configuration, the default is `false`. If the `.ear` file contains an embedded configuration, the default is `true`.

5. On the **Step: Map modules to servers** panel, for every module select a target server or cluster from the **Clusters and Servers** list. Select the check box beside **Module** to select all of the application modules or select individual modules. Ensure that you are installing your application onto an appropriate deployment target. You can specify Web servers as targets that route requests to the application. The plug-in configuration file `plugin-cfg.xml` for each Web server is generated based on the applications which are routed through it. If you want a Web server to serve the application, use the **Ctrl** key to select an application server or cluster and the Web server together in order to have the plug-in configuration file `plugin-cfg.xml` for that Web server generated based on the applications which are routed through it.
6. If your application uses EJB modules, on the **Step: Provide JNDI Names for Beans** panel, specify a JNDI name for each enterprise bean in every EJB module. You must specify a JNDI name for every enterprise bean defined in the application. For example, for the EJB module `MyBean.jar`, specify `MyBean`.
7. If your application uses EJB modules that contain Container Managed Persistence (CMP) beans that are based on the EJB 1.x specification, for **Step: Provide default datasource mapping for modules containing 1.x entity beans**, specify a JNDI name for the default data source for the EJB modules. The default data source for the EJB modules is optional if data sources are specified for individual CMP beans.
8. If your application has CMP beans that are based on the EJB 1.x specification, for **Step: Map datasources for all 1.x CMP**, specify a JNDI name for data sources to be used for each of the 1.x CMP beans. The data source attribute is optional for individual CMP beans if a default data source is specified for the EJB module that contains CMP beans. If neither a default data source for the EJB module nor a data source for individual CMP beans are specified, then a validation error displays after you click **Finish** and the installation is cancelled.
9. If your application defines EJB references, for **Step: Map EJB references to beans**, specify JNDI names for enterprise beans that represent the logical names specified in EJB references. Each EJB reference defined in the application must be bound to an EJB file before clicking **Finish** on the Summary panel.
10. If your application defines resource references, for **Step: Map resource references to resources**, specify JNDI names for the resources that represent the logical names defined in resource references. You can optionally specify login configuration name and authentication properties for the resource. After specifying authentication properties, click **OK** to save the values and return to the mapping step. Each resource reference defined in the application must be bound to a resource defined in your WebSphere Application Server configuration before clicking on **Finish** on the Summary panel.
11. If your application uses Web modules, for **Step: Map virtual hosts for web modules**, select a virtual host from the list that should map to a Web module defined in the application. The port number specified in the virtual host definition is used in the URL that is used to access artifacts such as servlets and JSP files in the Web module. Each Web module must have a virtual host to which it maps. Not specifying all needed virtual hosts will result in a validation error displaying after you click **Finish** on the Summary panel.
12. If the application has security roles defined in its deployment descriptor then, for **Step: Map security roles to users/groups**, specify users and groups that are mapped to each of the security roles. Select **Role** to select all of the roles or select individual roles. For each role, you can specify if predefined users such as **Everyone** or **All authenticated users** are mapped to it. To select specific users or groups from the user registry:
    a. Select a role and click **Lookup users** or **Lookup groups**.
    b. On the Lookup users/groups panel displayed, enter search criteria to extract a list of users or groups from the user registry.
    c. Select individual users or groups from the results displayed.

d. Click **OK** to map the selected users or groups to the role selected on the **Step: Map security roles to users/groups** panel.

13. If the application has Run As roles defined in its deployment descriptor, for **Step: Map RunAs roles to user**, specify the Run As user name and password for every Run As role. Run As roles are used by enterprise beans that must run as a particular role while interacting with another enterprise bean. Select **Role** to select all of the roles or select individual roles. After selecting a role, enter values for the user name, password, and verify password and click **Apply**.
14. If your application contains EJB 1.x CMP beans that do not have method permissions defined for some of the EJB methods, for **Step: Ensure all unprotected 1.x methods have the correct level of protection**, specify if you want to leave such methods unprotected or assign protection with deny all access.
15. If your application contains message driven enterprise beans, for **Step: Provide Listener Ports or activation specification JNDI name for messaging beans**, provide a listener port name or an activation specification JNDI name for every message driven bean. A listener port name must be provided when using the JMS providers: Version 5 default messaging, WebSphere MQ, or generic. An activation specification must be provided when the application's resources are configured using the default messaging provider or any generic J2C resource adapter that supports inbound messaging. If neither is specified, then a validation error is displayed after you click **Finish** on the Summary panel. Also, if the module containing the message driven bean is deployed on a 5.x deployment target and a listener port is not specified, then a validation error is displayed after you click **Next**.
16. If your application uses EJB modules that contain CMP beans that are based on the EJB 2.x specification, for **Step: Provide default datasource mapping for modules containing 2.x entity beans**, specify a JNDI name for the default data source and the type of resource authorization to be used for the default data source for the EJB modules. You can optionally specify a login configuration name and authentication properties for the data source. When creating authentication properties, you must click **OK** to save the values and return to the mapping step. The default data source for EJB modules is optional if data sources are specified for individual CMP beans.
17. If your application has CMP beans that are based on the EJB 2.x specification, on the **Step: Map datasources for all 2.x CMP** panel, for each of the 2.x CMP beans specify a JNDI name and the type of resource authorization for data sources to be used. You can optionally specify a login configuration name and authentication properties for the data source. When creating authentication properties, you must click **OK** to save the values and return to the mapping step. The data source attribute is optional for individual CMP beans if a default data source is specified for the EJB module that contains CMP beans. If neither a default data source for the EJB module nor a data source for individual CMP beans are specified, then a validation error is displayed after you click **Finish** and installation is cancelled.
18. If your application contains EJB 2.x CMP beans that do not have method permissions defined in the deployment descriptors for some of the EJB methods, on the **Step: Ensure all unprotected 2.x methods have the correct level of protection** panel, specify whether you want to assign a specific role to the unprotected methods, add the methods to the exclude list, or mark them as unchecked. Methods added to the exclude list are marked as uncallable. For methods marked unchecked no authorization check is performed prior to their invocation.
19. If the **Deploy enterprise beans** setting is enabled on the **Select installation options** panel, then you can specify options for the EJBDeploy tool on the **Step: Provide options to perform the EJB Deploy** panel. On this panel, you can specify extra class paths, RMIC options, database types, and database schema names to be used while running the EJBDeploy tool. The tool is run on the EAR file during installation after you click **Finish**.
20. If your application contains resource environment references, for **Step: Map resource environment references to resources**, specify JNDI names of resources that map to the logical names defined in resource environment references. If each resource environment reference does not have a resource associated with it, after you click **Finish** a validation error is displayed.
21. If your application defines **Run-As Identity** as *System Identity*, for **Step: Replace RunAs System to RunAs Roles**, you can optionally change it to *Run-As role* and specify a user name and password

for the Run As role specified. Selecting *System Identity* implies that the invocation is done using the WebSphere Application Server security server ID and should be used with caution as this ID has more privileges.

22. If your application has resource references that map to resources that have an Oracle database doing backend processing, for **Step: Specify the isolation level for Oracle type provider**, specify or correct the isolation level to be used for such resources when used by the application. Oracle databases support ReadCommitted and Serializable isolation levels only.
23. If your application uses message driven beans, for **Step: Build message destination to administered objects**, specify the JNDI name of the J2C administered object to bind the message destination reference to the message driven beans.
24. If your application contains an embedded `.rar` file, for **Step: Map JCA resources to resources**, specify the name and JNDI name of each J2C connection factory, J2C administered object and J2C activation specification.
25. If your application contains an embedded `.rar` file, its activationSpec property has the value `Destination`, and its introspected type is `javax.jms.Destination`, for **Step: Bind J2CActivationSpec to Destination Jndi name**, specify the jndiName value for each activation bound to it.
26. If your application has EJB modules for which deployment code has been generated for multiple backend databases using an assembly tool, for **Step: Select a backend ID**, specify the backend ID representing the backend database to be used when the EJB module runs. See ″Mapping enterprise beans to database tables″ in the information center
27. On the Summary panel, verify the cell, node, and server onto which the application modules will install:
    a. Beside **Cell/Node/Server**, click **Click here**.
    b. Verify the settings.
    c. Click **Finish**.

Several messages are displayed, indicating whether your application file is installing successfully.

If you receive an OutOfMemory exception and the source application file does not install, your system might not have enough memory or your application might have too many modules in it to install successfully onto the server. If lack of system memory is not the cause of the exception, package your application again so the `.ear` file has fewer modules. If lack of system memory and the number of modules are not the cause of the exception, check the options you specified on the Java Virtual Machine page of the application server running the administrative console. Then, try installing the application file again.

After the application file installs successfully, do the following:

1. Associate any shared libraries that the application needs to the application. See ″Managing shared libraries″ in the information center.
2. Save the changes to your configuration. The application is registered with the administrative configuration and application files are copied to the target directory, which is *install_root*/installedApps/*cell_name* by default or the directory that you designate. For the Network Deployment installation, files are copied to remote nodes when the configuration on the deployment manager synchronizes with the configuration on individual nodes.
3. Start the application.
4. Test the application. For example, point a Web browser at the URL for the deployed application and examine the performance of the application. If necessary, update the application.

Preparing for application installation settings

Use this page to install an application (EAR file) or module (JAR or WAR file).

To view this administrative console page, click **Applications > Install New Application**.

Follow the steps on this page to install an application or module. You must complete, at minimum, the first step; you must complete some or all of the later steps, depending on whether you are installing an application, EJB module, or Web module.

Path:

Specifies the fully qualified path to the `.ear`, `.jar`, or `.war` file for the enterprise application.

Use **Local file system** if the browser and application files are on the same machine (whether or not the server is on that machine, too).

Use **Remote file system** if the application file resides on any node in the current cell context.You can browse the entire file system of a node if the node agent or deployment manager is running on that selected node. Only `.ear`, `.jar`, or `.war` files are shown during the browsing.

During application installation, application files typically are uploaded from a client machine running the browser to the server machine running the administrative console, where they are deployed. In such cases, use the Web browser running the administrative console to select EAR, WAR, or JAR modules to upload to the server machine.

In some cases, however, the application files reside on the file system of any of the nodes in a cell. To have the application server install these files, use the **Remote file system** option.

Also use the **Remote file system** option to specify an application file already residing on the machine running the application server. For example, the field value on a Windows machine might be `C:\WebSphere\AppServer\installableApps\test.ear`. If you are installing a stand-alone WAR module, then specify the context root as well.

After the application file is transferred, the **Remote file system** value shows the path of the temporary location on the deployment manager orserver machine.

Context root:

Specifies the context root of the Web application (WAR).

This field is used only to install a stand-alone WAR file. The context root is combined with the defined servlet mapping (from the WAR file) to compose the full URL that users type to access the servlet. For example, if the context root is `/gettingstarted` and the servlet mapping is `MySession`, then the URL is `http://host:port/gettingstarted/MySession`.

Generate Default Bindings:

Specifies whether to generate default bindings. If you place a check mark in the check box, then any incomplete bindings in the application are filled in with default values. Existing bindings are not altered.

By choosing this option, you can directly jump to the Summary step and install the application if none of the steps have a red asterisk (*) next to them. A red asterisk denotes that the step has incomplete data and requires a valid value. On the Summary panel, verify the cell, node and server on which the application is installed.

Bindings are generated as follows:

- EJB JNDI names are generated of the form *prefix*/*ejb-name*. The default prefix is `ejb`, but can be overridden. The *ejb-name* is as specified in the deployment descriptors `<ejb-name>` tag.
- EJB references are bound as follows: If an `<ejb-link>` is found, it is honored. Otherwise, if a unique enterprise bean is found with a matching home (or local home) interface as the referenced bean, the reference is resolved automatically.

- Resource reference bindings are derived from the <res-ref-name> tag. Note that this action assumes that the java:comp/env name is the same as the resource global JNDI name.
- Connection factory bindings (for EJB 2.0 JAR files) are generated based on the JNDI name and authorization information provided. This action results in default connection factory settings for each EJB 2.0 JAR file in the application being installed. No bean-level connection factory bindings are generated.
- Data source bindings (for EJB 1.1 JAR files) are generated based on the JNDI name, data source user name password options. This results in default data source settings for each EJB JAR file. No bean-level data source bindings are generated.
- For EJB2.1 or EJB2.0 message-driven beans deployed as JCA 1.5-compliant resources, the JNDI names corresponding to activationSpec instances are generated in the form eis/*MDB_ejb-name*. Message Destination references are bound as follows: if a <message-destination-link> is found then the JNDI name is set to ejs/*message-destination-link*Name. Otherwise the JNDI name is set to eis/*message-destination-ref*Name.
- For EJB 2.0 message-driven beans deployed against a listener ports, the listener ports are derived from the MDB <ejb-name> tag with the string Port appended.
- For .war files, the virtual host is set as default_host unless otherwise specified.

The default strategy suffices for most applications or at least for most bindings in most applications. However, it does not work if:
- You want to explicitly control the global JNDI names of one or more EJB files.
- You need tighter control of data source bindings for container-managed persistence (CMP) beans. That is, you have multiple data sources and need more than one global data source.
- You must map resource references to global resource JNDI names that are different from the java:comp/env name.

In such cases, you can change the behavior with an XML document (a custom strategy). Use the **Specific bindings file** field to specify a custom strategy and see the field's help for examples.

Prefixes:

Specifies prefixes to use for generated JNDI names.

Override:

Specifies whether generated bindings are to override existing bindings.

If **Override existing bindings** is selected, the existing bindings are overridden by the generated ones.

Connection Factory Bindings:

Specifies the default data source JNDI name.

If **Default connection factory bindings** is selected, specify the JNDI name for the default data source to be used with the bindings. Also specify the resource authorization.

Virtual Host:

Specifies the virtual host for the Web module.

Specific bindings file:

Specifies a bindings file that overrides the default binding.

Change the behavior of the default binding with an XML document (a custom strategy). Custom strategies extend the default strategy so you only need to customize those areas where the default strategy is

insufficient. Thus, you only need to describe how you want to change the bindings generated by the default strategy; you do not have to define bindings for the entire application.

Brief examples of how to override various aspects of the default bindings generator follow:

Controlling an EJB JNDI name

```
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>helloEjb.jar</jar-name>
      <ejb-bindings>
        <ejb-binding>
         <ejb-name>HelloEjb</ejb-name>
         <jndi-name>com/acme/ejb/HelloHome</jndi-name>
        </ejb-binding>
      </ejb-bindings>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Note: Ensure that the setting for `<ejb-name>` matches the `ejb-name` entry in the EJB JAR deployment descriptor. Here the setting is `<ejb-name>HelloEjb</ejb-name>`.

Setting the connection factory binding for an EJB JAR file

```
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>yourEjb20.jar</jar-name>
      <connection-factory>
        <jndi-name>eis/jdbc/YourData_CMP</jndi-name>
        <res-auth>Container</res-auth>
      </connection-factory>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Setting the connection factory binding for an EJB file

```
<?xml version="1.0">
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>yourEjb20.jar</jar-name>
      <ejb-bindings>
        <ejb-binding>
          <ejb-name>YourCmp20</ejb-name>
          <connection-factory>
           <jndi-name>eis/jdbc/YourData_CMP</jndi-name>
           <res-auth>PerConnFact</res-auth>
          </connection-factory>
        </ejb-binding>
      </ejb-bindings>
    </ejb-jar-binding>
 </module-bindings>
</dfltbndngs>
```

Note: Ensure that the setting for `<ejb-name>` matches the `ejb-name` tag in the deployment descriptor. Here the setting is `<ejb-name>YourCmp20</ejb-name>`.

Setting the message destination reference JNDI for a specific enterprise bean

Example XML extract in a custom strategy file for setting message-destination-refs for a specific enterprise bean.

```
<?xml version="1.0">
 <!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
 <dfltbndngs>
  <module-bindings>
   <ejb-jar-binding>
    <jar-name>yourEjb21.jar</jar-name>
    <ejb-bindings>
     <ejb-binding>
      <ejb-name>YourSession21</ejb-name>
      <message-destination-ref-bindings>
       <message-destination-ref-binding>
        <message-destination-ref-name>jdbc/MyDataSrc</message-destination-ref-name>
        <jndi-name>eis/somAO</jndi-name>
       </message-destination-ref-binding>
      </message-destination-ref-bindings>
     </ejb-binding>
    </ejb-bindings>
   </ejb-jar-binding>
  </module-bindings>
 </dfltbndngs>
```

Note: Ensure that the setting for `<ejb-name>` matches the `ejb-name` tag in the deployment descriptor. Here the setting is `<ejb-name>YourSession21</ejb-name>`. Also ensure that the setting for `<message-destination-ref-name>` matches the `message-destination-ref-name` tag in the deployment descriptor. Here the setting is `<message-destination-ref-name>jdbc/MyDataSrc</message-destination-ref-name>`.

Overriding a resource reference binding from a WAR, EJB JAR file, or J2EE client JAR file

Example code for overriding a resource reference binding from a WAR file follows. Use similar code to override a resource reference binding from an enterprise bean (EJB) JAR file or a J2EE client JAR file.

```
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <war-binding>
      <jar-name>hello.war</jar-name>
      <resource-ref-bindings>
        <resource-ref-binding>
          <resource-ref-name>jdbc/MyDataSrc</resource-ref-name>
          <jndi-name>war/override/dataSource</jndi-name>
        </resource-ref-binding>
      </resource-ref-bindings>
    </war-binding>
  </module-bindings>
</dfltbndngs>
```

Note: Ensure that the setting for `<resource-ref-name>` matches the `resource-ref` tag in the deployment descriptor. Here the setting is `<resource-ref-name>jdbc/MyDataSrc</resource-ref-name>`.

Overriding the JNDI name for a message-driven bean deployed as a JCA 1.5-compliant resource

Example XML extract in a custom strategy file for overriding the JMS activationSpec JNDI name for an EJB 2.1 or EJB 2.0 message-driven bean deployed as a JCA 1.5-compliant resource.

```
<?xml version="1.0"?>
 <!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
  <dfltbndngs>
```

```
  <module-bindings>
   <ejb-jar-binding>
     <jar-name>YourEjbJar.jar</jar-name>
     <ejb-bindings>
      <ejb-binding>
        <ejb-name>YourMDB</ejb-name>
        <activationspec-jndi-name>activationSpecJNDI</activationspec-jndi-name>
      </ejb-binding>
     </ejb-bindings>
   </ejb-jar-binding>
  </module-bindings>
 </dfltbndngs>
```

Overriding the JMS listener port name for an EJB 2.0 message-driven bean

Example XML extract in a custom strategy file for overriding the JMS listener port name for an EJB 2.0 message-driven bean deployed against a listener port.

```
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>YourEjbJar.jar</jar-name>
      <ejb-bindings>
        <ejb-binding>
          <ejb-name>YourMDB</ejb-name>
          <listener-port>yourMdbListPort</listener-port>
        </ejb-binding>
      </ejb-bindings>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Overriding an EJB reference binding from an EJB JAR, WAR file, or EJB file

Example code for overriding an EJB reference binding from an EJB JAR file follows. Use similar code to override an EJB reference binding from a WAR file or an EJB file.

```
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>YourEjbJar.jar</jar-name>
      <ejb-ref-bindings>
        <ejb-ref-binding>
          <ejb-ref-name>YourEjb</ejb-ref-name>
          <jndi-name>YourEjb/JNDI</jndi-name>
        </ejb-ref-binding>
      </ejb-ref-bindings>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Example: Installing an EAR file using the default bindings

If application bindings were not specified for all enterprise beans or resources in an application during application development or assembly, you can select to generate default bindings. See ″Editing deployment descriptors″ in the information center. After application installation, you can modify the bindings as needed using the administrative console.

An example of a simple `.ear` file installation using the default bindings follows:

1. Go to the Preparing for application install pages.

Click **Applications > Install New Application** in the console navigation tree.

2. For **Path to the new application**, specify the full path name of the `.ear` file.

   For this example, the base file name is `my_appl.ear` and the file resides on a server at `C:\sample_apps`.

   a. Select the **Remote file system** radio button and click **Browse**.
   b. On the Browse Remote Filesystems page, click on the name of the node that holds the `my_appl.ear` file, **C:**, **sample_apps**, **my_appl.ear**, and then **OK**.
3. Now that a value is given for **Specify path**, on the first Preparing for application installation page, click **Next**.
4. On the second Preparing for application installation page, select **Generate Default Bindings** and click **Next**.

   Using the default bindings causes any incomplete bindings in the application to be filled in with default values. Existing bindings are not changed. By choosing this option, you can skip many of the steps on the Install New Application page and go directly to the Summary step.
5. If application security warnings are displayed, read the warnings and click **Continue**.
6. On the Install New Application page, click on **Summary**, the last step.
7. On the Summary panel, verify the cell, node, and server onto which the application files will install.

   a. Beside the **Cell/Node/Server** option, click **Click here**.
   b. On the **Map modules to servers** panel, select the server onto which the application files will install from the **Clusters and Servers** list, click **Module** to select all of the application modules, and click **Next**.

      Note that on the **Map modules to servers** panel, you can map modules to other servers such as Web servers. If you want a Web server to serve the application, use the **Ctrl** key to select an application server or cluster and the Web server together in order to have the plug-in configuration file `plugin-cfg.xml` for that Web server generated based on the applications which are routed through it.

   Because `my_appl.ear` does not require any additional settings to complete an installation, the Summary panel is displayed again.
8. On the Summary panel, click **Finish**.

Examine the application installation progress messages. If the application installs successfully, save your administrative configuration. You can now see the name of your application in the list of deployed applications on the Enterprise Applications page accessed by clicking **Applications > Enterprise Applications** in the console navigation tree.

If the application does not install successfully, read the messages to identify why the installation failed. Correct problems with the application as needed and try installing the application again.

Installing J2EE modules with JSR-88

You can install Java 2 Platform, Enterprise Edition (J2EE) modules on an application server provided by a WebSphere Application Server product using the J2EE Deployment API Specification (JSR-88).

JSR-88 defines standard application programming interfaces (APIs) to enable deployment of J2EE applications and stand-alone modules to J2EE product platforms. The J2EE Deployment Specification Version 1.1 is available at http://java.sun.com/j2ee/tools/deployment/reference/docs/index.html as part of the J2EE 1.4 Application Server Developer Release.

Read about JSR-88 and APIs used to manage applications at http://java.sun.com/j2ee/tools/deployment/.

JSR-88 defines a contract between a tool provider and a platform that enables tools from multiple vendors to configure, deploy and manage applications on any J2EE product platform. The tool provider typically supplies software tools and an integrated development environment (IDE) for developing and assembly of J2EE application modules. The J2EE platform provides application management functions that deploy, undeploy, start, stop, and otherwise manage J2EE applications.

WebSphere Application Server is a J2EE 1.4 specification-compliant platform that implements the JSR-88 APIs. Complete the following steps to deploy (install) J2EE modules on an application server provided by the WebSphere Application Server platform.

1. Code a Java program that can access the JSR-88 DeploymentManager class for WebSphere Application Server.
   a. Write code that finds the JAR manifest file key J2EE-DeploymentFactory-Implementation-Class. Under JSR-88, your code finds the DeploymentFactory using the JAR manifest file key J2EE-DeploymentFactory-Implementation-Class. For WebSphere Application Server, the application management JAR file containing this key and providing support is *install_root*/lib/wjmxapp.jar. After your code finds the DeploymentFactory, the deployment tool can create an instance of the WebSphere DeploymentFactory and register the instance with its DeploymentFactoryManager. For example:

```
import javax.enterprise.deploy.shared.factories.DeploymentFactoryManager;
import javax.enterprise.deploy.spi.DeploymentManager;
import javax.enterprise.deploy.spi.factories.DeploymentFactory;
import java.util.jar.JarFile;

// Get the DeploymentFactory implementation class from the MANIFEST.MF file.
JarFile wjmxappJar = new JarFile(new File(wasHome + "/lib/wjmxapp.jar"));
java.util.jar.Manifest manifestFile = wjmxappJar.getManifest();
Attributes attributes = manifestFile.getMainAttributes();
String key = "J2EE-DeploymentFactory-Implementation-Class";
String className = attributes.getValue(key);
// Get an instance of the DeploymentFactoryManager
DeploymentFactoryManager dfm = DeploymentFactoryManager.getInstance();

// Create an instance of the WebSphere Application Server DeploymentFactory.
Class deploymentFactory = Class.forName(className);
DeploymentFactory deploymentFactoryInstance =
   (DeploymentFactory) deploymentFactory.newInstance();

// Register the DeploymentFactory instance with the DeploymentFactoryManager.
dfm.registerDeploymentFactory(deploymentFactoryInstance);

// Provide WebSphere Application Server URL, user ID, and password.
// For more information, see the step that follows.
wsDM = dfm.getDeploymentManager(
   "deployer:WebSphere:myserver:8880", null, null);
```

   b. Write code that accesses the DeploymentManager instance for WebSphere Application Server. The WebSphere Application Server URL for deployment has the format

      "deployer:WebSphere:*host*:*port*"

      The example in the previous step, "deployer:WebSphere:myserver:8880", tries to connect to host *myserver* at port *8880* using the SOAP connector, which is the default.

      The URL for deployment can have an optional parameter *connectorType*. For example, to use the RMI connector to access *myserver*, code the URL as follows:

      "deployer:WebSphere:myserver:2809?connectorType=RMI"

2. **Optional:** Code a Java program that can customize or deploy J2EE applications or modules using the JSR-88 support provided by WebSphere Application Server.
3. Start the deployed J2EE applications or standalone J2EE modules using the JSR-88 API used to start applications or modules.

Test the deployed applications or modules. For example, point a Web browser at the URL for a deployed application and examine the performance of the application. If necessary, update the application.

Customizing modules using DConfigBeans

You can configure J2EE applications or standalone modules during deployment using the DConfigBean class in the Java 2 Platform, Enterprise Edition (J2EE) Deployment API Specification (JSR-88).

This article assumes that you are deploying (installing) J2EE modules on an application server provided by the WebSphere Application Server platform using the WebSphere Application Server support for JSR-88.

Read about the JSR-88 specification and using the DConfigBean class at http://java.sun.com/j2ee/tools/deployment/.

The DConfigBean class in JSR-88 provides JavaBeans-based support for platform-specific configuration of J2EE applications and modules during deployment. Your code can inspect DConfigBean instances to get platform-specific configuration attributes. The DConfigBean instances provided by WebSphere Application Server contain a single attribute which has an array of java.util.Hashtable objects. The hashtable entries contain configuration attributes, for which your code can get and set values.

1. Write code that installs J2EE modules on an application server using JSR-88.
2. Write code that accesses DConfigBeans generated by WebSphere Application Server during JSR-88 deployment. You (or a deployer) can then customize the accessed DConfigBeans instances. The following pseudocode shows how a J2EE tool provider can get DConfigBean instance attributes generated by WebSphere Application Server during JSR-88 deployment and set values for the attributes:

```
import javax.enterprise.deploy.model.*;
import javax.enterprise.deploy.spi.*;
{
DeploymentConfiguration dConfig = ___; // Get from DeploymentManager
DDBeanRoot ddRoot = ___;               // Provided by J2EE tool

// Obtain root bean.
DConfigBeanRoot dcRoot = dConfig.getDConfigBeanRoot(dr);

// Configure DConfigBean.
configureDCBean (dcRoot);
}

// Get children from DConfigBeanRoot and configure each child.
method configureDCBean (DConfigBean dcBean)
{
   // Get DConfigBean attributes for a given archive.
   BeanInfo bInfo = Introspector.getBeanInfo(dcBean.getClass());
   IndexedPropertyDescriptor ipDesc =
      (IndexedPropertyDescriptor)bInfo.getPropertyDescriptors()[0];

   // Get the 0th table.
   int index = 0;
   Hashtable tbl = (Hashtable)
      ipDesc.getIndexedReadMethod().invoke
         (dcBean, new Object[]{new Integer(index)});

   while (tbl != null)
   {
      // Iterate over the hashtable and set values for attributes.

      // Set the table back into the DCBean.
      ipDesc.getIndexedWriteMethod().invoke
         (dcBean, new Object[]{new Integer(index), tbl});

      // Get the next entry in the indexed property
      tbl = (Hashtable)
         ipDesc.getIndexedReadMethod().invoke
            (dcBean, new Object[]{new Integer(++index)});
   }
}
```

Enterprise application collection

Use this page to view and manage enterprise applications.

This page lists installed J2EE enterprise applications. System applications, which are central to the product, are not shown in the list because users cannot edit them. Examples of system applications include *adminconsole* and *filetransfer*.

To view this administrative console page, click **Applications > Enterprise Applications**.

To view the values specified for an application's configuration, click the application name in the list. The displayed application settings page shows the values specified. On the settings page, you can change existing configuration values and link to additional console pages that assist you in configuring the application.

To manage an installed J2EE enterprise application, enable the **Select** check box beside the application name in the list and click a button:

Button	Resulting action
Start	Attempts to run the application. After the application starts up successfully, the state of the application changes to *Started* if the application starts up on all deployment targets, else the state changes to *Partial Started*.
Stop	Attempts to stop the processing of the application. After the application stops successfully, the state of the application changes to *Stopped* if the application stops on all deployment targets, else the state changes to *Partial Stopped*.
Install	Opens a wizard that helps you deploy an application or a module such as a `.jar`, `.war` or `.rar` file onto a server or a cluster.
Uninstall	Deletes the application from the WebSphere Application Server configuration repository and deletes the application binaries from the file system of all nodes where the application modules are installed after the configuration is saved and synchronized with the nodes.
Update	Opens a wizard that helps you update application files deployed on a server. You can update the full application, a single module, a single file, or part of the application. If a new file or module has the same name as a file or module already existing on the server, the new file or module replaces the existing file or module. If the new file or module does not exist on the server, it is added to the deployed application.
Rollout Update	Sequentially updates an application installed on multiple cluster members across a cluster. After you update an application's files or configuration, click **Rollout Update** to install the application's updated files or configuration on all cluster members of a cluster on which the application is installed. **Rollout Update** does the following for each cluster member in sequence: 1. Saves the updated application configuration. 2. Stops all of the cluster members on one node. 3. Updates the application on the node by synchronizing the configuration. 4. Restarts the stopped cluster members. 5. Repeats steps 2 through 4 for all of the nodes that have cluster members. This action updates an application on multiple cluster members while providing continuous availability of the application.
Remove File	Deletes a file of the deployed application or module. **Remove File** deletes a file from the WebSphere Application Server configuration repository and from the file system of all nodes where the file is installed. If the application or module is deployed on a cluster, after removing a file click **Rollout Update** to roll out the changes across the entire cluster.
Export	Accesses the Export Application EAR files page, which you use to export an enterprise application to an EAR file at a location of your choice. Use the **Export** action to back up a deployed application and to preserve its binding information.
Export DDL	Accesses the Export Application DDL files page, which you use to export DDL files (`Table.ddl`) in the EJB modules of an enterprise application to a location of your choice.

Name

Specifies the name of the installed (or deployed) application. Application names must be unique within a cell and cannot contain characters that are not allowed in object names.

Status

Indicates whether the application deployed on the application server is started, stopped, or unavailable.

	**Started**	Application is running.
	**Partial Start**	Application is in the process of changing from a *Stopped* state to a *Started* state. Application is starting to run but is not fully running yet.
	**Stopped**	Application is not running.
	**Partial Stop**	Application is in the process of changing from a *Started* state to a *Stopped* state. Application has not stopped running yet.
	**Unavailable**	Status cannot be determined.
	**Not applicable**	Application does not provide information as to whether it is running.

Enterprise application settings

Use this page to configure an enterprise application.

To view this administrative console page, click **Applications** > **Enterprise Applications** >*application_name*.

Name

Specifies a logical name for the application. An application name must be unique within a cell and cannot contain an unallowed character.

An application name cannot begin with a period (**.**), cannot contain leading or trailing spaces, and cannot contain any of the following characters:

/	**forward slash**	**$**	**dollar sign**	**'**	**single quote mark**
****	backslash	**=**	equal sign	**"**	double quote mark
*****	asterisk	**%**	percent sign	**|**	vertical bar
,	comma	**+**	plus sign	**<**	left angle bracket
:	colon	**@**	at sign	**>**	right angle bracket
;	semi-colon	**#**	hash mark	**&**	ampersand (and sign)
?	question mark	**]]>**	No specific name exists for this character combination		

Data type String

Application binaries

Specifies the directory to which the application EAR file will be installed. The default value is the value of `APP_INSTALL_ROOT/`*`cell_name`*, where the `APP_INSTALL_ROOT` variable is *`install_root`*`/installedApps`; for example, `C:\WebSphere\AppServer\profiles\`*`profile _name`*`\installedApps\`*`cell_name`*.

You can specify an absolute path or use a pathmap variable such as `${MY_APPS}`. You can use a pathmap variable in any installation though it is particularly needed when installing an application on a cluster with members on heterogeneous nodes because, in such cases, there might not be a single way to specify an

absolute path. A WebSphere Application Server variable ${CELL} that denotes the current cell name can also be in the pathmap variable; for example, ${MY_APP}/${CELL}.

You can define WebSphere Application Server variables on the WebSphere Variables page of the administrative console, accessed by clicking **Environment > WebSphere Variables**.

Data type String
Units Full path name

Use metadata from binaries

Specifies whether the application server uses the binding, extensions, and deployment descriptors located with the application deployment document, the deployment.xml file (default), or those located in the enterprise application resource (EAR) file.

This **Use metadata from binaries** setting is the same as the **Use Binary Configuration** field on the application installation and update wizards. Select this setting for applications installed on 6.x deployment targets only. This setting is not valid for applications installed on 5.x deployment targets.

Data type Boolean
Default false

Enable distribution

Specifies whether WebSphere Application Server expands or deletes application binaries in the installation destination. The default is to enable application distribution. Application binaries for installed applications are expanded to the directory specified. The binaries are also deleted when you uninstall and save changes to the configuration. If you disable this option, then you must ensure that the application binaries are expanded appropriately in the destination directories of all nodes where the application runs.

Important: If you disable this option and you do not copy and expand the application binaries to the nodes, a later saving of the configuration or manual synchronization does not move the application binaries to the nodes for you.

This **Enable distribution** setting is the same as the **Distribute application** field on the application installation and update wizards.

Data type Boolean
Default true

Validation

Specifies whether WebSphere Application Server examines the application references specified during application installation or updating and, if validation is enabled, warns the users of incorrect references or fails the operation.

An application typically refers to resources using data sources for container managed persistence (CMP) beans or using resource references or resource environment references defined in deployment descriptors. The validation checks whether the resource referred to by the application is defined in the scope of the deployment target of that application.

The resource can be defined on the server, its node, cell or the cluster if the server belongs to a cluster. Select **off** for no resource validation, **warn** for warning messages about incorrect resource references, or **fail** to stop operations that fail as a result of incorrect resource references.

This **Validation** setting is the same as the **Validate Input off/warn/fail** field on the application installation and update wizards.

Data type	String
Default	warn

Class loader mode

Specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The standard for development kit class loaders and WebSphere Application Server class loaders is `Parent First`. By specifying `Parent Last`, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or LinkageErrors if you have mixed use of overridden classes and non-overridden classes.

The options are `Parent First` and `Parent Last`. The default is to search in the parent class loader before searching in the application class loader to load a class.

Data type	String
Default	Parent First

WAR class loader policy

Specifies whether to use a single class loader to load all WAR files of this application or to use a different class loader for each WAR file.

The options are `Application` and `Module`. The default is to use a separate class loader to load each WAR file.

Data type	String
Default	Module

Enable class reloading

Specifies whether to enable class reloading when application files are updated.

For EJB modules or any non-Web modules, selecting **Enable class reloading** sets reloadEnabled to `true` in the `deployment.xml` file for the application. If an application's class definition changes, the application server run time stops and starts the application to reload application classes.

For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is set to `true`. You can set reloadingEnabled to `true` when editing your Web module's extended deployment descriptors in an assembly tool.

To enable reloading of a Web module, where you also want reloading of EJB and non-Web modules enabled:
1. Set the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file to `true`.
2. Select this **Enable class reloading** property.
3. Set the **Reloading interval** property to a value greater than zero (for example, 1 to 2147483647).

To enable reloading of a Web module only, and not enable reloading of EJB or non-Web modules:
1. Set the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file to `true`.
2. Set the IBM extension reload interval attribute in the `ibm-web-ext.xmi` file to a value greater than zero (for example, 1 to 2147483647).
3. Do not select this **Enable class reloading** property.

To disable reloading of a Web module, set the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file to `false`. Or, if the Web module has the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file set to `true`, to disable reloading using the administrative console:
1. Select this **Enable class reloading** property.

2. Set the **Reloading interval** property to zero (0).

Data type	Boolean
Default	false

Reloading interval

Specifies the number of seconds to scan the application's file system for updated files. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-application-ext.xmi`) file of the EAR file.

This **Reloading interval** setting is the same as the **Reload interval in seconds** field on the application installation and update wizards.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). To disable reloading, specify zero (0).

The reloading interval specified here overrides the value specified in the IBM extensions for each non-Web module in the EAR file (which in turn overrides the reload interval specified in the IBM extensions for the application in the EAR file). The reloading interval attribute takes effect only if class reloading is enabled.

The range is from 0 to 2147483647.

Data type	Integer
Units	Seconds
Default	3

Starting weight

Specifies the order in which applications are started when the server starts. The application with the lowest starting weight is started first.

Data type	Integer
Default	1
Range	0 to 2147483647

Background application

Specifies whether the application must initialize fully before the server starts.

The default setting of `false` indicates that server startup will not complete until the application starts.

A setting of `true` informs WebSphere Application Server that the application might start on a background thread and thus server startup might continue without waiting for the application to start. Thus, the application might not be ready for use when the application server starts.

This setting applies only if the application is run on a Version 6 application server.

Data type	Boolean
Default	false

Create MBeans for resources

Specifies whether to create MBean files for various resources (such as servlets or JSP files) within an application when the application starts. The default is to create MBean files.

Data type	Boolean
Default	true

Configuring an application

You can change the configuration of an application or module deployed on a server.

You can change the contents of and deployment descriptors for an application or module before deployment, such as in an assembly tool. However, this article assumes that the module is already deployed on a server.

Changing an application or module configuration consists of one or more of the following:
- Changing the settings of the application or module.
- Removing a file from an application or module.
- Updating the application or its modules.

This article describes how to change the settings of an application or module using the administrative console.

- Change the settings of the application or module on the settings page for the enterprise application.
  1. Click **Applications > Enterprise Applications >***application_name* in the console navigation tree.
  2. Change the values for settings as needed. The settings page help provides detailed information on the settings and allowed values. When you installed the application or module, you specified most, if not all, of the settings values. After installation, the settings on this page that you are likely to change include the following:

Enable class reloading and **Reloading interval**	These settings control whether classes are reloaded when application files are updated. For enterprise bean (EJB) modules or any non-Web modules, enabling class reloading causes the application server run time to stop and start the application to reload application classes. For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is set to `true`. Refer to the settings page help for detailed information on enabling or disabling class reloading.
Starting weight	If your application starts automatically when its server starts, this value controls how quickly the application starts. **Starting weight** specifies the order in which applications are started when the server starts. The application with the lowest starting weight is started first.
Background application	If your application starts automatically when its server starts, **Background application** specifies whether the application must initialize fully before its server is considered started. Background applications can be initialized on an independent thread, thus allowing the server startup to complete without waiting for the application. This setting applies only if the application is run on a Version 6 (or later) application server.

  3. Click **OK**.
- Map each module of your application to a target server. Specify the application servers, clusters of application servers, or Web servers onto which to install modules of your application.
- Map a virtual host for each Web module of your application. ″Configuring virtual hosts″ provides information on virtual hosts.
- Change application bindings or other settings of the application or module.
  1. Click **Applications > Enterprise Applications >***application_name* **>** *property_or_item_name* in the console navigation tree. From the application settings page, you can access console pages for further configuring of the application or module.
     – Stateful session bean failover
     – Session management
     – Application profiles
     – Libraries or library references - See ″Library reference collection″
     – Target mappings

- Last participant support extension
- Deployment descriptors
- Publish WSDL files - See ″Publish WSDL zip files settings″
- Provide JMS and EJB endpoint URL information
- ″Provide HTTP endpoint URL information″
- Provide JNDI Names for Beans. For more information, refer to “Task overview: Using enterprise beans in applications” on page 169.
- Map resource references to resources
- Map EJB references to beans. For more information, refer to “Task overview: Using enterprise beans in applications” on page 169.
- Map data sources for all 2.x CMP beans
- Provide default data source mapping for modules containing 2.x entity beans. For more information, refer to “Creating and configuring a data source using the administrative console” on page 589.
- Map modules to servers
- Map virtual hosts for Web modules
- Web modules
- EJB modules
- Connector modules

2. Change the values for settings as needed, and click **OK**.

- **Optional:** Configure the application so it does not start automatically when the server starts. By default, an installed application starts when the server on which the application resides starts. You can configure the target mapping for the application so the application does not start automatically when the server starts. To start the application, you must then start it manually.
- If the installed application or module uses a resource adapter archive (RAR file), ensure that the **Classpath** setting for the RAR file enables the RAR file to find the classes and resources that it needs. Examine the **Classpath** setting on the console Resource adapter settings page.

The application or module configuration is changed. The application or standalone Web module is restarted so the changes take effect.

Save changes to your administrative configuration.

In the Network Deployment product, the application binaries are transferred to nodes when the configuration changes on the deployment manager synchronize with configurations for individual nodes on which the application will run.

If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Application bindings

Before an application that is installed on an application server can start, all enterprise bean (EJB) references and resource references defined in the application must be bound to the actual artifacts (enterprise beans or resources) defined in the application server.

When defining bindings, you specify Java Naming and Directory Interface (JNDI) names for the referenceable and referenced artifacts in an application. An example referenceable artifact is an EJB defined in an application. An example referenced artifact is an EJB or a resource reference used by the application. Binding definitions are stored in the `ibm-xxx-bnd.xmi` files of an application. The *xxx* can be `ejb-jar`, `web`, `application` or `application-client`.

Times when bindings can be defined

You can define bindings at the following times:

- During application development

  An application developer can create binding definitions in `ibm-xxx-bnd.xmi` files using a tool such as an IBM Rational developer tool. The developer then gives an enterprise application (`.ear` file) complete with bindings to a deployer. When assembling the application and then installing it onto a server supported by WebSphere Application Server, the deployer does not modify or override the bindings or generate default bindings unless changes to the bindings are necessary for successful deployment of the application.

- During application assembly

  An application assembler can define bindings when modifying deployment descriptors of an application. Bindings are specified in the **WebSphere Bindings** section of a deployment descriptor editor. Modifying the deployment descriptors might change the binding definitions in the `ibm-xxx-bnd.xmi` files created when assembling an application. After defining the bindings, the deployer can install the application onto a server supported by WebSphere Application Server without selecting to override the bindings or generate default bindings unless changes to the bindings are necessary for successful deployment of the application.

- During application installation

  An application deployer or server administrator can modify the bindings when installing the application onto a server supported by WebSphere Application Server using the administrative console. New binding definitions can be specified on the install wizard pages.

  If the deployer or administrator selects to override any existing bindings or to generate default bindings during application installation, default bindings are assigned to the application and new bindings might need to be specified using the console.

  Selecting **Generate Default Bindings** during application installation causes any incomplete bindings in the application to be filled in with default values. Existing bindings are not changed.

  Note: Bindings can be defined or overridden during application installation for all modules except application clients. For clients, you must define bindings for application client modules during assembly and store the bindings in the `ibm-application-client-bnd.xmi` file.

- During configuration of an installed application

  After an application is installed onto a server supported by WebSphere Application Server, an application deployer or server administrator can modify the bindings by changing values in administrative console pages such as those accessed from the settings page for the enterprise application.

Required bindings

Before an application can be successfully deployed, bindings must be defined for references to the following artifacts:

EJB JNDI names

For each enterprise bean (EJB), you must specify a JNDI name. The name is used to bind an entry in the global JNDI name space for the EJB home object. An example JNDI name for a *Product* EJB in a *Store* application might be `store/ejb/Product`. The binding definition is stored in the `META-INF/ibm-ejb-jar-bnd.xmi` file.

If a deployer chooses to generate default bindings when installing the application, the install wizard assigns EJB JNDI names having the form *prefix/EJB_name* to incomplete bindings. The default prefix is `ejb`, but can be overridden. The *EJB_name* is as specified in the deployment descriptor `<ejb-name>` tag.

During and after application installation, EJB JNDI names can be specified on the Provide JNDI Names for Beans panel. After installation, click **Applications > Enterprise Applications >***application_name* **> Provide JNDI Names for Beans** in the administrative console.

Data sources for entity beans

Entity beans such as container-managed persistence (CMP) beans store persistent data in data stores. See ″Developing enterprise beans″ and ″Developing data access applications″ in the information center. With CMP beans, an EJB container manages the persistent state of the beans. You specify which data store a bean uses by binding an EJB module or an individual EJB to a data source. Binding an EJB module to a data source causes all entity beans in that module to use the same data source for persistence.

An example JNDI name for a *Store* data source in a *Store* application might be `store/jdbc/store`. The binding definition is stored in IBM binding files such as `ibm-ejb-jar-bnd.xmi`. A deployer can also specify whether authentication is handled at the container or application level.

If a deployer chooses to generate default bindings when installing the application, the install wizard generates the following for incomplete bindings:

- For EJB 2.x `.jar` files, connection factory bindings based on the JNDI name and authorization information specified
- For EJB 1.1 `.jar` files, data source bindings based on the JNDI name, data source user name and password specified

The generated bindings provide default connection factory settings for each EJB 2.x `.jar` file and default data source settings for each EJB 1.1 `.jar` file in the application being installed. No bean-level connection factory bindings or data source bindings are generated.

During and after application installation, data sources can be mapped to 2.x entity beans on the Map data sources for all 2.x CMP beans panel and on the Provide default data source mapping for modules containing 2.x entity beans panel. After installation, click **Applications > Enterprise Applications >***application_name* in the administrative console, then select **Map data sources for all 2.x CMP beans** or **Provide default data source mapping for modules containing 2.x entity beans**. Data sources can be mapped to 1.x entity beans on the Map data sources for all 1.x CMP beans panel and on the Provide default data source mapping for modules containing 1.x entity beans panel. After installation, access console pages similar to those for 2.x CMP beans, except click links for 1.x CMP beans.

Backend ID for EJB modules

If an EJB `.jar` file that defines CMP beans contains mappings for multiple backend databases, specify the appropriate backend ID that determines which persister classes are loaded at run time.

Specify the backend ID during application installation. You cannot select a backend ID after the application is installed onto a server.

EJB references

An enterprise bean (EJB) reference is a logical name used to locate the home interface of an enterprise bean. EJB references are specified during deployment. At run time, EJB references are bound to the physical location (global JNDI name) of the enterprise beans in the target operational environment. EJB references are made available in the `java:comp/env/ejb` Java naming subcontext.

For each EJB reference, you must specify a JNDI name. An example JNDI name for a *Supplier* EJB reference in a *Store* application might be `store/ejb/Supplier`. The binding definition is stored in IBM binding files such as `ibm-ejb-jar-bnd.xmi`. When the referenced EJB is also deployed in the same application server, you can specify a server-scoped JNDI name. But if the referenced EJB is deployed on a different application server or if `ejb-ref` is defined in an application client module, then you should specify the global cell-scoped JNDI name.

If a deployer chooses to generate default bindings when installing the application, the install wizard binds EJB references as follows: If an `<ejb-link>` is found, it is honored. If the `ejb-name` of an EJB defined in the application matches the `ejb-ref` name, then that EJB is chosen. Otherwise, if a unique EJB is found with a matching home (or local home) interface as the referenced bean, the reference is resolved automatically.

During and after application installation, EJB reference JNDI names can be specified on the Map EJB references to beans panel. After installation, click **Applications > Enterprise Applications >***application_name* **> Map EJB references to beans** in the administrative console.

Resource references

A resource reference is a logical name used to locate an external resource for an application. Resource references are specified during deployment. At run time, the references are bound to the physical location (global JNDI name) of the resource in the target operational environment. Resource references are made available as follows:

Resource reference type	Subcontext declared in
Java DataBase Connectivity (JDBC) data source	`java:comp/env/jdbc`
JMS connection factory	`java:comp/env/jms`
JavaMail connection factory	`java:comp/env/mail`
Uniform Resource Locator (URL) connection factory	`java:comp/env/url`

For each resource reference, you must specify a JNDI name. If a deployer chooses to generate default bindings when installing the application, the install wizard generates resource reference bindings derived from the `<res-ref-name>` tag, assuming that the `java:comp/env` name is the same as the resource global JNDI name.

During application installation, resource reference JNDI names can be specified on the Map resource references to references panel. Specify JNDI names for the resources that represent the logical names defined in resource references. You can optionally specify login configuration name and authentication properties for the resource. After specifying authentication properties, click **OK** to save the values and return to the mapping step. Each resource reference defined in an application must be bound to a resource defined in your WebSphere Application Server configuration. After installation, click **Applications > Enterprise Applications >***application_name* **> Map resource references to resources** in the administrative console to access the Map resource references to resources panel.

Virtual host bindings for Web modules

You must bind each Web module to a specific virtual host. The binding informs a Web server plug-in that all requests that match the virtual host must be handled by the Web application. An example virtual host to be bound to a *Store* Web application might be `store_host`. The binding definition is stored in IBM binding files such as `WEB-INF/ibm-web-bnd.xmi`.

If a deployer chooses to generate default bindings when installing the application, the install wizard sets the virtual host to `default_host` for each `.war` file.

During and after application installation, you can map a virtual host to a Web module defined in your application. See ″How requests map to virtual host aliases″ in the information center. On the Map virtual hosts for Web modules panel, specify a virtual host. The port number specified in the virtual host definition is used in the URL that is used to access artifacts such as servlets and JSP files in the Web module. For example, an external URL for a Web artifact such as a JSP file is `http://`*`host_name`*`:`*`virtual_host_port`*`/`*`context_root`*`/`*`jsp_path`*. After installation, click **Applications > Enterprise Applications >***application_name* **> Map virtual hosts for Web modules** in the administrative console.

Message-driven beans

For each message-driven bean, you must specify a queue or topic to which the bean will listen. A message-driven bean is invoked by a Java Messaging Service (JMS) listener when a message arrives on the input queue that the listener is monitoring. A deployer specifies a listener port or JNDI name of an activation spec as defined in a connector module (`.rar` file) under **WebSphere Bindings** on the **Beans** page of an assembly tool EJB deployment descriptor editor. See ″Developing an enterprise application to use message-driven beans″ for additional information. An

example JNDI name for a listener port to be used by a `Store` application might be `StoreMdbListener`. The binding definition is stored in IBM bindings files such as `ibm-ejb-jar-bnd.xmi`.

If a deployer chooses to generate default bindings when installing the application, the install wizard assigns JNDI names to incomplete bindings.

- For EJB 2.x message-driven beans deployed as JCA 1.5-compliant resources, the install wizard assigns JNDI names corresponding to activationSpec instances in the form `eis/MDB_ejb-name`.
- For EJB 2.x message-driven beans deployed against listener ports, the listener ports are derived from the message-driven bean `<ejb-name>` tag with the string `Port` appended.

During application installation using the administrative console, you can specify a listener port name or an activation specification JNDI name for every message-driven bean on the panel **Provide Listener Ports or activation specification JNDI name for messaging beans**. A listener port name must be provided when using the JMS providers: Version 5 default messaging, WebSphere MQ, or generic. An activation specification must be provided when the application's resources are configured using the default messaging provider or any generic J2C resource adapter that supports inbound messaging. If neither is specified, then a validation error is displayed after you click **Finish** on the Summary panel. Also, if the module containing the message-driven bean is deployed on a 5.x deployment target and a listener port is not specified, then a validation error is displayed after you click **Next**.

After application installation, you can specify JNDI names and configure message-driven beans on console pages under **Resources > JMS Providers** or under **Resources > Resource Adapters**. For more information, refer to "Using asynchronous messaging" on page 643.

Message destination references

A message destination reference is a logical name used to locate an enterprise bean in an EJB module that acts as a message destination. Message destination references exist only in J2EE 1.4 artifacts such as--

- J2EE 1.4 application clients
- EJB 2.1 projects
- 2.4 Web applications

If multiple message destination references are associated with a single message destination link, then a single JNDI name for an enterprise bean that maps to the message destination link, and in turn to all of the linked message destination references, is collected during deployment. At run time, the message destination references are bound to the administered message destinations in the target operational environment.

If a deployer chooses to generate default bindings when installing the application, the install wizard assigns JNDI names to incomplete message destination references as follows: If a message destination reference has a `<message-destination-link>`, then the JNDI name is set to `ejs/message-destination-linkName`. Otherwise, the JNDI name is set to `eis/message-destination-refName`.

Other bindings that might be needed

Depending on the references in and artifacts used by your application, you might need to define bindings for references and artifacts not listed in this article.

Mapping modules to servers

Each module of a deployed application must be mapped to one or more target servers. The target server can be an application server, cluster of application servers or Web server.

You can map modules of an application or standalone Web module to one or more target servers during or after application installation using the console. This article assumes that the module is already installed on a server and that you want to change the mappings.

Before you change a mapping, check the deployment targets. You must specify an appropriate deployment target for a module. Modules that use Version 6.x features cannot be installed onto a Version 5.x target server.

During application installation, different deployment targets might have been specified.

You use the Map modules to servers panel of the administrative console to view and change mappings. This panel is displayed during application installation using the console and, after the application is installed, can be accessed from the settings page for an enterprise application.

On the Map modules to servers panel, specify target servers where you want to install the modules contained in your application. Modules can be installed on the same application server or dispersed among several application servers. Also, specify the Web servers as targets that will serve as routers for requests to your application. The plug-in configuration file `plugin-cfg.xml` for each Web server is generated based on the applications which are routed through it.

1. Click **Applications > Enterprise Applications >***application_name* **> Map modules to servers** in the console navigation tree. The Selecting servers - Map modules to servers panel is displayed.
2. Examine the list of mappings. Ensure that each **Module** entry is mapped to the desired target(s), identified under **Server**.
3. Change a mapping as needed.
   a. Select each module that you want mapped to the same target(s). In the list of mappings, place a check mark in the **Select** check boxes beside the modules.
   b. From the **Clusters and Servers** drop-down list, select one or more targets. Use the **Ctrl** key to select multiple targets. For example, to have a Web server serve your application, use the **Ctrl** key to select an application server or cluster and the Web server together in order to have the plug-in configuration file `plugin-cfg.xml` for that Web server generated based on the applications which are routed through it.
   c. Click **Apply**.
4. Repeat steps 2 and 3 until each module maps to the desired target(s).
5. Click **OK**.

The application or module configurations are changed. The application or standalone Web module is restarted so the changes take effect.

Save changes to your administrative configuration.

In the Network Deployment product, the application binaries are transferred to nodes when the configuration changes on the deployment manager synchronize with configurations for individual nodes on which the application will run.

If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Selecting servers - Map modules to servers settings

Use this panel to specify deployment targets where you want to install the modules contained in your application. Modules can be installed on the same deployment target or dispersed among several deployment targets. Each module must be mapped to a target server. A deployment target can be an application server, cluster of application servers or Web server.

To view this administrative console panel, click **Applications > Enterprise Applications >***application_name* **> Map modules to servers**. This panel is the same as the **Map modules to servers** panel on the application installation and update wizards.

On this panel, each **Module** must map to one or more desired targets, identified under **Server**. To change a mapping:

1. In the list of mappings, select the **Select** check box beside each module that you want mapped to the same target(s).
2. From the **Clusters and Servers** drop-down list, select one or more targets. Select only appropriate deployment targets for a module. Modules that use WebSphere Application Server Version 6.x features cannot be installed onto a Version 5.x target server.

   Use the Ctrl key to select multiple targets. For example, to have a Web server serve your application, press the Ctrl key and then select an application server or cluster and the Web server together. The plug-in configuration file `plugin-cfg.xml` for that Web server will be generated based on the applications which are routed through it.
3. Click **Apply**.

Clusters and Servers:

Lists the names of available target servers and clusters. This list is the same for every application that is installed in the cell.

From this list, select only appropriate deployment targets for a module. You can install an application, enterprise bean (EJB) module or Web module developed for a Version 5.x product on a 5.x or 6.x deployment target, provided the module--

- Does not support Java 2 Platform, Enterprise Edition (J2EE) 1.4;
- Does not call any 6.x runtime application programming interfaces (APIs); and
- Does not use any 6.x product features.

If the module supports J2EE 1.4, calls a 6.x API or uses a 6.x feature, then you must install the module on a 6.x deployment target.

Module:

Specifies the name of a module in the installed (or deployed) application that you selected on the Enterprise Applications page.

URI:

Specifies the location of the module archive contents on a file system. The location is relative to the application URL. The URI must match the URI of a ModuleRef URI in the deployment descriptor of the deployed application (`.ear` file).

Server:

Specifies the name of each server or cluster to which the module currently is mapped--that is, the deployment targets.

To change the deployment targets for a module, select one or more targets from the **Clusters and Servers** drop-down list and click **Apply**. The new mapping replaces the previous mapping.

Mapping virtual hosts for Web modules

A virtual host must be mapped to each Web module of a deployed application. Web modules can be installed on the same virtual host or dispersed among several virtual hosts.

You can map a virtual host to a Web module during or after application installation using the console. This article assumes that the Web module is already installed on a server and that you want to change the mappings.

Before you change a mapping, check the virtual hosts definitions. You can install a Web module on any defined virtual host. To view information on previously defined virtual hosts, click **Environment > Virtual Hosts** in the administrative console. Virtual hosts enable you to associate a unique port with a module or application. The aliases of a virtual host identify the port numbers defined for that virtual host. A port number specified in a virtual host alias is used in the URL that is used to access artifacts such as servlets and JavaServer Pages (JSP) files in a Web module. For example, the alias `myhost:8080` is the `host_name:port_number` portion of the URL `http://myhost:8080/servlet/snoop`.

During application installation, a virtual host other than the one you want mapped to your Web module might have been specified.

The default virtual host setting usually is `default_host`, which provides several port numbers through its aliases:
80 An internal, insecure port used when no port number is specified
9080 An internal port
9443 An external, secure port

Unless you want to isolate your Web module from other modules or resources on the same node (physical machine), `default_host` is a suitable virtual host for your Web module.

In addition to `default_host`, WebSphere Application Server provides `admin_host`, which is the virtual host for the administrative console system application. `admin_host` is on port 9060. Its secure port is 9043.

Use the Map virtual hosts for Web modules panel of the administrative console to view and change mappings. This panel is displayed during application installation using the console and, after the application is installed, can be accessed from the settings page for an enterprise application.

On the Map virtual hosts for Web modules panel, specify a virtual host for each Web module. Web modules of an application can be installed on the same virtual host or on different virtual hosts.

1. Click **Applications > Enterprise Applications >***application_name* **> Map virtual hosts for Web modules** in the console navigation tree. The Selecting virtual hosts for Web modules - Map virtual hosts for Web modules panel is displayed.
2. Examine the list of mappings. Ensure that each **Web module** entry has the desired virtual host mapped to it, identified under **Virtual host**.
3. Change the mappings as needed.
   a. Select each Web module that you want mapped to a particular virtual host. In the list of mappings, place a check mark in the **Select** check boxes beside the Web modules.
   b. From the **Virtual host** drop-down list, select the desired virtual host. If you selected more than one virtual host in step 1:
      1) Expand **Apply Multiple Mappings**.
      2) Select the desired virtual host from the **Virtual Host** drop-down list.
      3) Click **Apply**.
4. Repeat steps 2 and 3 until a desired virtual host is mapped to each Web module.
5. Click **OK**.

The application or Web module configurations are changed. The application or standalone Web module is restarted so the changes take effect.

Save changes to your administrative configuration.

In the Network Deployment product, the application binaries are transferred to nodes when the configuration changes on the deployment manager synchronize with configurations for individual nodes on which the application will run.

If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Selecting virtual hosts - Map virtual hosts for Web modules settings

Use this panel to specify virtual hosts for Web modules contained in your application. Web modules can be installed on the same virtual host or dispersed among several virtual hosts.

To view this administrative console panel, click **Applications > Enterprise Applications >***application_name* **> Map virtual hosts for Web modules**. This panel is the same as the **Map virtual hosts for Web modules** panel on the application installation and update wizards.

On this panel, each Web module must map to a previously defined virtual host, identified under **Virtual host**. You can see information on previously defined virtual hosts by clicking **Environment > Virtual Hosts** in the administrative console. Virtual hosts enable you to associate a unique port with a module or application. The aliases of a virtual host identify the port numbers defined for that virtual host. A port number specified in a virtual host alias is used in the URL that is used to access artifacts such as servlets and JavaServer Pages (JSP) files in a Web module. For example, the alias `myhost:8080` is the `host_name:port_number` portion of the URL `http://myhost:8080/servlet/snoop`.

The default virtual host setting usually is `default_host`, which provides several port numbers through its aliases:

80 An internal, insecure port used when no port number is specified
9080 An internal port
9443 An external, secure port

Unless you want to isolate your Web module from other modules or resources on the same node (physical machine), `default_host` is a suitable virtual host for your Web module.

In addition to `default_host`, WebSphere Application Server provides `admin_host`, which is the virtual host for the administrative console system application. `admin_host` is on port 9060. Its secure port is 9043.

To change a mapping:

1. In the list of mappings, select the **Select** check box beside each Web module that you want mapped to a particular virtual host.
2. From the **Virtual host** drop-down list, select the desired virtual host. If you selected more than one virtual host in step 1:
   a. Expand **Apply Multiple Mappings**.
   b. Select the desired virtual host from the **Virtual Host** drop-down list.
   c. Click **Apply**.
3. Click **OK**.

Web module:

Specifies the name of a Web module in the installed (or deployed) application that you selected on the Enterprise Applications page.

Virtual host:

Specifies the name of the virtual host to which the Web module currently is mapped.

Expanding the drop-down list displays a list of previously defined virtual hosts. To change a mapping, select a different virtual host from the list.

Starting and stopping applications

You can start an application that is not running (has a status of *Stopped*) or stop an application that is running (has a status of *Started*).

This article assumes that the application is installed on a server. By default, the application starts automatically when the server starts.

You can start and stop applications manually using the following:
- Administrative console
- wsadmin startApplication and stopApplication commands - See ″Stopping applications with scripting″ in the information center.
- Java programs that use ApplicationManager or AppManagement MBeans

This article describes how to use the administrative console to start or stop an application.

1. Go to the Enterprise Applications page. Click **Applications > Enterprise Applications** in the console navigation tree.
2. Select the check box for the application you want started or stopped.
3. Click a button:

Option	Description
Start	Runs the application and changes the state of the application to *Started*. The status is changed to *partially started* if not all servers on which the application is deployed are running.
Stop	Stops the processing of the application and changes the state of the application to *Stopped*.

   To restart a running application, select the application you want to restart, click **Stop** and then click **Start**.

The status of the application changes and a message stating that the application started or stopped displays at the top the page.

You can configure an application so it does not start automatically when the server on which it resides starts. You then start the application manually using options described in this article.

If you want your application to start automatically when its server starts, you can adjust values that control how quickly the application or its server starts:

1. Go the settings page for your enterprise application. Click **Applications > Enterprise Applications >***application_name*.
2. Specify a different value for **Starting weight**.

   This setting specifies the order in which applications are started when the server starts. The default value is `1` in a range from 0 to 2147483647. The application with the lowest starting weight is started first.
3. Specify a different value for **Background application**.

   This setting specifies whether the application must initialize fully before its server starts. The default value of `false` prevents the server from starting completely until the application starts. To reduce the amount of time it takes to start the server, you can set the value to `true` and have the application start on a background thread, thus allowing server startup to continue without waiting for the application
4. Save the changes to the application configuration.

5. If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Disabling automatic starting of applications

By default, an installed application starts automatically when the server on which the application resides starts. You can disable the automatic starting of the application, and later enable the automatic starting again.

This article assumes that the enterprise application is installed on an application server and that the application starts automatically when the server starts.

You might want an application to run only after you start it manually and not to run every time after the server starts. The target mapping for an application controls whether an application starts automatically when the server starts or requires you to start the application manually.

1. Go to the Target Mapping settings page for your application. Click **Applications > Enterprise Applications >***application_name* **> Target Mappings >***target_name*. The *target_name* is the server on which the application resides. You use the Target Mapping settings page to map an installed application or module to a server or cluster.
2. Clear the **Enabled** check box.
3. Click **OK**.
4. Save changes to the administrative configuration.

The application does not start when its server starts. You must start the application manually.

To enable automatic starting of the application, select the **Enabled** check box on the Target Mappings settings page for the application, click **OK**, and then save changes to the configuration.

Target mapping collection

Use this page to view mappings of deployed applications or modules to servers or clusters.

To view this administrative console page, click **Applications > Enterprise Applications >***application_name* **> Target Mappings**.

Target

States the name of the target server or cluster to which the application or module maps. You specify the target on the Map modules to servers page accessed from the settings for an application.

Node

Specifies the node name if the target is a server.

Version

Specifies the version level of the target. The target can be a 5.x deployment target or a 6.x deployment target.

A *5.x deployment target* is a server or a cluster with at least one member on a WebSphere Application Server Version 5 product.

A *6.x deployment target* is a server or cluster with all members on a WebSphere Application Server Version 6 product.

An application, enterprise bean (EJB) module, Web module or application client module developed for a WebSphere Application Server Version 5.x product can reside on a 5.x or 6.x deployment target, provided the module--
- Does not support Java 2 Platform, Enterprise Edition (J2EE) 1.4;
- Does not call any 6.x run-time application programming interfaces (APIs); and
- Does not use any 6.x product features.

Similarly, a resource adapter (connector) module, or RAR file, developed for a Version 5.x product can reside on a 5.x or 6.x node, provided the module does not support Java Cryptography Architecture (JCA) 1.5 and does not call any 6.x run-time application programming interfaces (APIs). If the module supports JCA 1.5 or calls a 6.x API, then the module must reside on a 6.x node.

Status
Indicates whether the status of the target server or cluster is started, stopped or unavailable.

Target mapping settings
Use this page to map a deployed application or module to a server or cluster.

To view this administrative console page, click **Applications** > **Enterprise Applications** >*application_name* > **Target Mappings** >*target_name*.

Target:

States the name of the target server or cluster to which the application or module maps. You specify the target on the Map modules to servers page accessed from the settings for an application.

Data type String

Enabled:

Indicates whether the application modules installed on the target server are started (or enabled) when the server starts. This sets the initial state of application modules. A `true` value indicates that the corresponding modules are enabled and thus are accessible when the server starts. A `false` value indicates that the corresponding modules are not enabled and thus are not accessible when the server starts.

Data type Boolean
Default true

Exporting applications
You can export an enterprise application to a location of your choice.

Exporting applications enables you to back up your applications and preserve binding information for the applications. You might export your applications before updating installed applications or migrating to a later version of the WebSphere Application Server product.

1. Click **Applications** > **Enterprise Applications** in the console navigation tree to access the Enterprise Applications page.
2. Select the check box beside the application and click **Export**.
3. On the Export Application EAR Files page, click on the link to download the exported EAR file.
4. Use the browser dialogue to specify a location at which to save the exported EAR file.
5. Click **Back** to return to the Enterprise Applications page.

The file containing binding information is exported to the specified node and directory, and has the name *enterprise_application_name*.ear.

Exporting DDL files

You can export data definition language (DDL) files in the enterprise bean (EJB) modules of an application.

Exporting DDL (`Table.ddl`) files in the EJB modules of an application downloads the DDL files to a location of your choice.

1. Click **Applications > Enterprise Applications** in the administrative console navigation tree to access the Enterprise Applications page.
2. Place a check mark in the check box beside the application and click **Export DDL**. If the application has no DDL files in any of its EJB modules, then the message *No DDL files were found* is displayed at the top of the page. If the application has DDL files in its EJB modules, then a page listing DDL files in the format *application_name.ear/_module*.jar_Table.ddl is displayed.
3. Click on a file in the list and specify the location to which to download the file.

   Tip: Mozilla browsers might display the contents of the `Table.ddl` file instead of saving the file to disk. To save the file, edit the **Helper Application** preference settings of the Mozilla browser by adding a new type for DDL and specifying that you want to save DDL files to disk. That is, set `MIME type = ddl` and `Extension = ddl`.

The DDL file is downloaded to the specified location.

Updating applications

You can update application files deployed on a server.

Refer to “Ways to update application files” on page 76 and decide how to update your application files. You can update enterprise applications or modules using the administrative console or a wsadmin tool. Both ways provide identical updating capabilities. Further, in some situations, you can update applications or modules without restarting the application server.

Note that Version 6 supports Java 2 Platform, Enterprise Edition (J2EE) 1.4 enterprise applications and modules. If you are deploying J2EE 1.4 modules, ensure that the target server and its node support Version 6. The administrative console Server collection″ pages show the versions for servers and cluster members. You can deploy J2EE 1.4 modules to Version 6.x servers or to clusters that contain Version 6.x cluster members only. You cannot deploy J2EE 1.4 modules to servers on Version 5.x nodes or to clusters that contain Version 5.x cluster members. Refer to “Installable module versions” on page 39 for details.

This article describes how to update deployed applications or modules using the administrative console.

Updating consists of adding a new file or module to an installed application, or replacing or removing an installed application, file or module. After replacement of a full application, the old application is uninstalled. After replacement of a module, file or partial application, the old installed module, file or partial application is removed from the installed application.

1. Update your application or modules and reassemble them using an assembly tool. Typical tasks include adding or editing assembly properties, adding or importing modules into an application, and adding enterprise beans, Web components, and files.
2. Back up the installed application.
   a. Go to the ″Enterprise applications collection″ page of the administrative console. Click **Applications > Enterprise Applications** in the console navigation tree.

b. Export the application to an EAR file. Select the application you want uninstalled and click **Export**. Exporting the application preserves the binding information.

3. With the application selected on the Enterprise Applications page, click **Update**. The Preparing for application update page is displayed.
4. Under **Specify the EAR, WAR or JAR module to upload and install**:
   a. Ensure that **Application name** refers to the application to be updated.
   b. Under **Update options**, select the installed application, module, or file that you want to update. The online help Preparing for application update settings provides detailed information on the options. Briefly, the options are as follows:

      Full application

      Replaces the installed (old) application with the updated (new) application on the server. If you select **Full application**, specify the path for the new `.ear` file. The path provides the location of the new `.ear` file before installation.

      Single module

      Adds a new module to, or replaces a module in, the installed application. Specify the path for the new Web module (`.war`), EJB module (`.jar`), or resource adapter module (`.rar`). The path provides the location of the new module before installation.

      To replace a module, the value for **Relative path to module** (or module URI) must match the path of the module to be updated in the installed application.

      To add a new module to the installed application, the value for **Relative path to module** must *not* match the path of a module in the installed application. The value specifies the desired path for the new module.

      If you are installing a standalone Web module, specify a value for **Context root**.

      Single file

      Adds a new file to, or replaces a file in, the installed application. Specify the path for the new file. The path provides the location of the new file before installation.

      To replace a file, the value for **Relative path to file** must match the path of the file to be updated in the installed application.

      To add a new file to the installed application, the value for **Relative path to file** must *not* match the path of a file in the installed application. The value specifies the desired path for the new file.

      The relative path to a file from the root of the application is the concatenation of the module path and the file path within the module. For example, if the file is `com/mycompany/abc.class` within the module `foo.jar`, then the relative file path is `foo.jar/com/mycompany/abc.class`.

      Partial application

      Updates multiple files of an installed application by uploading a compressed file. Depending on the contents of the compressed file, a single use of this option can replace files in, add new files to, and delete files from the installed application. Each entry in the compressed file is treated as a single file and the path of the file from the root of the compressed file is treated as the relative path of the file in the installed application.

      Specify a valid compressed file format such as `.zip` or `.gzip`. The path provides the location of the compressed file before installation. This option unzips the compressed file into the installed application directory.

      To replace a file, a file in the compressed file must have the same relative path as the file to be updated in the installed application.

      To add a new file to the installed application, a file in the compressed file must have a different relative path than the files in the installed application.

      To remove a file from the installed application, specify metadata in the compressed file using a file named `META-INF/ibm-partialapp-delete.props` at any archive scope. The

ibm-partialapp-delete.props file must be an ASCII file that lists files to be deleted in that archive with one entry for each line. The entry can contain a string pattern such as a regular expression that identifies multiple files. The file paths for the files to be deleted must be relative to the archive path that has the META-INF/ibm-partialapp-delete.props file. Refer to Preparing for application update settings for more information.

After you select an option, specify a path. Use **Local file system** if the browser and application files are on the same machine (whether or not the server is on that machine, too). Use **Remote file system** if the application file resides on any node in the current cell context. You can browse the entire file system of a node if the node agent or deployment manager is running on that selected node. Only .ear, .jar, or .war files are shown during the browsing.

During application updating, application files typically are uploaded from a client machine running the browser to the server machine running the administrative console, where they are deployed. In such cases, use the Web browser running the administrative console to select EAR, WAR, or JAR modules to upload to the server machine.

In some cases, however, the application files reside on the file system of any of the nodes in a cell. To have the application server install these files, use the **Remote file system** option.

Also use the **Remote file system** option to specify an application file already residing on the machine running the application server. For example, the field value on a Windows machine might be C:\WebSphere\AppServer\installableApps\test.ear. If you are installing a standalone WAR module, then specify the context root as well.

After the application file is transferred, the **Remote file system** value shows the path of the temporary location on the deployment manager orserver machine.

5. If you selected the **Full application** or **Single module** option:
   a. Click **Next** to display a wizard for updating application files.
   b. Complete the steps in the update wizard. This update wizard, which is similar to the installation wizard, provides fields for specifying or editing application binding information. Refer to information on installing applications and on the settings page for application installation for guidance. Note that the installation steps have the merged binding information from the new version and the old version. If the new version has bindings for application artifacts such as EJB JNDI names, EJB references or resource references, then those bindings will be part of the merged binding information. If new bindings are not present, then bindings are taken from the installed (old) version. If bindings are not present in the old version and if the default binding generation option is enabled, then the default bindings will be part of the merged binding information. You can select whether to ignore bindings in the old version or ones in the new version.
6. Click **Finish**.
7. If you did not use the Map modules to servers page of the update wizard, after updating the application, map the installed application or module to servers or clusters. Use the Map modules to servers page accessed from the Enterprise Applications page.
   a. Go to the Map modules to servers page. Click **Applications > Enterprise Applications >***application_name* **> Map modules to servers**.
   b. Specify the application server where you want to install modules contained in your application and click **OK**. You can deploy J2EE 1.4 modules to servers on Version 6.x nodes or to clusters that contain cluster members on Version 6.x nodes only.

After the application file or module installs successfully, do the following:

1. Save the changes to your configuration.

   In the Network Deployment product, after you click **Save** the old application files are deleted and new files are copied when the configuration on the deployment manager synchronizes with the configuration on the node where the application is installed.

If the application is running when you update it, the application stops running before its files are copied to the destination directory of the node and restarts after the copy operation completes. Thus, the application is unavailable on the node during the time the node is synchronizing its configuration with the deployment manager.

2. Examine the values specified for **Reload Enabled** and **Reload Interval** on the settings page for your enterprise application.

   If reloading of application files is enabled and the reload interval is greater than zero (0), the application's files are reloaded after the application is updated. For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is also set to `true`. You can set reloadingEnabled to `true` when editing your Web module's extended deployment descriptors in an assembly tool.

3. If needed, restart the application manually so the changes take effect.

   If the application is updated while it is running, WebSphere Application Server automatically stops the application or only its changed components, updates the application logic, and restarts the stopped application or its components.

4. If the application you are updating is deployed on a server that has its application class loader policy set to `Single`, restart the server. See ″Application server settings″ in the information center.

5. If a changed application or module is deployed on a cluster, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Ways to update application files

You can update application files deployed on a server or cluster in several ways.

Table 4. Ways to update application files

Option	Method	Comments	Starting after update
Administrative console update wizard See "Updating applications" on page 73.	Briefly, do the following: 1. Go to the Enterprise Applications page. Click **Applications > Enterprise Applications** in the console navigation tree. 2. Select the application to update and click **Update**. 3. On the Preparing for application update page, identify the application, module or files to update and click **Next**. 4. Complete steps in the update wizard and click **Finish**.	On the Preparing for application update page: • Use **Full application** to update an `.ear` file. • Use **Single module** to update a `.war`, enterprise bean `.jar`, or connector `.rar` file. • Use **Single file** to update a file other than an `.ear`, `.war`, EJB `.jar`, or `.rar` file. • Use **Partial application** to update or remove multiple files.	On the Enterprise Applications page, select the updated application and click **Start**.
wsadmin scripts	Invoke AdminApp object *install* commands with the *-update* option in a script or at a command prompt.	Getting started with scripting provides an overview of wsadmin.	Invoke the wsadmin *startApplication* command.

Table 4. Ways to update application files (continued)

Java application programming interfaces See Using administrative programs (JMX).	Update deployed applications by completing the steps in Managing applications through programming.	Update an application in the following ways: • Update the entire application • Add to, update or delete multiple files in an application • Add a module to an application • Update a module in an application • Delete a module in an application • Add a file to an application • Update a file in an application • Delete a file in an application	Start the application by either of the following methods: • On the Enterprise Applications page, select the updated application and click **Start**. • Invoke the wsadmin *startApplication* command.
WebSphere rapid deployment Refer to articles under **Rapid deployment of J2EE applications** in this information center.	Briefly, do the following: 1. Update your J2EE application files. 2. Set up the rapid deployment environment. 3. Create a free-form project. 4. Launch a rapid deployment session. 5. Drop your updated application files into the free-form project.	WebSphere rapid deployment offers the following advantages: • You do not need to assemble your J2EE application files prior to deployment. • You do not need to use other installation tools mentioned in this table to deploy the files.	Use any of the above options to start the application. Clicking **Start** on the Enterprise Applications page is the easiest option.
Hot deployment and dynamic reloading	Briefly, do the following: 1. Update your application (`.ear`), Web module (`.war`), enterprise bean `.jar` or HTTP plug-in configuration file. 2. Follow instructions in Hot deployment and dynamic reloading to update your file.	If you are new to WebSphere Application Server, use the administrative console to update applications. That option is easier. Hot deployment and dynamic reloading is more difficult to complete. You must directly manipulate the application or module file on the server where the application is deployed.	Use any of the above options to start the application. Clicking **Start** on the Enterprise Applications page is the easiest option.

You can update `.ear`, enterprise bean `.jar`, Web module `.war`, connector `.rar`, application client `.jar`, and any other files used by an installed application.

If the application is updated while it is running, WebSphere Application Server automatically stops the application, updates the application logic and restarts the application. If the application does not start automatically, start it manually using one of the **Starting** options.

Preparing for application update settings

Use this page to update enterprise applications, modules or files already installed on a server.

To view this administrative console page, do the following:
1. Click **Applications > Enterprise Applications**.
2. Select the installed application or module that you want to update.
3. Click **Update**.

Clicking **Update** displays a page that helps you update application files deployed in the cell. You can update the full application, a single module, a single file, or part of the application. If a new file or module

has the same relative path as a file or module already existing on the server, the new file or module replaces the existing file or module. If the new file or module does not exist on the server, it is added to the deployed application.

Application name

Specifies the name of the installed (or deployed) application that you selected on the Enterprise Applications page.

Full application

Under **Update options**, specifies to replace the application already installed on the server with a new (updated) enterprise application `.ear` file.

After selecting this option, specify whether the `.ear` file is on a local or remote file system and the full path name of the application. The path provides the location of the updated `.ear` file before installation.

Use **Local file system** if the browser and the updated files or modules are on the same machine, whether or not the server is on that machine too. **Local file system** is available for all update options.

Use **Remote file system** if the application file resides on any node in the current cell context.You can browse the entire file system of a node if the node agent or deployment manager is running on that selected node. Only `.ear`, `.jar`, or `.war` files are shown during the browsing. Also use the **Remote file system** option to specify an application file already residing on the machine running the application server. For example, the field value on a Windows machine might be `C:\WebSphere\AppServer\installableApps\test.ear`.

Note: During application installation, application files typically are uploaded from a client machine running the browser to the server machine running the administrative console, where they are deployed. In such cases, use the Web browser running the administrative console to select `.ear`, `.war`, or `.jar` modules to upload to the server machine. In some cases, however, the application files reside on the file system of any of the nodes in a cell. To have the application server install these files, use the **Remote file system** option.

After specifying the required information on the `.ear` file, click **Next** to display a wizard for updating application files. The update wizard, which is similar to the installation wizard, provides fields for specifying or editing application binding information. Complete the steps in the update wizard as needed.

When the full application is updated, the old application is uninstalled and the new application is installed. When the configuration changes are saved and subsequently synchronized, the application files are expanded on the node where application will run. If the application is running on the node while it is updated, then the application is stopped, application files are updated, and application is started.

Single module

Under **Update options**, specifies to replace a module in or add a module to an installed application. The module can be a Web module (`.war` file), enterprise bean module (EJB `.jar` file), or resource adapter module (connector `.rar` file).

After selecting this option, specify whether the module is on a local or remote file system and the full path name of the module. The path provides the location of the updated module before installation. For information on **Local file system** and **Remote file system**, refer to the description of **Full application** above.

To replace a module, the value for **Relative path to module** (module URI) must match the path of the module to be updated in the installed application.

To add a new module to the installed application, the value for **Relative path to module** must *not* match the path of a module in the installed application. The value specifies the desired path for the new module.

If you are installing a standalone Web module, specify a value for **Context root**. The context root is combined with the defined servlet mapping (from the `.war` file) to compose the full URL that users type to access the servlet. For example, if the context root is `/gettingstarted` and the servlet mapping is `MySession`, then the URL is `http://host:port/gettingstarted/MySession`.

After specifying the required information on the module, click **Next** to display a wizard for updating application files. The update wizard, which is similar to the installation wizard, provides fields for specifying or editing module binding information. Complete the steps in the update wizard as needed.

After a single module is added or updated, when configuration changes are saved, the new or updated module is stored in the deployed application in the WebSphere Application Server configuration repository. When these changes are synchronized with the node, the module is added or updated to the node's file system. If the application is running on the node when the module is added or updated, then one of the following occurs:

- For updates to a Web module, the running Web module is stopped, Web module files are updated, and then the Web module is started.
- For module additions, the added module is started on the application servers where the application is running after it is expanded on the node. An application restart is not necessary.
- If the class loader policy for the application is set to `Single` so that all modules share a class loader, then the entire application is stopped and restarted for module level changes.
- If the security provider configured with WebSphere Application Server does not support dynamic updates, then the entire application is stopped and restarted for module level changes.
- For all other updates to a module, the entire application is stopped, the module files are updated, then the entire application is started.

Single file

Under **Update options**, specifies to replace a file in or add a file to an installed application.

Use this option to update a file used by the application that is not an `.ear`, `.war`, `.rar` or, in some instances, a `.jar` file. You can use this option to add or update .jar files that are not defined as modules in the application. To update an `.ear`, file use the **Full application** option. To update a `.war` file, `.rar` file , or `.jar` file that is defined as a module in the application, use the **Single module** option.

After selecting this option, specify whether the file is on a local or remote file system and the full path name of the file. The path provides the location of the updated file before installation. For information on **Local file system** and **Remote file system**, refer to the description of **Full application** above.

Next, specify a value for **Relative path to file**. The relative path of the file must start from the root of the `.ear` file. For example, if the file is located at `com/company/greeting.class` in module `hello.jar`, specify a relative path of `hello.jar/com/company/greeting.class`.

To replace a file, the value for **Relative path to file** must match the path of the file to be updated in the installed application.

To add a new file to the installed application, the value for **Relative path to file** must *not* match the path of a file in the installed application. The value specifies the desired path for the new file.

After a single file is added or updated, when configuration changes are saved, the new or updated file is stored in the deployed application in the WebSphere Application Server configuration repository. When these changes are synchronized with the node, the file is added or updated to the node's file system. If the application is running on the node when the file is added or updated, then one of the following occurs:

- When files are added at application metadata scope (`META-INF` directory) or updated at any application scope or in non-Web modules, the entire application is stopped, the file is added or updated, and then the entire application is restarted.
- When files are added at application non-metadata scope (outside of `META-INF` directory but not in any module), the changes are saved in the file system without restarting the running application.

- When files are added or updated to Web module metadata (META-INF or WEB-INF directory), the running Web module is stopped, the Web module file is added or updated, and then the Web module is started.
- For all other files in Web modules, the file is added or updated on the node's file system without stopping the application or any of its components.

Partial application

Under **Update options**, specifies to update multiple files of an installed application by uploading a compressed file. Depending on the contents of the compressed file, a single use of this option can replace files in, add new files to, and delete files from the installed application. Each entry in the compressed file is treated as a single file and the path of the file from the root of the compressed file is treated as the relative path of the file in the installed application.

After selecting this option, specify whether the compressed file is on a local or remote file system and the full path name of the compressed file. You will likely use **Local file system** because you are uploading a compressed file and remote browsing only works for .ear, .war or .jar files. Specify a valid compressed file format such as .zip or .gzip. The path provides the location of the compressed file before installation. This option unzips the compressed file into the installed application directory.

Use **Local file system** if the browser and the updated files or modules are on the same machine, whether or not the server is on that machine too. **Local file system** is available for all update options.

To replace a file, a file in the compressed file must have the same relative path as the file to be updated in the installed application.

To add a new file to the installed application, a file in the compressed file must have a different relative path than the files in the installed application.

The relative path of a file in the installed application is formed by concatenation of the relative path of the module (if the file is inside a module) and the relative path of the file from the root of the module separated by /.

To remove a file from the installed application, specify metadata in the compressed file using a file named META-INF/ibm-partialapp-delete.props at any archive scope. The ibm-partialapp-delete.props file must be an ASCII file that lists files to be deleted in that archive with one entry for each line. The entry can contain a string pattern such as a regular expression that identifies multiple files. The file paths for the files to be deleted must be relative to the archive path that has the META-INF/ibm-partialapp-delete.props file.

Level of files to delete	Metadata .props file to include in compressed file
Application	Include META-INF/ibm-partialapp-delete.props in the compressed file. In the metadata .props file, list files to be deleted. File paths are relative to the location of the META-INF/ibm-partialapp-delete.props file. For example, to delete a file named utils/config.xmi from the root of the my.ear file, include the line utils/config.xmi in the META-INF/ibm-partialapp-delete.props file.

Level of files to delete	Metadata .props file to include in compressed file
Module	Include *module_uri*/META-INF/ibm-partialapp-delete.props in the compressed file. To delete one file from a module, include the file path relative to the module in the metadata .props file. For example, to delete a/b/c.jsp from the my.jar module, include a/b/c.class in my.jar/META-INF/ibm-partialapp-delete.props file in the compressed file. To delete multiple files within a module, list the files to be deleted in the metadata .props file with one entry on each line. For example, to delete all JavaServer Pages (.jsp files) from the my.war file, include the line .*jsp in the my.war/META-INF/ibm-partialapp-delete.props file. The line uses a regular expression, .*jsp, to identify all .jsp files in my.war.

You can use a single partial application file to add, delete and update multiple files.

After a partial application update, when configuration changes are saved, the new or updated application file is stored in the deployed application in the WebSphere Application Server configuration repository. When these changes are synchronized with the node, the files are added or updated to the node's file system. Because the partial application option updates multiple files, the application components that are restarted are determined using individual files in the partial application.

An example of entries in a partial application compressed file follows:

```
util.jar
META-INF/ibm-partialapp-delete.props
foo.jar/com/mycomp/xyz.class
xyz.war/welcome.jsp
xyz.war/WEB-INF/web.xml
webmod.war/META-INF/ibm-partialapp-delete.props
```

For this example, the META-INF/ibm-partialapp-delete.props file contains the .*.dat and tools/test.jar files. The webmod.war/META-INF/ibm-partialapp-delete.props file contains the com/test/.*.jsp and WEB-INF/test.xmi files.

The partial application update option does the following:
- Adds or replaces util.jar in the deployed application.
- Adds or replaces com/mycomp/xyz.class inside the foo.jar file of the deployed application.
- Deletes *.dat files from the application, but not from any modules.
- Deletes tools/test.jar from the application.
- Adds or replaces welcome.jsp inside the xyz.war module of the deployed application.
- Replaces WEB-INF/web.xml inside the xyz.war module of the deployed application.
- Deletes com/test/*.jsp from the webmod.war module.
- Deletes WEB-INF/test.xmi from the webmod.war module.

Hot deployment and dynamic reloading

You can make various changes to applications and their modules without having to stop the server and start it again. Making these types of changes is known as *hot deployment and dynamic reloading*.

This article assumes that your application files are deployed on a server and you want to upgrade the files.

Hot deployment is the process of adding new components (such as WAR files, EJB Jar files, enterprise Java beans, servlets, and JSP files) to a running server without having to stop the application server process and start it again.

Dynamic reloading is the ability to change an existing component without needing to restart the server in order for the change to take effect. Dynamic reloading involves:
- Changes to the implementation of a component of an application, such as changing the implementation of a servlet
- Changes to the settings of the application, such as changing the deployment descriptor for a Web module

As opposed to the changes made to a deployed application described in "Updating applications" on page 73, changes made using hot deployment or dynamic reloading do not use the administrative console or a wsadmin scripting command. You must directly manipulate the application files on the server where the application is deployed.

If the application you are updating is deployed on a server that has its application class loader policy set to `Single`, you might not be able to dynamically reload your application. At minimum, you must restart the server after updating your application.

Important: Do not use hot deployment to update components in a production deployment manager managed cell. Hot deployment is well-suited for development and testing, but poses unacceptable risks to production environments. Full or partial resynchronization might erase hot deployed components. Also, running the `restoreconfig` command might overwrite changes made to expanded application files. Further, hot deployed components are not migrated between versions of WebSphere Application Server. To add new components or modules to an enterprise application, reassemble the application EAR file so it has the new components or modules and then redeploy the EAR file.

1. Locate your expanded application files. The application files are in the directory you specified when installing the application or, if you did not specify a custom target directory, are in the default target directory, *install_root*/installedApps/*cell_name*. Your EAR file, `${APP_INSTALL_ROOT}/`*`cell_name`*`/`*`application_name`*`.ear`, points to the target directory. The `variables.xml` file for the node defines ${APP_INSTALL_ROOT}. It is important to locate the expanded application files because, as part of installing applications, a WebSphere application server unjars portions of the EAR file onto the file system of the computer that will run the application. These expanded files are what the server looks at when running your application. If you cannot locate the expanded application files, look at the binariesURL attribute in the `deployment.xml` file for your application. The attribute designates the location the run time uses to find the application files. For the remainder of this information on hot deployment and dynamic reloading, *application_root* represents the root directory of the expanded application files.
2. Locate application metadata files. The metadata files include the deployment descriptors (web.xml, application.xml, ejb-jar.xml, and the like), the bindings files (`ibm-web-bnd.xmi`, `ibm-app-bnd.xmi`, and the like), and the extensions files (`ibm-web-ext.xmi`, `ibm-app-ext.xmi`, and the like). Metadata XML files for an application can be loaded from one of two locations. The metadata files can be loaded from the same location as the application binary files (such as *application_root*/META-INF) or they can be loaded from the WebSphere configuration tree, ${CONFIG_ROOT}/cells/*cell_name*/applications /*application_EAR_name*/deployments/*application_name*/. The value of the useMetadataFromBinary flag specified during application installation controls which location is used. If specified, the metadata files are loaded from the same location as the application binary files. If not specified, the metadata files are loaded from the application deployment folder in the configuration tree. For the remainder of this information, *metadata_root* represents the location of the metadata files for the specified application or module.
3. **Required:** If you are running WebSphere Application Server on a group of machines using Network Deployment and you are changing an application on a particular node, disable automatic synchronization.

a. Click **System administration > Node agents >***node_agent_name* **> File synchronization service** in the console navigation tree.
b. On the ″File synchronization service settings″ page, clear the check box for **Automatic synchronization** and click **OK**.

When you run WebSphere Application Server on a group of machines using Network Deployment and you change a file on the disk in the expanded application directory for a particular node, you can lose those changes the next time node synchronization occurs. In the Network Deployment environment, the configuration stored by the deployment manager is the master copy and any changes detected between that master copy and the copy on a particular machine trigger the master copy to be downloaded to the node.

4. **Optional:** Examine the values specified for **Enable class reloading** and **Reloading interval** on the settings page for your enterprise application. If reloading of application files is enabled and the reload interval is greater than zero (0), the application files are reloaded after the application is updated. For Web modules such as servlets and JavaServer page (JSP) files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is also set to `true`. You can set reloadingEnabled to `true` when editing your Web module's extended deployment descriptors in an assembly tool.
5. Change or add the following components or modules as needed:
   - Application files
   - WAR files
   - EJB Jar files
   - HTTP plug-in configuration files
6. For changes to take effect, you might need to start, stop, or restart an application. "Starting and stopping applications" on page 70 provides information on using the administrative console to start, stop, or restart an application. Starting applications with scripting and Stopping applications with scripting provide information on using the wsadmin scripting tool.
7. If you disabled automatic synchronization in step 3, enable automatic synchronization again:
   a. Return to the File synchronization service page.
   b. Select **Automatic synchronization**.
   c. Click **OK**.

Changing or adding application files

You can change or add application files on application servers without having to stop the server and start it again.

There are several changes that you can make to deployed application files without stopping the server and starting it again. You can use the update wizard of the administrative console to make the changes without having to stop and restart the server. This article describes how to make the following changes by manipulating an application file on the server where the application is deployed:

- Updating an existing application on a running server, providing a new enterprise application (EAR file)
- Adding a new application to a running server
- Removing an existing application from a running server
- Changing or adding files to existing enterprise bean (EJB) or Web modules
- Changing the `application.xml` file for an application
- Changing the `ibm-app-ext.xmi` file for an application
- Changing the `ibm-app-bnd.xmi` file for an application
- Changing a non-module Jar file contained in the EAR file

Updating an existing application on a running server (providing a new EAR file)

Reinstall an updated application using the administrative console or the wsadmin `$AdminApp install` command with the `-update` option.

Both reinstallation methods enable you to update an existing application using any of the other steps listed in this file, including changing classes, adding modules, removing modules, changing modules, or changing metadata files. The application reinstallation methods detect the changes in your application and prompt you for additional binding data that might be needed to install the application. The reinstallation process automatically stops and restarts your application on the appropriate servers.

Hot deployment Yes
Dynamic reloading Yes

Adding a new application to a running server

Install an application using the administrative console or the wsadmin `install` command.

Hot deployment Yes
Dynamic reloading No

Removing an existing application from a running server

Stop the application and then uninstall it from the server. Use the administrative console to stop the application and then uninstall it. Or run the wasadmin `stopApplication` command and then the `uninstall` command. See ″Uninstalling applications with the wsadmin tool″ in the information center.

Hot deployment Yes
Dynamic reloading No

Changing or adding files to existing EJB or Web modules

1. Update the application files in the *application_root* location.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment Yes
Dynamic reloading No

Changing the application.xml file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment Not applicable
Dynamic reloading Yes

Changing the ibm-app-ext.xmi file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment Not applicable
Dynamic reloading Yes

Changing the ibm-app-bnd.xmi file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Changing a non-module Jar file contained in the EAR file

1. Update the non-module Jar file in the *application_root* location.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

   If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Yes
Dynamic reloading	Yes

Changing or adding WAR files

You can change Web application archives (WAR files) on application servers without having to stop the server and start it again.

There are several changes that you can make to WAR files without stopping the server and starting it again. You can use the update wizard of the administrative console to make the changes without having to stop and restart the server. This article describes how to make the following changes by manipulating a WAR file on the server where the application is deployed:

- Changing an existing JavaServer Pages (JSP) file
- Adding a new JSP file to an existing application
- Changing an existing servlet class (editing and recompiling)
- Changing a dependent class of an existing servlet class
- Adding a new servlet using the Invoker (Serve Servlets by class name) facility or adding a dependent class to an existing application
- Adding a new servlet, including a new definition of the servlet in the `web.xml` deployment descriptor for the application
- Changing the `web.xml` file of a WAR file
- Changing the `ibm-web-ext.xmi` file of a WAR file
- Changing the `ibm-web-bnd.xmi` file of a WAR file

Changing an existing JSP file

Place the changed JSP file directly in the *application_root*/*module_name* directory or the appropriate subdirectory. The change will be automatically detected and the JSP will be recompiled and reloaded.

Hot deployment	Not applicable
Dynamic reloading	Yes

Adding a new JSP file to an existing application

Place the new JSP file directly in the *application_root*/*module_name* directory or the appropriate subdirectory. The new file will be automatically detected and compiled on the first request to the page.

Hot deployment	Yes
Dynamic reloading	Yes

Changing an existing servlet class (editing and recompiling)

1. Place the new version of the servlet .class file directly in the *application_root/module_name*/WEB-INF/classes directory. If the .class file is part of a Jar file, you can place the new version of the Jar file directly in *application_root/module_name*/WEB-INF/lib. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands.

   If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Not applicable
Dynamic reloading	Yes

Changing a dependent class of an existing servlet class

1. Place the new version of the dependent .class file directly in the *application_root/module_name*/WEB-INF/classes directory. If the .class file is part of a Jar file, you can place the new version of the Jar file directly in *application_root/module_name*/WEB-INF/lib. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands.

   If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Not applicable
Dynamic reloading	Yes

Adding a new servlet using the Invoker (Serve Servlets by class name) facility or adding a dependent class to an existing application

1. Place the new .class file directly in the *application_root/module_name*/WEB-INF/classes directory. If the .class file is part of a Jar file, you can place the new version of the Jar file directly in *application_root/module_name*/WEB-INF/lib. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.

   This case is treated the same as changing an existing class. The difference is that adding the servlet or class does not immediately cause the Web application to reload because the class has never been loaded before. The class simply becomes available for execution.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands.

   If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Yes
Dynamic reloading	Not applicable

Adding a new servlet, including a new definition of the servlet in the web.xml deployment descriptor for the application

1. Place the new .class file directly in the *application_root/module_name*/WEB-INF/classes directory. If the ".class" file is part of a Jar file, you can place the new version of the Jar file directly in *application_root/module_name*/WEB-INF/lib.

   You can edit the web.xml file in place or copy it into the *application_root/module_name*/WEB-INF/classes directory. The new .class file will not trigger a reloading of the application.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin stopApplication and startApplication commands. After the application restarts, the new servlet is available for service.

Hot deployment Yes
Dynamic reloading Not applicable

Changing the web.xml file of a WAR file
1. Edit the `web.xml` file in place or copy it into the *metadata_root*/*module_name*/`WEB-INF` directory.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment Yes
Dynamic reloading Yes

Changing the ibm-web-ext.xmi file of a WAR file

Edit the extension settings as needed. You can change all of the extension settings. The only warning is if you set the reloadInterval property to zero (`0`) or the reloadEnabled property to `false`, the application no longer automatically detects changes to class files. Both of these changes disable the automatic reloading function. The only way to re-enable automatic reloading is to change the appropriate property and restart the application. See other task descriptions in this file for information on restarting an application.

Hot deployment Not applicable
Dynamic reloading Yes

Changing the ibm-web-bnd.xmi file of a WAR file
1. Edit the bindings as needed. You can change all of the values but ensure that the entities you are binding to are present in the configuration of the server.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment Not applicable
Dynamic reloading Yes

Changing or adding EJB Jar files
You can change enterprise bean (EJB) Jar files on application servers without having to stop the server and start it again.

There are several changes that you can make to EJB Jar files without stopping the server and starting it again. You can use the update wizard of the administrative console to make the changes without having to stop and restart the server. This article describes how to make the following changes by manipulating an EJB file on the server where the application is deployed:
- Changing the `ejb-jar.xml` file of an EJB Jar file
- Changing the `ibm-ejb-jar-ext.xmi` or `ibm-ejb-jar-bnd.xmi` file of an EJB Jar file
- Changing the `Table.ddl` file for an EJB Jar file
- Changing the `Map.mapxmi` or `Schema.dbxmi` file for an EJB Jar file
- Updating the implementation class for an EJB file or a dependent class of the implementation class for an EJB file
- Updating the Home/Remote interface class for an EJB file
- Adding a new EJB file to an existing EJB Jar file

Changing the ejb-jar.xml file of an EJB Jar file

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment Not applicable
Dynamic reloading Yes

Change the ibm-ejb-jar-ext.xmi or ibm-ejb-jar-bnd.xmi file of an EJB Jar file

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment Not applicable
Dynamic reloading Yes

Changing the Table.ddl file for an EJB Jar file

Rerun the DDL file on the user database server. Changing the `Table.ddl` file has no effect on the application server and is a change to the database table schema for the EJB files.

Hot deployment Not applicable
Dynamic reloading Not applicable

Changing the Map.mapxmi or Schema.dbxmi file for an EJB Jar file

1. Change the `Map.mapxmi` or `Schema.dbxmi` file for an EJB Jar file.
2. Regenerate the deployed code artifacts for the EJB file.
3. Apply the new EJB Jar file to the server.
4. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment Not applicable
Dynamic reloading Yes

Updating the implementation class for an EJB file or a dependent class of the implementation class for an EJB file

1. Update the class file in the *application_root*/*module_name*.jar file.
2. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

   If automatic reloading is not enabled, restart the application of which the EJB file is a member. If the updated module is used by other modules in other applications, restart those applications as well. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment Not applicable
Dynamic reloading Yes

Updating the Home/Remote interface class for an EJB file

1. Update the interface class of the EJB file.
2. Regenerate the deployed code artifacts for the EJB file.
3. Apply the new EJB Jar file to the server.
4. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

   If automatic reloading is not enabled, restart the application of which the EJB file is a member. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Adding a new EJB file to an existing EJB Jar file

1. Apply the new or updated Jar file to the *application_root* location.
2. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

   If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Yes
Dynamic reloading	Yes

Changing the HTTP plug-in configuration

You can change the HTTP plug-in configuration without having to stop the server and start it again.

There are several change that you can make to the HTTP plug-in configuration without stopping the server and starting it again. This file describes--

- Changing the `application.xml` file to change the context root of a Web application archive (WAR file)
- Changing the `web.xml` file to add, remove, or modify a servlet mapping
- Changing the `server.xml` file to add, remove, or modify an HTTP transport or changing the `virtualhost.xml` file to add or remove a virtual host or to add, remove, or modify a virtual host alias

Changing the application.xml file to change the context root of a WAR file

1. Change the `application.xml` file.
2. If the plug-in configuration property Automatically propagate plug-in configuration file is selected for this plug-in, it is automatically regenerated whenever the `application.xml` file changes. (See ″Web server plug-in properties settings″ for information on how to set this property.) You can also run the `GenPluginCfg.bat/sh` script, or issue a wsadmin command to regenerate the plug-in configuration file.

Hot deployment	Yes
Dynamic reloading	No

Changing the web.xml file to add, remove, or modify a servlet mapping

1. Change the `web.xml` file.
2. If the plug-in configuration property Automatically propagate plug-in configuration file is selected for this plug-in, it is automatically regenerated whenever the web.xml file changes. (See Web server plug-in properties settings for information on how to set this property.) You can also run the `GenPluginCfg.bat/sh` script, or issue a wsadmin command to regenerate the plug-in configuration file.

   If the Web application has file serving enabled or has a servlet mapping of `/`, the plug-in configuration does not have to be regenerated. In all other cases a regeneration is required.

Hot deployment	Yes
Dynamic reloading	Yes

Changing the server.xml file to add, remove, or modify an HTTP transport or changing the virtualhost.xml file to add or remove a virtual host or to add, remove, or modify a virtual host alias

1. Change the `server.xml` file to add, remove, or modify an HTTP transport or change the `virtualhost.xml` file to add or remove a virtual host or to add, remove, or modify a virtual host alias.
2. If the plug-in configuration property **Automatically propagate plug-in configuration file** is selected for this plug-in, it is automatically regenerated whenever the `server.xml` file changes. (See Web server plug-in properties settings for information on how to set this property.) You can also run the `GenPluginCfg.bat/sh` script, or issue a wsadmin command to regenerate the plug-in configuration file.

Hot deployment	Yes
Dynamic reloading	Yes

Uninstalling applications

After an application no longer is needed, you can uninstall it.

Uninstalling an application deletes the application from the WebSphere Application Server configuration repository and it deletes the application binaries from the file system of all nodes where the application modules are installed.

1. Click **Applications > Enterprise Applications** in the administrative console navigation tree to access the Enterprise Applications page.
2. If you need to retain a copy of the application, back up the application.
   a. Select the application you want uninstalled.
   b. Click **Export**.

   The application is exported to an enterprise application (`.ear` file), preserving the binding information.
3. Uninstall the application.
   a. Select the application you want uninstalled.
   b. Click **Uninstall**.
4. Save changes made to the administrative configuration.

Application binaries are deleted when configuration changes on the deployment manager synchronize with configurations for individual nodes.

Removing a file

After a file is no longer needed, you can remove the file from an application or module deployed on a server.

Removing a file deletes the file from the WebSphere Application Server configuration repository and it deletes the file from the file system of all nodes where the file is installed.

- Remove a file from an application.
  1. Go to the Enterprise Applications page. Click **Applications > Enterprise Applications** in the console navigation tree.
  2. Select the application that contains a file you want removed.
  3. Click **Remove File**. The Remove a file from an application page is displayed
  4. Select the URI of the file that you want removed from the application.
  5. Select **Export before removing file** to back up the application.
  6. Specify the location to which you want the file exported.
  7. Click **Back** to return to the Enterprise Applications page.
- Remove a file from a module.
  1. Go to the settings page for the application. Click **Applications > Enterprise Applications >***application_name* in the console navigation tree.
  2. Under **Related Items**, click Web modules, EJB Modules, or Connector Modules.
  3. Select the module from which you want to delete a file.
  4. Click **Remove File**. The Remove a file from a module page is displayed.
  5. Select the URI of the file that you want removed from the module.

6. Optional: Back up the application. Select the application name and then specify the location to which you want the file exported.
7. Click **OK** to remove the file.

The file is exported to the designated location and removed from the application or module. The application or standalone Web module that had a file removed is restarted so the changes take effect.

Save the changes to your administrative configuration. Application binaries are deleted when configuration changes on the deployment manager synchronize with configurations for individual nodes.

If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Deploying and administering applications: Resources for learning

Use the following links to find relevant supplemental information about deploying and administering applications using the administrative console. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Refer to Web resources for learning for links to information applicable to WebSphere Application Server generally, such as lists of IBM technical papers, Redbooks and samples.

Web applications

Task overview: Developing and deploying Web applications

A developer creates the files comprising a Web application, and then assembles the Web application components into a Web module. Next, the deployer (typically the developer in a unit-testing environment or the administrator in a production environment) installs the Web application on the server.

1. **(Optional)** Migrate existing Web applications to run in the new version of WebSphere.
2. Design the Web application and develop its code artifacts: Servlets, JavaServer Pages (JSP) files, and static files, as for example, images and Hyper Text Markup Language (HTML) files. See ″Developing servlets with WebSphere Application Server extensions″ and the ″Resources for learning″ article for links to design documentation.
3. Develop the Web application, using WebSphere Application Server extensions to enhance its functionality. See ″Developing Web applications″ in the information center.

4. Assemble the Web application into a Web module using an assembly tool. See ″Assembling Web applications″ in the information center. Web module assembly properties might include the ability to:
   - Configure servlet page lists.
   - Configure servlet filters.
   - Serve servlets by class name.
   - Enable file serving.
5. Deploy the Web module or application module that contains the Web application.

   Following deployment, you might find it handy to use the tool that enables batch compiling of the JSP files for quicker initial response times.
6. **(Optional)**Troubleshoot your Web application. See ″Web container troubleshooting tips″ in the information center.
7. **(Optional)** Modify the default Web container configuration in the application server in which you deployed the Web module or application module containing the Web application.
8. **(Optional)** Manage the deployed Web application.

Web applications

A Web application is comprised of one or more related servlets, JavaServer Pages technology (JSP files), and Hyper Text Markup Language (HTML) files that you can manage as a unit.

The files in a Web application are related in that they work together to perform a business logic function. For example, one of the WebSphere Application Server samples is a *Simple Greeting* Web application. See ″Accessing the Samples (Samples Gallery)″ in the information center. This application, comprised of a servlet and Web pages, greets new users when the application is accessed.

The Web application is a concept supported by the Java Servlet Specification. Web applications are typically packaged as `.war` files.

web.xml file

The `web.xml` file provides configuration and deployment information for the Web components that comprise a Web application. Examples of Web components are servlet parameters, servlet and JavaServer Pages (JSP) definitions, and Uniform Resource Locators (URL) mappings.

The Java Servlet 2.4 specification defines the `web.xml` deployment descriptor file in terms of an XML schema document. For backwards compatibility of applications written to the Java Servlet 2.2 Specification, Web containers are also required to support the Java Servlet 2.2 specification. For backwards compatibility of applications written to the Java Servlet 2.3 specification, Web containers are also required to support the Java Servlet 2.3 specification.

Location

The `web.xml` file must reside in the `WEB-INF` directory under the context of the hierarchy of directories that exist for a Web application. For example, if the application is `client.war`, then the `web.xml` file is placed in the *install_root*/*client war*/`WEB-INF` directory.

Usage notes

- Is this file read-only?

  No
- Is this file updated by a product component?

  This file is updated by the Application Server Toolkit.
- If so, what triggers its update?

  The Application Server Toolkit updates the `web.xml` file when you assemble Web components into a Web module, or when you modify the properties of the Web components or the Web module.
- How and when are the contents of this file used?

WebSphere Application Server functions use information in this file during the configuration and deployment phases of Web application development.

Default Application

The IBM WebSphere Application Server provides a default configuration that allows administrators to easily verify that the Application Server is running. When the product is installed, it includes an application server called *server1* and an enterprise application called *Default Application*.

Default Application contains a Web Module called *DefaultWebApplication* and an enterprise bean JAR file called *Increment*. The *Default Application* provides a number of servlets, described below. These servlets are available in the product.

For additional code examples, visit the Samples Gallery. Learn how to locate and install the Samples Gallery by viewing the Samples Gallery reference page.

The URL for accessing Samples is: `http://localhost:9080/WSsamples/`

Snoop

Use the Snoop servlet to retrieve information about a servlet request. This servlet returns the following information:

- Servlet initialization parameters
- Servlet context initialization parameters
- URL invocation request parameters
- Preferred client locale
- Context path
- User principal
- Request headers and their values
- Request parameter names and their values
- HTTPS protocol information
- Servlet request attributes and their values
- HTTP session information
- Session attributes and their values

The Snoop servlet includes security configuration so that when WebSphere Security is enabled, clients must supply a user ID and password to execute the servlet.

The URL for the Snoop servlet is: `http://localhost:9080/snoop/`.

HelloHTML

Use the HelloHTML pervasive servlet to exercise the PageList support provided by the WebSphere Web container. This servlet extends the PageListServlet, which provides APIs that allow servlets to call other Web resources by name or, when using the *Client Type detection* support, by type.

You can invoke the Hello servlet from an HTML browser, speech client, or most Wireless Application Protocol (WAP) enabled browsers using the URL: `http://localhost:9080/HelloHTML.jsp`.

HitCount

Use the HitCount Demonstration application to demonstrate how to increment a counter using a variety of methods, including:
- A servlet instance variable
- An HTTP session
- An enterprise bean

You can instruct the servlet to execute any of these methods within a transaction that you can commit or roll back. If the transaction is committed, the counter is incremented. If the transaction is rolled back, the counter is not incremented.

The enterprise bean method uses a container-managed persistence enterprise bean that persists the counter value to a Cloudscape database. This enterprise bean is configured to use the Default Datasource, which is set to the DefaultDB database.

When using the enterprise bean method, you can instruct the servlet to look up the enterprise bean, either in the WebSphere global namespace, or in the namespace local to the application.

The URL for the HitCount application is: `http://localhost:9080/HitCount.jsp`.

Servlets

Servlets are Java programs that use the Java Servlet Application Programming Interface (API). You must package servlets in a Web archive (WAR) file or Web module for deployment to the application server. *Servlets* run on a Java-enabled Web server and extend the capabilities of a Web server, similar to the way applets run on a browser and extend the capabilities of a browser.

Servlets can support dynamic Web page content, provide database access, serve multiple clients at one time, and filter data.

For the purposes of WebSphere Application Server, discussions of servlets focus on Hyper Text Transfer Protocol (HTTP) servlets, which serve Web-based clients.

With the introduction of Java Servlet 2.4 specification, you can define servlets as welcome files. Non servlet resources are served only when the FileServingEnabled attribute is set to true. Serving welcome files is connected to serving static content, therefore fileServing enabled is set in the Web module.

JavaServer Pages

JavaServer Pages (JSP) are application components coded to the JavaServer Pages Specification. JavaServer Pages enable the separation of the Hypertext Markup Language (HTML) code from the business logic in Web pages so that HTML programmers and Java programmers can more easily collaborate in creating and maintaining pages.

JSP files support a division of roles:

HTML authors
: Develop JSP files that access databases and reusable Java components, such as servlets and beans.

Java programmers
: Create the reusable Java components and provide the HTML authors with the component names and attributes.

Database administrators
: Provide the HTML authors with the name of the database access and table information.

WebSphere Application Server 6.0 supports the JSP 2.0 specification. The sub-topics below discuss WebSphere Application Server's JSP 2.0 implementation, focusing on configuration, tools and extensions.

JSP engine:

The WebSphere Application Server JavaServer Pages (JSP) engine is the implementation of the JavaServer Pages Specification.

WebSphere Application Server 6.0 supports the JSP 2.0 specification.

The JSP engine

- Validates JSP source, both classic and XML styles
- Translates JSP source to Java classes
- Compiles Java classes, reporting any errors
- Generates Java classes for any tag files that are used by the JSP
- Interfaces with the Web container to load JSP class files
- Supports JSP batch compilation, JSP compilation during application installation, and JSP compilation during the build process of customer applications, through an Ant task.
- Loads class files, and manage life-cycle (reloading, unloading as necessary)
- Supports debugging of JavaServer Pages files through support for JSR 45 (Debugging Support for Other Languages)

JSP engine configuration parameters: In WebSphere Application Server, you can configure the JavaServer Pages (JSP) engine for optimal performance in a production server environment and for the needs of developers in a development environment. The configuration parameters are described below.

The JSP engine parameters are case sensitive. If the value specified for a parameter is comprised of two or more words separated by spaces, you must add quotation marks around the value. Some parameters affect the Java source that is generated for a JSP or tag file. These parameters are identified by the statement ″This parameter requires regeneration of Java source.″ This statement indicates that if the configuration parameter is modified, the new value for the parameter does not have any effect until the JSP files are retranslated and the Java sources are recompiled.

- **compileWithAssert**

  Specifies whether the generated Java classes should contain support for the Developer Kit, Java Technology Edition 1.4 Assertion facility. The effect of setting this parameter to true is that the –source 1.4 option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **classdebuginfo**

  Indicates whether the compiler includes debugging information in the generated class file. When you set this parameter to true, the –g option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **deprecation**

  Specifies whether the compiler generates deprecation warnings when compiling the generated Java source. When you set this parameter to true, the -deprecation option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **disableJspRuntimeCompilation**

  If this option is set to true, the JSP engine at runtime does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load class files. When this option is set to true, you can install an application without JSP source, but the application must have precompiled class files. There is a Web container custom property with the same name that is used to determine the behavior of all Web modules installed in a server. If both the Web container custom property and the JSP engine option are set, the JSP engine option takes precedence. The default for this parameter is `false`.
- **extendedDocumentRoot**

  To allow a JSP file resource to be shared across Web application archives, specify a comma delimited list of directories and/or Java Archive (JAR) files as search paths to be used if the requested resource

cannot be located in the Web application archive's public document tree. If the JSP file is located inside a JAR file and reloadEnabled is true, the timestamp of the JAR file is used for isOutDated checks for recompile purposes. The default for this parameter is null.

- **ieClassID**

  Indicates the Java plug-in COM class ID for Internet Explorer. The `<jsp:plugin>` tags use this value. The default classid is `clsid:8AD9C840-044E-11D1-B3E9-00805F499D93`. This parameter requires regeneration of Java source.
- **javaEncoding**

  Specifies the encoding that is used when the `.java` file is generated, and when it is compiled by the Java compiler. Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible. When javaEncoding is set, the encoding is passed to the Java compiler through the -encoding argument. Note that encoding is not supported by Jikes. The default is UTF-8. This parameter requires regeneration of Java source.
- **jspCompileClasspath**

  This parameter tells the JSP engine to use a small class path for the Java compilation phase. The small class path speeds up the compilation process. This small class path is not used by default because it includes only a subset of WebSphere JAR files and excludes many WebSphere JAR files that contain WebSphere public APIs.

  If your JSP files do not use WebSphere public APIs within scriptlets, you can enable the small class path by using the jspCompileClasspath parameter with no value. See the example in ″Configuring JSP engine parameters″ in the information center. If your JSP files do use WebSphere public APIs within scriptlets, then add those additional JAR files to the jspCompileClasspath option. The JAR file entries are separated by spaces, and are assumed to be relative to the WebSphere Application Server installation root.

  The entire WebSphere class path is used by default. This parameter requires regeneration of Java source.
- **jsp.file.extensions**

  For JSP files with extensions other than the four standard extensions, *.jsp, *.jspx, *.jsw, and *.jsv, you can configure this the extensions using this parameter. These extensions are added to the standard extensions. The preferred method for doing this is to create a `<jsp-property-group>`in web.xml, and add a `<url-pattern>` tag for each extension.

  The JSP engine can handle a list of file extensions that is separated by a colon or semi-colon. For example, *.ext1;*.ext2:*.extn
- **keepgenerated**

  Indicates that the Java files generated by the JSP compiler during the translation phase of the processing are retained. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **keepGeneratedclassfiles**

  Indicates that the class files generated by the JSP compiler during the translation phase of the processing are retained. The default for this parameter is `true`. This parameter requires regeneration of Java source.
- **reloadEnabled**

  Determines whether or not a JSP file is translated and compiled at runtime if the JSP file or its dependencies (see trackDependencies) are modified. If reloadEnabled is false, a JSP file is still compiled, if necessary, on the first request to it unless the parameter disableJspRuntimeCompilation is true. The default for this parameter is `false`.

  If this JSP engine parameter is not specified, the equivalent Web container parameter for Web module class reloading is used. However, for an application whose deployment descriptor is at the Servlet 2.2 level, the default is true. This is done for the support of applications being migrated from WebSphere Application Server Version 4.x.
- **reloadInterval**

  If reloading is enabled, reloadInterval determines the delay between checks to see if a JSP file is outdated. For example, if reloadInterval is 5, the JSP engine checks to see if a JSP file is outdated only

when the last such check was done more than 5 seconds prior to the current request for the JSP file. The larger the reloadInterval, the less frequently the JSP engine checks for the need to reload a JSP file. If this JSP engine parameter is not specified, the equivalent Web container parameter for Web module class reloading is used. However, for an application whose deployment descriptor is at the Servlet 2.2 level, the default is 5 seconds. This is done for the support of applications being migrated from WebSphere Application Server Version 4.x.

- **scratchdir**

  Specifies the directory where the generated class files are created. The system property com.ibm.websphere.servlet.temp.dir is used to set the scratchdir option on a server-wide basis. The JSP engine scratchdir parameter takes precedence over the system property com.ibm.websphere.servlet.temp.dir. The default for this parameter is `{WAS_ROOT}/profiles/profilename/temp`. This parameter requires regeneration of Java source.
- **trackDependencies**

  If reloading is enabled, trackDependencies determines whether the JSP engine tracks modifications to the requested JavaServer Pages files dependencies as well as to the JSP file itself. The dependencies tracked by the JSP engine are :
  1. files statically included in the JSP file
  2. tag files referenced in the JSP file (excluding tag files that are in JARs)
  3. TLD files referenced in the JSP file (excluding TLDs that are in JARs)

  The default is `false`.
- **useFullPackageNames**

  If useFullPackageNames is true, the JSP engine generates and loads JSP classes using full package names. The default is to generate all JSP classes in the same package. (For more information, see “Packages and directories for generated .java and .class files” on page 102). The JSP engine’s class loader knows how to load JSP classes when they are all in the same package.

  The default method of generating all JSP classes in the same package has the benefit of generating smaller file-system paths. Full package names has the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without the use of the jsp-file attribute, resulting in a single class loader, the Web application’s class loader, that is used to load all such JSP classes. Similarly, when the JSP engine’s configuration attributes useFullPackageNames and disableJspRuntimeCompilation are both true, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

  When useFullPackageNames is set to true, the batch compiler generates a file called `generated_web.xml` in the Web module’s `WEB-INF` directory. This file contains servlet configuration information for each JSP file that was successfully translated and compiled. The information can optionally be copied into the Web module’s `web.xml` file so that the JSP files are loaded as servlets by the Web container. Note that if a JSP file is configured as a servlet in this way, no reloading of the JSP file is done at runtime if the JSP file is modified. This is because the JSP file is treated as a regular servlet and requests for it do not pass through the JSP engine. This parameter requires regeneration of Java source.
- **useImplicitTagLibs**

  The JSP engine implicitly recognizes tsx and jsx as tag library prefixes for tag libraries supplied by the JSP engine. If tsx or jsx are used as prefixes for a customer‘s tag library, the customer‘s tag library overrides the implicit tag library. However, the implicit tag library is still cached by the JSP engine. Explicitly setting this parameter to false tells the engine not to cache the implicit tag library, and save resources. The default for this parameter is `true`.
- **useJikes**

  Specifies whether Jikes is used for compiling Java sources. NOTE: Jikes is not shipped with WebSphere Application Server. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **usePageTagPool**

  *Enables or disables the reuse of custom tag handlers on an individual JavaServer Pages basis. The default for this parameter is `false`. This parameter requires regeneration of Java source.
- **useThreadTagPool**

*When thread-level tag handler pooling is used, tag handlers may be reused among separate occurrences of a custom action across all JSP pages in a single Web module across separate requests. The default for this parameter is `false`. This parameter requires regeneration of Java source.

- **verbose**

  Indicates that the compiler generates verbose output when compiling the generated Java source code. The effect of setting this parameter to true is that the -verbose option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

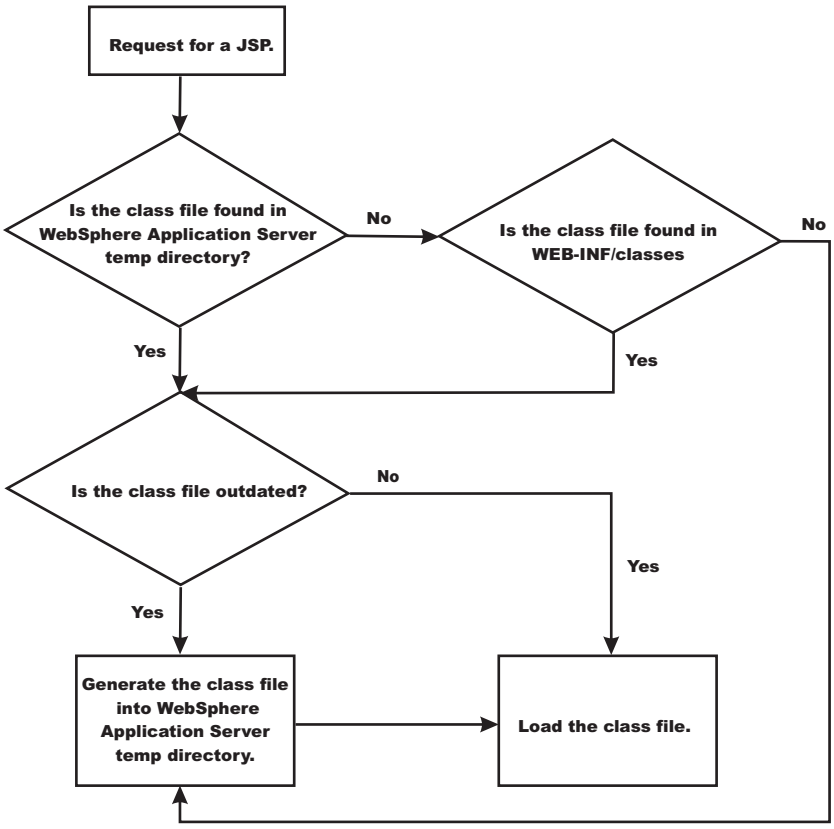
*Enabling custom tag handler reuse might reveal problems in the tag handler code with regard to the tag's ability to be reused. A custom tag handler should always do two things:

- The release method of the tag handler should reset its state and release any private resources that it might have used. The JSP engine ensures the release method is called before the tag handler is garbage collected.
- In the doEndTag method, all instance states associated with this instance must be reset.

JSP class file generation: At runtime, the WebSphere Application Server JavaServer Pages (JSP) engine loads JSP class files from either the WebSphere Application Server `temp` directory or a Web module's `WEB-INF/classes` directory. The WebSphere Application Server `temp` directory is typically *WAS_INSTALL_ROOT*/AppServer/profiles/default/temp/*node_name*/*server_name*. The JSP engine first searches for a class file in the `temp` directory and then it searches in the Web module's `WEB-INF/classes` directory. Figure 1 shows the processing logic of the JSP engine at runtime.

You should not use the `CANCEL appserver_proc_name` command to stop a server. Every time a server is cleanly stopped, these `temp` directories are removed. However, if the server is frequently not stopped cleanly, which happens if you cancel rather than stop the server, these directories are not removed and the HFS used for the temp directory eventually becomes full.

You can also prevent this storage problem from occurring if you precompile your JSPs when you install an application or if you use the JspBatchCompiler function to precompile them before they are invoked.



The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a Web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables the generation of class files into any directory on the filesystem, outside of the target application. Generating class files into a Web module's `WEB-INF/classes` directory enables you to deploy the Web module as a self-contained Web archive (WAR) file, or a WAR file inside an enterprise archive (EAR) file. The following table shows the batch compiler's behavior when compiling class files.

	ear.path or war.path supplied	enterpriseApp.name supplied
compileToDir not supplied; *compileToWebInf* not supplied, or is true	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the Web module's `WEB-INF/classes` directory.
compileToDir not supplied; *compileToWebInf* is false	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the WebSphere temp directory, usually `{WAS_ROOT}/profiles/profilename/temp`.
compileToDir is supplied; *compileToWebInf* not supplied, or is either true or false	The class files are compiled into the directory indicated by *compileToDir*.	The class files are compiled into the directory indicated by *compileToDir*.

Packages and directories for generated .java and .class files:

By default, the .java files for all JavaServer Pages (JSP) files are generated with the package statement, `package com.ibm._jsp;`. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The .java files are located in the filesystem within a directory structure mirroring the JSP source directory structure.

If the JSP engine configuration parameter **useFullPackageNames** is set to true, the .java files are generated with the package statement

```
Package _ibmjsp.<directory structure in which the jsp is located>;
```

The usage of full package names enables the configuration of a JSP as a servlet in the `web.xml` file. See "JSP class loading" on page 104 for more information. The table below gives examples of packages and directory structures for generated .java and .class files.

	Java package		Location of .java or .class files in file system	
JSP file	**default**	**useFullPackage Names=true**	**default**	**useFullPackageNames=true**
/myJsp.jsp	com.ibm._jsp	_ibmjsp	/	/_ibmjsp
/jspFiles/ jspOne.jsp	com.ibm._jsp	_ibmjsp.jspFiles	/jspFiles	/_ibmjsp/jspFiles
/dir with spaces/jspTwo.jsp	com.ibm._jsp	_ibmjsp.dir_20_ with_20_spaces	/dir with spaces	/_ibmjsp/dir_20_with_20_spaces

Generated .java files: When the JSP engine's **keepgenerated** configuration parameter is set to true, the `.java` file that is generated for JavaServer Pages (JSP) is retained. This file contains information that is useful in debugging.

Dependency information

In the `.java` file, immediately following the class declaration, an array of dependent files is defined, if the source JSP has any dependencies. There are three types of files that are tracked as dependencies:

1. Files that are statically included in the JSP
2. Tag files that are used by the JSP, but only tag files that are not in Java Archive (JAR) files
3. TLD files that are used by the JSP, but only TLDs that are not in JAR files

This array is always generated, but the JSP engine uses it, in determining whether a JSP needs to be recompiled, only when the trackDependencies parameter is set to true.

In the example below, three JSP fragments, one TLD and one tag file are dependencies of the JSP jsp1.jsp. There are three parts to each array entry:

1. The path to the dependency, relative to the Web module's context root. For example: `/dir1/frag1.jspf`
2. The long value representing the time the file was last modified. For example: 1082407108000
3. The String representation of the long value. For example: Mon Apr 19 16:38:28 EDT 2004

```
public final class _jsp1 extends com.ibm.ws.jsp.runtime.HttpJspBase
  implements com.ibm.ws.jsp.runtime.JspClassInformation {

  private static String[] _jspx_dependants;
  static {
  _jspx_dependants = new String[5];
  _jspx_dependants[0] = "/Banner.jspf^1082407108000^Mon Apr 19 16:38:28 EDT 2004";
  _jspx_dependants[1] = "/Footer.jspf^1077657462000^Tue Feb 24 16:17:42 EST 2004";
  _jspx_dependants[2] = "/dir1/frag1.jspf^1035396680000^Wed Oct 23 14:11:20 EDT 2002";
  _jspx_dependants[3] = "/utility.tld^1080069938000^Tue Mar 23 14:25:38 EST 2004";
  _jspx_dependants[4] = "/WEB-INF/tags/top.tag^1065440490000^Mon Oct 06 07:41:30 EDT 2003";
  }
```

Version, JSP engine options, and WEB.XML information

The generated .java source contains a comment that lists information about the file which is located at the bottom of the generated file. This information includes:

- The date and time the `.java` file was generated
- The version, build number and build date of the WebSphere Application Server on which the `.java` file was generated
- The values of the JSP engine configuration parameters that were in effect when the file was generated
- The values of any `<jsp-config>` elements in the `web.xml` file that pertained to the source JSP file.

```

JSP class loading:

You can configure a JavaServer Pages (JSP) class to be loaded by either the JSP engine‘s class loader or by the Web module‘s class loader.

By default, a JSP class is loaded by a unique instance of the JSP engine's class loader. The JSP engine's class loader enables reloading at runtime of a JSP class when the JSP source or one of its dependents is modified. This allows you to reload a single JSP class when necessary, without affecting any other loaded JSP classes.

JSP classes are loaded by the Web module's class loader under either of the following scenarios.

1. 1. The JSP engine configuration parameter useFullPackageNames is set to true, and the JSP file is configured as a servlet in the `web.xml` file using the <servlet-class> scenario in the table below.
2. 2. The JSP engine configuration parameters useFullPackageNames and disableJspRuntimeCompilation are both set to true. In this case, you do not need to configure a JSP file does as a servlet in the `web.xml` file.

Configuring JSP files as Servlets

You can configure a JSP file as a servlet in the `web.xml` file. There are two ways to do this. They are described in the table below.

Before you configure a JSP file as a servlet, consider the following.

1. Reloading capability - If runtime reloading of JavaServer Pages files is desired, requests for JavaServer Pages files must be handled by the JSP engine. The <servlet-class> scenario in the table below disables runtime JSP file reloading, while the <jsp-file> scenario is compatible with reloading.
2. Reducing the number of class loaders - If you do not require runtime reloading of modified JSP pages and you want to reduce the number of class loader instances, then you can use the <servlet-class> scenario in the table below. Similarly, scenario 2 in section 1 above can be used without having to configure a JSP file as a servlet.

Scenario	Example	compatible with runtime reloading	multiple class loaders used?	useFull PackageNames
<jsp-file>	<servlet> <servlet-name>jspOne</servlet-name> <jsp-file>jspOne.jsp</jsp-file> </servlet>	Yes	Yes	Can be true or false
<servlet-class>	<servlet> <servlet-name>jspTwo</servlet-name> <servlet-class>_ibmjsp.jspTwo</servlet-class> </servlet>	No	No	Must be true

The JSP batch compiler tool helps you configure JavaServer Pages files as servlets. When useFullPackageNames is true, the JSP batch compiler generates <servlet> and <servlet-mapping> elements for each JSP file that it successfully translates and compiles. The elements are written to a `web.xml` fragment file named `generated_web.xml` which is located in the binaries `WEB-INF` directory of a Web module processed by the JSP file batch compiler (this directory is located within the deployed application's ear file). You can copy and paste all or some of these elements into the `web.xml` file to configure JavaServer Pages files as servlets.

Take note of the location of the `web.xml` that is used by the application server. In WebSphere Application Server 6.0, application specific configuration is obtained from either the application binaries (the application's ear file) or from the configuration repository. If an application is deployed into WebSphere

Application Server with the flag Use Binary Configuration set to true, then the WEB-INF/web.xml file is looked for in a Web module's binaries directory, not in the configuration repository. Below are examples of these two locations.

1. An example of a configuration repository directory is
   {WAS_ROOT}/profiles/profilename/config/cells/cellname/applications/
   enterpriseappname/deployments/deployedname/webmodulename
2. An example of an application binaries directory is:
   {WAS_ROOT}/profiles/profilename/installedApps/nodename/EnterpriseAppName/WebModuleName/

If the JSP batch compiler is executed on a pre-deployed application then the web.xml file is in the Web module's WEB-INF directory.

Configuring JSP runtime reloading: JSP files can be translated and compiled at runtime when the JSP file or its dependencies are modified. This is known as JSP reloading. JSP reloading is enabled through the **reloadEnabled** JSP engine parameter in the WEB-INF/ibm-web-ext.xmi file:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadEnabled" value="true"/>
```

The following table contains the recommended reload settings for production and development environments.

	Recommended settings	
Configuration Attribute	**Production Environment**	**Development Environment**
reloadEnabled	false	true
reloadInterval	n/a (ignored if reloadEnabled is false)	approximately 5 seconds
trackDependencies	n/a (ignored if reloadEnabled is false)	true Alternatively, set this to false to improve response time if dependencies are not changing
disableJspRuntimeCompilation	true - Alternatively, set this to false if JSPs are not pre-compiled and therefore need to be compiled on the first request.	false

If the **reloadEnabled** parameter is set to true, a JSP file is reloaded at runtime if the JSP file and its class file do not have the same timestamp. In addition, if **trackDependencies** is set to true then the JSP file is reloaded if the timestamp of any of its dependencies has changed since the JSP class file was last generated. If the **reloadEnabled** parameter is set to false, a JSP file is still compiled if necessary on the first request to it unless the parameter **disableJspRuntimeCompilation** is true. For example, when **disableJspRuntimeCompilation** is false and **reloadEnabled** is false, a JSP file is compiled on the first request if the class file is outdated. It would not compiled on subsequent requests even if the JSP source file is modified or the class file is deleted unless **reloadEnabled** is true

Reload interval

The reload interval is set through the **reloadInterval** JSP engine parameter:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadInterval" value="5"/>
```

If reloading is enabled, the **reloadInterval** parameter value determines the delay between checks to see if a JSP file is outdated. For example, if **reloadInterval** is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than five seconds prior to the current request for the JSP file. Once the **reloadInterval** is exceeded, reload checking is performed and the reload interval timer is reset to 0 for that JSP file. The larger the **reloadInterval**, the less frequently the JSP engine checks for the need to reload a JSP file.

Dependency tracking

Dependency tracking is set through the **trackDependencies** JSP engine parameter:

```
<jspAttributes xmi:id="JSPAttribute_1" name="trackDependencies" value="true"/>
```

If reloading is enabled, the **trackDependencies** parameter value determines whether the JSP engine tracks modifications to the requested JSP file dependencies as well as to the JSP file itself. The three types of dependencies tracked by the JSP engine are:

- files statically included in the JSP file
- tag files that are referenced in the JSP file (excluding tag files that are in JAR files)
- TLDs that are referenced in the JSP file (excluding TLDs that are in JAR files)

Dependency tracking information is always included in the generated class file even if **trackDependencies** is false. The information is not used by the JSP engine or batch compiler unless the **trackDependencies** parameter is true. This means that you can enable dependency tracking without having to recompile JSP files.

For example, the `toplevel.jsp` file statically includes the `footer.jspf` file. When the `toplevel.jsp` file is compiled, the path to the `footer.jspf` file and its timestamp are stored in the `toplevel.jsp`'s class file. As a result, the `footer.jspf` file is modified and the `toplevel.jsp` file is requested. Now that the reload interval for the `toplevel.jsp` file has been exceeded, the JSP engine compares the timestamp stored in the class file with the `footer.jspf` file timestamp on disk. Because the timestamps are different, the `toplevel.jsp` file is compiled, picking up the modification to the `footer.jspf` file. In order for dependency tracking to work, the **trackDependencies** value must be set to true at the time a JSP file is requested at runtime or is processed by the batch compiler.

Disabling compilation

Disablement of runtime compilation of JavaServer Pages is set via the disableJspRuntimeCompilation JSP engine parameter:

```
<jspAttributes xmi:id="JSPAttribute_1" name="disableJspRuntimeCompilation" value="true"/>
```

If the **disableJspRuntimeCompilation** parameter is set to true, the JSP engine at runtime does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order for the class files to be loaded. With this option set to true, an application can be installed without JSP source, but must have precompiled class files. There is a Web container custom property of the same name that can be used to determine the behavior of all web modules installed in a server. If both the Web container custom property and the JSP engine option are set, the JSP engine option takes precedence. Setting the **disableJspRuntimeCompilation** parameter to true automatically sets **reloadEnabled** to false.

Reload processing sequence

The processing sequence pertaining to JSP file reloading when **trackDependencies** is false is shown in Figure 1.

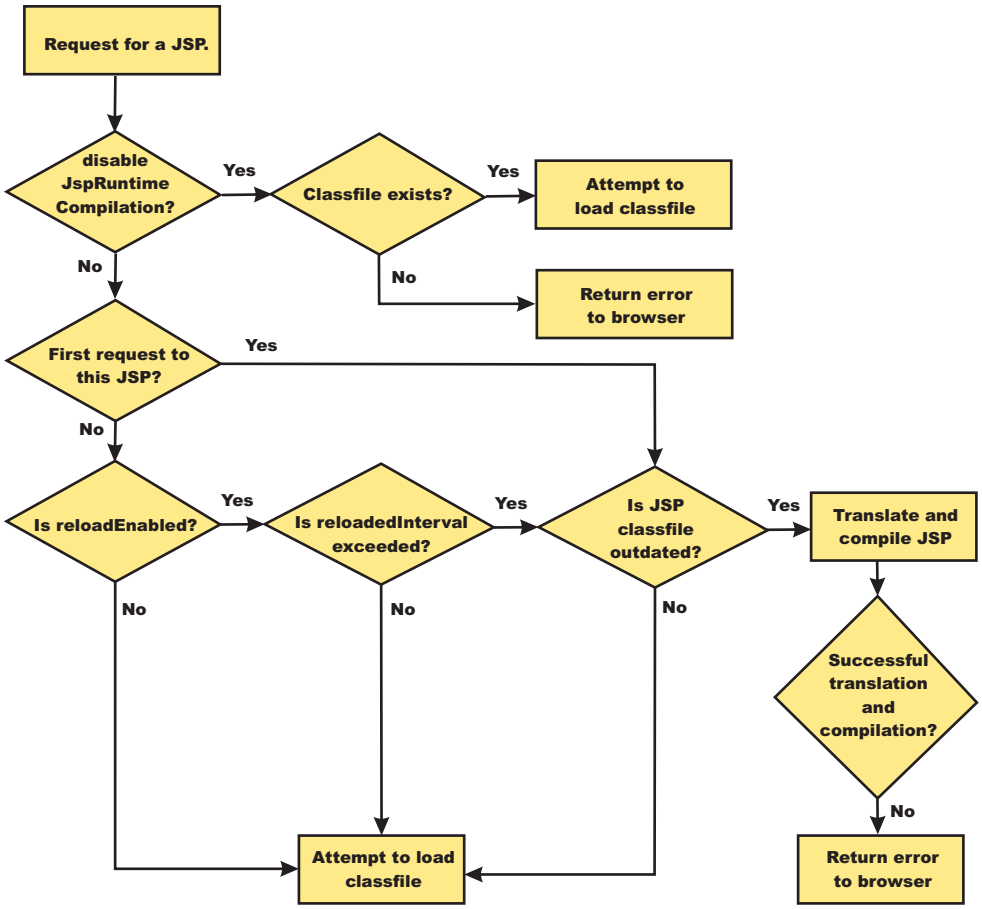

Figure 1. Reload processing sequence when **trackDependencies** *is false.*

When **trackDependencies** is true, the JSP engine does additional file system processing to determine if any of a JSP file's dependencies have changed since the JSP file was last translated and compiled. Figure 2 shows the additional processes that are performed on the 'No' path of flow chart labeled ″is JSP class file outdated?″. You can see that the path taken when disableJspRuntimeCompilation is true is the most efficient path.

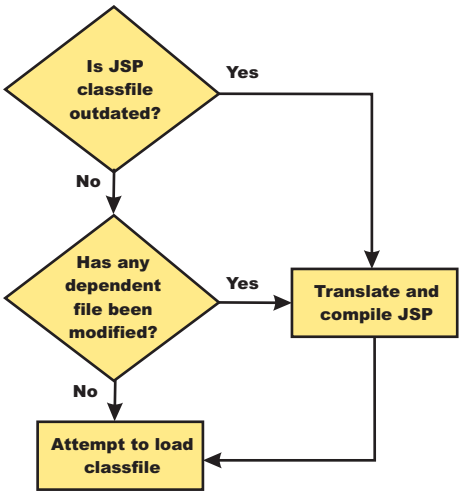

Figure 2. Additional reload processing performed when **trackDependencies** *is true.*

Disabling JavaServer Pages run-time compilation: By default, the JavaServer Pages (JSP) engine translates a requested JSP file, compiles the `.java` file, and loads the compiled servlet into the run-time environment. You can change the JSP engine default behaviour by indicating a JSP file should never be translated or compiled at run-time, even when a `.class` file does not exist.

If run-time compilation is disabled, you must precompile the JSP files, which provides the following advantages:

- Reduces compilation related disk operations.
- Minimizes disk storage requirements necessary for handling temporary `.java` files generated during a run-time compilation.
- Allows you to not include the JSP source files in the application.
- Allows verification that a JSP file compiled successfully before deploying and installing the application in WebSphere Application Server.

You can disable run-time JSP file compilation on a global or an individual Web application basis:

- To disable the translation and compilation of JSP files for all Web applications, set the Web container custom property `disableJspRuntimeCompilation` to `true`.

  Set this property through the Web container `Custom properties` panel in the administrative console. To view this administrative console page, click:

  Servers > **Application servers** > *server_name* > **Web container settings** > **Web container** > **Custom properties** > *property_name*

  Valid values for this setting are `true` or `false`. If this property is set to `true`, then translation and compilation of the JSP files is disabled at run time for all Web applications.
- To disable the translation and compilation of JSP files for a specific Web application, set the JSP engine initialization parameter `disableJspRuntimeCompilation` to `true`. This setting, if enabled, determines the run-time behavior of the JSP engine and overrides the Web container custom property setting.

  Set this parameter through the `JavaServer Pages attribute assembly settings` panel in the Assembling applications.

  Valid values for this setting are `true` or `false`. If this parameter is set to `true`, then, for that specific Web application, translation and compilation of the JSP files is disabled at run time, and the JSP engine only loads precompiled files.
- If neither the Web container custom property nor the JSP parameter is set, the first request for a JSP file results in the translation and compilation of the JSP file when the `.class` file does not exist or is outdated. Subsequent requests for the file also result in translations and compilations, but only if the following conditions are met:
  - Translations are required because the `.class` file is outdated.

- Reloading is enabled for the Web module.
- Reload interval is exceeded.

If you disable run-time compilation and a request arrives for a JSP file that does not have a matching `.class` file, the JSP engine returns HTTP error 500 (Internal server error) to the browser. In this case, an exception is written to the joblog (sysprint) file if ras_trace_outputLocation in `was.env` file is set to SYSPRINT or to CTRACE if ras_trace_outputLocation is set to BUFFER.

If a JSP file has a matching `.class` file but that file is out of date, the JSP engine still loads the `.class` file into memory.

JSP batch compilation:

As an IBM enhancement to JavaServer Pages (JSP) support, IBM WebSphere Application Server provides a batch JSP compiler that allows JSP page compilation before application deployment. The batch compiler validates the syntax of JSP pages, translates the JSP pages into Java source files, and compiles the Java source files into Java Servlet class files. The batch compiler also validates tag files and generates their Java implementation classes.

Batch compilation of JSP pages in a predeployed application simplifies the deployment process and improves the runtime performance of JSP page by eliminating first-request compilations. The batch compiler also operates on enterprise applications that have been deployed into WebSphere Application Server.

The JSP batch compiler works on Web modules that support Servlet 2.2 and up through Servlet 2.4 The batch compiler works on JSP pages written to the JSP 2.0 specification or previous specifications back to JSP 1.0. It recognizes a Servlet 2.4 deployment descriptor, `web.xml`, and can use any jsp-config elements that it may contain. In a Servlet 2.3 (JSP 1.2) or Servlet 2.2 (JSP 1.1) deployment descriptor the batch compiler recognizes and uses any taglib elements that the descriptor may contain.

Batch compiling makes the first request for a JSP page much faster because the JSP page is already translated and compiled into a servlet. Batch compiling is also useful as a fast way to resynchronize all of the JSP pages for an application.

The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a Web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables generation of class files into any directory on the filesystem, outside the target application. Generating class files into a Web module's `WEB-INF/classes` directory enables the Web module to be deployed as a self-contained WAR file, or a WAR inside an EAR.

JSP batch compiler tool: The batch compiler validates the syntax of JSP pages, translates the JSP pages into Java source files, and compiles the Java source files into Java Servlet class files. The batch compiler also validates tag files and generates their Java implementation classes. Use this function to batch compile your JSP files and thereby enable faster responses to the initial client requests for the JSP files on your production Web server.

The batch compiler can be executed against compressed or expanded enterprise archive (EAR) files and Web application archive (WAR) files, as well as enterprise applications and Web modules that have been deployed into WebSphere Application Server. When the target is a deployed enterprise application, the server does not need to be running to execute the batch compiler. If the batch compiler is executed while the target sever is running, the server is not aware of an updated class file and does not load that class file unless the enterprise application is restarted. When the target is a compressed EAR file or WAR file, the batch compiler must expand it before executing.

Processing of Web modules

The batch compiler operates on one Web module at a time. If the target is either an EAR file or an installed enterprise application that contains more than one Web module, the batch compiler operates on each Web module individually. This is done because JSP pages are configured on a Web module basis, through the Web module's web.xml deployment descriptor file. Within a Web module, the batch compiler processes one directory at a time. It validates and translates each JSP page individually, and then invokes the Java compiler for the entire group of generated Java sources files in that directory. If one JSP page fails during the Java compilation phase, the Java compiler might not create class files for most or all of the JSP pages that successfully compiled in that directory.

JSP file extensions

The batch compiler uses four things to determine what file extensions it should process:

1. Standard JSP file extensions
   - *.jsp
   - *.jspx
   - *.jsw
   - *.jsv
2. The url-pattern property of the jsp-property-group elements in the deployment descriptor file in Servlet 2.4 Web modules
3. The **jsp.file.extensions** JSP engine configuration parameter (for pre-Servlet 2.4 Web modules)
4. The batch compiler configuration parameter **jsp.file.extensions**

The standard extensions are always used by the batch compiler. If the Web module contains a Servlet 2.4 deployment descriptor, the batch compiler also processes any url-patterns found within the jsp-config element. If the batch compiler target contains the JSP engine configuration parameter **jsp.file.extensions**, then those extensions are also processed. If the batch compiler configuration parameter **jsp.file.extensions** is present, the extensions given are also processed and will override the JSP engine configuration parameter **jsp.file.extensions**.

It is a good idea to give JSP 'fragments' an extension that is not processed by the batch compiler. Statically-included fragments that do not stand alone generate translation or compilation errors if processed. The JSP 2.0 Specification suggests that you use the extension `.jspf` for such files.

Batch compiler command

Both a Windows batch file, `JspBatchCompiler.bat` and Unix shell script `JspBatchCompiler.sh` for running the batch compiler from the command line are found in the `{WAS_ROOT}/bin` directory. An Ant task (described in the topic Batch Compiler Ant Task) is also available for executing the batch compiler using Ant.

The batch compiler target is the only required parameter. The target is one of -ear.path, -war.path or -enterpriseapp.name.

```
JspBatchCompiler -ear.path | -war.path | -enterpriseapp.name <name>
   [-response.file <filename>]
   [-webmodule.name <name>]
   [-filename <jsp name | directory name>
   [-recurse <true | false>]
   [-config.root <path>]
   [-cell.name <name>]
   [-node.name <name>]
   [-server.name <name>]
   [-profileName <name>]
   [-extractToDir <path>]
   [-compileToDir <path>]
```

```
[-compileToWebInf <true | false>]
[-translate <true | false>]
[-compile <true | false>]
[-removeTempDir <true | false>]
[-forceCompilation <true | false>]
[-useFullPackageNames <true | false>]
[-trackDependencies <true | false>]
[-createDebugClassfiles <true | false>]
[-keepgenerated <true | false>]
[-keepGeneratedclassfiles <true | false>]
[-usePageTagPool <true | false>]
[-useThreadTagPool <true | false>]
[-classloader.parentFirst <true | false>]
[-classloader.singleWarClassloader <true | false>]
[-additional.classpath <classpath to additional JAR files and classes>]
[-jspCompileClasspath <classpath to Websphere Application Server public API JAR files; or no value at all>]
[-verbose <true | false>]
[-deprecation <true | false>]
[-javaEncoding <encoding>
[-compileWithAssert <true | false>]
[-compilerOptions <space-separated list of java compiler options>]
[-useJikes <true | false>]
[-jsp.file.extensions <file extensions to process>]
[-log.level <SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF>]

*** See batchcompiler.properties.default in {WAS_ROOT}/bin for more information. ***
     *** See JspCBuild.xml in {WAS_ROOT}/bin for information about the public WebSphere Ant task JspC. ***
```

The batch compiler is aware of three groups of configuration parameters:

1. JSP engine configuration parameters for a Web module.

   See the topic, “JSP engine configuration parameters” on page 98.
2. Batch compiler response file configuration parameters.

   These are the parameters that are found in a batch compiler response file. See -response.file, below.
3. Batch compiler command line configuration parameters.

   These are the parameters entered on the command line when running the batch compiler.

The batch compiler looks at all three groups of configuration parameters in order to determine which value for a parameter is used when compiling JSP pages. When resolving the value for a given parameter, the precedence is:

1. If the parameter is found on the command line, its value is used.
2. If the parameter is not found on the command line, the batch compiler looks for the parameter in a response file named on the command line.
3. If no response file is named, or if the parameter is not found therein, the batch compiler looks for the parameter in the Web module’s JSP engine configuration parameters.

If a configuration parameter is not found among these three groups, then a default value is used. The default values for the configuration parameters are given below along with the description of the parameters.

With one exception, these parameters are not case sensitive; -profileName is case sensitive. If the values specified for these arguments are comprised of two or more words separated by spaces, you must add quotation marks around the values.

The batch compiler does not create, or set the values of, equivalent JSP engine parameters. This means that if a JSP page in a deployed Web module is modified and is recompiled by the JSP engine at runtime, the JSP engine’s configuration parameters will determine the engine’s behavior. For example, if you use the batch compiler to compile a Web module and you use the -useFullPackageNames true option, the JSP files will be compiled to support that option. But the JSP engine parameter useFullPackageNames must

also be set to true in order for the JSP Runtime to be able to load the compiled JSP pages. If JSP pages are modified in a deployed Web module, then the engine's parameters should be set to the same values used in batch compilation.

To use the JSP batch compiler, enter the following command on a single line at an operating system command prompt:

where:

- **ear.path | war.path | enterpriseapp.name**

  Represents the full path to a single compressed or expanded enterprise application archive (EAR) file or Web application archive (WAR) file, or the name of the deployed enterprise application that you want to compile. For example:
  - `JspBatchCompiler -ear.path c:\myproject\sampleApp.ear`
  - `JspBatchCompiler -war.path c:\myWars\examples.war`
  - `JspBatchCompiler -enterpriseapp.name myEnterpriseApp -webmodule.name my.war -filename /aDir/main.jsp`
- **response.file**

  Specifies the path to a file that contains configuration parameters used by the batch compiler. The *response.file* is used only if it is given on the command-line; it is ignored if it is present in a response file. A template response file, batchcompiler.properties.default, is found in {WAS_ROOT}/bin. Copy this template to create your own response files containing defaults for the parameters in which you are interested. All the required and optional parameters (except response.file) can be configured in a response file.

  Example: JspBatchCompiler -response.file c:\myproject\batchc.props

  Default : null
- **webmodule.name**

  Represents the name of the specific Web module that you want to batch compile. If this argument is not set, all Web modules in the enterprise application are compiled. This parameter is used only when *ear.path* or *enterpriseapp.name* is given. This parameter is useful when JSP pages in a specific Web module within a deployed enterprise application need to be regenerated, because all Shared Library dependencies will be picked up.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -webmodule.name myWebModule.war

  Default: All Web modules in an EAR file or enterprise application are compiled if this parameter is not given.
- **filename**

  Represents the name of a single JSP file that you want to compile. If this argument is not set, all files in the Web module are compiled. Alternatively, if *filename* is set to the name of a directory, only the JSP files in that directory and that directory's child directories are complied. The name is relative to the context root of the Web module.

  Example 1: If you want to compile the file, `myTest.jsp`, and it is found in `/subdir/myJSPs`, you would enter `-filename /subdir/myJSPs/myTest.jsp`.

  Example 2: If you want to compile all JSP files in `/subdir/myJSPs` and its child directories, you would enter `-filename subdir/myJSPs`.

  Default: All JSP files in the Web module are compiled. Entering `-filename /` is equivalent to the default.
- **recurse**

  Determines whether subdirectories beneath the target directory are processed. This parameter is used only when the *filename* parameter is given. Set value to `false` to process only the directory named *filename* parameter; and not its subdirectories.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -filename /subdir1 -recurse false.

  Default: true; All directories beneath the target directory are processed.
- **config.root**

Specifies the location of the WebSpehere Application Server configuration directory. This parameter is used only when *enterpriseapp.name* is given.

Default: `{WAS_ROOT}/profiles/profilename/config`

- **cell.name**

  Specifies the name of the cell in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_CELL.

- **node.name**

  Specifies the name of the node in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_NODE.

- **server.name**

  Represents the name of the server in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: server1

- **profileName**

  Specifies the name of the profile you want to use. This parameter is used only when `enterpriseapp.name` is given.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -profileName AppServer-3

  Default: The default profile is used. This is obtained from the file `setupCmdLine.[bat/sh]` in `{WAS_ROOT}/bin`. The symbolic name is DEFAULT_PROFILE_SCRIPT.

- **extractToDir**

  Specifies the directory into which predeployed enterprise archive (EAR) files and Web application archive (WAR) files will be extracted before the batch compiler operates on them. This parameter is ignored when *enterpriseapp.name* is given. The extractToDir parameter is used as described in the table below.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -extractToDir c:\myTempDir.

  Use-case: You must extract a compressed archive before it is batch compiled. You can also extract an expanded archive to a new directory as well. In both cases, extraction leaves the original archive untouched, which may be useful while development is underway.

  Default values:

	Expanded archive	Compressed archive
extractToDir supplied	The batch compiler extracts the archive to extractToDir before operating on it. If a file or directory of the same name as the archive already exists in the extractToDir, the batch compiler removes the archive completely before extracting that archive. If the batch compiler exits with no errors, it compresses the archive in place in the extractToDir, even if the original EAR file or WAR file was expanded. If errors are encountered during compilation, the EAR file or WAR file is left in the expanded state even if the original EAR file or WAR file was compressed.	
extractToDir not supplied	The batch compiler operates on the EAR file or WAR file in place (does not extract it to another directory) and the archive remains expanded after the batch compiler finishes.	The batch compiler extracts the archive to the directory returned by the JVM property ″java.io.tmpdir″. The rest of the behavior described above, when extractToDir is supplied, is the same in this case.

  The default is `server1`.

- **compileToDir**

Specifies the directory into which JSP pages are translated into Java source files and compiled into class files. This directory can be anywhere on the filesystem, but the batch compiler's default behavior is usually adequate. The batch compiler's behavior when compiling class files is described in the table below

Example:: JspBatchCompiler -enterpriseApp.name sampleApp -compileToDir c:\myTargetDir

Use-case: This parameter enables you to generate the Java and class files into a directory outside of the target, which may be useful if you want to compare the newly generated files with their previous versions which remain untouched within the target.

Default values:

	ear.path or war.path supplied	enterpriseApp.name supplied
compileToDir not supplied; compileToWebInf not supplied, or is true	The class files are compiled into the Web module's `WEB-INF/classes` directory	The class files are compiled into the Web module's `WEB-INF/classes` directory.
compileToDir not supplied; compileToWebInf is false	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the WebSphere temp directory (usually `{WAS_ROOT}/temp`).
compileToDir is supplied; compileToWebInf not supplied, or is either true or false	The class files are compiled into the directory indicated by compileToDir.	The class files are compiled into the directory indicated by compileToDir.

- **compileToWebInf**

  Specifies whether the target directory for the compiled JSP class files should be the Web module's `WEB-INF/classes directory`. This parameter is used only when *enterpriseApp.name* is given, and it is overridden by *compileToDir* if *compileToDir* is given.

  The batch compiler's default behavior is to compile to the Web module's `WEB-INF/classes` directory. The batch compiler's behavior when compiling class files is described in the table above.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -compileToWebInf false.

  Use-case: Set this parameter to false when enterpriseApp.name is supplied and you want the class files to be compiled to the WebSphere Application Server temp directory instead of the Web module's `WEB-INF/classes` directory. Recommendation: if this parameter is set to false, set forceCompilation to true if there are any JSP class files in the `WEB-INF/classes` directory.

  Default: true; see the table above.
- **forceCompilation**

  Specifies whether the batch compiler is forced to recompile all JSP resources regardless or whether the JSP page is outdated.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -forceCompilation true.

  Use-case: Especially useful when creating an archive for deployment, to make sure all JSP classes are up to date.

  Default: false
- **useFullPackageNames**

  Specifies whether the batch compiler generates full package names for JSP classes. The default is to generate all JSP classes in the same package. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The default has the benefit of generating smaller file-system paths. Full package names have the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without use of the `jsp-file` attribute, resulting in a single class loader (the Web application's class loader) being used to load all such JSP classes. Similarly, when the JSP engine's configuration attributes **useFullPackageNames** and **disableJspRuntimeCompilation** are both true, a single class loader is used to load all JSP classes, even if the JSP pages are not configured as servlets in the`web.xml` file.

  When useFullPackageNames is set to true, the batch compiler generates a file called `generated_web.xml` in the Web module's `WEB-INF` directory. This file contains servlet configuration

information for each JSP page that is successfully translated and compiled. The information can optionally be copied into the Web module's `web.xml` file so that the JSP pages are loaded as servlets by the Web container. Note that if a JSP page is configured as a servlet in this way, no reloading of the JSP page is done at runtime if the JSP page is modified. This is because the JSP page is treated as a regular servlet and requests for it do not pass through the JSP engine.

Example: JspBatchCompiler –enterpriseApp.name sampleApp –useFullPackageNames true

Use-case: Enables JSP classes to be loaded by a single class loader.

Default: false

- **removeTempDir**

  Specifies whether the Web module's temp directory is removed. The batch compiler by default generates JSP class files into a Web module's `WEB-INF/classes` directory. JSP class files are generated into the `temp` directory at runtime if a JSP page is modified and JSP reloading is enabled. By batch compiling all the JSP pages in a Web module and also removing the `temp` directory, disk resources are preserved. You can only use the removeTempDir parameter when -enterpriseApp.name is given.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -removeTempDir true.

  Use-case: Free up disk space by clearing out a Web application's `temp` directory.

  Default: false

- **translate**

  Specifies whether JSP pages are translated and compiled. Set translate to false if you do not want JSP pages to be translated and compiled. You must use this option in conjunction with `-removeTempDir` to tell the batch compiler to remove only the `temp` directory and to do no further processing.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -translate false -removeTempDir true.

  Use-case: Free up disk space by clearing out a Web application's `temp` directory, without invoking JSP processing.

  Default: true

- **compile**

  Specifies whether JSP pages go through the Java compilation phase. Set compile to `false` if you do not want JSP pages to go through the Java compilation phase.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -compile false

  Use-case: If you only want JSP pages to be syntax-checked, set -compile to false. You can set -keepgenerated to true if you want to see the `.java` files that are generated during the translation phase.

  Default: true

- **trackDependencies**

  Specifies whether the batch compiler recompiles a JSP page when any of its dependencies have changed, even if the JSP page itself has not changed. Tracking dependencies incurs a significant runtime performance penalty because the JSP Engine checks the filesystem on every request to a JSP page to see if any of its dependencies have changed. The dependencies tracked by WebSphere Application Server are :

  1. Files statically included in the JSP page
  2. Tag files used by the JSP page (excluding tag files that are in JAR files)
  3. TLD files used by the JSP page (excluding TLD files that are in JAR files)

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -trackDependencies true.

  Use-case: Useful in a development environment.

  Default: false

- **createDebugClassfiles**

  Specifies whether the batch compiler generates class files that contain SMAP information, as per JSR 45, **Debugging support for Other Languages**.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -createDebugClassfiles true

Use-case: Use this parameter when you want to be able to debug JSP pages in your JSR 45-compliant IDE.

Default: false

- **keepgenerated**

  Specifies whether the batch compiler saves or erases the generated Java source files created during the translation phase.

  If set to `true`, WebSphere Application Server saves the generated `.java` files used for compilation on your server. By default, this argument is set to `false` and the `.java` files are erased after the class files have compiled.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -keepgenerated true

  Use-case: Use this parameter when you want to review the Java code generated by the batch compiler.

  Default: false

- **keepGeneratedclassfiles**

  Specifies whether the batch compiler saves or erases the class files generated during the compilation of Java source files.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -keepGeneratedclassfiles false -keepgenerated false

  Use-case: Set this parameter to false if you only want to see if there are any translation or compilation errors in your JSP pages. If paired with -keepgenerated false, this parameter results in all generated files being removed before the batch compiler completes.

  Default: true

- **usePageTagPool**

  Enables or disables the reuse of custom tag handlers on an individual JSP page basis.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -usePageTagPool true

  Use-case: Use this parameter to enable JSP-page-based reuse of tag handlers.

  Default: false

- **useThreadTagPool**

  Enables or disables the reuse of custom tag handlers on a per request thread basis per Web module.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -useThreadTagPool true

  Use-case: Use this parameter to enable Web module-based reuse of tag handlers.

  Default: false

- **classloader.parentFirst**

  Specifies the search order for loading classes by instructing the batch compiler to search the parent class loader prior to application class loader. This parameter is only used when *ear.path* or *enterpriseApp.name* is given.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -classloader.parentFirst false

  Use-case: Set this parameter to false when your Web module contains a JAR file that is also found in the server lib directory, and you want your Web module's JAR file to be picked up first.

  Default: true

- **classloader.singleWarClassloader**

  Specifies whether to use one class loader per enterprise archive (EAR) file or one class loader per Web application archive (WAR) file. Used only when *ear.path* or *enterpriseApp.name* is given.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -classloader.singleWarClassloader true

  Use-case: Set this parameter to true when a Web module depends on JAR files and classes in another Web module in the same enterprise application.

  Default: false; One class loader is created per WAR file with no visibility of classes in other Web modules.

- **additional.classpath**

Specifies additional class path entries to be used when parsing and compiling JSP pages. This parameter is used only when `war.path` is given. When `war.path` is the target, WebSphere Shared Libraries are not picked up by the batch compiler. Therefore, if your WAR file relies on, for example, a JAR file that is configured in WebSphere Application Server as a shared library, then use this option to point to that JAR file. In addition, if you give `war.path` and also use the `-extractToDir` parameter, then any JAR files that are in the WAR file's manifest class-path is not added to the class path (since the WAR file has now been extracted by itself outside the EAR file in which it resides). Use `-additional.classpath` in this case to point to the necessary JAR files. Add the full path to needed resources, separated by your system-dependent path separator.

Example: JspBatchCompiler -war.path c:\myproject\examples.war -additional.classpath c:\myJars\someJar.jar;c:\myClasses

Use-case: Use this parameter to add to the class path JAR files and classes outside of your WAR file. At runtime, these same JAR files and classes have to be made available through the standard WebSphere Application Server configuration mechanisms.

Default: null

- **jspCompileClasspath**

  This option instructs the batch compiler to use a small class path for the Java compilation phase. The small class path greatly speeds up the compilation process. This small class path is not used by default because it includes only a subset of WebSphere Application Server JAR files. The small class path excludes many WebSphere Application Server JAR files, among which are those that contain WebSphere public APIs.

  If your JSP pages do not use any WebSphere public APIs within scriptlets you can enable the small class path by using the jspCompileClasspath parameter with no value, as in Example 1 below.

  If your JSP pages do use WebSphere public APIs within scriptlets, then add those additional JAR files to the jspCompileClasspath option, as in Example 2 below.

  The entries are separated by spaces, and are assumed to be relative to the WebSphere Application Server installation root.

  Example 1: If no public APIs are needed in JSP pages: JspBatchCompiler -enterpriseApp.name sampleApp -jspCompileClasspath

  Example 2: public APIs from the `admin.jar` file needed in JSP pages: JspBatchCompiler -enterpriseApp.name sampleApp –jspCompileClasspath ″lib/admin.jar″

  Use-case: Use this parameter to speed up the Java compilation step of JSP page processing.

  Default: The entire WebSphere Application Server class path is used by default.

- **verbose**

  Specifies whether the batch compiler should generate verbose output while compiling the generated sources.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -verbose true

  Use-case: Set this parameter to true when you want to see Java compiler class loading and other messages.

  Default: false

- **deprecation**

  Indicates the compiler should generate deprecation warnings while compiling the generated sources.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -deprecation true

  Use-case: Set this parameter to true when you want to see Java compiler deprecation messages.

  Default: false

- **javaEncoding**

  Specifies the encoding that will be used when the .java file is generated, and when it is compiled by the Java compiler. When -javaEncoding is set, that encoding is passed to the java compiler via the -encoding argument. Note that encoding is not supported by Jikes.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -javaEncoding Shift-JIS

Use-case: Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible.

Default value: UTF-8.

- **compileWithAssert**

  Tells the batch compiler to enable assertions. If compileWithAssert is true, the batch compiler will pass the –source 1.4 option to the javac compiler. If compileWithAssert is false, no option is sent to the javac compiler. The default behavior of javac is to compile code normally even if the word assert is used as regular identifier.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -compileWithAssert true

  Use-case: Set this parameter to true when you want you use the assertion facility in your JSP pages and you want to be able to turn on assertions at runtime.

  Default value: false

- **compilerOptions**

  Specifies a list of strings to be passed on the Java compiler command. This is a space-separated list of the form ″arg1 arg2 argn″.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -compilerOptions ″ -bootclasspath <path>″

  Use-case: Use this parameter if you need Java compiler arguments other than verbose, deprecation and Assert facility support.

  Default: null

- **useJikes**

  Specifies whether Jikes should be used for compiling Java sources. NOTE: Jikes is not shipped with WebSphere Application Server.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -useJikes true

  Use-case: Set this parameter to true in order for the batch compiler to use Jikes as the Java compiler.

  Default value: false

- **jsp.file.extensions**

  Specifies the file extensions to be processed by the batch compiler. This is a semicolon- or colon-separated list of the form ″*.ext1;*.ext2:*.extn″. Note that this parameter is not necessary for Servlet 2.4 Web applications because the url-pattern property of the jsp-property-group elements in the deployment descriptor can be used to identify extensions that should be treated as JSP pages.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -jsp.file.extensions *jspz;*.jspt

  Use-case: Use this parameter to add additional extensions to the be processed by the batch compiler.

  Default: null; See the section, “JSP batch compiler tool” on page 110, for additional information.

- **log.level**

  Specifies the level of logging that is directed to the console during batch compilation. Values are SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -log.level FINEST

  Use-case: Set this parameter higher or lower to control logging output. FINEST generates the most output useful for debugging.

  Default: CONFIG

Batch compiler ant task:

The ant task **JspC** exposes all the batch compiler configuration options. It executes the batch compiler under the covers. It is backward compatible with the WebSphere Application Server 5.x version of the **JspC** ant task. The following table lists all the ant task attribute and their batch compiler equivalents.

JspC attribute	Equivalent batch complier parameter
earPath	-ear.path

warPath	-war.path
src Same as warPath, for backward compatiblity	-war.path
enterpriseAppName	-enterpriseapp.name
responseFile	-response.file
webmoduleName	-webmodule.name
fileName	-filename -config.root
configRoot	-config.root
cellName	-cell.name
nodeName	-node.name
serverName	-server.name
profileName	-profileName
extractToDir	-extractToDir
compileToDir same as compileToDir, for backward compatibility	-compileToDir -compileToDir
compileToWebInf	-compileToWebInf
jspCompileClasspath	-jspCompileClasspath
compilerOptions	-compilerOptions
recurse	-recurse
removeTempDir	-removeTempDir
translate	-translate
compile	-compile
forceCompilation	-forceCompilation
useFullPackageNames	-useFullPackageNames
trackDependencies	-trackDependencies
createDebugClassfiles	-createDebugClassfiles
keepgenerated	-keepgenerated
keepGeneratedclassfiles	-keepGeneratedclassfiles
usePageTagPool	-usePageTagPool
useThreadTagPool	-useThreadTagPool
classloaderParentFirst	-classloader.parentFirst
classloaderSingleWarClassloader	-classloader.singleWarClassloader
additionalClasspath	-additional.classpath
classpath same as additionalClasspath, for backward compatibility	-additional.classpath
verbose	-verbose
deprecation	-deprecation
javaEncoding	-javaEncoding
compileWithAssert	-compileWithAssert
useJikes	-useJikes
jspFileExtensions	-jsp.file.extensions

logLevel	-log.level
wasHome	none
Classpathref	none

Below is an example of a build script with multiple targets, each with different attributes. The following commands are used to execute the script:

On Windows:

```
ws_ant -Dwas.home=%WAS_HOME% -Dear.path=%EAR_PATH% -Dextract.dir=%EXTRACT_DIR%
ws_ant jspc2 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME%
ws_ant jspc3 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME% -Ddir.name=%DIR_NAME%
```

On Unix:

```
ws_ant -Dwas.home=$WAS_HOME -Dear.path=$EAR_PATH -Dextract.dir=$EXTRACT_DIR
ws_ant jspc2 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME
ws_ant jspc3 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME -Ddir.name=$DIR_NAME
```

Example build.xml Using the JspC Task

```
<project name="JSP Precompile" default="jspc1" basedir=".">
 <taskdef name="wsjspc" classname="com.ibm.websphere.ant.tasks.JspC"/>
 <target name="jspc1" description="example using  a path to an EAR,
  and extracting the EAR to a directory">
  <wsjspc wasHome="${was.home}"
            earpath="${ear.path}"
            forcecompilation="true"
            extractToDir="${extract.dir}"
            useThreadTagPool="true"
            keepgenerated="true"
            jspCompileClasspath=""

  />
 </target>
 <target name="jspc2" description="example using an enterprise app and webmodule">
  <wsjspc wasHome="${was.home}"
            enterpriseAppName="${app.name}"
            webmoduleName="${webmodule.name}"
            removeTempDir="true"
            forcecompilation="true"
            keepgenerated="true"
            jspCompileClasspath=""

  />
 </target>
 <target name="jspc3" description="example using an enterprise app, webmodule and
   specific directory">
  <wsjspc wasHome="${was.home}"
            enterpriseAppName="${app.name}"
            webmoduleName="${webmodule.name}"
            fileName="${dir.name}"
            recurse="false"
            forcecompilation="true"
            keepgenerated="true"
            jspCompileClasspath=""

  />
 </target>
</project>
```

Batch compiler class path:

The batch compiler builds its class path as shown in the table below. When the batch compiler target is a Web archive (WAR) file and `war.path` is supplied, the configuration *additional.classpath* parameter is used to give extra class path information.

	Batch compiler target		
Location added to class path	enterpriseapp.name	ear.path	war.path
WebSphere Application Server JAR files and classes	yes	yes	yes
JAR files listed in manifest class path for a Web module	yes	yes	yes, when the target WAR is inside an EAR and *–extractToDir* is not used; otherwise, no.
Shared libraries	yes	no	no
Web module JAR files and classes	yes	yes	yes
additional.classpath parameter to batch compiler	no	no	yes
jspCompileClassPath parameter	When this parameter is used, the only change to the information above is that a subset of WebSphere Application Server JAR files and classes is used for Java compilation. All JAR files and classes, that are given in the value for the *jspCompileClassPath* parameter are also added to the class path for Java compilation.		

Global tag libraries:

JavaServer Pages (JSP) tag libraries contain classes for common tasks such as processing forms and accessing databases from JSP files.

Tag libraries encapsulate, as simple tags, core functionality common to many Web applications. The Java Standard Tag Library (JSTL) supports common programming tasks such as iteration and conditional processing, and provides tags for:
- manipulating XML documents
- supporting internationalization
- using Structured Query Language (SQL)

Tag libraries also introduce the concept of an expression language to simplify page development, and include a version of the JSP expression language.

A tag library has two parts - a Tag Library Descriptor (TLD) file and a Java archive (JAR) file.

tsx:dbconnect tag JavaServer Pages syntax: Use the <tsx:dbconnect> tag to specify information needed to make a connection to a database through Java DataBase Connectivity (JDBC) or Open Database Connectivity (ODBC) technology.

The <tsx:dbconnect> syntax does not establish the connection. Use the <tsx:dbquery> and <tsx:dbmodify> syntax instead to reference a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file to establish the connection.

When the JSP file compiles into a servlet, the Java processor adds the Java coding for the <tsx:dbconnect> syntax to the servlet service() method, which means a new database connection is created for each request for the JSP file.

This section describes the syntax of the <tsx:dbconnect> tag.

```
<tsx:dbconnect id="connection_id"
    userid="db_user" passwd="user_password"
    url="jdbc:subprotocol:database"
    driver="database_driver_name"
    jndiname="JNDI_context/logical_name">
</tsx:dbconnect>
```

where:

- **id**

  Represents a required identifier. The scope is the JSP file. This identifier is referenced by the connection attribute of a <tsx:dbquery> tag.
- **userid**

  Represents an optional attribute that specifies a valid user ID for the database that you want to access. Specify this attribute to add the attribute and its value to the request object.

  Although the userid attribute is optional, you must provide the user ID. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this information in the JSP file.
- **passwd**

  Represents an optional attribute that specifies the user password for the userid attribute. (This attribute is not optional if the userid attribute is specified.) If you specify this attribute, the attribute and its value are added to the request object.

  Although the passwd attribute is optional, you must provide the password. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this attribute in the JSP file.
- **url** and **driver**

  Respresents a required attribute if you want to establish a database connection. You must provide the URL and driver.

  The application server supports connection to JDBC databases and ODBC databases.
  - For a JDBC database, the URL consists of the following colon-separated elements: jdbc, the subprotocol name, and the name of the database to access. An example for a connection to the Sample database included with IBM DB2 is:

    ```
    url="jdbc:db2:sample"
    driver="COM.ibm.db2.jdbc.app.DB2Driver"
    ```
  - For an ODBC database, use the Sun JDBC-to-ODBC bridge driver included in their Java2 Software Developers Kit (SDK) or another vendor's ODBC driver.

    The url attribute specifies the location of the database. The driver attribute specifies the name of the driver to use in establishing the database connection.

    If the database is an ODBC database, you can use an ODBC driver or the Sun JDBC-to-ODBC bridge. If you want to use an ODBC driver, refer to the driver documentation for instructions on specifying the database location with the url attribute and the driver name.

    If you use the bridge, the url syntax is `jdbc:odbc:`*`database`*. An example follows:

    ```
    url="jdbc:odbc:autos"
    driver="sun.jdbc.odbc.JdbcOdbcDriver"
    ```

    Note: To enable the application server to access the ODBC database, use the ODBC Data Source Administrator to add the ODBC data source to the System DSN configuration. To access the ODBC Administrator, click the ODBC icon on the Windows NT Control Panel.
- **jndiname**

  Represents an optional attribute that identifies a valid context in the application server Java Naming and Directory Interface (JNDI) naming context and the logical name of the data source in that context. The Web administrator configures the context using an administrative client such as the WebSphere Administrative Console.

  If you specify the jndiname attribute, the JSP processor ignores the driver and url attributes on the <tsx:dbconnect> tag.

An empty element (such as <url></url>) is valid.

dbquery tag JavaServer Pages syntax: Use the <tsx:dbquery> tag to establish a connection to a database, submit database queries, and return the results set.

The <tsx:dbquery> tag does the following:
1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information the tag provides to determine the database URL and driver. You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are provided in the <tsx:dbconnect> tag.
2. Establishes a new connection
3. Retrieves and caches data in the results object.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbquery> tag.

```
<%-- SELECT commands and (optional) JSP syntax can be placed within the tsx:dbquery. --%>
<%-- Any other syntax, including HTML comments, are not valid. --%>
<tsx:dbquery id="query_id" connection="connection_id" limit="value" >
</tsx:dbquery>
```

where:
- **id**

  Represents the identifier of this query. The scope is the JSP file. Use `id` to reference the query. For example, from the <tsx:getProperty> tag, use `id` to display the query results.

  The `id` is a tsx reference to the bean and can be used to retrieve the bean from the page contect. For example, if id is named mySingleDBBean, instead of using:
  – if (mySingleDBBean.getValue(″UISEAM″,0).startsWith(″N″))

  use:
  – com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults bean = (com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults)pageContext. findAttribute(″mySingleDBBean″); if (bean.getValue(″UISEAM″,0).startsWith(″N″)). . .

  The bean properties are dynamic and the property names are the names of the columns in the results set. If you want different column names, use the SQL keyword for specifying an alias on the SELECT command. In the following example, the database table contains columns named FNAME and LNAME, but the SELECT statement uses the `AS` keyword to map those column names to FirstName and LastName in the results set:

  ```
  Select FNAME, LNAME AS FirstName, LastName from Employee where FNAME='Jim'
  ```
- **connection**

  Represents the identifier of a <tsx:dbconnect> tag in this JSP file. The <tsx:dbconnect> tag provides the database URL, driver name, and optionally, the user ID and password for the connection.
- **limit**

  Represents an optional attribute that constrains the maximum number of records returned by a query. If this attribute is not specified, no limit is used. In such a case, the effective limit is determined by the number of records and the system caching capability.
- SELECT command and JSP syntax

  Represents the only valid SQL command, SELECT. The <tsx:dbquery> tag must return a results set. Refer to your database documentation for information about the SELECT command. See other articles in this section for a description of JSP syntax for variable data and inline Java code.

dbmodify tag JavaServer Pages syntax: The <tsx:dbmodify> tag establishes a connection to a database and then adds records to a database table.

The <tsx:dbmodify> tag does the following:
1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information provided by that tag to determine the database URL and driver.

   Note: You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are provided in the <tsx:dbconnect> tag.

2. Establishes a new connection.
3. Updates a table in the database.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbmodify> tag.

```
<%-- Any valid database update commands can be placed within the DBMODIFY tag. -->
<%-- Any other syntax, including HTML comments, are not valid. -->
<tsx:dbmodify connection="connection_id">
</tsx:dbmodify>
```

where:

- **connection**

  Represents the identifier of a <tsx:dbconnect> tag in this JSP file. The <tsx:dbconnect> tag provides the database URL, driver name, and (optionally) the user ID and password for the connection.
- Database commands

  Represents valid database commands. Refer to your database documentation for details

tsx:getProperty tag JavaServer Pages syntax and examples: The `<tsx:getProperty>` tag gets the value of a bean to display in a JavaServer Pages (JSP) file.

This IBM extension of the Sun JSP <jsp:getProperty> tag implements all of the <jsp:getProperty> function and adds the ability to introspect a database bean created using the IBM extension <tsx:dbquery> or <tsx:dbmodify>.

Note: You cannot assign the value from this tag to a variable. The value, generated as output from this tag, displays in the browser window.

This section describes the syntax of the `<tsx:getProperty>` tag:

```
<tsx:getProperty name="bean_name"
  property="property_name" />
```

where:

- **name**

  Represents the name of the bean declared by the `id` attribute of a <tsx:dbquery> syntax within the JSP file. See <tsx:dbquery> for an explanation. The value of this attribute is case-sensitive.
- **property**

  Represents the property of the bean to access for substitution. The value of the attribute is case-sensitive and is the locale-independent name of the property.

Tag example:

```
<tsx:getProperty name="userProfile" property="username" />
```

tsx:userid and tsx:passwd tag JavaServer Pages syntax: With the <tsx:userid> and <tsx:passwd> tags, you do not have to hard code a user ID and password in the <tsx:dbconnect> tag.

Use the <tsx:userid> and <tsx:passwd> tags to accept user input for the values and then add that data to the request object. You can access the request object with a JavaServer Pages (JSP) file, such as the *JSPEmployee.jsp* example that requests the database connection.

You must use <tsx:userid> and <tsx:passwd> tags within a <tsx:dbconnect> tag.

This section describes the syntax of the <tsx:userid> and <tsx:passwd> tags.

```
<tsx:dbconnect id="connection_id"
    <font color="red"><userid></font>
    <tsx:getProperty name="request" property=request.getParameter("userid") />
    <font color="red"></userid></font>
```

```
    <font color="red"><passwd></font>
    <tsx:getProperty name="request" property=request.getParameter("passwd") />
    <font color="red"></passwd></font>
    url="protocol:database_name:database_table"
    driver="JDBC_driver_name">
</tsx:dbconnect>
```

where:

- **<tsx:getProperty>**

  Represents the syntax as a mechanism for embedding variable data.
- **userid**

  Represents a reference to the request parameter that contains the user ID. You must add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string to pass the user-specified request parameters.
- **passwd**

  Represents a reference to the request parameter that contains the password. Add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string, to pass user-specified values.

tsx:repeat tag JavaServer Pages syntax: The <tsx:getProperty> tag repeats a block of HTML tagging.

Use the <tsx:repeat> syntax to iterate over a database query results set. The <tsx:repeat> syntax iterates from the start value to the end value until one of the following conditions is met:

- The end value is reached.
- An exception is thrown.

If an exception of the types **ArrayIndexOutOfBoundsException** or **NoSuchElementException** is created before a block completes, output is written only for the iterations up to and not including the iteration during which the exception was created. All other exceptions results in no output being written for that tag instance.

This section describes the syntax of the <tsx:repeat> tag:

```
<tsx:repeat index="name" start="starting_index" end="ending_index">
</tsx:repeat>
```

where:

- **index**

  Represents an optional name used to identify the index of this repeat block. The scope of the index is NESTED. Its type must be integer.
- **start**

  Represents an optional starting index value for this repeat block. The default is 0.
- **end**

  Represents an optional ending index value for this repeat block. The maximum value is 2,147,483,647.

  If the value of the end attribute is less than the value of the start attribute, the end attribute is ignored.

Example: Combining tsx:repeat and tsx:getProperty JavaServer Pages tags: The following code snippet shows you how to code these tags:

```
<tsx:repeat>
<tr>
    <td><tsx:getProperty name="empqs" property="EMPNO" />
    <tsx:getProperty name="empqs" property="FIRSTNME" />
    <tsx:getProperty name="empqs" property="WORKDEPT" />
    <tsx:getProperty name="empqs" property="EDLEVEL" />
    </td>
</tr>
</tsx:repeat>
```

Example: tsx:dbmodify tag syntax: In the following example, a new employee record is added to a database. The values of the fields are based on user input from this JavaServer Pages (JSP) file and referenced in the database commands using the <tsx:getProperty> tag.

```
<tsx:dbmodify connection="conn" >
insert into EMPLOYEE
    (EMPNO,FIRSTNME,MIDINIT,LASTNAME,WORKDEPT,EDLEVEL)
values
('<tsx:getProperty name="request" property=request.getParameter("EMPNO") />',
'<tsx:getProperty name="request" property=request.getParameter("FIRSTNME") />',
'<tsx:getProperty name="request" property=request.getParameter("MIDINIT") />',
'<tsx:getProperty name="request" property=request.getParameter("LASTNAME") />',
'<tsx:getProperty name="request" property=request.getParameter("WORKDEPT") />',
<tsx:getProperty name="request" property=request.getParameter("EDLEVEL") />)
</tsx:dbmodify>
```

Example: Using tsx:repeat JavaServer Pages tag to iterate over a results set: The <tsx:repeat> tag iterates over a results set. The results set is contained within a bean. The bean can be a static bean, for example, a bean created by using the IBM WebSphere Studio database wizard, or a dynamically generated bean, for example, a bean generated by the <tsx:dbquery> syntax. The following table is a graphic representation of the contents of a bean called, *myBean*:

	col1	col2	col3
row0	friends	Romans	countrymen
row1	bacon	lettuce	tomato
row2	May	June	July

Some observations about the bean:

- The column names in the database table become the property names of the bean. The <tsx:dbquery> section describes a technique for mapping the column names to different property names.
- The bean properties are indexed. For example, `myBean.get(Col1(row2))` returns `May`.
- The query results are in the rows. The <tsx:repeat> tag iterates over the rows, beginning at the start row.

The following table compares using the <tsx:repeat> tag to iterate over a static bean, versus a dynamically generated bean:

Static Bean Example	<tsx:repeat> Bean Example

myBean.class
`// Code to get a connection`
 	
`// Code to get the data`
`Select * from myTable;`
 	
`// Code to close the connection`
 	
JSP file
`<tsx:repeat index=abc>`
`<tsx:getProperty name="myBean"`
`property="col1(abc)" />`
`</tsx:repeat>`
 	
Notes:
• The bean (myBean.class) is a static bean.
• The method to access the bean properties is myBean.get(*property*(*index*)).
• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.
• The <tsx:repeat> tag iterates over the bean properties row by row, beginning with the start row.
	JSP file
	`<tsx:dbconnect id="conn"`
	`userid="alice"passwd="test"`
	`url="jdbc:db2:sample"`
	`driver="COM.ibm.db2.jdbc.app.DB2Driver">`
	`</tsx:dbconnect >`
	
	`<tsx:dbquery id="dynamic"`
	`connection="conn" >`
	`Select * from myTable;`
	`</tsx:dbquery>`
	
	`<tsx:repeat index=abc>`
	`<tsx:getProperty name="dynamic"`
	`property="col1(abc)" />`
	`</tsx:repeat>`
	
	Notes:
	• The bean (dynamic) is generated by the <tsx:dbquery> tag and does not exist until the syntax executes.
	• The method to access the bean properties is dynamic.getValue(*"property"*, *index*).
	• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.
	• The <tsx:repeat> tag syntax iterates over the bean properties row by row, beginning with the start row.

Implicit and explicit indexing

Examples 1, 2, and 3 show how to use the <tsx:repeat> tag. The examples produce the same output if all indexed properties have 300 or fewer elements. If there are more than 300 elements, Examples 1 and 2 display all elements, while Example 3 shows only the first 300 elements.

Example 1 shows *implicit indexing* with the default start and default end index. The bean with the smallest number of indexed properties restricts the number of times the loop repeats.

```
<table>
<tsx:repeat>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone" />
  </tr></td>
</tsx:repeat>
</table>
```

Example 2 shows indexing, starting index, and ending index:

```
<table>
<tsx:repeat index=myIndex start=0 end=2147483647>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=city(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=address(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=telephone(myIndex) />
</tr></td>
</tsx:repeat>
</table>
```

Example 3 shows *explicit indexing* and ending index with implicit starting index. Although the index attribute is specified, you can still implicitly index the indexed property city because the (`myIndex`) tag is not required.

```
<table>
<tsx:repeat index=myIndex end=299>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" /t>
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address(myIndex)" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone(myIndex)" />
  </tr></td>
</tsx:repeat>
</table>
```

Nesting <tsx:repeat> blocks

You can nest <tsx:repeat> blocks. Each block is separately indexed. This capability is useful for interleaving properties on two beans, or properties that have subproperties. In the example, two <tsx:repeat> blocks are nested to display the list of songs on each compact disc in the user's shopping cart.

```
<tsx:repeat index=cdindex>
  <h1><tsx:getProperty name="shoppingCart" property=cds.title /></h1>
  <table>
  <tsx:repeat>
    <tr><td><tsx:getProperty name="shoppingCart" property=cds(cdindex).playlist />
    </td></tr>
  </tsx:repeat>
  </table>
 </tsx:repeat>
```

Web modules

A Web module represents a Web application. A Web module is created by assembling servlets, JavaServer Pages (JSP) files, and static content such as Hypertext Markup Language (HTML) pages into a single deployable unit. Web modules are stored in Web archive (WAR) files, which are standard Java archive files.

A Web module contains:

- One or more servlets, JSP files, and HTML files.
- A deployment descriptor, stored in an Extensible Markup Language (XML) file.

  The file, named `web.xml`, declares the contents of the module. It contains information about the structure and external dependencies of Web components in the module and describes how the components are used at run time.

You can create Web modules as stand-alone applications, or you can combine Web modules with other modules to create Java 2 Platform, Enterprise Edition (J2EE) applications. You install and run a Web module in the Web container of an application server.

Troubleshooting tips for Web application deployment

Deployment of a Web application is successful if you can access the application by typing a Uniform Resource Locator (URL) in a browser, or if you can access the application by following a link.

If you cannot access your application, follow these steps to eliminate some common errors that can occur during migration or deployment.

Web module does not run in WebSphere Application Server Version 5 or 6.

Symptom Your Web module does not run when you migrate it to Version 5 or 6

Problem In Version 4.x, the classpath setting that affected visibility was *Module Visibility Mode*. In Versions 5 and 6, you must use class loader policies to set visibility.

Recommended response Reassemble an existing module, or change the visibility settings in the class loader policies.

See the articles “Class loaders” on page 25 and Chapter 4, “Class loading,” on page 25 for more information.

Welcome page is not visible.

Symptom You cannot access an application with a Web path of:

```
/webapp/myapp
```

Problem The default welcome page for a Web application is assumed to be *index.html*. You cannot access the default page of the *myapp* application unless it is named *index.html*.

Recommended response To identify a different welcome page, modify the properties of the Web module during assembly. See the article Assembling Web applications for more information.

HTML files are not found.

Symptom Your Web application ran successfully on prior versions, but now you encounter errors that the welcome page (typically *index.html*), or referenced HTML files are not found:

```
Error 404: File not found: Banner.html
Error 404: File not found: HomeContent.html
```

Problem For security and consistency reasons, Web application URLs are now case-sensitive on all operating systems.

Suppose the content of the index page is as follows:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 5.0 Frameset//EN">
<HTML>
<TITLE>
Insurance Home Page
</TITLE>
    <frameset   rows="18,80">
    <frame      src="Banner.html"         name="BannerFrame"  SCROLLING=NO>
    <frame      src="HomeContent.html"    name="HomeContentFrame">
    </frameset>
</HTML>
```

However the actual file names in the `\WebSphere\AppServer\installedApps\...` directory where the application is deployed are:

```
banner.html
homecontent.html
```

Recommended response To correct this problem, modify the *index.html* file to change the names *Banner.html* and *HomeContent.html* to *banner.html* and *homecontent.html* to match the names of the files in the deployed application.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Web applications: Resources for learning

Use the following links to find relevant supplemental information about Web applications. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Task overview: Managing HTTP sessions

IBM WebSphere Application Server provides a service for managing HTTP sessions: Session Manager. The key activities for session management are summarized below.

Before you begin these steps, make sure you are familiar with the programming model for accessing HTTP session support in the applications following the Servlet 2.4 API.

1. Plan your approach to session management, which could include session tracking, session recovery, and session clustering.
2. Create or modify your own applications to use session support to maintain sessions on behalf of Web applications.
3. Assemble your application.
4. Deploy your application.
5. Ensure the administrator appropriately configures session management in the administrative domain.
6. Adjust configuration settings and perform other tuning activities for optimal use of sessions in your environment.

Sessions

A session is a series of requests to a servlet, originating from the same user at the same browser.

Sessions allow applications running in a Web container to keep track of individual users.

For example, a servlet might use sessions to provide ″shopping carts″ to online shoppers. Suppose the servlet is designed to record the items each shopper indicates he or she wants to purchase from the Web site. It is important that the servlet be able to associate incoming requests with particular shoppers. Otherwise, the servlet might mistakenly add Shopper_1's choices to the cart of Shopper_2.

A servlet distinguishes users by their unique session IDs. The session ID arrives with each request. If the user's browser is cookie-enabled, the session ID is stored as a cookie. As an alternative, the session ID can be conveyed to the servlet by URL rewriting, in which the session ID is appended to the URL of the servlet or JavaServer Pages (JSP) file from which the user is making requests. For requests over HTTPS or Secure Sockets Layer (SSL), Another alternative is to use SSL information to identify the session.

Session security support

You can integrate HTTP sessions and security in WebSphere Application Server. When security integration is enabled in the session management facility and a session is accessed in a protected resource, you can access that session only in protected resources from then on. You cannot mix secured and unsecured resources accessing sessions when security integration is turned on. Security integration in the session management facility is not supported in form-based login with SWAM.

Security integration rules for HTTP sessions

Only authenticated users can access sessions created in secured pages and are created under the identity of the authenticated user. Only this authenticated user can access these sessions in other secured pages. To protect these sessions from unauthorized users, you cannot access them from an unsecured page.

Programmatic details and scenarios

WebSphere Application Server maintains the security of individual sessions.

An identity or user name, readable by the com.ibm.websphere.servlet.session.IBMSession interface, is associated with a session. An unauthenticated identity is denoted by the user name `anonymous`. WebSphere Application Server includes the com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException class, which is used when a session is requested without the necessary credentials.

The session management facility uses the WebSphere Application Server security infrastructure to determine the authenticated identity associated with a client HTTP request that either retrieves or creates a session. WebSphere Application Server security determines identity using certificates, LPTA, and other methods.

After obtaining the identity of the current request, the session management facility determines whether to return the session requested using a getSession call.

The following table lists possible scenarios in which security integration is enabled with outcomes dependent on whether the HTTP request is authenticated and whether a valid session ID and user name was passed to the session management facility.

	Unauthenticated HTTP request is used to retrieve a session	**HTTP request is authenticated, with an identity of ″FRED″ used to retrieve a session**
No session ID was passed in for this request, or the ID is for a session that is no longer valid	A new session is created. The user name is `anonymous`	A new session is created. The user name is `FRED`
A session ID for a valid session is passed in. The current session user name is ″anonymous″	The session is returned.	The session is returned. session management changes the user name to `FRED`
A session ID for a valid session is passed in. The current session user name is `FRED`	The session is not returned. An UnauthorizedSessionRequestException error is created*	The session is returned.
A session ID for a valid session is passed in. The current session user name is `BOB`	The session is not returned. An UnauthorizedSessionRequestException error is created*	The session is not returned. An UnauthorizedSessionRequestException error is created*

* A com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException error is created to the servlet.

Session management support

WebSphere Application Server provides facilities, grouped under the heading *Session Management*, that support the javax.servlet.http.HttpSession interface described in the Servlet API specification.

In accordance with the Servlet 2.3 API specification, the session management facility supports session scoping by Web modules. Only servlets in the same Web module can access the data associated with a particular session. Multiple requests from the same browser, each specifying a unique Web application, result in multiple sessions with a shared session ID. You can invalidate any of the sessions that share a session ID without affecting the other sessions.

You can configure a session timeout for each Web application. A Web application timeout value of 0 (the default value) means that the invalidation timeout value from the session management facility is used.

When an HTTP client interacts with a servlet, the state information associated with a series of client requests is represented as an HTTP session and identified by a session ID. Session management is responsible for managing HTTP sessions, providing storage for session data, allocating session IDs, and tracking the session ID associated with each client request through the use of cookies or URL rewriting techniques. Session management can store session-related information in several ways:

- In application server memory (the default). This information cannot be shared with other application servers.
- In a database. This storage option is known as *database persistent sessions*.
- In another WebSphere Application Server instance. This storage option is known as *memory-to-memory sessions*.

The last two options are referred to as *distributed sessions*. Distributed sessions are essential for using HTTP sessions for the failover facility. When an application server receives a request associated with a session ID that it currently does not have in memory, it can obtain the required session state by accessing the external store (database or memory-to-memory). If distributed session support is not enabled, an application server cannot access session information for HTTP requests that are sent to servers other than the one where the session was originally created. Session management implements caching optimizations to minimize the overhead of accessing the external store, especially when consecutive requests are routed to the same application server.

Storing session states in an external store also provides a degree of fault tolerance. If an application server goes offline, the state of its current sessions is still available in the external store. This availability enables other application servers to continue processing subsequent client requests associated with that session.

Saving session states to an external location does not completely guarantee their preservation in case of a server failure. For example, if a server fails while it is modifying the state of a session, some information is lost and subsequent processing using that session can be affected. However, this situation represents a very small period of time when there is a risk of losing session information.

The drawback to saving session states in an external store is that accessing the session state in an external location can use valuable system resources. session management can improve system performance by caching the session data at the server level. Multiple consecutive requests that are directed to the same server can find the required state data in the cache, reducing the number of times that the actual session state is accessed in external store and consequently reducing the overhead associated with external location access.

Session tracking options

There are several options for session tracking, depending on what sort of tracking method you want to use:

- Session tracking with cookies
- Session tracking with URL rewriting
- Session tracking with Secure Sockets Layer (SSL) information

Session tracking with cookies: Tracking sessions with cookies is the default. No special programming is required to track sessions with cookies.

Session tracking with URL rewriting: An application that uses URL rewriting to track sessions must adhere to certain programming guidelines. The application developer needs to do the following:
- Program servlets to encode URLs
- Supply a servlet or JavaServer Pages (JSP) file as an entry point to the application

Using URL rewriting also requires that you enable URL rewriting in the session management facility.

Note: In certain cases, clients cannot accept cookies. Therefore, you cannot use cookies as a session tracking mechanism. Applications can use URL rewriting as a substitute.

Program session servlets to encode URLs

Depending on whether the servlet is returning URLs to the browser or redirecting them, include either the encodeURL method or the encodeRedirectURL method in the servlet code. Examples demonstrating what to replace in your current servlet code follow.

Rewrite URLs to return to the browser

Suppose you currently have this statement:

```
out.println("<a href=\"/store/catalog\">catalog<a>");
```

Change the servlet to call the encodeURL method before sending the URL to the output stream:

```
out.println("<a href=\"");
out.println(response.encodeURL ("/store/catalog"));
out.println("\">catalog</a>");
```

Rewrite URLs to redirect

Suppose you currently have the following statement:

```
response.sendRedirect ("http://myhost/store/catalog");
```

Change the servlet to call the encodeRedirectURL method before sending the URL to the output stream:

```
response.sendRedirect (response.encodeRedirectURL ("http://myhost/store/catalog"));
```

The encodeURL method and encodeRedirectURL method are part of the HttpServletResponse object. These calls check to see if URL rewriting is configured before encoding the URL. If it is not configured, the calls return the original URL.

If both cookies and URL rewriting are enabled and the response.encodeURL method or encodeRedirectURL method is called, the URL is encoded, even if the browser making the HTTP request processed the session cookie.

You can also configure session support to enable protocol switch rewriting. When this option is enabled, the product encodes the URL with the session ID for switching between HTTP and HTTPS protocols.

Supply a servlet or JSP file as an entry point

The entry point to an application, such as the initial screen presented, may not require the use of sessions. However, if the application in general requires session support (meaning some part of it, such as a servlet, requires session support), then after a session is created, all URLs are encoded to perpetuate the session ID for the servlet (or other application component) requiring the session support.

The following example shows how you can embed Java code within a JSP file:

```
<%
response.encodeURL ("/store/catalog");
%>
```

Session tracking with SSL information: No special programming is required to track sessions with Secure Sockets Layer (SSL) information.

To use SSL information, turn on **Enable SSL ID tracking** in the session management property page. Because the SSL session ID is negotiated between the Web browser and HTTP server, this ID cannot survive an HTTP server failure. However, the failure of an application server does not affect the SSL session ID if an external HTTP server is present between WebSphere Application Server and the browser.

SSL tracking is supported for the IBM HTTP Server and iPlanet Web servers only. You can control the lifetime of an SSL session ID by configuring options in the Web server. For example, in the IBM HTTP Server, set the configuration variable SSLV3TIMEOUT to provide an adequate lifetime for the SSL session ID. An interval that is too short can cause a premature termination of a session. Also, some Web browsers might have their own timers that affect the lifetime of the SSL session ID. These Web browsers may not leave the SSL session ID active long enough to serve as a useful mechanism for session tracking. The internal HTTP Server of WebSphere Application Server also supports SSL tracking.

When using the SSL session ID as the session tracking mechanism in a cloned environment, use either cookies or URL rewriting to maintain session affinity. The cookie or rewritten URL contains session affinity information that enables the Web server to properly route a session back to the same server for each request.

Distributed sessions

WebSphere Application Server provides the following session mechanisms in a distributed environment:

- **Database Session persistence**, where sessions are stored in the database specified.
- **Memory-to-memory Session replication**, where sessions are stored in one or more specified WebSphere Application Server instances.

When a session contains attributes that implement HttpSessionActivationListener, notification occurs anytime the session is activated (that is, session is read to the memory cache) or passivated (that is, session leaves the memory cache). Passivation can occur because of a server shutdown or when the session memory cache is full and an older session is removed from the memory cache to make room for a newer session. It is not guaranteed that a session is passivated in one application server prior to being activated in another.

Session recovery support

For session recovery support, WebSphere Application Server provides distributed session support in the form of database sessions and memory-to-memory replication. Use session recovery support under the following conditions:

- When the user's session data must be maintained across a server restart
- When the user's session data is too valuable to lose through an unexpected server failure

All the attributes set in a session must implement java.io.Serializable if the session requires external storage. In general, consider making all objects held by a session serialized, even if immediate plans do not call for session recovery support. If the Web site grows, and session recovery support becomes necessary, the transition occurs transparently to the application if the sessions only hold serialized objects. If not, a switch to session recovery support requires coding changes to make the session contents serialized.

Distributed environment settings:

Use this page to specify a type for saving a session in a distributed environment.

To view this administrative console page, click **Servers** > **Application servers** > *server_name* > **Web container settings** > **Session management** > **Distributed environment settings**.

Distributed sessions:

Specifies the type of distributed environment to be used for saving sessions.

None	Specifies that the session management facility discards the session data when the server shuts down.
Database	Specifies that the session management facility stores session information in the data source specified by the data source connection settings. Click **Database** to change these data source settings.
Memory-to-memory replication	Specifies that the session management facility stores the session information in a data source in memory. The session information is copied to other session management facilities for failure recovery.

Memory-to-memory replication

WebSphere Application Server supports session replication to another WebSphere Application Server instance. This support is referred to as *memory-to-memory session replication*. In this mode, sessions can replicate to one or more WebSphere Application Server instances to address HTTP Session single point of failure (SPOF).

The WebSphere Application Server instance in which the session is currently processed is referred to as the *owner of the session*. In a clustered environment, session affinity in the WebSphere Application Server plug-in routes the requests for a given session to the same server. If the current owner server instance of the session fails, then the WebSphere Application Server plug-in routes the requests to another appropriate server in the cluster. In a peer-to-peer cluster, the hot failover feature causes the plug-in to failover to a server that already contains the backup copy of the session, avoiding the overhead of session retrieval from another server containing the backup. In a client/server cluster, the server retrieves the session from a server that has the backup copy of the session. The server now becomes the owner of the session and affinity is now maintained to this server.

There are three possible modes. You can set up a WebSphere Application Server instance to run in:
- **Server mode:** Only store backup copies of other WebSphere Application Server sessions and not to send out copies of any session created in that particular server
- **Client mode:** Only broadcast or send out copies of the sessions it owns and not to receive backup copies of sessions from other servers
- **Both mode:** Simultaneously broadcast or send out copies of the sessions it owns and act as a backup table for sessions owned by other WebSphere Application Server instances

You can select the replication mode of server, client, or both when configuring the session management facility for memory-to-memory replication. The default is both. This storage option is controlled by the mode parameter.

The memory-to-memory replication function is accomplished by the creation of a data1 replication service instance in an application server that talks to other data replication service instances in remote application servers. You must configure this data replication service instance as a part of a replication domain. See ″Replication domain collection″ in the information center. Data replication service instances on disparate application servers that replicate to one another must be configured as a part of the same domain. You must configure all session managers connected to a replication domain to have the same topology. If one session manager instance in a domain is configured to use the client/server topology, then the rest of the session manager instances in that domain must be a combination of servers configured as Client only and Server only. If one session manager instance is configured to use the peer-to-peer topology, then all session manager instances must be configured as Both client and server. For example, a server only data

replication service instance and a both client and server data replication service instance cannot exist in the same replication domain. Multiple data replication service instances that exist on the same application server due to session manager memory-to-memory configuration at various levels that are configured to be part of the same domain must have the same mode.

With respect to mode, the following are the primary examples of memory-to-memory replication configuration:

- Peer-to-peer replication
- Client/server replication

Although the administrative console allows flexibility and additional possibilities for memory-to-memory replication configuration, only the configurations provided above are officially supported.

There is a single replica in a cluster by default. You can modify the number of replicas through the replication domain.

HTTP session replication in the controller

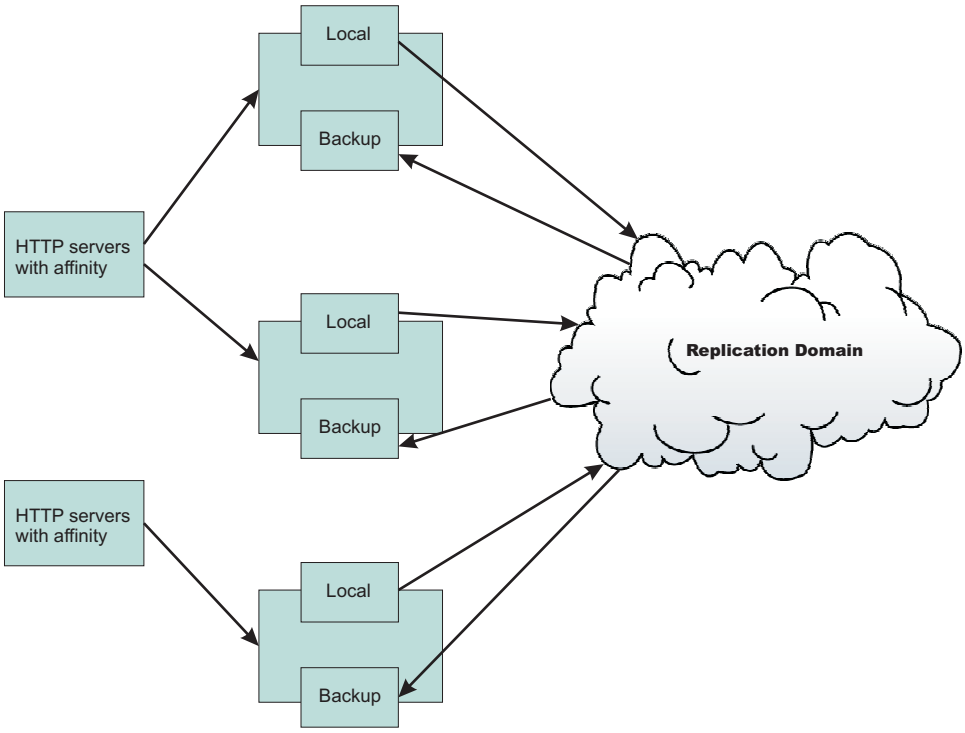
WebSphere Application Servers on z/OS that are enabled for HTTP session memory-to-memory replication can store replicated HTTP session data in the controller and replicate data to other WebSphere Application Servers. HTTP session data that is stored in a controller is retrievable by any of the servants of that controller. HTTP session affinity is still associated to a particular servant; however, if that servant should fail, any of the other servants can retrieve the HTTP session data stored in the controller and establish a new affinity.

The capability of storing HTTP sessions in the controller can also be enabled in unmanaged application servers on z/OS. When this capability is enabled, servants store the HTTP session data in the controller for retrieval when a servant fails which is similar to managed servers. HTTP session data stored in the controller of an unmanaged application server is not retrievable by other application servers and is not replicated to other application servers.

The capability to store HTTP session data in the controller in an unmanaged application server is enabled by setting the JVM custom property HttpSessionEnableUnmanagedServerReplication to true. You can set this property at **Servers > Application servers >***server_name* **> Java and Process Management > Process Definition > Servant > Java Virtual Machine > Custom Properties**.

Memory-to-memory topology: Peer-to-peer function:

The basic peer-to-peer (both client and server function, or both mode) topology is the default configuration and has a single replica. However, you can also add additional replicas by configuring the replication domain.



In this basic peer-to-peer topology, each server Java Virtual Machine (JVM) can:

- Host the Web application leveraging the HTTP session
- Send out changes to the HTTP session that it owns
- Receive backup copies of the HTTP session from all of the other servers in the cluster

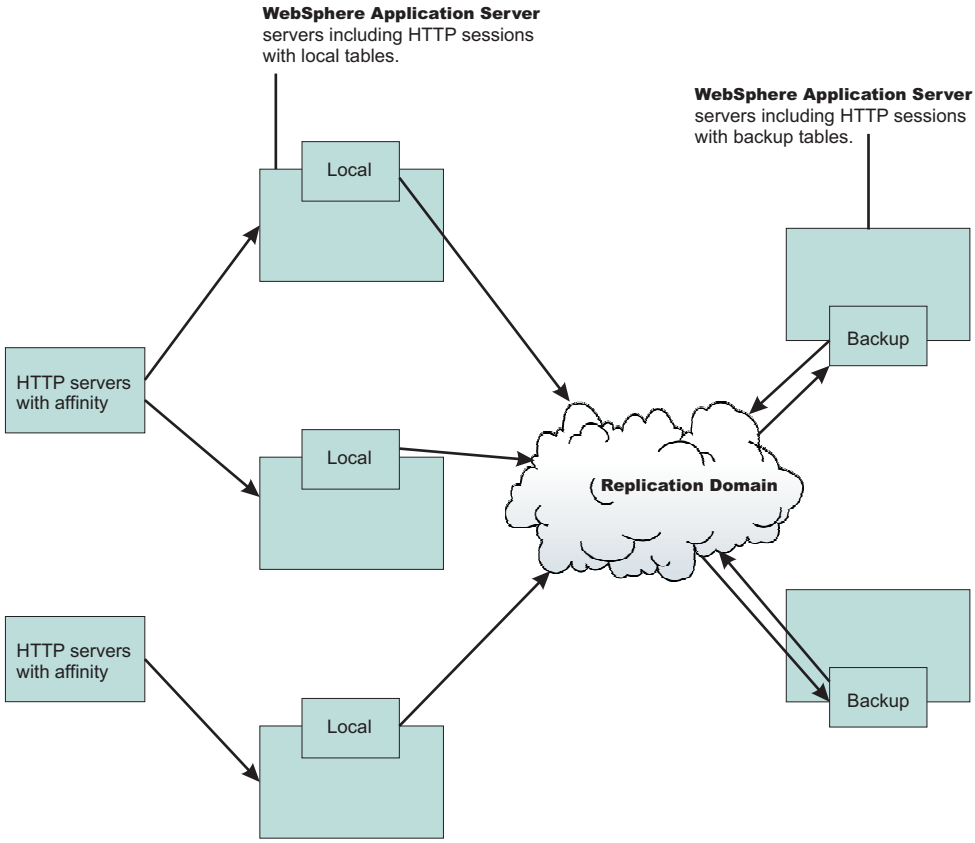
This configuration represents the most consolidated topology, where the various system parts are collocated and requires the fewest server processes. When using this configuration, the most stable implementation is achieved when each node has equal capabilities (CPU, memory, and so on), and each handles the same amount of work.

Session hot failover

A new feature called session hot failover has been added to this release. This feature is only applicable to the peer-to-peer mode. In a clustered environment, session affinity in the WebSphere Application Server plug-in routes the requests for a given session to the same server. If the current owner server instance of the session fails, then the WebSphere Application Server plug-in routes the requests to another appropriate server in the cluster. For a cluster configured to run in the peer-to-peer mode this feature causes the plug-in to failover to a server that already contains the backup copy of the session, therefore avoiding the overhead of session retrieval from another server containing the backup.

You must upgrade all WebSphere Application Server plug-in instances that front the Application Server cluster to version 6.0 to ensure session affinity when using the peer-to-peer mode.

Memory-to-memory topology: Client/server function: The following figure depicts the client/server mode. There is a tier of applications servers that host Web applications using HTTP sessions, and these sessions are replicated out as they are created and updated. There is a second tier of servers without a Web application installed, where the session manager receives updates from the replication clients.



Benefits of the client/server configuration include:

Isolation (for failure recovery)
In this case we are isolating the handling of backup data from local data; aside from isolating the moving parts in case of a catastrophic failure in one of them, you again free up memory and processing in the servers processing the Web application

Isolation for stopping and starting
You can recycle a backup server without affecting the servers running the application (when there are two or more backups, failure recovery is possible), and conversely recycle an application JVM without potentially losing that backup data for someone.

Consolidation
There is most likely no need to have a one-to-one correspondence between servers handling backups and those processing the applications; hence, you are again reducing the number of places to which you transfer the data.

Disparate hardware:
While you run your Web applications on cheaper hardware, you may have one or two more powerful computers in the back end of your enterprise that have the capacity to run a couple of session managers in replication server mode; allowing you to free up your cheaper Web application hardware to process the Web application.

Timing consideration: Start the backup application servers first to avoid unexpected timing windows. The clients attempt to replicate information and HTTP sessions to the backup servers as soon as they come up. As a result, HTTP sessions that are created prior to the time at which the servers come up might not replicate successfully.

Memory-to-memory session partitioning

Session partitioning gives the administrator the ability to filter or reduce the number of destinations that the session object gets sent to by the replication service. You can also configure session partitioning by specifying the number of replicas on the replication domain. The Single replica option is chosen by default. Since the number of replicas is global for the entire replication domain, all the session managers connected to the replication domain use the same setting.

Single replica

You can replicate a session to only one other server, creating a single replica. When this option is chosen, a session manager picks another session manager that is connected to the same replication domain to replicate the HTTP session to during session creation. All updates to the session are only replicated to that single server. This option is set at the replication domain level. When this option is set, every session manager connected to this replication domain creates a single backup copy of HTTP session state information on a backup server.

Full group replica

Each object is replicated to every application server that is configured as a consumer of the replication domain. However, this topology is the most redundant because everyone replicates to everyone and as you add servers, more overhead (both CPU and memory) is needed to deal with replication. This mode is most useful for dynamic caching replication.

Specific number of replicas

You can specify a specific number of replicas for any entry that is created in the replication domain. The number of replicas is the number of application servers that the user wants to use to replicate in the domain. This option eliminates redundancy that occurs in a full group replica and also provides additional backup than a single replica. The number of replicas cannot exceed the total number of application servers in the cluster.

Clustered session support

A clustered environment supports load balancing, where the workload is distributed among the application servers that compose the cluster. In a cluster environment, the same Web application must exist on each of the servers that can access the session. You can accomplish this setup by installing an application onto a cluster definition. Each of the servers in the group can then access the Web application

In a clustered environment, the session management facility requires an affinity mechanism so that all requests for a particular session are directed to the same application server instance in the cluster. This requirement conforms to the Servlet 2.3 specification in that multiple requests for a session cannot coexist in multiple application servers. One such solution provided by IBM WebSphere Application Server is *session affinity* in a cluster; this solution is available as part of the WebSphere Application Server plug-ins for Web servers. It also provides for better performance because the sessions are cached in memory. In clustered environments other than WebSphere Application Server clusters, you must use an affinity mechanism (for example, IBM WebSphere Edge Server affinity).

If one of the servers in the cluster fails, it is possible for the request to reroute to another server in the cluster. If distributed sessions support is enabled, the new server can access session data from the database or another WebSphere Application Server instance. You can retrieve the session data only if a new server has access to an external location from which it can retrieve the session.

Tuning session management

WebSphere Application Server session support has features for tuning session performance and operating characteristics, particularly when sessions are configured in a distributed environment. These options support the administrator flexibility in determining the performance and failover characteristics for their environment.

The table summarizes the features, including whether they apply to sessions tracked in memory, in a database, with memory-to-memory replication, or all. Click a feature for details about the feature. Some features are easily manipulated using administrative settings; others require code or database changes.

Feature or option	Goal	Applies to sessions in memory, database, or memory-to-memory
Write frequency	Minimize database write operations.	Database and Memory-to-Memory
Session affinity	Access the session in the same application server instance.	All
Multirow schema	Fully utilize database capacities.	Database
Base in-memory session pool size	Fully utilize system capacity without overburdening system.	All
Write contents	Allow flexibility in determining what session data to write	Database and Memory-to-Memory
Scheduled invalidation	Minimize contention between session requests and invalidation of sessions by the Session Management facility. Minimize write operations to database for updates to last access time only.	Database and Memory-to-Memory
Tablespace and row size	Increase efficiency of write operations to database.	Database (DB2 only)

Base in-memory session pool size: The base in-memory session pool size number has different meanings, depending on session support configuration:
- With in-memory sessions, session access is optimized for up to this number of sessions.
- With distributed sessions (meaning, when sessions are stored in a database or in another WebSphere Application Server instance); it also specifies the cache size and the number of last access time updates saved in manual update mode.

For distributed sessions, when the session cache has reached its maximum size and a new session is requested, the Session Management facility removes the least recently used session from the cache to make room for the new one.

General memory requirements for the hardware system, and the usage characteristics of the e-business site, determines the optimum value.

Note that increasing the base in-memory session pool size can necessitate increasing the heap sizes of the Java processes for the corresponding WebSphere Application Servers.

Overflow in non-distributed sessions

By default, the number of sessions maintained in memory is specified by base in-memory session pool size. If you do not wish to place a limit on the number of sessions maintained in memory and allow overflow, set overflow to *true*.

Allowing an unlimited amount of sessions can potentially exhaust system memory and even allow for system sabotage. Someone could write a malicious program that continually hits your site and creates sessions, but ignores any cookies or encoded URLs and never utilizes the same session from one HTTP request to the next.

When overflow is disallowed, the Session Management facility still returns a session with the HttpServletRequest getSession(true) method when the memory limit is reached, and this is an invalid session that is not saved.

With the WebSphere Application Server extension to HttpSession, com.ibm.websphere.servlet.session.IBMSession, an isOverflow method returns *true* if the session is such an invalid session. An application can check this status and react accordingly.

Tuning parameter settings:

Use this page to set tuning parameters for distributed sessions.

To view this administrative console page, click **Servers > Application servers >***server_name***> Web container settings > Session management >Distributed environment settings >Custom tuning parameters**.

Tuning level:

Specifies that the session management facility provides certain predefined settings that affect performance.

Select one of these predefined settings or customize a setting. To customize a setting, select one of the predefined settings that comes closest to the setting desired, click **Custom settings**, make your changes, and then click **OK**.

Very high (optimize for performance)

Write frequency	Time based
Write interval	300 seconds
Write contents	Only updated attributes
Schedule sessions cleanup	true
First time of day default	0
Second time of day default	2

High

Write frequency	Time based
Write interval	300 seconds
Write contents	All session attributes
Schedule sessions cleanup	false

Medium

Write frequency	End of servlet service
Write contents	Only updated attributes
Schedule sessions cleanup	false

Low (optimize for failover)

Write frequency	End of servlet service
Write contents	All session attributes
Schedule sessions cleanup	false

Custom settings

Write frequency default	Time based
Write interval default	10 seconds
Write contents default	All session attributes
Schedule sessions cleanup default	false

Tuning parameter custom settings:

Use this page to customize tuning parameters for distributed sessions.

To view this administrative console page, click **Servers** > **Application servers** > *server_name***Web container settings** > **Session management** > **Distributed environment settings** > **Custom tuning parameters** > **Custom settings**.

Write frequency:

Specifies when the session is written to the persistent store.

End of servlet service	A session writes to a database or another WebSphere Application Server instance after the servlet completes execution.
Manual update	A programmatic sync on the IBMSession object is required to write the session data to the database or another WebSphere Application Server instance.
Time based	Session data writes to the database or another WebSphere Application Server instance based on the specified Write interval value. Default: 10 seconds

Write contents:

Specifies whether updated attributes are only written to the external location or all of the session attributes are written to the external location, regardless of whether or not they changed. The external location can be either a database or another application server instance.

Only updated attributes	Only updated attributes are written to the persistent store.
All session attribute	All attributes are written to the persistent store.

Schedule sessions cleanup:

Specifies when to clean the invalid sessions from a database or another application server instance.

Specify distributed sessions cleanup schedule	Enables the scheduled invalidation process for cleaning up the invalidated HTTP sessions from the external location. Enable this option to reduce the number of updates to a database or another application server instance required to keep the HTTP sessions alive. When this option is not enabled, the invalidator process runs every few minutes to remove invalidated HTTP sessions. When this option is enabled, specify the two hours of a day for the process to clean up the invalidated sessions in the external location. Specify the times when there is the least activity in the application servers. An external location can be either a database or another application server instance.
First Time of Day (0 - 23)	Indicates the first hour during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.

Second Time of Day (0 - 23)

Indicates the second hour during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.

Best practices for using HTTP Sessions

- **Enable Security integration for securing HTTP sessions**

  HTTP sessions are identified by session IDs. A session ID is a pseudo-random number generated at the runtime. Session hijacking is a known attack HTTP sessions and can be prevented if all the requests going over the network are enforced to be over a secure connection (meaning, HTTPS). But not every configuration in a customer environment enforces this constraint because of the performance impact of SSL connections. Due to this relaxed mode, HTTP session is vulnerable to hijacking and because of this vulnerability, WebSphere Application Server has the option to tightly integrate HTTP sessions and WebSphere Application Server security. Enable security in WebSphere Application Server so that the sessions are protected in a manner that only users who created the sessions are allowed to access them.
- **Release HttpSession objects using `javax.servlet.http.HttpSession.invalidate()` when finished.**

  HttpSession objects live inside the Web container until:
  - The application explicitly and programmatically releases it using the javax.servlet.http.HttpSession.invalidate method; quite often, programmatic invalidation is part of an application logout function.
  - WebSphere Application Server destroys the allocated HttpSession when it expires (default = 1800 seconds or 30 minutes). The WebSphere Application Server can only maintain a certain number of HTTP sessions in memory based on session management settings. In case of distributed sessions, when maximum cache limit is reached in memory, the session management facility removes the least recently used (LRU) one from cache to make room for a session.

  .
- **Avoid trying to save and reuse the HttpSession object outside of each servlet or JSP file.**

  The HttpSession object is a function of the HttpRequest (you can get it only through the req.getSession method), and a copy of it is valid only for the life of the service method of the servlet or JSP file. You *cannot* cache the HttpSession object and refer to it outside the scope of a servlet or JSP file.
- **Implement the java.io.Serializable interface when developing new objects to be stored in the HTTP session.**

  This action allows the object to properly serialize when using distributed sessions. Without this extension, the object cannot serialize correctly and throws an error. An example of this follows:

  ```
  public class MyObject implements java.io.Serializable {...}
  ```

  Make sure all instance variable objects that are not marked transient are serializable.
- **The HTTPSession API does not dictate transactional behavior for sessions.**

  Distributed HTTPSession support does not guarantee transactional integrity of an attribute in a failover scenario or when session affinity is broken. Use transactional aware resources like enterprise Java beans to guarantee the transaction integrity required by your application.
- **Ensure the Java objects you add to a session are in the correct class path.**

  If you add Java objects to a session, place the class files for those objects in the correct class path (the application class path if utilizing sharing across Web modules in an enterprise application, or the Web module class path if using the Servlet 2.2-complaint session sharing) or in the directory containing other servlets used in WebSphere Application Server. In the case of session clustering, this action applies to every node in the cluster.

  Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.
- **Avoid storing large object graphs in the HttpSession object.**

  In most applications each servlet only requires a fraction of the total session data. However, by storing the data in the HttpSession object as one large object, an application forces WebSphere Application Server to process all of it each time.

- **Utilize Session Affinity to help achieve higher cache hits in the WebSphere Application Server.**

  WebSphere Application Server has functionality in the HTTP Server plug-in to help with session affinity. The plug-in reads the cookie data (or encoded URL) from the browser and helps direct the request to the appropriate application or clone based on the assigned session key. This functionality increases use of the in-memory cache and reduces hits to the database or another WebSphere Application Server instance
- **Maximize use of session affinity and avoid breaking affinity.**

  Using session affinity properly can enhance the performance of the WebSphere Application Server. Session affinity in the WebSphere Application Server environment is a way to maximize the in-memory cache of session objects and reduce the amount of reads to the database or another WebSphere Application Server instance. Session affinity works by caching the session objects in the server instance of the application with which a user is interacting. If the application is deployed in multiple servers of a server group, the application can direct the user to any one of the servers. If the users starts on server1 and then comes in on server2 a little later, the server must write all of the session information to the external location so that the server instance in which server2 is running can read the database. You can avoid this database read using session affinity. With session affinity, the user starts on server1 for the first request; then for every successive request, the user is directed back to server1. Server1 has to look only at the cache to get the session information; server1 never has to make a call to the session database to get the information.

  You can improve performance by not breaking session affinity. Some suggestions to help avoid breaking session affinity are:
  - Combine all Web applications into a single application server instance, if possible, and use modeling or cloning to provide failover support.
  - Create the session for the frame page, but do not create sessions for the pages within the frame when using multi-frame JSP files. (See discussion later in this topic.)
- **When using multi-framed pages, follow these guidelines:**
  - Create a session in only one frame or before accessing any frame sets. For example, assuming there is no session already associated with the browser and a user accesses a multi-framed JSP file, the browser issues concurrent requests for the JSP files. Because the requests are not part of any session, the JSP files end up creating multiple sessions and all of the cookies are sent back to the browser. The browser honors only the last cookie that arrives. Therefore, only the client can retrieve the session associated with the last cookie. Creating a session before accessing multi-framed pages that utilize JSP files is recommended.
  - By default, JSP files get a HTTPSession using `request.getSession(true)` method. So by default JSP files create a new session if none exists for the client. Each JSP page in the browser is requesting a new session, but only one session is used per browser instance. A developer can use `<% @ page session="false" %>` to turn off the automatic session creation from the JSP files that do not access the session. Then if the page needs access to the session information, the developer can use `<%HttpSession session = javax.servlet.http.HttpServletRequest.getSession(false); %>` to get the already existing session that was created by the original session creating JSP file. This action helps prevent breaking session affinity on the initial loading of the frame pages.
  - Update session data using only one frame. When using framesets, requests come into the HTTP server concurrently. Modifying session data within only one frame so that session changes are not overwritten by session changes in concurrent frameset is recommended.
  - Avoid using multi-framed JSP files where the frames point to different Web applications. This action results in losing the session created by another Web application because the JSESSIONID cookie from the first Web application gets overwritten by the JSESSIONID created by the second Web application.
- **Secure all of the pages (not just some) when applying security to servlets or JSP files that use sessions with security integration enabled, .**

  When it comes to security and sessions, it is all or nothing. It does not make sense to protect access to session state only part of the time. When security integration is enabled in the session management facility, all resources from which a session is created or accessed must be either secured or unsecured. You cannot mix secured and unsecured resources.

The problem with securing only a couple of pages is that sessions created in secured pages are created under the identity of the authenticated user. Only the same user can access sessions in other secured pages. To protect these sessions from use by unauthorized users, you cannot access these sessions from an unsecured page. When a request from an unsecured page occurs, access is denied and an `UnauthorizedSessionRequestException` error is created. (`UnauthorizedSessionRequestException` is a runtime exception; it is logged for you.)

- **Use manual update and either the sync() method or time-based write in applications that read session data, and update infrequently.**

  With END_OF_SERVICE as write frequency, when an application uses sessions and anytime data is read from or written to that session, the LastAccess time field updates. If database sessions are used, a new write to the database is produced. This activity is a performance hit that you can avoid using the Manual Update option and having the record written back to the database only when data values update, not on every read or write of the record.

  To use manual update, turn it on in the session management service. (See the tables above for location information.) Additionally, the application code must use the `com.ibm.websphere.servlet.session.IBMSession` class instead of the generic HttpSession. Within the IBMSession object there is a sync method. This method tells the WebSphere Application Server to write the data in the session object to the database. This activity helps the developer to improve overall performance by having the session information persist only when necessary.

  Note: An alternative to using the manual updates is to utilize the timed updates to persist data at different time intervals. This action provides similar results as the manual update scheme.
- Implement the following suggestions to achieve high performance:
  - If your applications do not change the session data frequently, use Manual Update and the sync function (or timed interval update) to efficiently persist session information.
  - Keep the amount of data stored in the session as small as possible. With the ease of using sessions to hold data, sometimes too much data is stored in the session objects. Determine a proper balance of data storage and performance to effectively use sessions.
  - If using database sessions, use a dedicated database for the session database. Avoid using the application database. This helps to avoid contention for JDBC connections and allows for better database performance.
  - If using memory-to-memory sessions, employ partitioning (either group or single replica) as your clusters grow in size and scaling decreases.
  - Verify that you have the latest fix packs for the WebSphere Application Server.
- Utilize the following tools to help monitor session performance.
  - Run the com.ibm.servlet.personalization.sessiontracking.IBMTrackerDebug servlet. - To run this servlet, you must have the servlet invoker running in the Web application you want to run this from. Or, you can explicitly configure this servlet in the application you want to run.
  - Use the WebSphere Application Server Resource Analyzer which comes with WebSphere Application Server to monitor active sessions and statistics for the WebSphere Application Server environment.
  - Use database tracking tools such as ″Monitoring″ in DB2. (See the respective documentation for the database system used.)

Managing HTTP sessions: Resources for learning

Use the following links to find relevant supplemental information about HTTP sessions. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Modifying the default Web container configuration

The Web container is created initially with default properties values suitable for simple Web applications. However, these values might not be appropriate for more complex Web applications.

Your application is considered complex if it requires any of the following features:
- Virtual host
- Servlet caching
- Special client request loads
- Persistent HTTP session support
- Special HTTP transport settings
- Transaction class mappings

Make the following configuration changes if you have a complex application:

1. In the administrative console, click **Servers > Application servers >***server_name*. Then under Web container settings, click on one of the following:
   a. **Web container**, if your Web application requires a virtual host, other than the default_host, or requires servlet caching.
   b. **Web container transport chains**, if you need to reconfigure your HTTP connections.
   c. **Session management**, if your application requires persistent HTTP session support.
2. If your application requires global settings for internal servlets for WAR files packaged by third-party tools, iIn the administrative console, click **Servers > Application servers >***server_name* **> Web container settings > Web container**. Then under Additional Properties, click **Custom Properties** and enter the appropriate custom property.
3. If your application uses transaction class mappings to classify workload, in the administrative console, click **Resources > Asynchronous beans > Work managers >** *workmanager_name*. Then enter the name of the transaction class mapping file in the Default transaction class field.

Web container

A Web container handles requests for servlets, JavaServer Pages (JSP) files, and other types of files that include server-side code. The Web container creates servlet instances, loads and unloads servlets, creates and manages request and response objects, and performs other servlet management tasks.

The Web server plug-ins, provided by the WebSphere Application Server, help supported Web servers pass servlet requests to Web containers.

If the property to start servlets during application server startup is enabled, part of its startup process calls the Servlet.init method on its servlets when you start the Web container. Therefore, when the Web container starts and calls the init method, other components such as Naming and Work Load Management may not be fully started yet. As a result, application server related calls may not work since all of the

application server components may not be ready yet. Once the application server is 'ready for e-business', it is completely ready. If application server related calls fail during Servlet.init method, you can either:

- Start the servlet manually when the server is ready for e-business instead of starting the servlet upon startup or
- You can choose not to make application server related calls in the servlet's init method.

Web container settings

Use this page to configure the Web container settings.

To view this administrative console page, click **Servers** > **Application servers** > *server_instance* > **Web container settings** > **Web container**.

Default virtual host:

Specifies a virtual host that enables a single host machine to resemble multiple host machines. Resources associated with one virtual host cannot share data with resources associated with another virtual host, even if the virtual hosts share the same physical machine.

Select a virtual host option:

default_host
The product provides a default virtual host with some common aliases, such as the machine IP address, short host name, and fully qualified host name. The alias comprises the first part of the path for accessing a resource such as a servlet. For example, it is `localhost:9080` in the request `http://localhost:9080/myServlet`.

admin_host
This is another name for the application server; also known as *server1* in the base installation. This process supports the use of the administrative console.

Enable servlet caching:

Specifies that if a servlet is invoked once and it generates output to be cached, a cache entry is created containing not only the output, but also side effects of the invocation. These side effects can include calls to other servlets or Java Server Pages (JSP) files, as well as metadata about the entry, including timeout and entry priority information.

Web module deployment settings

Use this page to configure an instance of Web module deployment.

To view this administrative console page, click **Applications** > **Enterprise Application** > *application_instance* > **Web modules** > *Web_module_instance*.

URI:

Specifies a URI that, when resolved relative to the application URL, specifies the location of the module archive contents on a file system. The URI must match the module URI in the deployment descriptor of an application if the module was packaged as part of a deployed application or enterprise archive (EAR) file.

Alternate deployment descriptor:

Specifies the file name for an alternative deployment descriptor file to use instead of the original deployment descriptor file in the module JAR file.

This file is the *post-assembly* version of the deployment descriptor file. You can edit the original deployment descriptor file to resolve dependencies and security information. Specifying the use of the alternative deployment descriptor keeps the original deployment descriptor file intact.

The value of the *Alternate deployment descriptor* property must be the full path name of the deployment descriptor file, relative to the module root directory. By convention, the file is in the `ALT-INF` directory. If this property is not specified, the deployment descriptor file is read from the module JAR file.

Starting weight:

Specifies the order in which modules are started. Lower weighted modules are started before higher weighted modules.

Class loader mode:

Specifies whether the class loader should search in the parent class loader or in the application class loader first to load a class. The standard for JDK class loaders and WebSphere class loaders is Parent First. By specifying Parent Last, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or LinkageErrors if you have mixed use of overriden classes and non-overriden classes.

The options are Parent First and Parent Last. The default is to search in the parent class loader before searching in the application class loader to load a class.

Data type	String
Default	Parent First

Web container advanced settings

Use this page to support Web container advanced settings. This support includes Network QoS and transaction class mapping

To view this administrative console page, click **Servers** > **Application Servers** > *server name* > **Web Container** > **Advanced Settings**.

Network QoS:

Specifies the parameter that will be used to classify outbound data that is delivered in response to HTTP and HTTPS requests.

The classification parameters are used to construct an ApplicationData parameter for the TCP/IP network service, which is called Quality of Service (QoS). The ApplicationData parameter is used in a QoS PolicyRule statement.

You can specify at most one classification parameter. If you do not specify a classification parameter, the response data will not be classified to the network agent.

Parameter	Description
HOST	Indicates that the Host value from the Host header, not including the port, is to be used to construct an ApplicationData parameter. If you specify this parameter, WebSphere Application Server for z/OS classifies the outbound response data by using the HOST value. In the request: `http://www.mycompany.com/mywebap/myservlet` `www.mycompany.com` represents the host value.

URI
Indicates that the part of the Universal Resource Locator that specifies the path to a resource is to be used to construct an ApplicationData parameter. If you specify this parameter, WebSphere Application Server for z/OS classifies the outbound response data by using the URI value. The path must be specified exactly as it is entered in a browser because the check for this path is case sensitive.

In the request:

```
http://www.mycompany.com/mywebap/myservlet
```

`/mywebap/myservlet` represents the URI value.

HOSTURI
Indicates that the HOST and URI, concatenated together, are to be used to construct an ApplicationData parameter. If you specify this parameter, WebSphere Application Server for z/OS classifies the outbound response using the concatenated HOST and URI value.

In the request:

```
Get request: http://www.mycompany.com/mywebap/myservlet
```

`www.mycompany.com/mywebap/myservlet` represents the concatenated HOST and URI value.

TCLASS
Indicates that a valid Workload Management (WLM) transaction class is to be used to construct an ApplicationData parameter. If you specify this parameter, you must specify the fully qualified name of the transaction class mapping file on the Transaction Class Mapping property.

Transaction Class Mapping:

Specifies the fully qualified name of the file that contains the rules for classifying the Workload Management Transaction Class for HTTP or HTTPS requests. The file name is class sensitive.

For example, if `tclass.conf` is the name of your transaction class mapping file, you would specify the following for the value on this property:

`/mydir/tclass.conf`

where *mydir* is the fully qualified directory where the `tclass.conf` file is located.

For example

/mydir/tclass.conf

Web container custom properties

Use this page to configure arbitrary name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

To view this administrative console page, click **Servers > Application servers >***server_name* **> Web container settings > Web container > Custom properties**.

HTTP Transport custom properties can also be set at the Web container level. See ″HTTP transport custom properties″ for a description of these properties.

Name:

Specifies the name or key for the property.

Value:

Specifies the value that is paired with the specified name.

Data type String

Description:

Specifies information about the name-value pair.

Data type String

Global settings for internal servlets

Web application archive (WAR) files that are packaged using third-party tools cannot specify behavior for the services that are exposed by the Web container internal servlets. You can globally enable and disable internal servlets for all Web applications at the Web container level by creating name-value pairs such as:

Name	Value
fileServingEnabled	true
directoryBrowsingEnabled	true
serveServletsByClassnameEnabled	true

Settings that are defined in an assembly tool take precedence over the global settings that are set through the custom properties at the Web container level.

Web application deployment extensions continue to hold configuration information for the services that are provided by the internal servlets, and take precedence over the global settings that are set through the custom properties at the Web container level.

UTF-8 encoded URLs

The UTF-8 encoded URL feature, which provides UTF-8 encoded Uniform Resource Locators (URLs) to support the double-byte characters in URLs is enabled by default. You can prevent the Web container from explicitly decoding URLs in UTF-8 and have them use the ISO-8859 standard as per the current HTTP specification by using the following name-value pair:

Name	Value
DecodeUrlAsUTF8	false

Global configuration of servlet listeners

The servlet specification supports applications registering listeners for servlet-related events on an individual application basis through the `web.xml` descriptor. However, using the listeners custom property, a server can listen to servlet events across Web applications. To implement global listening, a listener is registered at the Web container level and is propagated to all of the installed and new Web applications. This global behavior of internal servlet listeners is controlled by the listeners custom property by using the following name-value pair format:

Name	Value
listeners	*listener_class*

The values for this property is a string specifying a comma separated list of listener classes. The listener supplied must implement standard listener classes from the Java Servlet API or IBM listener extension classes.

Binary Large Object (BLOB) data type for Oracle databases

The *UseOracleBLOB* custom property creates the HTTP session database table using the Binary Large Object (BLOB) data type for the medium column. This property increases performance of persistent sessions when Oracle databases are used. Due to an Oracle restriction, BLOB support requires use of the Oracle's oci database driver for more than 4000 bytes of data. You must also ensure that a new sessions table is created before the server is restarted by dropping your old sessions table or by changing the datasource definition to reference a database that does not contain a sessions table. To create a sessions table using the BLOB data type, use the following name-vaule pair:

Name	Value
UseOracleBLOB	true

Detecting Session Data Crossover

The *DebugSessionCrossover* custom property enables code to perform additional checks to verify that only the session associated with the request is accessed or referenced. Messages are logged if any discrepancies are detected. To enable session data crossover detection, use the following name-vaule pair:

Name	Value
DebugSessionCrossover	true

See article, ″Problems creating or using HTTP sessions″, for additional information.

Optimizing web services client to Web container communication

To improve performance, there is an optimized communication path between a Web services client application and a Web container that are located in the same application server process. Requests from the Web services client that are normally sent to the Web container using a network connection are delivered directly to the Web container using an optimized local path. The local path is available because the Web services client application and the Web container are running in the same process. This optimized communication path is disabled by default. Before enabling this property, make sure that wild cards are not specified for the Web container ports. Use specific ports for the web container when the optimized communication path is enabled. To enable the optimized communication path, use the following name-value pair:

Name	Value
enableInProcessConnections	true

See article, ″Web services client to Web container optimized communication″, for additional information.

Transaction class mapping file entries

Following is the syntax for entries in a transaction class mapping file:

```
TransClassMap host:port uritemplate tclass
```

where:

host Is the value compared against the hostname of the HOST: header of the request. This value can be a wildcard '*'.

Note: A value of '*' for the host:port value is acceptable and is equivalent to '*:*'.

port Is the value compared against the port of the request. This value can be a wildcard '*'.

uritemplate
Is the value compared against the URI of the request. Any query string will not be used in the comparison. This value can be a wildcard '*', or end in a wildcard.

tclass Is the Workload Manager Transaction Class name that will be used in the creation of the enclave.

Examples:

```
TransClassMap www.ibm.com:80 /webap1/myservlet TCLASS1

TransClassMap www.ibm.com:* /webap1/myservlet TCLASS2

TransClassMap *:443 * TCLASS3

TransClassMap *:* /webap1/myservlet TCLASS4

TransClassMap www.ibm.com:* /webap2/* TCLASS5

TransClassMap * /myservlet TCLASS6

TransClassMap * * TCLASS6
```

Configuring session management by level

When you configure session management at the Web container level, all applications and the respective Web modules in the Web container normally inherit that configuration, setting up a basic default configuration for the applications and Web modules below it.

However, you can set up different configurations individually for specific applications and Web modules that vary from the Web container default. These different configurations override the default for these applications and Web modules only.

Note: When you overwrite the default session management settings on the application level, all the Web modules below that application inherit this new setting unless they too are set to overwrite these settings.

1. Open the Administrative console.
2. Select the level that this configuration applies to:
   - For the web container level:
     a. Click **Servers** > **Application Servers**.
     b. Select a server from the list of application servers.
     c. Under Additional Properties, click **Web Container**.
   - For the enterprise application level:
     a. Click **Applications** > **Applications**.
     b. Select an applications from the list of applications.
   - For the Web module level:
     a. Click **Applications** > **Enterprise Applications**.
     b. Select an applications from the list of applications.
     c. Under Related Items, click **Web Modules**.
     d. Select a Web module from the list of Web modules defined for this application.
3. Under **Additional Properties**, click **Session Management**.
4. Make whatever changes you need to manage sessions
5. If you are working on the Web module or application level and want these settings to override the inherited Session Management settings, under **General Properties**, select **Overwrite**.
6. Click **Apply** and **Save**.

Configuring session tracking

To configure session tracking, complete the following:

1. Go to the appropriate level of Session Management.
2. Specify which session tracking mechanism you want to pass the session ID between the browser and the servlet:
   - To track sessions with cookies, click **Enable Cookies**.

     To change the cookie settings, click **Modify**.
   - To track sessions with URL rewriting, click **Enable URL Rewriting**.

     If you want to enable protocol switch rewriting, click **Enable protocol switch rewriting.**
   - To track sessions with SSL information, click **Enable SSL ID tracking**.
3. Click **Apply**.
4. Click **Save**.
5. Define the session recovery characteristics.

Serializing access to session data

The Servlet API supports concurrent access to a session in a given server instance. WebSphere Application Server provides an option to prevent the concurrent access to a session in a given server instance so that concurrent modification of a session does not occur in a given server instance. This prevention is achieved by synchronizing the requests based on session. When this feature is turned on, a session is obtained for the request before invoking the servlet and requests are synchronized by locking the session for the servlet execution time. Note that synchronization is based on the memory copy of session. So this feature cannot serialize requests across servers based on session when session affinity fails.

Restriction: Use this feature only when concurrent modification of the same session data is possible and is not desirable by the application. This feature has overhead of serializing the requests based on a session.

Do the following to synchronize session access:

1. Select the level of Session Management on which you want to serialize session access.
2. Under Serialize Session access, click **Allow serial access**.
3. In the Maximum wait time box, type the amount of time, in milliseconds, a servlet waits on a session before continuing execution. The default is 120000 milliseconds or two minutes.
4. Select **Allow access on timeout** if you want the servlet to gain access to the session and continue normal execution even if the session is still locked by another servlet. If you do not select this box, the servlet execution will abort when the session request times out.
5. Click **Apply**.
6. Click **Save**.

Session management settings

Use this page to manage HTTP session support. This support includes specifying a session tracking mechanism, setting maximum in-memory session count, controlling overflow, and configuring session timeout.

To view this administrative console page, click **Servers** > **Application servers** > *server_name* > **Web container settings** > **Session management**.

Override session management:

Specifies whether or not these session management settings take precedence over those normally inherited from a higher level for the current application or web module.

By default, web modules inherit session management settings from the application level above it, and applications inherit session management settings from the Web container level above it.

Session tracking mechanism:

Specifies a mechanism for HTTP session management.

Mechanism	Function	Default
Enable SSL ID Tracking	Specifies that session tracking uses Secure Sockets Layer (SSL) information as a session ID. Enabling SSL tracking takes precedence over cookie-based session tracking and URL rewriting. There are two parameters available if you enable SSL ID tracking: SSLV3Timeout and Secure Authentication Service (SAS). SSLV3Timeout specifies the time interval after which SSL sessions are renegotiated. This is a high setting and modification does not provide any significant impact on performance. The SAS parameter establishes an SSL connection only if it goes out of the Java Virtual Machine (JVM) to another JVM. If all the beans are co-located within the same JVM, the SSL used by SAS does not hinder performance. These are set by editing the `sas.server.properties` and `sas.client.props` files located in the *product_installation_root*\properties directory, where *product_installation_root* is the directory where WebSphere Application Server is installed.	9600 seconds

Enable cookies	Specifies that session tracking uses cookies to carry session IDs. If cookies are enabled, session tracking recognizes session IDs that arrive as cookies and tries to use cookies for sending session IDs. If cookies are not enabled, session tracking uses Uniform Resource Identifier (URL) rewriting instead of cookies (if URL rewriting is enabled). Enabling cookies takes precedence over URL rewriting. Do not disable cookies in the session management facility of the application server that is running the administrative application because this action causes the administrative application not to function after a restart of the server. As an alternative, run the administrative application in a separate process from your applications. Click **Modify** to change these settings.
Enable URL rewriting	Specifies that the session management facility uses rewritten URLs to carry the session IDs. If URL rewriting is enabled, the session management facility recognizes session IDs that arrive in the URL if the encodeURL method is called in the servlet.
Enable protocol switch rewriting	Specifies that the session ID is added to a URL when the URL requires a switch from HTTP to HTTPS or from HTTPS to HTTP. If rewriting is enabled, the session ID is required to go between HTTP and HTTPS.

Maximum in-memory session count:

Specifies the maximum number of sessions to maintain in memory.

The meaning differs depending on whether you are using in-memory or distributed sessions. For in-memory sessions, this value specifies the number of sessions in the base session table. Use the Allow overflow property to specify whether to limit sessions to this number for the entire session management facility or to allow additional sessions to be stored in secondary tables. For distributed sessions, this value specifies the size of the memory cache for sessions. When the session cache has reached its maximum size and a new session is requested, the session management facility removes the least recently used session from the cache to make room for the new one.

Allow overflow:

Specifies that the number of sessions in memory can exceed the value specified by the Max in-memory session count property. This option is valid only in non-distributed sessions mode.

Session timeout:

Specifies how long a session can go unused before it is no longer valid. Specify either `Set timeout` or `No timeout`. Specify the value in minutes greater than or equal to two.

The value specified in a web module deployment descriptor file takes precedence over the administrative console settings. However, the value of this setting is used as a default when the session timeout is not specified in a web module deployment descriptor. Note that to preserve performance, the invalidation timer is not accurate to the second. When the write frequency is time based, ensure that this value is least twice as large as the write interval.

Security integration:

Specifies that when security integration is enabled, the session management facility associates the identity of users with their HTTP sessions

Serialize session access:

Specifies that concurrent session access in a given server is not allowed.

Maximum wait time	Specifies the maximum amount of time a servlet request waits on an HTTP session before continuing execution. This parameter is optional and expressed in seconds. The default is 120 seconds, or 2 minutes. Under normal conditions, a servlet request waiting for access to an HTTP session gets notified by the request that currently owns the given HTTP session when the request finishes.
Allow access on timeout	Specifies whether the servlet is executed normally or aborted in the event of a timeout. If this box is checked, the servlet executes normally. If this box is not checked, the servlet execution aborts and error logs are generated.

Cookie settings

Use this page to configure cookie settings for session management.

To view this administrative console page, click **Servers** > **Application servers** > *server_name* > **Web container settings** > **Session management** > **Enable cookies**.

Cookie name:

Specifies a unique name for the session management cookie. The servlet specification requires the name JSESSIONID. However, for flexibility this value can be configured.

Restrict cookies to HTTP sessions:

Specifies that the session cookies include the secure field. Enabling the feature restricts the exchange of cookies to HTTPS sessions only.

Cookie domain:

Specifies the domain field of a session tracking cookie. This value controls whether or not a browser sends a cookie to particular servers. For example, if you specify a particular domain, session cookies are sent to hosts in that domain. The default domain is the server.

Cookie path:

Specifies that a cookie is sent to the URL designated in the path. Specify any string representing a path on the server. ″/″ indicates root directory. Specify a value to restrict the paths to which the cookie will be

sent. By restricting paths, you prevent the cookie from going to certain URLs on the server. If you specify the root directory, the cookie is sent no matter which path on the given server is accessed.

Cookie maximum age:

Specifies the amount of time that the cookie lives on the client browser. Specify that the cookie lives only as long as the current browser session, or to a maximum age. If you choose the maximum age option, specify the age in seconds. This value corresponds to the Time to Live (TTL) value described in the Cookie specification.

Default is the current browser session which is equivalent to setting the value to -1.

Session management custom properties

Custom properties for session management:

CloneSeparatorChange

Use this property to maintain session affinity. The clone ID of the server is appended to session identifier separated by colon. On some Wireless Application Protocol (WAP) devices, a colon is not allowed. Set this property to ″true″ to change clone separator to a plus sign (+).

HttpSessionCloneId

Use this property to change the clone ID of the cluster member. Within a cluster, this name must be unique to maintain session affinity. When set, this name overwrites the default name generated by WebSphere Application Server. Default clone ID length: 40.

HttpSessionIdLength

Use this property to configure the session identifier length. Do not use an extremely low value; using a low value results in reduced number of combinations possible, thereby increasing risk of guessing the session identifier. In a cluster, all cluster members should be configured with same ID length. Allowed range: 8 to 128. Default length: 23.

HttpSessionReaperPollInterval

Use this property to set a wake-up interval for the process that removes invalid sessions. Default is based on maximum inactive interval set in session management. Allowed value: integer.

NoAdditionalSessionInfo

Set this value to ″true″ to force removal of information that is not needed in session identifiers. In WebSphere Application Server base edition,a clone ID is not included in base edition when this is set. Also, cache ID is not used with nonpersistent sessions; so the cache ID is not included with nonpersistent sessions when this value is set.

NoAffinitySwitchBack

Set this property to ″true″ to maintain affinity to the new member even after original one comes back up. When a cluster member fails, its requests routed to a different cluster member, and sessions are activated in that other member. Thus, session affinity is maintained to the new member, and when failed cluster member comes back up, the requests for sessions that were created in the original cluster member are routed back to it. Allowed values, true or false. Default: false.

It is recommended that you set this property to ″true″ when distributed sessions with time-based write is configured. Note that this property has no affect on the behavior when distributed sessions is not enabled.

SessionIdentifierMaxLength

Use this value to set maximum length that a session identifier can grow. In a cluster, because of fail-over when a request goes to new cluster member, session management appends a new clone ID to the existing clone ID. In a large cluster, if for some reason servers are failing more often, then it is possible that the session identifier length can be more than expected reducing room for URL. So this property helps to find out the condition and take appropriate action to address servers fail-over. When this is specified, message is logged when specified maximum length is reached. Allowed value: integer.

SessionRewriteIdentifier

Use this property to change the key used with URL rewriting. Default key: jsessionid.

Configuring session tracking for Wireless Application Protocol (WAP) devices

Most Wireless Application Protocol (WAP) devices do not support cookies. The preferred way to track sessions for WAP devices is to use URL rewriting. However on most WAP devices, the maximum allowed URL length is 128 characters. With URL rewriting, a session indentifier is added to the URL itself, effectively decreasing the space available for the actual URL and the number of parameters that can be sent on a request.

To reduce the length of session identifier, you can configure key (jsessionid), session ID length and clone ID. To make these configuration changes, complete the following:

1. Open the Administrative console.
2. Click **Servers** > **Application Servers**.
3. Select a server from the list of application servers.
4. Under Container Settings, click **Web Container Settings > Web container**
5. Under Additional Properties, click **Custom Properties**.
6. Add the appropriate properties from the following list:
   - HttpSessionIdLength
   - SessionRewriteIdentifier
   - HttpSessionCloneId
   - CloneSeparatorChange
   - NoAdditionalSessionInfo
   - SessionIdentifierMaxLength
7. Click **Apply** and **Save**.

Configuring for database session persistence

To configure the session management facility for database session persistence, complete the following:

1. Create and configure a JDBC provider.
2. Create a data source pointing to the z/OS DB2 database containing the DB2 table for session persistence, using the JDBC provider that you defined. **Resources > JDBC Providers >** *JDBC_provider* **> Data Sources > New**. The data source should be non-JTA, for example, non-XA enabled. Note the JNDI name of the data source.

   Example configuration for session persistence:

Name	Sessions
JNDI Name	jdbc/sessions
Container managed persistence	Selected
Component-managed Authentication Alias	CELL/jaasalias
Container-managed Authentication Alias	CELL/jaasalias

3. Verify that the correct database is listed for the value of the **databaseName** property under **Data Sources >** *datasource_name* **> Custom Properties**. If necessary, contact your database administrator to verify the correct database name.

   For example:

Database Name	LOC1 (specify your system)

4. Create a DB2 table in the z/OS DB2 database that will be used for session persistence.
5. Configure the DB2 table for session persistence.
6. Go to the appropriate level of Session Management.

7. Click **Distributed Environment Settings**
8. Select and click **Database**.
9. Specify the Data Source JNDI name from step 3.
10. Switch to a multirow schema.
11. Click **OK**.
12. If you want to change the tuning parameters, click **Custom Tuning Parameters** and select a setting or customize one.
13. Click **Apply**.
14. Click **Save**.

Switching to a multirow schema

By default, a single session maps to a single row in the database table used to hold sessions. With this setup, there are hard limits to the amount of user-defined, application-specific data that WebSphere Application Server can access.

1. Modify the Session Management facility properties to switch from single to multirow schema.
2. Manually drop and recreate the database table or delete all the rows in the database table that the product uses to maintain HttpSession objects.

   See the *DB2 UDB for OS/390 and z/OS V7 Administration Guide* for a description of how to drop a DB2 database table.

   Creating a DB2 table for session persistence describes how to create a new DB2 database table.

Creating a DB2 table for session persistence

If you are using DB2 for session persistence, a DB2 table, in which session data will be collected, must be created and defined to the application server.

To create a DB2 table for collecting session data, do the following:

1. Have your DB2 Administrator create a DB2 database table for storing your session data. (For more information about creating DB2 databases see the *DB2 UDB for OS/390 and z/OS V7 Administration Guide*.)

   The table space in which the database table is created must be defined with row level locking (`LOCKSIZE ROW`). It should also have a page size that is large enough for the objects that will be stored in the table during a session. Following is an example of a table space definition with row level locking specified and a buffer pool page size of 32K:

```
CREATE DATABASE database_name
  STOGROUP SYSDEFLT
  CCSID EBCDIC;

CREATE TABLESPACE tablespace_name IN database_name
  USING STOGROUP group_name
  PRIQTY 512
  SECQTY 1024
  LOCKSIZE ROW
  BUFFERPOOL BP32K;
```

   The Session Manager will use the DB2 table defined within this table space to process the session data. This table must have the following format:

```
CREATE TABLE database_name.table_name  (
  ID               VARCHAR(95) NOT NULL ,
  PROPID           VARCHAR(95) NOT NULL ,
  APPNAME          VARCHAR(64) ,
  LISTENERCNT      SMALLINT ,
  LASTACCESS       DECIMAL(19,0),
  CREATIONTIME     DECIMAL(19,0),
  MAXINACTIVETIME  INTEGER ,
```

```
USERNAME         VARCHAR(256) ,
SMALL            VARCHAR(3122)  FOR BIT DATA ,
MEDIUM           VARCHAR(28869) FOR BIT DATA ,
LARGE            BLOB(2097152),
SESSROW          ROWID NOT NULL GENERATED ALWAYS
)
IN database_name.tablespace_name;
```

Note: The length attributes specified for VARCHAR in this example are not necessarily the values your DB2 Administrator should use for the DB2 table he is creating. See the DB2 SQL Reference for the version of DB2 you will be using for guidance in determining appropriate values for these length attributes for your installation.

A unique index must be created on the `ID` and `PROPID` columns of this table. The following is an example of the index definition:

```
CREATE UNIQUE INDEX database_name.index_name.
      database_name.table_name
      (ID     ASC,
      PROPID  ASC,
      APPNAME ASC);
```

Note:

a. At run time, the Session Manager will access the target table using the identity of the J2EE server in which the owning Web application is deployed. Any Web container that is configured to use persistent sessions should be granted both read and update access to the subject database table.

b. HTTP session processing uses the index defined using the `CREATE INDEX` statement to avoid database deadlocks. In some situations, such as when a relatively small table size is defined for the database, DB2 may decide not to use this index. When the index isn't used, database deadlocks can occur. If this situation occurs, see the DB2 Administration Guide for the version of DB2 you are using for recommendations on how to calculate the space required for an index, and adjust the size of the tables you are using accordingly.

c. It may be necessary to tune DB2 in order to make efficient use of the sessions database table and to avoid deadlocks when accessing it. Your DB2 Administrator should refer to the DB2 Administration Guide for specific information about tuning the version of DB2 you are using.

A large object (LOB) table space must be defined and an auxiliary table must be defined within that table space. The following is an example of the LOB table space definition:

```
CREATE LOB TABLESPACE LOB_tablespace_name IN database_name
    BUFFERPOOL BP32K
    USING STOGROUP group_name
    PRIQTY 512
    SECQTY 1024
    LOCKSIZE LOB;

CREATE AUX TABLE database_name.aux_table_name
    IN database_name.LOB_tablespace_name
    STORES database_name.table_name
    COLUMN LARGE;
```

An index must be created for this auxiliary table. The following is an example of the index definition:

```
CREATE INDEX database_name.aux_index_name ON
      database_name.aux_table_name;
```

2. Have your DB2 Administrator grant the the z/OS userID, under which the server region is running, the appropriate access to this DB2 table. For example,issue the following command to grant z/OS userID CBASRU1, under which the server region is running, access to the table SESSIONS contained in the database SESSDB:

   ```
   GRANT ALL ON SESSDB.SESSIONS TO CBASRU1;
   ```

3. Configure DB2 table for session persistence.

Configuring a DB2 table for session persistence

If you are using DB2 for session persistence, a DB2 table, in which session data will be collected, must be created and defined to the application server, see “Creating a DB2 table for session persistence” on page 160, for more information.

To configure a DB2 table for collecting session data, use the administrative console to add the name of this DB2 table to the Web container’s configuration properties:

1. Open the administrative console.
2. Click **Servers** > **Application Servers**.
3. Select a server from the list of application servers.
4. Under Additional Properties, click **Web Container**.
5. Under Additional Properties, click **Custom Properties**.
6. Check **SessionTableName** and then click **New**.
7. In the **Value** field, enter the name of the DB2 Session Table if you are not using the default value **SESSION**. The name must be in the form *database_name.table_name*. For example, if the database name is SESSDB and the table name is SESSIONS, enter SESSDB.SESSIONS for **Value**.Optionally, you can update the description of this table in the **Description** field. For example, you might enter ″Table name for HTTP session data.″
8. Click **Apply** > **Save**.

When the product is restarted, the Session Management facility creates the new SESSIONS table in the specified tablespace.

Database settings

Use this page to specify the settings for database session support.

To view this administrative console page, click **Servers** > **Application servers** > *server_name* > **Web container settings** > **Session management** > **Distributed environment settings** > **Database**.

Datasource JNDI name:

Specifies the datasource description.

The JNDI name of the non-XA enabled data source from which session management obtains database connections. For example, if the JNDI name of the datasource is ″jdbc/sessions″, specify ″jdbc/sessions.″ The data source represents a pool of database connections and a configuration for that pool (such as the pool size). The data source must already exist as a configured resource in the environment.

User ID:

Specifies the user ID for database access.

Password:

Specifies the password for database access.

DB2 row size:

Specifies the table space page size configured for the sessions table, if using a DB2 database. Possible values are 4, 8, 16, and 32 kilobytes (KB). The default row size is 4KB.

The default row size is 4KB. In DB2, it can be updated to a larger value. This can help database performance in some environments. When this value is other than 4, you must specify table space name to use this property. For 4KB pages, the table space name is optional.

Table space name:

Specifies that table space to be used for the sessions table.

This value is required when the DB2 page size is other than 4KB.

Use multi row schema:

Specifies that each instance of application data be placed in a separate row in the database, allowing larger amounts of data to be stored for each session. This action can yield better performance in certain usage scenarios. If using multirow schema is not enabled, instances of application data can be placed in the same row.

Multirow schema considerations

WebSphere Application Server supports the use of a multirow schema option in which each piece of application specific data is stored in a separate row of the database. With this setup, the total amount of data you can place in a session is now bound only by the database capacities. The only practical limit that remains is the size of the session attribute object.

The multirow schema potentially has performance benefits in certain usage scenarios, such as when larger amounts of data are stored in the session but only small amounts are specifically accessed during a given servlet processing of an HTTP request. In such a scenario, avoiding unneeded Java object serialization is beneficial to performance.

Understand that switching between multirow and single row is not a trivial proposition.

In addition to allowing larger session records, using multirow schema can yield performance benefits. However, it requires a little work to switch from single-row to multirow schema, as shown in the instructions below.

Coding considerations and test environment

Consider configuring direct single-row usage to one database and multirow usage to another database while you verify which option suits your application needs. (Do this in code by switching the data source used; then monitor performance.)

Programming issue	Application scenario
Reasons to use single-row	• You can read or write all values with just one record read and write. • This takes up less space in a database because you are guaranteed that each session is only one record long.
Reasons **not** to use single-row	2-megabyte limit of stored data per session.
Reasons to use multirow	• The application can store an unlimited amount of data; that is, you are limited only by the size of the database and a 2-megabyte-per-record limit. • The application can read individual fields instead of the whole record. When large amounts of data are stored in the session but only small amounts are specifically accessed during servlet processing of an HTTP request, multirow sessions can improve performance by avoiding unneeded Java object serialization.

Programming issue	Application scenario
Reasons **not** to use multirow	If data is small in size, you probably do not want the extra overhead of multiple row reads when you can store everything in one row.

In the case of multirow usage, design your application data objects not to have references to each other, to prevent circular references. For example, suppose you are storing two objects A and B in the session using HttpSession.put(..) method, and A contains a reference to B. In the multirow case, because objects are stored in different rows of the database, when objects A and B are retrieved later, the object graph between A and B is different than stored. A and B behave as independent objects.

Configuring memory-to-memory replication for the peer-to-peer mode (default memory-to-memory replication)

To configure the session management facility for memory-to-memory session replication for peer-to-peer functions (both client and server function, or both mode) with a single replica, complete the following steps:

1. Create an application cluster. This cluster is used to deploy the application.
   a. Go to the Server Cluster page. Click **Servers**> **Clusters**.
   b. Click **New**.
   c. Type a cluster name for this application cluster.
   d. Define a replication domain. Select the **Create a replication domain for this cluster** check box.
   e. Click **Next**.
   f. Define each cluster member server. Type a cluster member name.
   g. Click **Apply**. Repeat steps **f** through **g** for each server created in this cluster.
   h. Click **Next** and review the summary of changes.
   i. Click **Finish** to complete the configuration.

   You have now created a cluster that contains the deployed application and the replication domain.
2. Enable memory-to-memory session replication for each server.
   a. Go to the appropriate level of session management for the Web container level. Click **Servers** > **Application servers**> *server_name*> **Container Settings**> **Web Container Settings**> **Session management**
   b. Click **Distributed environment settings** under Additional Properties.
   c. Click **Memory-to-memory replication**.
   d. Select the **Replication domain** that you want to use for the replication of sessions.
   e. Select the both client and server **Replication mode**. You must configure all session managers connected to a replication domain to have the same topology. If one session manager instance in a domain is configured to use the client/server topology, then the rest of the session manager instances in that domain must be a combination of servers configured as ″Client only″ and ″Server only″. If one session manager instance is configured to use the peer-to-peer topology, then all session manager instances must be configured as ″Both client and server″.
   f. Click **OK** on the Memory-to-memory replication page.
   g. Optional: If you want to change the tuning parameters, click **Custom tuning parameters** and select a setting or customize one. Click **OK**. Click **Save**.

      Note: Using the default tuning parameter custom settings, which specifies time based write interval of 10 seconds, may result in data loss when an application server in your cluster fails. However, this is just a small opportunity for lost data when compared to the significant improvement in performance.
   h. Click **OK** the Distributed environment settings page.

i. Click **OK** the Session management page.
j. Repeat **a** through **i** for each server.

Memory-to-memory replication settings

Use this page to configure memory-to-memory sessions.

To view the Memory-to-memory sessions page, click **Servers** > **Application servers** > *server_name* > **Web container settings** > **Web container** > **Session management** > **Distributed environment settings** > **Memory-to-memory replication**.

Replication domain:

Specifies the replication domain in which HTTP sessions are replicated.

Replication mode:

Select the mode in which this server has to run: Both, Client and Server. The mode implies whether data is only sent (client), only received (server), or both. The default is both.

Configuring memory-to-memory replication for the client/server mode

To configure the session management facility for memory-to-memory replication using the clients/server mode, complete the following steps:

1. Create an application cluster. This cluster is used to deploy the application.
   a. Go to the Server Cluster page. Click **Servers**> **Clusters**.
   b. Click **New**.
   c. Type a cluster name for this application cluster.
   d. Click **Next**.
   e. Define each cluster member server. Type a cluster member name.
   f. Click **Apply**. Complete steps **e** and **f** for each server created in this cluster.
   g. Click **Next** and review the summary of changes.
   h. Click **Finish** to complete the configuration.

   Do not create a replication domain for the application cluster. You have now created a cluster that contains the deployed application.
2. Create a cluster of session manager replication servers (backup cluster).
   a. Go to the Server Cluster page. Click **Servers**> **Clusters**.
   b. Click **New**.
   c. Type a cluster name for the cluster of session manager replication servers.
   d. Define a replication domain. Select the **Create a replication domain for this cluster** check box.
   e. Click **Next**.
   f. Define each cluster member server. Type a cluster member name.
   g. Click **Apply**. Complete steps **f** through **g** for each server created in this cluster.
   h. Click **Next** and review the summary of changes.
   i. Click **Finish** to complete the configuration.

   This step creates a cluster of backup session manager replication servers and associates a replication domain with that cluster.
3. Enable memory-to-memory session replication for each cluster member server in the application cluster.

a. Go to the appropriate level of session management for the Web container level. Click **Servers** > **Application Servers**> *server_name*> **Container Settings**> **Web Container Settings**> **Session management**
b. Click **Distributed Environment Settings** under Additional Properties.
c. Click **Memory-to-memory replication**.
d. Select the **Replication domain** that you want to use for the replication of sessions.
e. Select the Client only **Replication mode**. You must configure all session managers connected to a replication domain to have the same topology. If one session manager instance in a domain is configured to use the client/server topology, then the rest of the session manager instances in that domain must be a combination of servers configured as Client only and Server only. If one session manager instance is configured to use the peer-to-peer topology, then all session manager instances must be configured as Both client and server. Alternatively, if one DRS Instance is configured in the client only mode then all DRS Instances in the domain must be configured in either the client only or the server only modes.
f. Click **OK** on the Memory-to-memory replication page.
g. Optional: If you want to change the tuning parameters, click **Custom tuning parameters** and select a setting or customize one. Click **OK**. Click **Save**.

   Note: Using the default tuning parameter custom settings, which specifies time based write interval of 10 seconds, may result in data loss when an application server in your cluster fails. However, this is just a small opportunity for lost data when compared to the significant improvement in performance.
h. Click **OK** the Distributed environment settings page.
i. Click **OK** the Session management page.
j. Repeat **a** through **i** for each server.

4. Enable memory-to-memory session replication for each cluster member server in the replication cluster.
   a. Go to the appropriate level of session management for the Web container level. Click **Servers** > **Application Servers**> *server_name*> **Container Settings**> **Web Container Settings**> **Session management**
   b. Click **Distributed Environment Settings** under Additional Properties.
   c. Click **Memory-to-memory replication**.
   d. Select the **Replication domain** that you want to use for the replication of sessions.
   e. Select the Server only **Replication mode**. You must configure all session managers connected to a replication domain to have the same topology. If one session manager instance in a domain is configured to use the client/server topology, then the rest of the session manager instances in that domain must be a combination of servers configured as Client only and Server only. If one session manager instance is configured to use the peer-to-peer topology, then all session manager instances must be configured as Both client and server. Alternatively, if one DRS Instance is configured in the client only mode then all DRS Instances in the domain must be configured in either the client only or the server only modes.
   f. Click **OK** on the Memory-to-memory replication page.
   g. Optional: If you want to change the tuning parameters, click **Custom tuning parameters** and select a setting or customize one. Click **OK**. Click **Save**.

      Note: Using the default tuning parameter custom settings, which specifies time based write interval of 10 seconds, may result in data loss when an application server in your cluster fails. However, this is just a small opportunity for lost data when compared to the significant improvement in performance.
   h. Click **OK** the Distributed environment settings page.
   i. Click **OK** the Session management page.

j. Repeat **a** through **i** for each server.

Classifying WebSphere transaction workload for WLM

This topic describes how to use transaction classes to classify client workload for workload management. The workload is different WebSphere transactions targeted to separate servant regions, each with goals defined by appropriate service classes. Each transaction is dispatched in its own WLM enclave in a servant region process, and is managed according to the goals of its service class.

This topic describes steps to classify transaction workload as a way of managing the workload service objectives. You also need to define the service objectives (goals) for the service classes used. In addition, you must define the service objectives of the WebSphere Application Server for z/OS servers and your business application servers.

For more information about defining service objectives (goals) for each service class, see the *z/OS MVS Planning: Workload Management* book, SA22-7602, for example at http://publibz.boulder.ibm.com/epubs/pdf/iea2w131.pdf, or the z/OS WLM Web page at http://www.ibm.com/servers/eserver/zseries/zos/wlm/.

You can classify your WebSphere work using the WLM CB-type classification criteria:
- Server name (CN)
- Server instance name (SI)
- User ID assigned to the transaction (UI)
- Transaction class (TC)

Note: To get started, you do not need to define special classification rules and work qualifiers, but you may want to do this for your production system.

To classify work using server and userid criteria, you use a combination of the WLM Workload Classification rules in the WLM ISPF dialog panels. For more information about defining WLM Classification rules, see ″Workload management (WLM) for z/OS″ and its related article that includes an example of classification rules.

To classify work using transaction classes, you define and use transaction class mappings, as described in this task. The following steps are used to classify work using transaction classes:

1. Define transaction class mappings based on the HTTP virtual host name, port number, and URI (Universal Resource Identifier - encoded address for any resource on the Web) provided with each work HTTP or HTTPS request.
   a. Create a Transaction Class mapping file (as a simple text file). For example:
   `/wasconfig/t5was/MyTrMapFile.txt`
   b. Edit the Transaction Class mapping file to define each transaction class mapping that you want to use. Define each mapping on a separate line, using the following syntax:

   ```
   TransClassMap host:port uritemplate tclass
   ```

   Note: In the host or port fields, you can use wildcard characters only for the entire field as shown in the following example.

   This syntax is the same syntax as for WebSphere Application Server for z/OS Version 4.0.1. For more information about this syntax, see Transaction class mapping file entries. For example:

   ```
   TransClassMap wsc4.washington.ibm.com:9080  /MyIVT/index.*    TCLMYIVT
   TransClassMap wsc4.washington.ibm.com:9080  /MyIVT/ivtejb     TCLMYEJB
   TransClassMap wsc4.washington.ibm.com:*     /SuperSnoop*     TCLSNOOP
   TransClassMap wsc4.washington.ibm.com:*     /ssb/*           TCLSSB
   TransClassMap *:*                           /admin*          TCLADMIN
   ```
2. Specify the Transaction Class mapping file on the administrative properties for each server that is to handle work classified by transaction class. To specify the Transaction Class mapping file for a server, use the administrative console to complete the following steps:

a. In the navigation pane, click **Servers > Application Servers**.
b. In the content pane, select the server instance, *server_name*.
c. In the Additional Properties list in the contents pane, select **Web Container**.
d. In the Additional Properties list for the Web container, select **Advanced Settings**.
e. In the **Transaction Class Mapping** field, type the name of the Transaction Class mapping file that you edited in an earlier step. For example: `/wasconfig/t5was/MyTrMapFile.txt`

   This sets the following variable in the server's was.env file:

   ```
   protocol_http_transport_class_mapping_file=/wasconfig/t5was/MyTrMapFile.txt
   ```
f. If you want to use a transaction class to classify outbound data that is delivered in response to HTTP and HTTPS requests, select the TCLASS option in the **Network QoS** field. If you specify TCLASS, WebSphere Application Server for z/OS uses the transaction class value that was used to classify the inbound request to the z/OS Workload Manager.

The following table shows classification rules for CB-type work in which the default service class is WSMED and has a reporting class of RWSDEFLT. Work run in the WSPROD WebSphere server is classified as WSMED with a reporting class of RWSPROD, unless it has a transaction class of TCLASS1, TCLASS2, or TCLASS2 assigned through the transaction class mapping file below.

```
Qualifier    Qualifier Start       Service  Report
# type       name      position    Class    Class
- ---------  --------  --------    -------- --------
                         Default: WSMED    RWSDEFLT
1 CN         WSPROD    1           WSMED    RWSPROD
2 . TC       . TCLASS1             WSFAST   RWSPRD1
2 . TC       . TCLASS2             WSMED    RWSPRD2
2 . TC       . TCLASS5             WSSLOW   RWSPRD5
1 CN         WSTEST    1           WSSLOW   RTSTEST
2 . UI       . USER1               WSMED    RTSTSTU2
2 . TC       . TCLASS5             WSSLOW   RTSTST5
```

The following table shows how work can be assigned a transaction class based on its host name, port number, or URI. For example, a web request of http://ibm.com:80/Webap1/myservlet handled by the WSPROD server would be assigned a transaction class of TCLASS1, a service class of WSFAST, and a reporting class of RWSPRD1 by the classification rules shown above.

```
TransClassMap www.ibm.com:80 /Webap1/myservlet TCLASS1
TransClassMap www.ibm.com:* /Webap1/myservlet TCLASS2
TransClassMap *:443 * TCLASS3
TransClassMap *:* /Webap1/myservlet TCLASS4
TransClassMap www.ibm.com:* /Webap5/* TCLASS5
TransClassMap * * TCLASS6
```

Controller and Servant WLM classifications

You should classify the WebSphere Application servant regions to a high STC importance service class so that they can be initialized quickly when WLM determines they are needed. The service class chosen also determines the WLM goal when Java Garbage Collection (GC) is running, which can be CPU intensive. You do not want to set a servant higher in the service class hierarchy than more important work such as production WebSphere, CICS, or IMS transaction servers.

WebSphere application controller regions do some processing to receive work into the system, manage the HTTP transport handler, classify the work and do other housekeeping tasks. Therefore, controller regions should also be classified in SYSSTC or a high importance and velocity goal.

Here is a simple example of the WLM Classification Rules for STC-type work that covers the controller and servant regions started tasks:

```
          --------Qualifier--------           -------Class--------
Action    Type     Name     Start             Service     Report
                                  DEFAULTS: OPS_DEF     ________
```

```
_____ 1  TN      %%DMN    ___              OPS_HIGH    RWSDMN _____  1  TN      T5SRV*   ___              OPS_MED
_____ 1  TN      WS%%%%   ___              SYSSTC      RWSCTLR
 ____ 1  TN      WS%%%%S  ___              OPS_HIGH    RWSSRVR
```

EJB applications

Task overview: Using enterprise beans in applications

1. Design a J2EE application and the enterprise beans that it needs. For links to design information that is specific to enterprise beans, see “Data access : Resources for learning” on page 533.
2. Develop any enterprise beans that your application will use.
3. Prepare for assembly. For your EJB 2.x-compliant entity beans, decide on an appropriate access intent policy.
4. Assemble the beans into one or more EJB modules using the assembly tool. This process includes setting security. See ″Securing enterprise bean applications″ in the information center. For your EJB 2.x-compliant entity beans, you might also want to designate container-managed persistence (CMP) sequence groups..
5. Assemble the modules into a J2EE application using the assembly tool.
6. For a given application server, update the EJB container configuration if needed for the application to be deployed, and determine if you want to batch commands or defer commands for container managed persistence. See ″Setting the run time for batched commands with JVM arguments″ and ″Setting the run time for deferred create with JVM arguments″ in the information center.
7. Deploy the application in an application server.
8. Test the modules.
   - As needed, debug problems with the container. See ″Enterprise bean and EJB container troubleshooting tips″ in the information center.
   - Debug access problems. ″See Cannot access an enterprise bean from a servlet, a JSP file, a stand-alone program, or another client″ in the information center.
9. Assemble the production application using the assembly tools.
10. Deploy the application to a production environment.
11. Manage the application:
    a. Manage installed EJB modules. After an application has been installed, you can manage its EJB modules individually through the Assembly Service Toolkit.
    b. Manage other aspects of the J2EE application.
12. Update the module and redeploy it using the assembly tools.
13. Tune the performance of the application. See ″Best practices for developing enterprise beans″.

Enterprise beans

An enterprise bean is a Java component that can be combined with other resources to create J2EE applications. There are three types of enterprise beans, *entity* beans, *session* beans, and *message-driven* beans.

All beans reside in EJB containers, which provide an interface between the beans and the application server on which they reside.

Entity beans store permanent data, so they require connections to a form of persistent storage. This storage might be a database, an existing legacy application, a file, or another type of persistent storage.

Session beans typically contain the high-level and mid-level business logic for an application. Each method on a session bean typically performs a particular high-level operation. For example, submitting an order or transferring money between accounts. Session beans often invoke methods on entity beans in the course of their business logic.

Session beans can be either *stateful* or *stateless*. A stateful bean instance is intended for use by a single client during its lifetime, where the client performs a series of method calls that are related to each other in time for that client. One example is a ″shopping cart″ where the client adds items to the cart over the course of an online shopping session. In contrast, a stateless bean instance is typically used by many clients during its lifetime, so stateless beans are appropriate for business logic operations that can be completed in the span of a single method invocation. Stateful beans should be used only where absolutely necessary -- using stateless beans improves the ability to debug, maintain, and scale the application.

Message-driven beans enable asynchronous message servicing.

- The EJB container and a Java Message Service (JMS) provider work together to process messages. When a message arrives from another application component through JMS, the EJB container forwards it through an onMessage() call to a message-driven bean instance, which then processes the message. In other respects, message-driven beans are similar to stateless session beans.
- The EJB container and a Java Connector Architecture (JCA) resource adapter work together to process messages from an enterprise information system (EIS). When a message arrives from an EIS, the resource adapter receives the message and forwards it to a message-driven bean, which then processes the message. The message-driven bean is provided services such as transaction support by the EJB container in the same way that other enterprise beans are provided service.

Beans that require data access use *data sources*, which are administrative resources that define pools of connections to persistent storage mechanisms.

For more information about enterprise beans, see ″Resources for learning.″

EJB modules

An EJB module is used to assemble one or more enterprise beans into a single deployable unit. An EJB module is stored in a standard Java archive (JAR) file.

An EJB module contains the following:

- One or more deployable enterprise beans.
- A deployment descriptor, stored in an Extensible Markup Language (XML) file. This file declares the contents of the module, defines the structure and external dependencies of the beans in the module, and describes how the beans are to be used at run time.

You can deploy an EJB module as a stand alone application, or combine it with other EJB modules or with Web modules to create a J2EE application. An EJB module is installed and run in an enterprise bean container.

For more information about EJB modules, see ″Resources for learning.″

EJB containers

An Enterprise JavaBeans (EJB) container provides a run-time environment for enterprise beans within the application server. The container handles all aspects of an enterprise bean's operation within the application server and acts as an intermediary between the user-written business logic within the bean and the rest of the application server environment.

One or more EJB modules, each containing one or more enterprise beans, can be installed in a single container.

The EJB container provides many services to the enterprise bean, including the following:

- Beginning, committing, and rolling back transactions as necessary.
- Maintaining pools of enterprise bean instances ready for incoming requests and moving these instances between the inactive pools and an active state, ensuring that threading conditions within the bean are satisfied.
- Most importantly, automatically synchronizing data in an entity bean's instance variables with corresponding data items stored in persistent storage.

By dynamically maintaining a set of active bean instances and synchronizing bean state with persistent storage when beans are moved into and out of active state, the container makes it possible for an application to manage many more bean instances than could otherwise simultaneously be held in the application server's memory. In this respect, an EJB container provides services similar to virtual memory within an operating system.

Between transactions, the state of an entity bean can be cached. The EJB container supports option A, B, and C caching.

- With option A caching, the application server assumes that the entity bean is used within a single container. Clients of that bean must direct their requests to the bean instance within that container. The entity bean has exclusive access to the underlying database, which means that the bean cannot be cloned or participate in workload management if option A caching is used.

  If you intend to use read-only scenarios, WebSphere Application Server provides an alternate, higher-performance variation of option A entity beans. This caching option is called *Multithreaded Read-Only*. Similar to standard option A behavior, the EJB container continues to activate the bean just once and leave it active until the EJB container needs space in its active instance cache. However, the EJB container differs from standard option A in the following behaviors:
  - It reloads the state of the bean from persistent storage periodically in response to the user invoking a method on it to pick up any changes that may have been made to the persistent store since the last time the bean was loaded. You can configure this function through a *Reload Interval* setting in the bean‘s deployment descriptor. For more information, see ″Developing read-only entity beans″ in the information center.
  - The state of the bean is not written to persistent store by the EJB container at the end of the transaction, nor is the bean's ejbStore() method be invoked.
  - The EJB container permits method invocations from more than one client (thread) on the same bean instance. This differs from the standard EJB component for the internals of a bean. You must keep this aspect in mind when developing your bean, and ensure that any logic in the bean‘s business methods is overall thread-safe.
- With option B caching, the entity bean remains active in the cache throughout the transaction but is reloaded at the start of each method call.
- With option C caching (the default), the entity bean is always reloaded from the database at the beginning of each transaction. A client can attempt to access the bean and start a new transaction on any container that has been configured to host that bean. This is similar to the session clustering facility described for HTTP sessions in that the entity bean's state is maintained in a shared database that can be accessed from any server when required.

This product supports the cloning of stateful session bean home objects among multiple application servers. However, it does not support the cloning of a specific instance of a stateful session bean. Each instance of a particular stateful session bean can exist in just one application server and can be accessed only by directing requests to that particular application server. State information for a stateful session bean cannot be maintained across multiple members of a server cluster. However, enabling stateful session bean failover and configuring the EJB container to use memory-to-memory replication does enable stateful session bean failover to be replicated to other servers in the cluster so that failover can occur to the backup server if the primary server for a stateful session bean stops for some reason. For more information about stateful session bean failover, see “Stateful session bean failover for the EJB container” on page 187.

By default, an EJB container runs in the **quick start** mode. The EJB container startup logic delays the loading and processing of all EJB types *except* Message Driven Beans (because they must exist before messages are posted for them), Startup Beans (which must be processed at server startup time), and those EJB types that you specify to initialize at server start. For more information about disabling quick start for EJB types, see “Changing enterprise bean types to initialize at application start time using the Application Server Toolkit” on page 187.

All other EJB initialization is delayed until the first use of the EJB type. When using Local Interfaces, the first use is when you perform an *InitialContext.lookup()* method for the type. For Remote Interfaces, it is when you call the first method on an EJB or its Home.

For more information about EJB containers, see ″Resources for learning.″

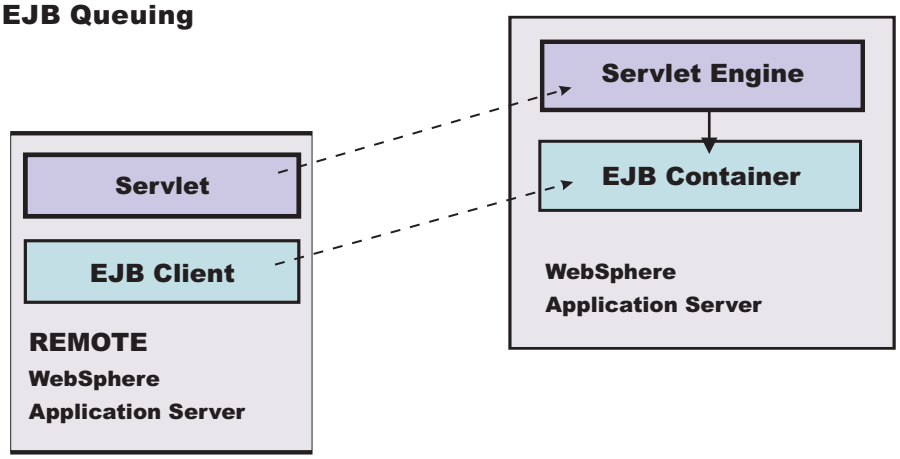
EJB method Invocation Queuing

Method invocations to enterprise beans are only queued for remote clients, making the method call. An example of a remote client is an enterprise Java bean (EJB) client running in a separate Java virtual machine (JVM) (another address space) from the enterprise bean. In contrast, no queuing occurs if the EJB client, either a servlet or another enterprise bean, is installed in the same JVM on which the EJB method runs and on the same thread of execution as the EJB client.

Remote enterprise beans communicate by using the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). Method invocations initiated over RMI-IIOP are processed by a server-side object request broker (ORB). The thread pool acts as a queue for incoming requests. However, if a remote method request is issued and there are no more available threads in the thread pool, a new thread is created. After the method request completes the thread is destroyed. Therefore, when the ORB is used to process remote method requests, the EJB container is an open queue, due to the use of unbounded threads. The following illustration depicts the two queuing options of enterprise beans.

EJB Queuing



Using access intent policies

You can use access intent policies to help the product run-time environment manage various aspects of Enterprise JavaBeans (EJB) persistence. You apply access intent policies to EJB Version 2.0 (and later) entity beans and their methods by using an application assembly tool. A set of default access intent policies comes with the Application Server Toolkit (AST) . You can also create your own custom policies.

1. Apply default access intent to CMP entity beans. For more information, see the online help available with the Application Server Toolkit .
2. Apply access intent policies to methods of CMP entity beans.
3. Create a custom access intent policy. See ″Creating a custom access intent policy″
4. Apply access intent policies to BMP entity bean methods by using the AccessIntent API.
5. Apply multiple access intent policies to methods by using application profiling.

Applying access intent policies to beans

You apply an access intent policy to an application’s entity beans through the assembly tools.

Note: This is the preferred technique to define access intent policies. Method level access intent is deprecated in Version 6.0.

1. Start the Application Server Toolkit - See ″Starting an assembly tool″ in the information center.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.

3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Access** tab.
7. In the **Access Intent for Entities 2.x (Bean Level)** panel, select the name of the bean.
8. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
9. In the **Access intent name** field, select wsPessimisticUpdate from the drop-down list.
10. **Optional:** Enter a **Description** to help you remember what this policy does.
11. **Optional:** Change the **Persistence Option** setting
12. Click **Finish**. The access intent policy for the entity bean is shown in the **Access Intent for Entities 2.x (Bean Level)** panel

Access intent policies

An access intent policy is a named set of properties (access intents) that governs data access for Enterprise JavaBeans (EJB) persistence. You can assign policies to an entity bean and to individual methods on an entity bean's home, remote, or local interfaces during assembly. You can set access intents only within EJB Version 2.x-compliant modules for entity beans with CMP Version 2.x.

This product supplies a number of access intent policies that specify permutations of read intent and concurrency control; the pessimistic/update policy can be qualified further. The selected policy determines the appropriate isolation level and locking strategy used by the run time environment.

Access intent policies are specifically designed to supplant the use of isolation level and access intent method-level modifiers found in the extended deployment descriptor for EJB version 1.1 enterprise beans. You cannot specify isolation level and read-only modifiers for EJB version 2.x enterprise beans.

Access intent policies configured on an entity basis define the default access intent for that entity. The default access intent controls the entity unless you specify a different access intent policy based on either method-level configuration or application profiling.

Note: Method level access intent has been deprecated for Version 6.

You can use application profiling or method level access intent policies to control access intent more precisely. Method-level access intent policies are named and defined at the module level. A module can have one or many such policies. Policies are assigned, and apply, to individual methods of the declared interfaces of entity beans and their associated home interfaces. A method-based policy is acted upon by the combination of the EJB container and persistence manager when the method causes the entity to load.

For entity beans that are backed by tables with nullable columns, use an optimistic policy with caution. Nullable columns are automatically excluded from overqualified updates at deployment time; concurrent changes to a nullable field might result in lost updates. When used with the IBM Rational Application Developer product, this product provides support for selecting a subset of the non-nullable columns that are to be reflected in the overqualified update statement that is generated in the deployment code to support optimistic policies.

Concurrency control:

Concurrency control is the management of contention for data resources. A concurrency control scheme is considered *pessimistic* when it locks a given resource early in the data-access transaction and does not release it until the transaction is closed. A concurrency control scheme is considered *optimistic* when locks are acquired and released over a very short period of time at the end of a transaction.

The objective of optimistic concurrency is to minimize the time over which a given resource would be unavailable for use by other transactions. This is especially important with long-running transactions, which under a pessimistic scheme would lock up a resource for unacceptably long periods of time.

Under an optimistic scheme, locks are obtained immediately before a read operation and released immediately afterwards. Update locks are obtained immediately before an update operation and held until the end of the transaction.

To enable optimistic concurrency, this product uses an *overqualified update scheme* to test whether the underlying data source has been updated by another transaction since the beginning of the current transaction. With this scheme, the columns marked for update and their original values are added explicitly through a WHERE clause in the UPDATE statement so that the statement fails if the underlying column values have been changed. As a result, this scheme can provide column-level concurrency control; pessimistic schemes can control concurrency at the row level only.

Optimistic schemes typically perform this type of test only at the end of a transaction. If the underlying columns have not been updated since the beginning of the transaction, pending updates to container-managed persistence fields are committed and the locks are released. If locks cannot be acquired or if some other transaction has updated the columns since the beginning of the current transaction, the transaction is rolled back: All work performed within the transaction is lost.

Pessimistic and optimistic concurrency schemes require different transaction isolation levels. Enterprise beans that participate in the same transaction and require different concurrency control schemes cannot operate on the same underlying data connection.

Whether or not to use optimistic concurrency depends on the type of transaction. Transactions with a high penalty for failure might be better managed with a pessimistic scheme. (A high-penalty transaction is one for which recovery would be risky or resource-intensive.) For low-penalty transactions, it is often worth the risk of failure to gain efficiency through the use of an optimistic scheme. In general, optimistic concurrency is more efficient when update collisions are expected to be infrequent; pessimistic concurrency is more efficient when update collisions are expected to occur often.

Read-ahead hints:

Read-ahead schemes enable applications to minimize the number of database round trips by retrieving a working set of container-managed persistence (CMP) beans for the transaction within one query. Read-ahead involves activating the requested CMP beans and caching the data for their related beans, which ensures that data is present for the beans that are most likely to be needed next by an application. A *read-ahead hint* is a representation of the related beans that are to be read. It is associated with the *findByPrimaryKey* method for the requested bean type, which must be an EJB 2.x-compliant CMP entity bean.

A read-ahead hint takes the form of a character string. You do not have to provide the string; the wizard generates it for you based on CMRs defined for the bean. The following example is provided as supplemental information only. Suppose a CMP bean type A has a finder method that returns instances of bean A. A read-ahead hint for this method is specified using the following notation: *RelB*.*RelC*; *RelD*

Interpret the preceding notation as follows:
- Bean type A has a CMR with bean types B and D.
- Bean type B has a CMR with bean type C.

For each bean of type A that is retrieved from the database, its directly-related B and D beans and its indirectly-related C beans are also retrieved. The order of the retrieved bean data columns in each row of the result set is the same as their order in the read-ahead hint: an A bean, a B bean (or null), a C bean (or null), a D bean (or null). For hints in which the same relationship is mentioned more than once (for example, *RelB*.*RelC*;*RelB*.*RelE*), a bean's data columns appear only once, at the position it first appears in the hint.

The tokens shown in the notation (*RelB* and so on) must be CMR field names for the relationships as defined in the deployment descriptor for the bean. In indirect relationships such as *RelB*.*RelC*, *RelC* is a CMR field name defined in the deployment descriptor for bean type B.

A single read-ahead hint cannot refer to the same bean type in more than one relationship. For example, if a Department bean has a relationship *employees* with the Employee bean and also has a relationship *manager* with the Employee bean, the read-ahead hint cannot specify both *employees* and *manager*.

For more information about how to set read-ahead hints, see the documentation for the Rational Application Developer product.

Some things to consider

When developing your read-ahead hints, you should keep the following in mind:
- Read ahead on long or complex paths can result in a query that is too complex to be useful. Read ahead on root or leaf inheritance mappings need particular care. You should add up the number of tables that are involved in the preload and then consider whether a join that complex is really a reasonable query on your target database.
- Read ahead does NOT work in the following cases:
  - preload paths across M:N relationships
  - preload paths across recursive enterprise bean relationships or recursive fk relationships
  - where multiple instances of the same table occur on the same path (whether through a recursive relationship or not).
  - when readAhead contains a table join. Different access intents can result in requiring a select for update statement. Check the matrix on the JDBC driver and select for update support to see if readAhead is enabled.

Using access intent policies to avoid database deadlocks caused by lock upgrades:

To avoid databse deadlocks caused by lock upgrades, you can change the access intent policy for entity beans from the default of wsPessimisticUpdate-WeakestLockAtLoad to wsPessimisticUpdate or can use an optimistic locking approach.

When accessing data in a database concurrently, an application must be aware of and prepared for database locking that must occur to insure the integrity of the data.

If an entity bean performs a findByPrimaryKey (which by default obtains a 'Read' lock in the database) then the entity bean is updated within the same transaction, this causes a lock upgrade (to 'Exclusive').

If this scenario occurs on multiple threads concurrently, then a deadlock can happen. This is because multiple 'Read' locks can be obtained concurrently, but only one 'Exclusive' lock can be obtained only when all other locks have been dropped. This one 'Exclusive' lock can never be obtained in this scenario, because all transactions are attempting the lock upgrade.

To avoid this problem, you can change the access intent policy for the entity bean from the default of wsPessimisticUpdate-WeakestLockAtLoad to wsPessimisticUpdate. This change in access intent enables the application to inform WebSphere and the database that the transaction will update the enterprise bean, and so an 'Update' lock is obtained immediately on the findByPrimaryKey. This avoids the lock upgrade when the update is performed later.

The preferred technique to define access intent policies is to change the access intent for the entire entity bean. You can change the access intent for the findByPrimaryKey method, but this is deprecated in Version 6.0. (You might want to change the access intent for an individual method if, for example, the entity bean is involved in some transactions that are read only.)

An alternative technique is to use an optimistic approach, where the findByPrimaryKey method does not hold a 'Read' lock, so there is no lock upgrade. However, this requires that the application is coded for this, to handle rollbacks that could occur. Optimistic locking is really intended for applications that do not expect database contention on a regular basis.

To change the access intent policy for an entity bean, you can use the assembly tool to set the ″Default Access Intent for Entities 2.x (Bean Level)″ on the Access tab of the EJB Deployment Descriptor, as described in "Applying access intent policies to beans" on page 173.

Configuring read-read consistency checking with the assembly tools

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction. For the Access Intents that are for *repeatable read* (RR), this means the product checks that the data is consistent with that in the data store, and ensures that no one updates it after the checking. For the Access Intents that are for *read committed* (RC), this means the product checks that the data is consistent at the point of checking, it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as non-LifeTimeInCache beans.

To perform this checking, you need to configure CMP entity beans with read-read consistency checking. You can do this using the Application Server Toolkit.

1. Start the Application Server Toolkit. See ″ Starting an assembly tool″ in the information center.
2. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
3. Select the **Access** tab. The Add Access Intent window appears. There are two areas of the panel that deal with adding access intent:
   - Default Access Intent for Entities 2.x (Bean Level)
   - Access Intent for Entities 2.x (Method Level)
4. Select the Bean or Method level. Another access intent window appears where you can set the properties you wish to use.
5. Use the dropdown list to select the Access intent name.
6. **Optional:** Enter a description.
7. Check the **Persistence Option** box.
8. Check the **Verify Read Only Data** box.
9. Use the dropdown list to select your choice for read-read consistency checking. You have three options:

   NONE No read-read checking is done.

AT_TRAN_BEGIN
During ejbLoad, if the data is from cache, check the database to ensure that the data of the bean has not changed since the last load (with proper locking based on access intent's concurrency control attribute.)

AT_TRAN_END
At the end of transaction, if the bean is not changed and did not load by the current transaction, check the database to ensure that the data of the bean has not changed from last load (with proper locking based on access intent's concurrency control attribute.) If the data has changed, fail the transaction.

10. Select **Finish**.

Examples: read-read consistency checking:
Usage Scenario

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction. For the Access Intents that are for *repeatable read* (RR), this means the product checks that the data is consistent with that in the data store, and ensures that no one updates it after the checking. For the Access Intents that are for *read committed* (RC), this means the product checks that the data is consistent at the point of checking, it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as non-LifeTimeInCache beans.

You have three options for setting consistency checking, as shown in the following scenarios concerning the calculation of interest in ″Ann's″ bank account. In each case, the data store is shared by this EJB CMP application (to calculate the interest) and other applications, such as EJB BMP, JDBC, or legacy applications. Also in each case, the EJB Account is configured as a "long-lifetime" bean.

NONE
- The server is started.
- User1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from cache, with a balance of $100.
- Calculate Ann's interest, but the result might not be correct because of the data integrity issue.

Read-read checking AT_TRAN_BEGIN
- The server is started.
- User1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from cache, with a balance of $100.
- PM performs read-read check on Ann's account and finds that the balance of 100 is changed. It issues a database query to retrieve balance of $120, and Ann's data in the cache is refreshed.
- Calculate Ann's interest, proceed with the transaction because data integrity is protected.

Read-read checking AT_TRAN_END
- The server is started.
- User1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.

- Ann‘s record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann‘s data is read from database, with balance of $100.
- Calculate Ann‘s interest.
- During end of transaction 2, PM performs read-read check on Ann’s account and finds that the balance of 100 is changed.
- PM rolls back the transaction and invalidates the cache. The transaction fails and again data integrity is protected.

Access intent service

Access intent is a WebSphere Application Server run-time service that enables you to more precisely manage an application’s persistence. The access intent service defines a set of declarative annotations used by the Enterprise JavaBeans (EJB) container and its agents to make performance optimizations for entity bean access. These annotations are organized into sets called *access intent policies*.

Access intent policies contain a set of annotations considered as hints by the EJB container and its agents. Most access intent policies are hints representing high-level abstractions that can be mapped to a specific back end resource manager. It is the responsibility of the EJB persistence machinery to ensure the necessary concurrency control, connection, and cache management when carrying out the persistence details. The EJB persistence manager can use access intent hints to make better performance decisions when carrying out its assigned task. A smaller number of access intents are hints to the EJB container, influencing the management of EJB collections.

Generally you configure *bean level* access intent for your applications. You can also apply access intent policies to beans within the scope of *application profiles*. Consequently, you can configure beans with multiple and opposing access intent policies. The application profiling documentation explains in more detail how to configure an application to apply a particular access intent policy to a bean for one request, then apply another access intent policy to the same bean for a different request.

Support for applying access intent policies at the method level is officially deprecated in WebSphere Application Server Version 6.0. (In this practice of configuring access intent, you apply a policy to methods within the scope of an EJB module so that the policy becomes the default access intent for all requests upon those methods.)

Access intent design considerations

Use the access intent service to solve clear performance problems. Identify usage patterns that lead to poor application performance and apply appropriate access intent policies.

Refrain from over-tuning an application. You can introduce errors by incorrectly using the access intent service. For example, misuse of the wsPessimisticUpdate-NoCollision policy can result in lost updates; inappropriately setting the collection increment value can introduce performance issues; and problem determination is more difficult when an application is confusingly configured with multiple access intent policies. Clarity and simplicity should be your guiding principles when using the access intent service. This is even more important when applying access intent polices within the scope of application profiles (a feature of WebSphere Business Integration Server Foundation).

Even though access intent policies can be configured on any method of an entity bean, some attributes of a policy can only be leveraged by the run-time environment under certain conditions. For example, concurrency and access intent are only used for CMP entity beans when the ejbLoad() method is driven to open a connection to, and read data from, a given resource; that data is cached and used to drive the proper queries during invocation of the ejbStore() method. Read-ahead hints are only used during the execution of a finder for a bean. Finally, the collection increment and resource manager prefetch increment are only used on multi-object finders. Configuring policies on methods that will not use the policy is not an error (only certain attributes of any policy are used, even when the policy is appropriately applied to a

method). However, configuring policies unnecessarily throughout an application obscures the design of the application and complicates the maintenance of the application.

Applying access intent policies to methods

You apply an access intent policy to a method, or set of methods, in an application's entity beans through the assembly tools.

Note: Method level access intent is deprecated in Version 6.0.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Access** tab.
7. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
8. Specify the **Name** for your new intent policy.
9. Select the **Access intent name** from the drop-down list.
10. Enter a **Description** to help you remember what this policy does.
11. **Optional:** Select **Read Ahead Hint**. A single access intent read ahead hint might not refer to the same bean type in more than one relationship. For example, if a **Department** enterprise bean has a relationship *employees* with the **Employee** enterprise bean, and also has a relationship *manager* with the **Employee** enterprise bean, then a read ahead hint cannot specify both *employees* and *manager*.
12. Click **Next**. The next **Add Access Intent** panel displays, with optional attributes.
13. **Optional:** Decide whether or not to overwrite these optional access intent attributes. Click on those you want to change.
14. Click **Next**. The next **Add Access Intent** panel, with a list of Enterprise Beans, displays.
15. Select one or more Enterprise Beans from the list.

    Note: If you selected **Read Ahead Hint** in an earlier step, you can only select **ONE** bean at this step.
16. Click **Next**. The next **Add Access Intent** panel, with a list of methods, displays.
17. Select the methods you want to use.
18. If you *DID NOT* select **Read Ahead Hint** in an earlier step, click **Finish**. If you *DID* select the Read Ahead Hint option, you can click **Next** to specify your Read Ahead Hint for the specified bean. The next **Add Access Intent** panel, with a list of EJB preload paths, displays.
19. Edit the EJB preload path by selecting relationship roles from the **Relationship roles:** window.

20. Click **Finish**. A new entry is created in the **Access Intent for Entities 2.x (Method Level)** panel

Using the AccessIntent API

This task describes how to programmatically retrieve and call the AccessIntent API during the execution of BMP entity bean methods.

1. Look up the current access intent in the namespace. For example:

```
InitialContext ic = new InitialContext();
AccessIntent ai = ic.lookup("java:comp/websphere/AppProfile/AccessIntent");
```

2. Call the necessary get() methods. For example:

```
int concurrency = ai.getConcurrencyControl();
int accessType = ai.getAccessType();
if ( (concurrency == AccessIntent.CONCURRENCY_CONTROL_PESSIMISTIC)
   && (accessType == AccessIntent.ACCESS_TYPE_UPDATE) ) {
     boolean exclusive = ai.getPessimisticUpdateLockHint();
     // . . .
}
// . . .
```

Note: The access intent object reference retrieved from the java:comp lookup is current for the duration of the method in which the reference was looked up. Depending on how you configured the application profile, subsequent calls of the same method might not retrieve the same access intent reference. You can only look up the object reference during the call of a BMP entity bean's method; the reference does not exist during a request on a CMP entity bean. Therefore, access intent object references should not be cached beyond, or used outside of, the scope of the execution of any given BMP method.

Access intent exceptions

The following exceptions are thrown in response to the application of access intent policies:

com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException

If the method that drives the ejbLoad() method is configured to be read-only but updates are then made within the transaction that loaded the bean's state, an exception is thrown during invocation of the ejbStore() method, and the transaction is rolled back. Likewise, the ejbRemove() method cannot succeed in a transaction that is set as read-only. If an update hint is applied to methods of entity beans with bean-managed persistence, the same behavior and exception results. The forwarded exception object contains the message string `PMGR1103E: update instance level read only bean beanName`

This exception is also thrown if the applied access intent policy cannot be honored because a finder, ejbSelect, or container-managed relationship (CMR) accessor method returns an inherently read-only result. The forwarded exception object contains the message string `PMGR1001: No such DataAccessSpec - methodName`

The most common occurrence of this error is when a custom finder that contains a read-only EJB Query Language (EJB QL) statement is called with an applied access intent of `wsPessimisticUpdate` or `wsPessimisticUpdate-Exclusive`. These policies require the use of a USE AND KEEP UPDATE LOCKS clause on the SQL SELECT statement to be executed, but a read-only query cannot support USE AND KEEP UPDATE LOCKS. Other examples of read-only queries include joins; the use of ORDER BY, GROUP BY, and DISTINCT keywords.

To eliminate the exception, edit the EJB query so that it does not return an inherently read-only result or change the access intent policy being applied.

- If an update access is required, change the applied access intent setting to `wsPessimisticUpdate-WeakestLockAtLoad` or `wsOptimisticUpdate`.
- If update access is not truly required, use `wsPessimisticRead` or `wsOptimisticRead`.
- If connection sharing between entity beans is required, use `wsPessimisticUpdate-WeakestLockAtLoad` or `wsPessimisticRead`.

com.ibm.websphere.ejb.container.CollectionCannotBeFurtherAccessed
If a lazy collection is driven after it is no longer in scope, and beyond what has already been locally buffered, a CollectionCannotBeFurtherAccessed exception is thrown.

com.ibm.ws.exception.RuntimeWarning
If an application is configured incorrectly, a run-time warning exception is thrown as the application starts; startup is ended. You can validate an application's configuration by choosing the verify function. Some examples of misconfiguration include:
- A method configured with two different access intent policies
- A method configured with an undefined access intent policy

Access intent assembly settings

Access intent policies contain data-access settings for use by the persistence manager. Default access intent policies are configured on the entity bean.

These settings are applicable only for EJB 2.x-compliant entity beans that are packaged in EJB 2.x-compliant modules. Connection sharing between beans with bean-managed persistence and those with container-managed persistence is possible if they all use the same access intent policy.

Name:

Specifies a name for a mapping between an access intent policy and one or more methods.

Description:

Contains text that describes the mapping.

Methods - Name:

Specifies the name of an enterprise bean method, or the asterisk character (*). The asterisk is used to denote all of the methods of an enterprise bean's remote and home interfaces.

Methods - Enterprise bean:

Specifies which enterprise bean contains the methods indicated in the Name setting.

Methods - Type:

Used to distinguish between a method with the same signature that is defined in both the home and remote interface. Use `Unspecified` if an access intent policy applies to all methods of the bean.

Data type	String
Range	Valid values are `Home`, `Remote`,`Local`, `LocalHome` or `Unspecified`

Methods - Parameters:

Contains a list of fully qualified Java type names of the method parameters. This setting is used to identify a single method among multiple methods with an overloaded method name.

Applied access intent:

Specifies how the container must manage data access for persistence. Configurable both as a default access intent for an entity and as part of a method-level access intent policy.

Data type	String

Range

Valid settings are `wsPessimisticUpdate`, `wsPessimisticUpdate-NoCollision`, `wsPessimisticUpdate-Exclusive`, `wsPessimisticUpdate-WeakestLockAtLoad`, `wsPessimisticRead`, `wsOptimisticUpdate`, or `wsOptimisticRead`. Only `wsPessimisticRead` and `wsOptimisticRead` are valid when class-level caching is enabled in the EJB container.

This product supports lazy collections. For each segment of a collection, iterating through the collection (*next()*) does not trigger a remote method call to retrieve the next remote reference. Two policies (`wsPessimisticUpdate` and `wsPessimisticUpdate-Exclusive`) are extremely lazy; the collection increment size is set to 1 to avoid overlocking the application. The other policies have a collection increment size of 25.

Additional information about valid settings follows:

Profile name	Concurrency control	Access type	Transaction isolation
wsPessimisticRead (Note 1)	pessimistic	read	For Oracle, read committed. Otherwise, repeatable read
wsPessimisticUpdate (Note 2)	pessimistic	update	For Oracle, read committed. Otherwise, repeatable read
wsPessimisticUpdate-Exclusive (Note 3)	pessimistic	update	serializable
wsPessimisticUpdate-NoCollision (Note 4)	pessimistic	update	read committed
wsPessimisticUpdate-WeakestLockAtLoad (Note 5)	pessimistic	update	Repeatable read
wsOptimisticRead	optimistic	read	read committed
wsOptimisticUpdate (Note 6)	optimistic	update	read committed

Notes:
1. Read locks are held for the duration of the transaction.
2. The generated SELECT FOR UPDATE query grabs locks at the beginning of the transaction.
3. SELECT FOR UPDATE is generated; locks are held for the duration of the transaction.
4. Generated overqualified-update query forces failure if CMP column values have changed since the beginning of the transaction.

Access intent best practices

This topic outlines issues to consider when applying access intent policies to Enterprise JavaBeans (EJB) methods.

- **Take care when applying `wsPessimisticUpdate-NoCollision`.** This policy does not ensure data integrity. No database locks are held, so concurrent transactions can overwrite each other's updates. Use this policy only if you can be sure that only one transaction will attempt to update persistent store at any given time.

Frequently asked questions: Access intent

I have not applied any access intent policies at all. My application runs just fine with a DB2 database, but it fails with an Oracle database with the following message: *com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException: PMGR1001E: No such DataAccessSpec :FindAllCustomers. The backend datastore does not support the SQLStatement needed by this AccessIntent: (pessimistic update-weakestLockAtLoad)(collections: transaction/25) (resource manager prefetch: 0) (AccessIntentImpl@d23690a)*. Why?

If you have not configured access intent, all of your data is accessed under the default access intent policy (`wsPessimisticUpdate-WeakestLockAtLoad`). On DB2 databases, the weakest lock is a shared one, and the query runs without a USE AND KEEP UPDATE LOCKS clause. On Oracle databases, however, the weakest lock is an update lock; this means that the SQL query must contain a USE AND KEEP UPDATE LOCKS clause. However, not every SQL statement necessarily supports USE AND KEEP UPDATE LOCKS; for example, if the query is being run against multiple tables in a join, USE AND KEEP UPDATE LOCKS is not supported. To avoid this problem, try either of the following:

- Modify your SQL query or reconfigure your application so that an update lock is supported
- Apply an access intent policy that supports optimistic concurrency

I am calling a finder method and I get an InconsistentAccessIntentException at run time. Why?

This can occur when you use method-level access intent policies to apply more control over how a bean instance is loaded. This exception indicates that the entity bean was previously loaded in the same transaction. This could happen if you called a multifinder method that returned the bean instance with access intent policy X applied; you are now trying to load the second bean again by calling its findByPrimaryKey method with access intent Y applied. Both methods must have the same access intent policy applied.

Likewise, if the entity was loaded once in the transaction using an access intent policy configured on a finder, you might have called a container-managed relationship (CMR) accessor method that returned the entity bean configured to load using that entity's default access intent.

To avoid this problem, ensure that your code does not load the same bean instance twice within the same transaction with different access intent policies applied. Avoid the use of method-level access intent unless absolutely necessary.

I have two beans in a container-managed relationship. I call findByPrimaryKey() on the first bean and then call getBean2( ), a CMR accessor method, on the returned instance. At that point, I get an InconsistentAccessIntentException. Why?

You are probably using read-ahead. When you loaded the first bean, you caused the second bean to be loaded under the access intent policy applied to the finder method for the first bean. However, you have configured your CMR accessor method from the first bean to the second with a different access intent policy. CMR accessor methods are really finder methods in disguise; the run-time environment behaves as if you were trying to change the access intent for an instance you have already read from persistent store.

To avoid this problem, beans configured in a read-ahead hint are all driven to load with the same access intent policy as the bean to which the read-ahead hint is applied.

I have a bean with a one-to-many relationship to a second bean. The first bean has a pessimistic-update intent policy applied. When I try to add an instance of the second bean to the first bean's collection, I get an UpdateCannotProceedWithIntegrityException. Why?

The second bean probably has a read intent policy applied. When you add the second bean to the first bean's collection, you are not updating the first bean's state, you are implicitly modifying the second bean's state. (The second bean contains a foreign key to the first bean, which is modified.)

To avoid this problem, ensure that both ends of the relationship have an update intent policy applied if you expect to change the relationship at run time.

Managing EJB containers

Each application server can have a single EJB container; one is created automatically for you when the application server is created. The following steps are to be performed only as needed to improve performance after the EJB application has been deployed.

1. Adjust EJB container settings.
2. Adjust EJB cache settings.

If adjustments do not improve performance, consider adjusting access intent policies for entity beans, reassembling the module, and redeploying the module in the application.

EJB container settings

Use this page to configure and manage the EJB container of this application server.

To view this administrative console page, click **Servers > Application Servers >** *serverName* **> EJB Container Settings** > **EJB container**.

Passivation directory:

Specifies the directory into which the container saves the persistent state of passivated stateful session beans.

Stateful session beans with an activation policy of TRANSACTION are passivated at the end of the transaction in which they are enlisted, and stateful session beans with an activation policy of ONCE (default) are passivated when the number of active bean instances becomes greater than the cache size specified in the container configuration. When a stateful bean is passivated, the container serializes the bean instance to a file in the passivation directory and discards the instance from the bean cache. If, at a later time, a request arrives for the passivated bean instance, the container retrieves it from the passivation directory, deserializes it, returns it to the cache, and dispatches the request to it. If any step fails (for example, if the bean instance is no longer in the passivation directory), the method invocation fails.

Inactive pool cleanup interval:

Specifies the interval at which the container examines the pools of available bean instances to determine if some instances can be deleted to reduce memory usage.

Data type	Integer
Units	Milliseconds
Range	0 to 2 147 483 674

Default datasource JNDI name:

Specifies the JNDI name of a data source to use if no data source is specified during application deployment. This setting is not applicable for EJB 2.x-compliant CMP beans.

Servlets and enterprise beans use *data sources* to obtain these connections. When configuring a container, you can specify a default data source for the container. This data source becomes the default data source used by any entity beans installed in the container that use container-managed persistence (CMP).

The default data source for a container is secure. When specifying it, you must provide a user ID and password for accessing the data source.

Specifying a default data source is optional if each CMP entity bean in the container has a data source specified in its configuration. If a default data source is not specified and a CMP entity bean is installed in the container without specifying a data source for that bean, applications cannot use that CMP entity bean.

Enable stateful session bean failover using memory-to-memory replication:

Specifies that failover is enabled for *all* stateful session beans installed in this EJB container.

This checkbox is disabled until you define a replication domain. This selection has a hyperlink to help you configure the replication settings. If no replication domains are configured, the link takes you to a panel where you can create one. If at least one domain is configured, the link takes you to a panel where you can select the replication settings to be used by the EJB container.

Data type	Checkbox
Default	Unselected
Range	Selected or unselected.

Initial state:

Specifies the execution state requested when the server first starts.

Data type	String
Default	Started
Range	Valid values are `Started` and `Stopped`

EJB container system properties

In addition to the settings accessible from the administrative console, you can set the following system property by command-line scripting:

com.ibm.websphere.ejbcontainer.poolSize

Specifies the size of the pool for the specified bean type. This property applies to stateless, message-driven and entity beans. If you do not specify a default value, the container defaults of 50 and 500 are used.

Set the pool size for a given entity bean as follows:

```
beantype=min,max[:beantype=min,max...]
```

beantype is the J2EE name of the bean, formed by concatenating the application name, the **#** character, the module name, the **#** character, and the name of the bean (that is, the string assigned to the `<ejb-name>` field in the bean's deployment descriptor). *min* and *max* are the minimum and maximum pool sizes, respectively, for that bean type. Do not specify the square brackets shown in the previous prototype; they denote optional additional bean types that you can specify after the first. Each bean-type specification is delimited by a colon (:).

Use an asterisk (*) as the value of *beantype* to indicate that all bean types are to use those values unless overridden by an exact bean-type specification somewhere else in the string, as follows:

```
*=30,100
```

To specify that a default value be used, omit either *min* or *max* but retain the comma (,) between the two values, as follows (split for publication):

```
SMApp#PerfModule#TunerBean=54,
   :SMApp#SMModule#TypeBean=100,200
```

You can specify the bean types in any order within the string.

com.ibm.websphere.ejbcontainer.allowEarlyInsert

Note: This property is applicable to CMP 1.1 beans only.

By default, the EJB Container creates the entity bean representation in the database only after the method ejbPostCreate(...) is called. However, some applications may rely on method ejbCreate(...) to have created the entity bean in the database. For such a requirement, setting the JVM property *com.ibm.websphere.ejbcontainer.allowEarlyInsert* to **true** overrides the default behavior.

Changing enterprise bean types to initialize at application start time using the Application Server Toolkit

By default, the WebSphere Application Server's Enterprise JavaBeans (EJB) Container delays the initialization (loading and processing) of most EJB types until they are needed during runtime. This helps to speed up the application start time.

EJB types can, however, be forced to initialize at application start time by setting a flag within the bean's deployment descriptor. If this flag is set to **true** then the bean is initialized at application start time.

1. Start the Application Server Toolkit.
2. Select **EJB Deployment Descriptor**.
3. In the property pane, select the **WebSphere Extensions** tab.
4. Check the box labeled **Start EJB at Application Start**.
5. Select **OK**.

Changing enterprise bean types to initialize at application start time using the administrative console

By default, the WebSphere Application Server's Enterprise JavaBeans (EJB) Container delays the initialization (loading of classes and processing of deployment descriptor metadata) of most EJB types until they are needed during runtime. This helps to speed up the application start time.

All EJB types within a server can, however, be forced to initialize at application start time by setting a system property within the administrative console. If the value of this property is set to **true** then all beans within the server are initialized at each application's start time.

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Server Infrastructure area, select **Java and Process Management**.
6. In the Server Infrastructure area, select **Process Definition**.
7. Select **Servant** process type.
8. In the Additional Properties area, select **Java Virtual Machine**.
9. In the Additional Properties area, select **Custom Properties**.
10. Select the **New** box.
11. In the **Name** entry field, type *com.ibm.websphere.ejbcontainer.initializeEJBsAtStartup*.
12. In the **Value** entry field, type *true*. Entering *true* causes all Enterprise JavaBeans to initialize when your application starts. Entering *false* causes initialization of all beans to be delayed.

    Note: Setting com.ibm.websphere.ejbcontainer.initializeEJBsAtStartup to either true or false takes precedence over any *Start EJB at Application Start* settings made on individual EJB types (see "Changing enterprise bean types to initialize at application start time using the Application Server Toolkit").
13. Select **OK**.

Stateful session bean failover for the EJB container

WebSphere Application Server Version 6.0 enables you to construct applications with the assumption that your applications using stateful session beans are not limited by unexpected server failures. This version of the product utilizes the functions of the Data Replication Service (DRS) and Workload Management (WLM) so you can enable stateful session bean failover.

Because you might not want to enable failover for every single stateful session bean installed in the EJB container, you can override the EJB container settings at either the application or EJB module level. You can either enable or disable failover at each of these levels. For example, consider the following situations:

- You want to enable failover for all applications except for a single application. To do this, you enable failover at the EJB container level and override the setting at the application level to disable failover on the single application.
- You want to enable failover for a single installed application. To do this, disable failover at the EJB container level and then override the setting at the application level to enable failover on the single application.
- You want to enable failover for all applications except for a single module of an application. To do this, enable failover at the EJB container level, then override the setting at the module application level to disable failover on the single module.
- You want to enable failover for a single installed EJB module. To do this, disable failover at the EJB container level and then override the setting at the EJB module level to enable failover on the single EJB module.

For information about enabling stateful session bean failover from the administrative console, see "Enabling or disabling stateful session bean failover with the EJB container panel" on page 192, "Enabling or disabling stateful session bean failover with the enterprise applications panel" on page 192, and "Enabling or disabling stateful session bean failover with the EJB modules panel" on page 193.

Stateful session bean activation policy with failover enabled

WebSphere Application Server enables an application assembler to specify an activation policy to use for stateful session beans. It is important to consider that the only time the EJB container prepares for failover (by replicating the stateful session bean data using DRS) is when the stateful session bean is passivated. If you configure the bean with an *activate once* policy, the bean is essentially never passivated. If you configure the *activate at transaction boundary* policy, the bean is passivated whenever the transaction that the bean is enlisted in completes. For stateful session bean failover to be useful, the activate at transaction boundary policy is required.

Rather than forcing you to edit the deployment descriptor of every stateful session bean and reinstall the bean, the EJB container simply ignores the configured activation policy for the bean when you enable failover. The container automatically uses the activate at transaction boundary policy.

Stateful session bean use of container managed units of work or bean managed units of work with failover enabled

The relevant "units of work" in this case are *transactions* and *activity sections*. The product supports stateful session bean failover for container managed transactions (CMT), bean managed transactions (BMT), container managed activity sessions (CMAS), and bean managed activity sections (BMAS). However, in the container managed cases, preparation for failover only occurs if trying to send a request for an enterprise bean method invocation results in no connection to the server. Also, if the server fails *after* a request is sent to it and acknowledged, failover does not occur. When a failure occurs in the middle of a request or unit of work, WLM cannot safely fail over to another server without some compensation code being executed by the application. When that happens, the application receives a Common Object Request Broker Architecture (CORBA) exception and minor code telling it that transparent failover could not occur because the failure happened during execution of a unit of work. The application should be written to check for the CORBA exception and minor code, and compensate for the failure. After the compensation code executes, the application can retry the requests and if a path exists to a backup server WLM routes the new request to a new primary server for the stateful session bean.

The same is true for bean managed units of work (transactions or activity sessions). However, bean managed work introduces a new possibility that needs to be considered.

For bean managed units of work, the failover process is not always able to detect that a BMT or BMAS started by a stateful session bean method has not completed. Thus, it is possible that failover to a new server can occur despite the unit of work failing during the middle of a transaction or session. Because the unit of work is implicitly rolled back, WLM behaves as if it is safe to transparently fail over to another server, when in fact some compensation code might be required. When this happens, the EJB container detects this on the new server and initiates an exception. This exception occurs under the following scenario:

1. A method of a stateful session bean using bean managed transaction or activity session calls begin on a UserTransaction it obtained from the SessionContext. The method does some work in the started unit of work, but does not complete the transaction or session before returning to the caller of the method.
2. During post invocation of the method started in step 1, the EJB container suspends the work started by the method. This is the action required by Enterprise JavaBeans specification for bean managed units of work when the bean is a stateful session bean.
3. The client starts several other methods on the stateful session bean. Each invocation causes the EJB container to resume the suspended transaction or activity session, dispatch the method invocation, and then suspend the work again before returning to the caller.
4. The client calls a method on the stateful session bean that completes the transaction or session started in step 1.

This scenario depicts a *sticky* bean managed unit of work. The transaction or activity session sticks around for more than a single stateful session bean method. If an application uses a sticky BMT or BMAS, and the server fails after a sticky unit of work completes and before another sticky unit of work starts, failover is successful. However, if the server fails *before* a sticky transaction or activity session completes, the failover is not successful. Instead, when the failover process routes the stateful session bean request to a new server, the EJB container detects that the failure occurred during an active sticky transaction or activity session. At that time, the EJB container initiates an exception.

Essentially, this means that failover for both container managed and bean managed units of work is not successful if the transaction or activity session is still active. The only real difference is the exception that occurs.

Application Design Considerations

You should consider the following when designing applications that use the stateful session bean failover process:

- To avoid the possibility described in the section above, you are encouraged to write your application to configure stateful session beans to use container managed transactions (CMT) rather than bean managed transactions (BMT).
- If you desire immediate failover, and your application creates either an HTTP session or a stateful session bean that stores a reference to another stateful session bean, then the administrator must ensure the HTTP session and stateful session bean are configured to use the same data replication service (DRS) replication domain.
- Do Not use a local and a remote reference to the same stateful session bean.

  Normally a stateful session bean instance with a given primary key can only exist on a single server at any given moment in time. Failover might cause the bean to be moved from one server to another, but it never exists on more than one server at a time. However, there are some unlikely scenarios that can result in the same bean instance (same primary key) existing on more than one server concurrently. When that happens, each copy of the bean is unaware of the other and no synchronization occurs between the two instances to ensure they have the same state data. Thus, your application receives unpredictable results.

  Attention: To be sure to avoid this situation you must remember that with failover enabled, your application should **never** get both a local (EJBLocalObject) and remote (EJBObject) reference to the same stateful session bean instance.

For z/OS users only

Stateful session bean failover on WebSphere Application Server Network Deployment for z/OS is slightly different than that on the WebSphere Application Server Network Deployment product. In addition to the failover solution discussed here, z/OS users can also enable failover among servants in an unmanaged server. For more information, refer to:

- "Peer recovery of transactions" on page 1308
- Setting up peer restart and recovery
- Considerations for clustered servers and stateful session beans

Because the z/OS product has a control region and servant regions and the Network Deployment product does not, there is one failover scenario that is unique to z/OS. That is failover from one servant region to another servant region (loss of a servant without loss of the controller).

Customers currently using the HFS-based technique on z/OS will likely want to continue with that choice.

In an unmanaged z/OS server, stateful session bean failover among servants can be enabled. Failover only occurs between the servants of a given unmanaged server. If an unmanaged z/OS server has only one servant, then enabling failover has no effect. An unmanaged z/OS server that has failover enabled does not fail over to another unmanaged z/OS server. To enable failover in an unmanaged server, refer to

Stateful session beans failover settings (applications):

Each Enterprise JavaBeans container provides a method for stateful session beans to fail over to other servers. This enables you to specify whether failover occurs for the stateful session beans in this module. You can also override the parent object's stateful session bean replication settings for this module.

To view this administrative console page, click **Applications > Enterprise Applications >** *application* **> Stateful Session Bean Failover Settings**.

Note: These settings are ignored for 5.x application targets.

Enable stateful session bean failover using memory to memory replication:

Specifies whether the EJB Container attempts failover for all of the stateful session beans in this application.

This checkbox overrides the default stateful session bean failover setting that the administrator configured for an EJB container. De-selecting this checkbox disables failover for this application.

Data type	Checkbox
Range	Selected or unselected.

Use replication settings from the EJB container:

Specifies that the replication settings configured for the EJB container are used for this application. If you select this option and you want the application to use stateful session bean failover, you must define memory to memory replication for the EJB container on each server you want to use failover.

Data type	Radio button
Range	Selected or unselected.

Use application replication settings:

Specifies that the replication settings configured for this application are used for memory to memory replication of the stateful session bean data.

If you select this button, you override the EJB container settings. This button is disabled until you define a replication domain. This selection has a hyperlink to help you configure the replication settings. If no replication domains are configured, the link takes you to a panel where you can create one. If at least one domain is configured, the link takes you to a panel where you can select the replication settings to be used by the application.

Data type	Radio button
Range	Selected or unselected.

Stateful session beans failover settings (EJB modules):

Each Enterprise JavaBeans container provides a method for stateful session beans to fail over to other servers. This enables you to specify whether failover occurs for the stateful session beans in this module. You can also override the parent object's stateful session bean replication settings for this module.

To view this administrative console page, click **Applications > Enterprise Applications >** *application* **> EJB modules** > *.jar* > **Stateful session bean failover settings**.

Note: These settings are ignored for 5.x application targets.

Enable stateful session bean failover using memory to memory replication:

Specifies whether the EJB Container attempts failover for all of the stateful session beans in this module.

This checkbox overrides the default stateful session bean failover setting that the administrator configured for an EJB container or the module's application. De-selecting this checkbox disables failover for this module.

Data type	Checkbox
Range	Selected or unselected.

Use application or EJB container replication settings:

Specifies that the replication settings configured for the EJB container or application are used for this module. If you select this option and you want the application to use stateful session bean failover, you must define memory to memory replication for the EJB container on each server you want to use failover.

Data type	Radio button
Range	Selected or unselected.

Use EJB module replication settings:

Specifies that the replication settings configured for this EJB module are used for memory to memory replication of the stateful session bean data.

If you select this button, you override the replication settings for the EJB container and application. This button is disabled until you define a replication domain. This selection has a hyperlink to help you configure the replication settings. If no replication domains are configured, the link takes you to a panel where you can create one. If at least one domain is configured, the link takes you to a panel where you can select the replication settings to be used by the EJB container.

Data type	Radio button
Range	Selected or unselected.

Enabling failover of servants in an unmanaged server:

In an unmanaged z/OS server, stateful session bean failover among servants can be enabled. Failover only occurs between the servants of a given unmanaged server. If an unmanaged z/OS server has only one servant, then enabling failover has no effect. An unmanaged z/OS server that has failover enabled does not fail over to another unmanaged z/OS server.

Failover in an unmanaged server is enabled by setting a JVM property.

1. Start the administration console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server that you want to modify.
5. In the Server Infrastructure area, select **Java and Process Management**.
6. Select **Process Definition**.
7. Select **Servant**.
8. Under Additional Properties, select **Java Virtual Machine**.
9. Under Additional Properties, select **Custom Properties**.
10. Click on the **New** button.
11. In the Name input field, type **EJBContainerEnableUnmanagedServerReplication**.
12. In the Value input field, type **true**.
13. Click **Apply**.
14. Click **OK**.

Enabling or disabling stateful session bean failover with the EJB container panel

You can use the EJB Container administrative console panel to enable stateful session bean failover. Selecting the checkbox on the panel enables you to configure whether the failover is active for all stateful session beans in the specified EJB container.

1. Start the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to work with.
5. Select **EJB Container Settings**.
6. Select **EJB container**.
7. Check the box labeled **Enable stateful session bean failover using memory-to-memory replication**. This checkbox is disabled until you define a replication domain. This selection has a hyperlink to help you configure the replication settings. If no replication domains are configured, the link takes you to a panel where you can create one. If at least one domain is configured, the link takes you to a panel where you can select the replication settings to be used by the EJB container.
8. Select **OK**.

Enabling or disabling stateful session bean failover with the enterprise applications panel

You can use the enterprise applications administrative console panel to enable or disable stateful session bean failover for all stateful session beans in the specified application.

1. Start the administrative console.

2. Select **Applications**.
3. Select **Enterprise Applications**.
4. Select the application you want to work with.
5. Under Additional Properties, select **Stateful Session Bean Failover Settings**. The Stateful Session Bean Failover Settings panel appears.
6. Select **Enable stateful session bean failover using memory to memory replication**. This enables failover for all stateful session beans in this application. If you want to *disable* the failover, clear this checkbox.
7. Select your choice of **Replication settings**. You have a choice of two radio buttons:

   Use replication settings from EJB container
   If you select this button, any replication settings defined for this application are ignored.

   Attention: Note to the system administrator: if you use this radio button, then memory to memory replication must be configured at the EJB container level. Otherwise, the settings on this panel are ignored by EJB container during server startup and the EJB container will log a message indicating that stateful session bean failover is not enabled for this application.

   Use application replication settings
   If you select this button, you override the EJB container settings. This button is disabled until you define a replication domain. This selection has a hyperlink to help you configure the replication settings. If no replication domains are configured, the link takes you to a panel where you can create one. If at least one domain is configured, the link takes you to a panel where you can select the replication settings to be used by the application.
8. Select **OK**.

Enabling or disabling stateful session bean failover with the EJB modules panel

You can use the enterprise applications administrative console panel to enable or disable stateful session bean failover for all stateful session beans in the specified module.

1. Start the administrative console.
2. Select **Applications**.
3. Select **Enterprise Applications**.
4. Select the application you want to work with.
5. Under Related items, select **EJB modules**.
6. Select the *.jar* file you want to work with.
7. Select **Stateful session bean failover settings**.
8. Select **Enable stateful session bean failover using memory to memory replication**.
9. Select your choice of **Replication settings**. You have a choice of two radio buttons:

   Use application or EJB container replication settings
   If you select this button, any replication settings defined for this EJB module are ignored.

   Attention: Note to the system administrator: if you use this radio button, then memory to memory replication must be configured at the EJB container level. Otherwise, the settings on this panel are ignored by EJB container during server startup and the EJB container will log a message indicating that stateful session bean failover is not enabled for this application.

   Use EJB module replication settings
   If you select this button, you override the replication settings for the EJB container and application. This button is disabled until you define a replication domain. This selection has a hyperlink to help you configure the replication settings. If no replication domains are

configured, the link takes you to a panel where you can create one. If at least one domain is configured, the link takes you to a panel where you can select the replication settings to be used by the EJB container.

10. Select **OK**.

EJB cache settings

Use this page to configure and manage the cache for a specific EJB container. To determine the cache absolute limit, multiply the number of enterprise beans active in any given transaction by the total number of concurrent transactions expected. Then, add the number of active session bean instances.

To view this administrative console page, click **Servers > Application Servers >** *serverName* **> EJB Container Settings > EJB cache settings**.

Cleanup interval:

Specifies the interval at which the container attempts to remove unused items from the cache in order to reduce the total number of items to the value of the cache size.

The cache manager tries to maintain some unallocated entries that can be allocated quickly as needed. A background thread attempts to free some entries while maintaining some unallocated entries. If the thread runs while the application server is idle, when the application server needs to allocate new cache entries, it does not pay the performance cost of removing entries from the cache. In general, increase this parameter as the cache size increases.

Data type	Integer
Units	Milliseconds
Range	0 to 2 147 483 674
Default	3000

Cache size:

Specifies the number of buckets in the active instance list within the EJB container.

A bucket can contain more than one active enterprise bean instance, but performance is maximized if each bucket in the table has a minimum number of instances assigned to it. When the number of active instances within the container exceeds the number of buckets, that is, the cache size, the container periodically attempts to reduce the number of active instances in the table by passivating some of the active instances. For the best balance of performance and memory, set this value to the maximum number of active instances expected during a typical workload.

Data type	Integer
Units	Buckets in the hash table
Range	Greater than 0. The container selects the next largest prime number equal to or greater than the specified value.
Default	2053

Container interoperability

Container interoperability describes the ability of WebSphere Application Server clients and servers at different versions to successfully negotiate differences in native Enterprise JavaBeans (EJB) finder methods support and Java 2 Platform, Enterprise Edition (J2EE) compliance.

The product uses interoperable versions of some class types to enable interoperability. However, older 4.0.x client and application server versions do not support the interoperability classes, which makes them uninteroperable with versions that use the classes. The system property *com.ibm.websphere.container.portable* remedies this situation by enabling newer versions of the

application server to turn off the interoperability classes. This lets a more recent application server return class types that are interoperable with an older client.

Depending on the value of com.ibm.websphere.container.portable, application servers at versions 5 and later, and 4.0.3 and later, return different classes for the following:
- Enumerations and collections returned by EJB 1.1 finder methods
- EJBMetaData
- Handles to:
  - Entity beans
  - Session beans
  - Home interfaces

If the property is set to `false`, application servers return the old class types, to enable interoperability with 4.0.2 and earlier. If the property is set to `true`, application servers return the new classes.

The following tables show interoperability characteristics for various version combinations of application servers and clients as well as default property values for each combination.

Interoperability of Version 4.0.x client with Version 5 (and later) application server

Ideally, all 4.0.x clients that use Version 5 or later application servers should be at Version 4.0.3 or later.

Version 5 and later application servers return the interoperability class types by default (`true`). This can cause interoperability problems for distributed clients at versions 4.0.1 or 4.0.2. In particular, problems can occur with collections and enumerations returned by Enterprise JavaBeans Version 1.1 finder methods.

Although it is strongly discouraged, you can set com.ibm.websphere.container.portable to `false` on a Version 5 and later application server. This causes the application server to return the old class types, providing interoperability with clients at Version 4.0.2 and earlier. This is discouraged because:
- The Version 5 application server instance would become non-J2EE 1.3 (and later) compliant with regard to handles, home interface handles, and EJBMetaData.
- EJB 1.x finder methods return collection and enumeration objects that do not originate from ejbportable.jar.
- Interoperability restrictions still exist with the property set to `false`.
- Version 5 and later client handles to entity beans and home interfaces do not work across domains for the server you set to `false`.

  If you would like to use updated Handle classes in EJB 2.x-compliant beans but have one of the older clients (versions 4.0.2 and earlier) installed, set the system property com.ibm.websphere.container.portable.finder to `false`. With this setting in place, the Version 5 and later application server uses the updated handles but returns the enumerations and collections that were used in the earlier clients.

Interoperability of client at Version 4.0.2 and earlier with Version 5 (and later) application server

Client at Version 4.0.2 and earlier, using this function	Application server at Version 5 and later, property true (default)	Application server at Version 5 and later, property false
EJBMetaData	Does not work	Works for 4.0.2 client
Handle to session bean	Does not work	Works
Handle to entity bean	Does not work	Does not work across cells
Enumeration returned by EJB 1.x finder method	Does not work	Works
Collection returned by EJB 1.x finder method	Does not work	Works
Handle to home interface	Does not work	Does not work across cells

If you would like to use updated Handle classes in EJB 2.x-compliant beans but have one of the older clients (versions 4.0.2 and earlier) installed, set the system property com.ibm.websphere.container.portable.finder to `false`. With this setting in place, the Version 5 and later server uses the new Handle classes but returns the older enumeration and collection classes.

Interoperability of client at Version 4.0.3 and later with Version 5 and later application server

Clients at Version 4.0.3 and later work well with Version 5 and later application servers. However, if you set the com.ibm.websphere.container.portable to `false`, client handles to entity beans and home interfaces do not work across domains for the server you set to `false`.

Client at Version 4.0.3 and later, using this function	Application server at Version 5 and later, property true (default)	Application server at Version 5 and later, property false
EJBMetaData	Works	Works
Handle to session bean	Works	Works
Handle to entity bean	Works	Does not work across cells
Enumeration returned by EJB 1.x finder method	Works	Works
Collection returned by EJB 1.x finder method	Works	Works
Handle to home interface	Works	Does not work across cells

Interoperability of Version 5 and later client with Version 4.0.x application server

Clients at Version 5 and later work well with Version 4.0.3 application servers if you set com.ibm.websphere.container.portable to `true`. Client handles to entity beans and home interfaces do not work across domains for any Version 4.0.3 server with com.ibm.websphere.container.portable at the default value, `false`. Version 5 client handles to application servers at Version 4.0.2 and earlier also have restrictions.

Client at Version 5 and later, using this function	Application server at Version 4.0.3, property true	Application server at Version 4.0.3, property false (default)	Application server at Version 4.0.2 or earlier
EJBMetaData	Works	Works	Works for 4.0.2 server only
Handle to session bean	Works	Works	Works
Handle to entity bean	Works	Does not work across domains	Does not work across domains
Enumeration returned by EJB 1.x finder method	Works	Works	Works
Collection returned by EJB 1.x finder method	Works	Works	Works
Handle to home interface	Works	Does not work across domains	Does not work across domains

Interoperability of zSeries Version 4.0.x client with Version 5 and later application server

The only valid configuration for container interoperability with zSeries Version 4.0.x clients is the default configuration for the Version 5 application server.

Interoperability of Version 5 and later client with zSeries Version 4.0.x application server

Version 5 clients should work with a zSeries Version 4.0.x application server with the correct interoperability fixes described in the zSeries documentation. The interoperability characteristics should be the same as for a Version 4.0.3 distributed application server with the property set to `true`.

Client at Version 5 and later, using this function	zSeries application server at Version 4.0.x
EJBMetaData	Works
Handle to session bean	Works
Handle to entity bean	Works
Enumeration returned by EJB 1.x finder method	Works
Collection returned by EJB 1.x finder method	Works
Handle to home interface	Works

EJB Container Cache tuning

Monitoring Tivoli Performance Viewer (TPV) is a great way to diagnose if the EJB Container Cache size setting is tuned correctly for your application. If the application has filled the cache causing evictions to occur, TPV will show a very high rate of ejbStores() being called and probably a lower than expected CPU utilization on the application server machine.

All applications using enterprise beans should have this setting adjusted from the default if the following formula works out to more than 2000.

```
EJB_Cache_Size = (Largest number of Option B or C Entity Beans enlisted in a
transaction * maximum number of concurrent transactions) +
(Largest number of unique Option A Entity Beans expected to be accessed during
typical application workload) +
(Number of stateful Session Beans active during typical workload) +
(Number of stateless SessionBean types used during typical workload)

Where:
Option B and C Entity Beans are only held in the EJB cache during the lifetime
of the transaction they are enlisted in. Therefore, the first term in the formula
computes the average EJB cache requirements for these types of beans.

Option A Entity Beans are held in the EJB cache indefinitely, and are only removed
 from the cache if there start to become more beans in the cache than the cache
size has been set to.

Stateful Session Beans are held in the EJB cache until they are removed by the
application, or their session timeout value is reached.

Only a single stateless Session Bean instance for each EJB type is held in the
cache during the time any methods are being executed on that stateless Session
Bean. If two or more methods are being executed simultaneously on the same
stateless Session Bean type, each method executes on its own bean instance, but
only one cache location is used for all of these instances.
```

This calculates the upper bound on the maximum possible number of enterprise beans active at one time inside the application server. Because the EJB Containers cache is built to contain all these beans for performance optimizations, best performance can be achieved by setting this cache size to be larger than the number resulting from the calculation above.

```
<tuning parameter>
This setting can be found under Servers > Application Servers > serverName >
         EJB Container > EJB Cache Settings
```

Also while adjusting the EJB Cache Size, the EJB Container management thread parameter can be tuned to meet the needs of the application. The management thread is controlled through the Clean Up Interval

setting. This setting controls how frequently a daemon thread inside of WebSphere Application Server wakes up and attempts to remove bean instances from the cache that have not been used recently, attempting to keep the number of bean instances at or below the cache size. This allows the EJB container to place and look up items in the cache as quickly as possible. It normally is best to leave this interval set to the default, however, in some cases, it may be worthwhile to see if there is a benefit to reducing this interval.

EJB Container Pool Size

If the application is using the majority of the instances in the pool, TPV indicates this. When this occurs, then the size of those bean pools that are being exhausted should be increased. This can be done by adding the following parameter in the JVM's custom properties tag .

```
-Dcom.ibm.websphere.ejbcontainer.poolSize=<application_name>#<module_name>#
<enterprisebean_name>=<minSize>,<maxSize>

where:
 <application_name> is the J2EE application name as defined in the application
archive (.ear) file deployment descriptor, for the bean whose pool size is being
set

<module_name> is the .jar file name of the EJB module, for the bean whose pool size
 is being set,

<bean_name> is the J2EE Enterprise Bean name as defined in the EJB module
deployment descriptor, for the bean whose pool size is being set

<minSize> is the number of bean instances the container maintains in the pool,
 irrespective of how long the beans have been in the pool (beans greater than this
 number are cleared from the pool over time to optimize memory usage)

<maxSize> is the number of bean instances in the pool where no more bean instances
 are placed in the pool after they are used (that is, once the pool is at this
 size, any additional beans are discarded rather than added into the pool --
this ensures the number of beans in the pool has an upper limit so memory usage
does not grow in an unbounded fashion).

To keep the number of instances in the pool at a fixed size, minSize and maxSize
can be set to the same number. Note that there is a separate instance pool for
every EJB type running in the application server, and that every pool starts out
with no instances in it - that is, the number of instances grows as beans are
used and then placed in the pool. When a bean instance is needed by the container
and no beans are available in the pool, the container creates a new bean
instance, uses it, then places that instance in the pool (unless there are
already maxSize instances in the pool).

For example, the statement
-Dcom.ibm.websphere.ejbcontainer.poolSize=ivtApp#ivtEJB.jar#ivtEJBObject=125,1327

would set a minSize of 125 and a maxSize of 1327 on the bean named "ivtEJBObject"
within the ivtEJB.jar file, in the application "ivtApp".
```

Where ivtApp is replaced by the actual application name, ivtEJB.jar is replaced by the jar containing the bean that needs to have its pool size increased, and ivtEJBObject is the bean name of the enterprise bean whose pool size should be increased. The 125,1327 is the minimum and maximum number of beans that will be held in the pool. These should be set so no more evictions occur from the pool and in most cases should be set equal if memory is plentiful because no growth and shrinkage of the pool will occur.

EJB Container Primary Key Mutation

Application developers and administrators should have a good idea of how their application handles the creation of primary key objects for use by container-managed persistence (CMP) beans and bean-managed persistence (BMP) beans inside of WebSphere Application Server. The IBM EJB Container

uses the primary key of an Entity bean as an identifier inside of many internal data structures to optimize performance. However, the EJB Container must copy these primary key objects upon the first access to the bean to ensure that the objects stored in the internal caches are separate from the ones used in an application, in case the application changes or mutates the primary key, to keep the internal structures consistent.

If the application does not mutate any of the primary keys used to create and access entity beans after they are created, then a special flag can be used that allows the EJB Container to skip the copy of the primary key object, thus saving CPU cycles and increasing performance. This mechanism can be enabled *at your own risk* by adding the following –D property to the JVM custom property field.

```
<tuning parameter>
-Dcom.ibm.websphere.ejbcontainer.noPrimaryKeyMutation=true
```

The performance benefit of this optimization depends on the application. If the application uses primitive types for enterprise beans' primary keys there will be no gain because these objects are already immutable and the copy mechanism takes this into account. If, however, the application uses many complex primary keys (that is, And object for a primary key or multiple fields) then this parameter can yield significant improvements.

Persistence Manager Deferred Insert on EJB Create

The IBM Persistence manager is used by the EJB Container to persist data to the database from CMP entity beans. When creating entity beans by calling the ejbCreate() method, by default the Persistence manager immediately inserts the empty row with only the primary key in the database. In most cases applications, after creating the bean, modify fields in the bean created or in other beans inside of the same transaction. If the user wishes to postpone the insert into the database until the end of the transaction, so that it will eliminate one trip to the database, they may set this –D flag inside of the JVM custom properties field. The data will still be inserted into the database and consistency will be maintained.

```
<tuning parameter>
-Dcom.ibm.ws.pm.deferredcreate=true
```

The performance benefit of this optimization depends on the application. If the EJB applications transactions are very insert intensive the application could benefit largely from this optimization. If the application performs very few inserts then the benefit of this optimization will be much less.

Persistence Manager Database Batch Update on EJB Update

When an EJB application accesses multiple CMP beans inside of a single transaction, depending on the operations performed on the beans (updates, inserts, reads), the number of operations issued to the database will correspond directly to the operations performed on the CMP beans. If the database system you are using supports batching of update statements you can enable this flag and gain a performance boost on all interactions with the database that involve more than two updates in a single transaction. This flag will let the persistence manager add all the update statements into one single batch statement which will then be issued to the database. This saves round trips to the database, thus increasing performance. If the user knows their application exhibits the behavior of updating multiple CMP beans in a single transaction and the database supports batch updates they may set this –D flag inside of the JVM custom properties field.

```
<tuning parameter>
-Dcom.ibm.ws.pm.batch=true
```

The performance benefit of this optimization depends on the application. If the application never or infrequently updates CMP beans or only updates a single bean per transaction there will be no performance gain. If the application updates multiple beans per transaction then this parameter will benefit your applications performance.

Deploying EJB modules

When you deploy an EJB module, you install that module on a server that has been configured to support deployed modules.

Assemble one or more EJB modules, assemble one or more Web modules, and assemble them into a J2EE application.

1. Prepare the deployment environment. See ″Preparing to host applications″ in the information center for additional information.
2. Update the configuration for each EJB module as needed for the deployment environment.
3. Deploy the application.

If you specify that EJB deploy be run during application installation and the installation fails with a NameNotFoundException message, ensure that the input JAR or EAR file does not contain source files. Either remove the source files or include all dependent classes and resource files on the class path. If there are source files in the input JAR or EAR file, the EJB deployment tools runs a rebuild before generating the deployment code.

If the module deploys successfully, test and debug the module. See ″Diagnosing problems (using diagnosis tools)″ in the information center.

Troubleshooting tips for EJBDEPLOY relationships

Problems may exist when EJBDeploy creates a data relationship in DB2 for z/OS Version 7.x. EJBDeploy creates a table with a composite of the two primary keys of the EJBs that are related to each other. If the composite keys are larger than 254 characters, DB2 for z/OS V7.x will not accept this relationship and the user will be conforonted with errors such as:

```
DSNT408I SQLCODE = -613, ERROR:  THE PRIMARY KEY OR A UNIQUE CONSTRAINT
IS TOO LONG OR HAS TOO MANY COLUMNS
DSNT418I SQLSTATE   = 54008 SQLSTATE RETURN CODE
```

This problem can be seen when the primary keys that are created for the two related beans have primary keys that are strings. This results in the composite being made up of 2 varchar(250) primary keys for a total of 500, which is greater than 254 maximum in DB2 for z/OS version 7.x.

Things to consider when utilizing top-down mappings to ensure you do not experience this problem:

- Top-down mappings are a guideline and must be reviewed with the DBA.
- Schemas created 'top-down' by EJBDeploy are designed only for testing, and as a guideline for the actual schema required. The use of the 'meet-in-the-middle' mapping does not present this problem.
- The composite key constraint problem is not experienced when using DB2 V8, which has 2K max key lengths.

EJBDEPLOY_JVM_OPTIONS

Set the `EJBDEPLOY_JVM_OPTIONS` property to override Java virtual machine (JVM) options that are passed to the code that deploys EJBs (ejbdeploy.sh). Set this property in one of the following locations: *deploymentmanager*/bin/setupCmdLine.sh or *appServerHome*/bin/setupCmdLine.sh

For example, the following command increases the heap size of the JVM for ejbdeploy.sh:

```
export EJBDEPLOY_JVM_OPTIONS="-Xms128m -Xmx512m"
```

EJB module collection

Use this page to manage the EJB modules deployed in a specific application.

To view this administrative console page, click **Applications > Enterprise Applications >** *applicationName* **> EJB modules**. Click the check boxes to select one or more of the EJB modules in your collection.

Remove: Removes a module from the deployed application. The module is deleted from the application in the WebSphere Application Server configuration repository and also from all the nodes where the application is installed and running (or expected to run). If the application is running on a node when the module file is deleted from the node as a result of configuration synchronization then the application is stopped, the module file is deleted from the node's file system, and then the application is restarted.

Update: Opens a wizard that helps you update module in an application. If a module has the same URI as a module already existing in the application, the new module replaces the existing module. If the new module does not exist in the application, it is added to the deployed application. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and then the application is restarted. If the application is running on a node when the module file is added as a result of configuration synchronization then the newly added module is started without stopping and restarting the running application.

Remove File: Deletes a file from a module of a deployed application. The file is also deleted from all the nodes where the module is installed after configuration is synchronized with nodes. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and then the application is restarted.

URI:

When resolved relative to the application URL, this specifies the location of the module's archive contents on a file system. The URI matches the <ejb> or <web> tag in the <module> tag of the application deployment descriptor.

There are three buttons on this panel.

Remove
removes the EJB Module

Remove File
removes the specified file from the EJB Module

Update
updates the module or the application. With Update, you can add, remove, or replace modules

EJB module settings

Use this page to configure and manage a specific deployed EJB module.

Note: You cannot start or stop an individual EJB module for modification. You must start or stop the appropriate application entirely.

To view this administrative console page, click **Applications > Enterprise Applications >** *applicationName* **> EJB modules >** *moduleName*.

URI:

When resolved relative to the application URL, this specifies the location of the module archive contents on a file system. The URI must match the URI of a ModuleRef URI in the deployment descriptor of the deployed application (EAR).

Alternate DD:

Specifies a deployment descriptor to be used at run time instead of the one installed in the module.

Starting weight:

Specifies the order in which modules are started when the server starts. The module with the lowest starting weight is started first.

Data type	Integer
Default	5000
Range	Greater than 0

Client applications

Using application clients

An application client module is a Java Archive (JAR) file that contains a client for accessing a Java application. Complete the following steps for developing different types of application clients.

1. Decide on a type of application client.
2. Develop the application client code.
   a. Develop ActiveX application client code. See ″Developing ActiveX application client code″ in the information center.
   b. Develop J2EE application client code. See ″Developing J2EE application client code″ in the information center.
   c. Develop pluggable application client code. See ″Developing Pluggable application client code″ in the information center.
   d. Develop thin application client code. See ″Developing Thin application client code″ in the information center.

View the WebSphere Application Server Clients Samples Gallery for more information. To access these samples, install WebSphere Application Server Clients, and retrieve the samples from your local file system as the following command indicates:

<*install_root*>/samples/index.html

Application Client for WebSphere Application Server

In a traditional client-server environment, the client requests a service and the server fulfills the request. Multiple clients use a single server. Clients can also access several different servers. This model persists for Java clients except that now these requests use a client run-time environment.

In this model, the client application requires a servlet to communicate with the enterprise bean, and the servlet must reside on the same machine as the WebSphere Application Server.

The Application Client for WebSphere Application Server Version 6 (Application Client) consists of the following client applications:

- J2EE application client application (Uses services provided by the J2EE Client Container)
- Thin application client application (Does not use services provided by the J2EE Client Container)
- Applet application client application
- ActiveX to EJB Bridge application client application

The Application Client is packaged with the following components:

- Java Runtime Environment (JRE) (or an optional full Software Development Kit) that IBM provides
- WebSphere Application Server run time for J2EE application client applications or Thin application client applications.
- An ActiveX to EJB Bridge run time for ActiveX to EJB Bridge application client applications (only for Windows)
- IBM plug-in for Java platforms for Applet client applications (Windows only).

Note: The Pluggable application client is a kind of Thin application client. However, the Pluggable application client uses a Sun JRE and Software Development Kit instead of the JRE and Software Development Kit that IBM provides.

The *ActiveX application client* model, uses the Java Native Interface (JNI) architecture to programmatically access the Java virtual machine (JVM) API. Therefore the JVM code exists in the same process space as the ActiveX application (Visual Basic, VBScript, or Active Server Pages (ASP) files) and remains attached to the process until that process terminates.

In the *Applet client* model, a Java applet embeds in a HyperText Markup Language (HTML) document residing on a remote client machine from the WebSphere Application Server. With this type of client, the user accesses an enterprise bean in the WebSphere Application Server through the Java applet in the HTML document.

The *J2EE application client* is a Java application program that accesses enterprise beans, Java DataBase Connectivity (JDBC) APIs, and Java Message Service message queues. The J2EE application client program runs on client machines. This program follows the same Java programming model as other Java programs; however, the J2EE application client depends on the Application Client run time to configure its execution environment, and uses the Java Naming and Directory Interface (JNDI) name space to access resources.

The *Pluggable and Thin application clients* provide a lightweight Java client programming model. These clients are useful in situations where a Java client application exists but the application needs enhancements to use enterprise beans, or where the client application requires a thinner, more lightweight environment than the one offered by the J2EE application client. The difference between the Thin application client and the Pluggable application client is that the Thin application client includes a Java virtual machine (JVM) API, and the Pluggable application client requires the user to provide this code. The Pluggable application client uses the Sun Java Development Kit, and the Thin application client uses the IBM Developer Kit for the Java platform.

The J2EE application client programming model provides the benefits of the J2EE platform for the Java client application. Use the J2EE application client to develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the J2EE platform, you can put the client application code from one J2EE platform implementation to another. The client application package can require redeployment using each J2EE platform deployment tool, but the code that comprises the client application remains the same.

The Application Client run time supplies a container that provides access to system services for the client application code. The client application code must contain a main method. The Application Client run time invokes this main method after the environment initializes and runs until the Java virtual machine code terminates.

The J2EE platform supports the Application Client use of *nicknames* or *short names*, defined within the client application deployment descriptor. These deployment descriptors identify enterprise beans or local resources (JDBC, Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI. This simplified resolution to the enterprise bean reference and local resource reference also eliminates changes to the client application code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the Application Client can require redeployment.

The Application Client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The Application Client run time also provides support for security authentication to enterprise beans and local resources.

The Application Client uses the Java Remote Method Invocation-Internet InterORB Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the J2EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

View the Samples gallery for more information about the Application Client.

Application client functions: Use the following table to identify the available functions in the different types of clients.

Available functions	ActiveX client	Applet client	J2EE client	Pluggable client	Thin client
Provides all the benefits of a J2EE platform	Yes	No	Yes	No	No
Portable across all J2EE platforms	No	No	Yes	No	No
Provides the necessary run-time support for communication between a client and a server	Yes	Yes	Yes	Yes	Yes
Supports the use of nicknames in the deployment descriptor files. **Note:** Although you can edit deployment descriptor files, do not use the administrative console to modify them.	Yes	No	Yes	No	No
Supports use of the RMI-IIOP protocol	Yes	Yes	Yes	Yes	Yes
Browser-based application	No	Yes	No	No	No
Enables development of client applications that can access enterprise bean references and CORBA object references	Yes	Yes	Yes	Yes	Yes
Enables the initialization of the client application run-time environment	Yes	No	Yes	No	No
Supports security authentication to enterprise beans	Yes	Limited	Yes	Yes	Yes
Supports security authentication to local resources	Yes	No	Yes	No	No
Requires distribution of application to client machines	Yes	No	Yes	Yes	Yes
Enables access to enterprise beans and other Java classes through Visual Basic, VBScript, and Active Server Pages (ASP) code	Yes	No	No	No	No
Provides a lightweight client suitable for download	No	Yes	No	Yes	Yes

Enables access JNDI APIs for enterprise bean resolution	Yes	Yes	Yes	Yes	Yes
Runs on client machines that use the Sun Java Runtime Environment	No	No	No	Yes	No
Supports CORBA services (using CORBA services can render the application client code nonportable)	No	No	Yes	No	No

ActiveX application clients:

WebSphere Application Server provides an ActiveX to EJB bridge that enables ActiveX programs to access enterprise beans through a set of ActiveX automation objects.

The bridge accomplishes this access by loading the Java virtual machine (JVM) into any ActiveX automation container such as Visual Basic, VBScript, and Active Server Pages (ASP).

There are two main environments in which the ActiveX to EJB bridge runs:
- **Client applications**, such as Visual Basic and VBScript, are programs that a user starts from the command line, desktop icon, or Start menu shortcut.
- **Client services**, such as Active Server Pages, are programs started by some automated means like the Services control panel applet.

The ActiveX to EJB bridge uses the Java Native Interface (JNI) architecture to programmatically access the JVM code. Therefore the JVM code exists in the same process space as the ActiveX application (Visual Basic, VBScript, or ASP) and remains attached to the process until that process terminates. To create JVM code, an ActiveX client program calls the XJBInit() method of the XJB.JClassFactory object. For more information about creating JVM code for an ActiveX program, see ″ActiveX to EJB bridge, initializing JVM code″ in the information center..

After an ActiveX client program has initialized the JVM code, the program calls several methods to create a proxy object for the Java class. When accessing a Java class or object, the real Java object exists in the JVM code; the automation container contains the proxy for that Java object. The ActiveX program can use the proxy object to access the Java class, object fields, and methods. For more information about using Java proxy objects, see ″ActiveX to EJB bridge, using Java proxy objects″. For more information about calling methods and access fields, see ″ActiveX to EJB bridge, calling Java methods″ and ″ActiveX to EJB bridge, accessing Java fields″ in the information center.

The client program performs primitive data type conversion through the COM IDispatch interface (use of the IUnknown interface is not directly supported). Primitive data types are automatically converted between native automation types and Java types. All other types are handled automatically by the proxy objects For more information about data type conversion, see ″ActiveX to EJB bridge, converting data types″.

Any exceptions thrown in Java code are encapsulated and thrown again as a COM error, from which the ActiveX program can determine the actual Java exceptions. For more information about handling exceptions, see ″ActiveX to EJB bridge, handling errors″.

The ActiveX to EJB bridge supports both free-threaded and apartment-threaded access and implements the free threaded marshaler (FTM) to work in a hybrid environment such as Active Server Pages. For more information about the support for threading, see ″ActiveX to EJB bridge, using threading″.

Applet clients:

The applet client provides a browser-based Java run time capable of interacting with enterprise beans directly, instead of indirectly through a servlet.

This client is designed to support users who want a browser-based Java client application programming environment that provides a richer and more robust environment than the one offered by the **Applet > Servlet > enterprise bean** model.

The programming model for this client is a hybrid of the Java application thin client and a servlet client. When accessing enterprise beans from this client, the applet can consider the enterprise bean object references as CORBA object references.

No tooling support exists for this client to develop, assemble or deploy the applet. You are responsible for developing the applet, generating the necessary client bindings for the enterprise beans and CORBA objects, and bundling these pieces together to install or download to the client machine. The Java applet client provides the necessary run time to support communication between the client and the server. The applet client run time is provided through the Java applet browser plug-in that you install on the client machine.

Generate client-side bindings using an assembly tool such as the Application Server Toolkit (AST) or Rational Web Developer. An applet can utilize these bindings, or you can generate client-side bindings using the **rmic** command. This command is part of the IBM Developer Kit, Java edition that is installed with the WebSphere Application Server.

The applet client uses the RMI-IIOP protocol. Using this protocol enables the applet to access enterprise bean references and CORBA object references, but the applet is restricted in using some supported CORBA services.

If you combine the enterprise bean and CORBA environments in one applet, you must understand the differences between the two programming models, and you must use and manage each model appropriately.

The applet environment restricts access to external resources from the browser run-time environment. You can make some of these resources available to the applet by setting the correct security policy settings in the WebSphere Application Server `client.policy` file. If given the correct set of permissions, the applet client must explicitly create the connection to the resource using the appropriate API. This client does not perform initialization of any service that the client applet can need. For example, the client application is responsible for the initialization of the naming service, either through the CosNaming, or the Java Naming and Directory Interface (JNDI) APIs.

J2EE application clients:

The J2EE application client programming model provides the benefits of the Java 2 Platform for WebSphere Application Server Enterprise product.

The J2EE platform offers the ability to seamlessly develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the J2EE platform, you can put the client application code from one J2EE platform implementation to another. The client application package can require redeployment using each J2EE platform deployment tool, but the code that comprises the client application does not change.

The J2EE application client run time supplies a container that provides access to system services for the application client code. The J2EE application client code must contain a main method. The J2EE application client run time invokes this main method after the environment initializes and runs until the Java virtual machine application terminates.

Application clients can use *nicknames* or *short names*, defined within the client application deployment descriptor with the J2EE platform. These deployment descriptors identify enterprise beans or local resources (JDBC data sources, J2C connection factories, Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI use. This simplified resolution to the enterprise bean reference and local resource reference also eliminates changes to the application client code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the application client can require redeployment. Although you can edit deployment descriptor files, do not use the administrative console to modify them.

The J2EE application client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The J2EE application client run time also provides support for security authentication to the enterprise beans and local resources.

The J2EE application client uses the Java Remote Method Invocation technology run over Internet Inter-Orb Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the J2EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the J2EE and the CORBA WebSphere Application Server Enterprise environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

Pluggable application clients:

The Pluggable application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

The Pluggable application client requires that you have previously installed the Sun Java Runtime Environment (JRE) files. In all other aspects, the Pluggable application client, and the Thin application client are similar.

Note: The Pluggable application client is only available on the Windows platform.

This client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the J2EE platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client; however, tooling does exists on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and after bundling these pieces together, installing them on the client machine.

The Pluggable application client provides the necessary run time to support the communication needs between the client and the server.

The Pluggable application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access enterprise bean references and CORBA object references and use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

The Pluggable application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Serviceability (RAS), and other services. However, this client does not support a container that provides easy access to these services. For example, no support exists for using *nicknames* for enterprise beans or local resource resolution. When resolving to an enterprise bean (using either the Java Naming and Directory Interface (JNDI) API or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space.

When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The Pluggable application client offers access to most of the available client services in the J2EE application client. However, you cannot access the services in the Pluggable application client as easily as you can in the J2EE application client. The J2EE client has the advantage of performing a simple Java Naming and Directory Interface (JNDI) name space lookup to access the desired service or resource. The Pluggable application client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home object requires the following code in a J2EE application client:

```
        java.lang.Object ejbHome =  initialContext.lookup("java:/comp/env/ejb/MyEJBHome"
);
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,
MyEJBHome.class);
```

However, you need more explicit code in a Pluggable application client for Java:

```
        java.lang.Object ejbHome =  initialContext.lookup("the/fully/qualified
/path/to/actual/home/in/namespace/MyEJBHome");
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,
MyEJBHome.class);
```

In this example, the J2EE application client accesses a logical name from the `java:/comp` name space. The J2EE client run time resolves that name to the physical location and returns the reference to the client application. The pluggable client must know the fully qualified physical location of the enterprise bean Home object in the name space. If this location changes, the pluggable client application must also change the value placed on the lookup() statement.

In the J2EE client, the client application is protected from these changes because it uses the logical name. A change can require a redeployment of the EAR file, but the actual client application code remains the same.

The Pluggable application client is a traditional Java application that contains a *main* function. The WebSphere Pluggable application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services (security, Workload Management (WLM), and others). This client can also access CORBA objects and CORBA-based services. When using both

environments in one client application, you need to understand the differences between the enterprise bean and the CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the Java Naming and Directory Interface (JNDI) implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The Pluggable application client provides a batch command that you can use to set the CLASSPATH and JAVA_HOME environment variables to enable the Pluggable application client run time.

Thin application clients:

The thin application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

This client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the J2EE platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client, it exists on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and bundling these pieces together to install on the client machine.

The thin application client provides the necessary run-time to support the communication needs between the client and the server.

The thin application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access not only enterprise bean references and CORBA object references, but also allows the client application to use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments in one client application, you must understand the differences between the two programming models, to use and manage each appropriately.

The thin application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Servicability (RAS), and other services. However, this client does not support a container that provides easy access to these services. For example, no support exists for using *nicknames* for enterprise beans or local resource resolution. When resolving to an enterprise bean (using either Java Naming and Directory Interface (JNDI) or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space. When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The thin application client offers access to most of the available client services in the J2EE application client. However, you cannot access the services in the thin client as easily as you can in the J2EE application client. The J2EE client has the advantage of performing a simple Java Naming and Directory Interface (JNDI) name space lookup to access the desired service or resource. The thin client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home requires the following code in a J2EE application client:

```
        java.lang.Object ejbHome =  initialContext.lookup("java:/comp/env/ejb/MyEJBHome");
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,  MyEJBHome.class);
```

However, you need more explicit code in a Java thin application client:

```
        java.lang.Object ejbHome =
initialContext.lookup("the/fully/qualified/path/to/actual/home/in/namespace/MyEJBHome");
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,  MyEJBHome.class);
```

In this example, the J2EE application client accesses a logical name from the `java:/comp` name space. The J2EE client run time resolves that name to the physical location and returns the reference to the client application. The thin client must know the fully qualified physical location of the enterprise bean Home in the name space. If this location changes, the thin client application must also change the value placed on the lookup() statement.

In the J2EE client, the client application is protected from these changes because it uses the logical name. A change might require a redeployment of the EAR file, but the actual client application code remains the same.

The thin application client is a traditional Java application that contains a *main* function. The WebSphere thin application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services (security, Workload Management (WLM), and others). This client can also access CORBA objects and CORBA based services. When using both environments in one client application, you need to understand the differences between the enterprise bean and CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the Java Naming and Directory Interface (JNDI) implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The thin application client provides a batch command that you can use to set the CLASSPATH and JAVA_HOME environment variables to enable the thin application client run time.

Application client troubleshooting tips

This section provides some debugging tips for resolving common Java 2 Platform Enterprise Edition (J2EE) application client problems. To use this troubleshooting guide, review the trace entries for one of the J2EE application client exceptions, and then locate the exception in the guide. Some of the errors in the guide are samples, and the actual error you receive can be different than what is shown here. You might find it useful to rerun the `launchClient` command specifying the `-CCverbose=true` option. This option provides additional information when the J2EE application client run time is initializing

Error: java.lang.NoClassDefFoundError

Explanation This exception is thrown when Java code cannot load the specified class.

Possible causes

- Invalid or non-existent class
- Class path problem
- Manifest problem

Recommended response

Check to determine if the specified class exists in a Java Archive (JAR) file within your Enterprise Archive (EAR) file. If it does, make sure the path for the class is correct. For example, if you get the exception:

```
java.lang.NoClassDefFoundError:
WebSphereSamples.HelloEJB.HelloHome
```

verify that the HelloHome class exists in one of the JAR files in your EAR file. If it exists, verify that the path for the class is WebSphereSamples.HelloEJB.

If both the class and path are correct, then it is a class path issue. Most likely, you do not have the failing class JAR file specified in the client JAR file manifest. To verify this situation, perform the following steps:

1. Open your EAR file with the Application Server Toolkit or the Rational Web Developer assembly tool, and select the Application Client.
2. Add the names of the other JAR files in the EAR file to the Classpath field.

This exception is generally caused by a missing Enterprise Java Beans (EJB) module name from the Classpath field.

If you have multiple JAR files to enter in the Classpath field, be sure to separate the JAR names with spaces.

If you still have the problem, you have a situation where a class is loaded from the file system instead of the EAR file. This error is difficult to debug because the offending class is not the one specified in the exception. Instead, another class is loaded from the file system before the one specified in the exception. To correct this error, review the class paths specified with the -CCclasspath option and the class paths configured with the Application Client Resource Configuration Tool. Look for classes that also exist in the EAR file. You must resolve the situation where one of the classes is found on the file system instead of in the `.ear` file. Remove entries from the classpaths, or include the `.jar` files and classes in the `.ear` file instead of referencing them from the file system.

If you use the -CCclasspath parameter or resource classpaths in the Application Client Resource Configuration Tool, and you have configured multiple JAR files or classes, verify they are separated with the correct character for your operating system. Unlike the Classpath field, these class path fields use platform-specific separator characters, usually a colon (on UNIX platforms) or a semi-colon (on Windows systems).
Note: The system class path is not used by the Application Client run time if you use the launchClient batch or shell files. In this case, the system class path would not cause this problem. However, if you load the launchClient class directly, you do have to search through the system class path as well.

Error: com.ibm.websphere.naming.CannotInstantiateObjectException: Exception occurred while attempting to get an instance of the object for the specified reference object. [Root exception is javax.naming.NameNotFoundException: xxxxxxxxxx]

Explanation

This exception occurs when you perform a lookup on an object that is not installed on the host server. Your program can look up the name in the local client Java Naming and Directory Interface (JNDI) name space, but received a NameNotFoundException exception because it is not located on the host server. One typical example is looking up an EJB component that is not installed on the host server that you access. This exception might also occur if the JNDI name you configured in your Application Client module does not match the actual JNDI name of the resource on the host server.

Possible causes

- Incorrect host server invoked
- Resource is not defined
- Resource is not installed
- Application server is not started
- Invalid JNDI configuration

Recommended response

If you are accessing the wrong host server, run the `launchClient` command again with the -CCBootstrapHost parameter specifying the correct host server name. If you are accessing the correct host server, use the product `dumpnamespace` command line tool to see a listing of the host server JNDI name space. If you do not see the failing object name, the resource is either not installed on the host server or the appropriate application server is not started. If you determine the resource is already installed and started, your JNDI name in your client application does not match the global JNDI name on the host server. Use the Application Server Toolkit to compare the JNDI bindings value of the failing object name in the client application to the JNDI bindings value of the object in the host server application. The values must match.

Error: javax.naming.ServiceUnavailableException: A communication failure occurred while attempting to obtain an initial context using the provider url: ″iiop://[invalidhostname]″. Make sure that the host and port information is correct and that the server identified by the provider URL is a running name server. If no port number is specified, the default port number 2809 is used. Other possible causes include the network environment or workstation network configuration. Root exception is org.omg.CORBA.INTERNAL: JORB0050E: In Profile.getIPAddress(), InetAddress.getByName[invalidhostname] threw an UnknownHostException. minor code: 4942F5B6 completed: Maybe

Explanation

This exception occurs when you specify an invalid host server name.

Possible causes

- Incorrect host server invoked
- Invalid host server name

Recommended response

Run the `launchClient` command again and specify the correct name of your host server with the -CCBootstrapHost parameter.

Error: javax.naming.CommunicationException: Could not obtain an initial context due to a communication failure. Since no provider URL was specified, either the bootrap host and port of an existing ORB was used, or a new ORB instance was created and initialized with the default bootstrap host of ″localhost″ and the default bootstrap port of 2809. Make sure the ORB bootstrap host and port resolve to a running name server. Root exception is org.omg.CORBA.COMM_FAILURE: WRITE_ERROR_SEND_1 minor code: 49421050 completed: No

Explanation

This exception occurs when you run the `launchClient` command to a host server that does not have the Application Server started. You also receive this exception when you specify an invalid host server name. This situation might occur if you do not specify a host server name when you run the launchClient tool. The default behavior is for the launchClient tool to run to the local host, because WebSphere Application Server does not know the name of your host server. This default behavior only works when you are running the client on the same machine with WebSphere Application Server is installed.

Possible causes

- Incorrect host server invoked
- Invalid host server name
- Invalid reference to `localhost`
- Application server is not started
- Invalid bootstrap port

Recommended response

If you are not running to the correct host server, run the `launchClient` command again and specify the name of your host server with the `-CCBootstrapHost` parameter. Otherwise, start the Application Server on the host server and run the `launchClient` command again.

Error: javax.naming.NameNotFoundException: Name comp/env/ejb not found in context ″java:″

Explanation

This exception is thrown when the Java code cannot locate the specified name in the local JNDI name space.

Possible causes

- No binding information for the specified name
- Binding information for the specified name is incorrect
- Wrong class loader was used to load one of the program classes
- A resource reference does not include any client configuration information

Recommended response

Open the EAR file with the Application Server Toolkit, and check the bindings for the failing name. Ensure this information is correct. If you are using Resource References, open the EAR file with the Application Client Resource Configuration Tool, and verify that the Resource Reference has client configuration information and the name of the Resource Reference exactly matches the JNDI name of the client configuration. If the values are correct, you might have a class loader error.

Error: java.lang.ClassCastException: Unable to load class: org.omg.stub.WebSphereSamples.HelloEJB._HelloHome_Stub at com.ibm.rmi.javax.rmi.PortableRemoteObject.narrow(portableRemoteObject.java:269)

Explanation

This exception occurs when the application program attempts to narrow to the EJB home class and the class loaders cannot find the EJB client side bindings.

Possible causes

- The files, *_Stub.class and _Tie.class, are not in the EJB `.jar` file
- Class loader could not find the classes

Recommended response

Look at the EJB `.jar` file located in the `.ear` file and verify the class contains the Enterprise Java Beans (EJB) client side bindings. These are class files with file names that end in `_Stub` and `_Tie`. If the binding classes are in the EJB `.jar` file, then you might have a class loader error.

Error: WSCL0210E: The Enterprise archive file [EAR file name] could not be found. com.ibm.websphere.client.applicationclient.ClientContainerException: com.ibm.etools.archive.exception.OpenFailureException

Explanation

This error occurs when the application client run time cannot read the Enterprise Archive (EAR) file.

Possible causes

The most likely cause of this error is that the system cannot find the EAR file cannot be found in the path specified on the `launchClient` command.

Recommended response

Verify that the path and file name specified on the `launchclient` command are correct. If you are running on the Windows operating system and the path and file name are correct, use a short version of the path and file name (8 character file name and 3 character extension).

The launchClient command appears to hang and does not return to the command line when the client application has finished.

Explanation

When running your application client using the `launchClient` command the WebSphere Application Server run time might need to display the security login dialog. To display this dialog, WebSphere Application Server run time creates an Abstract Window Toolkit (AWT) thread. When your application returns from its main method to the application client run time, the application client run time attempts to return to the operating system and end the Java virtual machine (JVM) code. However, since there is an AWT thread, the JVM code will not end until `System.exit` is called.

Possible causes

The JVM code does not end because there is an AWT thread. Java code requires that `System.exit()` be called to end AWT threads.

Recommended response

- Modify your application to call `System.exit(0)` as the last statement.
- Use the `-CCexitVM=true` parameter when you call the `launchClient` command.

For current information available from IBM Support on known problems and their resolution, see the IBM customer support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM customer support page.

Running application clients

The J2EE specification requires support for a client container that runs stand-alone Java applications (known as J2EE application clients) and provides J2EE services to the applications. J2EE services include naming, security, and resource connections.

You are ready to run your application client using this tool after you have:
1. Written the application client program.
2. Assembled and installed an application module (`.ear` file) in the application server run time.
3. Deployed the application using the Application Client Resource Configuration Tool (ACRCT).

This task only applies to J2EE application clients.

1. Open a command window and invoke the following script to launch J2EE application clients using the launchClient shell:

   ```
   install_root/bin/launchClient.bat
   ```

   The launchClient batch command starts the application client run time, which:
   - Initializes the client run time.
   - Loads the class that you designated as the main class with an assembly tool.
   - Runs the main method of the application client program.

   When your program terminates, the application client run time cleans up the environment and the Java virtual machine (JVM) code ends.

2. Pass parameters to the `launchClient` command or to your application client program as well. The `launchClient` command allows you to do both. The `launchClient` command requires that the first parameter is either:
   - An EAR file specifying the application client to launch.
   - A request for `launchClient` usage information.

   The following example illustrates the command line invocation syntax for the launchClient tool:

   ```
   launchClient [-profileName pName | -JVMOptions options | -help | -?] <userapp> [-CC<name>=<value>] [app args]
   ```

   where

   - *userapp.ear* is the path and the name of the EAR file that contains the application client.
   - *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
   - *app args* are arguments that pass to the application client.
   - *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation. The default is **default_profile**.
   - *-JVMOptions* is a valid Java standard or non-standard option string. Insert quotation marks around the string.
   - *-help, -?* prints the usage information.

   All other parameters intended for the `launchClient` command must begin with the -CC prefix.

   Parameters that are not EAR files, or usage requests, or that do not begin with the -CC prefix, are ignored by the application client run time, and are passed directly to the application client program.

   The `launchClient` command retrieves parameters from three places:
   - The command line
   - A properties file
   - System properties

   The parameters are resolved in the order listed above, with command line values having the highest priority and system properties the lowest. Using this prioritization you can set and override default values.
3. Specify the server name. By default, the **launchClient** command uses the localhost for the `BootstrapHost` property value. This setting is effective for testing your application client when it is installed on the same computer as the server. However, in other cases override this value with the name of your server.

   You can override the `BootstrapHost` value by invoking `launchClient` command with the following parameters:

   ```
   launchClient myapp.ear -CCBootstrapHost=abc.midwest.mycompany.com
   ```

   You can also override the default by specifying the value in a properties file and passing the file name to the launchClient shell.

   Security is controlled by the server. You do not need to configure security on the client because the client assumes that security is enabled. If server security is not enabled, then the server ignores the security request, and the application client functions as expected.

You can store launchClient values in a properties file, which is a good method for distributing default values. You can then override one or more values on the command line. The format of the file is one `launchClient -CC` parameter per line without the `-CC` prefix. For example:

```
 verbose=true classpath=c:\mydir\util.jar;c:\mydir\harness.jar;c:\production\G19
\global.jar BootstrapHost=abc.westcoast.mycompany.com tracefile=c:\WebSphere\mylog.txt
```

launchClient tool

This section describes the Java 2 Platform Enterprise Edition (J2EE) command line syntax for the launchClient tool for WebSphere Application Server. You can use the `launchClient` command from a node within a Network Deployment environment. **However, do not attempt to use the `launchClient` command from the Deployment Manager.**

The following example illustrates the command line invocation syntax for the launchClient tool:

```
launchClient [-profileName pName | -JVMOptions options | -help | -?] <userapp> [-CC<name>=<value>] [app args]
```

where

- *userapp.ear* is the path and the name of the EAR file that contains the application client.
- *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
- *app args* are arguments that pass to the application client.
- *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation. The default is **default_profile**.
- *-JVMOptions* is a valid Java standard or nonstandard option string. Insert quotation marks around the string.
- *-help, -?* prints the usage information.

The first parameter must be `-help`, `-?` or contain no parameter at all. The `-profileName pName` and `-JVMOptions` options are optional parameters. If used, they must appear before the *<userapp>* parameter. All other parameters are optional and can appear in any order after the *<userapp>* parameter. The J2EE Application client run time ignores any optional parameters that do not begin with a `-CC` prefix and passes those parameters to the application client.

Client container parameters

Supported arguments include:

-CCsoapConnectorPort
The Simple Object Access Protocol (SOAP) connector port. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCverbose
This option displays additional information messages. The default is `false`.

-CCclasspath
A class path value. When you launch an application, the system class path is used. If you want to access classes that are not in the EAR file or part of the system class paths, specify the appropriate class path here. Multiple paths can be concatenated.

-CCjar
The name of the client Java Archive (JAR) file that resides within the EAR file for the application you wish to launch. Use this argument when you have multiple client JAR files in the EAR file.

-CCadminConnectorHost
Specifies the host name of the server from which configuration information is retrieved. The default is the value of the `-CCBootstrapHost` parameter or the value, `localhost`, if the `-CCBootstrapHost` parameter is not specified.

-CCadminConnectorPort
Indicates the port number for the administrative client function to use. The default value is `8880` for SOAP connections and `2809` for Remote Method Invocation (RMI) connections.

-CCadminConnectorType
Specifies how the administrative client connects to the server. Specify `RMI` to use the RMI connection type, or specify `SOAP` to use the SOAP connection type. The default value is `SOAP`.

-CCadminConnectorUser
Administrative clients use this user name when a server requires authentication. If the connection type is SOAP, and security is enabled on the server, this parameter is required. The SOAP connector does not prompt for authentication.

-CCadminConnectorPassword
The password for the user name that the `-CCadminConnectorUser` parameter specifies.

-CCaltDD
The name of an alternate deployment descriptor file. This parameter is used with the `-CCjar` parameter to specify the deployment descriptor to use. Use this argument when a client JAR file is configured with more than one deployment descriptor. Set the value to `null` to use the client JAR file standard deployment descriptor.

-CCBootstrapHost
The name of the host server you want to connect to initially. The format is:
your_server_of_choice.com

-CCBootstrapPort
The server port number. If you do not specify this argument, the WebSphere Application Server default value is `used`.

-CCproviderURL
Provides bootstrap server information that the initial context factory can use to obtain an initial context. WebSphere Application Server initial context factory can use either a Common Object Request Broker Architecture (CORBA) object URL or an Internet Inter-ORB Protocol (IIOP) URL. CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. This value can contain more than one bootstrap server address. This feature can be used when attempting to obtain an initial context from a server cluster. You can specify bootstrap server addresses, for all servers in the cluster, in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. The address list does not process in a particular order. For naming operations, this value overrides the `-CCBootstrapHost` and `-CCBootstrapPort` parameters. A CORBA object URL specifying multiple systems is illustrated in the following example:

```
-CCproviderURL=corbaloc:iiop:myserver.mycompany.com:9810,:mybackupserver.mycompany.com:2809
```

This value is mapped to the `java.naming.provider.url` system property.

-CCinitonly
Use this option to initialize application client run time for ActiveX application clients without launching the client application. The default is `false`.

-CCtrace
Use this option to obtain debug trace information. You might need this information when reporting a problem to IBM customer support. The default is `false` For more information, read the topic ″Enabling trace.″

-CCtracefile
Indicates the name of the file to which trace information is written. The default is to write output to the console.

-CCpropfile
Indicates the name of a properties file that contains launchClient properties. Specify the properties without the `-CC` prefix in the file. For example: `verbose=true`.

-CCsecurityManager
Enables and runs the WebSphere Application Server with a security manager. The default is `disable`.

-CCsecurityMgrClass
Indicates the fully qualified name of a class that implements a security manager. Only use this argument if the -CCsecurityManager parameter is set to enable. The default is java.lang.SecurityManager.

-CCsecurityMgrPolicy
Indicates the name of a security manager policy file. Only use this argument if the -CCsecurityManager parameter is set to enable. When you enable this parameter, the java.security.policy system property is set. The default is <*install_root*>/ properties/client.policy.

-CCD
Use this option to have the WebSphere Application Server set the specified system property during initialization. Do not use the equals (=) character after the -CCD. For example: -CCDcom.ibm.test.property=testvalue. You can specify multiple -CCD parameters. The general format of this parameter is -CCD<property key>=<property value>.

-CCexitVM
Use this option to have the WebSphere Application Server call the System.exit() method after the client application completes. The default is false.

-CCdumpJavaNameSpace
Prints out the Java portion of the Java Naming and Directory Interface (JNDI) name space for WebSphere Application Server. The true value uses the short format that prints out the binding name and the type of the object bound at that location. The long value uses the long format that prints out the binding name, bound object type, local object, type and string representation of the local object, for example, IORs and string values. The default value is false.

-CCtraceMode
Specifies the trace format to use for tracing. If the valid value, basic, is not specified the default is advanced. Basic tracing format is a more compact form of tracing.

-CCclassLoaderMode
Specifies the class loader mode. If PARENT_LAST is specified, the class loader loads classes from the local class path before delegating the class loading to its parent. The classes loaded for the following are affected:

- Classes defined for the J2EE application client
- Resources defined in the J2EE application
- Classes specified on the manifest of the J2EE client JAR file
- Classes specified using the -CCclasspath option

If PARENT_LAST is not specified, then the default mode, PARENT_FIRST, causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path.

The following examples demonstrate correct syntax.

On the Windows operating system:

```
launchClient c:\earfiles\myapp.ear -CCBootstrapHost=myWASServer -CCverbose=true
app_parm1 app_parm2
```

On the UNIX operating system:

```
./launchClient.sh /usr/earfiles/myapp.ear -CCBootstrapHost=myWASServer -CCverbose=true
app_parm1 app_parm2
```

Specifying the directory for an expanded EAR file:

Each time the launchClient tool is called, it extracts the Enterprise Archive (EAR) file to a random directory name in the temporary directory on your hard drive. Then the tool sets up the thread ClassLoader to use the extracted EAR file directory and JAR files included in the Manifest.mf client Java Archive (JAR) file. In a normal J2EE Java client, these files are automatically cleaned up after the application exits. This

cleanup occurs when the client container shutdown hook is called. To avoid extracting the EAR file (and removing the temporary directory) each time the launchClient tool is called, complete the following steps:

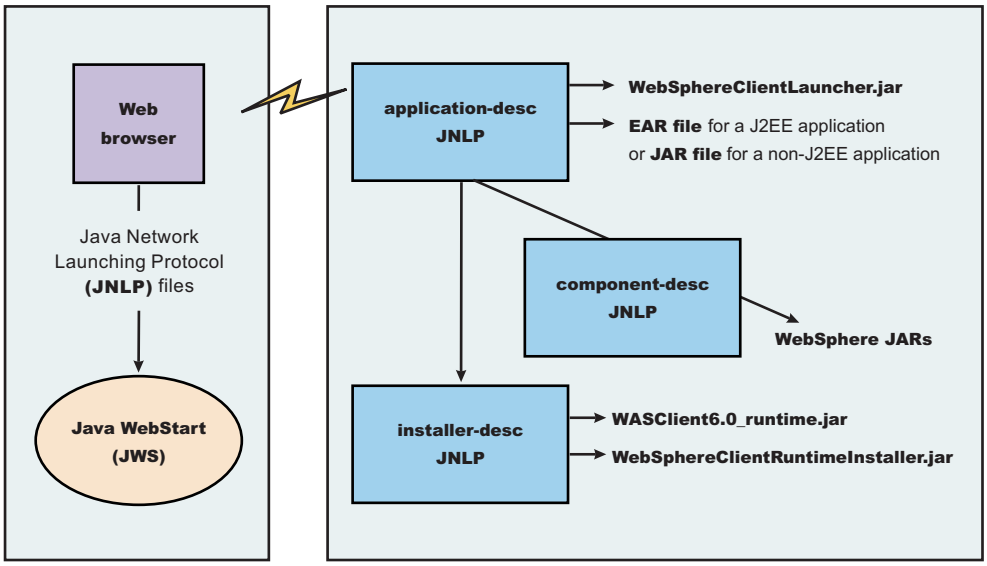
1. Specify a directory to extract the EAR file by setting the `com.ibm.websphere.client.applicationclient.archivedir` Java system property. If the directory does not exist or is empty, the EAR file is extracted normally. If the EAR file was previously extracted, the launchClient tool reuses the directory.
2. Delete the directory before running the launchClient tool again, if you need to update your EAR file. When you call the `launchClient` command, it extracts the new EAR file to the directory. If you do not delete the directory or change the system property value to point to a different directory, the launchClient tool reuses the currently extracted EAR file and does not use your changed EAR file. When specifying the `com.ibm.websphere.client.applicationclient.archivedir` property, make sure that the directory you specify is unique for each EAR file you use. For example, do not point the `MyEar1.ear` and the `MyEar2.ear` files to the same directory.

Java Web Start architecture for deploying application clients

Java Web Start is an application-deployment technology that includes the portability of applets, the maintainability of servlets and JavaServer Pages (JSP) file technology, and the simplicity of mark-up languages such as XML and HTML. It is a Java application that allows full-featured Java 2 client applications to be launched, deployed and updated from a standard Web server. Upon launching Java Web Start for the first time, you might download new client applications from the Web. Each time you launch JWS thereafter, you can initiate applications either through a link on a Web page or (in Windows) from desktop icons or the Start menu. You can deploy applications quickly using Java Web Start, cache applications on the client machine, and launch applications remotely offline. Additionally, because Java Web Start is built from the J2EE infrastructure, the technology inherits the complete security architecture of the J2EE platform.

The technology underlying Java Web Start is the Java Network Launching Protocol & API (JNLP). Java Web Start is a JNLP client and it reads and parses a JNLP descriptor file (JNLP file). Base on the JNLP descriptor, it downloads appropriate pieces of a client application and any of its dependencies. If any of the pieces of the application are already cached on the client machine, then those components are not downloaded again, unless they have been updated on the server machine. After you download and cache the client application, JWS launches it natively on the client machine.

The following diagram shows an overview of launching a client application, include the Application Client for WebSphere Application Server, Version 6 as a dependent resource, using Java Web Start.



The Web browser running on a client machine connects to a Web application located on a server machine. The client application JNLP descriptor file is downloaded and processed by Java Web Start on the client machine.

In this diagram, there are three JNLP descriptor files:

- Client application JNLP descriptor (application-desc in the diagram)
- Application Clients run-time installer JNLP descriptor (installer-desc in the diagram)
- Application Clients run-time library component JNLP descriptor (component-desc in the diagram)

Each of these JNLP descriptor files, the client application (JAR or EAR) and the dependent resource JAR files are packaged as Web applications in an EAR file. This EAR file is deployed to an Application server. The client machine with JWS installed uses a Web browser to connect to the url of the client application JNLP descriptor file to download and run the client application.

Using Java Web Start product version 1.4.2 or later is highly recommended. The following operating systems support running J2EE application client applications and or Thin application client applications using Java Web Start:

- Red Hat Enterprise Linux for Intel, Version 3.0
- SuSE Linux Enterprise Server, Versions 8 and 9
- Windows 2000 Professional, Windows 2000 Professional, Windows Advance Server, and Windows 2000 Advance Server
- AIX, Versions 5.1, 5.2, and 5.3
- Solaris, Versions 8 and 9
- HP-UX 11i

You can use Java Web Start on the Java 2 Standard Edition Developer Kits that IBM provides, packaged in Application Client for WebSphere Application Server, Version 6; Java Web Start on Sun Microsystems J2SE Software Development Kit or J2SE Java Runtime Environment 1.4.2, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems, or the Java Web Start on HP SDK or RTE for Java 2 version 1.4.2, which you can download from the HP Web site.

Using Java Web Start

Before you begin this task, see the following topics to understand Java Web Start technology and its components:

- “Java Web Start architecture for deploying application clients” on page 219
- “Client application Java Network Launcher Protocol deployment descriptor file” on page 221
- “ClientLauncher class” on page 224

Note: You can use Java Web Start on Java 2 Standard Edition Developer Kits that IBM provides, packaged in the Application Client for WebSphere Application Server, Version 6; Java Web Start on Sun Microsystems J2SE Software Development Kit or J2SE Java Runtime Environment 1.4.2, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems, or the Java Web Start on HP SDK or RTE for Java 2 version 1.4.2, which you can download from the HP Web site.

1. Prepare the Application Clients run-time dependency component for JWS.
2. Prepare the Application Clients run-time library component for JWS.
3. **Optional:** Run the Java Web Start sample.

   Problem: When you run Web services clients from Java Web Start using a Mozilla browser, you might get errors if the client argument contains quotations in the jnlp.jsp file. For example, the following argument results in an error:

```
<argument>-url="wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=
com/ibm/wssvt/tc/pli/ejb/WSMultiProtocolHome&"</argument>
```

Error: The following errors display in the Java Web Start console:

If using the EJB protocol, the following error is displayed:

```
Client caught exception getting the InsuranceWebServicesPort
using the URL
"wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=com/ibm/wssvt/tc/pli/ejb/WSMultiProtocolHome&"
java.net.MalformedURLException: no protocol: "wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=
 com/ibm/wssvt/tc/pli/ejb/WSMultiProtocolHome&"
 at java.net.URL.<init>(URL.java(Compiled Code))
 at java.net.URL.<init>(URL.java(Compiled Code))
 at java.net.URL.<init>(URL.java:411)
 at com.ibm.wssvt.tc.pli.webservice.InsuranceWebServicesClient.getInsuranceServicesClientURL
 (InsuranceWebServicesClient.java:231)
 at com.ibm.wssvt.tc.pli.webservice.InsuranceWebServicesClient.main(InsuranceWebServicesClient.java:748)
 at sun.reflect.NativeMethodAccessorImpl.invoke0(Native Method)
 at sun.reflect.NativeMethodAccessorImpl.invoke(NativeMethodAccessorImpl.java:85)
 at sun.reflect.NativeMethodAccessorImpl.invoke(NativeMethodAccessorImpl.java:58)
 at sun.reflect.DelegatingMethodAccessorImpl.invoke(DelegatingMethodAccessorImpl.java:60)
 at java.lang.reflect.Method.invoke(Method.java:391)
 at com.ibm.websphere.client.applicationclient.launchClient.createContainerAndLaunchApp(launchClient.java:649)
```

If using the HTTP protocol, the following error is displayed:

```
Client caught exception getting the InsruanceWebServicesPort
using the URL
"http://svtlnx1:9081/WebSvcsInsSession20EJB/services/WSMultiProtocol"
java.net.MalformedURLException: no protocol:
"http://svtlnx1:9081/WebSvcsInsSession20EJB/services/WSMultiProtocol"
```

If using the JMS protocol, the following error is displayed:

```
Client caught exception getting the InsruanceWebServicesPort
using the URL
"jms:/queue?destination=jms/MultiProtocol_Q&connectionFactory=jms/InsuranceServices_Q

CF&targetService=WSMultiProtocolJMS&jndiProviderURL=IIOP://svtlnx1.austin.ibm.com:981
1"
java.net.MalformedURLException: no protocol:
"jms:/queue?destination=jms/MultiProtocol_Q&connectionFactory=jms/InsuranceServices_Q

CF&targetService=WSMultiProtocolJMS&jndiProviderURL=IIOP://svtlnx1.austin.ibm.com:981
1"
       at java.net.URL.<init> (URL.java(Compiled Code))
Making calls to methods in WSMultiprotocolWebServicesBean ...
```

Solution: To resolve the problem, update the jnlp.jsp file to remove the quotations (″ ″) from the argument.

For the EJB protocol, use the following example argument to correct the errors:

```
<argument>-url=wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=
  com/ibm/wssvt/tc/pli/ejb/WSMultiProtocolHome&</argument>
```

For the HTTP protocol, use the following argument to correct the errors:

```
<argument>-url=http://svtaix23:9081/WebSvcsInsSession20EJB/services/WSMultiProtocol</argument>
```

For the JMS protocol, use the following argument to correct the errors:

```
<argument>-url=jms:/queue?destination=jms/MultiProtocol_Q&connectionFactory=
jms/InsuranceServices_QCF&targetService=WSMultiProtocolJMS&jndiProviderURL=
IIOP://svtaix23.austin.ibm.com:9811</argument>
```

Now, rerun the client from Java Web Start.

Client application Java Network Launcher Protocol deployment descriptor file: The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application. The client application has an Application Clients run-time dependency that provides the Java 2 Runtime

Environment from IBM, Application Clients run-time properties, the SSL KeyStore and TrustStore file, and the Application Clients run-time library JAR files (optional for Thin Application client applications). If the Application Clients run-time dependency is not met, it is downloaded and installed in Java Web Start (JWS), as described by the Application Clients run-time installer JNLP descriptor file.

```
<j2se version="WASclient6.0" href="/WebSphereClientRuntimeWeb/Runtime/jnlp.jsp"/>
```

It must also include the `WebSphereClientLauncher.jar` file, which contains the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, that completes one of the following actions:

- If it is a J2EE Application client application (that is the resources for the application contain an EAR file with a client application), then the launcher class starts a second Java Virtual Machine (JVM) using the JRE provided by the Application Clients run-time dependency and launches the J2EE Application client application which is packaged in the EAR file.

  The EAR file must be specified as a JAR resource so that it can be downloaded to JWS and specified in the system property, `com.ibm.websphere.client.launcher.ear`. See the following example for details:

  ```
  <resources>
  <j2se version="WASclient6.0" href="/WebSphereClientRuntimeWeb/Runtime/jnlp.jsp"/>
  <jar href="Launcher/WebSphereClientLauncher.jar" main="true"/>
  <jar href="lib/j2eeclient.ear"/>
  <property name="com.ibm.websphere.client.launcher.ear" value="j2eeclient.ear"/>
  </resources>
  ```

- If it is a Thin Application client application, then the launcher class uses the current JVM from the Application Clients run-time dependency and invokes the Thin Application client application main method.

  The Thin Application client application JAR file must be specified as a JAR resource so that it can be download to JWS and the name of the class containing main method entry point is specified in the system property, `com.ibm.websphere.launcher.main`.

  ```
  <resources>
  <j2se version="WASclient6.0" href="/WebSphereClientRuntimeWeb/Runtime/jnlp.jsp"/>
      <extension name="WebSphere Runtime"
                          href="/WebSphereClientRuntimeWeb/Runtime/WebSphereJars/jnlp.jsp"/>
      <jar href="Launcher/WebSphereClientLauncher.jar" main="true"/>
      <jar href="lib/thinclient.jar"/>
      <property name="com.ibm.websphere.client.launcher.main"
                        value="myapp.sample.thinclient.ThinClientMain"/>

  </resources>
  ```

  Unlike the J2EE Application client application, the Thin Application client application is not loading the Application Clients run-time library JAR files from the Application Clients run-time dependency. It is downloaded from the server directly as it is for the Thin Application client application JAR file. An Application Clients run-time library component JNLP descriptor is used for specifying the Application Clients run-time library JAR files resources, as shown in the following example:

  ```
  <extension name="WebSphere Runtime"
                      href="/WebSphereClientRuntimeWeb/Runtime/WebSphereJars/jnlp.jsp"/>
  ```

  The JNLP specification requires all the resource (JAR or EAR) files used in a JNLP file to be signed.

  You can specify the –CC arguments defined in the launchClient tool for a J2EE Application client application in application arguments section of the JNLP descriptor files. However, only –CCD is supported for a Thin Application client application to define system properties and the JNLP <property> tag can also be used to define system properties. See the following example for details:

  ```
  <property name="java.naming.provider.url" value="corbaloc:iiop:myserver.com:9089"/>
  ```

  For a J2EE Application client application, specify the following application arguments as defined in the JNLP.

  1. Specify your target server provider URL, as shown in the following example:

     ```
     <argument> >-CCDjava.naming.provider.url =corbaloc:iiop:myserver.mydomain.com:9080 </argument>
     ```

2. Specify the SSL Key File and SSL Trust File location. These files are expected to be available in the client machine. To use the ones in the Application Clients run-time dependency installed in JWS cache, specify these application arguments:

   ```
   <argument> -CCDcom.ibm.ssl.keyStore=${WAS_ROOT}/etc/DummyClientKeyFile.jks </argument>
   <argument>-CCDcom.ibm.ssl.trustStore=${WAS_ROOT}/etc/DummyClientTrustFile.jks </argument>
   ```

3. Specify the initial naming context factor, as shown in the following example:

   ```
   <argument>-CCDjava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory </argument>
   ```

   For a Thin Application client application, you also need to specify the actual location of the `sas.client.props` file located in the Application Clients run-time dependency that is installed in the JWS cache.

   ```
   <argument>-CCDcom.ibm.CORBA.ConfigURL=file:${WAS_ROOT}/properties/sas.client.props </argument>
   ```

   If any of the default settings in the `sas.client.props` file need modifying, use the –CCD to change the settings through the system properties, as shown in the following example:

   ```
   <argument>-CCDjavacom.ibm.CORBA.securityEnabled=false </argument>
   ```

   Note: The ${*install_root*} token used in the JNLP file is replaced by the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, to the actual location of the Application Clients run-time dependency installation in the JWS cache. If you are using JSP to dynamically create this JNLP description file, you must escape this token because it has a different meaning in JSP 2.0. See the following example for details:

   ```
   <argument>-CCDcom.ibm.ssl.keyStore=\${WAS_ROOT}/etc/DummyClientKeyFile.jks </argument>
   <argument>-CCDcom.ibm.ssl.trustStore=\${WAS_ROOT}/etc/DummyClientTrustFile.jks </argument>
   ```

Here is an example of the client application JNLP descriptor file for a J2EE Application client application.

```
<%--    This is a generic jnlp for a client app.  It will specify the WAS JRE
    as a dependency as well as the client launcher
-->
<%! private final String description="J2EE Client Example";    private final
String earName="J2EEWebStart.ear";
%>
<%  // locally declared variable

String urlSt = request.getRequestURL().toString();
String jnlpCodeBase=urlSt.substring(0,urlSt.lastIndexOf('/'));
String jnlpRefURL=urlSt.substring(urlSt.lastIndexOf('/')+1,urlSt.length());
// The client application descriptor noted a resource reference to be resolved at deploy time as following
%>
<%--
 Need to set a JNLP mime type - if Web Start is installed on the client,
 this header will induce the browser to drive the Web Start Client

--%><%
 response.setContentType("application/x-java-jnlp-file");   1
 response.setHeader("Cache-Control", null);
 response.setHeader("Set-Cookie", null);
 response.setHeader("Vary", null);
%>

  <%-- Specify the client launcher --%>
    <jar href="../Launcher/WebSphereClientLauncher.jar" main="true"> </jar> 3

  <%-- Ear we want to download to the client --%>

   <jar href="<%=earName%>"></jar> 4
    <%-- The launcher depends on this property to be set --%>
    <property name="com.ibm.websphere.client.launcher.ear"
value="<%=earName%>"><property> 5

  <resources>
<%-- Web Start will consider the Launcher as the application to run -->
<application-desc> 6
<argument>-CCproviderURL=corbaloc:iiop:your_server_hostname </argument>  7
<
 <argument>-
CCDcom.ibm.ssl.keyStore=\${install_root}/etc/DummyClientKeyFile.jks</argument>  8

<argument>-
CCDcom.ibm.ssl.trustStore=\${install_root}/etc/DummyClientTrustFile.jksCCDcom.ibm.ssl.trustStore=
    \${install_root}/etc/DummyClientTrustFile.jks</argument> 9
</application-desc>
</jnlp>
```

- **1**--Specifies the mime type of the file must be JNLP so that the browser will know what to do with the file.
- **2**--Specifies that the application is depending on the `WASclient6.0` Java Runtime Environment and specifies the URL of the JNLP for the Application Clients run-time dependency.
- **3**--Specifies the JAR file containing the launcher class. This should be the first jar specified and must contain the URL of the JAR file.
- **4**--Specifies the EAR file to be downloaded, which is similar to the one you run on an Application Client for WebSphere Application Server installation.
- **5**--Specifies the value of the EAR file name of the J2EE application.
- **6**--Specifies an application descriptor.
- **7**--Specifies the arguments for the J2EE Application client application as they are specified on the launchClient call.
- **8, 9**--Overrides the values in the `sas.client.props` file. They are needed because the installation location of the Application Clients run-time dependency component is unknown before it is actually installed. By default, security is turned on for the client application, and these values are required. The ${*install_root*} directory name is substituted with the Application Clients run-time dependency component installation location at run time.

ClientLauncher class: The class, com.ibm.websphere.client.installer.ClientLauncher, contains a main() method that is called by Java Web Start (JWS) to launch the client application. It is packaged in the `WebSphereClientLauncher.jar` file that is located in a WebSphere Application Server clients installation under the <*install_root*>/ JWS directory.

This launcher class configures the run-time environment for J2EE application clients and thin client applications (not J2EE application clients).

The launcher class requires that the following properties are defined. These properties are not defined in a separate properties file. Instead, they are defined as part of the Java Network Launching Protocol (JNLP) files.

com.ibm.websphere.client.launcher.main
If the client application is a Thin Application client, then this property should be specified. It specifies the class where the main entry point of the client application resides.

com.ibm.websphere.client.launcher.ear
If the client application is a J2EE Application client, then this property should be specified. It specifies the name of the EAR file to be executed. This property takes precedence over com.ibm.websphere.client.launcher.main. However, only one of the two properties should be specified.

com.ibm.websphere.client.launcher.classpath.* (required for J2EE client applications only)
There can be a set of properties that are prefixed with com.ibm.websphere.client.launcher.classpath. Each property specifies a JAR file that is to be added to the class path of the client application. This JAR file is a JAR file that is already defined as a resource for the client application. This file is needed so that the correct elements of the class path of the Java Virtual Machine (JVM) starting the client launcher can be retrieved and added to the class path of the (JVM) that is to be spawned for the client application.

Preparing the Application Client run-time dependency component for Java Web Start:

For a J2EE application client application and or Thin application client application to be launched using Java Web Start (JWS), an Java Runtime Environment that IBM provides, the library JAR files and properties files bundled in Application Client for WebSphere Application Server must be installed in the JWS. This article provides the steps to build the Application Client run-time dependency component from an Application Client installation. It is packaged as a Web Archive Resource (WAR) file that can be installed in an Application Server.

Install the Application Client for WebSphere Application Server for the platform to which the client application deploys. If there is a requirement to deploy the client application to multiple platforms, the Application Client run-time dependency component must be built separately for each platform that client application supports.

For example, if the client application deploys to both the Windows platform and Linux platform, follows the steps for this task to build the Application Client run-time dependency component for Windows on a Windows platform machine with the Application Client for WebSphere Application Server for Windows installed. Now, repeat the steps for this task to build the Application Client run-time dependency component for Linux on a Linux platform machine with the Application Client for WebSphere Application Server for Linux installed.

1. Install the Application Client for WebSphere Application Server for the client application supported operating systems. Install Application Client in the `C:\Program Files\IBM\WebSphere\AppClient` directory.
2. Change the directory to the installation bin directory. See the following example for help:
   ```
   CD C:\Program files\IBM\WebSphere\AppClient\bin
   ```
3. Run the buildClientRuntime tool to generate the Application Client run-time JAR file in a temporary directory which contains the Java 2 Runtime Environment, Application Client run-time properties, the SSL KeyStore and TrustStore file, and the Application Client run-time library JAR files. See the following example for help:
   ```
   buildClientRuntime C:\WebApp1\runtime\WASClient6.0_windows.jar
   ```
   If you are building an Application Client run-time JAR file only for serving Thin application client applications and not for J2EE application client applications, you can reduce the size of the generated JAR file by not including the Application Client run-time library JAR files. An extra parameter is passed to the buildClientRuntime tool, as the following example shows:

```
buildClientRuntime C:\WebApp1\runtime\WASClient6.0_windows.jar
                   buildThin
```

4. Copy the WebSphereClientRuntimeInstaller.jar file to the same location of the JAR file generated in the previous step. This JAR file is located in the JWS directory of the WebSphere Application Server clients installation. See the following example for help:

   ```
   copy ..\JWS\WebSphereClientRuntimeInstaller.jar   C:\WebApp1\runtime
   ```

5. Sign the JAR files created from the previous steps, using the Java 2 SDK jarsigner utility, as the following example shows:

   ```
   cd C:\WebApp1\runtime

   jarsigner -keystore myKeystore -storepass myPassword
                 WASClient6.0_windows.jar myKeyAliasName

   jarsigner -keystore myKeystore -storepass myPassword
                 WebSphereClientRuntimeInstaller.jar myKeyAliasName
   ```

   a. This step also requires you to , such as myKeystore.

   b. You must also for the myKeystore file. For more information, see the topic, ″.″

   Note: When running the JAR signer tool on HP platforms, add the -J″-Xmx256m″ flag to the jarsigner command to increase the available heap size and prevent the error, OutOfMemoryError. See the following example for help:

   ```
   jarsigner -J"-Xmx256m" -keystore myKeystore -storepass myPassword
                   WebSphereClientRuntimeInstaller.jar myKeyAliasName
   ```

6. Create an Application Client run-time installer JNLP descriptor file or a JavaServer Pages (JSP) file if it is generated dynamically in the same temporary directory as previous step. See the sample JNLP file shown in the Example section of this topic.
7. Package the two signed JAR files and the Application Client run-time installer JNLP descriptor file into a WAR file. This WAR file is packaged into an EAR file that can be deployed to an Application Server.

Your Web application is ready to serve the Application Client run time and the JRE environment.

```
<%--
     This is an Installer JNLP
     It will download two .jars:
     WebSphereClientRuntimeInstaller.jar - includes the installer utility
     WASClient6.0_<platform>.jar - the client runtime JRE image

  The installer will unzip the client runtime jar on the client machine, and register
     it with Java Web Start

  --%>
<%! private final String description=″WebSphere Client 6.0 Runtime JRE″;
    // The version here is (WAS based) JRE version - as to be managed on the client
    private final String JREversion=″WASclient6.0″;%>
<%
      // locally declared variable
      String url=request.getRequestURL().toString();
      String jnlpCodeBase=url.substring(0,url.lastIndexOf('/'));
      String jnlpRefURL=url.substring(url.lastIndexOf('/')+1,url.length());

      // Need to set a JNLP mime type - if Web Start is installed on the client,
      // this header will induce the browser to drive the Web Start Client
      response.setContentType(″application/x-java-jnlp-file″);    1
      response.setHeader(″Cache-Control″, null);
      response.setHeader(″Set-Cookie″, null);
```

```
      response.setHeader("Vary", null);

      // An installer must reply with the version number for a given install
      if (response.containsHeader("x-java-jnlp-version-id"))
        response.setHeader("x-java-jnlp-version-id", JREversion);     2
      else
        response.addHeader("x-java-jnlp-version-id", JREversion);

%>
<?xml version="1.0" encoding="utf-8"?>
<!-- JNLP File for <%=description %> -->

 <resources os="Linux">
  <jar href="linux/WASClient6.0_linux.jar"/>

  <property name="com.ibm.websphere.client.jre.launch.java" value="java/jre/bin/java"/>
 </resources>
 <installer-desc />
</jnlp>
```

1. Specifies that the file is a JNLP mime type so that the browser can process the JNLP file.
2. Specifies the exact version of this Application Client run-time dependency component in the response by setting the HTTP header field: `x-java-jnlp-version-id`.
3. Specifies the required JRE version to run the installer program.

4. Specifies the installer `WebSphereClientRuntimeInstaller.jar` file, which contains the ClientRuntimeInstaller class.
5. Specifies a system property that defines the version of Application Client run-time dependency component. This version is registered to the JNLP client.
6. Specifies resources for a particular platform. Each supported client application platform needs its own separate JAR file.
7. Specifies the Application Client run-time dependency component JAR file.
8. Specifies the program to call that starts a JVM for the client application.

Preparing Application Client run-time library component for Java Web Start.

buildClientRuntime tool: The buildClientRuntime tool builds the required components from the WebSphere Application Server clients installation into the JAR file specified on the command. This JAR file contains:

- License files
- Java 2 Runtime Environment (JRE) that IBM provides
- Application Clients run-time properties and configuration
- SSL KeyStore and TrustStore files
- Run-time library JAR files

In the case of building an Application Clients run-time JAR file only for serving Thin Application client applications and not for J2EE Application client applications, the run-time library JAR files and the Application Clients run-time properties files are not included, except the two configuration files, `sas.client.props` and `soap.client.props`.

The command-line invocation syntax for the buildClientRuntime tool is shown in the following example:

```
Windows Usage:  buildClientRuntime .bat  jar_file  [type]
Unix Usage:          buildClientRuntime.sh    jar_file  [type]
Where:
      jar_file    Specifies the target jar file name.
      type             Range:
                                  buildJ2EE - Default value that builds a Application Clients
                                              run-time library for J2EE application.
                                  buildThin  - Builds a Application Clients run-time library
                                              for Thin application.
```

ClientRuntimeInstaller class: This class, com.ibm.websphere.client.installer.ClientRuntimeInstaller, contains a main() method that Java Web Start (JWS) calls to install the Application Client for WebSphere Application Server run-time dependency component in JWS cache. It is packaged in `WebSphereClientRuntimeInstaller.jar` file located in the Application Client for WebSphere Application Server installation in the *<install_root>*`/JWS` directory.

Specify the `WebSphereClientRuntimeInstaller.jar` file and the Application Client run-time dependency component JAR file as JAR resources in the Application Client run-time installer Java Network Launcher Protocol (JNLP) descriptor file. See the following example for details:

```
<jar href="Launcher/WebSphereClientRuntimeInstall.jar" main="true"/>
<jar href="Launcher/WASClient6.0_windows.jarRuntimeInstall.jar" main="true"/>
```

The ClientRuntimeInstaller class main method requires the following properties to be set in the JNLP file:

com.ibm.websphere.client.jre.version
Specifies a Java Runtime Environment (JRE) version name that is to be used when referring to the Application Client run-time dependency component.

com.ibm.websphere.client.jre.launch.java
Specifies the relative location of the javaw.exe program in the Application Client run-time dependency component JAR file.

The previously mentioned properties, JRE version name and the location of the javaw.exe program are registered to the Java Web Start Application Manager, as shown in the following example:

```
<property name="com.ibm.websphere.client.jre.version" value="java\jre\bin\javaw.exe"/>
<property name="com.ibm.websphere.client.jre.launch.java" value="WASclient6.0"/>
```

Preparing Application Clients run-time library component for Java Web Start:

For a Thin Application client application to be launched using Java Web Start (JWS), you also need to create a Java Network Launching Protocol (JNLP) component to serve the Application Clients run-time library JAR files from the Application server. This JNLP component is referenced in the client application JNLP file with the <extension> tag. This article provides the steps to build the Application Clients run-time library component from an Application Clients installation. It is packaged as its own Web Archive Resource (WAR) file or to the same WAR file that contains the Application Clients run-time dependency component, and can be installed in an Application server.

Install the Application Client for WebSphere Application Server for the platform to which client applications deploy.

1. Install the Application Clients on the client application supported operating system. For example, install Application Clients in the `C:\Program Files\IBM\WebSphere\AppClient` directory.
2. Change directory to the installation bin directory. See the following example for help:

   ```
   CD C:\Program files\IBM\WebSphere\AppClient\bin
   ```
3. Run `buildClientLibJars` to copy the Application Clients run-time library JAR files from the Application Clients installation to a temporary directory. All the JAR files in the temporary directory are signed, as shown in the following example.

   ```
   buildClientLibJars C:\WebApp1\runtime\WebSphereJars
                      myKeystore myPassword myKeyAliasName
   ```

   a. This step also requires you to , such as `myKeystore`.

   b. You must also for the `myKeystore` file. For more information, see the topic, ″.″
4. Create an Application Clients run-time installer JNLP descriptor file or a JavaServer Pages (JSP) file, if it is generated dynamically in the same temporary directory as previous step. See the sample JNLP file shown in the Example section of this topic.
5. Package these JAR files and the Application Clients run-time library component JNLP descriptor file into a WAR file. You can also package both Application Clients run-time library component and Application Clients run-time dependency component in the same WAR file. This WAR file is packaged into an EAR file that can deployed to an Application server.

```

```

- **1**--Specifies that the file is a JNLP mime type so that the browser can process the JNLP file.
- **2**--Specifies the Last-Modified header so that any changes to this JSP file are downloaded to the JNLP client.
- **3**--Specifies all the JAR files in the Application Clients run-time library component that are generated by the buildClientLibJars tool.

buildClientLibJars tool: The buildClientLibJars tool copies the JAR files from the Application Client for WebSphere Application Server installation and creates a `properties.jar` file, which contains the properties

files from the Application Clients installation properties directory to a specified location. When this property is created, the tool uses the value of keystore, storepass and alias to sign all the JAR files in the specified location.

```
Windows Usage: buildClientLibJars.bat  target_dir keystore  storepass  alias
Unix Usage:        buildClientLibJars.sh  target_dir keystore  storepass  alias
Where:
     target_dir       Specifies the target directory where the Application
                           Clients library JAR files copied to.
    keystore         Specifies a keystore file.
    storepass       Specifies the keystore password.
    alias               Specifies an alias for the key object in the key file.
```

Using the Java Web Start sample:

The EAR file, WebSphereClientRuntime.ear, is provided in the JWS directory of the Client Application for WebSphere Application Server installation. This EAR file provides a sample Application Clients run-time installer JNLP descriptor file and a sample Application Clients run-time library component JNLP descriptor file. Follow the steps in this task to build the Application Clients run-time dependency component and the Application Clients run-time library component. Add these components to the WebSphereClientRuntime.ear file, and then install the EAR file in an Application Server to be used by the client application.

Install the Application Client for WebSphere Application Server for the platform to which the client application deploys. If there is a requirement to deploy the client application to multiple platforms, the Application Clients run-time dependency component must be built separately for each platform that the client application supports.

1. Install the Application Clients on the client application supported operating system. For example, install Application Clients in the C:\Program Files\IBM\WebSphere\AppClient directory.
2. Create the following temporary working directories:

   ```
   MKDIR C:\WebApp1
   MKDIR C:\WebApp1\runtime
   MKDIR C:\WebApp1\runtime\Widnows
   MKDIR C:\WebApp1\runtime\WebSphereJars
   ```
3. Change directory to the installation bin directory. See the following example for help:

   ```
   CD C:\Program files\IBM\WebSphere\AppClient\bin
   ```
4. Run the buildClientRuntime tool to generate the Application Clients run-time JAR file in a temporary directory that contains the Java 2 Runtime Environment that IBM provides, Application Clients run-time properties, the SSL KeyStore and TrustStore files, and the Application Clients run-time library JAR files. See the following example for details:

   ```
   buildClientRuntime C:\WebApp1\runtime\windows\WASClient6.0_windows.jar
   ```
5. Copy the WebSphereClientRuntimeInstaller.jar file to the same location of the JAR file generated in the previous step. This JAR file is located in the JWS directory of the Application Client for WebSphere Application Server installation. For example, copy the ..\JWS\WebSphereClientRuntimeInstaller.jar file to the C:\WebApp1\runtime directory.
6. Sign the JAR files created from the previous steps, using the Java 2 SDK jarsigner utility. See the following example for details:

   ```
   cd C:\WebApp1\runtime

   jarsigner -keystore myKeystore -storepass myPassword
                   WASClient6.0_windows.jar myKeyAliasName

   jarsigner -keystore myKeystore -storepass myPassword
                   WebSphereClientRuntimeInstaller.jar myKeyAliasName
   ```

   a. This step also requires you to , such as myKeystore.

   b. You must also for the myKeystore file. For more information, see the topic, ″.″

7. Run buildClientLibJars to copy the Application Clients run-time library JAR files from the Application Client for WebSphere Application Server installation to a temporary directory. All the JAR files in the temporary directory are signed. See the following example for details:

```
buildClientLibJars C:\WebApp1\runtime\WebSphereJars
                   myKeystore myPassword myKeyAliasName
```

   a. This step also requires you to , such as `myKeystore`.

   b. You must also for the `myKeystore` file. For more information, see the topic, ″.″

8. Add all the JAR files created in the previous steps in the `C:\WebApp1` directory to the WAR file within the `WebSphereClientRuntime.ear` file. The contents of the WAR file are shown in the following example:

```
The root of the WAR
├──META-INF
│                MANIFEST.MF
│
├──Runtime
│   │          jnlp.jsp
│   │          WebSphereClientRuntimeInstaller.jar
│   ├──windows │
│   │               WASClient6.0_windows.jar
│   │
│   └──WebSphereJars
│                     jnlp.jsp
│                     activities.jar
│                          :
│                     (all the jars created in step 7 under
│                       c:\WebApp1\Runtime\WebSphereJars)
│
├──theme
│              Master.css
│
└──WEB-INF
                  ibm-web-bnd.xmi
                  ibm-web-ext.xmi
                   web.xml
```

9. Install the `WebSphereClientRuntime.ear` file to an Application Server. You have just created an Application Clients run-time dependency component and Application Clients run-time libraries for serving J2EE Application client applications and Thin Application client applications using Java Network Launching Protocol (JNLP) or Java Web Start (JWS).

Deploying application clients on z/OS

For J2EE application clients that will run on z/OS or OS/390, you may use one of the following options to define resources:

- Run the Application Client Resource Configuration Tool (ACRCT) on Windows.
- Run the Application Client Resource Configuration Tool (ACRCT) scripting tool on z/OS.

Both options produce identical output with one possible exception: the sequence in which resource definitions are stored in the Enterprise Archive (EAR) file of the application client. The client container on z/OS uses these resource definitions for resolving and creating an instance of the resources for the application client.

Before you begin: Make sure you have completed the following tasks:

1. Develop the J2EE application client according to guidelines.
2. Assemble the application client. See ″Assembling application clients″ in the information center.
3. Find out what resources are available on the z/OS system on which you will install the client. These resources include:
   - Enterprise beans
   - JMS message resources
   - JDBC databases

- Java Mail providers
- Environment entries (native types)
- URLs

4. Decide whether you want to provide resource properties for the ACRCT scripting tool on the command line or through an input file. If you do not specify required properties, the ACRCT scripting tool issues an error message to the MVS console and ends its processing.

   Recommendation: Determine which resource or provider properties are required.

1. Use the administrative console to install the application client on z/OS or OS/390.
2. (Optional) Set up a plain text input file to provide on the command line when you start the ACRCT scripting tool.

   Rules:
   - Each line in the input file may contain only one key and value pair that defines a property of the resource to be configured.
   - For each resource to be configured, determine which resource or provider properties are required.
   - Follow the syntax rules explained in Application Client Resource Configuration Tool (ACRCT) Scripting tool for z/OS.
   - You may define your own properties for the resource, using the format property.name=value.

   Sample: Input file for a data source provider:

   ```
   providertype=DataSourceProvider
   providername=DB2UDBV7
   name=″PolicyDatasource″
   description=″Datasource for Policy App″
   jndiname=jdbc/PolicyDS
   databasename=POLICYAPP
   user=dbuser
   password=dbpw
   reenterpassword=dbpw
   property.my.resource.property.one=value1
   property.my.resource.property.two=value2
   ```

3. On z/OS or OS/390, start the ACRCT scripting tool by invoking the shell script clientConfig in the UNIX System Services (USS) environment.

   Example:

   ```
   /usr/lpp/WebSphere/V5R0M0/bin/clientConfig.sh
   ```

   Rule: You must specify the application client's Enterprise Archive (EAR) file on the command line. You may either specify resource parameters directly on the command line, or specify an input file. The syntax and parameter descriptions appear in Application Client Resource Configuration Tool (ACRCT) Scripting tool for z/OS.
   - If the resource parameters are properly specified, the ACRCT scripting tool updates the application client's client-resources.xmi file with appropriate resource definitions.
   - If the resource parameters are not properly specified or are missing, the ACRCT scripting tool issues an error message to the MVS console, and ends its processing.

   Tip: If you receive an error message in response to the invocation, consider using the help function described in Application Client Resource Configuration Tool (ACRCT) Scripting tool for z/OS.

When the scripting tool successfully completes, the application client's EAR file is updated with the appropriate resource definitions.

When you have finished defining or updating the application client's resources, launch the application client.

Installing the Client Development Kit for z/OS

The Client Development Kit (CDK) for z/OS contains the following command-line tools that are used to configure and deploy client applications for WebSphere Application Server:

- **clientConfig**

  The **clientConfig** command is used to start the Application Client Resource Configuration Tool (ACRCT). The most common task that you perform with the ACRCT is opening and modifying the components of enterprise archive (EAR) files.
- **clientUpgrade**

  The **clientUpgrade** command migrates the V4.0.x and V5.x client resources to the V6.0 level resources.
- **endptEnabler**

  The **endptEnabler** command enables a set of Web services within an EAR file. See ″endptEnabler command″ in the information center for additional information.
- **Java2WSDL**

  The **Java2WSDL** command maps a Java class to a Web Services Description Language (WSDL) file by following the Java API for XML-based Remote Procedure Call (JAX-RPC) specification. See Java2WSDL command″ in the information center for additional information.
- **WSDL2Java**

  The **WSDL2Java** command is run against the WSDL file to create Java APIs and deployment descriptor templates according to the JAX-RPC and Web Services for Java 2 Platform, Enterprise Edition (J2EE) specifications. See ″WSDL2Java command″ in the information center for additional information.
- **wsdeploy**

  The **wsdeploy** command adds WebSphere product-specific deployment classes to a Web services-compatible enterprise application EAR file or an application client Java archive (JAR) file.
- **EJBDeploy**

  The EJB deployment tool provides a command-line interface (ejbdeploy) that you can use to generate enterprise bean deployment code. To learn more about this command line refer to the Application Server Toolkit information center.
- **UDDI Utility Tools**

  The UDDI Utility Tools is a suite of functions that can be used to migrate, move, and copy UDDI Version 2 entities, including child entities and their respective Version 2 entity keys, into a Version 3 UDDI Registry.

The Client Development Kit is included with the WebSphere Application Server z/OS product and located in the following directory:

```
$WAS_HOME/downloads/ClientDevKit/setup.exe
```

When the Client Development Kit is installed, the directory looks as if it is a Windows platform directory.

To install the Client Development Kit:

1. Install and Customize your z/OS WebSphere Application Server. See ″Task overview: installing″ in the information center.
2. Locate the Client Development Kit executable file in the `$WAS_HOME/downloads/ClientDevKit/` directory. FTP the **setup.exe** file in binary mode to your Windows-based client machine.
3. Execute the **setup.exe** installation file.
4. Follow the InstallWizard prompts to complete the installation.

You are now ready to configure applications that can be deployed into the WebSphere Application server runtime.

Application Client Resource Configuration Scripting tool for z/OS

This section describes the command line syntax for the z/OS scripting version of the Application Client Resource Configuration Tool (ACRCT). The ACRCT scripting tool for z/OS allows you to:
- Define or delete resources for an application client that will run on z/OS.
- List the properties of a resource or provider that is already defined for the application client.

For define and delete actions, the ACRCT scripting tool alters the Enterprise Archive (EAR) file for the application client, as instructed by options you specify. If the ACRCT scripting tool encounters an error at any time during its processing, the tool issues an error message to the MVS console and terminates without changing the original contents of the application client EAR file.

When you use the ACRCT scripting tool, you may specify:
- More than one action (define, delete, or list) to perform for a specific application client.
- More than one EAR file, to define or delete resources for more than one application client at a time.

The command line invocation syntax for the ACRCT scripting tool follows. When you have a choice of one required keyword, those keywords appear within brackets [].
- To define or delete resources:

```
acrct -earfile earfile [-define | -delete] [-provider | -resource]
[-f inputfile | key=value]
```
- To list resources:

```
acrct -list [-provider | -resource] [-f inputfile | -p key=value]
```
- To get help information:

```
acrct -help
```

Parameters

where:

-earfile
Is a required parameter that indicates the input filename of the application client EAR file.

earfilename
Identifies the location and name of the EAR file that contains the application client. This path and filename must directly follow the -earfile parameter.

-define
Instructs the scripting tool to define a provider or resource based on the input properties.

-delete
Instructs the scripting tool to delete a provider or resource based on the input properties.

-list
Instructs the scripting tool to the properties of a particular provider or resource, based on the input properties.

-help
Instructs the scripting tool to list basic examples and guidelines for using quotes around key values.

-provider
Indicates that the object to be defined or deleted, or for which properties are to be listed, is a provider.

-resource
Indicates that the object to be defined or deleted, or for which properties are to be listed, is a resource.

-f Indicates that the input properties for the provider or resource are provided in an input file, rather than specified directly on the command line.

inputfile
Identifies the location and name of the input file that contains the provider or resource properties. This path and filename must directly follow the -f parameter.

key=*value*
Specifies an input property for the provider or resource, in the form of key and value pairs.

Rules:
- You must use lowercase for keys.
- You cannot use blanks within a key and value pair; a blank signals the end of one key/value pair.
- Because blanks separate key and value pairs, you must be careful when a value you supply contains blanks. When you specify a value that contains blanks, enclose the value in single quotes or double quotes. Because some shells processes quotes differently, you might have to do some testing to determine whether you must use single or double quotes.

  Example: Suppose you invoke the scripting tool, passing this input:

  ```
  /WebSphere/V5R0M0/AppServer/bin:>acrct  -earfile
  usr/lpp/myapps/applclient2.ear  -define
  -provider  providername='WebSphere  JMS  Provider'
  ```

  The response is an error message along with an echo of the input string that the shell receives, followed by the input string as the scripting tool will process it:

  ```
  -earfile  usr/lpp/myapps/applclient2.ear  -define
  -provider  providername=WebSphere  JMS  Provider

  String  to  be  parsed  by  the  Scripting  Tool:

  -earfile  usr/lpp/myapps/applclient2.ear  -define
  -provider  providername=WebSphere  JMS  Provider

  Ear  file  is  missing  or  is  improperly  specified.
  Invalid  syntax:  -earfile  usr/lpp/myapps/applclient2.ear  -define  -provider  providername=
  WebSphere  JMS  Provider
  ```

  As you can see from the response, the shell has stripped off the single quotes, and passes invalid input to the scripting tool. To correct the problem, you need to use double quotes.
- The number of key and value pairs you specify depends on the type of resource or provider you are configuring. For each resource to be configured, use this information to determine which resource or provider properties are required.

The following examples demonstrate correct syntax:

Defining a new provider for an application client, using an input file:
```
acrct -earfile usr/lpp/myapps/applclient1.ear -define -provider -f
usr/lpp/myapps/inputProvider1.def
```
Defining a new provider for an application client, specifying properties directly on the command line:
```
acrct -earfile usr/lpp/myapps/applclient2.ear -define -provider -p
providertype=DataSourceProvider name=DB2UDBV7
```
Defining a new provider and deleting the resource it replaces, in the same EAR file:
```
acrct -earfile usr/lpp/myapps/applclient1.ear -define -provider -f
usr/lpp/myapps/inputProvider2.def -delete -resource -f usr/lpp/myapps/inputProvider1.def
```
Defining a new provider in more than one EAR file:
```
acrct -earfile usr/lpp/myapps/applclient1.ear -define -provider -f
usr/lpp/myapps/inputProvider2.def -earfile usr/lpp/myapps/applclient2.ear -define
-provider -f usr/lpp/myapps/inputProvider2.def
```

Determining required properties for z/OS application client resources

When you deploy application clients on z/OS or OS/390, you need to determine the required properties to specify when using the z/OS scripting version of the Application Client Resource Configuration Tool (ACRCT).

Note: This procedure applies only for J2EE application clients.

Use the following information to determine required properties to specify for application client resources.

If the application uses this type of resource or provider:	Find required and optional properties in these articles:
Data source	• Datasource Provider • Datasource
JMS	• JMS Provider • JMS Connection • JMS Destination
Mail session	• Mail provider • Mail session
Resource environment	• Resource environment provider • Resource environment entry
URL	• URL provider • URL factory
WebSphere MQ queue	• WebSphere MQ queue connection factory • WebSphere MQ queue destination factory
WebSphere MQ topic	• WebSphere MQ topic connection factory • WebSphere MQ topic destination factory
WebSphere queue	• WebSphere queue connection factory • WebSphere queue destination factory
WebSphere topic	• WebSphere topic connection factory • WebSphere topic destination factory

Properties for data source providers:

Type	Value	Description
name	required	
description	optional	
implementation	required	
classpath	required	
native library path	required for specific providers	required for • DB2 for zOS JDBC Provider (RRS) • DB2 Universal JDBC Driver Provider (optional for all others)

Properties for data sources:

Type	Value
providertype=DataSourceProvider	required
providername	required

Type	Value
name	required
description	optional

Deploying J2EE application clients on workstation platforms

After developing an application client, deploy this application on client machines. *Deployment* consists of pulling together the various artifacts that the application client requires.

The *Application Client Resource Configuration Tool* (ACRCT) defines resources for the application client. These configurations are stored in the client `.jar` file within the application `.ear` file. The application client run time uses these configurations for resolving and creating an instance of the resources for the application client.

Note: This task only applies to J2EE application clients. Only perform this task if you configured your J2EE application client to use resource references.

1. Start the ACRCT and open an EAR file.
2. Configure new data source providers.
3. Configure mail providers and sessions.
4. Configure URL providers and sessions.
5. Configure Java messaging resources.
6. Configure new environment entries.
7. (Optional) Remove application client resources.
8. Save the EAR file.

Resource Adapters for the client

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application client and provides connectivity between the EIS and the enterprise application.

The resource adapter support for the J2EE client applications is a subset of the support for the server. For any resource adapter installed using the clientRAR tool, the client resource adapter is used in a non-managed environment and must conform to the J2EE Connector Architecture Specification Version 1.5 or higher. Only outbound connections to the EIS are supported through the ManagedConnectionFactory interfaces. The inbound messaging support (from the EIS), life cycle management, and work management aspects of the specification are not supported on the client.

For a client application to use a resource adapter, it must be installed in the directory specified by the environment variable, CLIENT_CONNECTOR_INSTALL_ROOT, defined when the setupCmdLine.bat command (on Windows systems) or setupCmdLine.sh (on UNIX platforms) command runs. The launchClient tool, Application Client Resource Configuration Tool (ACRCT) and clientRAR tool all use this variable to find the default location of all installed resource adapters. To install a resource adapter in the client, use the clientRAR tool. Once the resource adapter is installed, it must be configured using the ACRCT. The client configuration tool adds the resource adapter configuration to the EAR file. Then, connection factories and administered objects are defined.

When running J2EE application clients, the `launchClient` script specifies a system property called `com.ibm.ws.client.installedConnector`, which is set to the same value as the `CLIENT_CONNECTOR_INSTALL_ROOT` variable. This is the default location for installed resource adapters and can be overridden for each `launchClient` call by specifying the `-CCD` parameter. When the client container is activated, all resource adapter subdirectories under the specified default location for the resource adapters directory are added to the classpath. This action allows the client application to use the resource adapters without using the ACRCT to specify any of the client resources.

Using resource adapters is a new mechanism for easily extending client applications.

Configuring resource adapters

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new resource adapters. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new resource adapters from the tree.
4. Expand the JAR file to view its contents.
5. Right-click the **Resource Adapters** folder, and click **New**.
6. Configure the resource adapter settings in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save** on the menu bar to save your changes.

Resource adapter settings:

Use this panel to view or change the configuration properties of the resource adapter. These configuration properties control how resource adapters are created.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapter**. Right-click **Resource Adapter** and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this Resource Adapter is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the Resource Adapters across the product administrative domain.

Data type String

Description:

A description of this resource adapter for administrative purposes within IBM WebSphere Application Server.

Data type String

Class Path:

Any additional class path. The path to the resource adapter directory is automatically added.

Data type String
Default The path to your Resource Adapter directory.

Native Path:

The native path where the Resource Adapter is located. Enter any additional native class path here.

Data type String

Resource Adapter Name:

A mandatory field that points to an installed resource adapter subdirectory. The entry does not represent the full directory name for the resource adapter. The full directory name is the installed resource adapter path, plus the resource adapter name.

Data type String

Installed Resource Adapter Path:

The directory where resource adapters are installed. If you do not complete this field, then the default takes effect.

If you specify the value, `${CONNECTOR_INSTALL_ROOT}`, then this value replaces the value of the `CLIENT_CONNECTOR_INSTALL_ROOT` variable on the machine on which the client application runs. This action allows the application to run easily on different machines, where the client installation might be in different locations.

Data type String
Default ${CONNECTOR_INSTALL_ROOT}

clientRAR tool:

This section describes the command line syntax for the client resource adapter installation tool. If this tool is used to add or delete resource adapters on the server, then only the client can use the resource adapter. If the resource adapter is installed on the server using the wsadmin tool or the administrative

console, then do not use the clientRAR tool remove it. Only resource adapters that are installed using the clientRAR tool should be removed using the clientRAR tool.

The command line invocation syntax for the `clientRAR` tool follows:

clientRAR [-help | -?] [-CRDcom.ibm.ws.client.installedConnectors=<dir>] <task> <archive>

where
-help, -?
Print the usage information.
-CRDcom.ibm.ws.client.installedConnectors
The directory where resource adapters are installed. This will override the system property of the same name (com.ibm.ws.client.installedConnectors).

<task>
The task to perform: add - install, delete - uninstall.

<archive>
if task=add then this is the fully qualified name of the resource adapter archive file.
If task=delete then this is the filename of the resource adapter archive to be uninstalled.

The following examples demonstrate correct syntax.

On the Windows operating systems:

- clientRAR add c:\rars\myrar.rar
- clientRAR delete myrar.rar

On the UNIX operating systems:

- ./clientRAR add /usr/rars/myrar.rar
- ./clientRAR delete myrar.rar

Configuring new connection factories for resource adapters:

Complete this task to configure new connection factories for resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new connection factories. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new connection factories from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create connection factories.
7. Right-click the **Connection Factories** folder and click **New**.
8. Configure the connection factory properties in the resulting property dialog.
9. Click **OK**.
10. Click **File** > **Save** on the menu bar to save your changes.

Resource adapter connection factory settings:

Use this panel to view or change the configuration properties of the selected resource adapter connection factory.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters**. Right-click the **Connection Factories** folder, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the resource adapter connection factories across the product administrative domain.

Data type String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this resource adapter connection factory definition to the deployment descriptor. This entry should be a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly when getting a connection. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly when getting a connection.

Data type String

Password:

Specifies an encrypted password. If you complete this field, then the **Password** field in the Properties box is ignored.

If you specify a value for the **UserName** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Type:

A drop-down list of all the `connectionFactoryInterfaces` as defined for the factories in the Resource Adapter Archive.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each connection definition object. For any existing connection factories that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type String

Configuring administered objects:

Before you configure new administered objects, you must complete the following prerequisites:

1. Install the Resource Adapter Archive file (RAR) using the clientRAR tool.
2. Configure the resource adapter for the `.ear` file, using the Application Client Resource Configuration Tool (ACRCT) tool.

Complete this task to configure new administered objects for installed resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new administered objects. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new administered objects from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create administered objects.
7. Right-click the **Administered Objects** folder and click **New**.
8. Configure the administered object properties in the resulting property dialog.
9. Click **OK**.
10. Click **File** > **Save** on the menu bar to save your changes.

Administered objects settings:

Use this panel to view or change the configuration properties of the selected administered objects.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters** > *resource_adapter_instance*. Right-click **Administered Objects** and click **New**. The following fields appear on the **General** tab.

The settings for administered objects are handled similarly to connection factories. When updating administered objects, use the same panels that you used to create administered objects.

Name:

The name by which this administered object is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the resource adapter administered objects across the product administrative domain.

Data type String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

This entry is a `resource-env-ref` name, a `message-destination-ref` name (if the `message-destination-ref` has no link), or a `message-destination` link.

Data type String

Type:

A drop-down list of all the administered object class-interface pairs as defined for the admin objects in the Resource Adapter Archive (RAR) file.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each administered object definition. For any existing administered objects that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type String

Starting the Application Client Resource Configuration Tool and opening an EAR file

Note: This task only applies to J2EE application clients.

Use these steps to start the Application Client Resource Configuration Tool. When you start the tool, one of the most common tasks that you perform is opening and modifying the components of EAR files.

1. Open a command prompt and change to the `install_root\bin` directory.
2. Run the `clientConfig.bat` file for a Windows system or the `clientConfig.sh` file for a UNIX system.
3. Open an EAR file within the Application Client Resource Configuration Tool (ACRCT):
   - Click **File** > **Open**.
   - Select the file and click **Open**.
4. Save your changes to the file and close the tool:
   - Click **File** > **Save**.
   - Click **File** > **Exit**.

Data sources for the Application Client

WebSphere Application Server and the Application Client for WebSphere Application Server do not provide client database drivers to be used directly from a J2EE application client. If your application client accesses a database directly, you must provide the database drivers on the client machine. You might contact your database vendor to acquire client database driver code and licenses. In addition, data sources configured on the server and looked up on the client do not participate in global transactions. Instead of accessing the database directly, it is recommended that your client application use an enterprise bean. Accessing a database through an enterprise bean eliminates the need to have database drivers on the client machine, since the database access is handled by the enterprise bean running on WebSphere Application Server. For a current list of providers that are supported on WebSphere Application Server visit the Supported hardware, software, and APIs Web site:

Configuring new data source providers (JDBC providers) for application clients

During this task, you create new data source providers, also known as JDBC providers, for your application client. In a separate administrative task, install the Java code for the required data source provider on the client machine on which the application client resides.

Use this task to connect application clients to relational databases.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file for which you want to configure the new data source provider. The EAR file contents display in a tree view.
2. Select the JAR file in which you want to configure the new data source provider from the tree.
3. Expand the JAR file to view its contents.
4. Click the **Data Source Providers** folder. Do one of the following:
   - Right-click the folder and click **New Provider**.
   - Click **Edit > New** on the menu bar.
5. Configure the data source provider properties in the resulting property dialog.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Example: Configuring data source provider and data source settings: The purpose of this article is to help you to configure data source provider and data source settings.

- Required fields:
  - Data Source Provider Properties page: name
  - Data Source Properties page: name, jndiName
- Special cases:
  - The user name and password fields have no equivalent XMI tags. You must specify these fields in the custom properties.
  - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.
- Example:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classPath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
value="{xor}NTs9PBk+PCswLSZlMT4yOg==">
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

Data source provider settings for application clients:

Use this page to create a data source under a JDBC provider which provides the specific JDBC driver implementation class.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Data Source Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the display name for the data source.

For example you can set this field to *Test Data Source*.

Data type String

Description:

Specifies a text description for the resource.

Data type String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Implementation class:

Use this setting to perform database specific functions.

Data type String
Default Dependent on JDBC driver implementation class

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Data source properties for application clients:

Use this page to create or modify the data sources.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Data Source Providers** > *Data source provider instance*. Right-click **Data Sources** and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the display name of this data source.

Data type String

Description:

Specifies a text description of the data source.

Data type String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Database Name:

The name of the database to which you want to connect.

User:

Use the user ID with the Password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the User ID property, then you must also specify a value for the Password property. The connection factory User ID and Password properties are used if the calling application does not provide a user ID and password explicitly.

Password:

Use the password with the User ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the Password property, then you must also specify a value for the User ID property.

Re-Enter Password:

Confirms the password.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new data sources for application clients

During this task, you create new data sources for your application client.

1. Click the data source provider for which you want to create a data source in the tree. Take one of the following actions as needed:
   - Configure a new data source provider.
   - Click an existing data source provider.
2. Expand the data source provider to view its **Data Sources** folder.
3. Click the data source folder. Take one of the following actions as needed:
   - Right click the data source folder and click **New Factory**.
   - Click **Edit > New** on the menu bar.
4. Configure the data source properties in the displayed fields.
5. Click **OK** when you finish.

6. Click **File > Save** on the menu bar to save your changes.

Configuring mail providers and sessions for application clients

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of JavaMail sessions and providers for your application clients to use.

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the JavaMail objects in the tree that displays. For example, if your file contains JavaMail sessions, expand **Resources** > ***application*.jar** > **JavaMail Providers** > ***java_mail_provider_instance*** > **JavaMail Sessions**.

   In this example, ***java_mail_provider_instance*** is a particular JavaMail provider.

The JavaMail session instances are located in the **JavaMail Sessions** folder.

Mail provider settings for application clients:

Use this page to implement the JavaMail API and create mail sessions.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Mail Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

The name of the JavaMail resource provider.

Description:

An optional description for the resource provider.

Class Path:

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Specifies the name of the protocol.

Classname:

Specifies the name of the class implementing the protocol. Leave this field blank if you want to use the default implementation.

Type:

This menu contains the following two values: `TRANSPORT` or `STORE`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Mail session settings for application clients:

Use this page to configure mail session properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Mail Providers** > *mail provider instance*. Right-click **Mail Sessions** and click **New**. The following fields appear on the **General** tab:

Name:

Represents the administrative name of the JavaMail session object.

Description:

Provides an optional description for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Mail Transport Host:

Specifies the server to connect to when sending mail.

Mail Transport Protocol:

Specifies the transport protocol to use when sending mail.

Mail Transport User:

Specifies the user ID to use when the mail transport host requires authentication.

Mail Transport Password:

Specifies the password to use when the mail transport host requires authentication.

Enable strict Internet address parsing:

Specifies whether the recipient addresses must be parsed strictly in compliance with RFC 822, which is a specifications document issued by the Internet Architecture Board.

This setting is not generally used for most mail applications. RFC 822 syntax for parsing addresses effectively enforces a strict definition of a valid e-mail address. If you select this setting, JavaMail will adhere to RFC 822 syntax and reject recipient addresses that do not parse into valid e-mail addresses (as defined by the specification). If you do not select this setting, JavaMail will not adhere to RFC 822 syntax and will accept recipient addresses that do not comply with the specification. By default, this setting is deselected. You can view the RFC 822 specification at the following URL for the World Wide Web Consortium (W3C): http://www.w3.org/Protocols/rfc822/.

Re-Enter Password:

Confirms the password.

Mail From:

Specifies the mail originator.

Mail Store Host:

Specifies the mail account host (or ″domain″) name.

Mail Store User:

Specifies the user ID of the mail account.

Mail Store Password:

Specifies the password of the mail account.

Re-Enter Password:

Confirms the password.

Mail Store Protocol:

Specifies the protocol to be used when receiving mail.

Mail Debug:

When `true`, JavaMail interaction with mail servers, along with these mail session properties are printed to the `stdout` file.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JavaMail provider and JavaMail session settings for application clients: The purpose of this article is to help you configure JavaMail provider and JavaMail session settings.

- Required fields:
  - JavaMail Provider Properties page: name, and at least one protocol provider
  - JavaMail Session Properties page: name, jndiName, mail transport protocol, mail store protocol
- Special cases:
  - The password is encrypted when using the ACRCT tool. Without the tool, you cannot encrypt this field.
- Example:

```
<resources.mail:MailProvider xmi:id="MailProvider_1" name="Default Mail Provider"
description="IBM JavaMail Implementation">
<classpath>mailProvider:classpath</classpath>
<factories xmi:type="resources.mail:MailSession" xmi:id="MailSession_1"
name="mailSession:name" jndiName="mailSession:jndiName"
description="mailSession:description" mailTransportHost="mailSession:mailTransportHost"
mailTransportUser="mailSession:mailTransportUser"
mailTransportPassword="{xor}Mj42Mww6LCw2MDFlMT4yOg=="
mailFrom="mailSession:mailFrom" mailStoreHost="mailSession:mailStoreHost"
mailStoreUser="mailSession:mailStoreUser"
mailStorePassword="{xor}Mj42Mww6LCw2MDFlMT4yOg==" debug="true"
```

```
mailTransportProtocol="ProtocolProvider_1" mailStoreProvider="ProtocolProvider_1">
<propertySet xmi:id="J2EEResourcePropertySet_1">
<resourceProperties xmi:id="J2EEResourceProperty_1"
name="mailSession:customName" value="mailSession:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_2">
<resourceProperties xmi:id="J2EEResourceProperty_2" name="mailProvider:customName"
value="mailProvider:customValue"/>
</propertySet>
<protocolProviders xmi:id="ProtocolProvider_1" protocol="smtp"
classname="smtp:className"/>
<protocolProviders xmi:id="ProtocolProvider_2" protocol="pop3"
classname="pop3:className"/>
<protocolProviders xmi:id="ProtocolProvider_3" protocol="imap"
classname="imap:className"/>
</resources.mail:MailProvider>
```

Configuring new mail sessions for application clients

During this task, you configure new mail sessions for your application client. The mail sessions are associated with the pre-configured default mail provider supplied by the product.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file. The EAR file contents are displayed in a tree view.
2. Select the JAR file in which you want to configure the new JavaMail session.
3. Expand the JAR file to view its contents.
4. Click **JavaMail Providers** > **MailProvider** > **JavaMail Sessions**. Complete one of the following actions:
   - Right click the **JavaMail Sessions** folder and select **New Factory**.
   - Click **Edit** > **New** on the menu bar.
5. Configure the JavaMail session properties in the displayed fields.
6. Click **OK**.
7. Click **File** > **Save** on the menu bar to save your changes.

URLs for application clients

A *Uniform Resource Locator* (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format *scheme*:*scheme_information*.

You can represent a *scheme* as `http`, `ftp`, `file`, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a World Wide Web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with `http:`. An example is `http://www.ibm.com`. Files available using File Transfer Protocol (FTP) start with `ftp:`. Files available locally start with `file:`.

The *scheme_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The scheme_information for HTTP, FTP and File generally starts with two slashes (//), then provides the Internet address separated from the resource path name with one slash (/). For example,

`http://www-4.ibm.com/software/webservers/appserv/library.html`.

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

URL providers for the Application Client Resource Configuration Tool

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of a pair of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Configuring new URL providers for application clients

During this task, you create URL providers and URLs for your client application. In a separate administrative task, you must install the Java code for the required URL provider on the client machine on which the client application resides.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new URL provider. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new URL provider from the tree.
4. Expand the JAR file to view the contents.
5. Click the folder called **URL Providers**. Complete one of the following actions:
   - Right click the folder and select **New Provider**.
   - Click **Edit** > **New** on the menu bar.
6. Configure the URL provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save** on the menu bar to save your changes.

Configuring URL providers and sessions using the Application Client Resource Configuration Tool:

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of URL providers and URLs to be used by your application clients.

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the URL objects in the tree that displays. For example, if your file contains URL providers and URLs, expand **Resources** -> ***application*.jar** -> **URL Providers** -> ***url_provider_instance***

   where ***url_provider_instance*** is a particular URL provider.
4. If you expand the tree further, you will also see the **URLs** folders containing the URL instances for each URL provider instance.

URL settings for application clients:

Use this page to implement the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP).

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **URL Providers** > *URL provider instance*. Right-click **URLs** and click **New**. The following fields appear on the **General** tab.

This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

The administrative name for the URL.

Description:

This is an optional description of the URL for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

URL:

A Uniform Resource Locator (URL) name that points to an Internet or intranet resource. For example: `http://www.ibm.com`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

URL provider settings for application clients:

Use this page create new URL providers.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **URL Providers**, and click **New**. The following fields appear on the **General** tab.

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

Administrative name for the URL.

Description:

Optional description of the URL, for your administrative records.

Class Path:

A list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Protocol supported by this stream handler. For example, `nntp`, `smtp`, `ftp`, and so on.

To use the default protocol, leave this field blank.

Stream handler class:

Fully qualified name of a User-defined Java class that extends the `java.net.URLStreamHandler` for a particular URL protocol, such as FTP.

To use the default stream handler, leave this field blank.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring URL and URL provider settings for application clients: The purpose of this article is to help you to configure URL and URL provider settings.

- Required fields:
  - URL Properties page: name, jndiName, url
  - URL Provider Properties page: name
- Example:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

Configuring new URLs with the Application Client Resource Configuration Tool

During this task, you create URLs for your client application.

1. Click the URL provider for which you want to create a URL in the tree. Do one of the following:
   - Configure a new URL provider.
   - Click an existing URL provider.
2. Expand the URL provider to view the **URLs** folder.
3. Click the URL folder. Complete one of the following actions:
   - Right click the folder and click **New Factory**.
   - Click **Edit -> New** on the menu bar.
4. Configure the URL properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File** > **Save** in the menu bar to save your changes.

WebSphere asynchronous messaging using the Java Message Service API for the Application Client Resource Configuration Tool

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. The JMS interface provides a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests as JMS messages.

This topic provides an overview of asynchronous messaging using JMS support provided by the WebSphere Application Server.

The base support for asynchronous messaging using the JMS API provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This support enables WebSphere product J2EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients, by using JMS destinations (queues or topics). A J2EE application can use JMS queue destinations for point-to-point messaging and JMS topic destinations for Publisher and Subscriber messaging. A J2EE application can explicitly poll for messages on a destination, and then retrieve messages for processing by business logic beans (enterprise beans).

With the base JMS and XA support, the J2EE application uses standard JMS calls to process messages, including any responses or outbound messaging. An enterprise bean can handle responses acting as a sender bean, or within the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of function for asynchronous messaging is called *bean-managed messaging*, and gives an enterprise bean complete control over the messaging infrastructure, for example, connection and session pool management. The common container has no role in bean-managed messaging.

WebSphere Application Server also supports automatic asynchronous messaging using message-driven beans (a type of enterprise bean defined in the EJB 2.0 specification) and JMS listeners (part of the JMS application server facilities). Messages are automatically retrieved from JMS destinations, optionally within a transaction, then sent to the message-driven bean in a J2EE application, without the application having to explicitly poll JMS destinations.

Java Message Service (JMS) providers for clients

This topic describes the different ways that client applications can use JMS providers with WebSphere Application Server. A JMS provider enables use of the Java Message Service (JMS) and other message resources in WebSphere Application Server.

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

The service integration technologies of IBM WebSphere Application Server can act as a messaging system when you have configured a service integration bus that is accessed through the default messaging provider. This support is installed as part of WebSphere Application Server, administered through the administrative console, and is fully integrated with the WebSphere Application Server runtime.

WebSphere Application Server also includes support for the following JMS providers:

WebSphere MQ
: Provided for use with supported versions of WebSphere MQ.

Generic
: Provided for use with any 3rd party messaging system which supports ASF.

For backwards compatibility with earlier releases, WebSphere Application Server also includes support for the V5 default messaging provider which enables you to configure resources for use with the WebSphere Application Server version 5 Embedded Messaging system. The V5 default messaging provider can also be used with a service integration bus.

WebSphere applications can use messaging resources provided by any of these JMS providers. However the choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you may already have a messaging infrastructure based on WebSphere MQ. In this case you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

Configuring Java messaging client resources

In a separate administrative task, install the Java Message Service (JMS) client on the client machine where the application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

During this task, you create new JMS provider configurations for your application client. The application client can use a messaging service through the Java Message Service APIs. A JMS provider provides two kinds of J2EE factories. One is a *JMS connection factory*, and the other is a *JMS destination factory*.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new JMS provider. The EAR file contents are in the displayed tree view.
3. Select the JAR file in which you want to configure the new JMS provider from the tree.
4. Expand the JAR file to view its contents.
5. Right-click **Messaging Providers** and select **New**.
6. Configure the JMS provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save**.

Configuring new JMS providers with the Application Client Resource Configuration Tool:

During this task, you create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces. A JMS provider provides two kinds of J2EE resources. One is a JMS connection factory, and the other is a JMS destination.

In a separate administrative task, you must install the JMS client on the client machine where your particular application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

1. Start the Application Client Resource Configuration Tool and open the EAR file for which you want to configure the new JMS provider. The EAR file contents are displayed in a tree view.
2. From the tree, select the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Right-click **Messaging Providers**. Complete one of the following actions:
   - Right click the folder and select **New**.
   - On the menu bar, click **Edit > New**.
5. In the resulting property dialog, configure the JMS provider properties.
6. Click **OK** when finished.
7. Click **File -> Save** on the menu bar to save your changes.

JMS provider settings for application clients:

Use this page to configure properties of the Java Message Service (JMS) provider, if you want to use a JMS provider other than the default messaging provider or the WebSphere MQ as a JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **Messaging Providers**, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which the JMS provider is known for administrative purposes.

Data type String

Description:

A description of the JMS provider, for administrative purposes.

Data type String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Context factory class:

The Java class name of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Data type String

Provider URL:

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a JMS provider has the form: `ldap://hostname.company.com/contextName`.

Data type String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Default Provider connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the connection factory.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this Resource Adapter connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used with the **Password** property for connecting to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to authenticate connection to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the connection factory connects.

Data type String

Client Identifier:

The name of the client. Required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type Selection list
Default In cluster
Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default Default
Range Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default BusMember
Range BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default Preferred
Range Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example

```
merlin:7276:BootstrapBasicMessaging,Gandalf:5557:
 BootstrapSecureMessaging
```

where

`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).

Default

- If the host name is not specified, then the default `localhost` is used as a default value.
- If the port number is not specified, then `7276` is used as a default value.
- If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default Bus
Range Bus, Host, Cluster, Server

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Data type String

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type String

Default Provider queue connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS queue connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the queue connection factory.

Data type String

Description:

A description of this queue connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this queue connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the queue connection factory connects.

Data type String

Client Identifier:

The client identifier. Required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default Default
Range Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default BusMember
Range BusMember, Custom, Destination, ME

Target Significance:

The priority of significance for the target specified.

Default Preferred
Range Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example `localhost:7777:BootstrapBasicMessaging`

where

`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).

Default

- If the host name is not specified, then the default `localhost` is used as a default value.
- If the port number is not specified, then `7276` is used as a default value.
- If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default Bus, Cluster, Server
Range Bus, Host

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Data type String

Default Provider topic connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS topic connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display that appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the topic connection factory.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this topic connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the topic connection factory connects.

Data type String

Client Identifier:

The name of the client. This field is required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type Selection list
Default In cluster
Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default	BusMember
Range	BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example	`localhost:7777:BootstrapBasicMessaging` where `BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).
Default	• If the host name is not specified, then the default `localhost` is used as a default value. • If the port number is not specified, then `7276` is used as a default value. • If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default Bus
Range Bus, Host, Cluster, Server

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type String

Default Provider queue destination settings:

Use this panel to view or change the configuration properties of the selected JMS queue destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Destinations**. Click **New**. The following fields appear on the **General** tab.

Name:

The name of the queue destination factory. You must complete this field.

Data type String

Description:

A description of this queue destination for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Data type String

Queue Name:

The name of the queue.

Data type String

Delivery Mode:

The delivery mode for messages sent to this destination.

Data type String
Range Application, Persistent or NonPersistent

Default	Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if the Time to Live field is not completed.

Data type	Integer
Units	Milliseconds

Priority:

The priority for messages sent to this destination. The value from the producer is used if not completed.

Data type	Integer
Range	0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type	String
Range	AsConnection, AlwaysOn and AlwaysOff
Default	AsConnection

Default Provider topic destination settings:

Use this panel to view or change the configuration properties of the selected JMS topic destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Destinations**, and click **New**. The following fields appear on the **General** tab.

Name:

The name of the topic destination entry.

Data type	String

Description:

A description of the entry.

Data type	String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Data type String

Topic Space:

The name of the topic space. This field is required.

Data type String
Default DEFAULT_TOPIC_SPACE

Topic Name:

The name of the topic. This field is required.

Data type String

Delivery Mode:

The default mode for messages sent to this destination.

Data type String
Range Application, Persistent or NonPersistent
Default Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if not completed.

Data type Long
Units Milliseconds

Priority:

The priority for messages sent to this destination. Value from producer is used if not completed.

Data type Integer
Range 0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type String
Range AsConnection, AlwaysOn and AlwaysOff
Default AsConnection

Version 5 Default Provider queue connection factory settings for application clients:

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server version 5 applications. These configuration properties control how connections are created between the JMS provider and the default messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Provider** > **Version 5 Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

A queue connection factory is used to create JMS connections to queue destinations. The queue connection factory is created by the internal WebSphere Application Server product JMS provider. A Version 5 Default Provider queue connection factory has the following properties:

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The User ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a User ID and password explicitly, for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Re-Enter Password:

Confirms the password.

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type String

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the internal product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

A Version 5 Default Provider topic connection factory has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere Application Server administrative domain.

Data type String

Description:

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type	String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type	String

Re-Enter Password:

Confirms the password.

Node:

The WebSphere Application Server node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Range	Pull-down list of nodes in the WebSphere Application Server administrative domain.

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Port:

Which of the two ports that connections use to connect to the JMS Server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for nonpersistent, nontransactional, nondurable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish or subscribe support. Therefore, any topic connection factory configured with the Port set to `Direct` cannot be used with message-driven beans.

Data type	Enum
Default	QUEUED

Range

QUEUED
The listener port used for full-function JMS compliant, publish or subscribe support.

DIRECT
The listener port used for direct TCP/IP connection (nontransactional, nonpersistent, and nondurable subscriptions only) for publish or subscribe support.

The TCP/IP port numbers for these ports are defined on the product internal JMS server.

Client ID:

The JMS client identifier used for connections to the MQSeries queue manager.

Data type String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider queue destination settings for application clients:

Use this panel to view or change the configuration properties of the selected queue destination for use with product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

A queue destination is used to configure the properties of a JMS queue. A Version 5 Default Provider queue destination has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes.

Data type String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Persistent
Messages on the destination are persistent.
Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Specified
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or whether messages on the queue expire (have an unlimited expiry timeout).

Data type Enum

Default APPLICATION_DEFINED

Range

Application defined
The expiry timeout for messages in this queue is defined by the application that put them onto the queue.

Specified
The expiry timeout for messages in this queue is defined by the **Specified expiry** property.If you select this option, you must define a time out on the **Specified expiry** property.

Unlimited
Messages in this queue have no expiry timeout, and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, specify the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer

Units Milliseconds

Range Greater than or equal to 0

- 0 indicates that messages never timeout.
- Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic destination settings for application clients:

Use this panel to view or change the configuration properties of the selected topic destination for use with the internal product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Destinations** and click **New**. The following fields appear on the **General** tab.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A Version 5 Default Provider topic has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type String

Description:

A description of the topic, for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information.

Topic Name: The name of the topic as defined to the JMS provider.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Persistent
Messages on the destination are persistent.
Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Specified
The priority of messages on this destination is defined by the **Specified priority** property.*If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout).

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.
Specified
The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*
Unlimited
Messages on this queue have no expiry timeout, so those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer
Units Milliseconds
Range Greater than or equal to 0
- 0 indicates that messages never time out.
- Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider queue connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the MQSeries product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Queue Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book, located in the WebSphere MQ Family library.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

A queue connection factory for the JMS provider has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type	String
Default	Null

Re-Enter Password:

Confirms the password.

Queue manager:

The name of the MQSeries queue manager for this connection factory.

Connections created by this factory connect to that queue manager.

Data type	String

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connection only.

Data type	String
Default	Null
Range	A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Default	Null
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type	String
Default	Null
Range	1 through 20 ASCII characters

Transport type:

Specifies whether the WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, nondurable, nontransactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type Enum

Units Not applicable

Default BINDINGS

Range

BINDINGS

JNDI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and poses security risks that should be addressed through the use of EJB roles.

CLIENT

WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.

DIRECT

For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in nontransactional, nondurable and nonpersistent Publish/Subscribe messaging. DIRECT only works for clients and message-driven beans using the non-ASF protocol.

QUEUED

QUEUED is a standard TCP protocol.

Recommended

Queue connection factory transport type

BINDINGS is faster by 30% or more, but it lacks security. When you have security concerns, BINDINGS is more desirable than CLIENT.

Topic connection factory transport type

DIRECT is the fastest type and should be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is the fallback for all other cases. WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This loss also happens with client-side applications unless the broker maxClientQueueSize is set to 0. You can set this to 0 with the command:

```
#wempschangeproperties WAS_nodeName_server1
-e default -o DynamicSubscriptionEngine
-n maxClientQueueSize -v 0
-x executionGroupUUID
```

where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000.

Client ID:

The JMS client identifier used for connections to the MQSeries queue manager.

Data type String

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type String

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These references are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Message Retention:

Select this check box to specify that unwanted messages are to be left on the queue. Otherwise, unwanted messages are handled according to their disposition options.

Data type Enum
Units Not applicable
Default Cleared
Range
Selected
Unwanted messages are left on the queue.
Cleared
Unwanted messages are handled according to their disposition options.

Temporary model:

The name of the model definition used to create temporary connection factories if a connection factory does not already exist.

Data type String
Range 1 through 48 ASCII characters

Temporary queue prefix:

The prefix used for dynamic queue naming.

Data type String

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Data type Check box
Default Selected

Local Server Address:

Specifies the local server address.

Data type String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery

Data type	Integer
Units	Milliseconds
Default	5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:
`ldap://`*`hostname`*`:[`*`port`*`]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at:
http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a distinguished name skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:
`CN=QMGR.*, OU=IBM, OU=WEBSPHERE`

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the section "Distinguished Names" in the WebSphere MQ Security book.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type	Check box
Default	Selected

WebSphere MQ Provider topic connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Topic Connection Factories** and click **New**.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ product JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

A topic connection factory for the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which this topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS provider.

Data type	String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The Java Naming and Directory Interface (JNDI) name that is used to bind the topic connection factory into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String
Units En_US ASCII characters
Range 1 through 45 ASCII characters

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User** property, you must also specify a value for the **Password** property.

The connection factory **User** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

Data type String

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connections only.

Data type String
Range A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type Integer
Range A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for client connections to the WebSphere MQ queue manager for client connection only.

Data type String
Range 1 through 20 ASCII characters

Transport Type:

Whether WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager.

Data type Enum
Default BINDINGS
Range
CLIENT
WebSphere MQ client connection is used to connect to the WebSphere MQ queue manager.
BINDINGS
JNDI bindings are used to connect to the WebSphere MQ queue manager.

Client ID:

The JMS client identifier used for connections to the WebSphere MQ queue manager.

Data type String

CCSID:

The coded character set identifier to be used with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type String

Broker Control Queue:

The name of the broker control queue to which all command messages (except publications and requests to delete publications) are sent.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Queue Manager:

The name of the WebSphere MQ queue manager that provides the Publisher and Subscriber message broker.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Publish Queue:

The name of the broker input queue that receives all publication messages for the default stream.

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Subscribe Queue:

The name of the broker queue from which nondurable subscription messages are retrieved.

The name of the broker queue from which nondurable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker CCSubQ:

The name of the broker queue from which nondurable subscription messages are retrieved for a ConnectionConsumer request. This property applies only for use of the Web container.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Version:

Specifies whether the message broker is provided by the WebSphere MQ MA0C SupportPac or newer versions of WebSphere family message broker products.

Data type Enum
Default Advanced
Range
Advanced
The message broker is provided by newer versions of WebSphere family message broker products (MQ Integrator and MQ Publish and Subscribe).
Basic The message broker is provided by the WebSphere MQ MA0C SupportPac (WebSphere MQ - Publish and Subscribe).

Cleanup level:

Specifies the level of clean up provided by the publish or subscribe cleanup utility.

Data type Enum
Default SAFE
Range
ASPROP
NONE
STRONG

Cleanup interval:

Specifies the interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

Data type Integer
Units Milliseconds
Default 6000

Message selection:

Specifies where broker message selection is performed.

Data type Enum
Default BROKER
Range
BROKER
Message selection is done at the broker location.
Message CLIENT
Message selection is done at the client location.

Publish acknowledge interval:

The interval, in number of messages, between publish requests that require acknowledgement from the broker.

Data type Integer
Default 25

Sparse subscriptions:

Enables sparse subscriptions.

Data type Check box
Default Cleared

Status refresh interval:

The interval, in milliseconds, between transactions to refresh publish or subscribe status.

Data type Integer
Default 6000

Subscription store:

Specifies where WebSphere MQ stores data relating to active JMS subscriptions.

Data type Enum
Default MIGRATE
Range

MIGRATE

QUEUE

BROKER

Multicast:

Specifies whether this connection factory uses multicast transport.

Data type Enum
Default NOT USED
Range

NOT USED
This connection factory does not use multicast transport.

ENABLED
This connection factory always uses multicast transport.

ENABLED_IF_AVAILABLE
This connection factory uses multicast transport.

ENABLED_RELIABLE
This connection factory uses reliable multicast transport.

ENABLED_RELIABLE_IF_AVAILABLE
This connection factory uses reliable multicast transport if available.

Direct authentication:

Specifies whether to use direct broker authorization.

Data type Enum

Default NONE

Range

NONE Direct broker authorization is not used.

PASSWORD
Direct broker authorization is authenticated with a password.

CERTIFICATE
Direct broker authorization is authenticated with a certificates.

Proxy Host Name:

Specifies the host name of a proxy to be used for communication with WebSphere MQ.

Data type String

Proxy Port:

Specifies the port number of a proxy to be used for communication with WebSphere MQ.

Data type Integer
Default 0

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Data type Check box
Default Selected

Local Server Address:

Specifies the local server address.

Data type String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery.

Data type Integer
Units Milliseconds
Default 5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:
`ldap://hostname:[port]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at:
http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a distinguished name skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:
`CN=QMGR.*, OU=IBM, OU=WEBSPHERE`

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the section “Distinguished Names” in the WebSphere MQ Security book.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type Check box
Default Selected

WebSphere MQ Provider queue destination settings for application clients:

Use this panel to view or change the configuration properties of the selected queue destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product for JMS resources. For more information about configuring WebSphere MQ product for JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters.

A queue for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes.

Data type String

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED

Range

Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent
Messages on the destination are persistent.

Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Units Not applicable
Default APPLICATION_DEFINED
Range

Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Specified
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout value for this queue is defined by the application or the by **Specified expiry** property or whether messages on the queue never expire (have an unlimited expiry time out).

Data type Enum
Units Not applicable
Default APPLICATION_DEFINED

Range

Application defined
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

Specified
The expiry timeout for messages on this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout on the **Specified expiry** property.

Unlimited
Messages on this queue have no expiry timeout and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer
Units Milliseconds
Range Greater than or equal to 0
- 0 indicates that messages never time out
- Other values are an integer number of milliseconds

Base Queue Name:

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property.

Data type String

Base Queue Manager Name:

The name of the WebSphere MQ queue manager to which messages are sent.

This queue manager provides the queue specified by the **Base queue name** property.

Data type String
Units En_US ASCII characters
Range A valid WebSphere MQ Queue Manager name, as 1 through 48 ASCII characters

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifier supported by WebSphere MQ queue manager.

Data type String

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal integer encoding is used.
REVERSED
Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

Indicates that if native encoding is not enabled to select whether decimal encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal decimal encoding is used.
REVERSED
Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates that if native encoding is not enabled to select the type of floating point encoding.

Data type Enum
Default IEEENORMAL
Range
IEEENORMAL
IEEE normal floating point encoding is used.
IEEEREVERSED
IEEE reversed floating point encoding is used.
S390 S390 floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination use native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type Enum
Default Cleared
Range
Cleared
Native encoding is not used, so specify the following properties for integer, decimal and floating point encoding.
Selected
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Target client:

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application.

Data type Enum
Default WebSphere MQ
Range
WebSphere MQ The target is a traditional WebSphere MQ application that does not support JMS.
JMS The target application supports JMS.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider topic destination settings for application clients:

Use this panel to view or change the configuration properties of the selected topic destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Topic Destinations**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ product JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A topic for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type String

Description:

A description of the topic for administrative purposes within IBM WebSphere Application Server.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Persistence:

Specifies whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
Messages on the destination have their persistence defined by the application that put them in the queue.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Persistent
Messages on the destination are persistent.
Nonpersistent
Messages on the destination are not persistent.

Priority:

Specifies whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
The priority of messages on this destination is defined by the application that put them in the destination.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Specified
The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority for the **Specified priority** property.

Specified Priority:

If the **Priority** property is set to `Specified`, type the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or by the **Specified expiry** property or by messages on the queue never expire (have an unlimited expiry timeout).

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
The expiry timeout for messages on this queue is defined by the application that put them in the queue.
Specified
The expiry timeout for messages in this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout value for the **Specified expiry** property.
Unlimited
Messages on this queue have no expiry timeout, and these messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer
Units Milliseconds
Range Greater than or equal to 0
- 0 indicates that messages never time out.
- Other values are an integer number of milliseconds.

Base Topic Name:

The name of the topic to which messages are sent.

Data type String

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifiers that WebSphere MQ supports.

Data type String

Integer encoding:

Indicates whether integer encoding is normal or reversed when native encoding is not enabled.

Data type Enum
Default NORMAL
Range
NORMAL
Normal integer encoding is used.
REVERSED
Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal decimal encoding is used.
REVERSED
Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates the type of floating point encoding when native encoding is not enabled.

Data type Enum
Default IEEENORMAL
Range
IEEENORMAL
IEEE normal floating point encoding is used.
IEEEREVERSED
IEEE reversed floating point encoding is used.
S390 S/390 floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type Enum
Default Cleared
Range
Cleared
Native encoding is not used, so specify the previous properties for integer, decimal and floating point encoding.
Selected
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

BrokerDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved.

The subscriber specifies the name of the queue when it registers a subscription.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

BrokerCCDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Target Client:

Specifies whether the receiving application is JMS compliant or is a traditional WebSphere MQ application.

Data type Enum
Default WebSphere MQ
Range
WebSphere MQ The target is a traditional WebSphere MQ application that does not support JMS.
JMS The target is a JMS compliant application.

Multicast:

Specifies whether this connection factory uses multicast transport.

Data type Enum
Default AS_CF
Range

AS_CF This connection factory uses multicast transport.

DISABLED
This connection factory does not use multicast transport.

NOT_RELIABLE
This connection factory always uses multicast transport.

RELIABLE
This connection factory uses multicast transport when the topic destination is not reliable.

ENABLED
This connection factory uses reliable multicast transport.

Generic JMS connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected Java Message Service (JMS) connection factory for use with the associated JMS provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new_JMS_Provider_instance*. Right-click **Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

A Java Message Service (JMS) connection factory creates connections to JMS destinations. The JMS connection factory is created by the associated JMS provider. A JMS connection factory for a generic JMS provider (other than the internal default messaging provider or WebSphere MQ as a JMS provider) has the following properties:

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated JMS provider.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

Indicates the user ID used with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used with the **User ID** property for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String
Default Null

Re-Enter Password:

Confirms the password entered in the **Password** field.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name, for example, jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI API by the platform.

Data type String

Connection Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publication or subscription).

Select one of the following options:
Queue
A JMS queue destination for point-to-point messaging.
Topic A JMS topic destination for publish subscribe messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Generic JMS destination settings for application clients:

Use this panel to view or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new JMS Provider instance*. Right-click **Destinations**, and click **New**. The following fields are displayed on the **General** tab.

A JMS destination is used to configure the properties of a JMS destination for the associated generic JMS provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS destination for use with a generic JMS provider (not the default messaging provider or WebSphere MQ as a JMS provider) has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes.

JNDI Name:

The JNDI name of the actual (physical) name of the JMS destination bound into JNDI.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Destination Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publishing or subscribing).

Select one of the following options:
Queue
A JMS queue destination for point-to-point messaging.
Topic A JMS topic destination for pub/sub messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JMS provider, JMS connection factory and JMS destination settings for application clients: The purpose of this article is to help you to configure JMS Provider, JMS Connection Factory and JMS Destination settings.

- Required fields include:
  - JMS Provider Properties page: name, and at least one protocol provider
  - JMS Connection Factory Properties page: name, jndiName, destination type
  - JMS Destination Properties page: name, jndiName, destination type
- Special cases:
  - The destination type must be `QUEUE`, or `TOPIC`.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHBllMT4yOg=="
```

```
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Configuring new JMS connection factories for application clients

Use this task to create a new Java Message Service (JMS) connection factory configuration for your application client.

1. Click the JMS provider for which you want to create a connection factory in the tree. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its **JMS Connection Factories** folder.
3. Click the connection factory folder, and complete one of the following actions:
   - Right-click the folder and select**New Factory**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS connection factory properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new Java Message Service destinations for application clients

Use this task to create a new Java Message Service (JMS) destination configuration for your application client.

1. Click the JMS provider in the tree for which you want to create a destination. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its **JMS Destinations** folder.
3. Click the provider folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS destination properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Example: Configuring MQ Queue and Topic connection factories and destination factories for application clients

The purpose of this article is to help you configure MQ Queue connection factory, MQ Topic connection factory, MQ Queue destination factory, and MQ Topic destination factory settings.

- Required fields:
  - MQ Queue Connection Factory Properties page: name, jndiName and transport type
  - MQ Topic Connection Factory Properties page: name, jndiName and broker Version
  - MQ Queue Factory Properties page: name, jndiName, persistence, priority, expiry, baseQueueName and targetClient
  - MQ Topic Factory Properties page: name, jndiName, persistence, priority, expiry, baseQueueName and targetClient
- Special cases:
  - The transport type must be `CLIENT`, or `BINDINGS`.

- The Broker Version must be MA0C, or MQSI.
- The port must be a numerical value between -2417483648 and 2417483647.
- The CCSID must be a numerical value between -2417483648 and 2417483647.
- The persistence value must be APPLICATION_DEFINED, QUEUE_DEFINED, PERSISTENT or, NONPERSISTENT.
- The priority must be APPLICATION_DEFINED, QUEUE_DEFINED, or SPECIFIED.
- The expiry must be APPLICATION_DEFINED, UNLIMITED, or SPECIFIED.
- The integer encoding must be Normal, or Reversed.
- The decimal encoding must be Normal, or Reversed.
- The floating encoding must be IEEENormal, IEEEReversed or S390.
- The target client must be JMS or MQ.
- On the MQ Queue Connection Factory Properties page, only set the queueManager, host, and port values. These are required fields if the transport type is CLIENT.
- On the MQ Topic Connection Factory Properties page, only set the queueManager, host, and port (required) fields if the transport type is CLIENT.
- On the MQ Topic Factory Properties, and the MQ Queue Factory Properties pages, only set the Integer encoding, decimal encoding, and floating point encoding (required) fields if you do not set the nativeEncoding value.
- On the MQ Topic Factory Properties and the MQ Queue Factory Properties pages, the specified priority entry field must be an integer between 0 and 9 if priority is set to SPECIFIED .
- On the MQ Topic Factory Properties and the MQ Queue Factory Properties pages, the specified expiry entry field must be a value greater than 0 if the expiry value is set to SPECIFIED.

• Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_1" name="MQ JMS Provider"
description="mqJMSProvider:description"
externalInitialContextFactory="mqJMSProvider:contextFactoryClass"
externalProviderURL="mqJMSProvider:providerUrl">
<classpath>mqJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms.mqseries:MQQueueConnectionFactory"
xmi:id="MQQueueConnectionFactory_1" name="mqQCF:name" jndiName="mqQCF:jndiName"
description="mqQCF:description" userID="mqQCF:user" password="{xor}Mi4OHBllMT4yOg=="
queueManager="mqQCF:queueManager" host="mqQCF:host" port="1" channel="mqQCF:channel"
transportType="CLIENT" clientID="mqQCF:clientId" CCSID="2">
<propertySet xmi:id="J2EEResourcePropertySet_3">
<resourceProperties xmi:id="J2EEResourceProperty_3" name="mqQCF:customName"
value="mqQCF:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.mqseries:MQTopicConnectionFactory"
xmi:id="MQTopicConnectionFactory_1" name="mqTCF:name" jndiName="mqTCF:jndiName"
description="mqTCF:description" userID="mqTCF:user"
password="{xor}Mi4LHBllNTE7NhE+Mjo=" host="mqTCF:host" port="1"
transportType="CLIENT" channel="mqTCF:channel" queueManager="mqTCF:queueManager"
brokerControlQueue="mqTCF:brokerControlQueue"
brokerQueueManager="mqTCF:brokerQueueManager" brokerPubQueue="mqTCF:brokerPubQueue"
brokerSubQueue="mqTCF:brokerSubQueue" brokerCCSubQ="mqTCF:brokerCCSubQ"
brokerVersion="MA0C" clientID="mqTCF:clientId" CCSID="2">
<propertySet xmi:id="J2EEResourcePropertySet_4">
<resourceProperties xmi:id="J2EEResourceProperty_4" name="mqTCF:customName"
value="mqTCF:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.mqseries:MQQueue" xmi:id="MQQueue_1" name="mqQ:name"
jndiName="mqQ:jndiName" description="mqQ:description" persistence="APPLICATION_DEFINED"

targetClient="JMS" brokerDurSubQueue="mqT:brokerDurSubQueue"
brokerCCDurSubQueue="mqT:brokerCCDurSubQueue">
<propertySet xmi:id="J2EEResourcePropertySet_6">
<resourceProperties xmi:id="J2EEResourceProperty_6" name="mqT:customName"
value="mqT:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_7">
<resourceProperties xmi:id="J2EEResourceProperty_7" name="mqJMSProvider:customName"
value="mqJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Example: Configuring WAS Queue and Topic connection factories and destination factories for application clients

The purpose of this article is to help you configure Queue connection factory, Topic connection factory, Queue destination factory, and Topic destination factory settings.

- Required fields include:
  - Java Message Service (JMS) Provider Properties page: name
  - WebSphere Application Server Queue Connection Factory Properties page: name, jndiName and node
  - WebSphere Application Server Topic Connection Factory Properties page: name, jndiName, node and port
  - WebSphere Application Server Queue Factory Properties page: name, jndiName, node, persistence, priority and expiry
  - WebSphere Application Server Topic Factory Properties page: name, jndiName, topic name, persistence, priority and expiry
- Special cases:
  - The port value must be `QUEUED` or `DIRECT`.
  - The CCSID must be a numerical value between -2417483648 and 2417483647.
  - The persistence value must be `APPLICATION_DEFINED`, `PERSISTENT`, or `NONPERSISTENT`.
  - The priority value must be `APPLICATION_DEFINED`, or `SPECIFIED`.
  - The expiry value must be `APPLICATION_DEFINED`, `UNLIMITED`, or `SPECIFIED`.
  - On the WAS Topic Factory Properties, and the WAS Queue Factory Properties pages, the specified priority entry field must be an integer between 0 and 9, if the priority value is set to `SPECIFIED` .
  - On the WAS Topic Factory Properties, and the WAS Queue Factory Properties pages, the specified expiry entry field must be a value greater than 0 if expiry is set to `SPECIFIED`.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_2" name="WebSphere JMS Provider"
description="wasJMSProvider:description"
externalInitialContextFactory="wasJMSProvider:contextfactoryclass"
externalProviderURL="wasJMSProvider:providerURL">
<classpath>wasJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms.internalmessaging:WASQueueConnectionFactory"
xmi:id="WASQueueConnectionFactory_1" name="wasQCF:name" jndiName="wasQCF:jndiName"
description="wasQCF:description" userID="wasQCF:user" password="{xor}KD4sDhwZZSosOi0="
node="wasQCF:Node">
<propertySet xmi:id="J2EEResourcePropertySet_8">
<resourceProperties xmi:id="J2EEResourceProperty_8" name="wasQCF:customName"
value="wasQCF:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.internalmessaging:WASTopicConnectionFactory"
xmi:id="WASTopicConnectionFactory_1" name="wasTCF:name" jndiName="wasTCF:jndiName"
description="wasTCF:description" userID="wasTCF:user" password="{xor}KD4sCxwZZTE+Mjo="
node="wasTCF:node" port="QUEUED" clientID="wasTCF:clientId">
<propertySet xmi:id="J2EEResourcePropertySet_9">
```

```
<resourceProperties xmi:id="J2EEResourceProperty_9" name="wasTCF:customName"
value="wasTCF:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.internalmessaging:WASQueue" xmi:id="WASQueue_1"
name="wasQ:name" jndiName="wasQ:jndiName" description="wasQ:description"
node="wasQ:node" persistence="APPLICATION_DEFINED" priority="SPECIFIED"
specifiedPriority="1" expiry="SPECIFIED" specifiedExpiry="1">
<propertySet xmi:id="J2EEResourcePropertySet_10">
<resourceProperties xmi:id="J2EEResourceProperty_10" name="wasQ:customName"
value="wasQ:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms.internalmessaging:WASTopic" xmi:id="WASTopic_1"
name="wasT:name" jndiName="wasT:jndiName" description="wasT:description"
topic="wasT:topicName" persistence="APPLICATION_DEFINED" priority="SPECIFIED"
specifiedPriority="1" expiry="SPECIFIED" specifiedExpiry="1">

</propertySet>
</resources.jms:JMSProvider>
```

Configuring new resource environment providers for application clients

During this task, you create new resource environment provider configurations for your application client.

To configure a new resource environment provider, perform the following steps:

1. Start the Application Configuration Resource Tool and open the EAR file for which you want to configure the new Java Message Service (JMS) provider. The EAR file contents display in a tree view.
2. Select from the tree the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Click the **Resource Environment Providers** folder. Take one of the following actions:
   - Right-click the provider folder, and click **New Provider**.
   - Click **Edit > New** on the menu bar.
5. Configure the JMS provider properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Resource environment provider settings for application clients:

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected Java Archive (JAR) file. Right-click **Resource Environment Providers**, and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the administrative name for the resource environment provider.

Description:

Specifies a description of the resource environment provider for your administrative records.

Class Path:

Specifies the path to the JAR file that contains the implementation classes for the resource environment provider.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new resource environment entries for application clients

During this task, you create new resource environment entries for your client application.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new resource environment entry. The EAR file contents are in the displayed tree view.
3. Click the desired resource environment provider, and complete the following action to configure new providers:
   - Configure a new resource environment provider.
4. Expand the resource environment provider to view the **Resource Environment Entries** folder.
5. Click the resource environment entries folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
6. Configure the resource environment entry properties in the displayed fields.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Resource environment entry settings for application clients:

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Environment Providers** > *resource environment instance*. Right-click **Resource environment entry**, and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the administrative name for the resource environment entry.

Description:

Specifies a description of the URL for your administrative records.

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

Use this name to link to the binding information of the platform. The binding associates the resources defined in the deployment descriptor of the module to the actual (or physical) resources bound into JNDI by the platform.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Creating locally defined objects for message destination references and message destinations

After developing an application client, deploy this application on client machines. *Deployment* consists of pulling together the various artifacts that the application client requires.

The *Application Client Resource Configuration Tool* (ACRCT) defines resources for the application client. These configurations are stored in the application client `.ear` file. The application client run time uses these configurations for resolving and creating an instance of the resources for the application client.

Note: This task only applies to J2EE application clients. Only perform this task if you configured your J2EE application client to use resource references.

When a local object definition is created using the ACRCT, the JNDI name of the local object definition points to the reference for which the local object definition applies. The object might be a `resource-ref`, `resource-env-ref` or `message-destination-ref`. If the `message-destination-ref` has a `message-destination-link`, then point the local object definition to the message-destination. Local object definitions either point to the `message-destination-ref` (if the `message-destination-ref` has no link) or to the `message-destination` (if the message-destination-ref has a link). Any local object definitions pointing to `message-destination-refs` that have a link are ignored.

1. Start an assembly tool such as Application Server Toolkit (AST) or Rational Web Developer, and open an EAR file.
2. Create a locally defined object.
3. Point the object to the appropriate message destination.
4. Save the EAR file.

Managing application clients

Perform the following tasks after deploying application clients. This task only applies to J2EE application clients.

1. Update data source and data source provider configurations.
2. Update URLs and URL provider configurations.
3. Update mail session configurations.
4. Update JMS provider, connection factories, and destination configurations.
5. Update MQ JMS provider, MQ connection factories and MQ destination configurations.
6. Update Resource Environment Entry and Resource Environment Provider configurations.
7. (Optional) Remove application client resources.

Updating data source and data source provider configurations with the Application Client Resource Configuration Tool:

During this task, you update the configuration of an existing data source or data source provider. Perform this task when your database configuration changes.

1. Start the Application Client Resource Configuration Tool (ACRCT), and open the Enterprise Archive (EAR) file containing the data source or data source provider. The EAR file contents display in a tree view.
2. Select Java Archive (JAR) file from the navigation tree containing the data source or data source provider to update.
3. Expand the JAR file to view its contents until you locate the particular data source or data source provider to update. Take one of the following actions:
   - Right-click the data source object and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - Data source provider properties
   - Data source properties
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Updating URLs and URL provider configurations for application clients:

1. Start the tool and open the Enterprise Archive (EAR) file containing the URL or URL provider. The EAR file contents are displayed in a tree view.
2. Select from the tree the Java Archive (JAR) file containing the URL or URL provider to update.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular URL or URL provider to update. Take one of the following actions:
   a. Right-click the URL object and click **Properties**.
   b. Click **Edit** > **Properties** on the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File** > **Save** on the menu bar to save your changes.

Updating mail session configurations for application clients:

During this task, you update the configuration of an existing JavaMail session. You cannot update the name of the default JavaMail provider, and you cannot delete the default JavaMail provider from the navigation tree.

1. Start the tool and open the Enterprise Archive (EAR) file containing the JavaMail session. The EAR file contents are displayed in the navigation tree view.
2. Select the Java Archive (JAR) file containing the JavaMail session to update from the navigation tree.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular JavaMail session to update. Take one of the following actions:
   a. Right-click the object and click **Properties**
   b. Click **Edit** > **Properties** from the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Select **File** > **Save** from the menu bar to save your changes.

Updating Java Message Service provider, connection factories, and destination configurations for application clients:

During this task, you update the configuration of an existing Java Message Service (JMS) provider, connection factory or destination.

1. Start the tool and open the Enterprise Archive (EAR) file containing the Java Message Service (JMS) provider, connection factory, or destination. The EAR file contents display in a tree view.
2. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update from the navigation tree.
3. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination to update. When you find it, do one of the following actions:
   - Right-click the provider, and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - JMS provider properties
   - WebSphere Application Server Queue connection factory properties
   - WebSphere Application Server Topic connection factory properties
   - WebSphere Application Server Queue destination properties
   - WebSphere Application Server Topic destination properties
5. Click **OK**.
6. Click **File > Save** to save your changes.

Updating WebSphere MQ as a Java Message Service provider, and its JMS resource configurations, for application clients:

Use this task to update an existing configuration of WebSphere MQ as a Java Message Service (JMS) provider, and to update the configuration of WebSphere MQ connection factories or WebSphere MQ destinations.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the Enterprise Archive (EAR) file containing the WebSphere MQ JMS provider, WebSphere MQ connection factory, or WebSphere MQ destination. The EAR file contents are displayed in the navigation tree view.
3. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update.
4. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination that you want to update. Complete one of the following actions:
   - Right-click the appropriate object and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
5. Update the properties in the displayed fields. For detailed field help, see:
   - JMS provider properties
   - MQ Queue connection factory properties
   - MQ Topic connection factory properties
   - MQ Queue destination properties
   - MQ Topic destination properties
6. Click **OK**.
7. Click **File > Save** to save your changes.

Updating resource environment entry and resource environment provider configurations for application clients:

During this task, you update the configuration of an existing resource environment entry or resource environment provider.

1. Start the tool and open the Enterprise Archive (EAR) file containing the resource environment entry or resource environment provider. The EAR file contents display in a navigation tree view.

2. Select from the tree the Java Archive (JAR) file containing the resource environment entry or resource environment provider to update.
3. Expand the JAR file to view its contents until you locate the resource environment entry or resource environment provider to update. Take one of the following actions:
   - Right-click the resource environment object, and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - Resource environment provider properties
   - Resource environment entry properties
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Example: Configuring Resource Environment settings: The purpose of this topic is to help you configure Resource Environment settings.

- Required fields:
  - Resource Environment Provider page: **Name**
  - Resource Environment Entry page: **Name, JNDI Name**
- Example:

```
<resources.env:ResourceEnvironmentProvider xmi:id="ResourceEnvironmentProvider_1"
name="resourceEnvProvider:name" description="resourceEnvProvider:description">
<classpath>resourceEnvProvider:classpath</classpath>
<factories xmi:type="resources.env:ResourceEnvEntry" xmi:id="ResourceEnvEntry_1"
name="resourceEnvEntry:name" jndiName="resourceEnvEntry:jndiName"
description="resourceEnvEntry:description">
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_21">
<resourceProperties xmi:id="J2EEResourceProperty_23"
name="resourceEnvProvider:customName" value="resourceEnvProvider:customValue"/>
</propertySet>
</resources.env:ResourceEnvironmentProvider>
```

Example: Configuring resource environment custom settings for application clients: The purpose of this topic is to help you configure resource environment custom settings.

- The custom page applies to every resource type. You can specify as many custom names and values as you need.
- Example:

```
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
```

Removing application client resources:

The option to delete an item does not offer a confirmation dialog. As a safeguard, consider saving your work right before you begin this task. If you change your mind after removing an item, you can close the EAR file without saving your changes, canceling your deletion. Remember to close the EAR file immediately after the deletion, or you also lose any unsaved work that you performed since the deletion.

This task only applies to J2EE application clients.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the Enterprise Archive (EAR) file from which you want to remove an object. The EAR file contents display in the navigation tree view. If you already have an EAR file open and have made some changes, click **File** > **Save** to save your work before preceding to delete an object.

2. Locate the object that you want to remove in the tree.
3. Right-click the object, and click **Delete**.
4. Click **File** > **Save**.

Web services

Implementing Web services applications

This topic introduces you to using Web services that are based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification. WebSphere Application Server supports Web services that are developed and implemented based on Web Services for J2EE. Use Web services when operating across a variety of platforms, including the J2EE 1.4 and non-J2EE platforms.

Using Web services makes most sense if your application clients are non-J2EE applications, unless you have J2EE applications spread across the Web. It is recommended that you use J2EE technologies if all your clients are J2EE applications because performance can decrease when you use a Web service in a J2EE exclusive environment.

Decide if a Web service implementation benefits your business process.

Implementing Web services applications is an easy way to integrate application systems together within or outside your company's infrastructure that otherwise function as a standalone systems. For example, your customer information database is a standalone application, but you want your accounting application to be able to access the customer data. You can create a web service for the customer database and then enable the accounting application as Web service client. Now, the accounting application can access the customer information. By implementing a Web service, these two applications can share information in an efficient manner.

Because Web services are easily applied to existing applications and information technology assets, new solutions can be deployed quickly and recomposed to address new opportunities. As Web services become more popular, the pool of services grows, promoting development of more robust models of just-in-time application and business integration over the Internet.

Use Web services applications with WebSphere Application Server by following the steps provided:

1. Plan to use Web services. Review the Universal Description, Discovery, and Integration (UDDI) and Web services enablement of the service integration bus (SIBWS) concepts to learn how these components can make your Web services plan more robust.
2. (Optional) Migrate existing Web services. See ″Migrating Apache SOAP Web services to Web Services for J2EE standards″ in the information center.

   If you have used Web services based on Apache SOAP and now want to develop and implement Web services based on the Web Services for J2EE specification, you need to migrate client applications developed with all versions of 4.0, and versions of 5.0 prior to 5.0.2.
3. Develop Web services. See ″Developing Web services applications″.

   This topic is a good starting point in learning about how to develop a J2EE Web service.
4. Configure Web services deployment descriptors. See ″Configuring Web services deployment descriptors″ in the information center.

   You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming Web services requests.
5. Assemble Web services. See ″Assembling Web services applications″.

   This topic presents what you need to assemble a Web service and in what order you should assemble the parts, for example an enterprise archive (EAR) file.
6. Deploy Web services.

This topic presents the steps necessary to deploy the EAR file that has been configured and enabled for Web services.

7. Configure Web service client bindings. This topic explains how to edit bindings for a Web service after these bindings are deployed on a server. When one Web service communicates with another Web service, you must configure the client bindings to access the downstream Web service.
8. Publish the WSDL file.

   After installing a Web services application, and optionally modifying the endpoint information, you might need WSDL files containing the updated endpoint information. This topic presents the steps necessary to publish the WSDL files so that this information is available.
9. Develop Web services clients. See ″Developing Web services clients″.

   This topic explains how to develop a Web services client based on the Web Services for J2EE specification.
10. Secure Web services.

    This topic presents the methods used to integrate message-level security into a WebSphere Application Server environment. I If you are using V5.x, refer to ″Securing Web services for version 5.x applications based on WS-Security″in the information center. If you are using V6.x, refer to ″Securing Web services for version 6 applications based on WS-Security″
11. Tune Web services. See ″Monitoring the performance of Web services applications″ in the information center.

    This topic includes information to help you use the Performance Monitoring Infrastructure (PMI) to measure the time required to process Web services requests.
12. Troubleshoot Web services. See ″Troubleshooting Web services″.

    You can use this topic to learn more about troubleshooting different processes used to develop, implement and use Web services, including command-line tools, Java compiling errors, client runtime errors and exceptions, serialization and deserialization errors, and authentication challenges and authorization failures with Web services security.

The following example illustrates how a business might use Web services.

The owner of a flower shop wants to start receiving orders from customers through the Web. This owner starts the process by finding wholesale flower suppliers, pricing the product, and completing contracts for future flower orders.

Using Web services, the flower shop owner can find wholesale flower suppliers. One way to find new suppliers is to use a Universal Description, Discovery and Integration (UDDI) registry to search for potential suppliers. When the suppliers are chosen, the registry sends back information on how to contact the flower distributors that meet the flower shop owner's criteria.

The flower shop owner can request price lists from each of the suppliers by obtaining a Web Services Description Language (WSDL) file for each potential supplier. The WSDL can be downloaded from the supplier's Web page, received through e-mail, or retrieved from the supplier's UDDI registry entry.

The WSDL describes the procedure call. When using WebSphere Application Server, the procedure call is a Java API for XML-based remote procedure call (JAX-RPC), which retrieves price lists. The WSDL file also specifies the Universal Resource Locator (URL) where the request is sent.

The flower shop owner now has to compare the prices received back from each supplier, decide which suppliers to do business with, and make arrangements for future orders to fill. The flower shop can now sell merchandise through the Web by using Web services to communicate with suppliers for the best prices and complete the ordering processes. The merchandise price lists need publishing to the Web site and a mechanism is needed for customers to order flowers.

The Web services clients of the flower supplier are deployed on the flower shop server. When a customer makes a transaction to purchase flowers through the Web, the order is sent to the supplier through JAX-RPC. The supplier responds by sending a confirmation with the order number and shipping date. The suppliers maintain the inventory and the flower shop owner handles billing and customer order management.

Similarly, the flower shop catalog can be composed automatically from the catalogs of all the suppliers. If the supplier ships directly to the customer, the order tracking inquiries can pass directly to the supplier's order tracking system. The supplier can also use Web services to send invoices for orders and by the flower shop to pay the supplier's invoices. Processes that previously required forms to fill manually, and fax or mail, can now be done automatically, saving labor costs for both the flower shop and the supplier.

Using Web services is beneficial because a much larger inventory is made available to the flower shop. No merchandise maintenance overhead exists, but the flower shop can offer their customers products that they otherwise might not have. Selling flowers through the Web increases capital for the flower shop without overhead of another store or money invested into additional product.

For a more detailed scenario, see ″Overview: Online garden retailer Web services scenarios″ which tells the story of a fictional online garden supply retailer named Plants by WebSphere and how they incorporated the Web services concept.

Web services

Web services are self-contained, modular applications that you can describe, publish, locate, and invoke over a network.

WebSphere Application Server supports Web services that are developed and implemented based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification.

A typical Web services scenario is a business application requesting a service from another existing application. The request is processed through a given Web address using SOAP messages over a HTTP, Java Message Service (JMS) transport or invoked directly as Enterprise JavaBeans (EJB). The service receives the request, processes it, and returns a response. Examples of a simple Web service include weather reports or getting stock quotes. The method call is synchronous, that is, it waits until the result is available. Transaction Web services, supporting quotes, business-to-business (B2B) or business-to-client (B2C) operations include airline reservations and purchase orders.

Web services can include the actual service or the client that accesses the service.

Web services are Web applications that help you be more flexible in your business processes by integrating with applications that otherwise do not communicate. The inner-library loan program at your local library is a good example of the Web services concept and its evolution. The Web service concept existed even before the term; the concept became widely accepted with the creation of the Internet. Before the Internet was created, you visited your library, searched the collections and checked out your books. If you did not find the book that you wanted, the librarian did a search for you by computer or phone and located the book at a nearby library. The librarian ordered the book for you and you picked it up after it was delivered to your local library. By incorporating Web services applications, you can streamline your library visit.

Now, you can search the local library collection and other local libraries at the same time. When other libraries provide your library with a Web service to search their collection (the service might have been provided through UDDI), your results yield their resources. Another Web service application might enable you to check the book out and get it sent to your home. Using Web services applications saves time and provides a convenience for you, as well as freeing the librarian to do other business tasks.

Web services reflect the service-oriented architecture (SOA) approach to programming. This approach is based on the idea of building applications by discovering and implementing network-available services, or

by invoking the available applications to accomplish a task. Web services deliver interoperability, for example, Web services applications provide components created in different programming languages to work together as if they were created using the same language. Web services rely on existing transport technologies, such as HTTP, and standard data encoding techniques, such as Extensible Markup Language (XML), for invoking the implementation.

The key components of Web services include:

- Web Services Description Language (WSDL)

  WSDL is the XML-based file that describes the Web service. The Web service request uses this file to bind to the service.
- SOAP

  SOAP is the XML-based protocol that the Web service request uses to invoke the service.
- Universal Description, Discovery and Integration Protocol (UDDI)

  UDDI is the registry that hosts the service broker. UDDI is similar to the Yellow Pages in a phone book.

For a more detailed scenario, see ″Web services scenario: Overview″ in the information center, which tells the story of a fictional online garden supply retailer named Plants by WebSphere, and how this retailer incorporated the Web services concept.

Web Services for J2EE specification

The *Web services for Java 2 Platform, Enterprise Edition (J2EE)* specification defines the programming model and run-time architecture for implementing Web services based on the Java language. Another name for the Web Services for J2EE specification is the Java Specification Requirements (JSR) 109. The specification includes open standards for developing and implementing Web services.

Version 6.0 uses Web Services for J2EE 1.1 as the standard for developing and implementing Web services. Web Services for J2EE 1.1 is one of the Web service APIs available in J2EE 1.4.

The Web Services for J2EE specification focuses on Extensible Markup Language (XML) remote procedure call (RPC) and the Java language, including representing XML-based interface definitions in the Java language; Java language definitions in XML-based definition languages, such as SOAP, and assembling.

The J2EE technology can be integrated with Web services in a variety of ways. J2EE components, for example, JavaBeans and enterprise beans, can be exposed as Web services. These services can be accessed by clients written in Java code or by existing Web service clients that are not written in Java code. J2EE components can also act as Web service clients.

The Web Services for J2EE specification is the preferred platform for Web-based programming because it provides open standards allowing different types of languages, operating systems and software to communicate seamlessly through the Internet.

For a Java application to act as Web service client, a mapping between the Web Services Description Language (WSDL) file and the Java application must exist. The mapping is defined by the Java API for XML-based RPC (JAX-RPC) specification.

You can use a Java component to implement a Web service by specifying the component interface and binding information in the WSDL file and designing the application server infrastructure to accept the service request.

This entire process encompassed is based on the Web Services for J2EE specification.

The specification brings with it the `webservices.xml` deployment descriptor specifically for Web services. You are responsible for providing various elements to the deployment descriptor, including:

- Port name

- Port service implementation
- Port service endpoint interface
- Port WSDL definition
- Port QName
- JAX-RPC mapping
- Handlers (optional)
- Servlet mapping (optional)

The Enterprise JavaBeans (EJB) 2.1 specification also states that for a Web service developed from a session bean, the EJB deployment descriptor, `ejb-jar.xml`, must contain the service-endpoint element. The service-endpoint value must be the same as that stated in the webservices.xml deployment descriptor. To learn more about the EJB 2.1 specification see Enterprise beans: Resources for learning.

To review the entire Web Services for J2EE specification, see Web services: Resources for learning.

JAX-RPC

The *Java API for XML-based RPC (JAX-RPC)* specification enables you to develop SOAP-based interoperable and portable Web services and Web service clients. JAX-RPC 1.1 provides core APIs for developing and deploying Web services on a Java platform and is a required part of the J2EE 1.4 platform. The J2EE 1.4 platform allows you to develop portable Web services. Web services can also be developed and deployed on J2EE 1.3 containers.

WebSphere Application Server implements JAX-RPC 1.1 standards.

The JAX-RPC standard covers the programming model and bindings for using Web Services Description Language (WSDL) for Web services in the Java language. JAX-RPC simplifies development of Web services by shielding you from the underlying complexity of SOAP communication.

On the surface, JAX-RPC looks like another instantiation of remote method invocation (RMI). Essentially, JAX-RPC allows clients to access a Web service as if the Web service was a local object mapped into the client's address space even though the Web service provider is located in another part of the world. The JAX-RPC is done by using the XML-based protocol SOAP, which typically rides on top of HTTP.

JAX-RPC defines the mappings between the WSDL port types and the Java interfaces, as well as between Java language and Extensible Markup Language (XML) schema types.

A JAX-RPC Web service can be created from a JavaBean or a enterprise bean implementation. You can specify the remote procedures by defining remote methods in a Java interface. You only need to code one or more classes that implement the methods. The remaining classes and other artifacts are generated by the Web service vendor's tools. The following is an example of a Web service interface:

```
package com.ibm.mybank.ejb;
import java.rmi.RemoteException;
import com.ibm.mybank.exception.InsufficientFundsException;
/**
 * Remote interface for Enterprise Bean: Transfer
 */
public interface Transfer_SEI extends java.rmi.Remote {
   public void transferFunds(int fromAcctId, int toAcctId, float amount)
      throws java.rmi.RemoteException;

}
```

The interface definition in JAX-RPC must follow specific rules; most of these rules are from RMI with some additions for JAX-RPC. The following are the rules for defining a JAX-RPC interface:

- The interface must extend `java.rmi.Remote` just like RMI.
- Methods must throw `java.rmi.RemoteException`.

- Method parameters cannot be remote references.
- Method parameter must be one of the parameters supported by the JAX-RPC specification. The following list are examples of method parameters that are supported. For a complete list of method parameters see the JAX-RPC specification.
  - Primitive types: `boolean`, `byte`, `double`, `float`, `short`, `int` and `long`
  - Object wrappers of primitive types: `java.lang.Boolean`, `java.lang.Byte`, `java.lang.Double`, `java.lang.Float`, `java.lang.Integer`, `java.lang.Long`, `java.lang.Short`
  - `java.lang.String`
  - `java.lang.BigDecimal`
  - `java.lang.BigInteger`
  - `java.lang.Calendar`
  - `java.lang.Date`
- Methods can take value objects which consist of a composite of the types previously listed, in addition to aggregate value objects.

A client creates a stub and invokes methods on it. The stub acts like a proxy for the Web service. From the client code perspective, it seems like a local method invocation. However, each method invocation gets marshaled to the remote server. Marshaling includes encoding the method invocation in XML as prescribed by the SOAP protocol.

The following are key classes and interfaces needed to write Web services and Web service clients:

- **Service interface**: A factory for stubs or dynamic invocation and proxy objects used to invoke methods
- **ServiceFactory class**: A factory for Services.
- **`loadService`**

  The `loadService` method is provided in WebSphere Application Server Version 6.0 to generate the service locator which is required by a JAX-RPC implementation. If you recall, in previous versions there was no specific way to acquire a generated service locator. For managed clients you used a JNDI method to get the service locator and for non-managed clients, you were required to instantiate IBM's specific service locator `ServiceLocator service=new ServiceLocator(...);` which does not offer portability. The `loadService` parameters include:
  - **`wsdlDocumentLocation:`** A URL for the WSDL document location for the service or null.
  - **`serviceName`**: A qualified name for the service
  - **`properties`**: A set of implementation-specific properties to help locate the generated service implementation class.
- **`isUserInRole`**

  The `isUserInRole` method returns a boolean indicating whether the authenticated user for the current method invocation on the endpoint instance is included in the specified logical role.
  - **`role`**: The role parameter is a String specifying the name of the role.
- **Service**
- **Call interface**: Used for dynamic invocation
- **Stub interface**: Base interface for stubs

If you are using a stub to access the Web service provider, most of the JAX-RPC API details are hidden from you. The client creates a ServiceFactory (`java.xml.rpc.ServiceFactory`). The client instantiates a Service (`java.xml.rpc.Service`) from the ServiceFactory. The service is a factory object that creates the port. The port is the remote service endpoint interface to the Web service. In the case of DII, the Service object is used to create Call objects, which you can configure to call methods on the Web service's port.

To learn more about JAX-RPC see Web services: Resources for learning.

SOAP

Simple Object Access Protocol (SOAP) is a specification for the exchange of structured information in a decentralized, distributed environment. As such, it represents the main way of communication between the three key actors in a service oriented architecture (SOA): service provider, service requestor and service broker. The main goal of its design is to be simple and extensible. A SOAP message is used to request a Web service.

WebSphere Application Server follows the standards outlined in SOAP 1.1.

SOAP was submitted to the World Wide Web Consortium (W3C) as the basis of the Extensible Markup Language (XML) Protocol Working Group by several companies, including IBM and Lotus. This protocol consists of three parts:

- An *envelope* that defines a framework for describing message content and processing instructions.
- A set of *encoding rules* for expressing instances of application-defined data types.
- A *convention* for representing remote procedure calls and responses.

SOAP is a protocol-independent transport and can be used in combination with a variety of protocols. In Web services that are developed and implemented with WebSphere Application Server, SOAP is used in combination with HTTP, HTTP extension framework, and Java Message Service (JMS). SOAP is also operating-system independent and not tied to any programming language or component technology.

As long as the client can issue XML messages, it does not matter what technology is used to implement the client. Similarly, the service can be implemented in any language, as long as the service can process SOAP messages. Also, both server and client sides can reside on any suitable platform.

For more information about SOAP, see Web services: Resources for learning.

SOAP with Attachments API for Java

SOAP with Attachments API for Java (SAAJ) is used for SOAP messaging that works behind the scenes in the Java API for XML-based RPC (JAX-RPC) implementation.

Web services uses SOAP messages to represent remote procedure calls between the client and the server. In normal JAX-RPC flows, the SOAP message is deserialized into a series of Java value type business objects that represent the parameters and return values. In addition, JAX-RPC provides APIs that support applications and handlers to manipulate the SOAP message directly. The SOAP message is manipulated using the SAAJ data model. The primary interface in the SAAJ model is javax.xml.soap.SOAPElement.

WebSphere Application Server uses SAAJ Version 1.2. The main benefit of SAAJ Version 1.2 is that the model extends the Document Object Model (DOM) model. The DOM model is used by applications that manipulate XML. Using this model applications are able to process an SAAJ model that uses pre-existing DOM code. It is also easier to convert pre-existing DOM objects to SAAJ objects.

Messages created using SAAJ follow SOAP standards. A SOAP message is represented in the SAAJ model as a javax.xml.soap.SOAPMessage object. The XML content of the message is represented by a javax.xml.soap.SOAPPart object. Each SOAP part has a SOAP envelope. This envelope is represented by the SAAJ javax.xml.SOAPEnvelope object. The SOAP specification defines various elements that reside in the SOAP envelope; SAAJ defines objects for the various elements in the SOAP envelope.

The SOAP message can also contain non-XML data that is called attachments. These attachments are represented by SAAJ AttachmentPart objects that are accessible from the SOAPMessage object.

A number of reasons exist as to why handlers and applications use the generic SOAPElement API instead of a tightly bound mapping:

- The Web service might be a conduit to another Web service. In this case, the SOAP message is only forwarded.
- The Web service might manipulate the message using a different data model, for example a Service Data Object (SDO). It is easier to convert the message from a SAAJ Document Object Model (DOM) to a different data model.
- A handler, for example, a digital signature validation handler, might want to manipulate the message generically.

To review the entire SAAJ API, see Web services: Resources for learning.

Web Services-Interoperability Basic Profile

The *Web Services-Interoperability (WS-I) Basic Profile* is a set of non-proprietary Web services specifications that promote interoperability.

WebSphere Application Server conforms to the WS-I Basic Profile 1.1.

The WS-I Basic Profile is governed by a consortium of industry-leading corporations, including IBM, under direction of the WS-I Organization. The profile consists of a set of principles that relate to bringing about open standards for Web services technology. All organizations that are interested in promoting interoperability among Web services are encouraged to become members of the Web Services Interoperability Organization.

Several technology components are used in the composition and implementation of Web services, including messaging, description, discovery, and security. Each of these components are supported by specifications and standards, including SOAP 1.1, Extensible Markup Language (XML) 1.0, HTTP 1.1, Web Services Description Language (WSDL) 1.1, and Universal Description, Discovery and Integration (UDDI). The WS-I Basic Profile specifies how these technology components are used together to achieve interoperability, and mandates specific use of each of the technologies when appropriate. You can read more about the WS-I Basic Profile at the WS-I Organization Web site. A link to this Web site is listed in Web services: Resources for learning.

Each of the technology components have requirements that you can read about in more detail at the WS-I Organization Web site. For example, support for Universal Transformation Format (UTF)-16 encoding is required by WS-I Basic Profile. UTF-16 is a kind of Unicode encoding scheme using 16-bit values to store Universal Character Set (UCS) characters. UTF-8 is the most common encoding that is used on the Internet; UTF-16 encoding is typically used for Java and Windows product applications; and UTF-32 is used by various Linux and Unix systems. Unlike UTF-8, UTF-16 has issues with big-endian and little-endian, and often involves Byte Order Mark (BOM) to indicate the endian. BOM is mandatory for UTF-16 encoding and it can be used in UTF-8.

See ″How to change encoding from UTF-8 to UTF-16″ in the information center if you need to change from UTF-8 to UTF-16.

The following table summarizes some of the properties of each UTF:

Bytes	Encoding form
EF BB BF	UTF-8
FF FE	UTF-16, little-endian
FE FF	UTF-16, big-endian
00 00 FE FF	UTF-32, big-endian
FF FE 00 00	UTF-32, little-endian

BOM is written prior to the XML text, and it indicates to the parser how the XML is encoded. The XML declaration contains the encoding, for example: <?xml version=*xxx* encoding="utf-*xxx*"?>. BOM is used with the encoding to determine how to interpret the XML. Here is an example of a SOAP message and how BOM and UTF encoding are used:

```
POST http://www.whitemesa.net/soap12/add-test-rpc HTTP/1.1
Content-Type: application/soap+xml; charset=utf-16; action=""
SOAPAction:
Host: localhost: 8080
Content-Length: 562

0xFF0xFE<?xml version="1.0" encoding="utf-16"?>
<soap:Envelope xmlns:soap="http://www.w3.org/2002/12/soap-envelope"
 xmlns:soapenc="http://www.w3.org/2002/12/soap-encoding
 xmlns:tns="http://whitemesa.net/wsdl/soap12-test"
 xmlns:types="http://whitemesa.net/wsdl/soap12-test/encodedTypes"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <soap:Body>
  <q1:echoString xmlns:q1="http://soapinterop.org/">
   <inputString soap:encodingStyle="http://example.org/unknownEncoding"
   xsi:type="xsd:string">
    Hello SOAP 1.2
   </inputString>
  </q1:echoString>
 </soap:Body>
</soap:Envelope>
```

In the example code, 0xFF0xFE represents the byte codes, while the *<?xml>* declaration is the textual representation.

To learn more about the WS-Basic profile, including scenarios, UTF and BOM, see Web services: Resources for learning.

RMI-IIOP using JAX-RPC

Java API for XML-based Remote Procedure Call (JAX-RPC) is the Java standard API for invoking Web services through remote procedure calls. A transport is used by a programming language to communicate over the Internet. You can use protocols with the transport such as SOAP and Remote Method Invocation (RMI). You can use Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) with JAX-RPC to support non-SOAP bindings.

Using RMI-IIOP with JAX-RPC, enables WebSphere Java clients to invoke enterprise beans using a WSDL file and the JAX-RPC programming model instead of using the standard J2EE programming model. When a enterprise JavaBeans implementation is used to invoke a Web service, multiprotocol JAX-RPC permits the Web service invocation path to be optimized for WebSphere Java clients. Learn more about this by reviewing ″Using enterprise bean bindings to invoke an EJB from a Web services client″.

Benefits of using the RMI/IIOP protocol instead of a SOAP- based protocol are:

- XML processing is not required to send and receive messages; Java serialization is used instead.
- The client JAX-RPC call can participate in a user transaction, which is not the case when SOAP is used.

WS-I Attachments Profile

The *Web Services-Interoperability (WS-I) Attachments Profile* is a set of non-proprietary Web services specifications that promote interoperability. This profile compliments the WS-I Basic Profile 1.1 to add support for interoperable SOAP messages with attachments-based Web services.

WebSphere Application Server conforms to the WS-I Attachments Profile 1.0.

Attachments are typically used to send binary data, for example, data that is mapped in Java code to java.awt.Image and javax.activation.DataHandler. The raw data can be sent in the SOAP message, however, this approach is inefficient because an XML parser has to scan the data as it parses the message.

The WS-I Attachments Profile provides a solution to the limitations that are presented by Web Services Description Language (WSDL) 1.1. Because WSDL 1.1 attachments are not part of the XML schema type space, they can be message parts only. As message parts, the attachments cannot be arrays or properties of Java beans. The profile defines the wsi:swaRef XML schema type.Use the wsi:swaRef XML schema type to overcome the limitations of WSDL 1.1 attachments.

The wsi:swaRef type is an extension of the xsd:anyURI type, where its value contains the content-ID of the attachment.

Web services migration best practices

This topic presents best practices when migrating Web services applications.

Migrating a Version 5 JAX-RPC client that uses SOAP over JMS to invoke a Web service

A Java API for XML-based remote procedure call (JAX-RPC) client running on WebSphere Application Server Version 5, can use SOAP over Java Messaging Service to invoke a Web service that is running on a Version 5 application server.

A user ID and password are not required on the target MQ Series queue. After the application server is migrated to Version 6, and uses the Version 6 default messaging feature, client requests can fail because basic authentication is enabled. The following error message displays when this migration problem occurs:

```
SibMessage W [:] CWSIT0009W: A client request failed in the application server with endpoint <endpoint name>
in bus <bus_name> with reason: CWSIT0016E: The user ID null failed authentication in bus <bus_name>.
```

When the application server is migrated to Version 6, and the default messaging provider (service integration technologies) is used, and global security is enabled for the server or the cell, the service integration bus queue destination inherits the security characteristics of the server or the cell by default. If the server or the cell has basic authentication enabled, the client request fails.

The following options are available to solve this problem. The solutions are listed by the level of security that they impose:

- Disable global security on the Global security panel within the administrative console. To disable global security, click **Security > Global security**. Deselect the **Enable global security** option.
- Modify the settings for the service integration bus that hosts the queue destination so that the bus security is disabled and the bus does not inherit security characteristics from the server or the cell. This option is equivalent to the level of security that you can configure in Version 5.
- Configure the basic authentication on each client that uses the service. See ″Configuring HTTP basic authentication with the administrative console″ in the information center.

Migrating Apache SOAP Web services

See ″Migrating Apache SOAP Web services to Web Services for J2EE standards″ in the information center to learn how to migrate Apache SOAP Web services. This topic explains how to migrate Web services that were developed using Apache SOAP to Web services that are developed based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification.

Migrating Web services assembled with early versions of the Application Server Toolkit or Assembly Toolkit

If you are migrating your Web service or Web service components from earlier versions of the Application Server Toolkit or Assembly Toolkit, refer to the following hints and tips to improve your success:

- Secure Web services are not migrated by the J2EE Migration Wizard when Web services are migrated from J2EE 1.3 to J2EE 1.4.
- The migration of secure Web services requires manual steps.
- After the J2EE migration, the secure binding and extension files must be migrated manually to J2EE 1.4 as follows:
  1. Double click on the `webservices.xml` file to open the Web Services editor.
  2. Select the **Binding Configurations** tab to edit the binding file.
  3. Add all the necessary binding configurations under the new sections **Request Consumer Binding Configuration Details** and **Response Generator Binding Configuration Details**.
  4. Select the **Extension** tab to edit the extension file.
  5. Add all the necessary extension configurations under the new sections **Request Consumer Service Configuration Details** and **Response Generator Service Configuration Details**.
  6. Save and exit the editor.

.

Web services: Resources for learning

This topic provides relevant supplemental information about the following Web services-related topics:

- Web services overview
- Developing Web services:

  Includes developing Web services based on the Java 2 Platform, Enterprise Edition (J2EE) and Java API for XML-based remote procedure call (JAX-RPC) specifications.
- Performance

  Includes key Web sites that discuss performance best practices.
- Universal Description Discovery and Integration (UDDI)

  Includes an overview about UDDI and information about the UDDI Java API.
- The Web Services Invocation Framework (WSIF)

  Includes a look into the Apache Software Foundation and its maintenance of WSIF.
- Web Services-Interoperability (WS-I) Basic Profile

  Includes an overview about the WS-I Basic Profile.
- SOAP

  Includes an overview about SOAP, information about the SOAP syntax and processing rules.
- Security

  Includes a roadmap to security, the WS-Security specification, best practices, a profile of the OASIS Security Assertion Markup Language (SAML) and more.
- Samples

  Includes the Samples Gallery for WebSphere Application Server and Samples Central for UDDI and WSIF.

The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to an IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Web services overview

- WebSphere Version 5.1.1 Web Services Handbook

  This IBM Redbook describes the new concept of Web services from various perspectives. It presents the major building blocks on which Web services rely. Well-defined standards and new concepts are presented and discussed.
- Web services (r)evolution, Part 1

  This article focuses on the benefits and challenges of building Web services applications. Web services might be an evolutionary step in designing distributed applications, however, the technology is not without problems. Outlined are the difficulties developers face in creating a truly workable distributed system of Web services. This article also outlines author Graham Glass's plan for building peer-to-peer Web applications.

Developing Web services

- Java Web Services: SOAP with Attachments API for Java (SAAJ)

  This document describes the SOAP with Attachments API for Java (SAAJ) and how this API provides a standard way to send XML documents over the Internet from the Java platform.
- JSR 109: Implementing Enterprise Web services

  This document describes the Java 2 Platform, Enterprise Edition (J2EE) specification.
- JAX-RPC: Core Web services API in the Java platform

  This document reviews the JAX-RPC specification which enables Java technology developers to develop SOAP-based interoperable and portable Web services.
- A developer introduction to the JAX-RPC specification, Part 1: Learn the ins and outs of the JAX-RPC type-mapping system. The JAX-RPC specification is an important step forward in the quest for Web services interoperability. This DeveloperWorks WebSphere article explains the mapping between WSDL and XML types and Java types. It explains how the JAX-RPC standard defines this feature and some of the important points on designing an interoperable type system.
- A developer introduction to JAX-RPC, Part 2: Mine the JAX-RPC specification to improve Web service interoperability. This DeveloperWorks WebSphere article explains how you can achieve the next level of Web service interoperability using the JAX-RPC standard client and server side interface definitions and message processing model. It includes information on developing JAX-RPC handlers and handler chains.
- Getting Started with JAX-RPC. This article explains some of the basic JAX-RPC programming concepts. It describes the JAX-RPC client and server programming models and provides some simple examples for illustration. The article is intended to give developers a good grasp of how to use the JAX-RPC specification to develop or use Web services.
- Web Services Description Language

  This article is a detailed overview of Web Services Description Language (WSDL), which includes programming specifications.

Performance

The following Web sites offer tips and best practices to get the best performance from your Web services applications:

- Best practices for Web services: Part 1, Back to the basics
- SOA and Web services: Articles
- IBM WebSphere Developer Technical Journal: Web Services Architectures and Best Practices
- Web services programming tips and tricks: How to create a simple JAX-RPC handler
- Web services programming tips and tricks: Using SOAP headers with JAX-RPC
- Web services programming tips and tricks: Extend JAX-RPC Web services using SOAP headers
- Web services programming tips and tricks: Roundtrip issues in Java coding conventions

UDDI

- Universal Description, Discovery and Integration

  This article is a detailed overview of Universal Description, Discovery, and Integration (UDDI).
- A new approach to UDDI and WSDL: Introduction to the new OASIS UDDI WSDL Technical Note

  This article is about using WSDL with UDDI. Although it is based on the UDDI Registry in WebSphere Application Server Version 5, it remains a useful description of the recommended approach for use of WSDL with UDDI.
- UDDI Version 3 Features List

  This article is an introduction to the new features in UDDI Version 3.

WSIF

- The Apache Software Foundation. The Apache Software Foundation provides support for the Apache community of open-source software projects. Of particular interest is the Apache Web services project. The WSIF source code is donated by IBM to the Apache Software Foundation, and is maintained here as an Apache project.

WS-I Basic Profile

- Web Services Interoperability Organization This Web site offers resources and guidelines for Web services interoperability. You can also view the latest specification documents for WS-I Basic Profile from the documentation link on the home page.
- UTF and BOM Frequently Asked Questions. This Web site offers general information about UTF-8, UTF-16, UTF-32, along with Byte Order Mark (BOM) in a question and answer format.

SOAP

- SOAP

  This article is a detailed overview of SOAP, which includes programming specifications.
- SOAP Security Extensions: Digital Signature

  This document specifies the syntax and processing rules of a SOAP header entry to carry digital signature information within a SOAP 1.1 Envelope

Security

- Security in a Web Services World: A Proposed Architecture and Roadmap

  This document describes a proposed model for addressing security within a Web service environment. It defines a comprehensive Web Services Security model that supports, integrates, and unifies several popular security models, mechanisms, and technologies, including both symmetric and public key technologies. Enable a variety of systems to securely interoperate in a platform and language-neutral manner. It also describes a set of specifications and scenarios that show how these specifications can be used together.
- Web Services Security (WS-Security)

  The Web Services security specifications describe enhancements to SOAP messaging to provide the quality of protection through message integrity, message confidentiality, and single message authentication. Use these mechanisms to accommodate a wide variety of security models and encryption technologies. Web Services security also provides a general-purpose mechanism for associating security tokens with messages. Additionally, Web Services Security describes how to encode binary security tokens. Specifically, the specification describes how to encode X.509 certificates and Kerberos tickets, as well as how to include opaque encrypted keys. It also includes extensibility mechanisms that can be used to further describe the characteristics of the credentials that are included with a message.
- SOAP Security Extensions: Digital Signature

  This document specifies the syntax and processing rules of a SOAP header entry to carry digital signature information within a SOAP 1.1 envelope
- Web Services Security Addendum

This document describes clarifications, enhancements, best practices, and errata of the Web Services Security specification.

- WS-Security Profile of the OASIS Security Assertion Markup Language (SAML) Working Draft 04, 10 September 2002

  This document proposes a set of standards for SOAP extensions used to increase message confidentiality.
- Web Services Security: SOAP Message Security Working Draft 12, Monday 21 April 2003

  This document describes the support for multiple token formats, trust domains, signature formats, and encyrption technologies.
- JSR 55:Certification Path API

  This document provides a short description of the certification path API.
- XML-Signature Syntax and Processing

  This document specifies XML digital signature processing rules and syntax. XML signatures provide integrity, message authentication, or signer authentication services for data of any type, whether located within the XML that includes the signature or elsewhere.
- Canonical XML Version 1.0

  This specification describes a method for generating a physical representation, the canonical form, of an XML document that accounts for the permissible changes.
- Exclusive XML Canonicalization Version 1.0

  Canonical XML [XML-C14N] specifies a standard serialization of XML that, when applied to a subdocument, includes the subdocument ancestor context including all of the namespace declarations and attributes in the ″xml:″namespace.
- XML Encryption Syntax and Processing

  This document specifies a process for encrypting data and representing the result in XML.
- Decryption Transform for XML Signature

  This document specifies an XML Signature decryption transform that enables XML Signature applications to distinguish between those XML encryption structures that are encrypted before signing, and must not be decrypted, and those that are encrypted after signing, and must be decrypted, for the signature to validate.
- WS-Security

  This document specifies resources for the April 2002 Web Services Security Specification. The following addenda and drafts are available:
  - http://schemas.xmlsoap.org/ws/2002/07/secext/
  - http://schemas.xmlsoap.org/ws/2002/07/utility/
  - OASIS draft 12 for secext
  - OASIS draft 12 for utility
- Specification: Web Services Security (WS-Security) Version 1.0 05 April 2002
- XML Encryption Syntax and Processing W3C Recommendation 10 December 2002
- XML-Signature Syntax and Processing W3C Recommendation 12 February 2002
- Web Services Security Addendum
- Web Services Security Core Specification Working Draft 01, 20 September 2002
- Web Services Security: SOAP Message Security Working Draft 13, Thursday, 01 May 2003

- OASIS Web Services Security Technical Committee

Samples

- Samples Gallery
- Samples Central. Samples and associated documentation for the following Web services components are available through the Samples Central page of the DeveloperWorks WebSphere Web site:
  - The IBM WebSphere UDDI Registry.
  - The Web Services Invocation Framework (WSIF).

Deploying Web services

This task explains how to deploy a Web service into WebSphere Application Server.

To deploy Web services that are based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification, you need an enterprise application, also known as an enterprise archive (EAR) file that is configured and enabled for Web services.

If you have a Web service that was deployed on a previous version of WebSphere Application Server, you might want to run the **wsdeploy** command so that you can benefit from performance features that have been added to this release.

This task is one of the steps in developing and implementing Web services.

You can use either the administrative console or the **wsadmin** scripting tool to deploy an EAR file. If you are installing an application containing Web services by using the **wsadmin** command, specify the -deployws option. If you are installing an application containing Web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. For more information about installing applications using the administrative console see Installing a new application.

If the Web services application is previously deployed with the **wsdeploy** command, it is not necessary to specify Web services deployment during installation.

The following actions deploy the EAR file with the **wsadmin** command:

1. Start *install_root*\bin\wsadmin from a command prompt. If you are using Linux or Unix platforms, start *install_root*/bin/wsadmin.sh.
2. Enter the **$AdminApp install *EARfile* "-usedefaultbindings -deployws"** command at the **wsadmin** prompt.

You have a Web service installed into the Application Server.

You can confirm that the Web services application was deployed by entering the Web service endpoint URL in a browser, then viewing an informative page. The information page contains the following information:

```
{http://webservice.pli.tc.wssvt.ibm.com}RetireWebServices
Hi there, this is a Web service!
```

The first line of this information is variable, depending on your Web service. The URI in the brackets is the namespace and the string following that (in this example, RetireWebServices), is the name of the port used to access the Web service.

The next step you might want to consider is to apply security to the applications. See "Securing Web services for version 5.x applications based on WS-Security" in the information center.

wsdeploy command

The Client Development Kit (CDK) for z/OS contains the wsdeploy command-line tool needed for deploying Web services. See Installing the Client Development Kit to start using the tool.

This topic explains how to use the **wsdeploy** command-line tool with Web services that are based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification. The **wsdeploy** command adds WebSphere product-specific deployment classes to a Web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file. These classes include:

- Stubs
- Serializers and deserializers
- Implementations of service interfaces

This deployment step must be performed at least once, and can be performed more often. Deployment can be performed separately using the **wsdeploy** command, assembly tools, or when the application is installed. When using the **wsadmin** command for installation, specify the **-deployws** option.

The **wsdeploy** command operates as noted in the following list:
- Each module in the enterprise application or JAR file is examined
- If the module contains Web services implementations, indicated by the presence of the `webservices.xml` deployment descriptor, the associated Web Services Description Language (WSDL) files are located and the **WSDL2Java** command is run with the role deploy-server option.
- If the module contains Web services clients, indicated by the presence of the client deployment descriptor, the associated WSDL files are located and the **WSDL2Java** command is run with the role deploy-client option.
- The files generated by the **WSDL2Java** command are compiled and repackaged.

See ″**WSDL2Java** command″ in the information center for more information about the files that are generated for deployment.

When the generated files are compiled, they can reference application-specific classes outside the EAR or JAR file, if the EAR or JAR file is not self-contained. In this case, use either the -jardir or -cp option to specify additional JAR or zip files to be added to CLASSPATH variable when the generated files are compiled.

wsdeploy command syntax

The command syntax is noted in the following example:

`wsdeploy` *`Input_filename Output_filename`* `[options]`

Required options:
- ***Input_filename***

  Specifies the path to the EAR or JAR file to deploy.
- ***Output_filename***

  Specifies the path of the deployed EAR or JAR file. If *output_filename* already exists, it is silently overwritten. The *output_filename* can be the same as the*input_filename*.

Other options:
- **-jardir** *directory*

  Specifies a directory that contains JAR or zip files. All JAR and zip files in this directory are added to the CLASSPATH used to compile the generated files. This option can be specified zero or more times.
- **-cp** *entries*

  Specifies entries to add to the CLASSPATH when the generated classes are compiled. Multiple entries are separated the same as they are in the CLASSPATH environment variable, with a semicolon on Windows platforms and a colon for Linux and Unix platforms.
- **-codegen**

  Specifies to generate but not compile deployment code. This option implicitly specifies the -keep option.
- **-debug**

  Includes debugging information when compiling, that is, use javac -g to compile.
- **-help**

  Displays a help message and exit.
- **-ignoreerrors**

  Do not stop deployment if validation or compilation errors are encountered.
- **-keep**

  Do not delete working directories containing generated classes. A message is displayed indicating the name of the working directory that is retained.
- **-novalidate**

Do not validate the Web services deployment descriptors in the input file.

- **-trace**

  Displays processing information, including the names of the generated files.

Example The following example illustrates how the options are used with the **wsdeploy** command:

```
wsdeploy x.ear x_deployed.ear -trace -keep
Processing web service module x_client.jar.
Keeping directory: f:\temp\Base53383.tmp for module: x_client.jar.
Parsing XML file:f:\temp\Base53383.tmp\WarDeploy.wsdl
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java.
Done processing module x_client.jar.
```

Messages

- Flag *-f*is not valid.

  Option *f* was not recognized as a valid option.
- Flag *-c* is ambiguous.

  Options can be abbreviated, but the abbreviation must be unique. In this case, the **wsdeploy** command cannot determine which option was intended.
- Flag *-c* is missing parameter *-p*.

  A required parameter for an option is omitted.
- Missing *p* parameter.

  A required option is omitted.

Configuring Web service client bindings

When a Web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the Web module or enterprise JavaBean (EJB) module, including client bindings.

Deploy the Web service into WebSphere Application Server.

To complete this task, you need to know the topology of the URL endpoint address of the Web services servers and which Web service the client depends upon. You can view the deployment descriptors in the administrative console to find topology information. See the article ″View Web services server deployment descriptors″ for more information.

The client bindings define the Web Services Description Language (WSDL) file name and preferred ports. The relative path of a Web service in a module is specified within a compatible WSDL file that contains the actual URL to be used for requests. The address is only needed if the original WSDL file did not contain a URL, or when a different address is needed. For a service endpoint with multiple ports, you need to define an alternative WSDL file name.

The following steps describe how to edit bindings for a Web service after these bindings are deployed on a server. When one Web service communicates with another Web service, you must configure the client bindings to access the downstream Web service.

You can also configure client bindings with **wsadmin**. See ″Configuring a Web service client deployed WSDL file name with the wsadmin tool″ in the information center.

To configure client bindings through the administrative console:

1. Open the administrative console.

2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Web modules** > *module_instance* > **Web services client bindings**.

   For EJB modules, click **Applications** >**Enterprise Applications** > *application_instance* > **EJB modules** > *module_instance* > **Web services client bindings**.
3. Find the Web service you want to update.

   The Web services are listed in the **Web Service** field.
4. Select the WSDL file name from the drop down box in the WSDL file name field.
5. Click **Edit** in the Preferred port mappings field to configure the default port to use.
   a. Specify the port type and the preferred ports in the Port type and Preferred ports fields.

      Configuring the preferred port enables you to select an optimal port implementation use non-SOAP protocols. See RMI-IIOP Web services using JAX-RPC for more information about using non-SOAP protocols.
   b. Click **Apply** and **OK**.
6. Click **Edit** in the Port information field to configure the request timeout, the overridden endpoint, and the overridden binding namespace for a port.

   Configuring the request timeout accommodates complex topologies that can have multiple cascaded Web services that involve multiple hops or long-running services.

   Timeout values can be configured based on observed behavior of the overall system as integration proceeds. For example, a Web service client might time out because of changing network conditions or the performance of an external Web service. When you have applications containing Web services clients that timeout, you can change the request time out values for the clients.
   a. Click **Apply** and **OK**.

Your Web service client bindings are configured.

Now you can finish any other configurations, start or restart the application, and verify the expected behavior of the Web service.

Web services client bindings

The client bindings define the Web Service Description Language (WSDL) file name, preferred ports and other port information. Use this page to specify the client bindings and the port mappings for the Web services in a module.

A Web service can specify the relative path within the module of a compatible WSDL file containing the actual URL to be used for requests. The relative path only needs to be specified if the original WSDL file does not contain a URL or when a different URL is needed. For a service endpoint with multiple ports defined, a preferred mapping specifies the default port to use for a port type.

To view this page, click **Applications** >**Enterprise Applications** > *application_instance* > **Web modules** > *module_instance*>**Web services client bindings**.

For EJB modules, click **Applications** >**Enterprise Applications** > *application_instance* > **EJB modules** > *module_instance*>**Web services client bindings**.

Web service:

Identifies the name of this Web service. A module can contain one or more Web services.

EJB:

Identifies the name of the EJB for the EJB modules.

WSDL file name:

Specifies the WSDL file name, which is relative to the module. Locate the WSDL file name in the drop down menu.

Preferred port mappings:

Specifies and manages the preferred port type mapping for a Web service when a particular port type is requested.

Click **Edit** to edit the preferred port mapping information on the **Preferred port mappings** panel.

Port information:

Specifies additional configuration information for the ports of this Web service.

Click **Edit** to edit the port information on the **Port information** panel. You can set a request timeout, override an endpoint and override a binding namespace for each client port.

Preferred port mappings:

Use this page to view and manage a preferred portType mapping for a Web service.

When you have multiple ports that reference the same portType (service endpoint interface), a preferred port specifies the port to use when the `Service.getPort(Class SEI)` method is called with only the service endpoint interface.

To view this administrative console page, click **Applications** >**Enterprise Application** > *application_instance* > **Web modules** > *module_instance*>**Web services client bindings** > **Edit**> *preferred_port_instance*.

For EJB modules, click **Applications** >**Enterprise Application** > *application_instance* > **EJB modules** > *module_instance*>**Web services client bindings** > **Edit**> *preferred_port_instance*.

portType:

Specifies the portType.

The preferred port and the portType values are both of the type `java.xml.namespace.QName`.

Preferred port:

Specifies the preferred port to be associated with a particular portType. The `Service.getPort(Class)` method returns the preferred port associated with the specified service endpoint interface class (portType).

The preferred ports available are listed, as well as a value of `None`, which indicates no preferred port is selected.

Web services client port information:

Use this page to specify a request timeout, override an endpoint, and override a binding namespace for a Web services client port.

A Web service can have multiple ports. You can view and configure the port attributes for each defined Web service port. The Web services are listed on the Web services client bindings panel.

To view this page, click **Applications** >**Enterprise Applications** > *application_instance* > **Web modules** > *module_instance*>**Web services client bindings** > **Edit**.

For EJB modules, click **Applications** >**Enterprise Applications** > *application_instance* > **EJB modules** > *module_instance*>**Web services client bindings** > **Edit**.

Port:

Identifies the name of a port.

Request timeout:

Specifies the time, in seconds, that the Web service client waits for a request to complete on this port. If a timeout is not specified, the default request timeout for the client to wait is `360` seconds. If the value is set at `0` (zero), the client's request does not timeout.

A typical use for this setting is to customize the client's behavior when it is configured to use a JMS transport to access a Web service to make it wait longer for an expected completion. Depending upon network conditions, or the nature of a Web service implementation, it might be necessary to tune the timeout.

Overridden endpoint:

Specifies the name of an endpoint that is used to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file.

If an assembled application contains a Web service client that is statically bound, the client is locked into using the implementation (service end point) identified in the WSDL file used during development. Overriding the endpoint is an alternative to configuring the deployed WSDL attribute.

The overridden endpoint URI attribute is specified on a per port basis. It does not require an alternative WSDL file within the module. The overridden endpoint URI takes precedence over the deployed WSDL attribute. The client uses this value for the service end point URI or SOAP address, instead of the value in the static client bindings.

Overridden binding:

Specifies the WSDL file binding namespace URI to use with this port, instead of the namespace in the WSDL file. This binding does not need to exist in the WSDL file. A client invoking a request on this port uses this binding instead of the binding specified in the WSDL file. An overridden binding namespace cannot be specified unless an overridden endpoint is specified.

Configuring the scope of a Web service port

When a Web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the Web module or enterprise bean module, including implementation scope, client bindings and deployment descriptor information. There are three levels of scope that can be set: application, session and request.

Deploy the Web service into WebSphere Application Server.

Web Services for Java 2 platform Enterprise Edition (J2EE) specifies that Web services implementations must be stateless. Therefore, to maintain specification compliance, the scope can remain at the application level because the state relevant to the individual sessions level or the requests level is not supposed to be maintained in the implementation. If you want to deviate from the specification and want to access a different JavaBean instance, because you are looking for information that is located in another JavaBean implementation, the scope settings need to change.

The setting that you configure for the scope determines how frequently a new instance of a service implementation class is created for the Web service ports in a module. Use this task to configure the scope of a Web service port.

You can also configure the scope with the wsadmin tool. See ″Configuring the scope of a Web service port with the wsadmin tool″ in the information center.

To change the scope setting through the administrative console:

1. Open the administrative console.
2. Click **Applications** >**Enterprise Applications** > *application_instance* > **Web Modules** > *module_instance*>**Web Services Implementation Scope**. If you are using an EJB module click **EJB Modules** instead of **Web Modules**.
3. Set the scope to application, session or request. The application scope causes the same instance of the implementation to be used for all requests on the application. The session scope causes the same instance to be used for all requests in each session. The request scope causes a new instance to be used for every request. For example, with the scope set to application, every message that comes to the server accesses the same JavaBean instance because that is the way the scope settings are configured.
4. Click **Apply**.
5. Click **OK**.

The scope for a Web service port is configured.

Now you can finish any other configurations, start or stop the application, and verify the expected behavior of the Web service.

Web services implementation scope

The scope determines when a new implementation instance is created for Web service ports. For example, setting the scope to `application` causes the same instance of the implementation to be used for each request. Setting the scope to `session` causes the same instance of the implementation to be used for each requests of a session. Setting the scope to `request` causes a new instance to be created for each request.

Use this page to view and manage the scope of the ports of a Web service application.

To view this administrative console page, click **Applications** >**Enterprise Applications** > *application_instance* > **Web modules** > *module_instance*>**Web services implementation scope**.

Port:

Specifies a port name for a Web service. A module can contain one or more Web services, each of which can contain one or more ports.

Web service:

Specifies the name of the Web service. A module can contain one or more Web services.

URI:

Specifies the Uniform Resource Identifier (URI) of the binding file that defines the scope. The URI is relative to the Web module.

Scope:

Specifies the scope of a port. The valid values for scope are `request`, `session` and `application`.

Web Services Invocation Framework (WSIF): Enabling Web services

The Web Services Invocation Framework (WSIF) provides a Java API for invoking Web services, independent of the format of the service or the transport protocol through which it is invoked. This framework includes an EJB provider for EJB invocation using Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). However, for EJB(IIOP)-based Web service invocation you should instead invoke RMI-IIOP Web services using JAX-RPC.

The Web Services Invocation Framework (WSIF) is a WSDL-oriented Java API. You use this API to invoke Web services dynamically, regardless of the service implementation format (for example enterprise bean (EJB)) or the service access mechanism (for example Java Message Service (JMS)).

Using WSIF, you can move away from the usual Web services programming model of working directly with the SOAP APIs, towards a model where you interact with representations of the services. You can therefore work with the same programming model regardless of how the service is implemented and accessed.

If you want to know more about the issues that WSIF addresses, see Goals of WSIF.

If you want to know how WSIF addresses these issues, see An overview of WSIF.

To use WSIF, see the following topics:
- Using WSIF to invoke Web services.
- WSIF system management and administration.
- WSIF API.

For more information about working with WSIF, visit the Web sites listed in Web services: Resources for Learning.

Goals of WSIF

SOAP bindings for Web services are part of the WSDL specification, therefore when most developers think of using a Web service, they immediately think of assembling a SOAP message and sending it across the network to the service endpoint, using a SOAP client API. For example: using Apache SOAP the client creates and populates a Call object that encapsulates the service endpoint, the identification of the SOAP operation to invoke, the parameters to send, and so on.

While this process works for SOAP, it is limited in its use as a general model for invoking Web services for the following reasons:
- Web services are more than just SOAP services.
- Tying client code to a particular protocol implementation is restricting.
- Incorporating new bindings into client code is hard.
- Multiple bindings can be used in flexible ways.
- A freer Web services environment enables intermediaries.

The goals of the Web Services Invocation Framework (WSIF) are therefore:
- To give a binding-independent mechanism for Web service invocation.
- To free client code from the complexities of any particular protocol used to access a Web service.
- To enable dynamic selection between multiple bindings to a Web service.
- To help the development of Web service intermediaries.

WSIF - Web services are more than just SOAP services: You can deploy as a Web service any application that has a WSDL-based description of its functional aspects and access protocols. If you are using the Java 2 platform, Enterprise Edition (J2EE) environment, then the application is available over multiple transports and protocols.

For example, you can take a database-stored procedure, expose it as a stateless session bean, then deploy it into a SOAP router as a SOAP service. At each stage, the fundamental service is the same. All that changes is the access mechanism: from Java DataBase Connectivity (JDBC) to Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) and then to SOAP.

The WSDL specification defines a SOAP binding for Web services, but you can add binding extensions to the WSDL so that, for example, you can offer an enterprise bean as a Web service using RMI-IIOP as the access protocol. You can even treat a single Java class as a Web service, with in-thread Java method invocations as the access protocol. With this broader definition of a Web service, you need a binding-independent mechanism for service invocation.

WSIF - Tying client code to a particular protocol implementation is restricting:

If your client code is tightly bound to a client library for a particular protocol implementation, it can become hard to maintain.

For example, if you move from Apache SOAP to Java Message Service (JMS) or enterprise bean, the process can take a lot of time and effort. To avoid these problems, you need a protocol implementation-independent mechanism for service invocation.

WSIF - Incorporating new bindings into client code is hard: As is explained in Web services are not just SOAP services, if you want to make an application that uses a custom protocol work as a Web service, you can add extensibility elements to WSDL to define the new bindings. But in practice, achieving this capability is hard. For example you have to design the client APIs to use this protocol. If your application uses just the abstract interface of the Web service, you have to write tools to generate the stubs that enable an abstraction layer. These tasks can take a lot of time and effort. What you need is a service invocation mechanism that allows you to update existing bindings, and to add new bindings.

WSIF - Multiple bindings can be used in flexible ways: Imagine that you have successfully deployed an application that uses a Web service which offers multiple bindings. For example, imagine that you have a SOAP binding for the service and a local Java binding that lets you treat the local service implementation (a Java class) as a Web service.

The local Java binding for the service can only be used if the client is deployed in the same environment as the service. In this case, it is more efficient to communicate with the service by making direct Java calls than by using the SOAP binding.

If your clients could switch the actual binding used based on run-time information, they could choose the most efficient available binding for each situation. To take advantage of Web services that offer multiple bindings, you need a service invocation mechanism that can switch between the available service bindings at run time, without having to generate or recompile a stub.

WSIF - Enabling a freer Web services environment promotes intermediaries:

Web services offer application integrators a loosely-coupled paradigm. In such environments, intermediaries can be very powerful.

Intermediaries are applications that intercept the messages that flow between a service requester and a target Web service, and perform some mediating task (for example logging, high-availability or transformation) before passing on the message. The Web Services Invocation Framework (WSIF) is designed to make building intermediaries both possible and simple. Using WSIF, intermediaries can add value to the service invocation without needing transport-specific programming.

An overview of WSIF

The Web Services Invocation Framework (WSIF) provides a Java API for invoking Web services, independent of the format of the service or the transport protocol through which it is invoked. This framework addresses all of the issues identified in the goals of WSIF.

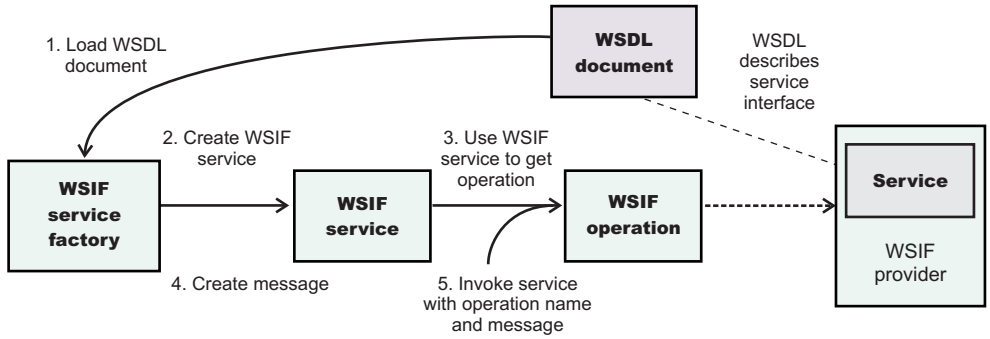
WSIF provides the following features:
- An API that provides binding-independent access to any Web service.
- A close relationship with WSDL, so it can invoke any service that you can describe in WSDL.
- A stubless and completely dynamic invocation of a Web service.
- The capability to plug a new or updated implementation of a binding into WSIF at run time.
- The option to defer the choice of a binding until run time.

WSIF is designed to work both in an unmanaged environment (stand-alone) and inside a managed container, see ″Running WSIF as a client″ and ″Interacting with the J2EE container in WebSphere Application Server″ in the information center. You can use the Java Naming and Directory Interface (JNDI) to find the WSIF service, or you can use the location described in the WSDL. See ″Using the Java Naming and Directory Interface (JNDI)″ in the information center.

For more conceptual information about WSIF and WSDL, see the following topics:
- WSIF and WSDL
- WSIF architecture
- Using WSIF with Web services that offer multiple bindings
- WSIF usage scenarios
- Dynamic invocation

WSIF supports Internet Protocol Version 6, and Java API for XML-based Remote Procedure Calls (JAX-RPC) Version 1.1 for SOAP.

WSIF architecture: The Web Services Invocation Framework (WSIF) architecture is shown in the figure.



The components of this architecture include:

WSDL document

The Web service WSDL document contains the location of the Web service. The binding document defines the protocol and format for operations and messages defined by a particular portType.

WSIF service

The WSIFService interface is responsible for generating an instance of the WSIFOperation interface to use for a particular invocation of a service operation. For more information, see ″WSIF API reference: Finding a port factory or service″ in the information center.

WSIF operation

The run-time representation of an operation, called WSIFOperation is responsible for invoking a service based on a particular binding. For more information, see ″WSIF API reference: Using ports″ in the information center.

WSIF provider

A WSIF provider is an implementation of a WSDL binding that can run a WSDL operation through a binding-specific protocol. WSIF includes SOAP providers, JMS providers, Java providers and EJB providers. For more information, see ″Using the WSIF providers″ in the information center.

Using WSIF with Web services that offer multiple bindings:

Using WSIF, a client application can choose dynamically the optimal binding to use for invoking Web service operations.

For example, a Web service might offer a SOAP binding, and also a local Java binding so that you can treat the local service implementation (a Java class) as a Web service. If a client application is deployed in the same environment as the service, then this client can use the local Java binding for the service. This provides more efficient communication between the client and the service by making direct Java calls rather than indirect calls using the SOAP binding.

For more information on how to configure a client to dynamically select between multiple bindings, see ″Developing a WSIF service″ in the information center.

WSIF and WSDL: WSDL is the acronym for Web Services Description Language.

In WSDL a service is defined in three distinct sections:

- The **portType**. This section defines the abstract interface offered by the service. A portType defines a set of *operations*. Each operation can be In-Out (request-response), In-Only, Out-Only and Out-In (Solicit-Response). Each operation defines the input and/or output *messages*. A message is defined as a set of *parts*, and each part has a schema-defined type.
- The **binding**. This section defines how to map between the abstract portType and a real service format and protocol. For example the SOAP binding defines the encoding style, the SOAPAction header, the namespace of the body (the targetURI), and so on.
- The **port**. This section defines the actual location (endpoint) of the available service. For example, the HTTP Web address at which a SOAP service is available.

Currently in WSDL, each port has one and only one binding, and each binding has a single portType. But (more importantly) each service (portType) can have multiple ports, each of which represents an alternative location and binding for accessing that service.

The Web Services Invocation Framework (WSIF) follows the semantics of WSDL as much as possible:

- The WSIF dynamic invocation API directly exposes run-time equivalents of the model from WSDL. For example, invocation of an operation involves executing an operation with an input message.
- WSDL has extension points that support the addition of new ports and bindings. This enables WSDL to describe new systems. The equivalent concept in WSIF is a provider, that enables WSIF to understand a class of extensions and thereby to support a new service implementation type.

As a metadata-based invocation framework, WSIF follows the design of the metadata. As WSDL is extended, WSIF is updated to follow.

The implicit and primary type system of WSIF is XML schema. WSIF supports invocation using dynamic proxies, which in turn support Java type systems, but when you use the WSIFMessage interface it is your responsibility to populate WSIFMessage objects with data based on the XML schema types as defined in the WSDL document. You should define your object types by a canonical and fixed mapping from schema types into the run-time environment.

For more information on WSDL, see Web services: Resources for learning.

WSIF usage scenarios:

This topic describes two brief scenarios that illustrate the role WSIF plays in the emerging Web services environment.

Scenario: Redevelopment and redeployment

When you first implement a Web service, you create a simple prototype. When you want to move a prototype Web service into production, you often need to redevelop and redeploy it.

The Web Services Invocation Framework (WSIF) uses the same API calls irrespective of the underlying technologies, therefore if you use WSIF:

- You can reimplement and redeploy your services without changing the client code.
- You can use existing reliable and high-performance infrastructures like Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) and Java Message Service (JMS) without sacrificing the location-independence that the Web service model offers.

Scenario: Service Flow composition

A service flow typically invokes a Web service, then passes the response from one Web service to the next Web service, perhaps performing some transformation in the middle.

There are two key aspects to this flow that WSIF provides:

- A representation of the service invocation based on the metadata in WSDL.
- The ability to build invocations based solely on the portType, which can therefore be used in any implementation.

For example, imagine that you build a meta-service that uses a number of services to build a process. Initially, several of those services are simple Java bean prototypes that are written and exposed through SOAP, but you plan to reimplement some of them as EJB components, and to out-source others.

If you use SOAP, it ties up multiple threads for every onward invocation, because they pass through the Web server and servlet engine and on to the SOAP router. If you use WSIF to call the beans directly, you get much better performance compared to SOAP and you do not lose access or location transparency. Using WSIF, you can replace the Java bean implementations with EJB implementations without changing the client code. To move some of the Web services from local implementations to external SOAP services, you just update the WSDL.

Dynamic invocation: For the Web Services Invocation Framework (WSIF), dynamic invocation means providing the following levels of support when invoking Web services:

1. Support for WSDL extensions and bindings that were not known at build time.
2. Support for Web services that were not known at build time.

WSIF supports (1) through the use of providers. See ″Using the WSIF providers″ in the information center.

The providers support (2) by using the WSDL description to access the target service.

Getting started with UDDI Registry

This section covers the basic knowledge you need to get started either as an administrator of a UDDI Registry or as a user of a UDDI Registry that has already been set up.

- Getting started for UDDI Administrators
- Getting started for UDDI users

Getting started for UDDI Administrators

Use this topic if you are involved in installing (setting up and deploying), customizing, or managing a UDDI Registry.

This section contains a list of some of the topics that you will need to refer to as an administrator of a UDDI Registry:

- UDDI Registry Terminology introduces some terms with which you will need to be familiar in order to administer a UDDI Registry
- Setting up and deploying a new UDDI Registry explains how to install a UDDI Registry node by setting up the resources that it will use, and deploying the UDDI Registry application.
- Managing the UDDI Registry explains how to use the UDDI pages in the WebSphere Administrative Console, or the UDDI Registry Administrative interface, to administer a UDDI Registry node. It also covers how to back up and restore your UDDI Registry data.
- UDDI node settings explains how to view and set UDDI properties and policies, and how to manage UDDI publishers, tiers and user entitlements.
- UDDI Registry Management Interfaces covers details of programmatic interfaces that you can use to administer a UDDI Registry node (UDDI Registry Administrative (JMX) Interface), to add custom Value Set data to a UDDI Registry (User Defined Value Set Support), and to export and import UDDI version 2 entities (UDDI Utility Tools).

UDDI Registry troubleshooting might be useful if you encounter any problems or unexpected behaviour while using the UDDI Registry, and UDDI Registry messages explains any UDDI messages which you might see.

Getting started for UDDI users

Use this topic if you use a UDDI Registry to publish or find UDDI entities either through a user interface or by writing UDDI client applications.

This section contains a list of some of the topics that you might want to refer to as a user of a UDDI Registry:

UDDI Registry Terminology introduces some terms with which you might need to be familiar with to use a UDDI Registry.

UDDI Registry user interface tells you how to access the UDDI User Console, which is a user interface that allows you to find UDDI entities and carry out simple UDDI publish operations.

See ″Displaying the user interface″ for the URL for the UDDI User Interface.

″UDDI Registry SOAP Service End Points″ contains details for accessing the UDDI version 3 Inquiry, Publish, Security, and custody transfer APIs, as well as the UDDI version 1 and version 2 APIs.

″UDDI Registry Client Programming″ explains how to write UDDI client application programs. The recommended client programming interface is the IBM UDDI version 3 Client for Java.

IBM JAXR Provider for the UDDI Registry is for users who want to use the Java API for XML Registries to access UDDI.

User Defined Value Set Support in the UDDI Registry explains how to add custom value set data to a UDDI Registry.

″UDDI Registry troubleshooting″ might be useful if you encounter any problems or unexpected behaviour while using the UDDI Registry, and UDDI Registry messages explains any UDDI messages which you might see.

Planning to use Web services

This topic discusses how to plan your use of Web services that are developed and implemented based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification.

Read the Web services scenario: Overview which tells the story of a fictional online garden supply retailer named Plants by WebSphere and how this retailer incorporated the Web services concept.

Web services are Web applications that help you be more flexible in your business processes by integrating with applications that otherwise do not communicate.

Web services reflect the service-oriented architecture approach to programming. This approach is based on the idea of building applications by discovering and implementing network-available services, or by invoking the available applications to accomplish a task. Web services deliver interoperability, for example, Web services applications provide a way for components created in different programming languages to work together as if they were created using the same language. Web services rely on existing transport technologies, such as HTTP, and standard data encoding techniques, such as Extensible Markup Language (XML), for invoking the implementation.

To plan to use Web services:

1. Identify your goals and design Web services to fit your e-business solution. Consider what you want to accomplish by using Web services. Decide how Web services fit into your current topology, applications and programming model. Determine how the Web services process requests on the server and how the clients manage and use the Web service.
2. Design your Web services for reliability, availability, manageability and security. For example, you want your Web services to process a transaction in a reasonable time at all hours of the day and provide users with good security characteristics, such as authentication for buyers. Planning to use Web services to work with WebSphere Application Server helps to meet these requirements.
3. To support Web services, extend WebSphere Application Server to support Web services standards. For interoperable Web services running on platforms supplied by multiple vendors, standards are essential.
4. Decide what development and implementation tools to use. You can use a variety of manual development and implementation tasks. Whether you have an existing Web service to implement or you want to develop your own from a Java bean or from Enterprise JavaBeans (EJB), you can choose different tasks respective to your resources. You can also use Rational Application Developer (RAD) to complete development and implementation tasks.

   See ″Developing Web services applications″ in the information center for information about developing Web services based on the Java language through the WebSphere Application Server. To read more about RAD see the information center for the product.
5. Install WebSphere Application Server. See ″Task overview: installing″ in the information center.
6. Review Web services Samples.

You have a design plan for implementing Web services applications into your business architecture.

Develop a Web service. See ″Developing Web services applications″ in the information center.

This topic explains how to develop a Web service using the Web Services for J2EE specification.

Service-oriented architecture

A *service-oriented architecture (SOA)* is a collection of services that communicate with each other, for example, passing data from one service to another or coordinating an activity between one or more services.

Companies want to integrate existing systems to implement Information Technology (IT) support for business processes that cover the entire business value chain. A variety of designs are used, ranging from rigid point-to-point electronic data interchange (EDI) to Web auctions. By using the Internet, companies make their IT systems available to internal departments or external customers, but the interactions are not flexible and are without standardized architecture.

Because of this increasing demand for technologies that support connecting and sharing resources and data, a need exists for a flexible, standardized architecture. SOA is a flexible architecture that unifies business processes by structuring large applications into building blocks, or small modular functional units or services, for different groups of people to use inside and outside the company. The building blocks can be one of three roles: service provider, service broker, or service requestor. See Web services approach to a service-oriented architecture to learn more about these roles.

Requirements for an SOA

To efficiently use an SOA, follow these requirements:

- **Interoperability between different systems and programming languages**.

  The most important basis for a simple integration between applications on different platforms is to provide a communication protocol. This protocol is available for most systems and programming languages.
- **Clear and unambiguous description language**.

  To use a service offered by a provider, it is not only necessary to be able to access the provider system, but the syntax of the service interface must also be clearly defined in a platform-independent fashion.
- **Retrieval of the service**.

  To support a convenient integration at design time or even system run time, a search mechanism is required to retrieve suitable services. Classify these services as *computer-accessible*, *hierarchical* or *taxonomies* based on what the services in each category do and how they can be invoked.

Web services approach to a service-oriented architecture

The Web services approach implements a service-oriented architecture (SOA). A major focus of Web services is to make functional building blocks accessible over standard Internet protocols that are independent from platforms and programming languages. These services can be new applications or just wrapped around existing legacy systems to make them network-enabled. A service can rely on another service to achieve its goals.

Each SOA building block can assume one or more of three roles:

- **Service provider**

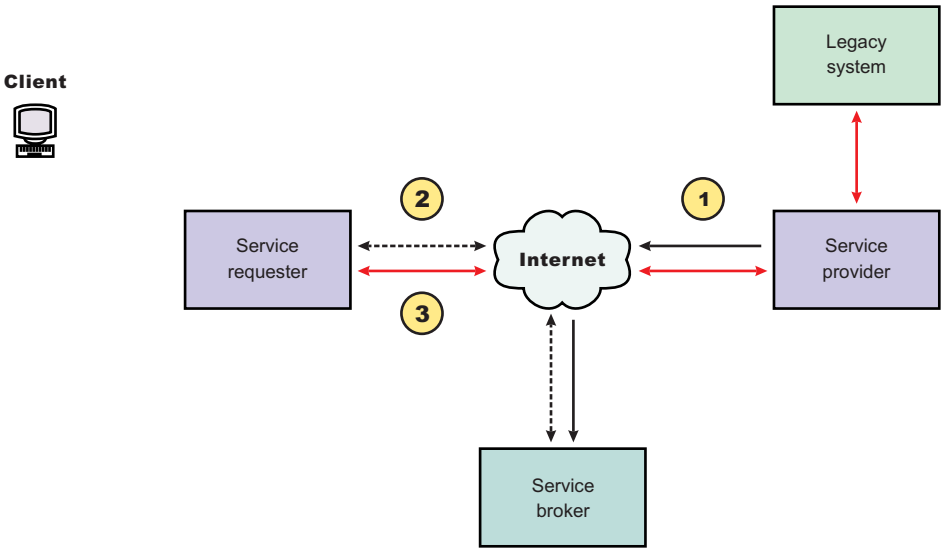
  The service provider creates a Web service and possibly publishes its interface and access information to the service registry. Each provider must decide which services to expose, how to make trade-offs between security and easy availability, how to price the services, or how to exploit free services for other value. The provider also has to decide which category to list the service in for a given broker service and what sort of trading partner agreements are required to use the service.
- **Service broker**

  The service broker, also known as *service registry*, is responsible for making the Web service interface and implementation access information available to any potential service requestor. The implementer of the broker decides the scope of the broker. Public brokers are available through the Internet, while private brokers are only accessible to a limited audience, for example, users of a company intranet. Furthermore, some decisions need to be made about the amount of the offered information. Some

brokers specialize in many listings. Others offer high levels of trust in the listed services. Some cover a broad landscape of services and others focus within an industry. Some brokers catalog other brokers. Depending on the business model, brokers can attempt to maximize look-up requests, the number of listings or the accuracy of the listings. The Universal Description, Discovery and Integration (UDDI) specification defines a way to publish and discover information about Web services.

- **Service requester**

  The service requestor or Web service client locates entries in the broker registry using various find operations and then binds to the service provider to invoke one of its Web services.



.

Characteristics of the SOA

The presented SOA illustrates a loose coupling between the participants, which provides greater flexibility in the following ways:

- A client is coupled to a service. Therefore, the integration of the server takes place outside the scope of the client application programs.
- Old and new functional blocks or applications and systems, are encapsulated into components that work as services.
- Functional components and their interfaces are separate, so that new interfaces can be plugged in more easily.
- Within complex applications, the control of business processes can be isolated. A business rule engine can be incorporated to control the workflow of a defined business process. Depending on the state of the workflow, the engine calls the respective services.
- Services can be incorporated dynamically during run time.
- Bindings are specified using configuration files and can be easily adapted to new needs.

Properties of a service-oriented architecture

The service-oriented architecture offers the following properties:

- **Web services are self-contained.**

  On the client side, no additional software is required. A programming language with Extensible Markup Language (XML) and HTTP client support is enough to get you started. On the server side, a Web server and a SOAP server are required. It is possible to enable an existing application for Web services without writing a single line of code.

- **Web services are self-describing.**

  Neither the client nor the server knows or cares about anything besides the format and content of the request and response messages (loosely coupled application integration). The definition of the message format travels with the message; no external metadata repositories or code generation tool are required.
- **Web services can be published, located, and invoked across the Internet.**

  This technology uses established lightweight Internet standards such as HTTP and it leverages the existing infrastructure. Some other standards that are required include, SOAP, Web Services Description Language (WSDL), and UDDI.
- **Web services are language-independent and interoperable.**

  Client and server can be implemented in different environments. Existing code does not have to change in order to be Web services enabled.
- **Web services are inherently open and standard-based.**

  XML and HTTP are the major technical foundation for Web services. A large part of the Web service technology has been built using open-source projects.
- **Web services are dynamic.**

  Dynamic e-business can become reality using Web services because with UDDI and WSDL you can automate the Web service description and discovery.
- **Web services are composable.**

  Simple Web services can be aggregated to more complex ones, either using workflow techniques or by calling lower-layer Web services from a Web service implementation. Web services can be chained together to perform higher-level business functions. This chaining shortens development time and enables best-of-breed implementations.
- **Web services are loosely coupled.**

  Traditionally, application design has depended on tight interconnections at both ends. Web services require a simpler level of coordination that supports a more flexible reconfiguration for an integration of the services.
- **Web services provide programmatic access.**

  The approach provides no graphical user interface; it operates at the code level. Service consumers need to know the interfaces to Web services, but do not need to know the implementation details of services.
- **Web services provide the ability to wrap existing applications.**

  Already existing stand-alone applications can easily integrate into the service-oriented architecture by implementing a Web service as an interface.

Web services business models supported

The properties and benefits of using a service-oriented architecture (SOA) such as Web services is well suited for binding small modules that perform independent tasks within a highly heterogeneous e-business model. Web services can be easily wrapped around existing applications in your business model and plugged into different business processes.

For connecting to a large monolithic system that does not support the implementation of different flexible business processes, other approaches might be better suited, for example, to satisfy specialized features, such as performance or security.

The following business models are easily implemented by using an architecture including Web services:

- **Business information**

  Sharing of information with consumers or other businesses. Web services can be used to expand the reach through such services as news streams, local weather reports, integrated travel planning, and intelligent agents.
- **Business integration**

Providing transactional, fee-based services for customers. A global network of suppliers can be easily created. Web services can be implemented in auctions, e-marketplaces, and reservation systems.

- **Business process externalization**

  Web services can be used to model value chains by dynamically integrating processes to a new solution within an organizational unit or even with those of other e-businesses. This modeling can be achieved by dynamically linking internal applications to new partners and suppliers, to offer their services to complement internal services.

Setting up and deploying a new UDDI Registry

Start the Installation of WebSphere Application Server and create the profile for your application server (for example, server1) to be used to host UDDI.

You have a choice of deploying either a default UDDI node, or a user customized UDDI node.

A default UDDI node would be a suitable option for initial evaluation of UDDI and for development and test purposes. With a customized UDDI node, you have more control over the database management system used for the UDDI database, and the properties used to set up the UDDI database. With a user customized UDDI node, you create the UDDI database and datasource to your own specifications, and then use the uddiDeploy.jacl script to deploy the UDDI application.

The main difference between *default* and *user customized*, in the context of these set up tasks, refers to a number of vital UDDI properties. For a default set up these vital properties are automatically set to default values and are not changeable by the user. For a user customizable set up, the user is given an opportunity to set these vital properties, but once set they cannot be changed for this configuration.

If you are setting up a UDDI node for production use, refer to Database considerations for production use of the UDDI Registry for information about choosing a database type.

The main guidance for deploying UDDI, elsewhere in this information center, is written for a single server configuration. This basic guidance applies to all configurations, however the following sections provide additional guidance for other variations such as:

- Network deployment
- Moving from a single server to a network deployment configuration
- Moving from a default to a customized node
- Moving between database types

If you are installing into a standalone application server you can proceed to either Setting up a default UDDI node, or Setting up a customized UDDI node.

Deploying into a Network Deployment cell (but not a cluster)

6.1+ The information in this section now applies to deploying into a cluster as well as a single server. For resources such as the JDBC provider and datasource, you can follow the guidelines for a non cluster configuration, however the resources may need updating on individual cluster members to correctly access the shared database for example.

It is important to note that the uddiDeploy.jacl script must be run with the Deployment Manager as the target.

If you are deploying into a network deployment cell you cannot create a default Cloudscape node using uddiDeploy.jacl. You may, however, manually create the default Cloudscape database (with a default profile) by following the instructions in Creating a Cloudscape database and adding the parameter 'DEFAULT' as the last argument.

You will not be able to use the default option on uddiRemove for a UDDI node that is deployed into an application server which is part of a Network Deployment cell. See Removing a UDDI Registry node for more information.

If you have a non default UDDI setup in a base application server, you can issue an *addNode -includeapps* command which will add the necessary definitions into the deployment manager.

Deploying into a cluster within a Network Deployment cell

6.1+ The scripts uddiDeploy.jacl and uddiRemove.jacl can now be used in a cluster environment, so the information in this section can be ignored.

It is important to note that uddiDeploy.jacl and uddiRemove.jacl cannot be used in a cluster environment.

It is assumed a single database will be used for all members of the cluster.

You can follow the same guidelines for a non cluster set up in general for the resources such as the JDBC provider and datasource as described in this Information Center, but they may need updating on individual cluster members to correctly access the shared database for example.

The options that are available are:

- Deploy UDDI into a standalone server, as described in this Information Center (using uddiDeploy), and then create a cluster using that server as a template for the other members.
- If using an cluster that already exists, you can use the admin console or wsadmin for example (and not uddiDeploy.jacl), to deploy the uddi.ear across the cluster members, but follow the additional advice in the main instructions.

Changing from a base application server to a Network Deployment cell.

It is possible to move from a base application server to a network deployment cell using the standard *addNode* command. During the move, any applications may be lost unless you use the *-includeapps* option. This applies to all applications and not just UDDI applications. See ″addNode command″ for details. This applies to a default or a customized UDDI node.

Moving from a default UDDI node to a user customized UDDI node.

After testing the UDDI deployment in a default UDDI node, you can move to a user customized node by recreating the database using the instructions in Setting up a customized UDDI node, but you must be aware that any data saved in the default node (policies, properties and user data) will be lost in the move.

Moving between Cloudscape and DB2 databases.

If you decide to move between one type of database to another, the datasource of the old database will still have a JNDI name of datasources/uddids. You must either rename this JNDI name to something different, or delete the datasource before you define the new database, create the new datasource and initialize the database.

You now have the choice of Setting up a default UDDI node orSetting up a customized UDDI node.

Database considerations for production use of the UDDI Registry

The IBM UDDI Registry fully supports a number of databases and can be used for development and test purposes, however you should be aware of the following factors when considering which database is appropriate for your anticipated UDDI Registry production use.

It is important to consult the information supplied by your chosen database vendor for advice, but additionally you need to consider the likely size and volume of requests, and whether the general performance and scalability of the UDDI registry is important to you.

For example, while Cloudscape supports the full function of the UDDI Registry, it is not an enterprise level database and consequently it does not have the same characteristics (for example, scaling or performance) as enterprise databases such as DB2 or Oracle.

If you need multiple connections to the UDDI Registry database (for example if you are using the UDDI Registry in a cluster configuration) and Cloudscape is your preferred database, you will need to use the network Cloudscape option as embedded Cloudscape has a limitation of allowing only one Java virtual machine to access or load a database instance at any one time (in other words two application servers cannot access the same Cloudscape database instance at the same time).

Note: The UDDI Registry can support multiple users even if there is a single database connection.

More information on Cloudscape is available in this information center.

Setting up a customized UDDI node

You can set up a customized UDDI node by completing the following steps:

1. Create a database schema to hold the UDDI registry by executing one of the following, ensuring that you do not perform the final step to set the default node indicator in the database:
   - Creating a DB2 database
   - Creating a Cloudscape database
2. Create a J2C Authentication Data Entry (not required for embedded Cloudscape, but required for network Cloudscape):
   a. Expand **Security**, **Global Security** and **JAAS Configuration** (on the right), then click **J2C Authentication Data**.
   b. Click **New** to create a new J2C authentication data entry
   c. Fill in the details as follows:

      Alias a suitable (short) name, such as ″UDDIAlias″

      Userid
      the database userid (such as db2admin for DB2), which is used to read and write to the UDDI registry database. For network Cloudscape the userid can be any value.

      Password
      the password associated with the userid specified above. For network Cloudscape the password can be any value.

      Description
      a suitable description to describe the chosen userid.

      Click **Apply** and then Save the changes to the master configuration.
3. Create a JDBC Provider (if a suitable one does not already exist), using the following table to determine the provider type and implementation type for your chosen database:

Database	Provider type	Implementation type
DB2	DB2 Universal JDBC Driver Provider	Connection Pool datasource
Embedded Cloudscape	Cloudscape JDBC Driver	Connection Pool datasource
Network Cloudscape	Cloudscape Network Server Using Universal JDBC Driver	Connection Pool datasource

For details on how to create a JDBC provider, see either Using a DB2 Universal JDBC Driver Provider with WebSphere Application Server for z/OS, if you are using DB2 (do not follow the instructions for

creating a datasource; this is covered within the current task), orCreating and configuring a JDBC provider using the administrative console, for other database types.

4. Create a datasource for the UDDI Registry by following these steps:
   a. Expand **Resources** and **JDBC Providers**.
   b. Select the desired 'scope' of the JDBC provider you selected or created earlier. For example, select:

      ```
      Server: yourservername
      ```

      to show the JDBC providers at the server level.
   c. Select the JDBC provider created earlier.
   d. Under **Additional Properties**, select **Data Sources** (*not* the Data Sources Version 4 option).
   e. Click **New** to create a new datasource.
   f. Fill in the details for the datasource as follows:

      Name a suitable name, such as UDDI Datasource

      JNDI name
      set to **datasources/uddids** - this value is obligatory.

      Note: You must not have any other datasources using this JNDI name. If you have another datasource using this JNDI name, then you must either remove it or change its JNDI name. For example, if you have previously created a default UDDI node using Cloudscape, you should use the uddiRemove.jacl script with the default option to remove the datasource and the UDDI application instance, before continuing.

      Use this Data Source in container-managed persistence (CMP)
      ensure the check box is cleared.

      Description
      a suitable description

      Category
      set to uddi

      Data store helper class name
      filled in for you as:

Database	Data store helper class name
DB2	com.ibm.websphere.rsadapter.DB2UniversalDataStore Helper
Embedded Cloudscape	com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper
Network Cloudscape	com.ibm.websphere.rsadapter.CloudscapeNetworkServer DataStoreHelper

      Component-managed authentication alias
      - for **DB2** or **network Cloudscape**, select the alias that you created in step 2 from the pulldown. It will have the node name appended in front of it, for example MyNode/UDDIAlias.
      - for **embedded Cloudscape** leave this set to (none).

      Container-managed authentication alias
      set to (none)

      Mapping-configuration alias
      set to DefaultPrincipalMapping

      Relational Database Management System **data source properties**
      - for **DB2**:

Database name
this is the local LOCATION value. To find this value, enter the following operator command using the DB2 interactive panels:

```
-DIS DDF
```

Driver type
set to 2

- for **Cloudscape** (embedded or network) - **Database name** - for example:

```
install_root/databases/com.ibm.uddi/UDDI30
```

For network Cloudscape, also make sure that the **Server name** and **Port number** match the network server.

Leave all other fields unchanged.

Click **Apply** and Save the changes to the master configuration.

5. Test the connection to your UDDI database by selecting the check box next to the datasource and clicking **Test connection**. You will see a message similar to ″Test Connection for datasource UDDI Datasource on server server1 at node MyNode was successful″. If you do not see this message investigate the problem with the help of the error message.
6. Deploy the UDDI Registry by running the wsadmin script uddiDeploy.jacl, as shown, from the *install_root*/bin directory.

   The syntax of the command is as follows:

```
wsadmin.sh [-conntype none] -f uddiDeploy.jacl
              node_name
              server_name
```

   6.1+

```
wsadmin.sh [-conntype none] -f uddiDeploy.jacl
              {node_name server_name | cluster_name}
```

   where

   - '-conntype none' is optional, and is only needed if the application server is not running.
   - *node_name* is the name of the WebSphere node on which the target server runs. Note that the node name is case sensitive.
   - *server_name* is the name of the target server on which you wish to deploy the UDDI Registry, such as server1. Note that the server name entered is case sensitive.
   - 6.1+ *cluster_name* is the name of the target cluster into which you wish to deploy the UDDI registry. Note that the cluster name entered is case sensitive.

   You are recommended to deploy the UDDI application using the uddiDeploy.jacl script, but note that you can also use the administrative console to deploy the application in the normal way. If you use the administrative console you must ensure that the Classloader Mode for the application is set to PARENT_LAST, and that the WAR class loader Policy is set to Application. The uddiDeploy.jacl script in a command prompt will do this for you.

   For example, to deploy UDDI on node 'MyNode' and server 'server1' (assuming that server1 is already started):

```
wsadmin.sh -f uddiDeploy.jacl MyNode server1
```

   6.1+ To deploy UDDI into cluster 'MyCluster' :

```
wsadmin.sh -f uddiDeploy.jacl MyCluster
```

7. Start the UDDI application, or start the application server if it is not already running. This will activate the UDDI node.

   Note: Restarting the UDDI application, or the application server, will always result in the reactivation of the UDDI node, even if the node was previously deactivated.

As you have chosen a user customized UDDI node, you will need to set the properties for the UDDI node using UDDI administration, and initialize the node before it is ready to accept UDDI requests (see “Initializing the UDDI Registry node” for details).

Initializing the UDDI Registry node:

Use this topic to initialize a UDDI Registry node after set up or migration.

You must have already set up a UDDI Registry node, either as a new node or to use for migrating a UDDI Registry Version 2 node.

The UDDI Registry node has various properties, some of which must be set before initializing the node. There are two categories of UDDI Registry node properties:

- Mandatory node properties. These properties must be set before the UDDI node can be initialized. You may set these properties as many times as you wish before initialization. However, once the UDDI node has been initialized, these properties will become read only for the lifetime of that UDDI node. It is very important to set these properties correctly.
- All other properties. These properties may be set before, and after, initialization.

Configure these properties and initialize the node using the UDDI administrative console or JMX management interface.

1. Click **UDDI** → **UDDI Nodes** > *UDDI_node_id* to display the properties page for the UDDI Registry node.
2. Set the mandatory node properties to suitable, and valid, values. These properties are indicated by the presence of a ’*’ next to the input field. The properties are listed below; more information on each property is given in the context help of the administrative console.

   UDDI node ID
   This must be a text string beginning with ’uddi:’ that is unique to this UDDI node. The default value may be sufficient, but if you accept it you should ensure that it is unique.

   UDDI node description
   This is a text string describing the node.

   Root key generator
   This must be a text string beginning with ’uddi:’ that is unique to this UDDI node. The default value may be sufficient but may contain text, such as ’keyspace_id’, that you should modify to match your system. If you accept the default value, ensure that it is unique for this UDDI node.

   Prefix for generated discoveryURLs
   This should be a valid URL.
3. If you are migrating from Version 2 of the UDDI Registry, use the table below to perform the following steps:
   - Set any properties from uddi.properties that **must** remain the same as Version 2.
   - Set any properties from uddi.properties that you would like to keep the same (such as dbMaxResultCount).

Version 2 UDDI property (set in uddi.property file)	Version 3 UDDI Property (set via Administrative Console or UDDI Administrative Interface)	Recommended Version 3 UDDI property setting
dbMaxResultCount	maximum inquiry response set size	You might want to retain the value from Version 2, but can safely change this (or use the default)
persister	no equivalent	Not applicable
defaultLanguage	default language code	You are recommended to retain the value from Version 2

Version 2 UDDI property (set in uddi.property file)	Version 3 UDDI Property (set via Administrative Console or UDDI Administrative Interface)	Recommended Version 3 UDDI property setting
operatorName	UDDI node ID	You must use a valid value for the UDDI node ID. This will be applied to your Version 2 data as it is migrated.
maxSearchKeys	maximum search keys	You might want to retain the value from Version 2, but can safely change this (or use the default)
getServletURLprefix	Prefix for generated discoveryURLs	You should enter a valid value for your configuration, which should therefore be the same as the value used for Version 2.
getServletName	no equivalent	Not applicable

4. Set any other properties, such as policy values, that you wish to change from the default settings (or these can be changed at a later time). For an explanation of policies and properties see Managing the UDDI Registry.
5. Once the properties have been set to appropriate values, click **Apply** to save your changes. It is important to save the changes before proceeding to the initialize step.
6. Initialize the UDDI node by clicking **Initialize**, at the top of the pane. If you are migrating from Version 2 of the UDDI Registry, the Version 2 data is migrated now. The initialization may take some time to complete.

If the node has been migrated from a previous version, return to ″Migrating to Version 3 of the UDDI Registry″ to verify that the migration was successful. If you have created a new node, you are now ready to use the UDDI Registry.

Setting up a default UDDI node

There are two ways to setup a default UDDI node:

- Either by executing the `uddiDeploy.jacl` script and specifying the **default** option. This creates a running default UDDI node within an embedded Cloudscape database, or
- Executing an additional step after you have created your database.

Run one of the following

1. **Optional: For a default Cloudscape UDDI node:**

   For a default Cloudscape network deployment configuration, read the section Installing into a Network Deployment Cell first.

   Deploy the UDDI Registry by running the wsadmin script uddiDeploy.jacl, as shown, from the *install_root*/bin directory.

   The syntax of the command is as follows:

```
wsadmin.sh [-conntype none] -wsadmin_classpath install_root/cloudscape/lib
               -f uddiDeploy.jacl
               node_name
               server_name
               default
```

   where

   - '-conntype none' is optional, and is only needed if the application server is not running.
   - *install_root* is the directory name of the WebSphere Application Server install location.
   - *node_name* is the name of the WebSphere node on which the target server runs. Note that the node name is case sensitive.

- *server_name* is the name of the target server on which you wish to deploy the UDDI Registry, such as server1. Note that the server name entered is case sensitive.
- 'default' causes the command to create a UDDI node, with default policies, within a Cloudscape database and datasource. This is a special case only for Cloudscape and creates everything required to run a UDDI node, in a standalone application server. Note that this option cannot be used in a network deployment configuration.

For example, to create a UDDI node called 'MyNode' on server 'server1', you might enter the following (this assumes server1 is started):

```
wsadmin.sh -wsadmin_classpath /WebSphere/V6R0M0/AppServer/cloudscape/lib -f uddiDeploy.jacl MyNode server1 default
```

(Note that these should be entered as one command on a single line)

You should now start the UDDI application, or start the application server if it is not already running. This will activate the UDDI node.

Note: Restarting the UDDI application, or the application server, will always result in the reactivation of the UDDI node, even if the node was previously deactivated.

2. **Optional: For a default DB2 or default Cloudscape UDDI node:**

   DB2 or Cloudscape may be used for a single application server installation or a Network Deployment installation, including a cluster configuration. For the cluster configuration you must use network Cloudscape, as embedded Cloudscape is not supported for this scenario.

   a. Create a database schema to hold the UDDI registry by executing one of the following, ensuring that you perform the final step to set the default node indicator in the database:
      - Creating a DB2 database
      - Creating a Cloudscape database

   b. Create a J2C Authentication Data Entry (not required for embedded Cloudscape, but required for network Cloudscape):
      1) Expand **Security**, **Global Security** and **JAAS Configuration** (on the right), then click **J2C Authentication Data**.
      2) Click **New** to create a new J2C authentication data entry
      3) Fill in the details as follows:

         Alias a suitable (short) name, such as ″UDDIAlias″

         Userid
         the database userid (such as db2admin for DB2), which is used to read and write to the UDDI registry database. For network Cloudscape the userid can be any value.

         Password
         the password associated with the userid specified above. For network Cloudscape the password can be any value.

         Description
         a suitable description to describe the chosen userid.

      Click **Apply** and then Save the changes to the master configuration.

   c. Create a JDBC Provider (if a suitable one does not already exist), using the following table to determine the provider type and implementation type for your chosen database:

Database	Provider type	Implementation type
DB2	DB2 Universal JDBC Driver Provider	Connection Pool datasource
Embedded Cloudscape	Cloudscape JDBC Driver	Connection Pool datasource
Network Cloudscape	Cloudscape Network Server Using Universal JDBC Driver	Connection Pool datasource

   For details on how to create a JDBC provider, see either Using a DB2 Universal JDBC Driver Provider with WebSphere Application Server for z/OS, if you are using DB2 (do not follow the

instructions for creating a datasource; this is covered within the current task), orCreating and configuring a JDBC provider using the administrative console, for other database types.

d. Create a datasource for the UDDI Registry by following these steps:
   1) Expand **Resources** and **JDBC Providers**.
   2) Select the desired 'scope' of the JDBC provider created earlier. For example, select:

      `Server: yourservername`

      to show the JDBC providers at the server level.
   3) Select the JDBC provider created earlier.
   4) Under **Additional Properties**, select **Data Sources** (*not* the Data Sources Version 4 option).
   5) Click **New** to create a new datasource.
   6) Fill in the details for the datasource as follows:

      Name a suitable name, such as UDDI Datasource

      JNDI name
      set to **datasources/uddids** - this value is obligatory.

      Note: You must not have any other datasources using this JNDI name. If you have another datasource using this JNDI name, then you must either remove it or change its JNDI name. For example, if you have previously created a default UDDI node using Cloudscape, you should use the uddiRemove.jacl script with the default option to remove the datasource and the UDDI application instance, before continuing.

      Use this Data Source in container-managed persistence (CMP)
      ensure the check box is cleared.

      Description
      a suitable description

      Category
      set to uddi

      Data store helper class name
      filled in for you as:

Database	Data store helper class name
DB2	com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper
Embedded Cloudscape	com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper
Network Cloudscape	com.ibm.websphere.rsadapter.CloudscapeNetworkServerDataStoreHelper

      Component-managed authentication alias
      - for **DB2** or **network Cloudscape**, select the alias that you created in step 2 from the pulldown. It will have the node name appended in front of it, for example MyNode/UDDIAlias.
      - for **embedded Cloudscape** leave this set to (none).

      Container-managed authentication alias
      Set to (none)

      Mapping-configuration alias
      Set to DefaultPrincipalMapping

      Relational Database Management System **data source properties**
      - for **DB2**:

Database name
this is the local LOCATION value. To find this value, enter the following operator command using the DB2 interactive panels:

```
-DIS DDF
```

Driver type
set to 2

- for **Cloudscape** (embedded or network) - **Database name** - for example:

  install_root/databases/com.ibm.uddi/UDDI30

  For network Cloudscape, also make sure that the **Server name** and **Port number** match the network server.

Leave all other fields unchanged.

Click **Apply** and Save the changes to the master configuration.

e. Test the connection to your UDDI database by selecting the check box next to the datasource and clicking **Test connection**. You will see a message similar to ″Test Connection for datasource UDDI Datasource on server server1 at node MyNode was successful″. If you do not see this message investigate the problem with the help of the error message.

f. Deploy the UDDI Registry by running the wsadmin script uddiDeploy.jacl, as shown, from the *install_root*/bin directory.

The syntax of the command is as follows:

```
wsadmin.sh [-conntype none] -f uddiDeploy.jacl
              node_name
              server_name
```

6.1+

```
wsadmin.sh [-conntype none] -f uddiDeploy.jacl
              {node_name server_name | cluster_name}
```

where

- '-conntype none' is optional, and is only needed if the application server is not running.
- *node_name* is the name of the WebSphere node on which the target server runs. Note that the node name is case sensitive.
- *server_name* is the name of the target server on which you wish to deploy the UDDI Registry, such as server1. Note the server name entered is case sensitive.
- 6.1+ *cluster_name* is the name of the target cluster into which you wish to deploy the UDDI registry. Note that the cluster name entered is case sensitive.

You are recommended to deploy the UDDI application using the uddiDeploy.jacl script, but note that you can also use the administrative console to deploy the application in the normal way. If you use the administrative console you must ensure that the Classloader Mode for the application is set to PARENT_LAST, and that the WAR class loader Policy is set to Application. The uddiDeploy.jacl script in a command prompt will do this for you.

For example, to deploy UDDI on node 'MyNode' and server 'server1' (assuming that server1 is already started):

```
wsadmin.sh -f uddiDeploy.jacl MyNode server1
```

6.1+ To deploy UDDI into cluster 'MyCluster' :

```
wsadmin.sh -f uddiDeploy.jacl MyCluster
```

g. Start the UDDI application, or start the application server if it is not already running. This will activate the UDDI node.

Note: Restarting the UDDI application, or the application server, will always result in the reactivation of the UDDI node, even if the node was previously deactivated.

As you have chosen to use a default UDDI node, it will be initialized when the UDDI application is started for the first time.

Creating a DB2 database for the UDDI Registry

Perform this task if you want to use DB2 as the database store for your UDDI Registry data. You only need to do this once for each UDDI Registry, as part of Setting up and deploying a UDDI Registry.

1. Using the UNIX System Services (USS) command prompt, edit the createddl.sh script supplied in *install_root*/UDDIReg/rexx, as follows:
   a. Search for the text 'Define some constants'.
   b. If you have installed WebSphere Application Server in a non default location, update the root_dir constant to reflect this (note that the UDDIReg directory must remain at the end of the path).
   c. Update the temp_dir constant to a temporary directory of your choice, if you do not want to accept the default.
2. Using the USS command prompt, run the createddl.sh script by entering the following command:

   ```
   createddl.sh database_name tablespace_name hlq
   ```

   where the parameters are as follows:

   database_name
   This is the name which will be used when defining the required DB2 tables and other components. The default is UDDI30.

   tablespace_name
   This is the tablespace in which the database's tables will be defined. The default is UDDI30TS.

   hlq This is the high level qualifier under which the SQL and JCL partitioned datasets (PDS) will be created. The default is IBMUSER.

   The script generates the partitioned data sets *hlq*.UDDI.SQL and *hlq*.UDDI.JCL, containing members that are required for subsequent steps.Using the default parameters listed above, a successful execution of the script results in the following output:

   ```
   database.tablespace = UDDI30.UDDI30TS
    HLQ = IBMUSER
    (  14) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_10_prereq_db2.sql
    ( 436) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_20_tables_generic.sql
    ( 136) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_25_tables_db2udb.sql
    ( 452) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_30_constraints_generic.sql
    (  14) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_35_constraints_db2udb.sql
    ( 559) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_40_views_generic.sql
    (  94) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_45_views_db2udb.sql
    ( 329) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_50_triggers_db2udb.sql
    (  16) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_60_insert_initial_static_data.sql
    (  39) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_70_insert_default_database_indicator.sql
    Conversion complete
    /tmp/udditmp/makedb71.jcl     ===> IBMUSER.UDDI.JCL(MAKEDB71)
    /tmp/udditmp/makedb81.jcl     ===> IBMUSER.UDDI.JCL(MAKEDB81)
    /tmp/udditmp/table.sql        ===> IBMUSER.UDDI.SQL(TABLE)
    /tmp/udditmp/table7.sql       ===> IBMUSER.UDDI.SQL(TABLE7)
    /tmp/udditmp/index.sql        ===> IBMUSER.UDDI.SQL(INDEX)
    /tmp/udditmp/view.sql         ===> IBMUSER.UDDI.SQL(VIEW)
    /tmp/udditmp/trigger.sql      ===> IBMUSER.UDDI.SQL(TRIGGER)
    /tmp/udditmp/alter.sql        ===> IBMUSER.UDDI.SQL(ALTER)
    /tmp/udditmp/initial.sql      ===> IBMUSER.UDDI.SQL(INITIAL)
    /tmp/udditmp/insert.sql       ===> IBMUSER.UDDI.SQL(INSERT)
   ```

3. There are two sample jobs in the JCL library for creating the DB2 database, one for DB2 version 7 and one for DB2 version 8. The JCL for these jobs can be found in members MAKEDB71 and MAKEDB81 respectively, in the *hlq*.UDDI.JCL PDS. These JCL scripts are templates; modify the template in the appropriate MAKEDB member according to your DB2 setup and whether you want a default or a customized UDDI node:
   - Add or modify the JOB accounting information, if required.

- If you used a different high level qualifier from the default when running the script in step one, ensure that all occurrences of IBMUSER are changed to the qualifier that you specified.
- If you do not want your database to be used as a default UDDI node, comment out the line of the job which specifies the INSERT member of the SQL PDS; this should be the last line in the job.
- Ensure that all occurrences of the LIB parameter correctly reflect the directory into which you installed DB2.

4. Use TSO to submit the job that you modified in the previous step. The job will create the DB2 database.

Continue with setting up and deploying your UDDI Registry node.

Creating a Cloudscape database for the UDDI Registry

Perform this task if you want to use Cloudscape (embedded or network) as the database store for your UDDI Registry, and you do not want to use the default option on uddiDeploy.jacl (see 'Setting up a default UDDI node'). The most likely reasons for not using the default option on uddiDeploy.jacl are that you want to set up a customized UDDI node, or that you are deploying UDDI into a Network Deployment cell. You need only perform this task once for each UDDI Registry, as part of the Setting up and deploying a UDDI Registry.

The commands below use a number of arguments for which you need to enter appropriate values. You should decide the values that you will use before you start. The arguments used, and suggested values, are:

arg1 is the path of the SQL files, which on a standard install will be *install_root*/UDDIReg/databaseScripts

arg2 is the path to the location where you want to install the Cloudscape database, for example *install_root*/profiles/*profile_name*/databases/com.ibm.uddi

arg3 is the name of the Cloudscape database. A recommended value is UDDI30, and this name is assumed throughout the UDDI documentation. If you use another name, you should substitute that name whenever you see 'UDDI30' in other sections of the UDDI documentation.

arg4 is an optional argument, and must either be omitted or be the string 'DEFAULT'. DEFAULT should only be specified if you want your database to be used as a default UDDI node. Note that this argument is case sensitive.

Run the following java -jar command from the *install_root*/lib directory, to create the UDDI Cloudscape database:

```
java -cp install_root/cloudscape/lib/db2j.jar -jar UDDICloudscapeCreate.jar arg1 arg2 arg3 arg4
```

Continue with setting up and deploying your UDDI Registry node.

Using a remote database for the UDDI Registry

It is possible for the UDDI Registry database to be hosted on a separate system (remote system) from the system on which the UDDI Registry application is deployed.

This is achieved using standard database capabilities of the database product used for the UDDI Registry database. You should refer to documentation for the database product if you are not familiar with these capabilities. Some considerations specific to each database product are:

Remote DB2

Create a DB2 UDDI database on the remote system, and use the DB2 Client to create an alias to reference it. Use the alias name as the Database name in the UDDI datasource.

Networked Cloudscape

Create a Cloudscape UDDI database on the remote system, and use the Cloudscape Network Server using Universal data source properties (Database name, Server name and Port number) of the UDDI datasource to reference the remote Cloudscape database.

For details of how to set up Cloudscape for multiple connections see Configuring Cloudscape Version 5.1.60x.

Note: Embedded Cloudscape is not supported for this configuration.

UDDI Registry Installation Verification Program (IVP)

This topic describes a simple test that you can carry out as an Installation Verification Program (IVP) to verify that you have deployed a UDDI Registry successfully. You should perform this task *after* you have followed the instructions in Setting up and Deploying a new UDDI Registry.

1. Open a browser window and enter the URL that accesses the UDDI Registry User Interface (see ″Displaying the user interface″ in the information center).
2. Under the **Quick Find** heading on the **Find** tab, click the **Business** radio button and enter % in the **Starting with** field.
3. Click **Find**. If you have deployed your UDDI Registry successfully, the detail frame displays the business entity which represents this UDDI node. You can click on the business entity to see its detail.

As a further installation verification test, you can publish and find more UDDI entities by using the UDDI Registry User Interface, or you can compile and run one or more of the UDDI Registry Samples.

Publishing WSDL files

To publish a Web Services Description Language (WSDL) file you need an enterprise application, also known as an enterprise archive (EAR) file, that contains a Web services-enabled module and has been deployed into WebSphere Application Server. See Deploying Web services based on Web Services for Java 2 platform, Enterprise Edition (J2EE).

The purpose of publishing the WSDL file is to provide clients with a description of the Web service, including the URL identifying the location of the service.

After installing a Web services application, and optionally modifying the endpoint information, you might need WSDL files containing the updated endpoint information. You can obtain the updated WSDL files by publishing them to the file system. If you are a client developer or a system administrator, you can use WSDL files to enable clients to connect to a Web service.

Before you publish a WSDL file, you can configure Web services to specify endpoint information in the form of URL fragments to enable full URL specification of WSDL ports. Refer to the tasks describing configuring endpoint URL information.

The WSDL files for each Web services-enabled module are published to the file system location you specify. You can provide these WSDL files to clients that want to invoke your Web services.

You can specify endpoint information for HTTP ports, Java Message Service (JMS) ports or directly access enterprise JavaBeans (EJBs) that are acting as Web services.

To publish a WSDL file:

1. Configure the URL endpoint information. Do one of the following depending on what kind of bindings you are using:

- Configure the URL endpoint information for HTTP bindings - See ″Configuring endpoint URL information for HTTP bindings″ in the information center.
- Configure the URL endpoint information for JMS bindings.
- Configure the URL endpoint information to directly access enterprise beans. See ″Configuring endpoint URL information to directly access enterprise beans″ in the information center.

2. Externalize or publish the WSDL file out of the application. You can complete this task in one of three ways:
   - Publish a WSDL file with the administrative console. See ″Publishing WSDL files using the administrative console″ in the information center.
   - Publish a WSDL file through a URL. See ″Publishing WSDL files using a URL″ in the information center.
   - Publish a WSDL file with the **wsadmin** command tool. See ″Publishing WSDL files using the wsadmin tool″ in the information center.

Apply security to the Web service.

WSDL

Web Services Description Language (WSDL) is an Extensible Markup Language (XML)-based description language. This language was submitted to the World-Wide Web Consortium (W3C) as the industry standard for describing Web services. The power of WSDL is derived from two main architectural principles: the ability to describe a set of business operations and the ability to separate the description into two basic units. These units are a description of the operations and the details of how the operation and the information associated with it are packaged.

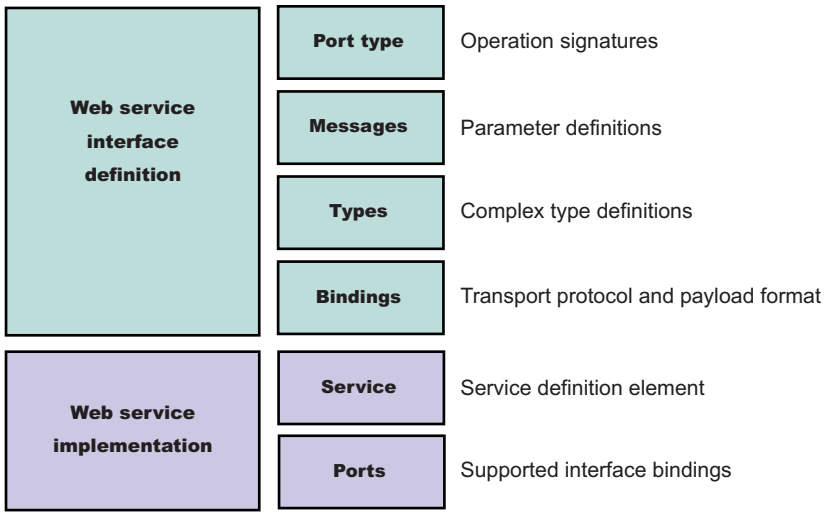
A WSDL document defines services as collections of network endpoints, or ports. In WSDL, the abstract definition of endpoints and messages is separated from their concrete network deployment or data format bindings. This separation supports the reuse of abstract definitions: messages, which are abstract descriptions of exchanged data, and port types, which are abstract collections of operations. The concrete protocol and data format specifications for a particular port type constitutes a reusable binding. A port is defined by associating a network address with a reusable binding, and a collection of ports define a service. Therefore, a WSDL document is composed of several elements. See WSDL architecture for more information and examples of the WSDL elements.

When creating Web services for WebSphere Application Server, you must first have an implementation bean that includes a service endpoint interface. Then, you use the Java2WSDL command-line tool to create a WSDL file that defines the Web services. To learn more about how the WSDL file is used in the development process, see Developing Web services.

WSDL architecture

Web Services Description Language (WSDL) files are written in Extensible Markup Language (XML). To learn more about XML, see Web services: Resources for learning.

The following is the structure of the information in a WSDL file:



A WSDL file contains the following parts:

- **Web service interface definition**
  This is part contains the elements, as well as the namespaces.
- **Web service implementation**
  This part contains the definition of the service and ports.

A WSDL file describes a Web service with the following elements:

portType

The description of the operations and associated messages. The portType element defines abstract operations.

```
<portType name="EightBall">
 <operation name="getAnswer">
  <input message="ebs:IngetAnswerRequest"/>
  <output message="ebs:OutgetAnswerResponse"/>
 </operation>
</portType>
```

message

The description of input and output parameters and return values.

```
<message name="IngetAnswerRequest">
 <part name="meth1_inType" type="ebs:questionType"/>
</message>
<message name="OutgetAnswerResponse">
 <part name="meth1_outType" type="ebs:answerType"/>
</message>
```

types

The schema for describing XML types used in the messages.

```
<types>
 <xsd:schema targetNamespace="...">
  <xsd:complexType name="questionType">
   <xsd:element name="question" type="string"/>
```

```
  </xsd:complexType>
  <xsd:complexType name="answerType">
  ...
</types>
```

binding

The bindings describe the protocol that is used to access a portType, as well as the data formats for the messages that are defined by a particular portType element.

```
<binding name="EightBallBinding" type="ebs:EightBall">
 <soap:binding style="rpc" transport="schemas.xmlsoap.org/soap/http">
 <operation name="ebs:getAnswer">
 <soap:operation soapAction="urn:EightBall"/>
  <input>
   <soap:body namespace="urn:EightBall" ... />
  ...
```

The services and ports define the location of the Web service.

Service

The service contains the Web service name and a list of ports.

Ports

The ports contain the location of the Web service and the binding used for service access.

```
<service name="EightBall">
 <port binding="ebs:EightBallBinding" name="EightBallPort">
  <soap:address location="localhost:8080/axis/EightBall"/>
 </port>
</service>
```

Multipart WSDL best practices

WebSphere Application Server supports deployment of Web services using a multipart Web Services Description Language (WSDL) file. In multipart WSDL files, an implementation WSDL file contains the wsdl:service. This implementation WSDL flie imports an interface WSDL file, which contains the other WSDL constructs. This supports multiple Web services using the same WSDL interface definition.

The <wsdl:import> element indicates a reference to another WSDL file. If the <wsdl:import> element location attribute does not contain a URL, that is, it contains only a file name, and does not begin with `http://`, `https://` or `file://`, the imported file must be located in the same directory and must not contain a relative path component. For example, if `META-INF/wsdl/A_Impl.wsdl` is in your module and contains the `<wsdl:import="A.wsdl" namespace="..."/>` import statement, the `A.wsdl` file must also be located in the module `META-INF/wsdl` directory.

It is recommended that you place all WSDL files in either the `META-INF/wsdl` directory, if you are using Enterprise JavaBeans (EJB), or the `WEB-INF/wsdl` directory, if you are using JavaBeans components, even if relative imports are located within the WSDL files. Otherwise, implications exist with the WSDL publication when you use a path like `<location="../interfaces/A_Interface.wsdl"namespace="..."/>`. Using a path like this example fails because the presence of the relative path, regardless of whether the file is located at that path or not. If the location is a Web address, it must be readable at both deployment and server startup.

WSDL publication

You can publish the files located in the `META-INF/wsdl` or the `WEB-INF/wsdl` directory through either a URL address or file, including WSDL or XSD files. For example, if the file referenced in the <wsdl-file> element

of the webservices.xml deployment descriptor is located in the META-INF/wsdl or the WEB-INF/wsdl directory, it is publishable. If the files imported by the <wsdl-file> are located in the wsdl/ directory or its subdirectory, they are publishable.

If the WSDL file referenced by the <wsdl-file> element is located in a directory other than wsdl, or its subdirectories, the file and its imported files, either WSDL or XSD files, which are in the same directory, are copied to the wsdl directory without modification when the application is installed. These types of files can also be published.

If the <wsdl-file> imports a file located in a different directory (a directory that is not -INF/wsdl or a subdirectory), the file is not copied to the wsdl directory and not available for publishing.

Configuring endpoint URL information for JMS bindings

WebSphere Application Server supports the use of the Java Message Service (JMS) API to transport Web services requests, as an alternative to using HTTP.

Review the topic ″Using the Java Message Service to transport Web services requests″ in the information center.

Configuring a service endpoint is necessary to connect Web service clients to any Web services among the components being assembled or to any external Web services. You can configure the endpoint URL information for JMS during application installation

In this task, enter the JMS endpoint URL prefix to use for each Web service-enabled enterprise JavaBean (EJB) Java archive (JAR) file that belong to the application. The JMS endpoint URLs are included in the Web Service Description Language (WSDL) files published for clients to use.

You can specify HTTP URL prefixes for Web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. These prefixes are used to form complete endpoint addresses that are included in WSDL files when published.

You can specify JMS URL prefixes by using the Provide JMS and EJB endpoint URL information panel in the administrative console during or after application installation.

To configure JMS URL prefixes:

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Provide JMS and EJB endpoint URL information**.
3. Locate the list of Web services modules that are accessible through JMS transport.
4. Type the JMS URL fragment in the **URL fragment** field. Enter a URL fragment that is a prefix to the initial URL part that is obtained by examining the deployment information of the Web service. See the usage scenario following this task for more information.

   The value that you enter is used to define the location attribute of the port soap:address element within the WSDL file that is published using the *application_name*_ExtendedWSDLFiles.zip or the *application_name*_WSDLFiles.zip file on the Publish WSDL zip files panel.

You have a Web service that is accessible through the JMS transport and configured with JMS bindings.

Suppose an application called StockQuoteService contains an EJB JAR file that is named StockQuoteEJB, which contains one or more Web services that are accessible through the JMS transport. In ″Using the Java Message Service API to transport Web services requests″ you defined a queue with the Java Naming and Directory Interface (JNDI) name of jms/StockQuote_Q, and a connection factory with the JNDI name of jms/StockQuote_CF, for your application. In this example, you specify the following string as the JMS URL prefix within the Provide JMS and EJB endpoint URL information panel:

jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF

The WSDL publisher uses this partial URL string to produce the actual JMS URL for each port component that is defined in the module. The targetService=<*port_name*> string is added to the end of the JMS URL, for example:

jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF&targetService=getQuote

The published WSDL file is used by clients to invoke the Web service.

Publish WSDL files.

Provide JMS and EJB endpoint URL information

Use this page to specify endpoint URL fragments for Web services accessed through SOAP and Java Message Service (JMS) or directly as enterprise JavaBean (EJBs). Fragments are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications** >**Enterprise Applications** > *application_instance* > **Provide JMS and EJB endpoint URL information**.

You can specify a fragment of the endpoint URL to be used in each Web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's soap:address element.

If you are using Web services modules that are configured to use JMS or configured to access EJBs directly, these modules are listed on this panel.

URL fragment for JMS:

Specifies a URL fragment for Web services accessed through a JMS transport. You can enter a value that is used to define the soap:address of a Web service. When WSDL files are published, a URL is formed using this fragment and is contained in the WSDL files.

The URL fragment that is entered as a value is a prefix to which the targetService=property is appended to form a complete JMS URL endpoint. The default value is obtained by examining the installed service's deployment information, for example, jms:/queue?destination=jms/MyQueue&connectionFactory=jms/MyCF.

This information is obtained from the Web service's configured JMS endpoint, which is a Message Driven Bean (MDB) defined by the **endpointEnabler** command-line tool. You can modify the URL fragment, for example, by adding properties. The URL fragment is combined with the targetService property to form the complete URL, for example,
jms:/queue?destination=jms/MyQueue&connectionFactory=jms/MyCF&priority=5&targetService=GetQuote.

URL fragment for EJB:

Specifies a URL fragment for Web services accessed through an EJB binding. You can enter a value used to define the location attribute of the port's generic:address element of a Web service. This port address is contained in the WSDL zip file when the zip file is published using the ***application_name_ExtendedWSDLFiles*.zip** field on the **Publish WSDL zip file** panel.

The URL fragment value entered is a suffix, which is appended to the initial part of the URL obtained by examining the Web service's deployment information. For example, the following URL fragment can be obtained from the EJB's deployment information:
wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome.

In this case, you can enter the following information in the URL fragment field, `jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809`, which results in this endpoint URL, `wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome&jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809`.

Configuring Web services applications with the wsadmin tool

You can use the wsadmin scripting tool to complete the several tasks for a Web services application.

Develop a Web services application.

The WebSphere Application Server wsadmin tool provides the ability to run scripts. You can use the wsadmin tool to manage a WebSphere Application Server installation, as well as configuration, application deployment, and server run-time operations. The WebSphere Application Server only supports the Jacl and Jython scripting languages.

To use the wsadmin tool to configure a Web services application or publish a Web Services Description Language (WSDL) file:

1. Launch a scripting command. See ″Starting the wsadmin scripting client″ in the information center.
2. Follow the steps in one of the following topics, depending on what task you want to complete:
   - Configure Web service client bindings. See ″Configuring a Web service client deployed WSDL file name with the wsadmin tool″ in the information center.
   - Configure Web service client preferred port mappings. See ″Configuring Web service client-preferred port mappings with the wsadmin tool″ in the information center.
   - Configure Web service client port information. See ″Configuring Web service client port information with the wsadmin tool″ in the information center.
   - Configure the scope of a Web service port. See ″Configuring the scope of a Web service port with the wsadmin tool″.

You have configured Web services applications with the wsadmin tool.

WSIF system management and administration

The Web Services Invocation Framework (WSIF) is provided as a stand-alone JAR file named `wsif.jar`. The JAR file contains the core WSIF classes, and the Java, EJB, SOAP over HTTP and SOAP over JMS providers. Additional providers are packaged as separate JAR files.

When you install WebSphere Application Server, the `wsif.jar` file is put on the WebSphere or Java Virtual Machine (JVM) class path.

WSIF requires no further configuration. WSIF is a thin abstraction layer between application code and the relevant invocation infrastructure.

For specific information on other aspects of managing your WSIF system, see the following topics:
- Maintaining the WSIF properties file
- Enabling security for WSIF
- Trace and logging for WSIF
- Troubleshooting the Web Services Invocation Framework
- WSIF (Web Services Invocation Framework) messages
- WSIF - Known restrictions.

Maintaining the WSIF properties file

The Web Services Invocation Framework (WSIF) properties are stored in the `wsif.jar` file, in a properties file named `wsif.properties`.

The wsif.jar file is located in the *install_root*/lib directory, where *install_root* is the root directory for your installation of IBM WebSphere Application Server.

You must keep the “as shipped” wsif.properties file on the class path, so that WSIF can find it and the client administrator can use it to configure WSIF. However if you make any changes to the file, you do not replace the original copy in the wsif.jar file. Instead, you save the modified version in the *install_root*/lib/properties directory.

Here is a copy of the initial contents of the wsif.properties file. All the possible properties are listed and described.

```
# Two properties are used to override which WSIFProvider is selected when there
# exists multiple providers supporting the same namespace URI. These properties are:
#
#    wsif.provider.default.CLASSNAME=N
#    wsif.provider.uri.M.CLASSNAME=URI
#
# CLASSNAME is the WSIFProvider class name
# N is the number of following default wsif.provider.uri.M.CLASSNAME properties
# M is a number from 1 to N to uniquely identify each wsif.provider.uri.M.CLASSNAME
#   property key.
# For example the following two properties would override the default SOAP provider
# to be the Apache SOAP provider:
#
# wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
# wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=\
# http://schemas.xmlsoap.org/wsdl/soap/
#

# maximum number of milliseconds to wait for a response to a synchronous request.
# Default value if not defined is to wait forever.
# Timeout properties are only used by providers which support timeouts.
wsif.syncrequest.timeout=10000

# maximum number of seconds to wait for a response to an async request.
# if not defined on invalid defaults to no timeout
# Timeout properties are only used by providers which support timeouts.
wsif.asyncrequest.timeout=60
```

To enable your legacy Web services to continue to work with WSIF, you might need to change the default WSIF SOAP provider back to the former Apache SOAP provider. See ″Changing the default WSIF SOAP provider″ in the information center.

Enabling security for WSIF

The Web Services Invocation Framework (WSIF) interacts with a security manager in the following ways:

- WSIF runs in the Java 2 platform, Enterprise Edition (J2EE) security context without modification.
- When WSIF is run under a J2EE container, port implementations can use the security context to pass on security tokens or credentials as necessary.
- WSIF implementations can automatically convert J2EE security context into appropriate context for onward services.

For WSIF to interact effectively with the WebSphere Application Server security manager, enable the following permission in the was.policy file: **FilePermission** to load the WSDL. This permission is required when a WSDL file is referred to using the file:// protocol.

Troubleshooting the Web Services Invocation Framework

For information on resolving WebSphere-level problems, see ″Diagnosing problems (using diagnosis tools)″ in the information center.

To identify and resolve Web Services Invocation Framework (WSIF)-related problems, you can use the standard WebSphere Application Server trace and logging facilities. If you encounter a problem that you think might be related to WSIF, you can check for error messages in the WebSphere Application Server administrative console, and in the application server `stdout.log` file. You can also enable the application server debug trace to provide a detailed exception dump.

A list of the WSIF run-time system messages, with details of what each message means, is provided in Message reference for WSIF.

A list of the main known restrictions that apply when using WSIF is provided in WSIF - Known restrictions.

Here is a checklist of major WSIF activities, with advice on common problems associated with each activity:

Create service
Handcrafted WSDL can cause numerous problems. To help ensure that your WSDL is valid, use a tool such as WebSphere Studio to create your service.

Define transport mechanism
For the Java Message Service (JMS), check that you have set up the Java Naming and Directory Interface (JNDI) correctly, and created the necessary connection factories and queues.

For SOAP, make sure that the deployment descriptor file `dds.xml` is correct - preferably by creating it using WebSphere Studio or similar tooling.

Create client - Java code
Follow the correct format for creating a WSIF service, port, operation and message. For examples of correct code, see the sample in ″Developing the WSIF client - the Address Book Sample″ in the information center.

Compile code (client and service)
Check that the build path against code is correct, and that it contains the correct levels of JAR files.

Create a valid EAR file for your service in preparation for deployment to a Web server.

Deploy service
When you install and deploy the service EAR file, check carefully any messages given when the service is deployed.

Server setup and start
Make sure that the WebSphere Application Server `server.policy` file (in the `/properties` directory) has the correct security settings. For more information, see Enabling security for WSIF.

WSIF setup
Check that the `wsif.properties` file is correctly set up. For more information, see Maintaining the WSIF properties file.

Run client
Either check that you have defined the class path correctly to include references to your client classes, WSIF JAR files and any other necessary JAR files, or (preferably) run your client using the WebSphere Application Server launchClient tool.

Here is a list of common errors, and information on their probable causes:

- **“No class definition” errors received when running client code.**

  This problem usually indicates an error in the class path setup. Check that the relevant JAR files are included.

- **“Cannot find WSDL” error.**

  Some likely causes are:
  – The application server is not running.
  – The server location and port number in the WSDL are not correct.
  – The WSDL is badly formed (check the error messages in the application server `stdout.log` file).
  – The application server has not been restarted since the service was installed.

  You might also try the following checks:

- Can you load the WSDL into your Web browser from the location specified in the error message?
- Can you load the corresponding WSDL binding files into your Web browser?

- **Your Web service EAR file does not install correctly onto the application server.**

  It is likely that the EAR file is badly formed. Verify the installation by completing the following steps:
  - For an EJB binding, run the WebSphere Application Server tool `\bin\dumpnamespace`. This tool lists the current contents of the JNDI directory.
  - For a SOAP over HTTP binding, open the `http://pathToServer/WebServiceName/admin/list.jsp` page (if you have the SOAP administration pages installed). This page lists all currently installed Web services.
  - For a SOAP over JMS binding, complete the following checks:
    - Check that the queue manager is running.
    - Check that the necessary queues are defined.
    - Check the JNDI setup.
    - Use the "display context" option in the `jmsadmin` tool to list the current JNDI definitions.
    - Check that the Remote Procedure Call (RPC) router is running.

- **There is a permissions problem or security error.**

  Check that the WebSphere Application Server `server.policy` file (in the `/properties` directory) has the correct security settings. For more information, see Enabling security for WSIF.

- **Using WSIF with multiple clients causes a SOAP parsing error.**

  Before you deploy a Web service to WebSphere Application Server, you must decide on the scope of the Web service. The deployment descriptor file `dds.xml` for the Web service includes the following line:

  ```
  <isd:provider type="java" scope="Application" ......
  ```

  You can set the `Scope` attribute to `Application` or `Session`. The default setting is `Application`, and this value is correct if each request to the Web service does not require objects to be maintained for longer than a single instance. If `Scope` is set to `Application` the objects are not available to another request during the execution of the single instance, and they are released on completion. If your Web service needs objects to be maintained for multiple requests, and to be unique within each request, you must set the scope to `Session`. If `Scope` is set to `Session`, the objects are not available to another request during the life of the session, and they are released on completion of the session. If scope is set to `Application` instead of `Session`, you might get the following SOAP error:

```
SOAPException: SOAP-ENV:ClientParsing error, response was:
FWK005 parse may not be called while parsing.;
nested exception is:

[SOAPException: faultCode=SOAP-ENV:Client; msg=Parsing error, response was:

FWK005 parse may not be called while parsing.;
        targetException=org.xml.sax.SAXException:
FWK005 parse may not be called while parsing.]
```

- **Using the same names for JMS messaging queues and queue connection factories that run on application servers on different machines can cause JNDI lookup errors.** You should not use the same names for messaging queues and queue connection factories that run on application servers on different machines, because WSIF always looks first for JMS destinations locally, and only uses the full JNDI reference if it cannot find the destination locally. For example, if you run a Web service on a remote machine, and have an application server running locally that uses the same names for the messaging queues and queue connection factories, then WSIF will find and use the local queues even if the remote JNDI destination is provided in full in the WSDL service definition.

- **A JAX-RPC client running on WebSphere Application Server Version 5 uses SOAP over JMS to invoke a Web service running on a Version 5 application server. No username or password is required on the target MQ Series queue. After the application server is migrated to Version 6, and using Version 6 default messaging, client requests fail because basic authentication is now enabled.**

  The problem appears as a log message:

```
SibMessage    W   [:] CWSIT0009W: A client request failed in the application server with endpoint <endpoint_name>
in bus your_bus with reason: CWSIT0016E: The user ID null failed authentication in bus your_bus.
```

When the application server is migrated to Version 6, and the default messaging provider (service integration technologies) is used, and global security is enabled for the server or cell, then by default the service integration bus queue destination inherits the security characteristics of the server or cell. So if the server or cell has basic authentication enabled, then the client request fails.

To resolve the problem, you have three choices (in order of security, from least secure to most secure):

– Disable global security.

– For an equivalent level of security to the configuration on Version 5, modify the settings for the service integration bus that hosts the queue destination so that bus security is disabled and therefore the bus does not inherit security characteristics from the server or cell.

– For a greater level of security than the configuration on Version 5, configure basic authentication on each client that uses the service.

To disable global security, refer to either of these topics:

– Global security settings.

– Enabling and disabling global security using scripting.

To disable bus security, use the administrative console to complete the following steps:

1. Navigate to **Service Integration** → **Buses [Content Pane]** → **your_bus**.
2. Clear the **Secure** check box.
3. Save your changes.

To configure basic authentication on each client, use either the administrative console or the `wsadmin` tool. To complete the task using the `wsadmin` tool, see ″Configuring Web service client port information with the wsadmin tool″ in the information center and use the `WebServicesClientBindPortInfo wsadmin` task option. To complete the task using the administrative console, complete the following steps:

1. Navigate to **Applications** → **Enterprise Applications** → **application_instance** → **Web Modules or EJB Modules** → **module_instance** → **Web services: Client security bindings**.
2. Click **HTTP basic authentication** to access the “Configuring HTTP basic authentication with the administrative console” panel.
3. Enter the values in the panel.
4. Save your changes.

- **The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are running on the former (Apache SOAP) provider.** This restriction is due to the fact that the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant Web service, and Apache SOAP cannot provide such a service. To enable interoperation, modify either your Web service or the WSIF default SOAP provider as described in ″WSIF SOAP provider: working with legacy applications″ in the information center.

Trace and logging for WSIF:

If you want to enable trace for the Web Services Invocation Framework (WSIF) API within WebSphere Application Server, and have trace, stdout and stderr for the application server written to a well-known location, see and ″Setting up component trace (CTRACE)″.

WSIF offers trace points at the opening and closing of ports, the invocation of services, and the responses from services.

To trace the WSIF API, you need to specify the following trace string:

```
wsif=all=enabled
```

WSIF also includes a `SimpleLog` utility through which you can run trace when using WSIF outside of WebSphere Application Server. To enable this utility, complete the following steps:

1. Create a file named `commons-logging.properties` with the following contents:

```
org.apache.commons.logging.LogFactory=org.apache.commons.logging.impl.LogFactoryImpl
org.apache.commons.logging.Log=org.apache.commons.logging.impl.SimpleLog
```

2. Create a file named `simplelog.properties` with the following contents:

```
org.apache.commons.logging.simplelog.defaultlog=trace
org.apache.commons.logging.simplelog.showShortLogname=true
org.apache.commons.logging.simplelog.showdatetime=true
```

3. Put both these files, and the `commons-logging.jar` file, on the class path.

The `SimpleLog` uitility writes trace to the `System.err` file.

WSIF (Web Services Invocation Framework) messages:

This topic contains a list of the WSIF run-time system messages, with details of what each message means.

WebSphere system messages are logged from a variety of sources, including application server components and applications. Messages logged by application server components and associated IBM products start with a unique message identifier that indicates the component or application that issued the message.

WSIF0001E: An extension registry was not found for the element type "{0}"

Explanation: Parameters: {0} element type. No extension registry was found for the element type specified.

User Response: Add the appropriate extension registry to the port factory in your code.

WSIF0002E: A failure occurred in loading WSDL from "{0}"

Explanation: Parameters: {0} location of the WSDL file. The WSDL file could not be found at the location specified or did not parse correctly

User Response: Check that the location of the WSDL file is correct. Check that any network connections required are available. Check that the WSDL file contains valid WSDL.

WSIF0003W: An error occurred finding pluggable providers: {0}

Explanation: Parameters: {0} specific details about the error. There was a problem locating a WSIF pluggable provider using the J2SE 1.3 JAR file extensions to support service providers architecture. The WSIF trace file will contain the full exception details.

User Response: Verify that a META-INF/services/org.apache.wsif.spi.WSIFProvider file exists in a provider jar, that each class referenced in the META-INF file exists in the class path, and that each class implements org.apache.wsif.spi.WSIFProvider. The class in error will be ignored and WSIF will continue locating other pluggable providers.

WSIF0004E: WSDL contains an operation type "{0}" which is not supported for "{1}"

Explanation: Parameters: {0} name of the operation type specified. {1} name of the portType for the operation. An operation type which is not supported has been specified in the WSDL.

User Response: Remove any operations of the unsupported type from the WSDL. If the operation is required then make sure all messages have been correctly specified for the operation.

WSIF0005E: An error occurred when invoking the method "{1}" . ("{0}")

Explanation: Parameters: {0} name of communication type. For example EJB or Apache SOAP. {1} name of the method that failed. An error was encountered when invoking a method on the Web service using the communication shown in brackets.

User Response: Check that the method exists on the Web service and that the correct parts have been added to the operation as described in the WSDL. Network problems might be a cause if the method is remote and so check any required connections.

WSIF0006W: Multiple WSIFProvider found supporting the same namespace URI "{0}" . Found ("{1}")

Explanation: Parameters: {0} the namespace URI. {1} a list of the WSIFProvider found.. There are multiple org.apache.wsif.spi.WSIFProvider classes in the service provider path that support the same namespace URI.

User Response: A following WSIF0007I message will be issued notifying which WSIPFProvider will be used. Which WSIFProvider is chosen is based on settings in the wsif.properties file, or if not defined in the properties, the last WSIFProvider found will be used. See the wsif.properties file for more details on how to define which provider should be used to support a namespace URI.

WSIF0007I: Using WSIFProvider "{0}" for namespaceURI "{1}"

Explanation: Parameters: {0} the classname of the WSIFProvider being used. {1} the namespaceURI the provider will be used to support.. Either a previous WSIF0006W message has been issued or the SetDynamicWSIFProvider method has been used to override the provider used to support a namespaceURI.

User Response: None. See also WSIF0006W.

WSIF0008W: WSIFDefaultCorrelationService removing correlator due to timeout. ID:"{0}"

Explanation: Parameters: {0} the ID of the correlator being removed from the correlation service. A stored correlator is being removed from the correlation service due to its timeout expiring.

User Response: Determine why no response has been received for the asynchronous request within the timeout period. The wsif.asyncrequest.timeout property of the wsif.properties file defines the length of the timeout period.

WSIF0009I: Using correlation service - "{0}"

Explanation: Parameters: {0} the name of the correlation service being used. This identifies the name of the correlation service that will be used to process asynchronous requests.

User Response: None. If a correlation service other than the default WSIF supplied one is required, ensure that it is correctly registered in the JNDI java:comp/wsif/WSIFCorrelationService namespace.

WSIF0010E: Exception thrown while processing asynchronous response - "{0}"

Explanation: Parameters: {0} the error message string of the exception. While processing the response from an executeRequestResponseAsync call an exception was thrown.

User Response: Use the exception error message string to determine the cause of the error. The WSIF trace will have more details on the error including the exception stack trace.

WSIF0011I: Preferred port "{0}" was not available

Explanation: Parameters: {0} the user's preferred port. The preferred port set by the user on org.apache.wsif.WSIFService is not available

User Response: None unless this message appears for long periods of time in which case the user might want to pick a different port as their preferred port.

WSIF - Known restrictions:

This topic lists the main known restrictions that apply when using WSIF.

Threading

WSIF is not thread-safe.

External Standards

WSIF supports:

- SOAP Version 1.1 (not 1.2 or later).
- WSDL Version 1.1 (not 1.2 or later).

WSIF does not provide WS-I compliance, and it does not support the Java API for XML-based Remote Procedure Calls (JAX-RPC) Version 1.1 (or later).

Full schema parsing

WSIF does not support full schema parsing. For example, WSDL references in complex types in the schema are not handled, and attributes are not handled.

XML Schema "redefine" elements are not handled and are ignored.

SOAP WSIF does not support:

- SOAP headers that are passed as `<parts>`.

- Unreferenced attachments in SOAP responses.
- Document Encoded style SOAP messages.

  Note: This is not primarily a WSIF restriction. Although you can specify Document Encoded style in WSDL, it is not generally considered to be a valid option and is not supported by the Web Services Interoperability Organization (WS-I).

SOAP provider interoperability

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are running on the former (Apache SOAP) provider. This restriction is due to the fact that the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant Web service, and Apache SOAP cannot provide such a service. For information on how to overcome this restriction, see ″WSIF SOAP provider: working with legacy applications″.

WSIF's support for SOAP faults is restricted to SOAP faults originating from a Web service that runs using the IBM Web Service SOAP provider.

Note: This is not primarily a WSIF restriction. The current SOAP faults specification does not prescribe how to encode a SOAP fault so that it maps to a Java exception. Consequently, each Web service run-time environment currently decides on its own SOAP fault format. The IBM Web Service SOAP provider can understand its own response SOAP faults, but not the SOAP faults from another provider.

Type mappings

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) conforms to the JAX-RPC type mapping rules that were finalized after the former (Apache SOAP) provider was created. The majority of types are mapped the same way by both providers. The exceptions are: `xsd:date`, `xsd:dateTime`, `xsd:hexBinary` and `xsd:QName`. Both client and service need to use the same mapping rules if any of these four types are used. Below is a table detailing the mapping rules for these four types:

XML Data Type	Apache SOAP Java Mapping	JAX-RPC Java Mapping
xsd:date	java.util.Date	Not supported
xsd:dateTime	Not supported	java.util.Calendar
xsd:hexBinary	Hexadecimal string	byte [ ]
xsd:QName	org.apache.soap.util.xml.QName	javax.xml.namespace.QName

Arrays and complex types

WSIF does not support general complex types, it only handles complex types that map to Java Beans. To use schema complex types, you must write your own custom serializers. The specific complex type and array support for WSIF outbound invocation of Web services is as follows:

- WSIF supports Java classes generated by WebSphere Studio Application Developer - Integration Edition (WSAD-IE) message generators (the normal case when WSDL files are downloaded from somewhere else). The WSAD-IE-based generation happens automatically when you use the BPEL editor, or the generation actions available on the Enterprise Services context menu, or the Business Integration toolbar.
- WSIF does not support Java beans generated by other tools, including the base WSAD tool.
- For WSAD-IE generated Java beans, attributes defined in the WSDL do not work. That is to say that these attributes, although they appear in the Java beans generated to represent the complex type, do not appear in the SOAP request created by WSIF.
- WSIF does not support arrays when they are a field of a Java bean. That is to say, WSIF only supports an array that is passed in as a named `<part>`. If an array is wrappered inside a Java bean, the array is not serialized in the same way.

Object Serialization
WSIF does not support serialization of objects across different releases.

Asynchronous invocation
WSIF supports synchronous invocation for all providers. For the JMS and the SOAP over JMS providers, WSIF also supports asynchronous invocation. You should call the `supportsAsync()` method before trying to execute an asynchronous operation.

The EJB provider
The target service of the WSIF EJB provider must be a remote-home interface, it cannot be an EJB local-home interface. In addition, the EJB stub classes must be available on the client class path.

Running outside WebSphere Application Server
WSIF is not supported for use outside WebSphere Application Server.

Using the UDDI Registry

Welcome to the IBM WebSphere UDDI Registry.

Use the table of contents (on the left and below) to view the various topics for a specific product or technology. Select the topic you are interested in to either open documentation locally or find information about how to locate documentation.

An overview of the IBM Version 3 UDDI Registry

The Universal Description, Discovery and Integration (UDDI) specification defines a way to publish and discover information about Web services. The term 'Web service' describes specific business functionality exposed by a company, usually through an Internet connection, to allow another company, or its subsidiaries, or software program to use the service. You can find the UDDI specification on the OASIS UDDI Web page.

The UDDI specification defines a standard for the visibility, reusability and manageability essential for a Service Oriented Architecture (SOA) registry service.

IBM WebSphere UDDI Registry

The IBM WebSphere UDDI Registry is a directory for Web services that is implemented using the UDDI specification. It is a component of WebSphere Application Server Version 6.

A critical component of IBM's on-demand Service Oriented Architecture, the IBM WebSphere UDDI Registry solves the problem of discovery of technical components for an enterprise and its partners by:

- Providing control, flexibility and confidentiality so that an enterprise can protect its e-business investments
- Increasing efficiency by making it easier to identify technical assets
- Leveraging existing infrastructures

For example, the IBM WebSphere UDDI Registry could be used in the following way within a larger enterprise:

A company has a legacy application that provides telephone numbers and Human Resources (HR) information about employees. This is turned into a Web service and published to the registry. A developer in the same company needs to write an application for a procurement function that also needs to provide HR information to the supplier. The application should allow the supplier to have access to the employee account codes once the employee provides his name or serial number. Before Web services, the developer would have been in one of the following situations:

- The developer would not have known about the similar application
- The developer would have known about the application, but been unable to reuse it due to technical barriers
- The developer would have known about the application and reused it only after significant time and negotiation

With UDDI, the developer can search for the Web service and reuse the existing technical component in their new application for the supplier in a matter of minutes. The developer saves time and gets the application up and running sooner than they would have otherwise, thereby increasing efficiency and saving the company time and money. The IBM WebSphere UDDI Registry was the first version 2 standard-compliant UDDI registry for private enterprise work. The IBM WebSphere UDDI Registry in WebSphere Application Server Version 6.0 builds upon previous versions and:

- Supports the UDDI Version 3.0 specification in addition to the Version 1.0 and Version 2.0 standard APIs.
- Leverages the proven, reliable WebSphere Application Server technology
- Uses a relational database, such as DB2, for its persistent store

What's new in UDDI Version 3

The main aspects of the UDDI Version 3 specification that are provided within WebSphere Application Server Version 6 are as follows (there are also some additional capabilities provided by the IBM WebSphere UDDI Registry in WebSphere Application Server Version 6.0 which are described in a section below) :

Improved recognition of the importance of Private UDDI Registries

These are registries that are installed, owned, managed and controlled by a separate body such as a department within a company, a company, an industry consortium or an e-marketplace.

Publisher-assigned keys

This allows the publisher of a UDDI entity to specify its key, rather than having a unique key assigned by the registry. As well as allowing more human-friendly, URI-based keys, this also makes it easier to manage multiple registries.

UDDI Information Model improvements

The UDDI data structures have been extended in a number of ways which improve the ability of UDDI to represent businesses and services via metadata.

Security Enhancements

The introduction of digital signatures provides additional security. Each of the main UDDI entities can be digitally signed, thus improving the integrity and trustworthiness of UDDI data.

Ownership transfer APIs

These allow the ownership of a UDDI entity to be transferred from one publisher to another.

UDDI Policy

Allows the behavior of a UDDI Registry to be defined by setting policy, thus recognizing the various different environments in which a UDDI Registry will be used.

HTTP GET support for UDDI entities

The HTTP GET service is extended beyond the scope for discovery URLs that is a part of the UDDI Version 2 specification. The service allows HTTP GET to be used to access XML representations of each of the UDDI data structures.

Additional Capabilities provided by the UDDI Registry

The Version 3 UDDI Registry provided in WebSphere Application Server Version 6.0 provides the following capabilities in addition to support for the UDDI Version 3 specification:

Version 2 UDDI Inquiry and Publish SOAP API compatibility

Backward compatibility is maintained for the Version 1 and Version 2 SOAP Inquiry and Publish APIs.

UDDI Admin Console extension

The WebSphere Application Server Version 6 Administrative Console includes a section which allows administrators to manage UDDI-specific aspects of their WebSphere environment. This includes the ability to set defaults for initialization of the UDDI node (such as its node ID), and to set the UDDI Version 3 Policy values.

UDDI Registry Administrative Interface

A JMX administrative interface allows administrators to manage UDDI-specific aspects of the WebSphere environment programmatically.

Multi-database support

The UDDI data is persisted to a registry database. In WebSphere Application Server Version 6 the databases that the UDDI Registry supports are DB2 and Cloudscape. Support is provided for remote access to these databases.

User-defined Value Set support

This allows users to create their own categorization schemes or value sets, in addition to the standard schemes, such as NAICS, that are provided with the UDDI registry.

UDDI Utility Tools

UDDI Utility Tools allow importing and exporting of entities using the UDDI Version 2 API.

UDDI user interface

The UDDI user console supports the Inquiry and Publish APIs providing a similar level of support for the Version 3 APIs as was offered for UDDI Version 2 in WebSphere Application Server Version 5.

UDDI Version 3 Client

The IBM Java Client for UDDI Version 3 is a Java client for UDDI which handles the construction of raw SOAP requests for the client application. It is a JAX-RPC client and uses Version 3 datatypes generated from the UDDI Version 3 WSDL and schema. These datatypes are serialized or deserialized to the XML which constitutes the raw UDDI requests.

UDDI Version 2 Clients

The following clients for UDDI Version 2 requests are provided:

- UDDI4J - a Java class library for issuing UDDI requests. This was provided in WebSphere Application Server Version 5 for both UDDI Version 1 requests (uddi4j.jar) and Version 2 requests (uddi4jv2.jar). These class libraries continue to be supported but are now both deprecated.
- JAXR - the Java API for XML Registries is a Java client API for accessing UDDI and ebXML registries. WebSphere Application Server 6.0 provides a JAXR Provider for accessing the IBM WebSphere UDDI Registry. It conforms to the JAXR 1.0 specification.
- EJB - an EJB interface for issuing UDDI version 2 requests. This continues to be supported but is now deprecated.

UDDI Registry terminology

Throughout the UDDI documentation in this Information Center the directory location of WebSphere Application Server is referred to as *install_root*. The default location is /WebSphere/V6R0M0/AppServer/.

UDDI Definitions

bindingTemplate
Technical information about a service entry point and construction specifications.

businessEntity
Information about the party who publishes information about a family of services.

businessService
Descriptive information about a particular service.

Customized UDDI node
This is a UDDI node that is initialized with customized settings for the UDDI properties and UDDI policies; in particular this kind of node will have non-default values for those properties that are read-only after initialization.

A customized UDDI node is recommended for anything other than simple testing purposes (for which a default UDDI node is sufficient). You can set up a customized UDDI node by following the instructions in Setting up a customized UDDI node.

When a customized UDDI node is first started, you must set values for certain properties and then initialize the node (using the Administrative Console or UDDI Administrative Interface), before the node is ready to accept UDDI requests. The properties that need to be set control characteristics of the UDDI node that cannot be changed after initialization.

An advantage of using a customized UDDI node is that it allows you to set these properties to values that are suitable for your environment and usage of UDDI.

After a customized UDDI node has been initialized, it differs from a default UDDI node only in that it uses customized UDDI property and policy values.

Default UDDI node
This is a UDDI node which has been initialized with default settings for the UDDI properties and UDDI policies, including the properties that are read-only after initialization. A default UDDI node is intended for test purposes and as a simple way to become familiar with the behavior of the UDDI Registry.

You can set up a default UDDI node in two ways. The first is to specify the 'default' option when you run the uddiDeploy.jacl script, in which case the UDDI database will be a Cloudscape database. The second is to make sure the PDS member INSERT is included in the JCL used to create the database, in which case the UDDI database can be Cloudscape or DB2.

After a default UDDI node has been initialized, it differs from a customized UDDI node only in that it uses default UDDI property and policy values.

Policy profile
A set of UDDI policies. The default policy profile is the profile created when the default UDDI node is created. In this instance, the nodeID and root key generator are set to read only and are unchangeable after installation.

publisherAssertion
Information about a relationship between two parties, asserted by one or both.

tModel
Short for technical model.

A tModel is a data structure representing a reusable concept, such as a Web service type, a protocol used by Web services, or a category system.

tModel keys within a service description are a technical ″fingerprint″ that you can use to trace the compatibility origins of a given service. They provide a common point of reference that allows you to identify compatible services.

tModels are used to establish the existence of a variety of concepts and to point to their technical definitions. tModels that represent value sets such as category, identifier, and relationship systems are used to provide additional data to the UDDI core entities to facilitate discovery along a number of dimensions. This additional data is captured in keyedReferences that reside in category Bags, identifierBags, or publisherAssertions. The tModelKey attributes in these keyedReferences refer to the value set that relates to the concept or namespace being represented. The keyValues contain the actual values from that value set. In some cases keyNames are significant, such as for describing relationships and when using the general keywords value set. In all other cases, however, keyNames are used to provide a human readable version of what is in the keyValue.

UDDI Application
The IBM WebSphere UDDI Registry J2EE application.

UDDI entitlement
An entitlement that a UDDI user or publisher has within a UDDI registry, such as the capability to publish keyGenerators, or the tier to which the publisher is assigned (in other words, the number of entities that the publisher is entitled to publish). Each UDDI publisher will have a range of settings for the various UDDI entitlements. A UDDI entitlement is sometimes referred to as a 'user entitlement', or as the UDDI publisher's set of 'user entitlements'.

UDDI Node
A set of Web Services supporting at least one of the UDDI API sets, which supports interaction with UDDI data through the UDDI APIs. There is no direct mapping between a UDDI node and a WebSphere Application Server node. A UDDI node consists of an instance of the UDDI application running in an application server (or a cluster of UDDI application instances running in a cluster of application servers) together with an instance of the UDDI database containing UDDI data.

UDDI node initialization
The process of node initialization sets up values in the UDDI database, and establishes the ″personality″ of the UDDI node. A UDDI node cannot accept UDDI API requests until it has been initialized.

UDDI node state
Describes the current state of the UDDI node, as opposed to the state of the UDDI application (which is either stopped or started). The state of a UDDI node can be one of not initialized, initialization pending, initialization in progress, activated or deactivated.

UDDI NodeId
A unique identifier of a UDDI node.

UDDI Policy
A UDDI policy is a statement of required and expected behavior of a UDDI Registry, specified via policy values for the various policies defined in the UDDI Version Specification.

UDDI property
A value for a property which controls the personality or behavior of a UDDI node.

UDDI publisher
A WebSphere user who is entitled to publish UDDI entities to a specified UDDI Registry. A UDDI publisher is sometimes referred to as a 'UDDI user', or simply as a 'publisher' when used in a UDDI context.

UDDI Registry
A UDDI Registry comprises one or more UDDI nodes. The IBM WebSphere UDDI Registry in WebSphere Application Server Version 6.0 only supports single-node UDDI registries.

UDDI Tier
Determines the number of UDDI entities of each type (business, services per business, bindings per service, tModel, publisher assertion) that a UDDI publisher is entitled to publish. Each UDDI publisher will be assigned (either by default or explicitly by a UDDI administrator) to a particular tier, and will not be able to publish more entities than are allowed for that tier. There are some predefined tiers supplied with the UDDI Registry, and a UDDI administrator can create additional tiers. A UDDI tier is often referred to simply as a 'tier' when used in a UDDI context.

Version 2 UDDI Registry
A shorthand term used to refer to an IBM WebSphere UDDI Registry implementation which supports Version 2 of the UDDI specification (and also Version 1). A Version 2 UDDI Registry is included in WebSphere Application Server Network Deployment Version 5.x.

Version 3 UDDI Registry
A shorthand term used to refer to an IBM WebSphere UDDI Registry implementation which supports Version 3 of the UDDI specification (and also Versions 1 and 2). A Version 3 UDDI Registry is included in WebSphere Application Server Version 6.0. It should be noted that the term 'Version 3 UDDI Registry' does not indicate a registry which only supports UDDI version 3 requests.

The following table shows how the various versions of the IBM UDDI Registry relate to the relevant OASIS specification and WebSphere Application Server level:

IBM UDDI Registry Version	OASIS UDDI specification levels supported	Supported on WebSphere Application Server version
1.1	• UDDI Version 1 • UDDI Version 2	4.0.2
1.1.1	• UDDI Version 1 • UDDI Version 2	4.0.3 and later

2.0.x	• UDDI Version 1 • UDDI Version 2	5.0.x and later
2.1.x	• UDDI Version 1 • UDDI Version 2	5.1.x and later
3.0.2	• UDDI Version 1 • UDDI Version 2.0.4 (APIs), Version 2.0.3 (data structures) • UDDI Version 3.0.2	6.0.1

UDDI Registry user interface

This topic describes the UDDI user interface (also referred to as the UDDI User Console), which you can use to explore the IBM WebSphere UDDI Registry.

For information about how to display the UDDI user console, see Displaying the user interface.

If you will be using the UDDI console, you must configure the application server into which you have installed the UDDI Registry for UTF-8 encoding support: To do this, refer to ″Configuring application servers for UTF-8 encoding″ elsewhere in this Information Center.

- The user console provides a graphical user interface to the majority of the UDDI Version 3 API. It is not intended to support the full API set. There is some focus on inquiry operations, as the main purpose of the UDDI user console is to allow users to issue inquiry requests and to familiarize themselves with general UDDI concepts. This section documents those areas for which support through the user console is not provided, together with other known restrictions to the user console.
  - General
    - Help is provided in the form of explanatory text on the screens.
    - Maximum rows cannot be specified on finds. The single maximum rows value for the registry can be set through the *Maximum inquiry result set size* general property on the WebSphere Administrative console.
  - Find business
    - The identifier feature is not supported.
  - Find technical model (tModel)
    - The identifier feature is not supported.
  - Add business
    - There is no support for adding Discovery URLs, Identifiers or Digital Signatures.
  - Add technical model (tModel)
    - There is no support for adding Identifiers or Digital Signatures.
  - Business Relationships
    - There is no support for Business Relationships
- **Note:** The UDDI Version 3 specification states that when a tModel is deleted, it should not be physically deleted. This allows the tModel to be reinstated. One effect of this is that, if you delete a tModel using the UDDI user console, the tModel is still visible through the Show Owned Entities display. Deleted tModels are displayed with the word 'deleted' against their name.

The UDDI user console is split into three areas. At the top of the screen are three links: **Home**, **Find** and **Publish**. The relevant panels appear below this bar when the links are clicked.

Home Returns you to the IBM WebSphere UDDI Registry welcome page

Find Activates the Find tab on the frame below to the left

Publish
Similarly activates the Publish tab on the frame below to the left

Below the WebSphere UDDI Registry banner the screen is split into two parts. On the left are the Find and Publish tabs:

Find tab

The Find pane is in two parts. At the top, a **Quick Find** service is provided. There are three radio buttons to enable a choice of 'service', 'business' and 'technical model' finds. Below these radio buttons is a text entry field for entering the name to search for and, beneath this, a **Find** button to start the search. Comments are provided to show you the wildcard character. The results of clicking **Find** are shown in the detail frame to the right.

Beneath the Quick Find is a section for **Advanced Find** functions which enables you to choose which entity they want to perform an advanced search on. There are three links: **Find services**, **Find businesses** and **Find technical models**. Clicking one of these links displays the corresponding advanced search form in the frame to the right, where you can specify search criteria. To perform a Find, first enter search criteria and select the required Find Qualifiers. Then click **Find Services** (or **Find Businesses** or **Find Technical Models**) to initiate the Find operation. The **Categorizations** section contains a link (**Show category tree**) which displays the tree from which you can select categories (or taxonomies) defining the types of item to find according to various classification systems. This is shown in the left-hand frame. In the advanced search form there are two buttons to start the search (mid-way down and at the bottom).

The results of the search are displayed in the same detail frame.

Publish tab

The *Publish* link on the top banner activates the Publish tab in the navigation frame to the left. The Publish pane is split into three sections.

1. **Quick Publish Function**

   The top part is a **Quick Publish** section to allow you to publish a business or technical model by name only. There are two radio buttons to enable a choice of 'business' or 'technical model'. Below these radio buttons is a text entry field for entering the name to assign to the selected entity and, beneath this, a **Publish** button to publish the entity. The results of clicking **Publish** are shown in the detail frame to the right.
2. **Advanced Publish Functions**

   To publish an entity with more detail, such as with multiple names, descriptions and categories, use the **Advanced Publish** section below this. The comments below each link (**Add a business** and **Add a technical model**) describe individual functions. Clicking one of these links displays the corresponding advanced publish form in the detail frame where you may enter details about the entity they want to publish. Similarly the **Categorizations** section allows taxonomies to be shown in the left frame from which you can select categories.

   Following entry of the relevant details in the **Advanced Publish** section, click **Publish Business** to publish the business to the UDDI Registry.
3. **Registered Information**

   Below the Advanced Publish section is a **Registered Information** section which has a link to **Show Owned Entities** in order to show the businesses, services and technical models registered to the individual user. Clicking the **Show Owned Entities** link displays the **Show Owned Entities** page in the detail frame at the right. The **Show Owned Entities** page is organized in two sections: **Registered Businesses** and **Registered Technical Models**. Each section shows the number of registered items.

   Edit and Delete Businesses

   You can **Edit** or **Delete** businesses owned by you, by clicking the appropriate links in the **Actions** column.

   After editing a business you *must* click **Update Business** to save the changes in the UDDI Registry.

   To delete a Business select the **Show Owner Entities** link and click the **Delete** link shown next to the business.

   Adding a Service to a Business

Services are added to a business by clicking the **Add Service** link in the **Actions** column of the **Registered Businesses** section.

Enter the details of the new service and click **Add Service** to publish the service to the UDDI Registry.

Technical Models

Technical Models owned by you are shown in the bottom **Registered Technical Models** section. As for businesses, users can Edit or Delete technical models owned by them by clicking the appropriate links in the **Actions** column.

Note: Users should take note that deletion of Technical Models (tModels) does **not** cause them to be physically deleted, but hidden. This is in accordance with the UDDI Registry Version 3.0 specifications. After deletion Technical Models are shown under the ″**Shown Owned Entities**″ link on the publish page but not via the Find links on the Find page. ALL other entities are deleted from the UDDI Registry in the normal way.

Example of publishing a Business, Service and tModel with the User Console

For the example, here, we will assume a business called Modern Cars that sells used cars

1. **Add the Business**

   Click the Publish tab in the left hand navigation frame. Then click 'Add a business' in the Advanced Publish in the left pane. This takes you to a 'Publish Business' pane on the right. Start by adding your Business Name in the text field labelled (Modern Cars in this example) and select a language and then click on the blue Add name to the right. This adds the business name. Below the Business Name is the descriptions field - free text can be added to describe the business. Enter a description and click the blue Add description link to add the description. You can add multiple descriptions in a variety of languages as required.

   Categorizations can be used to describe the business according to which categories it falls into. This example uses a Used car dealership. As an example, view the NAICS taxonomy by clicking 'Show category tree' and then expanding NAICS 2002 in the left hand panel. Expand the Retail Trade [44] entry by clicking the (+) plus sign next to it. You may need to drag the division between the left and right panes to be able to see all the category names. Similarly expand Motor Vehicle and Parts Dealers [441] then automobile Dealers [4411] and finally Used Car Dealers [44112]. Select 'Used Car Dealers [441120] and the 'Type', 'Key Name', 'Key Value' fields under categorizations will be filled in with the relevant values. Click the blue 'Add categorization' link to add the categorization details.

   Once all the fields are filled in, click **Publish Business** at the bottom of the form. A page is displayed showing the business details and the business is published to the UDDI Registry.

2. **Add a Service**

   Click the **Show owned entities** link to show the businesses in the UDDI Registry that are owned by you. In our Modern Cars example, to add the description of a service provided by the business click the **Add service** link and a Publish Service form is shown. At the top of the form in the Service Name field you can add a name, then select it's language and click the **Add name** link. You can also add a description (free text), one or more bindings (to add link points to the Service), and Categorizations (to add references to taxonomies to the service. After completing the required areas, clicking the 'Publish Service' button will Publish the service to the UDDI Registry with the current form contents.

3. **Adding a new technical model**

   Clicking the **Add a technical model** link in the left frame opens up the Publish Technical Model form on the right. Here you can enter the tModel name. Beneath this are the descriptions (a free text area to describe the technical model), overview documents (which gives a URL pointing to an overview document) and Categorizations (taxonomies describing the technical model). For each of these fields there is a blue Add link which must be clicked to add the relevant data. At the bottom of the form is a **Publish Technical Model** link which creates the technical model in the UDDI Registry.

UDDI Registry Management Interfaces

This topic explains interfaces and tools that you can use to manage UDDI nodes programmatically.

UDDI Registry Administrative (JMX) Interface

UDDI Registry Administrative (JMX) Interface provides a Java API that allows you to manage runtime configuration settings to control UDDI Registry runtime behavior, such as setting the maximum number of results that UDDI users can receive for inquiry requests, or creating publish limits for UDDI publishers. Sample client code is provided for you to build on.

User Defined Value Set Support in the UDDI Registry

User Defined Value Set Support in the UDDI Registry explains the tooling provided to manage your own categorization value sets, including loading value set data into a UDDI Registry node.

UDDI Utility Tools

UDDI Utility Tools explains the tooling and Java API for promoting version 2 entities from one UDDI registry to another while retaining entity keys. This is particularly useful for publishing canonical tModels with a predefined key.

UDDI Registry Administrative (JMX) Interface:

Each WebSphere UDDI Registry application registers an MBean with an MBean identifier of 'UddiNode'. This MBean may be used by client applications to inspect and manage the runtime configuration of a UDDI application. This includes managing the activation state of and information about a UDDI node, updating properties and policies, setting publish tier limits, registration of UDDI publishers, and controlling value set support.

You can read and invoke the UddiNode attributes and operations using standard JMX interfaces. A client utility class UddiNodeProxy.java provides a ready-made application to connect to a UddiNode MBean and perform all the available operations. Example classes are also provided to drive UddiNodeProxy and demonstrate how to use the various UDDI management data types.

UddiNodeProxy Usage

The following jars required for compilation can be found in *install_root*/lib/:

- admin.jar
- management.jar
- uddiadmin.jar
- wsexception.jar

The UddiNodeProxy class provides a utility method to programmatically interrogate the UddiNode MBean and output all the available attributes, operations and notifications to System.out. For each operation, the return type, operation name and parameter types are output as well as the impact property which indicates how the operation changes the state of the UddiNode MBean (and the UDDI node). As for all MBeans, the value for the impact property can be one of:

ACTION:
state of MBean will be changed

INFO: of the MBean remains unchanged and will return information

ACTION_INFO:
state of the MBean will change and return some information

UNKNOWN:
the impact of invoking the operation is not known

1. Invoke outputMBeanInterface:`uddiNode.outputMBeanInterface();`
   Expected output:

```

```

See ManageNodeInfoSample class for sample code that demonstrates the attributes and operations described in this section.

Managing UDDI Node States and Attributes

UDDI nodes can be in one of several states, depending on the way the UDDI application was installed (as a default configuration or one where the administrator controls when initialization occurs). The UddiNode MBean provides four read only attributes: nodeID, nodeState, nodeDescription and nodeApplicationName. In addition the following MBean operations change UDDI node state: activateNode, deactivateNode and initNode.

nodeID

The node ID is the unique identifier for a UDDI node. If the UDDI application is installed as a default configuration the node ID is automatically generated. If the UDDI application is set up manually, the node ID is set by the administrator. It must be a valid UDDI key.

```
String nodeID = uddiNode.getNode();

System.out.println("node ID: " + nodeId);
```

nodeState

The nodeState attribute can have one of the following values:

nodeState value	English text associated with state
node.state.uninitialized	Not initialized
node.state.initialized	Initialized
node.state.initPending	Initialization pending
node.state.initInProgress	Initialization in progress
node.state.activated	Activated
node.state.deactivated	Deactivated
node.state.unknown	Unknown

After installing a UDDI application using the default configuration, the UDDI node will be in activated state, that is, ready to receive and process UDDI API requests. The node ID and root key generator and some other properties are generated and cannot be changed. For a manually installed UDDI application where you want to specify the UDDI node ID and root key generator values, starting the UDDI application will put the UDDI node into initPending state. In this state, you can update all writable values up until the point you invoke the initNode operation. The initNode operation loads base tModels and value set data and writes all the configuration data to the UDDI node's database. During initialization the state is initInProgress. When initialization completes, the state changes momentarily to initialized and settles at activated. At this point the state can only be switched between activated and deactivated using deactivateNode and activateNode MBean operations.

Each node state value is in fact a message key which can be looked up in the messages.properties resource bundle. The attribute value can be retrieved using the getNodeState method of UddiNodeProxy:

1. Invoke getNodeState:

```
String nodeStateKey = uddiNode.getNodeState();
```

2. Look up translated text from ResourceBundle and output:

```
String messages = "com.ibm.uddi.v3.management.messages";

ResourceBundle bundle = ResourceBundle.getBundle(messages,
                                                 Locale.ENGLISH);

String nodeStateText =  bundle.getString(nodeStateKey);

System.out.println("node state: " + nodeStateText);
```

nodeDescription

You can get the administrator assigned description for the UDDI node using the getNodeDescription method of UddiNodeProxy:

1. Invoke getNodeDescription and output:

```
String nodeDescription = uddiNode.getNodeDescription();
System.out.println("node description: " + nodeDescription);
```

nodeApplicationName

The nodeApplicationName attribute is useful for discovering where the UDDI application that corresponds to the UDDI node is installed. The value will be a concatenation of the cell, node and server names, separated by colons. Retrieve the application location using the getApplicationId method of UddiNodeProxy:

1. Invoke getApplicationId and output:

```
String nodeApplicationId = uddiNode.getApplicationId();

System.out.println("node application location: " +
                                          nodeApplicationId);
```

activateNode

Changes the state of the UDDI node to activated, if the UDDI node was previously deactivated.

1. . Invoke activateNode:

```
uddiNode.activateNode();
```

deactivateNode

Changes the state of the UDDI node to deactivated, if the UDDI node was previously activated.

1. Invoke deactivateNode:

```
uddiNode.deactivateNode();
```

initNode

Causes UDDI node initialization, and when this completes the state of the UDDI node is 'activated'.

1. Invoke initNode:

```
uddiNode.initNode();
```

Managing Configuration Properties

UDDI node runtime behavior is affected by the setting of several configuration properties. The UddiNode MBean provides operations to inspect and update their values, as follows: getProperties, getProperty, updateProperty and updateProperties.

See ManagePropertiesSample class for sample code that demonstrates the operations described in this section.

getProperties

Returns collection of all configuration properties as ConfigurationProperty objects.

1. Invoke getProperties:

```
List properties = uddiNode.getProperties();
```

2. Cast each collection member to ConfigurationProperty:

```
if (properties != null) {
  for (Iterator iter = properties.iterator(); iter.hasNext();) {
       ConfigurationProperty property =
                         (ConfigurationProperty) iter.next();
       System.out.println(property);
  }
}
```

Once you have the ConfigurationProperty objects you can inspect attributes like the ID, value, type, whether the property is read only, required for initialization, and get name and description message keys. For example, invoking the toString method returns results similar to:

```
ConfigurationProperty
id: operatorNodeIDValue
nameKey: property.name.operatorNodeIDValue
descriptionKey: property.desc.operatorNodeIDValue
type: java.lang.String
value: uddi:capnscarlet:capnscarlet:server1:default
unitsKey:
readOnly: true
required: true
usingMessageKeys: false
validValues: none
```

The nameKey and descriptionKey values can be used to look up the translated name and description for a given locale, using the messages.properties resource in uddiadmin.jar.

getProperty

Returns ConfigurationProperty object with the specified ID. Available property IDs are specified in PropertyConstants together with descriptions of the purpose of the corresponding properties.

1. Invoke getProperty:

```
  ConfigurationProperty property =
uddiNode.getProperty(PropertyConstants.DATABASE_MAX_RESULT_COUNT);
```

2. To retrieve the value of the property you could use the getValue method which returns an Object, but in this case, the property is of type integer, so it's easier to retrieve the value using the convenience method getIntegerValue:

```
int maxResults = property.getIntegerValue();
```

updateProperty

Updates the value of the ConfigurationProperty object with the specified ID. Available property IDs are specified in PropertyConstants together with descriptions of the purpose of the corresponding properties. Although you can invoke the setter methods in a ConfigurationProperty object, the only value that is updated in the UDDI node is the value. So to update a property, the steps are typically:

1. Create a ConfigurationProperty object and set its ID:

```
ConfigurationProperty defaultLanguage = new ConfigurationProperty();
defaultLanguage.setId(PropertyConstants.DEFAULT_LANGUAGE);
```

2. Set the value:

```
defaultLanguage.setStringValue("ja");
```

3. Invoke updateProperty:

```
uddiNode.updateProperty(defaultLanguage);
```

updateProperties

Updates several ConfigurationProperty objects in a single request. Set up the ConfigurationProperty objects as for the updateProperty operation.

1. Add updated properties to a List:

```
List updatedProperties = new ArrayList();

updatedProperties.add(updatedProperty1);
updatedProperties.add(updatedProperty2);
```

2. Invoke updateProperties:

```
uddiNode.updateProperties(updatedProperties);
```

Managing Policies

Policies affecting behavior of the UDDI API are managed using the following UddiNode operations: getPolicyGroups, getPolicyGroup, getPolicy, updatePolicy and updatePolicies.

See ManagePoliciesSample class for sample code that demonstrates the attributes and operations described in this section.

getPolicyGroups

Returns collection of all policy groups as PolicyGroup objects.

1. Invoke getPolicyGroups:

```
List policyGroups = uddiNode.getPolicyGroups();
```

2. Cast each collection member to PolicyGroup:

```
if (policyGroups != null) {
for (Iterator iter = policyGroups.iterator(); iter.hasNext();) {
  PolicyGroup policyGroup = (PolicyGroup) iter.next();
  System.out.println(policyGroup);
}
}
```

Each policy group has an ID, name and description key (which can be looked up in the messages.properties resource in uddiadmin.jar). While the PolicyGroup class does have a getPolicies

method it is important to note that PolicyGroup objects returned by the getPolicyGroups operation do not contain any Policy objects. This is so clients can determine the known policy groups (and their IDs) without retrieving the entire set of policies in one request. To retrieve the policies within a policy group, you would use the getPolicyGroup operation.

getPolicyGroup

Returns the PolicyGroup object with the supplied ID.

1. Convert policy group ID to a String:

```
String groupId = Integer.toString(PolicyConstants.REG_APIS_GROUP);
```

2. Invoke getPolicyGroup:

```
PolicyGroup policyGroup = uddiNode.getPolicyGroup(groupId);
```

getPolicy

Returns the Policy object for the specified ID. Like a ConfigurationProperty, a Policy object has an ID, name and description keys, type, value and indicators specifying if the policy is read only or required for node initialization.

1. Convert policy ID to a String:

```
String policyId = Integer.toString(
            PolicyConstants.REG_AUTHORIZATION_FOR_INQUIRY_API);
```

2. Invoke getPolicy:

```
Policy policy = uddiNode.getPolicy(policyId);
```

updatePolicy

Updates the value of the Policy object with the specified ID. Available policy IDs are specified in PolicyConstants together with descriptions of the purpose of the corresponding policies. Although you can invoke the setter methods in a Policy object, the only value that is updated in the UDDI node is the value. So to update a policy, the steps are typically:

1. Create a Policy object and set its ID:

```
Policy updatedPolicy = new Policy();
String policyId =
      Integer.toString(PolicyConstants.REG_SUPPORTS_UUID_KEYS);
updatedPolicy.setId(policyId);
```

2. Set the value:

```
updatedPolicy.setBooleanValue(true);
```

3. Invoke updatePolicy:

```
uddiNode.updatePolicy(updatedPolicy);
```

updatePolicies

Updates several Policy objects in a single request. Set up the Policy objects as for the updatePolicy operation.

1. Add updated policies to a List:

```
List updatedPolicies = new ArrayList();

updatedPolicies.add(updatedPolicy1);
updatedPolicies.add(updatedPolicy2);
```

2. Invoke updatePolicies:

```
uddiNode.updatePolicies(updatedPolicies);
```

Managing Tiers

Tiers control how many of each type of UDDI entities a publisher can save in the UDDI registry. A tier has an ID, an administrator defined name and description, and a set of limits, one for each type of entity. Tiers are managed using the following UddiNode operations: createTier, getTierDetail, getTierInfos, getLimitInfos, setDefaultTier, updateTier, deleteTier and getUserCount.

See ManageTiersSample class for sample code that demonstrates the attributes and operations described in this section.

createTier

Creates a new tier, with specified publish limits for each UDDI entity.

1. Set tier name and description in a TierInfo object.

```
String tierName = "Tier 100";
String tierDescription = "A tier with all limits set to 100.";

TierInfo tierInfo = new TierInfo(null, tierName, tierDescription);
```

2. Define Limit objects for each UDDI entity:

```
 List limits = new ArrayList();

Limit businessLimit = new Limit();
businessLimit.setIntegerValue(100);

businessLimit.setId(LimitConstants.BUSINESS_LIMIT);

Limit serviceLimit = new Limit();
serviceLimit.setIntegerValue(100);
serviceLimit.setId(LimitConstants.SERVICE_LIMIT);

Limit bindingLimit = new Limit();
bindingLimit.setIntegerValue(100);
bindingLimit.setId(LimitConstants.BINDING_LIMIT);

Limit tModelLimit = new Limit();
tModelLimit.setIntegerValue(100);
tModelLimit.setId(LimitConstants.TMODEL_LIMIT);

Limit assertionLimit = new Limit();
assertionLimit.setIntegerValue(100);

assertionLimit.setId(LimitConstants.ASSERTION_LIMIT);
limits.add(businessLimit);
limits.add(serviceLimit);
limits.add(bindingLimit);
limits.add(tModelLimit);
limits.add(assertionLimit);
```

3. Create Tier object:

```
  Tier tier = new Tier(tierInfo, limits);
```

4. Invoke create Tier and retrieve created tier:

```
Tier createdTier = uddiNode.createTier(tier);
```

5. Inspect generated tier ID of created tier:

```
tierId = createdTier.getId();
System.out.println("created tier has ID: " + tierId);
```

getTierDetail

Returns the Tier object for the given tier ID. The Tier class has getter methods for the tier ID, tier name and description (as set by the administrator), and the collection of Limit objects which specify how many of

each UDDI entity type may be published by UDDI publishers allocated to the tier. The isDefault method indicates whether the tier is the default tier, that is, the tier that is allocated to UDDI publishers when auto registration is enabled.

1. Invoke getTierDetail:

```
Tier tier = uddiNode.getTierDetail("2");
```

updateTier

Updates tier contents with the supplied Tier object.

1. Update an existing Tier object (which may have been newly instantiated, or returned by the getTierDetail or createTier operations). This example retains the tier name and description, and all the limit values except the limit being updated:

```
modifiedTier.setName(tier.getName());
modifiedTier.setDescription(tier.getDescription());

Limit tModelLimit = new Limit();
tModelLimit.setId(LimitConstants.TMODEL_LIMIT);
tModelLimit.setIntegerValue(50);

List updatedLimits = new ArrayList();
updatedLimits.add(tModelLimit);

modifiedTier.setLimits(updatedLimits);
```

2. Invoke updateTier:

```
uddiNode.updateTier(modifiedTier);
```

getTierInfos

Returns collection of lightweight tier descriptor objects (TierInfo) which contain the tier ID, and tier name and description values, and whether the tier is the default tier.

1. Invoke getTierInfos:

```
List tierInfos = uddiNode.getTierInfos();
```

2. Output content of each TierInfo:

```
if (tierInfos != null) {

  for (Iterator iter = tierInfos.iterator(); iter.hasNext();) {
     TierInfo tierInfo = (TierInfo) iter.next();
     System.out.println(tierInfo);
  }
}
```

setDefaultTier

Specifies the tier with the given tier ID is the default tier. The default tier is the tier that is allocated to UDDI publishers when auto registration is enabled. Typically this would be set to a tier with low publish limits to prevent casual users publishing too many entities.

1. Invoke setDefaultTier:

```
uddiNode.setDefaultTier("4");
```

deleteTier

Removes the tier with the given tier ID. Tiers can only be removed if they have no UDDI publishers assigned to them, and the tier is not the default tier.

1. Invoke deleteTier:

```
uddiNode.deleteTier("4");
```

getUserCount

Returns the number of UDDI publishers assigned to tier specified by the tier ID.

1. Invoke getUserCount:

```
Integer userCount = uddiNode.getUserCount("4");
System.out.println("users in tier 4: " + userCount.intValue());
```

getLimitInfos

Returns collection of Limit objects representing the limit values for each type of UDDI entity. Limits are used in Tier objects.

1. Invoke getLimitInfos:

```
List limits = uddiNode.getLimitInfos();
```

2. Output the ID and limit value for each Limit object:

```
for (Iterator iter = limits.iterator(); iter.hasNext();) {
  Limit limit = (Limit) iter.next();

  System.out.println("limit ID: "
                     + limit.getId()
                     + ", limit value: "
                     + limit.getIntegerValue());
}
```

Managing UDDI Publishers

UDDI publishers are managed using the UddiNode MBean operations createUddiUser, createUddiUsers, updateUddiUser, deleteUddiUser, getUddiUser, getUserInfos, getEntitlementInfos, assignTier, getUserTier. An example is provided for each, making use of the UddiNodeProxy client class.

See ManagePublishersSample class for sample code that demonstrates the attributes and operations described in this section.

createUddiUser

Registers a single UDDI publisher, in a specified tier, with specified entitlements. The UddiUser class represents the UDDI publisher, and this is constructed using a user name (ID), a TierInfo object which specifies the tier ID to allocate the UDDI publisher to, and a collection of Entitlement objects which specify what the UDDI publisher is permitted to do.

Tip: to allocate the UDDI publisher default entitlements, set the entitlements parameter to null.

1. Create the UddiUser object:

```
UddiUser user = new UddiUser("user1", new TierInfo("3"), null);
```

2. Invoke createUddiUser:

```
uddiNode.createUddiUser(user);
```

createUddiUsers

Registers multiple UDDI publishers. This example shows how to register 7 UDDI publishers in one call, with default entitlements.

1. Create TierInfo objects for tiers that publishers will be allocated to:

```
TierInfo tier1 = new TierInfo("1");
TierInfo tier4 = new TierInfo("4");
```

2. Create UddiUser objects for each UDDI publisher, specifying tier to allocate to:

```
UddiUser publisher1 = new UddiUser("Publisher1", tier4, null);
UddiUser publisher2 = new UddiUser("Publisher2", tier4, null);
UddiUser publisher3 = new UddiUser("Publisher3", tier4, null);
UddiUser publisher4 = new UddiUser("Publisher4", tier1, null);
UddiUser publisher5 = new UddiUser("Publisher5", tier1, null);
UddiUser cts1 = new UddiUser("cts1", tier4, null);
UddiUser cts2 = new UddiUser("cts2", tier4, null);
```

3. Add the UddiUser objects to a List:

```
List uddiUsers = new ArrayList();

uddiUsers.add(publisher1);
uddiUsers.add(publisher2);
uddiUsers.add(publisher3);
uddiUsers.add(publisher4);
uddiUsers.add(publisher5);
uddiUsers.add(cts1);
uddiUsers.add(cts2);
```

4. Invoke createUddiUsers:

```
uddiNode.createUddiUsers(uddiUsers);
```

updateUddiUser

Updates a UDDI publisher with the details in the supplied UddiUser object. This is typically used to change the tier of one UDDI publisher or update their entitlements. Tip: only supply the entitlements you want to update – the remainder of available entitlements will retain their existing value.

1. Create Entitlement objects with appropriate permission. (the entitlement IDs are found in EntitlementConstants:

```
Entitlement publishUuiDKeyGenerator =
    new Entitlement(PUBLISH_UUID_KEY_GENERATOR, true);
Entitlement publishWithUuidKey =
    new Entitlement(PUBLISH_WITH_UUID_KEY, true);
```

2. Add Entitlement objects to a List:

```
List entitlements = new ArrayList();
entitlements.add(publishUuiDKeyGenerator);
entitlements.add(publishWithUuidKey);
```

3. Update a UddiUser object with the updated entitlements:

```
user.setEntitlements(entitlements);
```

4. Invoke updateUddiUser:

```
uddiNode.updateUddiUser(user);
```

getUddiUser

Retrieves details about a UDDI publisher in the form of a UddiUser object. This specifies the UDDI publisher ID, information about the tier they are assigned to and the entitlements they possess.

1. Invoke getUddiUser:

```
UddiUser user1 = uddiNode.getUddiUser("user1");
```

2. Output the contents of UddiUser:

```
System.out.println("retrieved user: " + user1);
```

getUserInfos

Returns a collection of UserInfo objects. Each UserInfo represents a UDDI publisher known to the UDDI node, and the name of the tier they are allocated to. To get details about a specific UDDI publisher, including the tier ID, and entitlements, use the getUddiUser operation.

1. Invoke getUserInfos:

```
List registeredUsers = uddiNode.getUserInfos();
```

2. Output the UserInfo objects:

```
System.out.println("retrieved registered users: ");
System.out.println(registeredUsers);
```

getEntitlementInfos

Returns a collection of Entitlement objects. Each entitlement is a property that controls whether permission is granted to a UDDI publisher to perform a specified action.

1. Invoke getEntitlementInfos:

```
List entitlementInfos = uddiNode.getEntitlementInfos();
```

2. Specify where to find message resources:

```
String messages = "com.ibm.uddi.v3.management.messages";
ResourceBundle bundle = ResourceBundle.getBundle(
                                    messages, Locale.ENGLISH);
```

3. Iterate through the Entitlement objects, displaying the ID, name and description:

```
for (Iterator iter = entitlementInfos.iterator(); iter.hasNext();) {
  Entitlement entitlement = (Entitlement) iter.next();

  StringBuffer entitlementOutput = new StringBuffer();

  String entitlementId = entitlement.getId();
  String entitlementName =
              bundle.getString(entitlement.getNameKey());
String entitlementDescription =
              bundle.getString(entitlement.getDescriptionKey());

  entitlementOutput.append("Entitlement id: ");
  entitlementOutput.append(entitlementId);
  entitlementOutput.append("\n  name: ");
  entitlementOutput.append(entitlementName);
  entitlementOutput.append("\n  description: ");
  entitlementOutput.append(entitlementDescription);

  System.out.println(entitlementOutput.toString());
}
```

deleteUddiUser

Removes the UDDI publisher with the specified user name (ID) from the UDDI registry.

1. Invoke deleteUddiUser:

```
uddiNode.deleteUddiUser("user1");
```

assignTier

Assigns UDDI publishers with supplied IDs to the specified tier. This is useful when you want to restrict several UDDI publishers, perhaps by assigning them all to a tier that doesn‘t allow publishing of any entities.

1. Create list of publisher IDs:

```
List uddiUserIds = new ArrayList();

uddiUserIds.add("Publisher1");
uddiUserIds.add("Publisher2");
uddiUserIds.add("Publisher3");
uddiUserIds.add("Publisher4");
uddiUserIds.add("Publisher5");
uddiUserIds.add("cts1");
uddiUserIds.add("cts2");
```

2. Invoke assignTier:

```
uddiNode.assignTier(uddiUserIds, "0");
```

getUserTier

Returns information about the tier a UDDI publisher is assigned to. The returned TierInfo has getters methods for retrieving the tier ID, tier name, tier description, and whether the tier is the default tier.

1. Invoke getUserTier:

```
TierInfo tierInfo = getUserTier("Publisher3");
```

2. Output the contents of the TierInfo object:

```
System.out.println(tierInfo);
```

Managing Value Sets

Value sets are represented in a UDDI registry as value set tModels, with a UDDI types keyedReference with value 'categorization'. Such value sets are backed with a set of valid values and for user defined value sets, this data is loaded into the UDDI registry using UddiNode MBean operations (although it is more convenient to use the User defined value set tool for this purpose). Each value set can be controlled by policy as being supported or not supported. When a value set is supported by policy, it can be referenced within UDDI publish requests. The UddiNode operations available to manage value sets and their data are: getValueSets, getValueSetDetail, getValueSetProperty, updateValueSet, updateValueSets, loadValueSet, changeValueSetTModelKey, unloadValueSet and isExistingValueSet.

See ManageValueSetsSample class for sample code that demonstrates the attributes and operations described in this section.

getValueSets

Returns collection of ValueSetStatus objects.

1. Invoke getValueSets:

```
List valueSets = uddiNode.getValueSets();
```

2. Cast each element to ValueSetStatus and output contents:

```
for (Iterator iter = valueSets.iterator(); iter.hasNext();) {

  ValueSetStatus valueSetStatus = (ValueSetStatus) iter.next();
  System.out.println(valueSetStatus);
}
```

getValueSetDetail

Returns ValueSetStatus object for the given value set tModel key.

1. Invoke getValueSetDetail:

```
uddiNode.getValueSetDetail(
                "uddi:uddi.org:ubr:categorization:naics:2002");
```

2. Retrieve and display details:

```
String name = valueSetStatus.getName();
String displayName = valueSetStatus.getDisplayName();
boolean supported = valueSetStatus.isSupported();

System.out.println("name: " + name);
System.out.println("display name: " + displayName);
System.out.println("supported: " + supported);
```

3. Display value set properties:

```
List properties = valueSetStatus.getProperties();

for (Iterator iter = properties.iterator(); iter.hasNext();) {

  ValueSetProperty property = (ValueSetProperty) iter.next();
  System.out.println(property);
}
```

getValueSetProperty

Returns a property of a value set as a ValueSetProperty object. This is mainly for use by the WebSphere administrative console to render properties of a value set as a row in a table. For example, one such property is the keyedReference which indicates whether the value set is checked.

1. Invoke getValueSetProperty:

```
uddiNode.getValueSetProperty(
               "uddi:uddi.org:ubr:categorization:naics:2002",
               ValueSetPropertyConstants.VS_CHECKED);
```

2. Read and display boolean value of the property:

```
boolean checked = valueSetProperty.getBooleanValue();

System.out.println("checked: " + checked);
```

updateValueSet

Updates value set status. Only the supported attribute can be updated (all other setter methods are used by the UDDI application).

1. Create a ValueSetStatus object specifying the tModel key and the updated supported value:

```
ValueSetStatus updatedStatus = new ValueSetStatus();
updatedStatus.setTModelKey(
              "uddi:uddi.org:ubr:categorization:naics:2002");
updatedStatus.setSupported(true);
```

2. Invoke updateValueSet:

```
uddiNode.updateValueSet(updatedStatus);
```

updateValueSets

Updates value set status for multiple value sets. As for the updateValueSet operation, only the supported attribute is updated.

1. Populate List with updated ValueSetStatus objects:

```
List valueSets = new ArrayList();

ValueSetStatus valueSetStatus = new ValueSetStatus();
valueSetStatus.setTModelKey(
             "uddi:uddi.org:ubr:categorization:naics:2002");
valueSetStatus.setSupported(false);
valueSets.add(valueSetStatus);

valueSetStatus = new ValueSetStatus();
 valueSetStatus.setTModelKey(
               "uddi:uddi.org:ubr:categorizationgroup:wgs84");
valueSetStatus.setSupported(false);
valueSets.add(valueSetStatus);

valueSetStatus = new ValueSetStatus();
valueSetStatus.setTModelKey(
               "uddi:uddi.org:ubr:identifier:iso6523:icd");
valueSetStatus.setSupported(false);
valueSets.add(valueSetStatus);
```

2. Invoke updateValueSets:

```
uddiNode.updateValueSets(valueSets);
```

loadValueSet

Loads values for a value set from a UDDI Registry V3/V2 taxonomy data file on the local file system. Note: there is also a loadValueSet operation that takes a ValueSetData object but this is only for use by the user defined value set tool.

1. Invoke loadValueSet:

```
uddiNode.loadValueSet(
                      "/valuesets/myvalueset.txt",
                      "uddi:cell:node:server:myValueSet");
```

changeValueSetTModelKey

Any value set values that were allocated to one value set tModel are allocated to the new value set tModel.

1. Invoke changeValueSetTModelKey with old and new tModel keys:

```
uddiNode.changeValueSetTModelKey(
             "uddi:cell:node:server:myValueSet",
             "uddi:cell:node:server:myNewValueSet");
```

unloadValueSet

Unloads values for a value set with the given tModel key.

1. Invoke unloadValueSet:

```
uddiNode.unloadValueSet("uddi:myValueSet");
```

isExistingValueSet

Determines if value set data exists for the given tModel key.

1. Invoke isExistingValueSet and display result:

```
boolean exists = uddiNode.isExistingValueSet(
                 "uddi:uddi.org:ubr:categorization:naics:2002");
System.out.println("NAICS 2002 is a value set: " + exists);
```

User-defined value set support in the UDDI registry:

In UDDI Version 2 this was called 'Custom Taxonomy Support'.

Data is worthless if it is lost within a mass of other data and cannot be distinguished or discovered. If a client of UDDI cannot effectively find information within a registry, the purpose of UDDI is considerably compromised. Providing the structure and modeling tools to address this problem is at the heart of UDDI's design. The verification of data within UDDI is core to its mission of description, discovery and integration. It achieves this by several means.

It allows users to define multiple value sets that can be used in UDDI. In such a way, multiple classification schemes can be overlaid on a single UDDI entity. This capability allows organizations to extend the set of such systems UDDI registries support. One is not tied to a single system, but can rather employ several different classification systems simultaneously.

While default value sets are shipped with the product, the UDDI Version 3 Registry provides tools enabling 'custom' value sets to be added, potentially enabling UDDI entities to be more specifically categorized when published and further enhancing the capability of client to find specific data.

These value sets can be either checked or unchecked, and this is indicated via a keyedReference in the categoryBag of the tModel that represents a value set (a ″categorization tModel″). These keyedReferences have the tModel key for uddi-org:types and are added to the categoryBag to further describe the behavior of the categorization tModel, as follows:

checked
: Marking a tModel with this classification asserts that it represents a categorization, identifier, or namespace tModel that has a validation service to check that category values are present in a specified value set.

unchecked
: Marking a tModel with this classification asserts that it represents a categorization, identifier, or namespace tModel that does not have a validation service.

The procedure defined below describes how to add additional user-defined value sets, and display their allowed values in the UDDI user console value set tree display. Rational Application Developer has a Web Services Explorer user interface that also allows addition and display of custom checked value sets. The publisher of a value set categorization tModel may specify a 'display name' for use in UDDI user console implementations.

Procedure for adding a user defined value set

To add a user defined value set to the IBM WebSphere UDDI Registry requires you to perform three tasks:

- publish a categorization tModel
- load the user defined value set data
- set the value set to **supported** status using the Administration console.

Only when all are complete will the checked value set be referenced. Value set data must be provided for validating checked value sets.

Value set data may also be used by user consoles for unchecked value sets, but it is not a requirement and is usually only used for presentation of deprecated value sets, such as unspc-org:unspc and back-level compatibility.

If the value set is checked, any publish requests that have a categoryBag containing keyedReferences with the new categorization tModel will be validated. If there is value set data corresponding to the categorization tModel in the registry database, only valid values will be accepted. If there is no value set data in the database **all** values will be rejected, and the publish request will fail. If the categorization tModel is unchecked, all values will be allowed, regardless of whether there is a corresponding value set present in the UDDI Registry database. The value set tModel is not available for use until the administrator enables support for it using the Administration console, or the JMX interface.

Suggested approach

To introduce a new value set:

1. Publish the categorization tModel with a keyedReference of type 'uddi-org:categorization:types' with a key value of **categorization**, a keyedReference of type 'uddi-org:categorization:types' with a Key Name of **'Checked value set'** and a Key Value of **'checked'**, or a Key Name of **'Unchecked value set'** and a Key Value of **'unchecked'** and a keyedReference of type 'uddi-org:categorization:general_keywords' supplying the value set display name (as described below).
2. Load user defined value set data into the UDDI Registry database using the UDDIUserDefinedValueSet utility (described below).
3. Use the Administration Console to set the status of the value set to supported (as described in Value set settings). This can also be achieved directly using the JMX interface.

Note: The SOAP and EJB interfaces will be able to make use of categorization tModels as soon as they are published. However, the UDDI Registry user console will require a restart of the UDDI application because it currently gathers its list of categorizations for use in the value set tree display when the application starts.

Publishing a Checked Categorization tModel

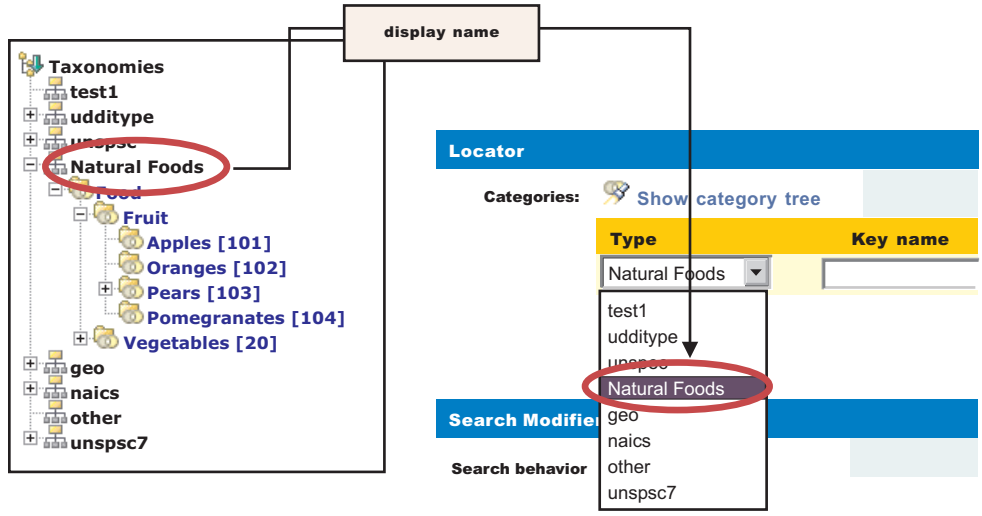
This section describes how to publish a checked categorization tModel with the **'Checked value set'** Key Name for use by a user defined value set.

Publish a tModel to the IBM WebSphere UDDI Registry with a categoryBag containing keyedReferences as follows:

Note	tModelKey	KeyName	KeyValue
1	uddi:uddi-org:categorization:types In the UDDI Registry user interface this tModelKey can be chosen by selecting the category type of **UDDI Types**	**categorization**	**categorization**
2	uddi:uddi-org: categorization:types In the UDDI Registry user interface this tModelKey can be chosen by selecting the category type of **UDDI Types**	**Checked value set**	**checked**
3	uddi:uddi-org:categorization: general_keywords In the UDDI Registry user interface this tModelKey can be chosen by selecting the category type of **categorization:general_keywords**	**urn:x-ibm:uddi:customTaxonomy:displayName**	*<User Defined Value Set displayName>*

1. Indicates this tModel is a categorization tModel (required).
2. Indicates use of the tModel will be checked against a list of valid data (required). (Omitting this keyedReference, or explicitly specifying a value of 'unchecked' will indicate this categorization is unchecked).
3. Indicates special use of the general keywords value set, with a proprietary urn as the keyName value, defines a name for the user defined value set that is intended for use in user console implementations where the full tModel name might be too long. The value can be 1-255 characters (inclusive) long.

The displayName is intended to provide a way to label a value set such that, when the UDDI user console displays it in a value set tree or in a pull-down list of available value sets, the meaning is clear to the user without being restricted to 8 characters and without needing to be the same as the published tModelName, which could be as long as 255 characters. An example is shown below:



The urn:x-ibm:customTaxonomy:displayName should be unique if only to avoid confusion when displayed in user interfaces but this is not validated.

To publish a new categorization tModel using SOAP, the message would be:

```
<save_tModel generic="3.0" xmlns="urn:uddi-org:api_v3">
  <authInfo></authInfo>>
  <tModel tModelKey="">
    <name>Natural Foods tModel</name>
    <categoryBag>
      <keyedReference tModelKey="uddi:uddi.org:categorization:types"
     keyName="categorization" keyValue="categorization"/>
      <keyedReference tModelKey="uddi:uddi.org:categorization:types"
     keyName="Checked value set" keyValue="checked"/>
      <keyedReference tModelKey="uddi:uddi.org:categorization:general_keywords"
     keyName="urn:x-ibm:uddi:customTaxonomy:displayName"
     keyValue="Natural Foods"/>
    </categoryBag>
  </tModel>
</save_tModel>
```

Note: to specify an unchecked categorization substitute the key name **'Checked value set'** with **'Unchecked value set'** and **'checked'** Key Value with **'unchecked'** or, more simply, omit the keyedReference completely.

Loading User Defined Value Set Data

User Defined Value Set Data File Format

Value set data is identified by a unique code value, an optional description and a parent code that specifies its relationship with other code values. Value set data must adhere to this format:

Column name	Maximum length	Description of use
Code	765	Unique value within the value set used for validation
description	765	Typically used by UDDI user consoles and optionally in the keyedReference as the keyName value
parentcode	765	Indicates which existing **code** is the logical parent of this one, and is used in tree displays

Typically columns are delimited in the value set data file by '#' characters as in this example:

```
00#Food#00
10#Fruit#00
101#Apples#10
102#Oranges#10
103#Pears#10
1031#Anjou#103
1032#Conference#103
1033#Bosc#103
104#Pomegranates#10
20#Vegetables#00
201#Carrots#20
202#Potatoes#20
203#Peas#20
204#Sprouts#20
```

In the example, 'Food' is the description for the root node with child nodes of 'Fruit' and 'Vegetables' (both of these have parentcode values the same as the code value for 'Food').

The value set data in the example file could then be rendered in a tree like this:

```
Food
  Fruit
    Apples
    Oranges
    Pears
      Anjou
      Conference
      Bosc
    Pomegranates
  Vegetables
    Carrots
    Potatoes
    Peas
    Sprouts
```

The file must be saved in UTF-8 format.

Custom Taxonomy files used in UDDI Version 2 are also supported by the utility.

UDDIUserDefinedValueSet

A utility is provided to load value set data into the IBM WebSphere UDDI Registry, assign existing value set data to another tModel and unload existing value set data. This utility uses the UDDI Registry's JMX interface and therefore requires a number of connection parameters.

```
Usage: UDDIUserDefinedValueSet[.sh|.bat] '{'function'}' [options]

function:
-load <path> <key>         Load value set data from specified file
-newKey <oldKey> <newKey>  Move value set to a new tModel
-unload <key>              Unload existing value set

options:
-properties <path>         Specify location of configuration file
-host <host name>          Application Server or Deployment Manager host
-port <port>               SOAP Lister port number
-node <node name>          Node running a UDDI server
-server <server name>      Server with UDDI deployed
-columnDelimiter <delim>   Character delimiter to denote field end
-stringDelimiter <delim>   Character delimiter to denote strings

Connector security parameters
```

```
-userName <name>
-password <password>
-trustStore <path>
-trustStorePassword <password>
-keyStore <name>
-keyStorePassword <password>
```

Note: Ensure that the command window from which the UDDIUserDefinedValueSet is run is using a suitable codepage and font for displaying the characters contained in the value set name. Use of an incorrect codepage/font may result in unclear messages on a successful load, and create difficulty using the -unload and -newKey options.

The UDDIUserDefinedValueSet.sh script is located in the *install_root*/bin directory.

If no connection parameters are supplied a connection is sought on the local host using firstly the Deployment Managers default SOAP port number, and, if there is no Deployment Manager running, the default Application Server SOAP port number.

Command arguments are case insensitive.

Usage examples

Load a value set data for a tModel on the local UDDI Registry using the '%' sign as a column marker in the valuesetdata.txt file:

```
UDDIUserDefinedValueSet.sh -load valuesetdata.txt uddi:a708b8a7-35b5-451c-aafc-718ae071fcfe
-columnDelimiter %
```

Move value set data from one checked tModel to another on a UDDI Registry in a Network Deployment:

```
UDDIUserDefinedValueSet.sh –newKey uddi:a708b8a7-35b5-451c-aafc-718ae071fcfe
uddi:b819c9b8-46c6-562d-bb0d-829bf1820d0f –host depmanagerhost.ibm.com
–port 8879 –node uddinode –server uddiserver -override
```

Unload a value set from a tModel from a server with security turned on supplying the connection and security parameters in myproperties.properties file, but supplying the server and password arguments on the command line (which augment or override those contained in the properties file):

```
UDDIUserDefinedValueSet.sh –unload uddi:b819c9b8-46c6-562d-bb0d-829bf1820d0f
–server uddiserver –properties myproperties.properties
–password myrealpassword
```

The configuration file, if specified by the optional **-properties** parameter, determines a number of optional parameters. These parameters can be specified on the command line and, if so, override the values in the properties file. These parameters are largely JMX connection parameters and security parameters.

The string.delimiter is typically used where a description value contains the same character as the column delimiter character. For example, if the column.delimiter was set to ',' (a comma), and there was a value set description value of 'Fruits, citrus', you could include this in the value set data file by setting the string.delimiter to ″ (double quote) and enclosing the description in quotes: 'Fruits, citrus'. Note that the quote character is escaped with a backslash ('\') to indicate the literal character is to be used.

If an attempt is made to load a value set to a tModel that has existing value set data, a warning message is given. To override this error provide the **-override** argument. This argument is also required if moving value set data to a new tModel using **-newKey** where the tModel is **checked**, and also unloaded value set data for a **checked** tModel.

Command line arguments and example data	Property and example data	Comments

-columnDelimiter #	column.delimiter=#	Column delimiter used in value set data files
-stringDelimiter \"	string.delimiter=\"	Field delimiter (must be different to the column.delimiter value
-host ibm.com	host=ibm.com	Host name of the system running Deployment Manager or Application Server
-port 8880	port=8880	SOAP port number of Deployment Manager or Application Server
-node ibmNode	node=ibmNode	Name of the Node running the server with the UDDI Registry
-server server1	server=server1	Server running the UDDI Registry
-userName ibmuser	security.username=ibmuser	User name. Required if WebSphere security is turned on
-password mypassword	security.password=mypassword	Password
-trustStore /TrustStoreLocation	security.truststore=/TrustStoreLocation	Truststore file location
-keyStore ibmkeystore	security.keystore=ibmkeystore	Keystore name
-trustStorepassword trustpass	security.truststore.password=trustpass	Truststore password
-keyStorePassword keypass	security.keystore.password=keypass	Keystore password

Set the value set to supported

Use the Administration console to set the value set to **supported** by:

- Click *UDDI Nodes* > *<node>* and *Value Sets* (under Additional Properties on the right of the screen)
- Select the Value Set (by checking the box next to it)
- Click *Enable Support* above the list of Value Sets

Validation and Error Handling

The UDDI Registry user console performs validation while a save tModel request is being built, that is, before the publish occurs. For example, if the user tries to add two customTaxonomy:displayName keyedReferences the following message is displayed:

```
Advice: Only one 'urn:x-ibm:uddi:customTaxonomy:displayName' key name is allowed
for the 'Other' taxonomy.
```

If a keyedReference containing a keyName value that starts with 'urn:x-ibm:uddi:customTaxonomy:' is followed by anything other than 'displayName', the following message is displayed:

```
Advice: Only key name values of 'urn:x-ibm:uddi:customTaxonomy:displayName' are supported.
```

For requests where the save_tModel message may have multiple tModels, if any one of the tModels is a categorization tModel and it fails validation, the request fails with a UDDIInvalidValueException (plus additional information explaining the likely cause), and none of the tModels is published. For example:

```
E_invalidValue (20200) A value that was passed in a keyValue attribute did not
pass validation.  This applies to checked categorizations, identifiers and other
validated code lists. The error text will clearly indicate the key and value
combination that failed validation. Invalid 'customTaxonomy:dbKey' keyValue
[naics] in keyedReference. KeyValue already in use by
tModelKey[UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2]
```

UDDI Utility Tools:

The UDDI Utility Tools is a suite of functions that can be used to migrate, move or copy UDDI Version 2 entities, including child entities and their respective Version 2 entity keys, into a Version 3 UDDI Registry.

Note: The UDDI Version 3 publish API supports publisher assigned keys (the Version 2 API did not) and promotion of entities between Version 3 registries can be achieved using normal API functions. UDDI Utility Tools supplied in this release is functionally equivalent to the version supplied in WebSphere Application Server 5.1. However, it is important to know that all UDDI Utility Tools functions in this release are performed using the UDDI Version 2 API. You can export from Version 2 and 3 registries (supplying only the Version 2 representation of the UDDI Entity key) and import into the Version 3 registry, using Version 2 API types. Entities from a Version 3 registry are exported as Version 2 entities and, as such, elements such as digital signatures will not be present. See section Saving Version 3 entities with a supplied key for an example on how to use the Version 3 API to assign your own keys to Version 3 entities.

Other uses of the tool include:

- Search and select entities from a source UDDI Registry by specifying Version 2 keys or search criteria
- Publishing canonical tModels in a UDDI Registry, including child entities
- Persist UDDI (Version 2) entities in an intermediate XML representation that can be used to customize and copy those entities to multiple target UDDI Registries, by specifying Version 2 Keys
- Update existing entities in a target UDDI Registry, including child entities
- Delete selected entities from a target UDDI Registry by specifying Version 2 keys

The UDDI Utility Tools are not supported on the z/OS platform; to use them you must install the Client Developer Kit for z/OS, on a non z/OS system, as described in Installing the Client Development Kit for z/OS. Alternatively, if you have another WebSphere Application Server installation on a non z/OS system, you can use the UDDI Utility Tools which are provided as part of that installation.

The UDDI Utility Tools can be used by running the UDDIUtilityTools.jar file. This file is located in the *install_root*/UDDIReg/scripts directory. Alternatively, all of the functions of UDDI Utility Tools can be invoked through the supplied public Java API.

There are five main functions in UDDI Utility Tools:

Export
Given an entity type and key, or a list of entity types and keys, UDDI Utility Tools gets the UDDI entities from the specified registry and writes them to the UDDI Entity Definition File. The entity type for each key can be one of business, service, bindingTemplate or tModel. The Entity Definition File contains XML that exactly describes each of the specified entities, according to the UDDI Utility Tools schema (which includes the UDDI Version 2 schema). The UDDI Entity Definition File separates entities by type, and automatically detects and records tModels referenced by the specified entities. You can use the 'referenced tModels' section of the file to ensure a target registry includes any referenced tModels before you try to import new entities to that registry.

Import
Given a list of UDDI entities (which can be supplied using the UDDI Entity Definition File generated by the export function, possibly with additional editing, or programmatically in a container object), the import function detects if the entities already exist in the target registry and, if they do not, creates a minimal entity (″stub″) with the specified key. The entities are then published updating the stubs with the supplied data and overwriting, or ignoring, existing entities as specified by the user. Note that the original key is maintained throughout.

Promote
Combines the export and import steps such that the specified entities are extracted (by key) from the source registry and then imported into the target registry in a single logical step. The generation of a UDDI Entity Definition File is optional for this function.

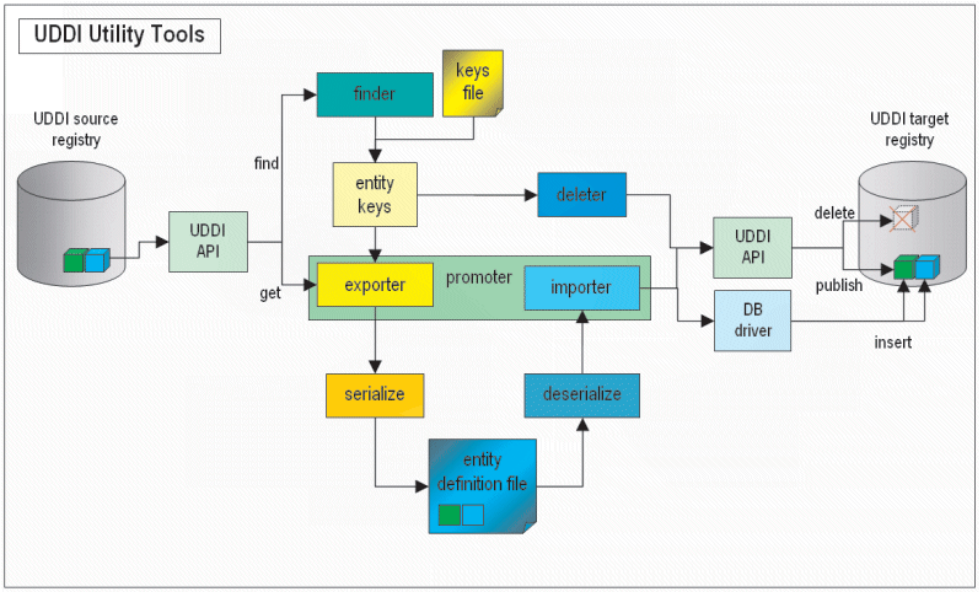
Delete Deletes the specified entities from the target UDDI Registry. The entities to delete are specified as an entity type, or a list of entity types, and keys, in the same way as for the export function.

Find Matching Entities

Takes as input search criteria in the form of UDDI Inquiry API objects for each of the various entity types. The set of entities that match the search criteria are used to generate a list of entity keys, and this in turn can be used as input to the export, promote and delete functions.

Note: This function is available only through the programmatic API.

The relationship between the functions, their input and output, and the source and target UDDI Registries is shown in this conceptual overview diagram:



Setting up the configuration file

Configuration data for UDDI Utility Tools resides in a configuration properties file, which describes the runtime environment, UDDI and database locations and access information, logging information, security configuration, entity definition file location, and other flags to control whether referenced entities are to be imported and/or overwritten.

UDDI Utility Tools is distributed with a sample configuration properties file (UDDIUtilityTools.properties) and this is searched for by default in the current directory if no properties path is specified. By default, this file is located in the *install_root*/UDDIReg/scripts directory. Copy this sample file to a user writable location, modify the file and specify this modified file when running the utility tools.

The most important property to set is the classpath, and this should include the current directory (.) and the UDDIUtilityTools.jar itself, plus all the dependent jars, most of which are located in the WebSphere AppServer lib directory. The classpath must include the database driver jar (for example db2java.zip). The other properties are well commented in the example properties file.

Below is an example properties file as distributed:

```
##########################################
# Runtime environment                    #
# (if invoking via java -jar...)         #
# "X Y" required around paths with spaces    #
# Replace WAS_HOME with your WAS home path.  #
# db2java.zip is for DB2 - replace this with #
# appropriate database driver file.          #
##########################################

Prerequisites

To run the UDDI Utility Tools you must use the IBM Development Kit for Java that is supplied with WebSphere Application Server. This Development Kit is located in *install_root*/java/bin. You must also ensure that the following .jar files are available to the UDDI Utility Tools. The locations of the .jar files should be specified in the classpath property in the UDDI Utility Tools properties file:

UDDIUtilityTools.jar
This is the tools JAR itself and is located in *install_root*/UDDIReg/scripts.

uddi4jv2.jar
This file contains the UDDI4J classes and is located in *install_root*/lib.

j2ee.jar
This file contains some required J2EE classes and is located in *install_root*/lib.

soap.jar
This is the Apache SOAP implementation and is located in *install_root*/lib.

DbDriver
This is the driver needed to allow the UDDIUtilityTool to connect to your target database. See the table below for the values you need to specify for your chosen database:

	DB2	**Cloudscape**
DBDriverLocation for classpath	*DB2_HOME*/jcc/classes/db2jcc.jar	*install_root*/cloudscape/ lib/otherJars/db2jcc.jar,*install_root* /cloudscape/lib/ db2jcc_license_c.jar
Driver	com.ibm.db2.jcc.DB2Driver	com.ibm.db2.jcc.DB2Driver
URL	jdbc:db2:*database_name*	jdbc:db2j:net://host: 1527/*database_name* (see note below)

where

- *install_root* is the directory location of WebSphere Application Server
- *DB2_HOME* is the directory location of DB2, for example c:\Program Files\SQLLIB\java12\
- *ORACLE_HOME* is the directory location of Oracle, for example c:\oracle\ora92\
- *database_name* is the name of your database. For Cloudscape, make sure that *database_name* includes the path to the database, for example *install_root*/profiles/AppSrv01/databases/com.ibm.uddi/UDDI30

If you are using Cloudscape, make the database network enabled so that it can handle multiple connections. See Configuring Cloudscape Version 5.1.60x for details on how to do this.

If you are using DB2, add DB2_HOME/jcc/lib to your LD_LIBRARY_PATH and LIBPATH environment variables.

The Security provider configuration section in the above properties file shows the location of the default DummyClientTrustFile.jks file. If you are using your own truststore, ensure that the location is placed here.

The UDDI Entity Definition File

You generate this file by the export and promote functions, or you can choose to create it (either by hand, or by modifying a version of the file output by UDDI Utility Tools specifying the export function). It is the input to the import function.

Note: The extension to the uddi:tModel type to add a 'deleted' attribute is not currently used in UDDI Utility Tools.

The file is validated for well formedness and that it complies with the UDDI Utility Tools schema, shown here.

```
<?xml version="1.0" encoding="UTF-8" ?>
<xsd:schema id="uddiPromote" attributeFormDefault="unqualified" elementFormDefault="qualified"

```

UDDI Entity Definition File example for canonical tModels

The example Entity Definition File following shows the five main sections for tModels, businesses, services, bindings and referencedTModels:

UDDI Utility Tools can be used to create new UDDI entities in a target UDDI Registry. A typical example of this is to introduce a new canonical tModel, which has a publicly known tModel key.

```
<?xml version="1.0" encoding="UTF-8"?>
<promote:uddiEntities xmlns="urn:uddi-org:api_v2" xmlns:promote=
 "http://www.ibm.com/xmlns/prod/WebSphere/UDDIUtilityTools">

  <!-- tModels -->
  <promote:tModels>

    <tModel tModelKey="uuid:ee3966a8-faa5-416e-9772-128554343571" >
      <name>http://schemas.xmlsoap.org/ws/2002/07/policytmodel</name>
      <description>WS-PolicyAttachment policy expression</description>
    </tModel>

    <tModel tModelKey="uuid:ad61de98-4db8-31b2-a299-a2373dc97212" >
      <name>uddi-org:wsdl:address</name>
 <description xml:lang="en">
This tModel is used to specify the URL fact that the address must be obtained
from the WSDL deployment file.
      </description>
      <overviewDoc>
        <overviewURL>
http://www.oasis-open.org/committees/uddi-spec/doc/tn/uddi-spec-tc-tn-wsdl-v2.htm#Address
        </overviewURL>
      </overviewDoc>
    </tModel>

  </promote:tModels>

  <!-- businesses -->
  <promote:businesses>
  </promote:businesses>
```

```
  <!-- services -->
  <promote:services>
  </promote:services>

  <!-- bindings -->
  <promote:bindings>
  </promote:bindings>

  <!-- referenced tModels -->
  <promote:referencedTModels>
  </promote:referencedTModels>

</promote:uddiEntities>
```

Starting UDDI Utility Tools at a command prompt

Ensure that you are using the correct level of java by setting the PATH statement to the level of java supplied with WebSphere. For example, from the command line, type:

```
export PATH=install_root/java/bin:$PATH
```

UDDI Utility Tools can be started using:

java - jar UDDIUtilityTools.jar <function> [options]
: using a specified properties file that sets up classpath and other parameters, or it can be called using:

java CommandLineProcessor
: where CommandLineProcessor is the class which processes command line arguments for UDDI Utility Tools, sets up configuration and invokes the appropriate function.

Note: Before executing UDDIUtilityTools.jar from the command line, ensure that you have edited the UDDIUtilityTools.properties file. If you have saved this properties file in a different directory from the directory containing the UDDIUtilityTools.jar file, make sure you specify the location of the properties file as part of the command line arguments. See the Setting up the configuration file section earlier in this topic for more details.

The usage is as follows:

```
Usage: java -jar UDDIUtilityTools.jar {function} [options]

function:
  -promote <entity source>   Promote entites between registries
  -export <entity source>    Extract entities from registry to XML
  -delete <entity source>    Delete entities from registry
  -import                    Create entities from XML to registry

where <entity source> is one of:
  -tmodel|-business|-service|-binding <key> Specify single entity type and key
  -keysFile | -f <filename>  Specify file containing entity types and keys

options:
  -properties <filename>     Specify path to configuration file
  -overwrite | -o            Overwrite an entity if it already exists
  -log | -v                  Output verbose messages
  -definitionFile <filename> Specify path to UDDI entity definition file
  -importReferenced          Import entities referenced by source entities

The following options override property settings in configuration file:
  -overwrite
  -log
  -definitionFile
  -importReferenced

Example: java -jar UDDIUtilityTools.jar -promote -keysFile /uddikeys.txt
```

Below are a set of UDDI Utility Tools command line examples:

To export a single business to the EDF file specified in a properties file in the current directory.

```
java -jar UDDIUtilityTools.jar -export -business 28B8B928-2B2E-4EC9-A647-1E40651E4752
```

As above but this time using a keys file to specify the entities to be exported

```
java -jar UDDIUtilityTools.jar -export -keysFile /myKeyFiles/keyFile01.txt
```

As above but also specifying verbose output to appear on the command line.

```
java -jar UDDIUtilityTools.jar -export -keysFile /myKeyFiles/keyFile02.txt -v
```

To import the contents of the default EDF specified in a UDDIUtilitiyTools.properties file in the current directory.

```
java -jar UDDIUtilityTools.jar -import
```

As above but also specifying that referenced tModels should be imported into the target registry.

```
java -jar UDDIUtilityTools.jar -import -importReferenced
```

To import the entities from an EDF at the specified location.

```
java -jar UDDIUtilityTools.jar -import -definitionFile /myEDFs/entities01.xml
```

To import the entities from the default EDF including referenced tModels. Overwrite specifies that any entities excluding referenced tModels that are found in the target registry should be overwritten.

```
java -jar UDDIUtilityTools.jar -import -overwrite -importReferenced
```

To promote a single service from a source to a target registry using the properties file at a specified location.

```
java -jar UDDIUtilityTools.jar -promote -service 67961D67-330F-4F14-8210-E74A58E710F3
-properties /UUT/myUUTProps.properties
```

To promote a set of entities specified in a keys file.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile03.txt
```

As above but specifying that existing entities in the target registry get overwritten.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile04.txt -overwrite
```

To promote a set of entities specified in a keys file including referenced tModels.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile05.txt -importReferenced
```

To promote a set of entities specified in a keys file but also create an EDF containing the promoted entities.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile06.txt
-definitionFile /myEDFs/entities02.xml
```

To logically delete a single tModel. Note that it is not possible to physically delete tModels.

```
java -jar UDDIUtilityTools.jar -delete -tModel UUID:1E2B9D1E-E53D-4D36-9D46-6CCC176C466A
```

To delete all the entities specified in the keys file. Note that with the exception tModels all other entities will be physically deleted from the target registry.

```
java -jar UDDIUtilityTools.jar -delete -keysFile /myKeyFiles/keyFile04.txt
```

A keys file example

Below is an example of the keys that are to be exported, promoted or deleted from the target registry:

```
#
# Keys of entities to be exported, promoted from source registry or deleted from target registry
#
# Note: keys must be comma separated and on SAME line
# Note: property names are case sensitive. ('tmodels=' will be ignored)

businesses=97C77097-AC6C-4CA0-A6C4-452F7045C470, 4975E949-581F-4FCA-AD5F-E08280E05F9F
services=BB3864BB-1578-4833-8179-14391F14791F
bindings=
tModels=273F1727-7BFF-4FB5-A1FD-BA5C45BAFD9C
```

Note: If the importReferenced property is set to true, the list of tModels in the referencedTModels section is imported to the target registry. Minimal entities are created if the referencedTModel is new. If the referencedTModel already exists it is never overwritten, regardless of the overwrite property value. This is so that commonly referenced tModels such as categorization tModels do not keep being updated unnecessarily.

Should you need to update a referencedTModel, you must manually move the referencedTModel definition to the tModels section in the entity definition file and set overwrite to true.

Content of the log files

Below shows examples of contents of two of the log files produced by running the tool. Note that some comments have been added in square brackets and in italic to highlight important points within the log file. The first is the messages.log which shows successful and unsuccessful operations for export, import and delete functions:

```

```

Starting UDDI Utility Tools through the API

UDDI Utility Tools provides a public API to functions for exporting, importing, promoting, finding and deleting UDDI entities. All of these functions can be invoked by using the PromoterAPI class. Usage of this class to perform these functions is typically to:

1. Create a Configuration object and populate it from a Properties object or from a configuration properties file.
2. Create a PromoterAPI object passing the Configuration in the constructor.
3. For keys based functions (export, delete and promote), set the keys by supplying a UDDIEntityKeys object, the location of the keys file, or, for one entity, by specifying an entity type and a key value.
4. Invoke the corresponding method for the function required: exportEntities, promoteEntities(boolean), importEntities, deleteEntities or extractKeysFromInquiry(FindTModel, FindBusiness, FindService, FindBinding, FindRelatedBusinesses).

There is some sample code for UDDI Utility Tools, demonstrating usage of the API classes, available from Samples Central.

The ″low-level″ API classes and methods have been deprecated in this release. Refer to the Javadoc welcome page in the information center topic, ″Reference: Generated API documentation″ for details.

Known limitations with UDDI Utility Tools and workarounds

There are some known limitations with UDDI Utility Tools and a workaround for each. See ″UDDI troubleshooting tips″ for more information.

Embedded Cloudscape Restriction

The ’export’ and ’delete’ functions when referencing a source registry with an embedded Cloudscape database are supported. However, the ’import’ and ’promote’ functions are not supported when referencing a target registry because of a limitation with the UDDI Registry when working with an embedded Cloudscape database. To allow the ’promote’ and ’import’ functions to work, the embedded Cloudscape database needs to be made network enabled, see Configuring Cloudscape Version 5.1.60x.

Saving Version 3 entities with a supplied key

An example of saving a Version 3 business with a defined key is shown below.

```
<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
  <Body>
    <save_business xmlns="urn:uddi-org:api_v3">
      <authInfo>a399c4a3-6387-47cd-a1bd-91f7bb91bdd7</authInfo>
      <businessEntity businessKey="uddi:mycompany-p1.com:computers">
        <name xml:lang="en">WithKey</name>
      </businessEntity>
    </save_business>
  </Body>
</Envelope>
```

Known limitations with UDDI Utility Tools and workarounds

There are known limitations with the UDDI Utility Tools and a workaround for each:

- PublisherAssertions are not supported and will not be promoted.

Workaround: After the user has promoted the businesses that are related, he must recreate the publisherAssertion relationship.

- Referenced businesses in service projections are not added automatically to the EDF in the same manner as referenced tModels.

  Workaround: Add the referenced business that will 'own' the projected service to the EDF. If the business is not present in the target registry, it should be placed before the service's owning business in the EDF.
- Cycle detection for service projections are not detected in the same manner as for referenced tModels.

  Workaround: If a circular reference is present between two or more service projections, break the cycle by removing one of the projections temporarily, perform the import and update the changed entity to reestablish the cycle in the target registry.
- tModels that were deleted (in the logical sense) in the source registry are imported and promoted as undeleted in the target registry. This is because, in the UDDI Version 2 specification, the deleted state of tModels is not exposed as API calls.

  Workaround: After importing the tModel, perform a delete. This is done using the UDDI Utility Tools delete function, or any other UDDI Registry API access method.
- BindingTemplates referenced by hostingRedirectors are not added automatically to the EDF in the same manner as referenced tModels.

  Workaround: Add the referenced bindingTemplate to the EDF.
- Businesses referenced by an 'owningBusiness' keyedReference are not automatically added to the EDF.

  Workaround: Import the referenced business into the target registry before importing the tModel that references it.
- The JSSE provider class is not configurable; it must be com.ibm.jsse.IBMJSSEProvider.
- A few combinations of command line arguments are not validated and prevented, for example, it is possible to specify -import with -keysFile <path to file> in the same command, although the -keysFile is ignored.

IBM Java API for XML Registries (JAXR) Provider for UDDI

Overview

The Java API for XML Registries (JAXR) is a Java client API for accessing both UDDI (Version 2 only) and ebXML registries. It is part of the J2EE 1.4 specification.

The JAXR API comprises the J2EE packages javax.xml.registry and javax.xml.registry.infomodel. J2EE API documentation can be found at http://java.sun.com/webservices/reference/api/index.html (this is a download site). More information on JAXR, including the JAXR Version 1.0 specification, can be found at http://java.sun.com/xml/jaxr/index.jsp.

Note that the preferred UDDI Java client APIs are UDDI4J Version 2 for UDDI Version 2, and the IBM UDDI Client for Java for UDDI Version 3.

JAXR Provider

The current JAXR specification (Version 1.0) defines a JAXR Provider as an implementation of the JAXR API. A JAXR Provider may be a JAXR Provider for UDDI, a JAXR Provider for ebXML, or a pluggable provider which supports both UDDI and ebXML. The IBM JAXR Provider for UDDI is a provider for UDDI only.

UDDI Versions

A JAXR Provider for UDDI accesses a UDDI Registry using the UDDI Version 2 SOAP APIs only. The IBM WebSphere UDDI Registry for UDDI Version 3 in WebSphere Application Server Version 6.0 supports the UDDI Version 1, 2 and 3 SOAP APIs, and so the IBM JAXR Provider for UDDI can be used to access this

registry. The IBM JAXR Provider can also be used to access the IBM WebSphere UDDI Registry for UDDI Version 2 in WebSphere Application Server Version 5.x. Note that to use the UDDI Version 3 SOAP APIs, JAXR cannot be used. The IBM UDDI Version 3 Client for Java is recommended for this.

Capability Level

The JAXR specification defines two Capability Profiles, Capability Level 0 and Capability Level 1. The JAXR API documentation categorizes each JAXR method as either Level 0 or Level 1. A JAXR provider for UDDI has Capability Level 0 and supports all Level 0 methods. A JAXR provider for ebXML has Capability Level 1 and supports all Level 0 and Level 1 methods. The IBM JAXR Provider for UDDI is a Capability Level 0 Provider, and supports only Level 0 methods.

JAXR for UDDI - getting started and advanced topics:
Getting started

A simple sample

The following sample program shows how to obtain the ConnectionFactory instance, create a Connection to the registry and save an Organization in the registry.

```
import java.net.PasswordAuthentication;
import java.util.ArrayList;
import java.util.Collection;
import java.util.HashSet;
import java.util.Properties;
import java.util.Set;

import javax.xml.registry.BulkResponse;
import javax.xml.registry.BusinessLifeCycleManager;
import javax.xml.registry.Connection;
import javax.xml.registry.ConnectionFactory;
import javax.xml.registry.JAXRException;
import javax.xml.registry.RegistryService;
import javax.xml.registry.infomodel.Key;
import javax.xml.registry.infomodel.Organization;

public class JAXRSample
{
    public static void main(String[] args) throws JAXRException
    {
        //Tell the ConnectionFactory to use the IBM JAXR Provider for UDDI
        System.setProperty("javax.xml.registry.ConnectionFactoryClass",
     "com.ibm.xml.registry.uddi.ConnectionFactoryImpl");
        ConnectionFactory connectionFactory = ConnectionFactory.newInstance();

        //Set the URLs for the UDDI inquiry and publish APIs.
        //These must be the URLs of the UDDI version 2 APIs.
        Properties props = new Properties();
        props.setProperty("javax.xml.registry.queryManagerURL",
     "http://localhost:9080/uddisoap/inquiryapi");
        props.setProperty("javax.xml.registry.lifeCycleManagerURL",
     "http://localhost:9080/uddisoap/publishapi");
        connectionFactory.setProperties(props);

        //Create a Connection to the UDDI registry accessible at the above URLs.
        Connection connection = connectionFactory.createConnection();

        //Set the user ID and password used to access the UDDI registry.
        PasswordAuthentication pa = new PasswordAuthentication("Publisher1",
     new char[] { 'p', 'a', 's', 's', 'w', 'o', 'r', 'd' });
        Set credentials = new HashSet();
        credentials.add(pa);
        connection.setCredentials(credentials);
```

```
        //Get the javax.xml.registry.BusinessLifeCycleManager interface, which contains
        //methods corresponding to UDDI publish API calls.
        RegistryService registryService = connection.getRegistryService();
        BusinessLifeCycleManager lifeCycleManager = registryService.getBusinessLifeCycleManager();

        //Create an Organization (UDDI businessEntity) with name "Organization 1".
        Organization org = lifeCycleManager.createOrganization("Organization 1");

        //Add the Organization to a Collection, ready to be saved in the UDDI registry.
        Collection orgs = new ArrayList();
        orgs.add(org);

        //Save the Organization in the UDDI registry.
        BulkResponse bulkResponse = lifeCycleManager.saveOrganizations(orgs);

        //Obtain the Organization's Key (the UDDI businessEntity's businessKey) from the response.
        if (bulkResponse.getExceptions() == null)
        {
            //1 Organization was saved, so 1 key will be returned in the response collection
            Collection responses = bulkResponse.getCollection();
            Key organizationKey = (Key)responses.iterator().next();
            System.out.println("\nOrganization Key = " + organizationKey.getId());
        }
    }
}
```

Classpath

The class libraries of the IBM JAXR Provider for UDDI are contained within the archive jaxruddi.jar, located in the *install_root*/lib directory. When using the JAXR API from within a J2EE application running under WebSphere Application Server Version 6.0, all required classes will automatically be on the classpath. When using the JAXR API from outside this environment, the following jars must be on the java classpath: bootstrap.jar, jaxruddi.jar, j2ee.jar, soap.jar and uddi4jv2.jar, which are all located in the *install_root*/lib directory.

javax.xml.registry.ConnectionFactory

To use the IBM JAXR Provider for UDDI, the name of the ConnectionFactory implementation class must first be specified by setting the System Property “javax.xml.registry.ConnectionFactoryClass” to “com.ibm.xml.registry.uddi.ConnectionFactoryImpl”. Failure to specify this will result in the value defaulting to “com.sun.xml.registry,common.ConnectionFactoryImpl”, which will not be found. This will result in a JAXRException when the ConnectionFactory.newInstance() method is called. The IBM JAXR Provider for UDDI does not support lookup of the ConnectionFactory via JNDI.

javax.xml.registry.Connection Properties

Connection specific properties must be specified by setting a java.util.Properties object on the JAXR ConnectionFactory before obtaining a Connection. The JAXR specification defines the full list of these properties. The table below lists the three most important properties, and what values they should take in order to use the IBM JAXR Provider for UDDI to access the IBM WebSphere UDDI Registry. The only required Connection property is “javax.xml.registry.queryManagerURL”, however it is recommended that “javax.xml.registry.lifeCycleManagerURL” is also set, and that the default value of “javax.xml.registry.security.authenticationMethod” is understood. The rest of the Connection properties defined in the JAXR specification are optional, and their values are not specific to the IBM WebSphere UDDI Registry. The IBM JAXR Provider for UDDI does not define any additional provider-specific properties.

Property	Description

javax.xml.registry.queryManagerURL	The URL of the IBM WebSphere UDDI Registry's inquiry API for UDDI Version 2. Typically this will be of the form: "http://<hostname>:<port>/uddisoap/inquiryapi". This property is required.
javax.xml.registry.lifeCycleManagerURL	The URL of the IBM WebSphere UDDI Registry's publish API for UDDI v2. Typically this will be of the form: "http://<hostname>:<port>/uddisoap/publishapi". If this property is not specified, it defaults to the value of the javax.xml.registry.queryManagerURL property, however the IBM UDDI Registry will typically have different URLs for the inquiry and publish APIs, and it is recommended to specifiy both properties.
javax.xml.registry.authenticationMethod	The method of authentication to use when authenticating with the registry. This may take one of two values, "UDDI_GET_AUTHTOKEN" and "HTTP_BASIC". The default value is "UDDI_GET_AUTHTOKEN" if none is specified. See section Authentication and Security below for more information.

Authentication and security

Authentication

The javax.xml.registry.authenticationMethod Connection property tells the JAXR Provider which method to use when authenticating with the UDDI registry. The two supported values of this property are "UDDI_GET_AUTHTOKEN" and "HTTP_BASIC". The IBM JAXR Provider for UDDI does not support the "CLIENT_CERTIFICATE" or "MS_PASSPORT" methods of authentication. If this property is not set, the default authentication method is "UDDI_GET_AUTHTOKEN".

UDDI_GET_AUTHTOKEN

The JAXR Provider uses the UDDI V2 get_authToken API to authenticate with the registry. The get_authToken call is made automatically by the JAXR Provider when the Connection credentials are set, and the UDDI V2 authToken returned by the call is saved by the JAXR Provider for use on subsequent UDDI publish API calls.

HTTP_BASIC

The JAXR Provider uses HTTP basic authentication to authenticate with the registry. This is supported by WebSphere when WebSphere Global Security is on. No UDDI V2 get_authToken API call is made, instead the username and password are sent in the HTTP headers using HTTP basic authentication every time a UDDI API call is made (both inquiry and publish). If the UDDI Registry does not require HTTP basic authentication, the credentials are ignored.

USING SSL (Secure Sockets Layer)

SSL can be used to encrypt HTTP traffic between the IBM JAXR Provider for UDDI and the IBM WebSphere UDDI Registry. To use SSL, the JAXR client program should do the following:

1. When setting the "javax.xml.registry.queryManagerURL" and "javax.xml.registry.lifeCycleManagerURL" Connection properties, specify a URL with the protocol "https" and the correct port for using SSL to access the UDDI registry. The IBM WebSphere UDDI Registry's default port for https is 9443. Often only the lifeCycleManager URL (the UDDI Publish API URL) will require SSL.
2. Add a new Security Provider to the java.security.Security object, according to the JSSE (Java Secure Sockets Extension) implementation being used. If running under the IBM JVM in WAS 6.0, the IBM JSSE will automatically be on the classpath. Add the IBM Security Provider as follows:

   ```
   java.security.Security.addProvider(new com.ibm.jsse.JSSEProvider());
   ```

3. Set the System property “javax.net.ssl.trustStore” to be the file name of the client trust store file. The client trust store file is a java key store (.jks) file and must contain the server certificate of the UDDI registry. Key store files can be managed using WebSphere‘s ikeyman tool
4. Set the System property “javax.net.ssl.trustStorePassword”. This is the password used to open the client trust store file.
5. If using an IBM JVM prior to that in WAS 6.0, it may be necessary to set the System property “java.protocol.handler.pkgs” to “com.ibm.net.ssl.internal.www.protocol”. For more information on SSL and the ikeyman tool refer to SSL and IKEYMAN in ″Introduction: Security″ within this Information Center.

Internal taxonomies

The IBM JAXR Provider for UDDI supplies the following internal taxonomies:

Taxonomy	ClassificationScheme name (UDDI tModel name)	ClassificationScheme id (UDDI Version 2 tModelKey)
NAICS 1997	ntis-gov:naics:1997	UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2
NAICS 2002	ntis-gov:naics:2002	UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2
UNSPSC 3.1	unspsc-org:unspsc:3-1	UUID:DB77450D-9FA8-45D4-A7BC-04411D14E384
UNSPSC 7	unspsc-org:unspsc	UUID:CD153257-086A-4237-B336-6BDCBDCC6634
ISO3166 2003	ubr-uddi-org:iso-ch:3166-2003	UUID:4E49A8D6-D5A2-4FC2-93A0-0411D8D19E88

The tModels corresponding to all of these taxonomies are available in the IBM UDDI Version 3 Registry. If using the IBM JAXR Provider to access an IBM UDDI Version 2 Registry, only the tModels corresponding to NAICS 1997, UNSPSC 3.1 and ISO3166 are available.

Custom internal taxonomies

A user may supply their own custom internal taxonomies. To create a new custom internal taxonomy and make it available to the JAXR provider, follow these steps:

1. Create a text file containing the taxonomy element data. As an example, look at the file geo-data.txt on the root of jaxruddi.jar. This is the taxonomy data file for the supplied ISO 3166 taxonomy. The first few lines are:

```
geo#--#World#--
geo#AE#United Arab Emirates#--
geo#AF#Afghanistan#--
geo#AG#Antigua And Barbuda#--
geo#AI#Anguilla#--
geo#AL#Albania#--
geo#AM#Armenia#--
geo#AN#Netherlands Antilles#--
geo#AO#Angola#--
geo#AQ#Antarctica#--
geo#AR#Argentina#--
geo#AR-A#Salta#AR
geo#AR-B#Buenos Aires#AR
```

   Each line represents one element of the taxonomy, or one Concept in the taxonomy Concept tree. Each line has the form:

```
<taxonomy ID>#<element value>#<element name>#<parent element value>
```

Token	Description
<taxonomy ID>	The taxonomy ID is the same for every element of a taxonomy.
<element value>	The Concept value (UDDI keyValue).

<element name>	The Concept name (UDDI keyName).
<parent element value>	This defines the element's parent element in the taxonomy tree. For every element (except the root element) in the data file, there should be another line which defines the element's parent element. The root element is denoted by defining itself as its own parent. There should be only one root element, and no parentless elements.
#	The delimiter character. This does not have to be "#" and can be defined for each taxonomy in the taxonomyConfig.properties file.

2. Save a ClassificationScheme (UDDI tModel) in the UDDI registry to represent the new internal taxonomy. This can be done using the javax.xml.registry.BusinessLifeCycleManager.saveClassificationSchemes() method.
3. Add the new taxonomy to the taxonomyConfig.properties file:
   a. Copy the supplied taxonomyConfig.properties file from the root of jaxruddi.jar.

      The content of the supplied taxonomyConfig.properties file is:

      ```
      naics-1997 = UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2, naics-1997-data.txt, #
      naics-2002 = UUID:1FF729F2-1948-46CF-B660-31EC107F1663, naics-2002-data.txt, #
      unspsc  = UUID:DB77450D-9FA8-45D4-A7BC-04411D14E384, unspsc-data.txt,     #
      unspsc7_data = UUID:CD153257-086A-4237-B336-6BDCBDCC6634, unspsc7-data.txt,    #
      iso3166-2003 = UUID:4E49A8D6-D5A2-4FC2-93A0-0411D8D19E88, iso3166-2003-data.txt,#
      ```

      This file has one line per supplied internal taxonomy, which is of the form:

      ```
      <taxonomy ID> = <tModelKey>,<data filename>,<data file delimiter>
      ```

Token	Description
<taxonomy ID>	This is used internally by the JAXR provider to identify each taxonomy. It does not have to be the same as the taxonomy ID in the corresponding taxonomy data file.
<tModelKey>	The tModelKey of the corresponding UDDI tModel. (The id of the corresponding JAXR ClassificationScheme).
<data filename>	The name of the corresponding taxonomy data file.
<data file delimiter>	The delimiter character used in the taxonomy data file. All supplied internal taxonomies use "#", but user-supplied internal taxonomies may use different delimiters.

   b. Add a new line for the new taxonomy to the copy of the taxonomyConfig.properties file. Do not remove any existing taxonomies from the file as this will make them unavailable to the JAXR provider.
4. Add the copied taxonomyConfig.properties file to the java classpath ahead of jaxruddi.jar.
5. If any JAXR client programs are still running that were started before the new taxonomy was added to the taxonomyConfig.properties file, a new Connection must be created in order to pick up the new taxonomy.

Important notes on internal taxonomies

Each internal taxonomy is loaded into memory once per JAXR Connection. The taxonomy's ClassificationScheme is created when the Connection is created. At this time the associated UDDI tModel is obtained from the registry and used to populate the ClassificationScheme attributes. The taxonomy's Concept object tree is not created until the first time the ClassificationScheme is requested by the user. All subsequent requests for the same internal taxonomy using the same Connection will return the same object tree.

Modification of the Concept object tree

Because there is only one ClassificationScheme and Concept object tree per internal taxonomy per Connection, a user should not attempt to modify programmatically any part of the Concept tree, because all future requests for this taxonomy using the same Connection will return the modified (and now possibly invalid) objects. Programmatic modification of the Concept tree will not result in any changes to the associated taxonomy data file. If a user wishes to make a change to the values in a user-defined internal taxonomy, they must first make the changes in the taxonomy data file, and then create a new Connection to pick up the changes in a new Concept tree.

Modification of the ClassificationScheme

Similarly, a user should not attempt to modify programmatically an internal ClassificationScheme, except in the case where a user wishes to modify and then save a user-defined internal ClassificationScheme. A new Connection is not required to pick up programmatic changes.

Logging and messages

UDDI4J Logging

The IBM JAXR Provider for UDDI uses UDDI4J Version 2 to communicate with the UDDI Registry. UDDI4J has its own logging which can be switched on by setting the value of the System property "org.uddi4j.logEnabled" to "true". This outputs to the standard error log the XML request and response bodies of every UDDI request.

Trace

Entry, exit, exception, warning and debug trace is provided using commons-logging. See http://jakarta.apache.org/commons/logging/ for more information on commons-logging. Trace will only be created if the JAXR client configures it. Entry, exit and debug trace uses the debug level of logging. Exception and warning trace uses the info level of logging. Additionally, info level logging is provided before each UDDI4J request is made.

Standard error log messages

The InternalTaxonomyManager, EnumerationManager and PostalSchemeManager send warning messages to System.err if error conditions occur that do not warrant an exception, but that the user should be informed of. Examples of these are if a taxonomy data file contains an invalid line, or if a tModel corresponding to an internal taxonomy could not be found in the registry.

UDDI Registry Messages

The UDDI Registry issues messages to report events or errors. The messages are in the form `CWUDxnnnns` where:

x is a character descriptor identifying which UDDI component is involved
nnnn is the error code
s is one of I (Information), E (Error) or W (Warning)

The prefix *CWUDxnnnns:* is followed by text that describes the event or error. For some messages, the first word of the text is one of the form (MSN=SSSS). The SSSS provides a message sequence number (or MSN), which identifies the unique circumstance in which the message was issued, and is of use where the same message can be issued in more than one circumstance.

To help you diagnose problems and minimize the need to enable trace in any of the above components, view the messages table. You can view the messages by prefix or component, whichever is easiest for you to find in the table. All messages are documented with user/system action and explanation.

The text for the UDDI messages is contained in the following files:

- *setupuddimessages.jar* and *UDDICloudscapeCreate.jar* for the CWUDD messages

- *jaxruddi.jar* for CWUDX messages
- *UDDIValueSetTools.jar* for CWUDV messages
- *UDDIUtilityTools.jar* for CWUDU messages
- *uddiresourcebundles.jar* for the remaining prefixes

which are placed, by the installation process, into the lib subdirectory of the WebSphere application server into which the UDDI Registry was installed (with the exception of UDDIUtilityTools.jar, which is placed into UDDIReg/scripts). If you will be running a console or log analyzer from another process; for example, to analyze the activity log, you must place a copy of the above jar files into a directory that is within the classpath of that process. Otherwise, the message lookup for the UDDI messages will fail.

UDDI Components Message Prefix Table **Click on individual links for message documentation for the component**	
CWUDDnnnns	UDDI Deploy and Removal
CWUDGnnnns	UDDI User Console
CWUDMnnnns	UDDI Management Interface
CWUDNnnnns	UDDI Node Management
CWUDQnnnns	UDDI Migration
CWUDRnnnns	UDDI Logging and Tracing
CWUDSnnnns	UDDI SOAP Interface
CWUDTnnnns	UDDI Transaction Manager

CWUDVnnnns	UDDI Value Set Tools
CWUDXnnnns	JAXR

CWUDDnnnns (Web Services UDDI Deployment and Removal) messages:

CWUDD0001I: Attempting to deploy UDDI Registry application.

Explanation: The UDDI deployment process is starting.

User Response: None..

CWUDD0002W: Failed to discard unsaved changes caught exception Exc. Value is: <Exception Message>

Explanation: This warning message indicates that changes in the wsadmin session previous to running the uddiDeploy.jacl script cannot be discarded. The <Exception Message> describes the error that occurred.

User Response: None.

CWUDD0003I: Application Manager found.

Explanation: An active Application Manager can be used to stop and start UDDI on the deployment server.

User Response: None.

CWUDD0004I: Application Manager unavailable, application will not be started/stopped.

Explanation: No active Application Manager can be found so there is no need to stop and start UDDI on the deployment server.

User Response: None.

CWUDD0005I: Application Manager not running, application will not be started/stopped.

Explanation: Application Manager has been found, but it is not running so there is no need to stop and start UDDI on the deployment server.

User Response: None.

CWUDD0006I: Checking for installed UDDI Registry application of name appname. Value is: <UDDI Application Name>

Explanation: The deployment script is checking for deployed UDDI applications.

User Response: None.

CWUDD0007I: Stopping application of name appname. Value is: <Application Name>

Explanation: Attempting to stop a deployed UDDI application.

User Response: None.

CWUDD0008W: Stopping application appname caught exception Exc. Application might not have been running on this server. Values are: <Application Name> <Exception Message>

Explanation: The UDDI application stop request failed.

User Response: Attempt to stop the UDDI application via the Administration Console and rerun the uddiDeploy.jacl script.

CWUDD0009I: Application appname stopped successfully. Value is: <Application Name>

Explanation: The UDDI application has stopped successfully.

User Response: None.

CWUDD0010I: Removing application appname. Value is: <Application Name>

Explanation: The deployment script is attempting to remove an existing UDDI application.

User Response: None.

CWUDD0011I: Application appname removed successfully. Value is: <Application Name>

Explanation: The UDDI application has been removed from the configuration.

User Response: None.

CWUDD0012I: Attempting to create default UDDI datasource.

Explanation: A default UDDI deployment has been requested and therefore a Cloudscape datasource will be created.

User Response: None.

CWUDD0013I: Multiple Cloudscape JDBC Providers found. Using first in list.

Explanation: The deployment script has detected a number of suitable Cloudscape JDBC providers and will use the first.

User Response: None.

CWUDD0014I: UDDI Datasource name successfully created. Value is: <Datasource Name>

Explanation: A Cloudscape datasource has been created for the default UDDI deployment.

User Response: None.

CWUDD0015I: Setting application classloader mode.

Explanation: The UDDI application requires PARENT_LAST class loading.

User Response: None.

CWUDD0016I: Altered classloader mode of application appname from oldmode to newmode. Values are: <Application Name> <Old Classloader Mode> <New Classloader Mode>

Explanation: The UDDI application class loader has been successfully changed.

User Response: None.

CWUDD0017I: Setting classloader mode for application modules.

Explanation: The UDDI application web modules require PARENT_LAST class loading.

User Response: None.

CWUDD0018I: Altered classloader mode of module modname in application appname from oldmode to newmode. Values are: <Web Module Name> <Application Name> <Old Classloader Mode> <New Classloader Mode>

Explanation: The UDDI Web modules class loader mode has been successfully changed.

User Response: None.

CWUDD0019I: UDDI successfully deployed.

Explanation: UDDI has been successfully deployed.

User Response: None.

CWUDD0020I: Attempting to save new configuration.

Explanation: Attempting to save the configuration after removing any existing UDDI application.

User Response: None.

CWUDD0021I: Changes saved successfully.

Explanation: The configuration changes have been successfully saved.

User Response: None.

CWUDD0022I: Attempting to save new configuration.

Explanation: Attempting to save the configuration after installing the UDDI application ear.

User Response: None.

CWUDD0023W: Changes saved successfully.

Explanation: The configuration changes have been successfully saved.

User Response: None.

CWUDD0024I: Attempting to save new configuration.

Explanation: Attempting to save the configuration after changing the class loader modes.

User Response: None.

CWUDD0025I: Changes saved successfully.

Explanation: The configuration changes have been successfully saved.

User Response: None.

CWUDD1001W: Failed to discard unsaved changes caught exception Exc. Value is: <Exception Message>

Explanation: This warning message indicates that changes in the wsadmin session previous to running the uddiDeploy.jacl script cannot be discarded. The <Exception Message> describes the error that occurred.

User Response: None.

CWUDD1002I: Application Manager found.

Explanation: An active Application Manager can be used to stop and start UDDI on the deployment server.

User Response: None.

CWUDD1003I: Application Manager unavailable, application will not be started/stopped.

Explanation: No active Application Manager can be found so there is no need to stop and start UDDI on the deployment server.

User Response: None.

CWUDD1004I: Application Manager not running, application will not be started/stopped.

Explanation: Application Manager has been found, but is not running so there is no need to stop and start UDDI on the deployment server.

User Response: None.

CWUDD1005I: Stopping application of name appname. Value is: <Application Name>

Explanation: Attempting to stop a deployed UDDI application.

User Response: None.

CWUDD1006W: Stopping application appname caught exception Exc. Application might not have been running on this server. Values are: <Application Name> <Exception Message>

Explanation: The UDDI application stop request failed.

User Response: Attempt to stop the UDDI application via the Administration Console and rerun the uddiDeploy.jacl script.

CWUDD1007I: Application appname stopped successfully. Value is: <Application Name>

Explanation: The UDDI application has stopped executing.

User Response: None.

CWUDD1008I: Removing application appname. Value is: <Application Name>

Explanation: The removal script is attempting to remove the UDDI application.

User Response: None.

CWUDD1009I: Attempting to remove UDDI Registry application.

Explanation: The UDDI removal process is starting.

User Response: None.

CWUDD1010I: Application appname removed successfully. Value is: <Application Name>

Explanation: The UDDI application has been removed from the configuration.

User Response: None.

CWUDD1011I: Attempting to remove the default UDDI datasource.

Explanation: A default UDDI removal has been requested and therefore the Cloudscape datasource used for UDDI will be removed.

User Response: None.

CWUDD1012I: UDDI Datasource name successfully removed. Value is: <Datasource Name>

Explanation: The UDDI Cloudscape datasource has been removed from the configuration.

User Response: None.

CWUDD1013I: UDDI Datasource name does not exist. No action required. Value is: <Datasource Name>

Explanation: The default UDDI Cloudscape datasource does not exist in this configuration and therefore does not need to be removed.

User Response: None.

CWUDD1014I: UDDI Registry application and default UDDI datasource removed successfully.

Explanation: UDDI has been successfully removed from the configuration.

User Response: None.

CWUDD1015I: Attempting to save new configuration.

Explanation: Attempting to save the configuration after removing the UDDI application.

User Response: None.

CWUDD1016I: Changes saved successfully.

Explanation: The configuration changes have been successfully saved.

User Response: None.

CWUDD1017I: UDDI Registry application removed successfully.

Explanation: UDDI has been successfully removed from the configuration.

User Response: None.

CWUDD1018W: Application appname is not installed. Value is: <Application Name>

Explanation: The UDDI application has not been deployed and therefore the application cannot be removed.

User Response: None.

CWUDD3001I: Commencing UDDI Cloudscape database creation

Explanation: This is an informational message. It indicates that creation of the UDDI Cloudscape database is being started.

User Response: None

CWUDD3002I: Path to scripts='<DBscriptsLocation>'.

Explanation: This is an informational message. It indicates the location (path) of the scripts for creating the UDDI database, in the <DBscriptsLocation> insert.

User Response: None

CWUDD3003I: Path of database='<DBlocation>'.

Explanation: This is an informational message. It indicates the location (path) to be used for the UDDI Cloudscape database, in the <DBlocation> insert.

User Response: None

CWUDD3004I: Database name='<DBname>'.

Explanation: This is an informational message. It indicates the name to be used for the UDDI Cloudscape database, in the <DBname> insert.

User Response: None

CWUDD3005I: Default profile requested

Explanation: This is an informational message. It indicates that the UDDI Cloudscape database is to be created as a default UDDI database, using the default UDDI profile.

User Response: None

CWUDD3006I: Default profile not requested

Explanation: This is an informational message. It indicates that the UDDI Cloudscape database is to be created as a non-default UDDI database.

User Response: None

CWUDD3007I: Attempting to create or connect to UDDI Cloudscape database container

Explanation: This is an informational message. It indicates that an attempt is being made to create, or connect to, the database container for the UDDI Cloudscape database.

User Response: None

CWUDD3008I: UDDI Cloudscape database container successfully created or connected to

Explanation: This is an informational message. It indicates that the database container for the UDDI Cloudscape database has been connected to successfully.

User Response: None

CWUDD3009I: UDDI Cloudscape database creation completed normally

Explanation: This is an informational message. It indicates that the UDDI Cloudscape database has been successfully created.

User Response: None

CWUDD3010I: Attempting to open DDL File List file of name FileName. Value is: FileName='<DDLlistFilename>'

Explanation: This is an informational message. It indicates that the DDL File List file, which lists the DDL Files (database scripts) to be used to create the UDDI Cloudscape database, has been successfully opened. The name of the DDL File List file is given in the <DDLlistFilename> insert.

User Response: None

CWUDD3011I: Reading the contents of the DDL File List file and verifying

Explanation: This is an informational message. It indicates that the contents of the DDL File List file are being read and verified.

User Response: None

CWUDD3012I: Comment from file: <DDLfileComment>

Explanation: This is an informational message. It indicates that a comment line has been read from the DDL File List file, and shows the comment in the <DDLfileComment> insert.

User Response: None

CWUDD3013I: Line from file: <DDLfileLine>

Explanation: This is an informational message. It indicates that a non-comment line has been read from the DDL File List file, and shows the line in the <DDLfileLine> insert.

User Response: None

CWUDD3014I: Extraneous attributes will be ignored

Explanation: This is an informational message. It indicates that more attributes have been specified than are required, and that the extraneous attributes will be ignored.

User Response: None

CWUDD3015I: Skipping the Default Profile record because Default Profile was not requested

Explanation: This is an informational message. It indicates that the default UDDI profile was not requested, and that therefore the record in the DDL File List file for setting up the default profile will be skipped.

User Response: None

CWUDD3016I: Attempting to populate the database container with schema structures.

Explanation: This is an informational message. It indicates that an attempt is being made to add schemas to the UDDI Cloudscape database container.

User Response: None

CWUDD3017I: Attempting to load the Cloudscape JDBC driver.

Explanation: This is an informational message. It indicates that an attempt is being made to load the JDBC driver class for Cloudscape.

User Response: None

CWUDD3018I: Cloudscape JDBC driver successfully loaded

Explanation: This is an informational message. It indicates that the JDBC driver for Cloudscape has been successfully loaded.

User Response: None

CWUDD3019I: Processing DDL file DDLFile using Term as the terminator. Values are: DDLFile=<DDLfilename>, Term=<terminator>.

Explanation: This is an informational message. It indicates that the DDLFile whose name is in the <DDLfilename> insert is being processed, with the character in the <terminator> insert being used as terminator.

User Response: None

CWUDD3020I: DDL file successfully processed. N statements processed. Value is: N=<numStatements>.

Explanation: This is an informational message. It indicates that the current DDL file has been successfully processed, and that the number of statements indicated by the <numStatements> insert were processed.

User Response: None

CWUDD3021I: End of file reached

Explanation: This is an informational message. It indicates that the end of the current DDL file has been reached.

User Response: None

CWUDD3022I: Converting SQL string Str to Cloudscape syntax. Value is: Str=<SQLstring>.

Explanation: This is an informational message. It indicates that the SQL string given in the <SQLstring> insert is being converted into an SQL syntax that is recognized by Cloudscape.

User Response: None

CWUDD3030I: UDDI Cloudscape database successfully completed

Explanation: This is an informational message. It indicates that creation of the UDDI Cloudscape database has completed successfully.

User Response: None

CWUDD4001E: An Exception Exc occurred during creation of UDDI Cloudscape database. Value is:

Explanation: An exception occurred during the attempt to create the UDDI Cloudscape database.

User Response: The <exception> insert provides information that should help you diagnose the cause of the problem.

CWUDD4002E: Abnormal exit from creation of UDDI Cloudscape database.

Explanation: The attempt to create the UDDI Cloudscape database is exiting abnormally.

User Response: Examine the preceding messages to determine the reason for the abnormal exit.

CWUDD4003E: Insufficient arguments supplied

Explanation: Insufficient arguments have been supplied for creating the UDDI Cloudscape database.

User Response: Retry the request, supplying the correct number of arguments.

CWUDD4004E: Usage is: java -jar <thisjar> <arg1> <arg2> <arg3> <arg4>

where:

- **<thisjar> = name of jar file for creating UDDI Cloudscape Database**
- **<arg1> = path to DDL (SQL) files**
- **<arg2> = path to location for UDDI Cloudscape database**
- **<arg3> = name of UDDI Cloudscape Database**
- **<arg4> = (optional), if specified must be the string DEFAULT**

Explanation: This message gives the correct usage syntax for creating the UDDI Cloudscape Database. It is issued when the incorrect syntax has been used.

User Response: Correct the syntax to match the usage indicated by the message. You might also need to specify the Cloudscape class library on the classpath, by using the -cp parameter on the java command. Refer to the Information Center documentation on setting up and deploying UDDI for more details.

CWUDD4005E: Creation of UDDI Cloudscape database was unsuccessful

Explanation: The attempt to create the UDDI Cloudscape database has been unsuccessful.

User Response: Examine the preceding messages to determine the reason for this failure.

CWUDD4006E: SQL Exception Exc encountered during database container creation. Value is: Exc=<exception>.

Explanation: An SQL exception occurred when attempting to create the database container for the UDDI Cloudscape database.

User Response: The <exception> insert should contain information which will help you to diagnose the problem.

CWUDD4007E: DDL File List file not found

Explanation: The DDL File List file, used to specify the DDL files to be used to create the UDDI Cloudscape database, could not be found.

User Response: The DDL File List file should be included in the UDDICloudscapeCreate.jar used to create the UDDI Cloudscape database, so this error indicates a possible corruption of that jar file. Check that you have a valid version of UDDICloudscapeCreate.jar.

CWUDD4008E: Invalid attribute Attr found in DDL File List file. Value should be true or false. Value is: Attr=<attribute>.

Explanation: An invalid attribute was found in the DDL File List file. The expected attribute is one of 'true' or 'false'. The <attribute> insert indicates the value that was found.

User Response: The DDL File List file is included in the UDDICloudscapeCreate.jar used to create the UDDI Cloudscape database, so this error indicates a possible corruption of that jar file. Check that you have a valid version of UDDICloudscapeCreate.jar.

CWUDD4009E: Insufficient attributes found in DDL File List file.

Explanation: Insufficient attributes were found in the DDL File List file.

User Response: The DDL File List file should be included in the UDDICloudscapeCreate.jar used to create the UDDI Cloudscape database, so this error indicates a possible corruption of that jar file. Check that you have a valid version of UDDICloudscapeCreate.jar.

CWUDD4010E: SQL exception Exc encountered during database population. Value is: Exc=<exception>.

Explanation: An SQL exception has occurred while populating the UDDI Cloudscape database.

User Response: The <exception> insert contains the SQL exception which occurred. Use this to diagnose the problem.

CWUDD4011E: Delete existing UDDI Cloudscape database if it is to be overwritten with a new one.

Explanation: This message is issued when an exception has occurred while populating the UDDI Cloudscape database. A common cause of this problem is that a UDDI Cloudscape database already exists.

User Response: You can ignore this message if you want to keep the existing data in your existing UDDI Cloudscape Database. If you want to overwrite this with a new UDDI Cloudscape database, then you should delete the existing database, then and rerun the request. Previous messages will have shown the location and name of the UDDI Cloudscape database.

CWUDD4012E: Exception Exc occurred while trying to find the Cloudscape JDBC Provider. Value is: Exc=<exception>.

Explanation: An exception occurred while trying to find the Cloudscape JDBC driver class.

User Response: The <exception> insert contains the exception which occurred. Examine this to diagnose the problem.

CWUDD4013E: Ensure that the Cloudscape libraries are on the classpath

Explanation: This message is issued when an exception has occurred when trying to find the Cloudscape JDBC driver class. A common cause of this problem is that the classpath has not been set up to include the path to the Cloudscape class library.

User Response: Ensure that you have specified the Cloudscape class library on the request to create the Cloudscape UDDI database. Depending on how you issued the request, this might involve specifying the classpath on the wsadmin command used to invoke uddiDeploy.jacl, or on the java -jar command used to invoke the UDDICloudscapeCreate.jar file. Refer to the Information Center documentation on setting up and deploying UDDI for more details.

CWUDD4014E: Exception Exc occurred while processing SQL statement Str. Character positions within Str shown by StrPos.

Values are:

- **Exc=<exception>,**
- **<SQLstring>,**
- **StrPos=<charPositions>**

Explanation: An exception occurred while processing an SQL statement used to create the UDDI Cloudscape database. The message shows the SQL exception message in the <exception> insert, the SQL string which was being processed in the <SQLstring> insert, and a string of character positions in the <charPositions> insert.

User Response: Examine the exception message to determine the cause of the problem. If the exception message indicates the position at which the problem occurred, then use the <charPositions> string to identify that position in the SQLstring.

CWUDD4015E: There were no SQL statements in the DDL file.

Explanation: No SQL statements have been found in the DDL file that is currently being processed.

User Response: Previous messages will tell you the path to the database scripts (DDL files), and the DDL file which is currently being processed. Use this information to find the DDL file and check that it is valid.

CWUDD4016E: Exception Exc occurred while processing DDL file. Value is: Exc=<exception>.

Explanation: An exception occurred while processing the current DDL file.

User Response: Examine the exception message in the <exception> insert to diagnose the problem.

CWUDD4017E: Location of database scripts not specified.

Explanation: The request issued to create the Cloudscape database has not specified a location for the database scripts.

User Response: Retry the request, providing a location for the database scripts. If this message is issued when using the uddiDeploy.jacl script with the default option, then check that you are using a valid version of uddiDeploy.jacl.

CWUDD4018E: Location of database not specified.

Explanation: The request issued to create the Cloudscape database has not specified a location for the UDDI Cloudscape database.

User Response: Retry the request, providing a location for the UDDI Cloudscape database. If this message is issued when using the uddiDeploy.jacl script with the default option, then check that you are using a valid version of uddiDeploy.jacl.

CWUDD4019E: Name of database not specified.

Explanation: The request issued to create the Cloudscape database has not specified a name for the UDDI Cloudscape database.

User Response: Retry the request, providing a name for the UDDI Cloudscape database. If this message is issued when using the uddiDeploy.jacl script with the default option, then check that you are using a valid version of uddiDeploy.jacl.

CWUDD4020E: Invalid value specified for Default Profile parameter Parm, value should be GoodParm. Values are: Parm=<suppliedparm>, GoodParm=<expectedparm>.

Explanation: The request issued to create the Cloudscape database has specified an invalid value for the default profile parameter. The <suppliedparm> insert indicates the value that was supplied, and the <expectedparm> indicates the value that was expected.

User Response: Retry the request, specifying a valid value for the default profile parameter, or omit this parameter altogether if you do not want to create the UDDI Cloudscape database with a default profile. If this message is issued when using the uddiDeploy.jacl script with the default option, then check that you are using a valid version of uddiDeploy.jacl.

CWUDD4021E: An error occurred while loading the Cloudscape JDBC driver.

Explanation: An error occurred while attempting to load the Cloudscape JDBC driver class.

User Response: Examine the preceding messages for details of the error.

CWUDD6001E: Incorrect number of arguments passed to script.

Explanation: The wrong number of arguments were passed to the script. Arguments are Node Name, Server Name, and optionally the **default** keyword.

User Response: Retry with the correct arguments.

CWUDD6002E: Usage is: <Command format description>.

Explanation: The deployment script has not been called with the correct arguments.

User Response: Retry with the correct arguments.

CWUDD6003E: Failed to determine server ID caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the Server ID.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6004E: Failed to determine server ID, possibly due to invalid nodename or servername (check case).

Explanation: The Server ID could not be located for the given node name and server name.

User Response: Check the node name and server name are correct and are in the correct case.

CWUDD6005E: Failed to determine the list of JDBC providers caught exception Exc. Value is: <Exception Message>.

Explanation: The deployment script was unable to determine the list of JDBC providers.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6006E: Failed to get JDBC provider name from id caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the list of JDBC providers for the server.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6007E: Attempt to create a Cloudscape JDBC provider caught exception Exc. Value is: <Exception Message>.

Explanation: A Cloudscape JDBC provider is required for the default deployment of UDDI and an Exception occurred whilst trying to create this JDBC provider.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6008E: Failed to create datasource caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the UDDI Cloudscape datasource.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6009E: Failed to create resource property set caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to J2EEResourcePropertySet.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6010E: Failed to create 'databaseName' resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property 'databaseName'.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6011E: Failed to create 'shutdownDatabase' resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property 'shutdownDatabase'.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6012E: Failed to create 'datasourceName' resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property 'datasourceName'.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6013E: Failed to create 'description' resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property 'description'.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6014E: Failed to create 'connectionAttributes' resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property 'connectionAttributes'.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6015E: Failed to create 'createDatabase' resource property caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the J2EE Resource Property 'createDatabase'.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6016E: Attempt to locate the WebSphere Installation Directory failed.

Explanation: The installation directory of WebSphere Application Server could not be determined.

User Response: Verify that WebSphere Application Server has been correctly installed and that the **WAS_INSTALL_ROOT** WebSphere environment variable exists in the configuration.

CWUDD6017E: Uninstall of application appname caught exception Exc. Values are: <Application Name> <Exception Message>.

Explanation: An Exception occurred whilst trying to uninstall an existing UDDI application.

User Response: This message is self-explanatory.

CWUDD6018E: Install of UDDI application caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to install the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6019E: Attempt to find application classloader failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to locate the classloader for the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6020E: Attempt to read current classloader mode failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the classloader mode of the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6021E: Attempt to modify classloader mode to newmode failed with exception Exc. Values are: <Classloader Mode> <Exception Message>.

Explanation: An Exception occurred whilst trying to change the classloader mode of the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6022E: Attempt to read new classloader mode failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to verify the new classloader mode of the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6023E: Attempt to read module list from application failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the list of modules held in the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6024E: Attempt to locate URI attribute on module failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the URI attribute of the application module.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6025E: Attempt to read current classloader mode from module failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the classloader mode of a UDDI module.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6026E: Attempt to modify module classloader mode to newmode failed with exception Exc. Values are: <Classloader Mode> <Exception Message>.

Explanation: An Exception occurred whilst trying to change the classloader mode of a UDDI module.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6027E: Attempt to read new module classloader mode failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to verify the new classloader mode of a UDDI module.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6028E: Attempt to create default UDDI Registry Cloudscape database failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to create the default Cloudscape database.

User Response: Refer to messages displayed during creation to determine cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6029E: Attempt to locate the Nodes Variable Map failed with exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to locate the configurations Variable Map for the given node.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6030E: Error saving configuration, changes not saved due to exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to save the configuration after creating default datasource and removing an existing UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6031E: Error saving configuration, changes not saved due to exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to save the configuration after installing the UDDI application.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6032E: Error saving configuration, changes not saved due to exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to save the final configuration.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6033E: Incorrect argument passed to script.

Explanation: The wrong argument was passed to the script. Arguments are Node Name, Server Name, and optionally the **default** keyword.

User Response: Retry with the correct arguments.

CWUDD6034E: 'default' keyword is not allowed in a WebSphere Application Server Network Deployment configuration.

Explanation: A default Cloudscape UDDI Registry is not permitted in a WebSphere Application Server Network Deployment configuration. Please follow the UDDI Installation instructions on how to create a non default UDDI Registry database.

User Response: Retry with the correct arguments.

CWUDD6035E: Cluster names are only allowed in a WebSphere Application Server Network Deployment configuration.

Explanation: UDDI can only be deployed to a Cluster in a Network Deployment configuration.

User Response: Deploy UDDI using the arguments Node and Server.

CWUDD6036E: Failed to determine cluster ID caught exception Exc. Value is: <Exception Message>

Explanation: An Exception occurred whilst trying to determine the Cluster ID.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD6037E: Failed to determine cluster ID, possibly due to invalid clusterName (check case).

Explanation: The Cluster ID could not be located for the given cluster name.

User Response: Check the cluster name is correct and is in the correct case.

CWUDD7001E: Incorrect number of arguments passed to script.

Explanation: The wrong number of arguments were passed to the script. Arguments are Node Name, and optionally the **default** keyword.

User Response: Retry with the correct arguments.

CWUDD7002E: Usage is: <Command format description>.

Explanation: The removal script has not been called with the correct arguments.

User Response: Retry with the correct arguments.

CWUDD7003E: Failed to determine server ID caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to determine the Server ID.

User Response: Retry the removal of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD7004E: Failed to determine server ID, possibly due to invalid nodename or servername (check case).

Explanation: The Server ID could not be located for the given node name and server name.

User Response: Check the node name and server name are correct and are in the correct case.

CWUDD7005E: Uninstall of application appname caught exception Exc. Values are: <Application Name> <Exception Message>.

Explanation: An Exception occurred whilst trying to uninstall the UDDI application.

User Response: Retry the removal of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD7006E: Failed to remove default UDDI datasource caught exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to remove the UDDI Cloudscape datasource.

User Response: Retry the removal of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD7007E: Error saving configuration, changes not saved due to exception Exc. Value is: <Exception Message>.

Explanation: An Exception occurred whilst trying to save the final configuration.

User Response: Retry the removal of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD7008E: Incorrect argument passed to script.

Explanation: The wrong argument was passed to the script. Arguments are Node Name, Server Name, and optionally the **default** keyword.

User Response: Retry with the correct arguments.

CWUDD7009E: 'default' keyword is not allowed in a WebSphere Application Server Network Deployment configuration.

Explanation: A default Cloudscape UDDI Registry is not permitted in a WebSphere Application Server Network Deployment configuration. Therefore there is no default Cloudscape UDDI datasource to remove.

User Response: Retry with the correct arguments.

CWUDD7010E: Cluster names are only allowed in a WebSphere Application Server Network Deployment configuration.

Explanation: UDDI can only be removed from a Cluster in a Network Deployment configuration.

User Response: Remove UDDI using the arguments Node and Server.

CWUDD7011E: Failed to determine cluster ID caught exception Exc. Value is: <Exception Message>

Explanation: An Exception occurred whilst trying to determine the Cluster ID.

User Response: Retry the deployment of UDDI. If the error persists, examine the Exception information on its cause. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDD7012E: Failed to determine cluster ID, possibly due to invalid clusterName (check case).

Explanation: The Cluster ID could not be located for the given cluster name.

User Response: Check the cluster name is correct and is in the correct case.

CWUDGnnnns (Web Services UDDI User Console) messages:

CWUDG0001I: IBM WebSphere UDDI Registry user console starting initialization.

Explanation: The user console control servlet is starting.

User Response: None.

CWUDG0002I: IBM WebSphere UDDI Registry user console finished initialization.

Explanation: The user console control servlet has completed startup successfully.

User Response: None.

CWUDG0003I: Reading init parameters.

Explanation: The user console control servlet has started reading external parameters in its init method

User Response: None.

CWUDG0004I: Finished reading init parameters.

Explanation: The user console control servlet has finished reading external parameters in its init method. This message indicates the user console is ready to accept client requests.

User Response: None.

CWUDG0005E: A serious error has occurred. Error message: <Message> error: <Throwable>. More information: <Additional information>.

Explanation: This error message indicates an unexpected error has occurred. The <Message> describes the error that has occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

User Response: A trace of the gui component is recommended. Contact IBM support with this information.

CWUDG0006E: A persistence error has occurred. Error message: <Message> error: <Throwable>. More information: <Additional information>.

Explanation: An error occurred while performing a database operation. The <Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

User Response: Check database connections and state. Provide IBM support with a trace, including the gui and persistence components.

CWUDG0007E: A User mismatch error has occurred. Error message: <Message> error: <Throwable>. More information: <Additional information>.

Explanation: The user id provided does not match the user id required or expected whilst performing an operation that requires authentication. The <Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

User Response: Check the user has authority for the operation being requested. If necessary, contact IBM support detailing the actions taken to recreate the problem.

CWUDG0008E: An invalid key was passed. Error message: <Message> error: <Throwable>. More information: <Additional information>.

Explanation: The requested operation is trying to retrieve information about an entity with a key that is invalid. This may occur if the entity has been deleted by another session. The <Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

User Response: Ask the client to close existing sessions and attempt the operation in a new browser session. If the problem persists, contact IBM support with a trace of the gui and api components.

CWUDG0009E: An invalid value was supplied. Error message: <Message> error: <Throwable>. More information: <Additional information>

Explanation: An invalid value was passed to an API call. The <Message> describes the error that occurred and the <Throwable> is the type of error that was caught. <Additional information> may provide further information, if available.

User Response: Contact IBM support with a trace of the gui and api components.

CWUDG0010E: Failed to introspect ActionForm properties. Exception: <Exception>.

Explanation: String properties of a form object could not be introspected which means that the form contents cannot be checked for invalid characters.

User Response: Contact IBM support with details of the Exception and a trace of the gui component.

CWUDG0011E: Failed to invoke reflected methods in ActionForm. Exception: <Exception>.

Explanation: A form object's declared public method for setting or getting a String value could not be invoked. This method is required to check for invalid characters.

User Response: Contact IBM support with details of the Exception and a trace of the gui component.

CWUDG0012E: User console initialization failed to connect to UDDI database. Exception: <Exception>.

Explanation: During user console initialization, connection to the database failed, and threw the exception specified.

User Response: Check the connection to the UDDI database. The included exception message may yield some clues to help you resolve the problem. If unresolved, contact IBM support with a trace of the gui component during startup.

CWUDG0013E: User console initialization failed to initialize tModels. Exception: <Exception>.

Explanation: Indicates that an error has occurred during initialization of ActionServlet, specifically when reading tModels (invoking init method in class TModelNames).

User Response: Check the state of the UDDI database. Visually inspect the TMODEL table and confirm it is populated with valid data. The included exception message may yield some clues to help you resolve the problem. If unresolved, contact IBM support with a trace of the gui component during startup.

CWUDG0014E: User console initialization failed to initialize taxonomies. Exception: <Exception>.

Explanation: Indicates that an error has occurred during initialization of ActionServlet, specifically when reading taxonomy data (invoking init method of CategoryTaxonomyTree).

User Response: Check the state of the UDDI database. The included exception message may yield some clues to help you resolve the problem. If unresolved, contact IBM support with a trace of the gui component during startup.

CWUDMnnnns (Web Services UDDI Management Interface) messages:

CWUDM0001E: Unexpected error in MBean operation: <operation name>

Explanation: An internal error occurred processing the specified UddiNode MBean operation.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0002E: MBean transaction failed. Commit flag was: <truelfalse>

Explanation: Failed to commit or rollback the current transaction.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0003E: MBean transaction did not begin.

Explanation: Failed to invoke begin method on the UserTransaction.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0004E: MBean transaction connection failed to release.

Explanation: Failed to release connection after transaction committed or rolled back.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0005E: MBean could not establish control with persistence manager.

Explanation: Message is self-explanatory.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0006E: MBean could not acquire connection for UDDI datasource.

Explanation: Message is self-explanatory.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0007E: UddiNode MBean with ObjectName <ObjectName value> could not be recognized.

Explanation: The UddiNode MBean for the UDDI application could not be unregistered from the MBeanServer.

User Response: Restart the UDDI application or the application server. If the problem cannot be resolved, contact your IBM Customer Service Center, supplying the ObjectName value reported in the message (if present).

CWUDM0008W: MBean notification for event <notification identifier> failed.

Explanation: Message is self-explanatory.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0009W: A UddiNode MBean is already registered.

Explanation: There is a UddiNode MBean registered in the same cell, node and server.

User Response: Ensure there is only one UDDI application deployed in the server. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0020E: Unable to retrieve UDDI node ID.

Explanation: A database error occurred.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0021E: Unable to retrieve UDDI node state.

Explanation: A database error occurred.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0022E: Unable to retrieve UDDI node application name.

Explanation: A database error occurred.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0023E: Unable to retrieve UDDI node description.

Explanation: A database error occurred.

User Response: Check database connectivity and UDDI application installation configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0024E: Unable to activate UDDI node.

Explanation: An error occurred trying to activate the UDDI node.

User Response: Check the running state of the UDDI application. Restart the application if necessary. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0025I: Unable to activate a UDDI node that is not initialized.

Explanation: The UDDI node must be initialized (and in deactivated state) before it can be activated.

User Response: If the UDDI node is ready to be initialized, invoke the initialization operation.

CWUDM0026E: Unable to deactivate UDDI node.

Explanation: An error occurred trying to deactivate the UDDI node.

User Response: Check the running state of the UDDI application. Restart the application if necessary. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0027I: Unable to deactivate UDDI node that is not initialized.

Explanation: The UDDI node must be initialized (and activated) before it can be deactivated.

User Response: If the UDDI node is ready to be initialized, invoke the initialization operation.

CWUDM0028E: Unable to initialize UDDI node.

Explanation: An error occurred during UDDI node initialization.

User Response: Check the UDDI application installation and datasource settings. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0029I: Unable to initialize UDDI node because a required property is missing or invalid: <property name>.

Explanation: A configuration property that is required for UDDI node initialization has not been populated.

User Response: Supply a value for the required property.

CWUDM0030I: Initialize operation did not occur because the UDDI node is already initialized.

Explanation: A UDDI node can only be initialized once.

User Response: None.

CWUDM0031I: Initialize operation did not occur because the UDDI node is in default configuration and is already initialized.

Explanation: A UDDI node can only be initialized once.

User Response: None.

CWUDM0032I: The initialize operation is already in progress.

Explanation: A UDDI node can only be initialized once.

User Response: Wait until the current initialization operation completes.

CWUDM0050I: The UDDI publisher with user name <user ID> does not exist.

Explanation: An operation that requires a UDDI publisher ID could not find a publisher with that ID.

User Response: Check the UDDI publisher is registered with the UDDI node using the administrative functions available.

CWUDM0051E: Unable to create UDDI publisher with user name <user ID>.

Explanation: An error occurred trying to register the UDDI publisher.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0052I: Unable to create UDDI publisher for user name <user ID> because a UDDI publisher with that name already exists.

Explanation: The UDDI publisher is already registered.

User Response: None.

CWUDM0053E: Unable to delete UDDI publisher with user name <user ID>.

Explanation: An error occurred trying to register the UDDI publisher.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0054I: Unable to delete UDDI publisher with user name <user ID> because that UDDI publisher does not exist.

Explanation: The UDDI publisher is not registered so cannot be removed.

User Response: None.

CWUDM0055E: Unable to create a UDDI publisher with user name <user ID> because one or more entitlement identifiers are invalid.

Explanation: UddiUser objects must contain Entitlement objects with valid entitlement IDs.

User Response: Use valid entitlement IDs for Entitlement objects. Valid IDs can be found in the EntitlementConstants interface.

CWUDM0056E: Unable to update UDDI publisher with user name <user ID>.

Explanation: An error occurred trying to update the UDDI publisher.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0057E: Unable to update UDDI publisher with user name <user ID> because one or more entitlement identifiers are invalid.

Explanation: UddiUser objects must contain Entitlement objects with valid entitlement IDs.

User Response: Use valid entitlement IDs for Entitlement objects. Valid IDs can be found in the EntitlementConstants interface.

CWUDM0058I: Unable to update the UDDI publisher with user name <user ID> because that UDDI publisher does not exist.

Explanation: The UDDI publisher is not registered so cannot be updated.

User Response: None.

CWUDM0059E: Unable to retrieve information for UDDI publisher with user name <user ID>.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0060E: Unable to retrieve collection of UDDI publishers.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0061E: Unable to get tier assigned to UDDI publisher with user name <user ID>.

Explanation: This may be because the UDDI publisher with the specified user name does not exist, or because a database error occurred performing the operation.

User Response: Check the UDDI publisher exists. If it does, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0062E: Unable to create UDDI publishers with user names: <user IDs>.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0070E: Unable to create tier with ID: <tier ID>.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0071E: Unable to delete tier with ID: <tier ID>.

Explanation: This may because the tier with the specified ID does not exist, or because a database error occurred performing the operation.

User Response: Check the tier ID. If it does exist, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0072E: Unable to retrieve information for tier with ID: <tier ID>.

Explanation: This may be because the supplied tier ID is not an integer, or the tier with the ID does not exist, or because of a database error performing the operation.

User Response: Check the tier ID is an integer and the tier exists. If it does exist, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0073E: Unable to retrieve collection of tiers.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0074E: Unable to set default tier to tier ID: <tier ID>.

Explanation: This may be because the tier with the specified ID does not exist, or because a database error occurred performing the operation.

User Response: Check the tier ID. If it does exist, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0075E: Unable to update tier with ID: <tier ID>.

Explanation: This is most likely because the tier with the specified ID does not exist, or because a database error occurred performing the operation.

User Response: Check the tier ID. If it does exist, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0076E: Unable to get count of UDDI publishers for tier ID: <tier ID>.

Explanation: This may be because the tier with the specified ID does not exist, or because a database error occurred performing the operation.

User Response: Check the tier ID. If it does exist, check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0077E: Unable to retrieve collection of entitlements.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0078E: Unable to retrieve collection of limits.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0079I: The default tier cannot be deleted.

Explanation: A tier must always exist that is designated as the tier assigned to UDDI publishers when auto-registration of UDDI publishers is enabled.

User Response: None.

CWUDM0080I: Unable to delete tier <tier ID> because it is currently assigned to a UDDI publisher.

Explanation: Tiers which have UDDI publishers assigned to them cannot be deleted.

User Response: If you want to remove the tier, assign the UDDI publishers to a different tier first.

CWUDM0100E: Unable to get configuration property information for property with ID: <property ID> **Explanation:** A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0101I: Unable to get configuration property information for property with ID: <property ID> because it does not exist.

Explanation: The configuration property with the specified ID does not exist.

User Response: None.

CWUDM0102E: Unable to retrieve collection of configuration properties.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0103E: Unable to update configuration properties.

Explanation: This may occur if any of the updated property objects fails validation. Check any cause exceptions for possible additional information. Alternatively database error may have occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0104E: Unable to update configuration property with ID: <property ID>

Explanation: This may occur if the updated property object fails validation. Check any cause exceptions for possible additional information. Alternatively a database error may have occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0105I: Unable to update configuration property with ID: <property ID> because it does not exist. **Explanation:** The configuration property with the specified ID does not exist.

User Response: Use a valid configuration property ID. These can be found in PropertyConstants.

CWUDM0106I: Unable to update configuration properties because one or more properties do not exist in the UDDI node.

Explanation: One or more supplied configuration properties do not exist in the UDDI registry.

User Response: Use valid configuration property IDs. These can be found in PropertyConstants.

CWUDM0107E: Failed to retrieve required properties from database.

Explanation: This indicates a database error occurred when trying to initialize a UDDI node.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0120E: Unable to get policy information for policy with ID: <policy ID>.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0121I: Unable to get policy information for policy with ID: <policy ID> because it does not exist. **Explanation:** The policy with the specified ID does not exist.

User Response: None.

CWUDM0122E: Unable to get policy group with group ID: <policy group ID>.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0123E: Unable to retrieve collection of policy groups.

Explanation: A database error occurred performing the operation.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0124E: Unable to update policies.

Explanation: This may occur if any of the updated policy objects fails validation. Check any cause exceptions for possible additional information. Alternatively a database error may have occurred performing the operation.

User Response: Ensure all policy IDs and values are valid. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0125E: Unable to update policy with ID: <policy ID>.

Explanation: This may occur if the updated policy object fails validation or the ID isn't recognized. Check any cause exceptions for possible additional information. Alternatively a database error may have occurred performing the operation.

User Response: Check the policy ID and value are valid. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0126I: Unable to get policy group information for policy group with ID: <policy group ID> because it does not exist.

Explanation: The policy group with the specified ID does not exist.

User Response: Use a valid policy group ID. These can be found in PolicyConstants.

CWUDM0127I: Unable to update policies because one or more policies do not exist in the UDDI node. **Explanation:** One or more supplied policies do not exist in the UDDI registry.

User Response: Use valid policy IDs. These can be found in PolicyConstants.

CWUDM0128I: Unable to update policy with ID: <policy ID> because it does not exist.

Explanation: The policy with the specified ID does not exist.

User Response: Use a valid policy ID. These can be found in PolicyConstants.

CWUDM0140E: Unable to change value set tModelKey from <original tModel key> to <new tModel key>. **Explanation:** The original tModel key or new tModel key supplied could not be found in the UDDI registry, or possibly there was a database error.

User Response: Supply keys for tModels that exist in the UDDI registry. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0141E: Unable to retrieve value set details for tModel key: <tModel key>.

Explanation: A database error occurred getting the value set details.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0142E: Unable to get value set property: <value set property ID> for value set with tModel key: <tModel key>.

Explanation: The value set property ID or tModel key supplied was not recognized.

User Response: Supply a valid value set property ID and tModel key. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0143E: Unable to retrieve value sets collection.

Explanation: A database error may have occurred.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0144E: Unable to determine if value set with tModel key: <tModel key> exists.

Explanation: The tModel key supplied is not valid or a database error may have occurred.

User Response: Ensure the tModel exists. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0145E: Unable to load value set data for value set with tModel key: <tModel key> and file name <1>.

Explanation: The original tModel key or new tModel key supplied could not be found in the UDDI registry, or possibly there was a database error.

User Response: Ensure the tModel exists and the value set data object is populated. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0146E: Unable to load value set data for value set with tModel key: <tModel key>.

Explanation: The tModel key is not recognized or a database error occurred.

User Response: Ensure the tModel exists and the value set data object is populated. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0147E: Could not update value set status with tModel key: <tModel key>.

Explanation: The value set status object supplied is null or the tModel key is not known.

User Response: Supply a valid value set status object with tModel key for a value set tModel that exists. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0148E: Could not update value set status with tModel key: <tModel key>, property: <value set property ID>.

Explanation: A database error occurred updating the supported status of the value set status.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0149E: Could not update value set status with tModel key: <tModel key>.

Explanation: One of the supplied value set status objects contained a tModel key which was not recognized.

User Response: Supply tModel keys for value set tModels that exist. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0150E: Could not update value set status with tModel key: <tModel key>, property: <value set property ID>.

Explanation: A database error occurred updating the supported status of one of the value set status objects.

User Response: Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0151E: Unable to unload value set data with tModel key: <tModel key>.

Explanation: The tModel key is not recognized or a database error occurred.

User Response: Ensure the tModel exists. Check UDDI application configuration and database connectivity. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0170E: Loading of configuration file <configuration file URL> failed.

Explanation:

User Response: Check UDDI application configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0171E: Parsing of configuration file <configuration file URL> failed.

Explanation:

User Response: Check UDDI application configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0172W: An unexpected date format was found while parsing configuration file.

Explanation:

User Response: Check UDDI application configuration. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDM0180I: UDDI node was activated.

Explanation: The UDDI node is ready to accept UDDI API requests.

User Response: None.

CWUDM0181I: UDDI node was deactivated.

Explanation: The UDDI node is set to not accept UDDI API requests. This typically occurs when configuration settings are being updated by administrative tasks.

User Response: None.

CWUDM0182I: UDDI node initialized successfully.

Explanation: The UDDI node is ready to accept UDDI API requests.

User Response: None.

CWUDM0183I: UDDI publisher <user ID> was created.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0184I: UDDI publisher <user ID> was updated.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0185I: UDDI publisher <user ID> was deleted.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0186I: Tier <tier ID> was created.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0187I: Tier <tier ID> was updated.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0188I: Tier <tier ID> was deleted.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0189I: Configuration property <property ID> was updated to value <property value>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0190I: Policy <policy ID> was updated to value <policy value>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0191I: Default tier was set to <tier ID>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0192I: Loaded value set for tModel key <tModel key> from file <1>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0193I: Loaded value set for tModel key <tModel key>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0194I: Unloaded value set for tModel key <tModel key>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0195I: Updated value set supported status for tModel key <tModel key> to <supported status>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0196I: Changed tModel key for value set from <original tModel key> to <new tModel key>.

Explanation: This message indicates the administrative operation completed successfully.

User Response: None.

CWUDM0220W: <value or ID> is too short. The length must be in the range <minimum length> to <maximum length> characters.

Explanation: A value or ID of type String is shorter than expected.

User Response: Supply a value or ID that is in the expected range.

CWUDM0221W: <value or ID> is too long. The length must be in the range <minimum length> to <maximum length> characters.

Explanation: A value or ID of type String is longer than expected.

User Response: Supply a value or ID that is in the expected range.

CWUDM0222W: <value or ID> is read-only and cannot be updated.

Explanation: The configuration setting is marked as read only, which may be because the setting is for information only, or because the setting is configured once during UDDI node initialization, such as the UDDI node ID or root key generator.

User Response: None.

CWUDM0223W: <value or ID> is required.

Explanation: The configuration setting expects a value to be entered.

User Response: Supply a non-empty, valid value for the configuration setting.

CWUDM0224W: <value or ID> must be a valid URL value.

Explanation: The configuration property is expected to be a valid URL.

User Response: Supply a valid URL.

CWUDM0225W: <value or ID> must be a valid xml:lang value.

Explanation: The configuration property supplied is not a valid xml:lang value.

User Response: Supply a valid xml:lang value.

CWUDM0226W: <value or ID> must be of type: <value type>.

Explanation: The value or ID is not of the expected type.

User Response: Supply a value or ID of the correct type.

CWUDM0227W: <value or ID> cannot be a null value.

Explanation: A property ID was expected but a null value was supplied.

User Response: Supply a valid, non-null ID.

CWUDM0228W: <value or ID> must be in the range <minimum value> to <maximum value>.

Explanation: The value is not in the expected range

User Response: Supply a value in the expected range.

CWUDM0229W: The entitlement object with ID: <entitlement ID> is not valid.

Explanation: The UDDI application doesn't recognize the entitlement with the supplied ID.

User Response: Supply a valid entitlement ID, which can be found in EntitlementConstants.

CWUDM0230W: The limit object with ID: <limit ID> is not valid.

Explanation: The UDDI application doesn't recognize the limit with the supplied ID.

User Response: Supply a valid limit ID, which can be found in LimitConstants.

CWUDM0231W: <value> must be a valid UDDI key value.

Explanation: The value supplied was not a UDDI key.

User Response: UDDI keys must start with the text 'uddi:'. See the UDDI specification for further information about UDDI keys.

CWUDM0232W: <value> must be a valid UDDI key generator key.

Explanation: The value supplied was not a UDDI key generator.

User Response: UDDI key generator values must be valid UDDI keys and end in the string 'keygenerator'. See the UDDI specification for further information about UDDI keys.

CWUDM0240W: The configuration property ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0241W: The policy group ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0242W: The policy ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0243W: The entitlement ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0244W: The limit ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0245W: The user ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0246W: The tier ID cannot be null or empty.

Explanation: The ID supplied was null or empty.

User Response: Supply a non-null, non-empty ID, valid for the context in which it is used.

CWUDM0250W: The configuration property parameter cannot be null or empty.
Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty configuration property parameter.
CWUDM0251W: The policy group parameter cannot be null or empty.
Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty policy group parameter.
CWUDM0252W: The policy parameter cannot be null or empty.
Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty policy parameter.
CWUDM0253W: The entitlement parameter cannot be null or empty.
Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty entitlement parameter.
CWUDM0254W: The limit parameter cannot be null or empty.
Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty limit parameter.
CWUDM0255W: The user parameter cannot be null or empty.
Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty user (UDDI publisher) parameter.
CWUDM0256W: The tier parameter cannot be null or empty.
Explanation: The parameter supplied was null or empty.

User Response: Supply a non-null, non-empty tier parameter.
CWUDM0257I: The collection cannot be null.
Explanation: The collection (typically a list of properties, policies, tiers or users to update) parameter supplied was null.

User Response: Supply a non-null collection parameter.

CWUDNnnnns (Web Services UDDI Node Manager) messages: Most of these messages are in the format 'Error', Class, Method, Exception. For example

```
CWUDN0005E: Error, NodeManager, txnlInit, UDDIFatalErrorException during init
```

indicates that a UDDIFatalErrorException was thrown by the txnlInit method of the NodeManager class, during execution of the init method.
CWUDN0001I: UDDI Node State change, new state:
Explanation: The UDDI has successfully changed to the identified new state.

User Response: None.
CWUDN0002I: Error, invalid Node State requested:
Explanation: The UDDI Registry detected a request for invalid state changes.

User Response: Contact the IBM Customer Service Center.
CWUDN0004E: Error, NodeManager, txnlInit, failed getting persister control
Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.
CWUDN0005E: Error, NodeManager, txnlInit, UDDIFatalErrorException during init
Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.
CWUDN0006E: Error, NodeManager, txnlInit, UDDIException during init.
Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.
CWUDN0007E: Error, NodeManager, txnlInit, Exception during init
Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.

CWUDN0008E: Error, NodeManager, txnIInit, Throwable during init

Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.

CWUDN0009E: Error, NodeManager, txnIInit, rollback exception

Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.

CWUDN0010E: Error, NodeManager, txnIInit, Throwable releasing connection

Explanation: NodeManager initialization failure.

User Response: Contact the IBM Customer Service Center.

CWUDN0011E: Error, NodeManager, txnIDestroy, failed getting Persister control

Explanation: NodeManager application stop or removal error.

User Response: Contact the IBM Customer Service Center.

CWUDN0012E: Error, NodeManager, txnIDestroy, UDDI Exception during destroy

Explanation: NodeManager application stop or removal error.

User Response: Contact the IBM Customer Service Center.

CWUDN0013E: Error, NodeManager, txnIDestroy, rollback Exception

Explanation: NodeManager application stop or removal error.

User Response: Contact the IBM Customer Service Center.

CWUDN0014E: Error, NodeManager, txnIDestroy, Exception releasing connection

Explanation: NodeManager application stop or removal error.

User Response: Contact the IBM Customer Service Center.

CWUDQnnnns (Web Services UDDI Migration) messages:

CWUDQ0001I: UDDI registry migration datasource is present.

Explanation: The UDDI migration datasource is defined when UDDI is started.

User Response: None.

CWUDQ0002I: UDDI registry migration has started.

Explanation: The UDDI database migration process has started. This may take some time to complete dependent on the size of your database.

User Response: None.

CWUDQ0003I: UDDI registry migration has completed.

Explanation: The UDDI database migration process has finished.

User Response: None.

CWUDQ0004W: UDDI registry not started due to migration errors.

Explanation: The UDDI registry has not been activated because migration errors were encountered.

User Response: Examine the messages produced during the migration process. Determine if the problem is user fixable, that is the Version 2 database is quiesced and so on. If the problem is fixable recreate the Version 3 UDDI database and restart the UDDI application. If the problem cannot be rectified contact your IBM Customer Service Center. It is still possible to use the UDDI Administration Console to start the UDDI registry.

CWUDQ0005I: <rows> rows have been inserted into table <table>.

Explanation: An informational message showing the number of database rows converted for each UDDI table.

User Response: None.

CWUDQ10001E: Row not inserted into <table>.

Explanation: A row was unable to be inserted into a database table.

User Response: See CWUDQ1003E for details of the SQL Exception details

CWUDQ1002E: Table <table> values are: <Key Values>.

Explanation: Contains the table in error and the significant key values of the row being migrated.

User Response: None.

CWUDQ1003E: SQL Exception during migration: <SQL Exception Message>.

Explanation: An SQL Exception has occurred during the migration process. The SQL Exception details are displayed in the message.

User Response: Examine the SQL Exception information on its cause. Message CWUDQ1002E contains table details and significant key values. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDQ1004E: <rows> rows have not been inserted into table <table>.

Explanation: A message showing the number of database rows not converted for a particular UDDI table.

User Response: None.

CWUDQ1005E: SQL Exception during key value extraction: <SQL Exception Message>.

Explanation: An SQL Exception occurred during the production of the CWUDQ1002E message.

User Response: None.

CWUDQ1006E: Exception during migration: <Exception Message>.

Explanation: An Exception has occurred during the migration process. The Exception details are displayed in the message.

User Response: Examine the Exception information on its cause. Message CWUDQ1002E contains table details and significant key values. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDRnnnns (Web Services UDDI Logging and Tracing) messages:

CWUDR0001E: Exception "<exception>" occurred while attempting to get UDDI Message Logger.

Explanation: This message is issued to stderr when an attempt to get the UDDI Message Logger fails with the indicated exception. Since the attempt to get the message logger failed, the message cannot be logged. No messages can be logged by this instance of the IBM WebSphere UDDI Registry.

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDR0002E: Exception "<exception>" occurred while attempting to get UDDI Trace Logger for "<component>".

Explanation: This message is logged when an attempt to get the UDDI Trace Logger for the specified component (or package) fails with the indicated exception. No trace entries can be logged for this component or package of the IBM WebSphere UDDI Registry.

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDSnnnns (Web Services UDDI SOAP Interface) messages:

CWUDS0001E: ParserPool found empty whilst attempting to process request. Request unsatisfied

Explanation: A SOAP request was received, but was unable to be dealt with, as there were no free Parsers within the ParserPool.

User Response: Consider increasing the number of Parsers within the ParserPool by modifying the Init Parameter on the SOAP servlets.

CWUDS0002E: Error locating schemas required for UDDI processing. SOAP Servlets unworkable.

Explanation: The SOAP servlet was unable to locate the schemas it requires in order to process SOAP requests. Without these, the servlet cannot process SOAP requests.

User Response: Check installation of UDDI was performed correctly. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDS0003W: Servlet unable to locate init parameter 'defaultPoolSize'. Using internal defaults.

Explanation: The SOAP servlet was unable to locate the init parameter which sets the default size of the ParserPool. It will fall back to an internal default.

User Response: If this message occurred after attempting to make changes to the defaultPoolSize init parameter, ensure the changes were correct. If this message has appeared after installed, ensure installation was performed correctly.

CWUDS0004W: Servlet unable to understand init parameter 'defaultPoolSize'. Using internal defaults.

Explanation: The SOAP servlet was unable to parse the init parameter which sets the default size of the ParserPool. It will fall back to an internal default.

User Response: If this message occurred after attempting to make changes to the defaultPoolSize init parameter, ensure the changes were correct. If this message has appeared after installed, ensure installation was performed correctly.

CWUDS0005E: Error occurred during parser creation.

Explanation: An unspecified error occurred during the creation of a SOAP parser

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDS0006E: Internal configuration error.

Explanation: This error may occur if there was a failure creating a Parser, with accompanying message CWUDS0005. It may also occur if there was a problem acquiring the Persistence layer.

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then please contact the IBM Customer Service Center.

CWUDS0007E: Error during servlet acquisition of persistence layer.

Explanation: The SOAP servlet was unable to acquire the persistence layer required for it to communicate with the UDDI datasource

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDS0008E: Error during servlet release of persistence layer.

Explanation: The persistence layer reported a problem when the SOAP servlet attempted to release it.

User Response: Restart the UDDI registry. If the error persists, examine the WebSphere logs for information on its cause. If the problem cannot be resolved, then contact the IBM Customer Service Center.

CWUDS0009E: Error during sending of response to client.

Explanation: An error occurred when sending a SOAP response message back to a client. The client may not have received the response

User Response: This error is recorded to enable logging of failed responses to clients. The error may be the fault of the client disconnecting before the reply could be sent, or may indicate a network problem. Examine the WebSphere logs for more information on its cause.

CWUDS0010E: Serious error while servlet attempting to process doPost Request.

Explanation: A serious error occurred processing a UDDI Version 1 or Version 2 SOAP request.

User Response: Check the validity of the UDDI Version 1 or Version 2 SOAP request.

CWUDS0011E: incomplete URL received processing doGet Request.

Explanation: An incomplete or incorrect UDDI Version 3 GET request was received.

User Response: Check the validity of the UDDI Version 3 GET request URL.

CWUDS0012E: non-UDDI exception received processing doGet Request.

Explanation: A serious error occurred while processing a UDDI Version 3 GET request.

User Response: Check the validity of the UDDI Version 3 GET request URL.

CWUDTnnnns (Web Services UDDI Registry Transaction Manager) messages:

CWUDT0001E: UDDIFatalErrorException processing request. persistenceManager.getControl() returned null, throwing UDDIFatalErrorException.

Explanation: A serious internal error occurred while processing a UDDI Version 3 SOAP request.

User Response: Check the configuration of the UDDI Enterprise Application. If the problem cannot be resolved, contact the IBM Customer Service Center.

CWUDT0002E: UDDIFatalErrorException processing request. UDDIFatalErrorException processing request.

Explanation: A serious UDDI error occurred while processing a UDDI Version 3 SOAP request.

User Response: Check the validity of the UDDI request.

CWUDT0003E: UDDIFatalErrorException processing request. Exception processing request.

Explanation: A serious non UDDI error occurred while processing a UDDI Version 3 SOAP request.

User Response: Check the validity of the UDDI request.

CWUDUnnnns (Web Services UDDI Utility Tools) messages:

```
CWUDU0001I: Usage: java -jar UDDIUtilityTools.jar '{'function'}' [options]
function:
  -promote entity source   Promote entities between registries
  -export entity source    Extract entities from registry to XML
  -delete entity source    Delete entities from registry
  -import                  Create entities from XML to registry

where entity source is one of:
  -tmodel|-business|-service|-binding key Specify single entity type and key
  -keysFile | -f filename  Specify file containing entity types and keys

options:
  -properties filename     Specify path to configuration file
  -overwrite | -o          Overwrite an entity if it already exists
  -log | -v                Output verbose messages
  -definitionFile filename Specify path to UDDI entity definition file
  -importReferenced        Import entities referenced by source entities

The following options override property settings in configuration file:
  -overwrite
  -log
  -definitionFile
  -importReferenced

Example: java -jar UDDIUtilityTools.jar -promote -keysFile /uddikeys.txt
```

Explanation: This is the usage message displayed at the command line when the user has entered an invalid combination of arguments or options.

User Response: Enter the command according to the usage message.

CWUDU0002I: ******** Starting UDDI Utility Tools ************

Explanation: This message is used as a marker in the message log file to indicate tool start points.

User Response: None.

CWUDU0003I: Promoting entityType<entity type> key<entity key>...

Explanation: Indicates which entity type (business, tModel and so on) is being promoted, and it's key value.

User Response: None.

CWUDU0004I: Bad entityType: received<incorrect entity type>, expected <tModel|business|service|binding>

Explanation: The user entered an incorrect entity type.

User Response: Use an entity type of tModel, business, service or binding.

CWUDU0005I: Promotion successful.

Explanation: Indicates the promote function completed successfully.

User Response: None.

CWUDU0006I: Import successful.

Explanation: Indicates the import function completed successfully.

User Response: None.

CWUDU0007I: Export successful.

Explanation: Indicates the export function completed successfully.

User Response: None.

CWUDU0008I: Delete successful.

Explanation: Indicates the delete function completed successfully.

User Response: None.

CWUDU0009I: Exporting entities ...

Explanation: Indicates the export function has started.

User Response: None.

CWUDU0010I: Exporting business, businessKey[<business key].

Explanation: Indicates that the businessEntity with the specified key is being exported.

User Response: None.

CWUDU0011I: Exporting service, serviceKey[<service key>].

Explanation: Indicates that the businessService with the specified key is being exported.

User Response: None.

CWUDU0012I: Exporting binding, bindingKey[<binding key>].

Explanation: Indicates that the bindingTemplate with the specified key is being exported.

User Response: None.

CWUDU0013I: Exporting tModel, tModelKey[<tModel key>].

Explanation: Indicates that the tModel with the specified key is being exported.

User Response: None.

CWUDU0014I: Exporting referenced tModel, tModelKey[<tModel key>].

Explanation: Indicates that the referenced tModel with the specified key is being exported.

User Response: None.

CWUDU0015I: Exported <entity count> entities.

Explanation: Indicates that the export function completed, and shows the number of entities exported.

User Response: None.

CWUDU0016I: Importing entities ...

Explanation: Indicates the import function has started.

User Response: None.

CWUDU0017I: Importing business, businessKey[<business key>].

Explanation: Indicates that the businessEntity with the specified key is being imported.

User Response: None.

CWUDU0018I: Importing service, serviceKey[<service key>].

Explanation: Indicates that the businessService with the specified key is being imported.

User Response: None.

CWUDU0019I: Importing binding, bindingKey[<binding key>]

Explanation: Indicates that the bindingTemplate with the specified key is being imported.

User Response: None.

CWUDU0020I: Importing tModel, tModelKey[<tModel key>].

Explanation: Indicates that the tModel with the specified key is being imported.

User Response: None.

CWUDU0021I: Importing referenced tModel, tModelKey[<tModel key>].

Explanation: Indicates that the referenced tModel with the specified key is being imported.

User Response: None.

CWUDU0022I: Imported <entity count> entities.

Explanation: Indicates that the import function completed, and shows the number of entities imported.

User Response: None.

CWUDU0023I: Deleting entities ...

Explanation: Indicates the delete function has started.

User Response: None.

CWUDU0024I: Deleting business, businessKey[<business key>].

Explanation: Indicates that the businessEntity with the specified key is being deleted.

User Response: None.

CWUDU0025I: Deleting service, serviceKey[<service key>].

Explanation: Indicates that the businessService with the specified key is being deleted.

User Response: None.

CWUDU0026I: Deleting binding, bindingKey[<binding key>].

Explanation: Indicates that the bindingTemplate with the specified key is being deleted.

User Response: None.

CWUDU0027I: Deleting tModel, tModelKey[<tModel key>].

Explanation: Indicates that the tModel with the specified key is being deleted.

User Response: None.

CWUDU0028I: Deleted <entity count> entities.

Explanation: Indicates that the delete function completed, and shows the number of entities deleted.

User Response: None.

CWUDU0029I: Serializing ...

Explanation: Indicates that generation of the Entity Definition File has started.

User Response: None.

CWUDU0030I: Serialized entities.

Explanation: Indicates that generation of the Entity Definition File completed successfully.

User Response: None.

CWUDU0031I: Deserializing ...

Explanation: Indicates that reading of the Entity Definition File and creation of UDDI entities has started.

User Response: None.

CWUDU0032I: Deserialized entities.

Explanation: Indicates that reading of the Entity Definition File and creation of UDDI entities completed successfully.

User Response: None.

CWUDU0033I: Function '<function>' completed successfully.

Explanation: Indicates the requested function completed successfully.

User Response: None.

CWUDU0034W: Function '<function>' did not complete successfully. See messages log for further information.

Explanation: Indicates the requested function did not complete successfully.

User Response: The messages log may yield further information if the verbose option is on. Check the configuration properties file setting are correct. If that does not identify the problem, try running with trace logging enabled. If that does not yield a solution, contact your IBM support center.

CWUDU0035W: Parser error: <warning description>

Explanation: The XML parser reports a warning about the content of the Entity Definition File.

User Response: Based on the context of the warning message, check the validity of the Entity Definition File.

CWUDU0036E: Parser error <error description>

Explanation: The XML parser reports an error about the content of the Entity Definition File.

User Response: Based on the context of the error message, check the validity of the Entity Definition File.

CWUDU0037E: Unrecognized parser feature: <feature description>

Explanation: A parser feature set by the UDDI Utility Tools is not recognized by the parser.

User Response: Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.

CWUDU0038E: Unsupported parser feature: <feature description>

Explanation: A parser feature set by the UDDI Utility Tools is not supported by the parser.

User Response: Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.

CWUDU0039E: Unrecognized parser property: <property description>, value: <value>

Explanation: A parser property set by the UDDI Utility Tools is not recognized by the parser.

User Response: Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.

CWUDU0040E: Unsupported parser property: <property description>, value: <value>

Explanation: A parser property set by the UDDI Utility Tools is not supported by the parser.

User Response: Check you are using the correct type and level of XML parser. If correct, contact your IBM support center.

CWUDU0042E: Unable to find the configuration file: <filepath>

Explanation: UDDI Utility Tools cannot locate the specified configuration file.

User Response: UDDI Utility Tools looks for a default configuration properties with the file name 'UDDIUtilityTools.properties' in the current directory. Check that the configuration file has this name, or that the argument value supplied with the '-properties' option is pointing at a file that exists.

CWUDU0043E: An Exception occurred trying to read the configuration file.

Explanation: The configuration file could not be read.

User Response: Check the file path points to a valid file and that the current user has permission to read the file.

CWUDU0044W: Configuration file is missing the '<property name>' property.

Explanation: A required property is missing from the configuration file.

User Response: Add the missing property name and value to the configuration file. Check that the property name is not misspelled.

CWUDU0045W: Property: '<property name>' has value '<property value>'. It must be either 'true' or 'false'.

Explanation: A value was given to a property other than 'true' or 'false'.

User Response: Set the property value to 'true' or 'false'.

CWUDU0046W: Property: '<property name>' has value '<property value>'. It must be an integer value. **Explanation:** A value was given to a property other than an integer value.

User Response: Set the property value to an integer value.

CWUDU0047E: Unable to find the keyFile file: <keys file path>

Explanation: The keys file could not be located at the specified path.

User Response: Check the file name and path and correct and that the file exists.

CWUDU0048E: Unable to read the keyFile file: <keys file path>

Explanation: The keys file could not be read due to an IO error.

User Response: Check that the current user has permission to read the file.

CWUDU0049E: Unable to write to entity definition file: <entity definition file path>

Explanation: During serialization, the Entity Definition File could not be written to.

User Response: Check the file's read only attribute is not set.

CWUDU0050E: Unable to find UDDI Entity definition file: <entity definition file path>

Explanation: The Entity Definition File could not be found at the specified file path.

User Response: Check the file path is correct and that the file exists.

CWUDU0051E: Unable to read UDDI Entity definition file: <entity definition file path>

Explanation: The Entity Definition File could not be read due to an IO error.

User Response: Check that the current user has permission to read the file.

CWUDU0052E: Unable to close the message file: <file path>

Explanation: The attempt to close the message log file failed.

User Response: The disk might be full. If so, clear some space or direct log output to a different disk.

CWUDU0053E: Unable to close the trace file: <file path>

Explanation: The attempt to close the trace log file failed.

User Response: The disk might be full. If so, clear some space or direct log output to a different disk.

CWUDU0054E: The logger was unable to find the file: <file path>

Explanation: The UDDI Utility Tools logger could not find the specified file.

User Response: None.

CWUDU0055E: ERROR OCCURRED ...

Explanation: General purpose error message used in development only.

User Response: None.

CWUDU0056E: Exception:

Explanation: General purpose message prefix used for reporting exceptions.

User Response: None.

CWUDU0057W: Only one function may be specified on the command line.

Explanation: Multiple function commands were entered on the command line.

User Response: Specify one function in accordance with the usage message.

CWUDU0058W: No function was specified.

Explanation: UDDI Utility Tools was invoked with no function specified.

User Response: Specify one function in accordance with the usage message.

CWUDU0059W: The function: <function> was not recognized.

Explanation: The function value did not match any of the allowed functions.

User Response: Specify one function in accordance with the usage message.

CWUDU0060W: The argument '<argument>' was not recognized.

Explanation: The argument value does not match any of the allowed arguments.

User Response: Specify arguments in accordance with the usage message.

CWUDU0061W: There was a missing value for <argument> argument.

Explanation: An expected value for the specified argument was not supplied.

User Response: Specify a value for the argument in accordance with the usage message.

CWUDU0062W: Unexpected argument: <argument> (entity key file is already specified).

Explanation: The entity type argument cannot be specified if the keysFile argument has already been specified.

User Response: Specify arguments in accordance with the usage message.

CWUDU0063W: Unexpected argument: <argument> (entity key is already specified).

Explanation: The keysFile argument cannot be specified if an entity type argument and key value has already been specified.

User Response: Specify arguments in accordance with the usage message.

CWUDU0064W: Argument: <argument> cannot be specified more than once.

Explanation: An argument was specified twice in the same command.

User Response: Specify arguments in accordance with the usage message.

CWUDU0065E: No entity keys were specified.

Explanation: A keys file or an entity type and key value must be specified for functions using keys.

User Response: Specify arguments in accordance with the usage message.

CWUDU0066E: Could not load Database driver: dbDriver<database driver>.

Explanation: The specified database driver could not be loaded.

User Response: Check the database driver value in the configuration file is valid, and the driver's class is present in the classpath property.

CWUDU0067E: Could not create Database connection: dbUrl, dbUser, (dbPasswd not shown).

Explanation: A connection could not be established with the database at the specified URL with the specified userid.

User Response: Check the database URL, userid and password values are correct n the configuration file, and that the database manager is running.

CWUDU0068E: Could not close the database connection.

Explanation: An attempt to close the database connection failed.

User Response: If the problem persists, contact your IBM support center.

CWUDU0069E: Could not create minimal entity for tModel.

Explanation: The minimal data necessary for a valid tModel could not be inserted in the target UDDI registry database.

User Response: Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

CWUDU0070E: Could not create minimal entity for Service.

Explanation: The minimal data necessary for a valid businessService could not be inserted in the target UDDI registry database.

User Response: Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

CWUDU0071E: Could not create minimal entity for Business.

Explanation: The minimal data necessary for a valid businessEntity could not be inserted in the target UDDI registry database.

User Response: Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

CWUDU0072E: Could not create minimal entity for Binding.

Explanation: The minimal data necessary for a valid bindingTemplate could not be inserted in the target UDDI registry database.

User Response: Check the database URL, userid and password values are correct in the configuration file, and that the database manager is running.

CWUDU0073E: There was an error while trying to create an XML Document.

Explanation: An attempt to create the Entity Definition File failed.

User Response: Check the file path specified in the configuration file for the Entity Definition File is valid and is not set to be read only.

CWUDU0074E: There was an error parsing the entity definition file.

Explanation: An unspecified error occurred when parsing the Entity Definition File.

User Response: Check the entity definition file content is valid according to the UDDI Utility Tools schema file, promoter.xsd.

CWUDU0075E: One or more errors occurred while parsing the entity definition file. See message log for details.

Explanation: Errors occurred when parsing the Entity Definition File.

User Response: Check the entity definition file content is valid according to the UDDI Utility Tools schema file, promoter.xsd.

CWUDU0076W: One or more warnings were raised while parsing the entity definition file. See message log for details.

Explanation: Warnings occurred when parsing the Entity Definition File.

User Response: Check the entity definition file content is valid according to the UDDI Utility Tools schema file, promoter.xsd.

CWUDU0078E: Unable to obtain authinfo.

Explanation: AuthInfo could not be obtained from the UDDI registry with the given userid and password.

User Response: Check the userid and password property values are correct in the configuration file.

CWUDU0079E: The inquiryURL is malformed: <inquiry URL>.

Explanation: The inquiry URL specified in the configuration file is not valid.

User Response: Correct the value for the inquiry URLs (fromInquiryURL and toInquiryURL) in the configuration file.

CWUDU0080E: The publishURL is malformed: <publish URL>

Explanation: The publish URL specified in the configuration file is not valid.

User Response: Correct the value for the publish URL (toPublishURL) in the configuration file.

CWUDU0081E: Could not get tModel detail for tModelKey[<tModel key>].

Explanation: The get tModel operation failed on the source registry.

User Response: Check the key exists in the source registry.

CWUDU0082E: Could not get service detail for serviceKey[<service key>].

Explanation: The get service operation failed on the source registry.

User Response: Check the key exists in the source registry.

CWUDU0083E: Could not get business detail for businessKey[<business key>].

Explanation: The get business operation failed on the source registry.

User Response: Check the key exists in the source registry.

CWUDU0084E: Could not get binding detail for bindingKey[<binding key>].

Explanation: The get binding operation failed on the source registry.

User Response: check the key exists in the source registry.

CWUDU0085E: Could not save tModel for tModelKey[<tModel key>].

Explanation: The publish operation failed at the target registry.

User Response: Check the tModel is not referencing another entity (such as a tModel) that is not present in the target registry. This may occur if the 'importReferenced' property is set to 'false'. Specify referenced tModels in the referencedtModels section of the Entity Definition File and set 'importReferenced' property in the configuration file to 'true'.

CWUDU0086E: Could not save business for businessKey[<business key>].

Explanation: The publish operation failed at the target registry.

User Response: Check the businessEntity is not referencing another entity (such as a tModel) that is not present in the target registry. This may occur if the 'importReferenced' property is set to 'false'. Specify referenced tModels in the referencedtModels section of the Entity Definition File and set 'importReferenced' property in the configuration file to 'true'.

CWUDU0087E: Could not save service for parent businessKey[<business key>].

Explanation: The publish operation failed at the target registry.

User Response: Check the businessEntity specified as the parent of the businessService exists in the target registry.

CWUDU0088E: Could not save binding for parent serviceKey[<service key>].

Explanation: The publish operation failed at the target registry.

User Response: Check the businessService specified as the parent of the bindingTemplate exists in the target registry.

CWUDU0089W: Did not save service for serviceKey[<service key>] because parent business did not exist.

Explanation: The parent business for the specified businessService does not exist.

User Response: Check the key value for the parent entity is correct in the Entity Definition File, and that the entity exists in the target registry.

CWUDU0090W: Did not save binding for bindingKey[<binding key>] because parent service did not exist. **Explanation:** The parent service for the specified bindingTemplate does not exist.

User Response: Check the key value for the parent entity is correct in the Entity Definition File, and that the entity exists in the target registry.

CWUDU0091E: Could not delete business for businessKey[<businness key>].

Explanation: The UDDI4J operation to delete the businessEntity with the specified key failed.

User Response: Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

CWUDU00921E: Could not delete service for serviceKey[<tModel key>].

Explanation: The UDDI4J operation to delete the businessService with the specified key failed.

User Response: Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

CWUDU0093E: Could not delete binding for bindingKey[<binding key>].

Explanation: The UDDI4J operation to delete the bindingTemplate with the specified key failed.

User Response: Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

CWUDU0094E: Could not delete tModel for tModelKey[<tModel key>].

Explanation: The UDDI4J operation to delete the tModel with the specified key failed.

User Response: Check the userid and password property values in the configuration file and that the entity exists in the target UDDI registry.

CWUDU0096W: <entity type><key value> is not a valid UUID.

Explanation: The key value entered does not comply with the format specified for a UUID in the UDDI specification.

User Response: Enter a valid UUID key.

CWUDU0097W: Did not save tModel for tModelKey[<tModel key>] as it already exists. Use the -overwrite argument to overwrite the tModel.

Explanation: The tModel was not saved because the overwrite property is false

User Response: If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

CWUDU0098W: Did not save business for businessKey[<business key>] as it already exists. Use the -overwrite argument to overwrite the business.

Explanation: The businessEntity was not saved because the overwrite property is false

User Response: If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

CWUDU0099W: Did not save service for serviceKey[<service key key>] as it already exists. Use the -overwrite argument to overwrite the service.

Explanation: The businessService was not saved because the overwrite property is false

User Response: If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

CWUDU0100W: Did not save binding for bindingKey[<binding key key>] as it already exists. Use the -overwrite argument to overwrite the binding.

Explanation: The bindingTemplate was not saved because the overwrite property is false

User Response: If the desired action is to overwrite existing entities, specify -overwrite on the command line or set the overwrite property in the configuration file to true.

CWUDU0101W: Bad entity type: received<entity type>, expected <tModel|business|service|binding>.

Explanation: The entered entity type was not recognized.

User Response: Specify arguments in accordance with the usage message.

CWUDU0102E: Promotion failed.

Explanation: The promote function failed to complete.

User Response: Check the configuration properties file has correct settings.

CWUDU0106E: Unable to commit transaction.

Explanation: The insertion of minimal entity data during the import function failed to commit to the database.

User Response: Check the database configuration. If necessary, turn on trace logging and look for the SQLException that is recorded.

CWUDU0107E: Unable to set auto-commit off on the database connection.

Explanation: UDDI Utility Tools needs to control commits of data changes, however the attempt to turn off auto-commit failed.

User Response: Check the database configuration. If necessary, turn on trace logging and look for the SQLExecption that is recorded.

CWUDU0109E: The import function requires a UDDI entity definition file to be specified.

Explanation: A required argument value was not supplied.

User Response: Specify -definition <path to Entity Definition File> on the command line, or set the value of the UDDIEntityDefinitionFile property in the configuration file to the path to the Entity Definition File.

CWUDU0110E: A cyclic dependency exists in the referenced tModels. The reference from tModel with key [<tModel key>] to the tModel with key [<tModel key>] completes the detected cycle.

Explanation: A cycle has been detected such that a tModel is being referenced by a tModel that it directly or indirectly references. This would cause the UDDI Utility Tools to enter an infinite loop trying to import referenced tModels, so the process is halted.

User Response: Edit the Entity Definition File and temporarily remove the reference to the tModel in the cycle, taking a note of the referenced details. After the import has successfully completed, update the tModel in the target registry to reintroduce the reference you previously removed. This can be done using the UDDI User Console, UDDI4J, or by creating a new Entity Definition File with just the tModel to be updated, and running the UDDI Utility Tools with the import function.

CWUDU0112E: An unexpected exception has occurred: <Exception message>.

Explanation: An unexpected error occurred.

User Response: Check configuration file settings and all registries and databases are active. If necessary, contact your IBM support center.

CWUDU0113E: Could not get a response from UDDI registry at URL: <URL>.

Explanation: A TransPortException occurred while performing an UDDI4J operation on the UDDI registry at the specified URL.

User Response: Check configuration properties for the UDDI registry in question and ensure the UDDI registry is active.

CWUDU0114E: An IOException occurred trying to invoke 'java'.

Explanation: When UDDI Utility Tools was invoked using the java -jar syntax, the invocation of the second JVM failed.

User Response: Check configuration property 'classpath' value is correct, and that Java is configured to run from the command line.

CWUDU0115I: Imported <entity count> entities and <referenced entity count> referenced entities.

Explanation: Indicate that the import step of the import or promote function has completed, showing the number of entities imported.

User Response: None.

CWUDU0116W: Not all minimal entities could be removed. The following remain in the database:

Explanation: A publish step was not successful which may have left one or more minimal entities in the target registry database. UDDI Utility Tools attempts to remove these minimal entities but in this case, the removal has failed. Following messages will indicate which minimal entities are left in the target registry.

User Response: You can attempt to remove the minimal entities using normal methods, such as the user console, UDDI4J, or using the delete function of the UDDI Utility Tools.

CWUDU0117W: Business minimal entities with businessKey [<business key>] has not been removed from the database.

Explanation: A business minimal entity was orphaned in the target registry database and attempts to remove it failed.

User Response: Identify the orphaned minimal entity in the target and attempt to remove using normal UDDI delete methods, or by using the delete function of the UDDI Utility Tools.

CWUDU0118W: Service minimal entity with serviceKey [<service key>] has not been removed from the database.

Explanation: A service minimal entity was orphaned in the target registry database and attempts to remove it failed.

User Response: Identify the orphaned minimal entity in the target registry and attempt to remove using normal UDDI delete methods, or by using the delete function of the UDDI Utility Tools.

CWUDU0119W: Binding Template minimal entity with bindingKey [<binding key>] has not been removed from the database.

Explanation: A binding minimal entity was orphaned in the target registry database and attempts to remove it failed.

User Response: Identify the orphaned minimal entity in the target registry and attempt to remove using normal UDDI delete methods, or by using the delete function of the UDDI Utility Tools.

CWUDU0120W: TModel minimal entity with tModelKey [<tModel key>] has not been removed from the database.

Explanation: A tModel minimal entity was orphaned in the target registry database and attempts to remove it failed.

User Response: Identify the orphaned minimal entity in the target registry and attempt to remove using normal UDDI delete methods, or by using the delete function of the UDDI Utility Tools.

CWUDU0121I: Created business minimal entity with businessKey [<business key>].

Explanation: Indicates the minimal data required for a businessEntity has successfully been inserted in the target UDDI registry database.

User Response: None.

CWUDU0122I: Created service minimal entity with serviceKey [<service key>].

Explanation: Indicates the minimal data required for a businessService has successfully been inserted in the target UDDI registry database.

User Response: None.

CWUDU0123I: Created binding template minimal entity with bindingKey [<binding key>].

Explanation: Indicates the minimal data required for a bindingTemplate has successfully been inserted in the target UDDI registry database.

User Response: None.

CWUDU0124I: Created tModel minimal entity with tModelKey [<tModel key>].

Explanation: Indicates the minimal data required for a tModel has successfully been inserted in the target UDDI registry database.

User Response: None.

CWUDU0125I: Deleted business minimal entity with businessKey [<business key>].

Explanation: Indicates the minimal data inserted for a businessEntity was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

User Response: None.

CWUDU0126I: Deleted service minimal entity with serviceKey [<service key>].

Explanation: Indicates the minimal data required for a businessService was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

User Response: None.

CWUDU0127I: Deleted binding template minimal entity with bindingKey [<binding key>].

Explanation: Indicates the minimal data required for a bindingTemplate was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

User Response: None.

CWUDU0128I: Deleted tModel minimal entity with tModelKey [<tModel key>].

Explanation: Indicates the minimal data required for a tModel was successfully removed from the target UDDI registry database. This would normally happen after a publish operation has failed.

User Response: None.

CWUDU0129E: Find related businesses failed.

Explanation: The UDDI4J find related businesses operation did not complete.

User Response: Check the configuration properties for the source registry, such as fromInquiryURL.

CWUDU0130E: Find businesses failed.

Explanation: The UDDI4J find businesses operation did not complete.

User Response: Check the configuration properties for the source registry, such as fromInquiryURL.

CWUDU0131E: Find services failed.

Explanation: The UDDI4J find services operation did not complete.

User Response: Check the configuration properties for the source registry, such as fromInquiryURL.

CWUDU0132E: Find tModels failed.

Explanation: The UDDI4J find tModels operation did not complete.

User Response: Check the configuration properties for the source registry, such as fromInquiryURL.

CWUDU0133E: Find bindings failed.

Explanation: The UDDI4J find bindings operation did not complete.

User Response: Check the configuration properties for the source registry, such as fromInquiryURL.

CWUDU0134I: Performing inquiry request ...

Explanation: Indicated the find operation for selecting keys has started.

User Response: None.

CWUDU0135I: Extracted keys from inquiry results.
Explanation: Indicates the find operation to select keys has completed successfully.

User Response: None
CWUDU0136E: node ID value could not be found in UDDI database.
Explanation: The UDDI registries Node ID could not be found in the UDDI database.

User Response: Check that the UDDI application and database have initialized correctly.
CWUDU0137E: Unexpected database SQL exception: <SQL Exception Message>.
Explanation: An unexpected SQL Exception has been encountered.

User Response: Examine the SQL Exception Message to determine the cause of the problem.
CWUDU0138E: Could not delete minimal entity for tModel with tModelKey[<tModel Key>].
Explanation: The entity with the supplied tModel key could not be located and therefore deleted.

User Response: Ensure tModel key is correct.
CWUDU0139E: Could not delete minimal entity for Service with serviceKey[<Service Key>].
Explanation: The entity with the supplied Service key could not be located and therefore deleted.

User Response: Ensure Service key is correct.
CWUDU0140E: Could not delete minimal entity for Business with businessKey[<Business Key>].
Explanation: The entity with the supplied Business Key could not be located and therefore deleted.

User Response: Ensure Business key is correct.
CWUDU0141E: Could not delete minimal entity for Binding with bindingKey[<Binding Key>].
Explanation: The entity with the supplied Binding key could not be located and therefore deleted.

User Response:
CWUDU0142E: Invalid sequence number for service: <Sequence Number>.
Explanation: The ServiceStub has an invalid sequence number.

User Response: Ensure the sequence number is greater than zero.
CWUDU0143E: Invalid sequence number for binding: <Sequence Number>.
Explanation: The BindingStub has an invalid sequence number.

User Response: Ensure the sequence number is greater than zero.

CWUDVnnnns (Web Services UDDI Value Set Tools) messages:
CWUDV0001E: Unable to find the properties file: >Property File>.
Explanation: The named property file could not be located.

User Response: Supply the correct location of the property file.
CWUDV0002E: The column and string delimiters must not be the same.
Explanation: The column and string delimiters cannot be the same.

User Response: Supply different characters for the column and string delimiters.
CWUDV0003E: A tModel for key <tModel Key> can not be found.
Explanation: The tModel for the given key cannot be found.

User Response: Supply a correct tModel key.
CWUDV0004E: Invalid command arguments.
Explanation: A command argument has been supplied that is unknown.

User Response: Check your arguments with the Usage information given with this error message.
CWUDV0005E: Different tModel keys are required when using -newKey.
Explanation: Two unique tModel keys are required to move a Value Set from one tModel to another.

User Response: Supply two unique tModel keys.
CWUDV0006E: Unable to find the value set data file: <Value Set File>.
Explanation: The named value set file could not be located.

User Response: Supply the correct location of the value set file.

CWUDV0007E: There is an unterminated string on line <Line Number>:<Line>.

Explanation: The line at <Line Number> has a starting string delimiter, but not a finishing one.

User Response: Correct the line, or consider using a different string delimiter (-stringDelimiter)

CWUDV0008E: There were fewer fields than expected on line <Line Number>:<Line>.

Explanation: The line at <Line Number> does not contain enough fields.

User Response: Correct the line, of consider using a different column delimiter (-columnDelimiter).

CWUDV0009E: There were more fields than expected on line <Line Number>:<Line>.

Explanation: The line at <Line Number> contains too many fields.

User Response: Correct the line, or consider using a different column delimiter (-columnDelimiter).

CWUDV0010E: There is a duplicate Key Code at the same level on line <Line Number>.

Explanation: The Value Set file contains two or more Key Codes of the same value for the same parent key code.

User Response: Correct the line.

CWUDV0011E: An invalid Parent Key Code has been detected on line <Line Number>.

Explanation: The Value Set file contains a parent key code that is invalid in its context.

User Response: Correct the parent key code.

CWUDV0012E: The value set file contains a value <Column Contents> in column <Column Number> at line <Line Number> that is too long for the database table.

Explanation: The Value Set file contains a value that is too large.

User Response: Decrease the size of the value.

CWUDV0013E: An IO Exception has occurred: <IO Exception Message>.

Explanation: An IO Exception was received when trying to read the Value Set file.

User Response: Ensure the Value Set file is readable and is in UTF-8 format.

CWUDV0014E: There was a problem reading from the properties file: <IO Exception Message>.

Explanation: An IO Exception was received when trying to read the Value Set file.

User Response: Ensure the Value Set file is readable and is in UTF-8 format.

CWUDV0015E: The value set data file <Value Set File> is in an unsupported encoding.

Explanation: The Value Set file is not in UTF-8 format.

User Response: Correct the file encoding format.

CWUDV0016E: Unable to find the UDDI JMX MBean. Verify UDDI is installed.

Explanation: The UDDI application could not be contacted.

User Response: Ensure UDDI is installed and running on the Host you have targeted. See arguments -host, -port, -node and -server.

CWUDV0017E: An unexpected Exception has occurred.

Explanation: An unexpected exception was received.

User Response: Examine the Exception stack trace on its cause. If the problem cannot be resolver, contact your IBM Customer Service Center.

CWUDV1001W: The tModel with key <tModel Key> is checked. To confirm this operation, enter the command with the -override argument.

Explanation: The targeted tModel has a ″checked″ status and therefore should not have its value set changed without care.

User Response: To confirm this operation, enter the command with the -override argument.

CWUDV1002W: The tModel with key <tModel Key> has existing value sets. To confirm this operation, enter the command with the -override argument.

Explanation: The targeted to be loaded already has a value set.

User Response: To confirm this operation and overwrite the existing value set, enter the command with the -override argument.

CWUDV1003W: UDDI Registry Message: <Number of Lines> lines of data file for tModel key <tModel Key>.

Explanation: UDDI Registry message was received.

User Response: Examine the message on its cause. If the problem cannot be resolved, contact your IBM Customer Service Center.

CWUDV2001I: Loaded <Number of Lines> line of data file for tModel key <tModelKey>.

Explanation: An informational message that confirms the number of value set lines loaded for the tModel.

User Response:

CWUDV2002I: Changed value set from tModel key <tModel Key> to tModel key <tModel Key>.

Explanation: An informational message that confirms the change of value set from one tModel to another.

User Response: None.

CWUDV2003I: Unloaded value set for tModel key <tModel Key>.

Explanation: An informational message that confirms the removal of the value set for the tModel.

User Response: None.

CWUDXnnnns (Web Services JAXR) messages:

CWUDX0001E: Caught UDDIException on <UDDI API name>

Explanation: This is an Exception message. This message may be received in a RegistryException thrown by any of the following methods:

- Any method which necessitates sending a request to the UDDI registry.

The JAXR provider caught a org.uddi4j.UDDIException while sending a request to the UDDI registry.

User Response: The user should interrogate the cause UDDIException of the JAXRException for more information.

CWUDX0002E: Caught TransportException sending request to registry

Explanation: This is an Exception message. This message may be received in a RegistryException thrown by any of the following methods:

- Any method which necessitates sending a request to the UDDI registry.

The JAXR provider caught a org.uddi4j.TransportException while sending a request to the UDDI registry.

User Response: The user should interrogate the cause TransportException of the JAXRException for more information.

CWUDX0003E: AccessURI and TargetBinding are mutually exclusive

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- ServiceBinding.setAccessURI(String uri)
- ServiceBinding.setTargetBinding(ServiceBinding binding)

An attempt was made to set both the AccessURI and the TargetBinding of a ServiceBinding.

User Response: The user should set only one of AccessURI and TargetBinding.

CWUDX0004E: Source object of an Association must be an Organization

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by the following method:

- Association.setSourceObject(RegistryObject srcObject)

The object passed to the setSourceObject method was not an Organization.

User Response: The user should only pass Organization objects to the setSourceObject method.

CWUDX0005E: Source and target objects of an Association must be set in order to save

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- BusinessLifeCycleManager.confirmAssociation(Association assoc)
- BusinesslifeCycleManager.saveAssociations(Collection associations, boolean replace)
- LifeCycleManager.saveObjects(Collection objects) when objects are Associations

An attempt was made to save an Association that did not have both source and target objects set.

User Response: The user should only attempt to save Associations which have both source and target objects set.

CWUDX0006E: Target object of an Association must be an Organization

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by the following method:

- Association.setTargetObject(RegistryObject targetObject)

The object passed to the setTargetObject method was not an Organization.

User Response: The user should only pass Organization objects to the setTargetObject method.

CWUDX0007E: Format of associationKey is incorrect. Correct format is <sourceObjectKey>:<targetObjectKey>:<associationType> : <associationKey>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- BusinessLifeCycleManager.deleteAssociations(Collection associationKeys)

The user passed an associationKey to the deleteAssociations method that did not have the correct format.

User Response: The user should ensure that associationKeys passed to the deleteAssociations method have the correct format.

CWUDX0008E: AssociationType Concept must come from the AssociationType enumeration, and have value either HasChild , HasParent, RelatedTo or EquivalentTo

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- BusinessQueryManager.findAssociations(Collection findQualifiers, String sourceObjectId, String targetObjectId, Collection associationTypes)
- BusinessQueryManager.findCallerAssociations(Collection findQualifiers, Boolean confirmedByCaller, Boolean confirmedByOtherParty, Collection associationTypes)
- BusinessLifeCycleManager.confirmAssociation(Association assoc)
- BusinessLifeCycleManager.saveAssociations(Collection associations, boolean replace)
- LifeCycleManager.saveObjects(Collection objects) when objects are Associations

When finding Associations, the user passed a Concept in the associationTypes Collection that was from the AssociationType enumeration, but did not have a value that is valid for UDDI. When saving Associations, the user passed an Association whose associationType Concept was from the AssociationType enumeration, but did not have a value that is valid for UDDI.

User Response: The user should only use Concepts for associationTypes that are from the AssociationType enumeration and have value either HasChild, HasParent, RelatedTo or EquivalentTo.

CWUDX0009E: AssocationType Concept must come from the AssociationType enumeration

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- BusinessQueryManager.findAssociations(Collection findQualifiers, String sourceObjectId, String targetObjectId, Collection associationTypes)
- BusinessQueryManager.findCallerAssociations(Collection findQualifiers, Boolean confirmedByCaller, Boolean confirmedByOtherParty, Collection associationTypes)
- BusinessLifeCycleManager.confirmAssociation(Association assoc)
- BusinessLifeCycleManager.saveAssociations(Collection associations, boolean replace)
- LifeCycleManager.saveObjects(Collection objects) when objects are Associations

When finding Associations, the user passed a Concept that was not from the AssociationType enumeration in the associationTypes Collection. When saving Associations, the user passed an Association whose associationType Concept was not from the AssociationType enumeration.

User Response: The user should only use Concepts from the AssociationType enumeration for associationTypes.

CWUDX0010E: Cannot create a ClassificationScheme from a taxonomy Concept

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- LifeCycleManager.createClassificationScheme(Concept concept)

The user passed a taxonomy Concept to the createClassificationScheme method.

User Response: This method is provided to allow for Concepts returned by the BusinessQueryManager.findConcepts call to be safely converted to ClassificationScheme. It is up to the programmer to make sure that the Concept is indeed semantically a ClassificationScheme.

CWUDX0011E: Connection is closed

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- All methods of BusinessQueryManager and BusinessLifeCycleManager.
- The saveObjects and deleteObjects methods of LifeCycleManager.
- The saveObjects and deleteObjects methods of LifeCycleManager.

The user called a method that required a connection to the registry after they had closed the Connection by calling the Connection.close() method.

User Response: The user should not call methods that require a connection to the registry after the Connection has been closed.

CWUDX0012E: ConnectionFactory properties are not set

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ConnectionFactory.createConnection()

The createConnection() method was called before the properties had been set on the ConnectionFactory.

User Response: Ensure that the ConnectionFactory properties have been set before attempting to create a Connection.

CWUDX0013E: Could not create DocumentBuilder

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- RegistryService.makeRegistrySpecificRequest(String request)

The JAXR provider caught a javax.xml.parsers.ParserConfigurationException while attempting to initialize the XML parser.

User Response: The user should interrogate the cause ParserConfigurationException of the JAXRException for more information.

CWUDX0014E: Could not parse XML input stream

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- RegistryService.makeRegistrySpecificRequest(String request)

The JAXR provider caught a java.io.IOException while attempting to parse the XML request.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0015E: Could not serialize XML response

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- RegistryService.makeRegistrySpecificRequest(String request)

The JAXR provider caught a java.io.IOException while attempting to serialize the XML response.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0016E: Interface name of object to create not specified

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- LifeCycleManager.createObject(String interfaceName)

The user passed a null interfaceName to the createObject method.

User Response: The user should ensure they only pass a valid interfaceName to the createObject method.

CWUDX0017W: Enumeration data file <filename> contains an invalid line: <line>

Explanation: This warning message will go to System.err if the JAXR provider encounters an invalid line in an enumeration data file while the Connection is initialized. The JAXR provider will ignore the invalid line. Otherwise the JAXR provider will be unaffected.

User Response: The user should ensure that the enumeration data file is valid in order to use all members of the enumeration. The correct format of each line is <enumeration name><separator char><concept value>.

CWUDX0018E: Could not read enumeration data file: <filename>

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- ConnectionFactory.createConnection(

The JAXR provider caught a java.io.IOException while attempting to read an enumeration data file.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0019W: enumerationConfig.properties file contains an invalid property value: <property value>

Explanation: This warning message will go to System.err if the JAXR provider encounters an invalid property value in the enumerationConfig.properties file while the Connection is initializsed. The JAXR provider will ignore the invalid property, and hence ignore the corresponding enumeration. Otherwise the JAXR provider will be unaffected.

User Response: The user should ensure that the enumerationConfig.properties file is valid in order to use all enumerations. The correct format of each line is <enumeration ID>=<enumeration name>,<data filename>,<separator char>

CWUDX0020E: An IOException occurred while attempting to read the enumerationConfig.properties file

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- ConnectionFactory.createConnection()

The JAXR provider caught a java.io.IOException while attempting to read the enumerationConfig.properties file.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0021E: An IOException occurred while attempting to read the taxonomyConfig.properties file

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- ConnectionFactory.createConnection()

The JAXR provider caught a java.io.IOException while attempting to read the taxonomyConfig.properties file.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0022E: External URI is malformed: <External URI>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ExternalLink.setExternalURI(String uri)

A malformed URI was passed to the setExternalURI method when URI validation has set to true by passing true to the ExternalLink.setValidateURI(boolean validate) method.

User Response: Either the user should ensure that the URI is well formed, or URI validation should be set to false.

CWUDX0023E: External URI is not accessible: <External URI>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ExternalLink.setExternalURI(String uri)

An inaccessible URI was passed to the setExternalURI method when URI validation has set to true by passing true to the ExternalLink.setValidateURI(boolean validate) method.

User Response: Either the user should ensure that the URI is accessible, or URI validation should be set to false.

CWUDX0024E: Invalid interface name: <interface name>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- LifeCycleManager.createObject(String interfaceName)

The user passed an invalid interface name to the createObject method.

User Response: The user should only pass valid interface names to the createObject method. Valid interface names are public final static String fields of the LifeCycleManager class.

CWUDX0025E: Cannot change the ClassificationScheme of an internal Classification

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Classification.setClassificationScheme(ClassificationScheme classificationScheme)

The user called the setClassificationScheme method of an internal Classification.

User Response: The user should not attempt to modify the ClassificationScheme of an internal Classification directly. The ClassificationScheme of an internal Classification is determined by the Classification's Concept and cannot be modified independently.

CWUDX0026E: Cannot change the name of an internal Classification

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Classification.setName(InternationalString name

The user called the setName method of an internal Classification.

User Response: The user should not attempt to modify the name of an internal Classification directly. The name of an internal Classification is determined by the Classification's Concept and cannot be modified independently.

CWUDX0027E: Cannot change the value of an internal Classification

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Classification.setValue(String value)

The user called the setValue method of an internal Classification.

User Response: The user should not attempt to modify the value of an internal Classification directly. The value of an internal Classification is determined by the Classification's Concept and cannot be modified independently.

CWUDX0028E: The Concept of an internal Classification must have a parent ClassificationScheme

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Classification.setConcept(Concept concept)

The user passed a non-null Concept without a parent ClassificationScheme to the setConcept method.

User Response: Setting a Classification's Concept causes a Classification to become internal. The Classification's ClassificationScheme is then set to the parent ClassificationScheme of the Concept. If the Concept has no parent ClassificationScheme (in other words, it is not a taxonomy Concept), this error will be encountered. The user should therefore only pass taxonomy Concepts to the setConcept method.

CWUDX0029E: Taxonomy Concepts cannot be saved as UDDI tModels

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:
- BusinessLifeCycleManager.saveConcepts(Collection concepts)
- LifeCycleManager.saveObjects(Collection objects) when the objects are Concepts.

The user attempted to save a taxonomy Concept as a UDDI tModel in the registry.

User Response: Taxonomy Concepts cannot be saved as tModels in a UDDI registry. They are used to classify objects saved in the registry but cannot be saved independently. The user should not attempt to save taxonomy Concepts in the registry.

CWUDX0030E: The parent RegistryObject of a taxonomy Concept must be either a Concept or a ClassificationScheme

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by any of the following methods:
- LifeCycleManager.createConcept(RegistryObject parent, InternationalString name, String value)
- LifeCycleManager.createConcept(RegistryObject parent, String name, String value)

The user attempted to create a taxonomy Concept whose parent was not a Concept or a ClassificationScheme.

User Response: The parent of a taxonomy Concept can only be another Concept or a ClassificationScheme, so the user should only attempt to set one of these as the parent of a taxonomy Concept.

CWUDX0031E: Concept does not have a parent, therefore does not have a path

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:
- Concept.getPath()

The user called the getPath() method on a Concept that was not a taxonomy Concept. Only taxonomy Concepts have parents.

User Response: Only taxonomy Concepts have parents, therefore only taxonomy Concepts have paths. The user should not attempt to call the getPath() method on a Concept that is not a taxonomy Concept.

CWUDX0032E: Concept does not have a value, therefore does not have a path

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:
- Concept.getPath()

The user called the getPath() method on a Concept that did not have a value.

User Response: A Concept must have a value in order to have a path, so the user should not attempt to call the getPath() method on Concepts that do not have a value.

CWUDX0033E: Concept's parent ClassificationScheme does not have an ID, therefore the Concept does not have a path

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:
- Concept.getPath()

The user called the getPath() method on a Concept whose ClassificationScheme did not have an ID.

User Response: A Concept's ClassificationScheme must have an ID in order for the Concept to have a path. The user should not attempt to call the getPath() method on a Concept whose ClassificationScheme does not have an ID.

CWUDX0034E: The ConnectionFactory property javax.xml.registry.uddi.maxRows does not contain a parsable integer:<javax.xml.registry.uddi.maxRows property value>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ConnectionFactory.createConnection()

The user called the createConnection method when the ConnectionFactory property javax.xml.registry.uddi.maxRows did not contain a parsable integer.

User Response: The user should ensure that if the javax.xml.registry.uddi.maxRows ConnectionFactory property is set that it contains a parsable integer.

CWUDX0035E: Invalid UDDI XML String

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by the following method:

- RegistryService.makeRegistrySpecificRequest(String xmlString)

The String passed to the makeRegistrySpecificRequest method was not valid XML.

User Response: The user should ensure that the String passed to the makeRegistrySpecificRequest method is valid XML.

CWUDX0036E: The ConnectionFactory property javax.xml.registry.lifeCycleManagerURL specifies a malformed URL

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ConnectionFactory.createConnection()

The user called the createConnection method when the ConnectionFactory property javax.xml.registry.lifeCycleManagerURL contained a malformed URL.

User Response: The user should ensure that the javax.xml.registry.lifeCycleManagerURL ConnectionFactory property contains a well formed URL.

CWUDX0037E: The ConnectionFactory property javax.xml.registry.queryManagerURL specifies a malformed URL

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- ConnectionFactory.createConnection()

The user called the createConnection method when the ConnectionFactory property javax.xml.registry.queryManagerURL contained a malformed URL.

User Response: The user should ensure that the javax.xml.registry.queryManagerURL ConnectionFactory property contains a well formed URL.

CWUDX0038E: Multiple matches on find ClassificationScheme by name

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- BusinessQueryManager.findClassificationSchemeByName(Collection findQualifiers, String namePattern)

More than one ClassificationScheme was found that matched the search criteria.

User Response: The user should narrow their search criteria to find only one ClassificationScheme.

CWUDX0039E: Invalid objectType: <object type>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- LifeCycleManager.deleteObjects(Collection keys, String objectType)
- QueryManager.getRegistryObjects(String objectType)
- QueryManager.getRegistryObject(String id, String objectType)
- QueryManager.getRegistryObjects(Collection objectKeys, String objectType)

The user passed an invalid objectType to one of the above methods.

User Response: The user should ensure they pass a valid objectType to the above methods. The valid objectTypes for these methods are:

```
LifeCycleManager.CLASSIFICATION_SCHEME
LifeCycleManager.CONCEPT
LifeCycleManager.ORGANIZATION
LifeCycleManager.SERVICE
LifeCycleManager.SERVICE_BINDING
```

The deletObjects method also accepts an objectType of LifeCycleManager.ASSOCIATION.

CWUDX0040E: Cannot save objects of type: <object class>

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by the following method:

- LifeCyclemanager.saveObjects(Collection objects)

An object was passed to the saveObjects method of a type that cannot be saved directly in the registry.

User Response: The user should ensure that objects passed to the saveObjects method are of a valid type. Valid types are Association, ClassificationScheme, Concept, Organization, Service and ServiceBinding.

CWUDX0041E: RegistryObject is a ClassificationScheme not a Concept: <RegistryObject ID>

Explanation: This is an Exception message. This message may be received in a FindException thrown by any of the following methods:

- QueryManager.getRegistryObject(String id, String objectType)
- QueryManager.getRegistryObjects(Collection objectKeys, String objectType)

An objectType of LifeCycleManager.CONCEPT was passed to one of the above methods, but the id or one of the objectKeys was that of a ClassificationScheme.

User Response: The user should ensure that they specify the correct objectType corresponding to the object keys.

CWUDX0042E: RegistryObject is a Concept not a ClassificationScheme: <RegistryObject ID>

Explanation: This is an Exception message. This message may be received in a FindException thrown by any of the following methods:

- QueryManager.getRegistryObject(String id, String objectType)
- QueryManager.getRegistryObjects(Collection objectKeys, String objectType)

An objectType of LifeCycleManager.CLASSIFICATIONSCHEME was passed to one of the above methods, but the id or one of the objectKeys was that of a Concept.

User Response: The user should ensure that they specify the correct objectType corresponding to the object keys.

CWUDX0043E: RequestID not found: <RequestID>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- RegistryService.getBulkResponse(String requestId

The requestId specified was not found.

User Response: The user should only pass valid requestIds to the getBulkResponse method. Note that once the getBulkResponse method has been called once for a particular requestId, that requestId is removed from the cache and subsequent calls to getBulkResponse passing that requestId will result in an InvalidRequestException.

CWUDX0044E: <concept path> is not a valid path of a concept in a defined internal taxonomy

Explanation: This message will go to System.err when a Connection is created if the javax.xml.registry.semanticEquivalences ConnectionFactory property defines a semantic equivalence between a Concept in the PostalAddressAttributes enumeration and a Concept which has not been defined in any internal taxonomy.

User Response: The user should ensure that the Concept paths used in the javax.xml.registry.semanticEquivalences ConnectionFactory property have been defined in a internal taxonomy.

CWUDX0045W: Semantic equivalence pair does not have exactly 2 elements: <keyPair>

Explanation: This message will go to System.err when a Connection is created if the javax.xml.registry.semanticEquivalences ConnectionFactory contains a keyPair which contains more than two elements.

User Response: The user should ensure that the javax.xml.registry.semanticEquivalences ConnectionFactory property has the correct format, as defined in the JAXR specification.

CWUDX0046E: Semantic equivalence pair does not contain a key in the postalAddressAttributes enumeration: <keyPair>

Explanation: This message will go to System.err when a Connection is created if the javax.xml.registry.semanticEquivalences ConnectionFactory contains a keyPair which does not contain the path of a Concept in the PostalAddressAttributes enumeration. Semantic equivalences for a UDDI JAXR providers are only allowed for Concepts in the PostalAddressAttributes enumeration.

User Response: The user should only attempt to define semantic equivalences for Concepts in the PostalAddressAttributes enumeration.

CWUDX0047E: Invalid Slot name: <Slot name>

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- All methods of the ExtensibleObject interface.

The user passed an invalid slot name to one of the methods of the ExtensibleObject interface.

User Response: The user should ensure that the slot name is valid for the particular instance of ExtensibleObject.

CWUDX0048E: A Slot instance cannot have duplicate values

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- Slot.setValues(Collection values)

The user passed a collection of values to the setValues method that contained duplicate values.

User Response: The user should pass only a collection of unique values to setValues method.

CWUDX0049E: A sortCode Slot must have only 1 value

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- PostalAddress.addSlot(Slot slot)

The user passed a Slot with name Slot.SORT_CODE_SLOT and multiple values to the addSlot method.

User Response: When adding a Slot with name Slot.SORT_CODE_SLOT to a PostalAddress, the user should ensure that it only has 1 value.

CWUDX0050E: A specificationLink can only have one ExternalLink

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- SpecificationLink.addExternalLink(ExternalLink externalLink)
- SpecificationLink.addExternalLinks(Collection externalLinks)
- SpecificationLink.setExternalLinks(Collection externalLinks)

The user attempted to give a SpecificationLink more than one ExternalLink. A SpecificationLink may only have one ExternalLink.

User Response: The user should give a SpecificationLink a maximum of one ExternalLink.

CWUDX0051E: A SpecificationLink can only have one UsageParameter

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:

- SpecificationLink.setUsageParameters(Collection usageParameters)

The user attempted to give the SpecificationLink more than one usage parameter. A SpecificationLink can only have one usage parameter.

User Response: The user should give a SpecificationLink a maximum of one usage parameter.

CWUDX0052E: SpecificationObject must be a Concept with no parent

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by any of the following methods:

- SpecificationLink.setSpecificationObject(RegistryObject obj)

The user attempted to set a Concept with a parent (that is, a taxonomy Concept) as the specification object of the SpecificationLink.

User Response: The user must set a specification Concept as the specification object of a SpecificationLink.

CWUDX0053E: SpecificationObject must be a Concept

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by the following method:

- SpecificationLink.setSpecificationObject(RegistryObject obj)

The user attempted to set a RegistryObject that was not a Concept as the specification object of a SpecificationLink.

User Response: The user must set a specification Concept as the specification object of a SpecificationLink.

CWUDX0054E: Invalid escape sequence found during SQL-92 LIKE Processing: <escape sequence>

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by any of the following methods:

- BusinessQueryManager.findClassificationSchemeByName(Collection findQualifiers, String namePattern)
- BusinessQueryManager.findClassificationSchemes(Collection findQualifiers, Collection namePatterns, Collection classifications, Collection externalLinks)

The user passed a namePattern to one of the above methods which contained an invalid escape sequence.

User Response: The user should ensure that namePatterns do not contain invalid escape sequences.

CWUDX0055E: Invalid escape sequence found terminating pattern during SQL-92 LIKE processing: <escape sequence>

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by any of the following methods:

- BusinessQueryManager.findClassificationSchemeByName(Collection findQualifiers, String namePattern)
- BusinessQueryManager.findClassificationSchemes(Collection findQualifiers, Collection namePatterns, Collection classifications, Collection externalLinks)

The user passed a namePattern to one of the above methods which contained an invalid escape sequence terminating the pattern.

User Response: The user should ensure that namePatterns do not contain invalid escape sequences.

CWUDX0056E: The System property http.proxyPort does not contain a parsable integer: <Value of http.proxyPort property>

Explanation: This is an Exception message. This message may be received in a java.lang.NumberFormatException thrown by the following method:

- ConnectionFactory.createConnection()

The user called the createConnection() method when the System property http.proxyPort contained a String that was not parsable as an integer.

User Response: The user should ensure that if the System property http.proxyPort is set it contains a parsable integer.

CWUDX0057W: Taxonomy data file <filename> contains an invalid line: <invalid line>

Explanation: This message will go to System.err when a Connection is created if a taxonomy data file contains an invalid line.

User Response: The format of each line is <taxonomy ID><Concept name><Concept value><Concept parent>

CWUDX0058W: Warning: Unable to locate parentConcept named <parent Concept name> for concept named <Concept name> in taxonomy datafile <filename>

Explanation: This message will go to System.err when a Connection is created if a taxonomy data file contains an line for a Concept whose parent cannot be located in that file.

User Response: The user should ensure that a parent exists for each Concept in the taxonomy data file.

CWUDX0059E: Could not read taxonomy data file: <filename>

Explanation: This is an Exception message. This message may be received in a JAXRException thrown by any of the following methods:

- ConnectionFactory.createConnection()

The JAXR provider caught a java.io.IOException while attempting to read the taxonomy data file.

User Response: The user should interrogate the cause IOException of the JAXRException for more information.

CWUDX0060W: taxonomyConfig.properties file contains an invalid property value: <property value>

Explanation: This warning message will go to System.err if the JAXR provider encounters an invalid property value in the taxonomyConfig.properties file while the Connection is initialized. The JAXR provider will ignore the invalid property, and hence ignore the corresponding taxonomy. Otherwise the JAXR provider will be unaffected.

User Response: The user should ensure that the taxonomyConfig.properties file is valid in order to use all taxonomies. The correct format of each line is <taxonomy ID>=<tModelKey>,<data filename>,<separator char>.

CWUDX0061E: Expecting object of type: <objectType String>. Got object of type: <object class>

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by the following method:

- All methods which accept objects of ambiguous type.

The user passed an object to a method that was not expecting an object of that type.

User Response: The user should only pass objects of the appropriate type to JAXR methods.

CWUDX0062E: Expecting object of type String or LocalizedString. Got object of type: <object class>

Explanation: This is an Exception message. This message may be received in an UnexpectedObjectException thrown by any of the following methods:

- All query methods which accept a Collection of namePattern objects.

The user passed an object which was not a String or a LocalizedString as a namePattern to a query method.

User Response: The user should only use Strings of LocalizedStrings as namePattern objects.

CWUDX0063E: The ConnectionFactory property javax.xml.registry.queryManagerURL is not specified

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:
- ConnectionFactory.createConnection(

The user attempted to create a Connection without specifying the javax.xml.registry.queryManagerURL ConnectionFactory property.

User Response: The user must specify the javax.xml.registry.queryManagerURL ConnectionFactory property before attempting to create a Connection.

CWUDX0064E: Unsupported value for the ConnectionFactory property

Explanation: This is an Exception message. This message may be received in an InvalidRequestException thrown by the following method:
- ConnectionFactory.createConnection()

The user attempted to create a Connection with an invalid value of the javax.xml.registry.security.authenticationMethod ConnectionFactory property.

User Response: The user should only use a valid vale for this property. Valid values are UDDI_GET_AUTHTOKEN and HTTP_BASIC.

UDDI Registry samples

The UDDI samples, and documentation on how to use them, are available through the Web Services UDDI samples link on the Samples Central page of the IBM WebSphere Developer Domain Web site.

Applying an upgrade to the UDDI Registry

Perform this task to apply an iFix, Fix Pack or Refresh Pack to the UDDI Registry.

Note: Some upgrades may require additional steps; refer to the readme file for the upgrade before you complete this task.

1. Apply the WebSphere Application Server iFix, Fix Pack or Refresh Pack to your application server or servers using the WebSphere Application Server Update Installer. Note that this process must be repeated for each server into which you choose to incorporate the UDDI upgrade.
2. If you have not yet deployed a UDDI Registry, no further action is required as updates to the UDDI Registry will take effect when you first deploy UDDI into any of your application server profiles.
3. If you have already deployed a UDDI Registry to one or more application server profiles, redeploy the UDDI application as described in Reinstalling the UDDI Registry application, to apply the upgrade. The existing UDDI application will be removed and the updated application will be deployed.

Configuring the UDDI Registry Application

The UDDI Registry is supplied as a J2EE application file, uddi.ear.

You can configure the following aspects of the UDDI Registry:
- Configuring UDDI Registry security
- Configuring SOAP API and GUI services
- Multiple language encoding support in UDDI
- Customizing the UDDI Registry user interface (GUI)

Configuring UDDI Registry security

The IBM UDDI Version 3 Registry is designed to exploit the advantages of WebSphere Application Server security. The registry also supports the UDDI Version 1 and Version 2 security features and the UDDI Version 3 Security API.

For production use, it is recommended that the IBM UDDI Version 3 Registry is configured to use WebSphere Application Server security, and that use of UDDI Version 1 and Version 2 security features and the Version 3 Security API is avoided. However, for solutions with a strong preference for UDDI security, the IBM UDDI Version 3 Registry can be configured to enable this, both when WebSphere Application Server security is enabled and when it is disabled.

To configure UDDI registry security, complete the following steps:

1. Follow the appropriate link for the type of configuration you wish to set up:
   - "Configuring the UDDI Registry to use WebSphere Application Server security"
   - "Configuring the UDDI Registry to use UDDI security" on page 482
2. Review the "UDDI Registry security additional considerations" on page 483.

Configuring the UDDI Registry to use WebSphere Application Server security:

Before starting this task complete the following two steps:

- Enable WebSphere Application Server global security (see Configuring global security). This will allow the UDDI Registry to exploit the WebSphere Application Server security features.
- Ensure that WebSphere Application Server is configured to use HTTPS (SSL); this will allow the use of secure access with the UDDI Registry. WebSphere Application Server is configured by default to accept SSL requests on port 9443, however if you need to make any additional SSL configuration changes, please refer to Secure Sockets Layer settings for custom properties.

There are two aspects of WebSphere Application Server security which are exploited by the UDDI registry:

Authorization
: Authorization determines whether users are allowed access to services. WebSphere Application Server uses Role Mappings to determine authorization. UDDI makes use of two special WebSphere Application Server roles: Everyone (all users are allowed access) and AllAuthenticatedUsers (only valid WebSphere Application Server registered users are allowed access).

Data confidentiality
: Data confidentiality determines security at the transport level. Data confidentiality for WebSphere Application Server services can be either 'none' (HTTP is used as the transport protocol) or 'confidential' (requiring the use of SSL; HTTPS is used as the transport protocol).

When WebSphere Application Server security is enabled, the default settings in the UDDI Version 3 Application and Web deployment descriptors result in the following features:

- Publish, Custody Transfer and Security services are mapped to the AllAuthenticatedUsers role, and data confidentiality is enforced (HTTPS is used). The services in question are as follows:
  - Versions 1 and 2 SOAP publish service (SOAP_Publish_User)
  - EJB publish service (EJB_Publish_Role)
  - Version 3 GUI publish service (GUI_Publish_User)
  - Version 3 publish service (V3SOAP_Publish_User_Role)
  - Version 3 custody transfer service (V3SOAP_CustodyTransfer_User_Role)
  - Version 3 security service (V3SOAP_Security_User_Role)

  Authentication uses the standard WebSphere security facilities and there is no separate registration function for the UDDI registry. You will need to supply your WebSphere user name and password for publish functions (unless you have modified the supplied publish role).
- Inquiry services are mapped to the Everyone role, and data confidentiality is not enforced (HTTP is used). The UDDI inquiry services are as follows:
  - Versions 1 and 2 SOAP inquiry service (SOAP_Inquiry_User)
  - EJB inquiry service (EJB_Inquiry_Role)

– Version 3 GUI inquiry service (GUI_Inquiry_User)
– Version 3 SOAP inquiry service (V3SOAP_Inquiry_User_Role)

No further configuration is necessary. However, if you wish to change the default settings follow the steps below:

1. To change the role mappings, use the administrative console to complete the following steps:
   a. In the navigation pane, click **Applications** → **Enterprise Applications**.
   b. In the content pane, click the UDDI Registry application.
   c. Under **Additional Properties** on the right hand side, click **Map security roles to users/groups**.
   d. Make any changes you require and click **OK**.
2. To change the data confidentiality settings, refer to “Configuring SOAP API and GUI services” on page 485.

Configuring the UDDI Registry to use UDDI security:

It is possible to exploit the UDDI registry security features when WebSphere Application Server security is either enabled or disabled. Each situation requires different configuration, and different behavior is achieved.

Note: While useful for test purposes, it is not anticipated that WebSphere Application Server security is disabled for production configurations.

To continue configuring the UDDI registry to use UDDI security, choose one of the following options:

- “Configuring UDDI Security with WebSphere Application Server security enabled”
- “Configuring UDDI Security with WebSphere Application Server security disabled” on page 483

Configuring UDDI Security with WebSphere Application Server security enabled:

When WebSphere Application Server security is enabled, to use the UDDI Version 1 and Version 2 publish security features (use of authentication tokens) or the UDDI Version 3 security API, use the administrative console to complete the following steps:

1. In the navigation pane, click **Applications** → **Enterprise Applications**.
2. In the content pane, click the UDDI Registry application. Under **Additional Properties** on the right hand side, click **Map security roles to users/groups**.
3. Set the WebSphere Application Server security role mappings to Everyone for the following UDDI services:
   - Versions 1 and 2 SOAP publish service (SOAP_Publish _User)
   - Version 3 publish service (V3SOAP_Publish_User_Role)
   - Version 3 custody transfer service (V3SOAP_CustodyTransfer_User_Role)
   - Version 3 security service (V3SOAP_Security_User_Role)

   Changing the role mappings to Everyone prevents WebSphere Application Server security from overriding UDDI security.
4. Ensure that UDDI Policy is set to require the use of authentication tokens for the UDDI Version 3 Publish and Custody Transfer services (use of authentication tokens is already required for Version 1 and Version 2 Publish services). To do this, click **UDDI** → **UDDI Nodes** > *uddi_node_name*, and under **Policy Groups** click **APIs**. Select the **Authorization for publish** and **Authorization for custody transfer** check boxes. (Select the **Authorization for inquiry** check box if you require authentication for UDDI Inquiry services).
5. Click **OK**.

With this configuration, no Security Role authentication restriction is imposed, but the credentials (user name and password) associated with the authentication token are authenticated by WebSphere Application Server.

Note: When WebSphere Application Server security is enabled, WebSphere Application Server data confidentiality management is independent of UDDI security and is managed as described in "Configuring the UDDI Registry to use WebSphere Application Server security" on page 481.

Configuring UDDI Security with WebSphere Application Server security disabled:

With WebSphere Application Server security disabled, neither WebSphere Application Server security roles nor data confidentiality constraints apply. This mode may be useful for test UDDI Registry configurations.

In this mode, UDDI Version 1 and Version 2 security features are active:

- UDDI Version 1 and Version 2 publish requests require UDDI Version 1 and Version 2 authentication tokens respectively. Publishers requesting or using an authentication token must be registered WebSphere Application Server users.
- UDDI Version 1 and Version 2 inquiry requests do not require authentication tokens.

No further configuration is required for UDDI Version 1 and Version 2 security.

For UDDI Version 3, the use of the UDDI Version 3 Security API, and the use of authentication tokens with Version 3 Publish and Custody Transfer APIs, is optional. To make use of these UDDI Version 3 security features, use the administrative console to complete the following steps:

1. Specify that use of authInfo is required: click **UDDI** → **UDDI Nodes** > *uddi_node_name*. In the **General Properties** section select the **Use authInfo credentials if provided** check box.
2. Ensure that UDDI Policy is set to require the use of authentication tokens for the UDDI Publish and Custody Transfer services: click **UDDI** → **UDDI Nodes** > *uddi_node_name*, and under **Policy Groups** click **APIs**. Select the **Authorization for publish** and **Authorization for custody transfer** check boxes. (Select the **Authorization for inquiry** check box if you require authentication for UDDI Inquiry services).

UDDI Registry security additional considerations: In addition to the configuration of UDDI Registry security, there a number of other UDDI Registry settings which may affect the behavior of the UDDI Registry. Some of these settings are security specific, others are points to bear in mind when configuring security.

Additional security considerations

The UDDI Registry also supports use of XML Digital Signatures to sign UDDI entities. This is described in ″Use of digital signatures with the UDDI Registry″.

Additional policy considerations

A number of the UDDI property and policy settings also determine the behavior of a UDDI Registry with respect to security.

To review or change the following property settings, click **UDDI** → **UDDI Nodes** > *uddi_node_name*. The settings are also detailed in the administrative console help.

Key space requests require digital signature
This setting determines whether all tModel:keyGenerator requests for key space must be digitally signed. To understand key space refer to ″UDDI Registry Version 3 Entity Keys″ in the information center.

Use authInfo credentials if provided
This setting applies only when WebSphere Application Server security is disabled. See Configuring UDDI Security with WebSphere Application Server security disabled.

Authentication token expiry period
The authentication token expiry period is the length of idle time (in minutes) allowed before an authentication token becomes invalid.

Default user name
The default user name is used for publish operations when WebSphere Application Server security is disabled and no authentication token data is supplied.

To review or change the following policy settings, click **UDDI** → **UDDI Nodes** > *uddi_node_name*, and under **Policy Groups**, click **APIs**. The settings are also detailed in the administrative console help.

Authorization for inquiry
Specifies whether authorization using authentication tokens is required for inquiry API requests.

Authorization for publish
Specifies whether authorization using authentication tokens is required for publish API requests.

Authorization for custody transfer
Specifies whether authorization using authentication tokens is required for custody transfer API requests.

The above policy settings apply when UDDI security features are being used. If WebSphere Application Server security is enabled and the UDDI service in question is mapped to the security role AllAuthenticatedUsers, these settings will be overridden. See Configuring UDDI Security with WebSphere Application Server security enabled and Configuring UDDI Security with WebSphere Application Server security disabled.

Other considerations

In addition to the property and policy settings above, be aware that some UDDI keying and user policy settings also influence publish behavior. These settings are not specific to security, but you should bear them in mind as they also place restrictions on successful completion of publish requests.

To review or change the following property settings, click **UDDI** → **UDDI Nodes** > *uddi_node_name*. The settings are also detailed in the administrative console help

Automatically register UDDI publishers
The UDDI Registry requires publisher entitlements to be set before allowing any publish requests. This option automatically registers users with default entitlements.

If this option is not selected, users (and their entitlements) can be registered. See UDDI Publisher settings.

Use tier limits
If selected, tier limits are enforced.

If this option is selected you should have one or more tiers configured (see Tier collection and UDDI Tier settings). You should also ensure that registered UDDI Publishers are assigned to a tier (see UDDI Publisher settings).

To review or change the following property setting, click **UDDI** → **UDDI Nodes** > *uddi_node_name*, and under **Policy Groups** click **UDDI Keying**. The setting is also detailed in the administrative console help.

Registry key generation
If this option is selected, publishers may request key space and, if successful, publish with publisher assigned keys.

Configuring SOAP API and GUI services

Configuring Version 1 and Version 2 SOAP API services

You can configure the following Version 1 and Version 2 SOAP interface properties:

- *defaultPoolSize*. This is the number of SOAP parsers with which to initialize the parser pool for the SOAP interface. You can set this independently for the Publish (uddipublish) and Inquiry (uddi) APIs. For example, if you expect more inquiries than publish requests through the SOAP interface, you can set a larger pool size for the Inquiry API. The default initial size for both APIs is 10.
- Whether the API is to be secure (accessed using HTTPS) or insecure (accessed using HTTP). The default for Publish is to use HTTPS and Inquiry to use HTTP.

To configure these properties after the UDDI application has been installed:

1. Edit the active deployment descriptor (web.xml) for the Version 1 and Version 2 SOAP module (soap.war). This file is located in the following directory:

   ```
   install_root/profiles/profile_name/config/cells/cell_name/applications/
     UDDIRegistry.node_name.server_name.ear/deployments/
       UDDIRegistry.node_name.server_name/soap.war/WEB-INF
   ```

2. To modify defaultPoolSize for Version 1 or Version 2 Publish, modify the 'param-value' element in the servlet with 'servlet-name' = uddipublish
3. To modify defaultPoolSize for Version 1 or Version 2 Inquiry, modify the 'param-value' element in the servlet with 'servlet-name' = uddi
4. To modify the user data constraint transport guarantee for Version 1 or Version 2 publish, which determines whether the Publish service is to be confidential (accessed using HTTPS) or insecure (using HTTP), find the 'security-constraint' with id = 'UDDIPublishTransportConstraint' and set its 'user-data-constraint' 'transport-guarantee' to CONFIDENTIAL or NONE.
5. Stop and restart the application server for the changes to take effect.

Configuring Version 3 SOAP API services

For the Version 3 SOAP interface, you can specify whether the Publish, Custody Transfer, Security and Inquiry API services are to be secure (accessed using HTTPS) or insecure (accessed using HTTP). The default for Publish, Custody Transfer and Security APIs is to use HTTPS, and Inquiry to use HTTP.

To configure these properties after the UDDI application has been installed:

1. Edit the active deployment descriptor (web.xml) for the Version 3 SOAP module (v3soap.war). This file is located in the following directory:

   ```
   install_root/profiles/profile_name/config/cells/cell_name/applications/
     UDDIRegistry.node_name.server_name.ear/deployments/
       UDDIRegistry.node_name.server_name/v3soap.war/WEB-INF
   ```

2. Modify the user data constraint transport guarantee which determines whether the service is to be confidential (accessed using HTTPS) or insecure (accessed using HTTP). Use the table below to find the value of 'security-constraint id' for the service you wish to modify. Find the relevant security-constraint id in the deployment descriptor and set its 'user-data-constraint' 'transport-guarantee' to either CONFIDENTIAL or NONE.

Type of UDDI service	Value of security-constraint id
Publish	AxisServlet Publish Resource Collection
Custody transfer	AxisServlet CustodyTransfer Resource Collection
Security	AxisServlet Security Resource Collection
Inquiry	AxisServlet Inquiry Resource Collection

3. Stop and restart the application server for the changes to take effect.

Configuring Version 3 GUI services

For the Version 3 GUI interface, you can specify whether the Publish and Inquiry API services are to be secure (accessed using HTTPS) or insecure (accessed using HTTP). The default for Publish is to use HTTPS, and Inquiry to use HTTP.

To configure these properties after the UDDI application has been installed:

1. Edit the active deployment descriptor (web.xml) for the Version 3 GUI module (v3gui.war). This file is located in the following directory:

   ```
   install_root/profiles/profile_name/config/cells/cell_name/applications/
     UDDIRegistry.node_name.server_name.ear/deployments/
       UDDIRegistry.node_name.server_name/v3gui.war/WEB-INF
   ```

2. Modify the user data constraint transport guarantee which determines whether the service is to be confidential (accessed using HTTPS) or insecure (accessed using HTTP). Use the table below to find the value of 'security-constraint id' for the service you wish to modify. Find the relevant security-constraint id in the deployment descriptor and set its 'user-data-constraint' 'transport-guarantee' to either CONFIDENTIAL or NONE.

Type of UDDI service	Value of security-constraint id
Publish	UDDIPublishSecurityConstraint
Inquiry	UDDIInquireSecurityConstraint

3. Stop and restart the application server for the changes to take effect.

Multiple language encoding support in UDDI

UDDI API

UDDI Version 3 supports both UTF-8 and UTF-16 encoding. Internally UTF-16 characters are stored as UTF-8. This is transparent to the user application.

UDDI User Console

The UDDI user console only supports UTF-8 encoding. To enable this, you must configure the application server into which the UDDI Registry application is installed with UTF-8 encoding enabled. To do this, refer to ″Configuring application servers for UTF-8 encoding″ elsewhere in the WebSphere Information Center.

Customizing the UDDI Registry user interface (GUI)

The look and feel of the UDDI Registry user interface is determined by the styles defined in the *.css* files located in the following directory:
install_root/profiles/*profile_name*/installedApps/*cell_name*/UDDIRegistry.*node_name*.*server_name*
.ear/v3gui.war/theme.

Style class definitions in these files can be edited to alter the overall theme of the UDDI Registry user interface, including font attributes, layout and colors.

Managing the UDDI Registry

You can use either the WebSphere Application Server administrative console or the Java Management Extensions (JMX) management interface to manage UDDI Registries.

In previous versions of WebSphere Application Server and the UDDI Registry, a properties file was used, but from WebSphere Application Server Version 6, all policies and properties are managed through either the JMX management interface or the administrative console.

JMX can be used to monitor and configure UDDI registries programmatically, and is explained in Using administrative programs (JMX). See IBM WebSphere Registry Administrative Interface for full details on using the UDDI administrative interface. To manage UDDI registries using the WebSphere Application Server administrative console, start from the UDDI link in the left navigation pane as described below.

Using the UDDI management functions available in the WebSphere Application Server administrative console, you can perform the following operations:

- view and manage the status of all UDDI nodes in a cell
- initialize UDDI nodes with required settings
- configure general properties that affect UDDI runtime behavior
- manage UDDI policy settings
- create, view and update UDDI publishers
- create, view and update publisher tiers which limit how many UDDI entries may be published
- view and manage the status of value sets

UDDI node collection

Start the associated UDDI application for this node, if it is not already running. If the application is not running you will not see the UDDI node in the list of available choices.

To configure node properties, policies, value set status and user entitlements, complete the following steps:

From the administrative console, expand **UDDI** in the navigation pane then click **UDDI Nodes**. This displays the collection of UDDI nodes in the cell.

Each UDDI node is represented by a UDDI Node ID, Description, UDDI Application Location and Status. The Status can be either *Initialization Pending*, *Activated* or *Deactivated*. To activate UDDI nodes that are *Deactivated*, select them by checking the corresponding check boxes in the Select column and click the *Activate* button. Similarly to deactivate UDDI nodes, select them and click the *Deactivate* button.

Note: Restarting the UDDI application, or the application server, will always result in the reactivation of the UDDI node, even if the node was previously deactivated.

To manage an individual UDDI node, click on its UDDI Node ID link. This takes you to the Configuration page where you can manage its general properties, initialize it if the status is set to *Initialization Pending*, and access pages for managing policies, UDDI publishers, tiers and value sets. Refer to UDDI node settings for details on the next available topic.

UDDI node settings:

This topic contains details of the general properties that you can configure for a UDDI node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id*.

By clicking on a node in the UDDI node ID column the UDDI node detail page is displayed. The UDDI node detail page displays a set of General Properties for the UDDI node, some of which may be editable depending on the state of the node. There are also links to Additional Properties (Value sets, Tiers and UDDI Publishers) and links to Policy Groups where UDDI node policy may be viewed and changed.

Unless the UDDI node has been installed as a default UDDI node (as defined in UDDI Registry terminology) there are some important general properties that need to be set before the UDDI node can be initialized. These properties are all marked as being required (indicated by the presence of a '*' next to the input field). You may set the values as many times as you wish before initialization. However, once the

UDDI node has been initialized, these properties will become read only for the lifetime of that UDDI node. It is very important to set these properties correctly. Other general properties of the UDDI node may be set before, and after, initialization.

Once the general properties have been set to appropriate values, you can click *OK* (which saves your changes and exits the page), or *Apply* (which saves your changes and leaves you on the same page). At this point the changes will have been stored.

If the UDDI node is in the *Not Initialized* state, indicated on the UDDI node detail page by the presence of an *Initialize* button (above the General Properties section), the UDDI node can be initialized by clicking the *Initialize* button. This operation may take a while to complete. It is important to remember to save any changes you have made to the general properties by clicking *Apply* or *OK* before the *Initialize* button is pressed.

The other UDDI settings that a UDDI administrator can manage are shown to the right of the screen and are described in the following topics:

- Value set collection

  This topic contains details of the value sets settings that you can configure for a UDDI node.
- Tier collection

  This topic contains details of the UDDI publisher tiers that you can configure for a UDDI node.
- UDDI Publisher collection

  This topic contains details of the publishers that have been registered with the UDDI node.
- Policy groups

  This topic contains links to the detailed settings information for every policy group that you can configure for a UDDI node.

UDDI Node ID:

The unique identifier given to a UDDI node in a UDDI registry. This must be a valid UDDI key.

The value for the node ID will also be the domain key for this UDDI node.

Required	Yes
Data type	String
Default	uddi:*cell_name*:*node_name*:*server_name*:node_id

UDDI node description:

The user supplied description of this UDDI node.

Required	Yes
Data type	String
Default	WebSphere UDDI Registry default node

Root key generator:

Specifies the root key space of the registry.

Registries intending to become affiliate registries may want to specify a root key space in a partition below the root key generator of the parent root registry, for example, uddi:thisregistry.com:keygenerator.

Required	Yes
Data type	String

Default uddi:*cell_name*:*node_name*:*server_name*:keyspace_id:keygenerator

Prefix for generated discoveryURLs:

The URL prefix for the GET servlet.

The URL prefix applied to generated discoveryURLs in businessEntity elements so they can be returned on HTTP GET requests. The format is 'http://hostname:port/uddisoap/', where 'uddisoap' is the UDDI version 2 SOAP servlet's context root. This property applies to UDDI version 2 API requests only.

Required Yes
Data type String
Default http://localhost:9080/uddisoap

Host name for UDDI node services:

The fully qualified domain name of the network host, or its IP address.

The hostname root used by the UDDI node to model API services in its own node business entity.

Data type String
Default localhost

Host HTTP port:

The port number used to access UDDI node services with HTTP.

This port number must match the WebSphere port for HTTP requests.

Data type Integer
Default 9080

Host HTTPS port:

The port number used to access UDDI node services with HTTPS.

This port number must match the WebSphere port for HTTPS requests.

Data type Integer
Default 9443

Maximum inquiry result set size:

The maximum size of result set which the registry will process for an inquiry API request. If the result set exceeds this value, an E_resultSetTooLarge error is returned to the user. Setting the value higher allows larger result sets but may cause increased response times.

CAUTION: If this value is set too low users will get an E_resultSetTooLarge error message, whereas setting to too high might cause increased response times. If the value is set too low and users use imprecise search criteria the likelihood of receiving the E_resultSetTooLarge is increased.

Data type Integer
Default 500

Range	0 to 1024

Maximum inquiry response set size:

For inquiry API requests, this value controls the maximum number of results returned in each response. If the number of results in the result set is greater than this value, the response will only include a subset of results. The user can retrieve remaining results using the listDescription feature as described in the UDDI specification. Setting this value too low will require the user to make more requests to retrieve the remainder of the result set.

CAUTION: This value can not be higher than the value set for ″Maximum inquiry results″. Setting this value too low increases the number of requests needed to achieve the full result set.

Data type	Integer
Default	500
Range	0 to 1024

Maximum search names:

The maximum number of names that can be supplied in an inquiry API request. Increasing this value can significantly slow response times of the UDDI node.

This can be used to control the complexity of requests that this UDDI node will allow. The recommendation is to not set this value above 8.

Data type	Integer
Default	5
Range	1 to 64

Maximum search keys:

The maximum number of keys that can be supplied in an inquiry API request. This limits the number of references that can be specified in categoryBag, identifierBag, tModelBag and discoveryURLs. Increasing this value can significantly increase response times for the UDDI node.

This can be used to control the complexity of requests that this UDDI node will allow. The recommended setting for this is 5 or less.

In exceptional cases, the UDDI node may reject complex requests with excessive numbers of keys even if the value of maxSearchKeys is not exceeded.

Data type	Integer
Default	5
Range	1 to 64

Key space requests require digital signature:

Specifies whether tModel:keyGenerator requests must be digitally signed.

Data type	Boolean (check box)
Default	False (cleared)

Use tier limits:

Specifies whether an approval manager is used to check publication tier limits.

If set to false, the number of UDDI entities that can be published is unlimited.

Data type	Boolean (check box)
Default	True (selected)

Use authInfo credentials if provided:

Specifies if authInfo contents in UDDI API requests are used to validate users when WebSphere global security is off. If this setting is true, the UDDI node will use the request's authInfo element, otherwise the default user name is used.

Data type	Boolean (check box)
Default	True (selected)

Authentication token expiry period:

The period after which authentication tokens are invalidated (in minutes), and a new authToken is required.

CAUTION: The setting should be sufficient to ensure operational success. Longer settings can increase the risk of illegal authToken use.

Data type	Integer
Default	30
Range	1 to 10080 minutes (10080 minutes = 1 week)

Automatically register UDDI publishers:

Specifies if UDDI publishers are automatically registered, and assigned to the default tier.

Automatically registered UDDI publishers are given default entitlements.

Data type	Boolean (check box)
Default	True (selected)

Default user name:

Specifies the user name used for publish operations when WebSphere security is disabled.

Data type	String
Default	UNAUTHENTICATED

Default language code:

Applies only to UDDI Version 1 and Version 2 requests, the default language code to be used for xml:lang when not otherwise specified.

Data type	String
Default	en

Value set collection:

Use this page to view and configure the value sets that have been installed in a UDDI node.

For information on adding new value sets please see User Defined Value Set Support in the UDDI Registry.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Value Sets**.

Value sets in a UDDI node are either supported or not supported by policy. By default, new value sets are *not* supported. When you have published a value set tModel and loaded value set data, you can control whether other UDDI entities can reference this value set tModel by setting the *Supported* policy.

To enable support for one or more value sets, select the value sets by clicking on the appropriate check boxes in the *Select* column. Click the *Enable Support* button. The supported field for all the selected value sets will be updated, with a value of true, to reflect the new status.

To disable support for a value set, which may be necessary before it is removed from the UDDI node, select the value sets in the same manner as for enabling support. Click the *Disable Support* button. The supported field for all the selected value sets will be updated, with a value of false, to reflect the new status.

Clicking on a value set name in the list takes you to the general properties page for that value set as described in Value set settings.

Name:

The name of the tModel that represents the value set.

tModelkey:

The key for the tModel that represents the value set.

Supported:

Supported Indicates whether references to this value set are supported (true) or not supported (false) by policy in this UDDI node.

Value set settings:

Use this page to view the attributes of a value set in a UDDI node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Value Sets** > *value_set_name*.

This page shows the values of keyedReferences in the tModel that represents this value set. It also shows the *Supported* status of the value set as described on the Value set collection page. All properties are read-only. The *Supported* status can be changed on the Value Set page.

Unvalidatable:

Specifies whether this value set is unvalidatable. This is set by the value set tModel publisher to indicate if the value set is available or not for use by publish requests.

Checked:

Specifies whether this value set is checked. If set to true, UDDI entities that reference this value set will be validated to ensure their values are present in this value set.

Cached:

Specifies whether this value set is cached in this UDDI node.

Externally cacheable:

Specifies whether this value set is externally cacheable.

Externally validated:

Specifies whether this value set is externally validated.

Supported:

Specifies whether this value set is supported by policy in this UDDI node.

Last cached:

Specifies the date when this value set was last cached in the UDDI node.

Tier collection:

This page contains a list of the available tiers for the UDDI node. You can modify tiers, create new tiers and delete tiers from this page.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Tiers**.

This page shows the available tiers for the UDDI node. Clicking a tier name will show the General Properties for the specific tier as detailed in Tier settings. To delete a Tier from the list, select the relevant name and click *Delete*. Clicking *New* will take you to the General Properties page with the same properties as described in Tier settings.

One of the tiers in the collection will be marked as the default tier, indicated by *(default)* appearing next to the tier's name. The default tier will be assigned to UDDI publishers that are registered automatically when automatic user registration is turned on. To set the default tier, select the appropriate tier in the collection and press the *Set default* button. Note that it is not possible to delete a tier if it is currently marked as the default tier, or it is currently assigned to a UDDI publisher.

Name:

The name of the tier.

Description:

User supplied descriptive text about the tier.

UDDI Tier settings:

This topic contains details of the general properties that you can configure for a UDDI publisher tier.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Tiers** > *tier_name*.

Name:

The name of the tier.

Required Yes

Data type	String
Default	No default
Range	1 to 255

Description:

The user supplied description of the tier.

Data type	String
Default	No default
Range	0 to 255

Maximum properties:

For each of the maximum fields described below, the data is:

Required	Yes
Data type	Integer
Default	No default
Range	0 to 2147483647

Maximum businesses:

The maximum number of businesses that UDDI publishers in this tier are allowed to publish in this tier.

Maximum services:

The maximum number of services UDDI publishers in this tier are allowed to publish.

Maximum bindings:

The maximum number of bindings UDDI publishers in this tier are allowed to publish.

Maximum tModels:

The maximum number of tModels UDDI publishers in this tier are allowed to publish.

Maximum publisher assertions:

The maximum number of publisher assertions UDDI publishers in this tier are allowed to add.

UDDI Publisher collection:

This page shows the WebSphere users that are currently registered as UDDI publishers.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**UDDI Publishers**.

To create a UDDI publisher click on the New button. This opens the UDDI Publisher settings page where details about the publisher can be entered.

It is possible to assign multiple publishers to a tier without having to edit each one individually. To do this select the appropriate publishers in the collection table. From the selection box at the top of the collection table choose from one of the tiers available on the UDDI node. Finally, click the *Assign tier* button to update the selected publishers.

To delete publishers select them in the collection table and then press the *Delete* button.

After the users have been registered as UDDI publishers, their entitlements can be edited as described in UDDI Publisher settings.

User name:

The name of the UDDI publisher.

Tier:

The publication limits tier to which the UDDI publisher has been assigned.

UDDI Publisher settings:

Use this page to view and edit the properties of a UDDI publisher, or to create a new UDDI publisher.

You can view this administrative console page in two ways:

- If you want to view and edit the properties of an existing UDDI publisher click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**UDDI Publishers** > *user_name*
- If you want to create a new UDDI publisher click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**UDDI Publishers** → **New**

This page shows the entitlements and publication limits tier for a particular UDDI publisher.

User name:

The name of the UDDI publisher.

If you are creating a new UDDI publisher, enter the name of a user known to the application server. If you are viewing or editing the properties of an existing publisher, the user name cannot be changed.

Allowed to publish keyGenerator with derived key:

The UDDI publisher has permission to publish tModel:keyGenerator with a derived key.

The tModel:keyGenerator is a request for key space. An example of a legal derived key is uddi:tempuri.com:fish:buyingService where the key is based on the derivedKey ″uddi:tempuri.com:fish″. the string 'buyingService' is the key's key specific string (KSS).

Data type	Boolean
Default	True (selected)

Allowed to publish keyGenerator with domain keys:

The UDDI publisher has permission to publish tModel:keyGenerator with a domain key.

Data type	Boolean
Default	True (selected)

Allowed to publish keyGenerator:

The UDDI publisher has permission to publish tModel:keyGenerator.

If false, UDDI publishers cannot publish keyGenerators of any kind. In this situation the following permissions ('Allowed to publish keyGenerator with derived key', 'Allowed to publish keyGenerator with domain keys', 'Allowed to publish with UUID key' and 'Allowed to publish keyGenerator with UUID keys') will be disregarded irrespective of how they are set.

Data type	Boolean
Default	True (selected)

Allowed to publish with UUID key:

The UDDI publisher has permission to publish elements providing a UUID key.

Data type	Boolean
Default	False (cleared)

Allowed to publish keyGenerator with UUID keys:

The UDDI publisher user has permission to publish tModel:keyGenerator providing a UUID key.

Data type	Boolean
Default	False (cleared)

Tier:

The tier to which the UDDI publisher is assigned.

Policy groups:

This topic contains links to the detailed settings information for every policy group that you can configure for a UDDI Registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id*.

To the right of the page is a list of the Policy Groups that can be acted upon. Clicking on a specific group will open the page for the group required.

The policy groups available to act upon are:
- "UDDI keying policy settings"
- "UDDI node API policy settings" on page 497
- "UDDI user policy settings" on page 497
- "UDDI data custody policy settings" on page 498
- "UDDI value set policy" on page 498
- "UDDI node miscellaneous" on page 499

UDDI keying policy settings:

This topic contains details of the UDDI keying settings that you can configure for a UDDI Registry.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**UDDI Keying**.

Registry key generation:

Allows publishers to publish key generator tModels.

Defines whether a given UDDI node or publisher is allowed to register a key generator tModel. When true, this allows the set of publishers to be managed using the facilities provided in the UDDI Publisher settings

Data type	Boolean
Default	True (selected)

Registry support of UUID keys:

Allow publisher supplied uuidKeys in publish requests.

If true, this allows the set of publishers to be managed using the facilities provided in UDDI Publisher settings

Data type	Boolean
Default	False (cleared)

UDDI user policy settings:

This topic contains details of the user policy settings that you can configure for a UDDI Registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**User policies**.

Allow transfer of ownership:

When true, data ownership can be transferred between owners within the UDDI node.

Data type	Boolean
Default	True (selected)

UDDI node API policy settings:

This topic contains details of the API settings that you can configure for a UDDI Registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **APIs**.

Note: This information applies only to UDDI Version 3. The settings for Versions 1 and 2 are not changeable; authentication tokens are required for publish requests, but not for inquiry requests (there are no custody transfer requests in Versions 1 or 2).

Authorization for inquiry:

Specifies if authorization using the authInfo element is required for inquiry API requests.

Typically, UDDI registries are configured not to require authorization for registry API requests. This setting is only relevant if the V3SOAP_Inquiry_User_Role is set to *everyone* and WebSphere Application Server global security is on. If WebSphere Application Server global security is off, this setting is ignored. If WebSphere Application Server global security is on and the V3SOAP_Inquiry_User_role is not set to *everyone*, this setting is ignored.

Data type	Boolean
Default	False (cleared)

Authorization for publish:

Specifies if authorization using the authInfo element is required for publish API requests.

Typically, UDDI registries are configured not to require authorization for registry API requests. This setting is only relevant if the V3SOAP_Publish_User_Role is set to *everyone* and WebSphere Application Server global security is on. If WebSphere Application Server global security is off, this setting is ignored. If WebSphere Application Server global security is on and the V3SOAP_Publish_User_role is not set to *everyone*, this setting is ignored.

Data type	Boolean
Default	True (selected)

Authorization for custody transfer:

Specifies if authorization using the authInfo element is required for custody transfer API requests.

Typically, UDDI registries are configured not to require authorization for registry API requests. This setting is only relevant if the V3SOAP_CustodyTransfer_User_Role is set to *everyone* and WebSphere Application Server global security is on. If WebSphere Application Server global security is off, this setting is ignored. If WebSphere Application Server global security is on and the V3SOAP_CustodyTransfer_User_role is not set to *everyone*, this setting is ignored.

Data type	Boolean
Default	True (selected)

UDDI data custody policy settings:

This topic contains details of the data custody settings that you can configure for a UDDI Registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Data custody**.

Transfer token expiration period:

The length of time (in minutes) after the issue of a transfer token before it expires.

CAUTION: Setting too large a value might expose the UDDI registry to a risk of misuse.

Data type	Integer
Default	1440
Range	1 to 2147483647 (for all intents and purposes, unlimited)

UDDI value set policy:

This topic contains details of the value set policy settings that you can configure for a UDDI Registry node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* >**Value Set Policy**.

Enable checked value sets:

Specifies if checked value sets are supported. When false, publish requests containing references to checked value sets are be rejected.

Data type	Boolean
Default	True (selected)

UDDI node miscellaneous:

This topic contains details of the miscellaneous settings that you can configure for a UDDI node.

To view this administrative console page, click **UDDI** → **UDDI Nodes** > *UDDI_node_id* > **Miscellaneous**.

Node generates discoveryURLs:

Defines whether the UDDI node generates discoveryURLs.

Data type	Boolean
Default	False (cleared)

Node supports HTTP Get Service:

Specifies if the UDDI node supports an HTTP GET service for access to the XML representations of UDDI data structures.

Data type	Boolean
Default	True (selected)

URL prefix for V3 GET servlet:

The URL prefix for the UDDI version 3 GET servlet

The prefix for the URL to the GET servlet used to retrieve the XML representation of a published entity. When a businessEntity is published, if the policy for Node Discovery URLs is set to true, the discoveryURL value is generated based on the prefix value. Otherwise, the discoveryURL value will be empty.

The UDDI Version 3 specification recommends that discoveryURLs are **not** generated as they can affect the use of digital signatures. If you do enable generation of discoveryURLs, it is recommended that the URL prefix is not changed after the point at which the policy to enable generation of discoveryURLs is enabled. Not doing so will mean discoveryURLs generated using the earlier URL prefix would no longer work.

Data type	URL
Default	http://localhost:9080/uddiv3soap/

UDDI Registry Administrative Interface Overview

The UDDI Registry Administrative Interface allows you to inspect and manage the runtime configuration of a UDDI application. This includes managing the information and the activation state about a UDDI node, updating properties and policies, setting publish tier limits, registration of UDDI publishers, and controlling value set support. The operations of the UDDI Registry Administrative Interface can be read and invoked using standard JMX (Java Management Extensions) interfaces.

The use of JMX is explained in Using administrative programs (JMX). See the IBM WebSphere UDDI Registry Administrative Interface for full details on using the UDDI administrative interface.

Backing up and restoring the UDDI Registry database

If you want to protect the data in your UDDI Registry database, you can back up and restore the database using the facilities of the database product your UDDI node is on.

Cloudscape

To backup a Cloudscape UDDI Registry database, ensure that the UDDI application is stopped (and hence, not accessing the Cloudscape database), and ensure that no other application is using the Cloudscape UDDI30 database, then make a copy of the UDDI30 directory using the file system that the directory resides upon.

To restore a Cloudscape database, replace the UDDI30 file structure with the back up. Note that any updates made since the back up was taken will be lost.

Non-Cloudscape

Use the appropriate import and export tools for the database being used to contain the UDDI Registry.

- Backup

  Include elements in schemas named IBMUDI30 and IBMUDS30
- Restore

  Restore the back up by deleting the schemas IBMUDI30 and IBMUDS30, recreating database structures using the original scripts (with slight modifications), and importing the previously saved data, as described in the steps below:

  1. Delete the schemas IBMUDI30 and IBMUDS30 *this will result in any IBM UDDI structures being destroyed.*
  2. Create database structures (for DB2 see Creating a DB2 database or for Cloudscape, see Creating a Cloudscape database for details) as for the original creation **except** that the final step (xxxxxx_**70**xxxx.*) must not be run. This will result in a database containing the basic data required by the UDDI Registry, into which your backed-up data may be imported.
  3. Delete all the rows in the table IBMUDS30.UDDIDBSCHEMAVER, to avoid a clash between a row inserted by the scripts and the row that was backed-up. To do this, use the following command:

     ```
     delete from IBMUDS30.UDDIDBSCHEMAVER
     ```
  4. Restore the previously backed-up data in schemas IBMUDI30 and IBMUDS30

Removing and reinstalling the UDDI Registry

An IBM WebSphere UDDI Registry node consists of a WebSphere application, a store of data (using a relational database management system or RDBMS) referred to as the UDDI database, and a means to connect the application to the data (a data source and related elements). All the data relating to UDDI is stored within the UDDI database and therefore exists irrespective of the UDDI application.

With these facts in mind, consider the following options:

- To remove a node from a WebSphere Application Server you do not have to delete the database. You only have to delete the UDDI application and any associated resources such as the data source used (and J2C Authentication Data if used), as the data in the UDDI database is separate from the UDDI application.
- You do not have to remove the UDDI application to start a new UDDI Registry node. Instead you can create a new, replacement node by changing the datasource which the UDDI application uses to access the new UDDI database.

Remove the UDDI application if you no longer want a UDDI facility on a particular WebSphere Application Server (you can subsequently move the UDDI Registry node to a different WebSphere Application Server).

Reinstall the UDDI application if you wish to continue to provide the UDDI facility on a particular WebSphere Application Server.

To reinstall a UDDI Registry node, see Reinstalling the UDDI application. To remove a UDDI application or to remove a UDDI Registry node, see Removing a UDDI Node.

Removing a UDDI Registry node

To completely remove a UDDI Registry node you need to remove the UDDI Registry application and delete the UDDI Registry database. However there may be situations where you only want to perform one of these tasks:

Removing the UDDI Registry application from an application server.
You might want to do this in order to reinstall the application because it has become corrupted for some reason, or to apply service. See also the topic on Reinstalling the UDDI Registry application.

Deleting the UDDI Registry database
You might want to do this in order to use a different database product as the persistence store for your UDDI data, to delete all your UDDI Registry data in order to publish fresh data (for example, if you have completed a test cycle), or to cause the UDDI Registry node to re-initialize with new UDDI property settings (for example, to move from a default UDDI node to a customized UDDI node). Note that deleting a UDDI Registry database will cause all UDDI data for that UDDI Registry to be lost.

Completely removing a UDDI Registry node from an application server
You might want to do this in order to move the UDDI Registry to a different application server, or to remove a UDDI Registry that has been used for testing.

Depending on what you wish to achieve, complete **one** of the following steps:

1. **Removing a UDDI Registry application**

   To remove the UDDI application from an application server, run the wsadmin script uddiRemove.jacl, as shown, from the *install_root*/bin directory.

   The syntax of the command is as follows:

   ```
   wsadmin.sh -f uddiRemove.jacl
                node_name
                server_name
                [default]
   ```

   6.1+

   ```
   wsadmin.sh -f uddiRemove.jacl
                {node_name server_name | cluster_name}
                [default]
   ```

   where

   - *node_name* and *server_name* are the names of the WebSphere node and application server in which the UDDI application is deployed (these are the names that you specified when you ran uddiDeploy.jacl to install the UDDI application).
   - 6.1+ *cluster_name* is the name of the WebSphere cluster in which the UDDI application is deployed. This is the name that you specified when you ran uddiDeploy.jacl to install the UDDI application.
   - 'default' is optional and is applicable only for Cloudscape in a standalone application server environment, and then only if the default option was used when the uddiDeploy.jacl script was run to deploy the UDDI Registry. Specifying default will remove the UDDI Cloudscape datasource but **not** the UDDI Cloudscape database.

   Output will appear on the screen by default. To direct the output to a log file, add '> *removeuddi.log*' (where removeuddi.log can be any log name of your choice) to the end of the command.

   For example, to remove the UDDI application from server 'server1' running in node 'MyNode' and send any messages to the file removeuddi.log:

   ```
   wsadmin.sh -f uddiRemove.jacl MyNode server1 > removeuddi.log
   ```

   6.1+ To remove the UDDI application from cluster 'MyCluster' and send any messages to the screen:

   ```
   wsadmin.sh -f uddiRemove.jacl MyCluster
   ```

Note: If running in a network deployment configuration, the command must be executed against the deployment manager profile.

2. **Deleting a UDDI Registry database**

   Note that this will cause all UDDI data in that UDDI Registry to be destroyed.

   a. Stop the server that is hosting the UDDI Registry application.

   b. Delete the database:

      - For DB2, use the database facilities to delete the UDDI database.
      - For Cloudscape, delete the directory tree containing the UDDI database. By default, this will be located in *install_root*/profiles/*profile_name*/databases/com.ibm.uddi/UDDI30.

3. **Completely removing a UDDI Registry node**

   To completely remove a UDDI Registry node from an application server, you need to remove the UDDI registry application and database, and also the resources that were used to reference the UDDI Registry database.

   a. Run the uddiRemove.jacl script as described above, to remove the UDDI Registry application.

   b. Delete the UDDI Registry database, as described above.

   c. If you ran the uddiRemove script using the default option, the datasource and related objects have already been deleted so no further action is required. If the default option was not valid for your configuration, delete the following objects:

      - the UDDI datasource that references the UDDI Registry database (this was created when you set up the UDDI Registry).
      - any UDDI JDBC provider that was created (if you did not reuse an existing JDBC provider).
      - any J2C Authentication Data Entry that was created.

Reinstalling the UDDI Registry application

Perform this task if you want to continue providing UDDI services with your existing UDDI database, but require that the UDDI application code be changed.

1. Make a note of any changes that you have made to the installed UDDI application that you wish to keep, for example changes to security role mappings, changes to the deployment descriptor (web.xml) in v3soap,war, v3gui.war, v3soap.war, or soap.war, or customization of the UDDI user interface (GUI). All such changes will be lost during the reinstallation process; any changes that you wish to keep will need to be reapplied later.

2. Run the wsadmin script uddiDeploy.jacl from the *install_root*/bin directory, as shown, noting that:

   - You should not specify the default option even if you previously used this option to set up a default UDDI node using Cloudscape.
   - If you are deploying the UDDI Registry into a network deployment scenario, ensure that the deployment manager is the target.

   At a command prompt enter:

```
wsadmin.sh [-conntype none] –f uddiDeploy.jacl
              node_name
              server_name
```

6.1 +

```
wsadmin.sh [-conntype none] –f uddiDeploy.jacl
              {node_name server_name | cluster_name}
```

   where

   - '-conntype none' is optional, and is only needed if the application server or deployment manger is not running.
   - *node_name* and *server_name* are the names of the WebSphere node and application server in which the UDDI application is deployed (these are the names that you specified when you ran uddiDeploy.jacl to install the UDDI application).

- 6.1+ *cluster_name* is the name of the WebSphere cluster in which the UDDI application is deployed. This is the name that you specified when you ran uddiDeploy.jacl to install the UDDI application.

The output from this command can optionally be redirected to a log file by adding '> *log_name*.log' at the end of the command, where *log_name*.log is the name of the log file to be created.

The command removes the existing UDDI application and reinstalls it.

Note: Your existing JDBC provider, datasource and any J2C authdata entry will be unchanged by this procedure . Your existing UDDI Registry data, including UDDI entities as well as property and policy settings, will also be unaffected.

3. If you noted any changes in step 1, reapply them now.
4. Start or restart the application server for the reapplied changes to take effect.

Data access resources

Task overview: Accessing data from applications

Various enterprise information systems (EIS) use different methods for storing data. These *backend* data stores might be relational databases, procedural transaction programs, or object-oriented databases. IBM WebSphere Application Server provides several options for accessing an information system's backend data store:

- Programming directly to the database through the JDBC 2.0 optional package API or the JDBC 3.0 API.
- Programming to the procedural backend transaction through various J2EE Connector Architecture (JCA) 1.0 or 1.5 compliant connectors.
- Programming in the bean-managed persistence (BMP) bean or servlets indirectly accessing the backend store through either the JDBC API or JCA compliant connectors.
- Using container-managed persistence (CMP) beans.
- Using embedded Structured Query Language in Java (SQLJ) support with applications that use DB2 as a backend database.
- Using the IBM data access beans, which also use the JDBC API, but give you a rich set of features and function that hide much of the complexity associated with accessing relational databases.

For all of these options, *except for using the JCA 1.0 or 1.5 compliant connectors*, the prerequisite Web site details which databases and drivers are currently supported. Consult the IBM Web address: http://www.ibm.com/software/webservers/appserv/doc/latest/prereq.html .

1. Develop data access applications. See ″Developing data access applications″. Develop your application to access data using the various ways available through the WebSphere Application Server. You can access data through APIs, container-managed persistence beans, bean-managed persistence beans, session beans, or Web components.
2. Assemble data access applications using the assembly tool. See ″Assembling data access applications″ in the information center. Assemble your application by creating and mapping resource references.
3. Prepare for deployment: Ensure that the appropriate database objects are available. Create or configure any databases or tables required, set necessary configuration parameters to handle expected load, and configure any necessary JDBC providers and data source objects for servlets, enterprise beans, and client applications to use.
4. Install the application on your application server.

Resource adapter

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS).

A resource adapter plugs into an application server and provides connectivity between the EIS, the application server, and the enterprise application.

An application server vendor extends its system once to support the J2EE Connector Architecture (JCA) and is then assured of seamless connectivity to multiple EISs. Likewise, an EIS vendor provides one standard resource adapter with the capability to plug into any application server that supports the connector architecture.

WebSphere Application Server provides the WebSphere Relational Resource Adapter (RRA) implementation. This resource adapter provides data access through JDBC calls to access the database dynamically. The connection management is based on the JCA connection management architecture. It provides connection pooling, transaction, and security support. WebSphere Application Server version 6.0 supports JCA versions 1.0 and 1.5.

Data access for container-managed persistence (CMP) beans is managed by the WebSphere Persistence Manager indirectly. The JCA specification supports persistence manager delegation of the data access to the JCA resource adapter without knowing the specific backend store. For the relational database access, the persistence manager uses the relational resource adapter to access the data from the database. You can find the supported database platforms for the JDBC API at the WebSphere Application Server prerequisite Web site.

J2EE Connector Architecture resource adapters:

A J2EE Connector Architecture (JCA) resource adapter is any resource adapter conforming to the JCA Specification.

The product supports any resource adapter that implements version 1.0 or 1.5 of this specification. IBM supplies resource adapters for many enterprise systems separately from the WebSphere Application Server package, including (but not limited to): the Customer Information Control System (CICS), Host On-Demand (HOD), Information Management System (IMS), and Systems, Applications, and Products (SAP) R/3 .

The general approach to writing an application that uses a JCA resource adapter is to develop EJB session beans or services with tools such as Rational Application Developer. The session bean uses the *javax.resource.cci* interfaces to communicate with an enterprise information system through the resource adapter.

Resource Recovery Services (RRS):

WebSphere Application Server for z/OS supports resource adapters that use Resource Recovery Services (RRS) to support global transaction processing. RRS is an z/OS extension to the JCA resource adapter specifications.

WebSphere Application Server for z/OS supports the J2EE Connector Architecture (JCA) 1.0., and because of this, any resource adapter that is designed to use the 1.0 level of the J2EE Connector Architecture (JCA) is supported.

In addition to the 3 types of transaction support defined by JCA, WebSphere Application Server for z/OS supports a fourth type, **RRSTransactional** support, which is a z/OS only extension to the architecture. Resource adapters that are capable of using RRS and that properly indicate to WAS z/OS they are RRSTransactional will be supported as RRS compliant resource adapters.

z/OS resource adapters that are capable of using RRS are:
- IMS Connector for Java
- CICS CTG ECI J2EE Connector
- IMS JDBC Connector

- DB2 for z/OS Local JDBC connector when used as aJDBC Provider under the WebSphere Relational Resource Adapter (RRA)

All RRS Compliant resource adapters are required to support the property **RRSTransactional** in their ManagedConnectionFactory and must support a getter method for the property.

```
java.lang.Boolean.RRSTransactional=true;

java.lang.Boolean getRRSTransactional(){
    // Determine if the adapter can run RRSTransactional based
   // on it's configuration, and set the RRSTransactional property
   // appropriately to true or false.
 return RRSTransactional;
}
```

RRS support is only applicable in a local environment, where the backend must reside on the system. CICS and IMS resources adapters may use **RRSTransactional** support only when these adapters are configured to use local interfaces to their backend resource manager, which as stated above must reside on the same system as the IBM WebSphere Application Server for z/OS. These adapters are also capable of being configured to a remote instance of their backend resource manager. In this case, the adapters will respond ″false″ when the getRRSTransactional() method is invoked and instead of running as RRSTransactional will use whichever one of the three types of J2EE Transaction support they have chosen to support.

WebSphere relational resource adapter settings:

Use this page to view the default WebSphere relational resource adapter settings.

This is the WebSphere-provided relational resource adapter for handling data access to any relational data base. This adapter is preinstalled by WebSphere Application Server. Although the default relational resource adapter settings are viewable, you cannot make changes to them.

To view this administrative console page, click **Resources** > **Resource Adapters** > **WebSphere Relational Resource Adapter**.

Name:

Specifies the name of the resource provider.

Data type String

Description:

Specifies a description of the relational resource adapter.

Data type String

Archive path:

Specifies the path to the Resource Adapter Archive (RAR) file containing the module for this resource adapter.

Data type String

Class path:

Specifies a list of paths or Java Archive (JAR) file names, which together form the location for the resource provider classes.

Data type String

Native path:

Specifies a list of paths that forms the location for the resource provider native libraries.

Data type String

WebSphere Relational Resource Adapter:

The WebSphere Relational Resource Adapter (RRA) provides enterprise applications deployed on WebSphere Application Server access to relational databases.

The WebSphere RRA is installed and runs as part of WebSphere Application Server, and needs no further administration.

The RRA supports both the configuration and use of JDBC data sources and J2EE Connection Architecture (JCA) connection factories. The RRA supports the configuration and use of data sources implemented as either JDBC data sources or J2EE Connector Architecture connection factories. Data sources can be used directly by applications, or they can be configured for use by container-managed persistence (CMP) entity beans.

For more information about the WebSphere Relational Resource Adapter, see the following topics:

- For information about resource adapters, see “Resource adapter” on page 503
- For information about resource adapters and data access, see “Data access portability features”
- For RRA settings, see “WebSphere relational resource adapter settings” on page 505
- For information about CMP connection factories, see “Connection factory” on page 510
- For information about enterprise beans, see ″Introduction: EJB applications″ in the information center.

Data access portability features: The WebSphere Application Server relational resource adapter (RRA) provides a portability feature that enables applications to access data from different databases without changing the application. In addition, WebSphere Application Server enables you to plug in a data source that is not supported by WebSphere persistence. However, the data source *must* be implemented as either the *XADataSource* type or the *ConnectionPoolDataSource* type, and it must be in compliance with the JDBC 2.x specification.

You can achieve application portability through the following:

DataStoreHelper interface

With this interface, each data store platform can plug in its own private data store specific functions that the relational resource adapter run time uses. WebSphere Application Server provides an implementation for each supported JDBC provider.

In addition, the interface also provides a GenericDataStoreHelper class for unsupported data sources to use. You can subclass the GenericDataStoreHelper class or other WebSphere provided helpers to support any new data source.

Note: If you are configuring data access through a user-defined JDBC provider, do not implement the DataStoreHelper interface directly. Either subclass the GenericDataStoreHelper class or subclass one of the DataStoreHelper implementation classes provided by IBM (if your database behavior or SQL syntax is similar to one of these provided classes).

For more information, see the API documentation **DataStoreHelper** topic (as listed in the API documentation index).

The following code segment shows how a new data store helper is created to add new error mappings for an unsupported data source.

```
public class NewDSHelper extends GenericDataStoreHelper
{
  public NewDSHelper(java.util.Properties dataStoreHelperProperties)
  {
    super(dataStoreHelperProperties);
    java.util.Hashtable myErrorMap = null;
    myErrorMap = new java.util.Hashtable();
    myErrorMap.put(new Integer(-803), myDuplicateKeyException.class);
    myErrorMap.put(new Integer(-1015), myStaleConnectionException.class);
    myErrorMap.put("S1000", MyTableNotFoundException.class);
    setUserDefinedMap(myErrorMap);
    ...
  }
}
```

WSCallHelper class

This class provides two methods that enable you to use vendor-specific methods and classes that do not conform to the standard JDBC APIs (and are not part of WebSphere Application Server extension packages).

- **jdbcCall() method**

  By using the static jdbcCall() method, you can invoke vendor-specific, nonstandard JDBC methods on your JDBC objects. (For more information, see the API documentation **WSCallHelper** topic.) The following code segment illustrates using this method with a DB2 data source:

  ```
  Connection conn = ds.getConnection();
  // get connection attribute
  String connectionAttribute =(String) WSCallHelper.jdbcCall(DataSource.class, ds,
   "getConnectionAttribute", null, null);
  // setAutoClose to false
  WSCallHelper.jdbcCall(java.sql.Connection.class,
  conn, "setAutoClose",
  new Object[] { new Boolean(false)},
  new Class[] { boolean.class });
  // get data store helper
  DataStoreHelper dshelper = WSCallHelper.getDataStoreHelper(ds);
  ```

- **jdbcPass() method**

  Use this method to exploit the nonstandard JDBC classes that some database vendors provide. These classes contain methods that require vendors' proprietary JDBC objects to be passed as parameters.

  In particular, implementations of Oracle can involve use of nonstandard classes furnished by the vendor. Methods contained within these classes include:

  ```
  oracle.sql.ArrayDescriptor ArrayDescriptor.createDescriptor(java.lang.String, java.sql.Connection)
  oracle.sql.ARRAY new ARRAY(oracle.sql.ArrayDescriptor, java.sql.Connection, java.lang.Object)
  oracle.xml.sql.query.OracleXMLQuery(java.sql.Connection, java.lang.String)
  oracle.sql.BLOB.createTemporary(java.sql.Connection, boolean, int)
  oracle.sql.CLOB.createTemporary(java.sql.Connection, boolean, int)
  oracle.xdb.XMLType.createXML(java.sql.Connection, java.lang.String)
  ```

  The following code examples demonstrate the difference between a call to the XMLType.createXML() method over a direct connection to Oracle, and a call to the same method within WebSphere Application Server.

  1. Over a direct connection:

     ```
     XMLType poXML = XMLType.createXML(conn, poString);
     ```

  2. Within Application Server, using the jdbcPass() method:

```
XMLType poXML (XMLType)(WSCallHelper.jdbcPass(XMLType.class,
"createXML", new Object[]{conn,poString},
 new Class[]{java.sql.Connection.class, java.lang.String.class},
 new int[]{WSCallHelper.CONNECTION,WSCallHelper.IGNORE}));
```

There are two different jdbcPass() methods available, one for use in invoking static methods, another for use when invoking non-static methods. See the API documentation **WSCallHelper** topic.

Note: Because of the possible problems that can occur by passing an underlying object to a method, WebSphere Application Server strictly controls which methods are allowed to be invoked using the jdbcPass() method support. If you require support for a method that is not listed previously in this document, please contact WebSphere Application Server support with information on the method you require.

WARNING: Use of the jdbcPass() method causes the JDBC object to be used outside of WebSphere's protective mechanisms. Performing certain operations (such as setting autoCommit, or transaction isolation settings, etc.) outside of these protective mechanisms will cause problems with the future use of these pooled connections. IBM does not guarantee stability of the object after invocation of this method; it is the user's responsibility to ensure that invocation of this method does not perform operations that harm the object. Use at your own risk.

Example: Developing your own DataStoreHelper class: The DataStoreHelper interface supports each data store platform plugging in its own private data store specific functions that are used by the Relational Resource Adapter run time.

```
package com.ibm.websphere.examples.adapter;

import java.sql.SQLException;
import javax.resource.ResourceException;

import com.ibm.websphere.appprofile.accessintent.AccessIntent;
import com.ibm.websphere.ce.cm.*;
import com.ibm.websphere.rsadapter.WSInteractionSpec;

/**
* Example DataStoreHelper class, demonstrating how to create a user-defined DataStoreHelper.
* Implementation for each method is provided only as an example.  More detail would likely be
* required for any custom DataStoreHelper created for use by a real application.
*/
public class ExampleDataStoreHelper extends com.ibm.websphere.rsadapter.GenericDataStoreHelper
{
    static final long serialVersionUID = 8788931090149908285L;

    public ExampleDataStoreHelper(java.util.Properties props)
    {
        super(props);

        // Update the DataStoreHelperMetaData values for this helper.
        getMetaData().setGetTypeMapSupport(false);

        // Update the exception mappings for this helper.
        java.util.Map xMap = new java.util.HashMap();

        // Add an Error Code mapping to StaleConnectionException.
        xMap.put(new Integer(2310),  StaleConnectionException.class);
        // Add an Error Code mapping to DuplicateKeyException.
        xMap.put(new Integer(1062),  DuplicateKeyException.class);
        // Add a SQL State mapping to the user-defined ColumnNotFoundException
        xMap.put("S0022",            ColumnNotFoundException.class);
        // Undo an inherited StaleConnection SQL State mapping.
        xMap.put("S1000",            Void.class);
```

```
    setUserDefinedMap(xMap);

    // Note: If you are extending a helper class, it is
    // normally not necessary to issue 'getMetaData().setHelperType(...)'
    // because your custom helper will inherit the helper type from its
    // parent class.  However, certain applications may need to differentiate
    // between a custom helper and an existing helper of the same type,
    // so WebSpehere has provided the value 'DataStoreHelper.CUSTOM_HELPER'
    // for this purpose.  If this functionality is needed by your application
    // insert the following line into your code:
    // getMetaData().setHelperType(DataStoreHelper.CUSTOM_HELPER);

}

public void doStatementCleanup(java.sql.PreparedStatement stmt) throws SQLException
{
    // Clean up the statement so it may be cached and reused.

    stmt.setCursorName("");
    stmt.setEscapeProcessing(true);
    stmt.setFetchDirection(java.sql.ResultSet.FETCH_FORWARD);
    stmt.setMaxFieldSize(0);
    stmt.setMaxRows(0);
    stmt.setQueryTimeout(0);
}

public int getIsolationLevel(AccessIntent intent) throws ResourceException
{
    // Determine an isolation level based on the AccessIntent.

    if (intent == null) return java.sql.Connection.TRANSACTION_SERIALIZABLE;

    return intent.getConcurrencyControl() == AccessIntent.CONCURRENCY_CONTROL_OPTIMISTIC ?
           java.sql.Connection.TRANSACTION_READ_COMMITTED :

* exception for exception mapping.
*/
public class ColumnNotFoundException extends PortableSQLException
{
    public ColumnNotFoundException(SQLException sqlX)
    {
        super(sqlX);
    }
}
```

Connection factory

An application component uses a *connection factory* to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS).

Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

CMP Connection Factories collection:

Use this page to view existing CMP connection factories settings.

These are the connection factories used by a container-managed persistence (CMP) bean to access any backend data store. A CMP Connection Factory is used by EJB model 2.x Entities with CMP version 2.x. Connection factories listed on this page are created automatically under the WebSphere Relational Resource Adapter when you check the box *Use this DataSource in container managed persistence (CMP)* in the General Properties area on the Data Source page. You cannot modify the settings for a CMP Connection Factory, and you can not delete CMP Connection Factories from this collection. To remove the CMP Connection Factory object, you must navigate to the data source associated with the CMP Connection Factory and uncheck the *Use this DataSource for CMP* checkbox.

To view this administrative console page, click **Resources** >**Resource Adapters** >*WebSphere Relational Resource Adapter* > **CMP Connection Factories**.

Name:

Specifies a list of the display names for the resources.

Data type String

JNDI Name:

Specifies the JNDI name of the resource.

Data type String

Description:

Specifies a description for the resource.

Data type String

Category:

Specifies a category string which can be used to classify or group the resource.

Data type String

CMP connection factory settings:

Use this page to view the settings of a connection factory that is used by a CMP bean to access any backend data store. This connection factory is only in ″read″ mode. It cannot be modified or deleted.

To view this administrative console page, click **Resources** >**Resource Adapters** > *WebSphere Relational Resource Adapter*> **CMP Connection Factories** > *connection_factory*

Name:

Specifies the display name for the resource.

Data type String

JNDI name:

Specifies the JNDI name of the resource.

Data type String

Description:

Specifies a description for the resource.

Data type String

Category:

Specifies a category string which can be used to classify or group the resource.

Data type String

Authentication Preference:

Specifies which of the authentication mechanisms that are defined for the corresponding resource adapter applies to this connection factory. This property is deprecated starting with version 6.0.

For example, if two authentication mechanism entries are defined for a resource adapter (*KerbV5* and *Basic Password*), this specifies one of those two types. If the authentication mechanism preference

specified is not an authentication mechanism available on the corresponding resource adapter, it is ignored.

Data type String

Component-managed authentication alias:

References authentication data for component-managed signon to the resource.

Data type Drop-down list

Container-managed authentication alias:

References authentication data for container-managed signon to the resource. This property is deprecated starting with version 6.0.

Data type Drop-down list

JDBC providers

Installed applications that must interact with *relational* databases use JDBC providers for data access. Together, the JDBC provider and data source objects are functionally equivalent to the J2EE Connector Architecture (JCA) connection factory (which provides access to non-relational databases).

The WebSphere Application Server prerequisite Web site has a current list of supported providers. If your database is DB2, however, you can proceed directly to the topic Vendor-specific data sources minimum required settings to learn which DB2 JDBC provider is appropriate for your database configuration and application requirements. This document contains descriptions of the following providers, including the supported data source classes and their required properties:

- DB2 for zOS Local JDBC Provider (RRS), for use with the DB2 for OS/390 and z/OS Legacy JDBC driver
- DB2 Universal JDBC Driver Provider, for use with the DB2 Universal JDBC driver
- DB2 Universal JDBC Driver Provider (XA), also for use with the DB2 Universal JDBC driver

Note: For software requirements and interoperability information regarding these providers, see the topics “DB2 Universal JDBC Driver Support” and “Provider coexistence considerations” on page 513.

DB2 Universal JDBC Driver Support:

This article lists the support details for using the DB2 Universal JDBC Driver with WebSphere Application Server for z/OS.

WebSphere Application Server for z/OS supports the DB2 Universal JDBC Driver. The capabilities available depend on the DB2 Universal JDBC Driver that you installed as follows:

- The z/OS Application Connectivity to DB2 for z/OS feature that provides DB2 Universal JDBC Driver Type 4 connectivity. This DB2 Universal JDBC Drive can be invoked only as a type 4 driver for z/OS. As a type 4 driver, it uses a communication protocol to communicate requests from a z/OS application to a remote DB2 database.

  When you install and configure this driver for WebSphere Application Server for z/OS, it permits your applications to use JDBC or Container Managed Persistence (CMP) support to access backend DB2 databases (DB2 V7 and up) residing on z/OS at any location. All global transactions are handled as J2EE XA transactions.
- The DB2 Universal JDBC Driver in DB2 UDB for z/OS Version 8. This driver provides both Type 2 and Type 4 support.

Type 4 driver support uses a communication protocol to communicate requests from a z/OS application to a remote DB2 database. This driver supports using J2EE XA transaction processing to process global transactions.

Type 2 driver support uses local API protocol to communicate requests from a z/OS application to a target DB2 running on the same z/OS system image as the application. When the Type 2 driver is used under z/OS, the driver supports the use of z/OS Resource Recovery Services (RRS) to coordinate global transactions across multiple resource manages using 2-phase commit processing.

When you install and configure this version of the driver, your applications can use JDBC or CMP support to access backend DB2 databases (DB2 V7 and up). These databases can reside on the same z/OS system image, or on a different z/OS system image. depending on the driver type used. Type 2 driver handles all global transactions as RRS-coordinated global transactions.

- The DB2 Universal JDBC Driver Provider by APAR PQ80841 on DB2 UDB for OS/390 and z/OS Version 7. This version provides both driver Type 2 and driver Type 4 support.

  Type 4 driver support uses a communication protocol to communicate requests from a z/OS application to a remote DB2 database. This driver supports using J2EE XA transaction processing to process global transactions.

  Type 2 driver support uses local API protocol to communicate requests from a z/OS application to a target DB2 running on the same z/OS system image as the application. When the Type 2 driver is used under z/OS, the driver supports the use of z/OS Resource Recovery Services (RRS) to coordinate global transactions across multiple resource manages using 2-phase commit processing.

  When you install and configure this version of the driver, your applications can use JDBC or CMP support to access backend DB2 databases (DB2 V7 and up). These databases can reside on the same z/OS system image, or on a different z/OS system image, depending on the driver type used.

Provider coexistence considerations: Following are provider coexistence possibilities.

DB2 Legacy JDBC Providers and DB2 Universal JDBC Driver Providers

- Under WebSphere Application Server for z/OS, JDBC Provider definitions that use the Legacy DB2 for OS/390 and z/OS JDBC Driver (db2j2classes.zip) and JDBC Provider definitions that use the new DB2 Universal JDBC Driver (db2jcc.jar) must be carefully configured to ensure they never coexist on the same server. This is because some of the same class names are used in both drivers and these duplicate classes are functionally different. Adding jar files for the two types of drivers to the same CLASSPATH causes unpredictable results, since incorrect classes will be used for the provider whose CLASSPATH definition is added last.
- Carefully define the scope in which the two different types of driver providers are used. If you define one provider type under one scope (cell, node, or server), and the other provider type under another scope, separation is not ensured if the two scopes include the same server.

  For example, if you define a DB2 for zOS Local JDBC Provider (RRS) at a node level, then define a DB2 Universal JDBC Driver Provider at a server level where the server is in the same node, the provider definition at the node level is propagated down to the server level. As a result, a conflict occurs between the JDBC drivers used by the two providers.

  To help you understand which WebSphere Application Server for z/OS providers cannot coexist together, the providers are listed below under the DB2 JDBC driver that it uses:

  1. Providers that use the DB2 for z/OS Legacy JDBC Driver
     - DB2 for zOS Local JDBC Provider (RRS)
  2. Providers that use the DB2 Universal JDBC Driver
     - DB2 Universal JDBC Driver Provider
     - DB2 Universal JDBC Driver Provider (XA)
     - Cloudscape Network Server Using Universal JDBC Driver Provider

DB2 Drivers and Cloudscape

- The Cloudscape Network Server Using Universal JDBC Driver Provider uses an embedded copy of the DB2 Universal JDBC Driver that is shipped with Cloudscape. This provider is configured to automatically use the new level of the DB2 Universal JDBC Driver when installing the DB2 Version 7, Version 8, or standalone Type 4 version of the DB2 Universal JDBC Driver on the system where WebSphere Application Server for z/OS is configured.

  The Cloudscape Network Server Using Universal JDBC Driver Provider can coexist on the same server as the DB2 for Universal JDBC Driver Providers since it uses the same DB2 JDBC driver.
- The Cloudscape Network Server Using Universal JDBC Driver Provider cannot coexist in the same server as the DB2 for zOS Local JDBC Provider (RRS), because the Cloudscape provider uses the DB2 Universal JDBC Driver and the DB2 for zOS Local JDBC Provider (RRS) uses the DB2 for OS/390 and z/OS Legacy JDBC Driver. These drivers conflict with one another.

Data sources

Installed applications uses a *data source* to access the data from the database.

A data source is associated with a JDBC provider that supplies the specific JDBC driver implementation class. The data source represents the J2EE Connector Architecture (JCA) connection factory for the relational resource adapter. Application components use the data source to access connection instances to a specific database; a connection pool is associated with each data source.

You can create multiple data sources with different settings, and associate them with the same JDBC provider. (One reason to do this is to provide access to different databases.) JDBC providers that are supported by WebSphere Application Server are required to implement one or both of the following data source interfaces, which are defined by Sun Microsystems. These interfaces enable the application to run in a single-phase or two-phase transaction protocol.

- *ConnectionPoolDataSource* - a data source that supports application participation in local and global transactions, excepting two-phase commit transactions.

  Note: In one case a connection pool data source does support two-phase commit transactions: when the JDBC provider is DB2 for z/OS Local JDBC provider (RRS).

  When a connection pool data source is involved in a global transaction, transaction recovery is not provided by the transaction manager. The application is responsible for providing the backup recovery process if multiple resource managers are involved.
- *XADataSource* - a data source that supports application participation in any single-phase or two-phase transaction environment. When this data source is involved in a global transaction, the WebSphere Application Server transaction manager provides transaction recovery.

In WebSphere Application Server releases prior to version 5.0, the function of data access was provided by a single connection manager (CM) architecture. This connection manager architecture remains available to support J2EE 1.2 applications, but another connection manager architecture is provided, based on the JCA architecture supporting the new J2EE 1.3 application style (also for J2EE 1.4 applications).

These two separate architectures are represented by two types of data sources. To choose the right data source, administrators must understand the nature of their applications, EJB modules, and enterprise beans.

- Data source (Version 4.0) - This data source runs under the original CM architecture. Applications using this data source behave as if they were running in Version 4.0.
- Data source - This data source uses the JCA standard architecture to provide support for J2EE version 1.3 and 1.4 applications. It runs under the JCA connection manager and the relational resource adapter.

Choice of data source

- J2EE 1.2 application - all EJB 1.1 enterprise beans, JDBC applications, or Servlet 2.2 components must use the **4.0** data source.

- J2EE 1.3 (and subsequent releases) application -
  - EJB 1.1 Module - all EJB 1.x beans must use the **4.0** data source.
  - EJB 2.0 (and subsequent releases) Module - enterprise beans that include container-managed persistence (CMP) Version 1.x, 2.0, and beyond must use the **new** data source.
  - JDBC applications and Servlet 2.3+ components - must use the **new** data source.

Data access beans

Data access beans provide a rich set of features and function, while hiding much of the complexity associated with accessing relational databases.

They are Java classes written to the Enterprise JavaBeans specification.

You can use the data access beans in JavaBeans-compliant tools, such as the IBM *Rational Application Developer*. Because the data access beans are also Java classes, you can use them like ordinary classes.

The data access beans (in the package *com.ibm.db*) offer the following capabilities:

Feature
: **Details**

Caching query results
: You can retrieve SQL query results all at once and place them in a cache. Programs using the result set can move forward and backward through the cache or jump directly to any result row in the cache.

  For large result sets, the data access beans provide ways to retrieve and manage *packets*, subsets of the complete result set.

Updating through result cache
: Programs can use standard Java statements (rather than SQL statements) to change, add, or delete rows in the result cache. You can propagate changes to the cache in the underlying relational table.

Querying parameter support
: The base SQL query is defined as a Java String, with parameters replacing some of the actual values. When the query runs, the data access beans provide a way to replace the parameters with values made available at run time. Default mappings for common data types are provided, but you can specify whatever your Java program and database require.

Supporting metadata
: A *StatementMetaData* object contains the base SQL query. Information about the query (*metadata*) enables the object to pass parameters into the query as Java data types.

  Metadata in the object maps Java data types to SQL data types (as well as the reverse). When the query runs, the Java-datatyped parameters are automatically converted to SQL data types as specified in the metadata mapping.

  When results return, the metadata object automatically converts SQL data types back into the Java data types specified in the metadata mapping.

Connection management architecture

The connection management architecture for both relational and procedural access to enterprise information systems (EIS) is based on the J2EE Connector Architecture (JCA) specification. The Connection Manager (CM), which pools and manages connections within an application server, is capable of managing connections obtained through both resource adapters (RAs) defined by the JCA specification, and data sources defined by the JDBC 2.0 (and later) Extensions specification.

To make data source connections manageable by the CM, the WebSphere Application Server provides a resource adapter (the WebSphere Relational Resource Adapter) that enables JDBC data sources to be managed by the same CM that manages JCA connections. From the CM point of view, JDBC data sources and JCA connection factories look the same. Users of data sources do not experience any

programmatic or behavioral differences in their applications because of the underlying JCA architecture. JDBC users still configure and use data sources according to the JDBC programming model.

Applications migrating from previous versions of WebSphere Application Server might experience some behavioral differences because of the specification changes from various J2EE requirements levels. These differences are not related to the adoption of the JCA architecture.

If you have J2EE 1.2 applications using the JDBC API that you wish to run in WebSphere Application Server 6.0, the JDBC CM from Application Server version 4.0 is still provided as a configuration option. Using this configuration option enables J2EE 1.2 applications to run unaltered. If you migrate a Version 4.0 application to Version 6.0, using the Version 6.0 migration tools, the application automatically uses the Version 4.0 connection manager after migration. However, EJB 2.x modules in J2EE 1.3 (or later versions) applications cannot use the JDBC CM from WebSphere Application Server Version 4.0.

Connection pooling:

Each time an application attempts to access a backend store (such as a database), it requires resources to create, maintain, and release a connection to that datastore. To mitigate the strain this process can place on overall application resources, WebSphere Application Server enables administrators to establish a pool of backend connections that applications can share on an application server. *Connection pooling* spreads the connection overhead across several user requests, thereby conserving application resources for future requests.

WebSphere Application Server supports JDBC 3.0 APIs for connection pooling and connection reuse. The connection pool is used to direct JDBC calls within the application, as well as for enterprise beans using the database.

Benefits of connection pooling

Connection pooling can improve the response time of any application that requires connections, especially Web-based applications. When a user makes a request over the Web to a resource, the resource accesses a data source. Because users connect and disconnect frequently with applications on the Internet, the application requests for data access can surge to considerable volume. Consequently, the total datastore overhead quickly becomes high for Web-based applications, and performance deteriorates. When connection pooling capabilities are used, however, Web applications can realize performance improvements of up to 20 times the normal results.

With connection pooling, most user requests do not incur the overhead of creating a new connection because the data source can locate and use an existing connection from the pool of connections. When the request is satisfied and the response is returned to the user, the resource returns the connection to the connection pool for reuse. The overhead of a disconnection is avoided. Each user request incurs a fraction of the cost for connecting or disconnecting. After the initial resources are used to produce the connections in the pool, additional overhead is insignificant because the existing connections are reused.

When to use connection pooling

Use WebSphere connection pooling in an application that meets any of the following criteria:
- It cannot tolerate the overhead of obtaining and releasing connections whenever a connection is used.
- It requires Java Transaction API (JTA) transactions within WebSphere Application Server.
- It needs to share connections among multiple users within the same transaction.
- It needs to take advantage of product features for managing local transactions within the application server.
- It does not manage the pooling of its own connections.
- It does not manage the specifics of creating a connection, such as the database name, user name, or password

How connections are pooled together

Whenever you configure a unique data source or connection factory, you are required to give it a unique Java Naming and Directory Interface (JNDI) name. This JNDI name, along with its configuration information, is used to create the connection pool. A separate connection pool exists for each configured data source or connection factory.

A separate instance of a given configured connection pool is created on each application server that uses that data source or connection factory. For example, if you run a three server cluster in which all of the servers use *myDataSource*, and *myDataSource* has a maximum connections setting of 10, then you can generate up to 30 connections (three servers times 10 connections). Be sure to consider this fact when determining how many connections to your backend resource you can support.

Other considerations for determining the maximum connections setting:

- Each entity bean transaction requires an additional database connection, dedicated to handling the transaction.
- On UNIX platforms, a separate DB2 process is created for each connection; these processes quickly affect performance on systems with low memory and cause errors.
- If clones are used, one data pool exists for each clone.

It is also important to note that when using *connection sharing*, it is only possible to share connections obtained from the same connection pool.

Avoiding a deadlock

Deadlock can occur if the application requires more than one concurrent connection per thread, and the database connection pool is not large enough for the number of threads. Suppose each of the application threads requires two concurrent database connections and the number of threads is equal to the maximum connection pool size. Deadlock can occur when both of the following are true:

- Each thread has its first database connection, and all are in use.
- Each thread is waiting for a second database connection, and none would become available since all threads are blocked.

To prevent the deadlock in this case, the **Maximum Connections** value for the database connection pool should be increased by at least one. Doing this allows for at least one of the waiting threads to obtain its second database connection and to avoid a deadlock.

To avoid deadlock, code the application to use, at most, one connection per thread. If the application is coded to require *C* concurrent database connections per thread, the connection pool must support at least the following number of connections, where *T* is the maximum number of threads.

```
T * (C - 1) + 1
```

The connection pool settings are directly related to the number of connections that the database server is configured to support. If the maximum number of connections in the pool is raised, and the corresponding settings in the database are not raised, the application fails and SQL exception errors are displayed in the SYSOUT of the application servant region.

Deferred Enlistment: In the WebSphere Application Server environment, *deferred enlistment* is a term used to refer to the technique of waiting until a connection is first used to enlist it in its unit of work (UOW) scope.

In one example, the technique works like this: a component calls getConnection() from within a global transaction, and at some point later in time, the component uses the connection. The call that uses the connection is intercepted, and the XA resource for that connection is enlisted with the transaction service (which in turn calls XAResource.start()). Next, the actual call is sent to the resource manager.

In contrast, if a component gets a connection within a global transaction without deferred enlistment, then the connection is enlisted in the transaction and has all the overhead associated with that transaction. For XA connections, this includes the two phase commit (2PC) protocol to the resource manager. Deferred enlistment offers better performance in the case where a connection is obtained, but not used within the UOW scope. This saves all the overhead of participating in the UOW when it is not needed.

The WebSphere Application Server relational resource adapter automatically supports deferred enlistment without any additional configuration needed.

Lazy Transaction Enlistment Optimization: The J2EE Connector Architecture (JCA) Version 1.5 specification calls the deferred enlistment technique *lazy transaction enlistment optimization*. This support comes through a marker interface (LazyEnlistableManagedConnection) and a new method on the connection manager (LazyEnlistableConnectionManager()):

```
package javax.resource.spi;
import javax.resource.ResourceException;
import javax.transaction.xa.Xid;

interface LazyEnlistableConnectionManager { // application server
    void lazyEnlist(ManagedConnection) throws ResourceException;
}

interface LazyEnlistableManagedConnection { // resource adapter
}
```

A resource adapter is not required to support this functionality. Check with the resource adapter provider if you need to know if the resource adapter provides this functionality.

Connection and connection pool statistics: Performance Monitoring Infrastructure (PMI) method calls that are supported in the two existing Connection Managers (JDBC and J2C) are still supported in this version of WebSphere Application Server. The calls include:

- ManagedConnectionsCreated
- ManagedConnectionsAllocated
- ManagedConnectionFreed
- ManagedConnectionDestroyed
- BeginWaitForConnection
- EndWaitForConnection
- ConnectionFaults
- Average number of ManagedConnections in the pool
- Percentage of the time that the connection pool is using the maximum number of ManagedConnections
- Average number of threads waiting for a ManagedConnection
- Average percent of the pool that is in use
- Average time spent waiting on a request
- Number of ManagedConnections that are in use
- Number of Connection Handles
- FreePoolSize
- UseTime

Java Specification Request (JSR) 77 requires statistical data to be accessed through managed beans (Mbeans) to facilitate this. The Connection Manager passes the ObjectNames of the Mbeans created for this pool. In the case of Java Message Service (JMS) *null* is passed in. The interface used is :

```
PmiFactory.createJ2CPerf(
    String pmiName, // a unique Identifier for JCA /JDBC.  This is the
                    // ConnectionFactory name.

    ObjectName providerName,// the ObjectName of the J2CResourceAdapter
                            // or JDBCProvider Mbean
```

```
    ObjectName factoryName // the ObjectName of the J2CConnectionFactory
                           // or DataSourceMbean.
)
```

The following Unified Modeling Language (UML) diagram shows how JSR 77 requires statistics to be reported :

In WebSphere Application Server Version 5.x, the JCAStats interface was implemented by the J2CResourceAdapter Mbean, and the JDBCStats interface was implemented by the JDBCProvider Mbean. The JCAConnectionStats and JDBCConnectionStats interfaces are not implemented because they collect statistics for non pooled connections - which are not present in the JCA 1.0 Specification. JCAConnectionPoolStats, and JDBCConnectionPoolStats do not have a direct implementing Mbean; those statistics are gathered through a call to PMI. A J2C resource adapter, and JDBC provider each contain a list of ConnectionFactory or DataSource ObjectNames, respectively. The ObjectNames are used by PMI to find the appropriate connection pool in the list of PMI modules.

The JCA 1.5 Specification allows an exception from the matchManagedConnection() method that indicates that the resource adapter requests that the connection not be pooled. In that case, statistics for that connection are provided separately from the statistics for the connection pool.

Connection life cycle:

A ManagedConnection object is always in one of three states: *DoesNotExist*, *InFreePool*, or *InUse*.

Before a connection is created, it must be in the DoesNotExist state. After a connection is created, it can be in either the InUse or the InFreePool state, depending on whether it is allocated to an application.

Between these three states are *transitions*. These transitions are controlled by *guarding conditions*. A guarding condition is one in which *true* indicates when you can take the transition into another legal state. For example, you can make the transition from the InFreePool state to InUse state only if:

- the application has called the data source or connection factory getConnection() method (the *getConnection* condition)
- a free connection is available in the pool with matching properties (the *freeConnectionAvailable* condition)
- and one of the two following conditions are true:
  - the getConnection() request is on behalf of a resource reference that is marked unsharable
  - the getConnection() request is on behalf of a resource reference that is marked shareable but no shareable connection in use has the same properties.

This transition description follows:

InFreePool > InUse:
getConnection AND
freeConnectionAvailable AND
NOT(shareableConnectionAvailable)

Here is a list of guarding conditions and descriptions.

Condition	Description
ageTimeoutExpired	Connection is older then its ageTimeout value.
close	Application calls close method on the Connection object.
fatalErrorNotification	A connection has just experienced a fatal error.
freeConnectionAvailable	A connection with matching properties is available in the free pool.
getConnection	Application calls getConnection method on a data source or connection factory object.
markedStale	Connection is marked as stale, typically in response to a fatal error notification.
noOtherReferences	There is only one connection handle to the managed connection, and the Transaction Service is not holding a reference to the managed connection.
noTx	No transaction is in force.
poolSizeGTMin	Connection pool size is greater than the minimum pool size (minimum number of connections)
poolSizeLTMax	Pool size is less than the maximum pool size (maximum number of connections)
shareableConnectionAvailable	The getConnection() request is for a shareable connection, and one with matching properties is in use and available to share.
TxEnds	The transaction has ended.
unshareableConnectionRequest	The getConnection() request is for an unshareable connection.
unusedTimeoutExpired	Connection is in the free pool and not in use past its unused timeout value.

Getting connections: The first set of transitions covered are those in which the application requests a connection from either a data source or a connection factory. In some of these scenarios, a new connection to the database results. In others, the connection might be retrieved from the connection pool or shared with another request for a connection.

DoesNotExist

Every connection begins its life cycle in the DoesNotExist state. When an application server starts, the connection pool does not exist. Therefore, there are no connections. The first connection is not created until an application requests its first connection. Additional connections are created as needed, according to the guarding condition.

```
getConnection AND
NOT(freeConnectionAvailable) AND
poolSizeLTMax AND
(NOT(shareableConnectionAvailable) OR
unshareableConnectionRequest)
```

This transition specifies that a connection object is not created unless the following conditions occur:
- The application calls the getConnection() method on the data source or connection factory
- No connections are available in the free pool (NOT(freeConnectionAvailable))
- The pool size is less than the maximum pool size (poolSizeLTMax)
- If the request is for a sharable connection and there is no sharable connection already in use with the same sharing properties (NOT(shareableConnectionAvailable)) OR the request is for an unsharable connection (unshareableConnectionRequest)

All connections begin in the DoesNotExist state and are only created when the application requests a connection. The pool grows from 0 to the maximum number of connections as applications request new connections. The pool is **not** created with the minimum number of connections when the server starts.

If the request is for a sharable connection and a connection with the same sharing properties is already in use by the application, the connection is shared by two or more requests for a connection. In this case, a new connection is not created. For users of the JDBC API these sharing properties are most often *userid/password* and *transaction context*; for users of the Resource Adapter Common Client Interface (CCI) they are typically *ConnectionSpec*, *Subject*, and *transaction context*.

InFreePool

The transition from the InFreePool state to the InUse state is the most common transition when the application requests a connection from the pool.

```
InFreePool>InUse:
getConnection AND
freeConnectionAvailable AND
(unshareableConnectionRequest OR
NOT(shareableConnectionAvailable))
```

This transition states that a connection is placed in use from the free pool if:
- the application has issued a getConnection() call
- a connection is available for use in the connection pool (freeConnectionAvailable),
- and one of the following is true:
  - the request is for an unsharable connection (unsharableConnectionRequest)
  - no connection with the same sharing properties is already in use in the transaction. (NOT(sharableConnectionAvailable)).

Any connection request that a connection from the free pool can fulfill does not result in a new connection to the database. Therefore, if there is never more than one connection used at a time from the pool by any number of applications, the pool never grows beyond a size of one. This number can be less than the minimum number of connections specified for the pool. One way that a pool grows to the minimum number of connections is if the application has multiple concurrent requests for connections that must result in a newly created connection.

InUse

The idea of connection sharing is seen in the transition on the InUse state.

```
InUse>InUse:
getConnection AND
ShareableConnectionAvailable
```

This transition indicates that if an application requests a shareable connection (getConnection) with the **same** sharing properties as a connection that is already in use (ShareableConnectionAvailable), the existing connection is shared.

The same user (*user name* and *password*, or *subject*, depending on authentication choice) can share connections but only within the same transaction and only when all of the sharing properties match. For JDBC connections, these properties include the *isolation level*, which is configurable on the resource-reference (IBM WebSphere extension) to data source default. For a resource adapter factory connection, these properties include those specified on the ConnectionSpec object. Because a transaction is normally associated with a single thread, you should **never** share connections across threads.

Note: It is possible to see the same connection on multiple threads at the same time, but this situation is an error state usually caused by an application programming error.

Returning connections: All of the transitions discussed previously involve getting a connection for application use. With that goal, the transitions result in a connection closing, and either returning to the free pool or being destroyed. Applications should explicitly close connections (note: the connection that the user gets back is really a connection handle) by calling close() on the connection object. In most cases, this action results in the following transition:

```
InUse>InFreePool:
(close AND
noOtherReferences AND
NoTx AND
UnshareableConnection)
OR
(ShareableConnection AND
TxEnds)
```

Conditions that cause the transition from the InUse state are:

- If the application or the container calls close() (producing the close condition) and there are no references (the noOtherReferences condition) either by the application (in the application sharing condition) or by the transaction manager (in the NoTx condition, meaning that the transaction manager holds a reference when the connection is enlisted in a transaction), the connection object returns to the free pool.
- If the connection was enlisted in a transaction but the transaction manager ends the transaction (the txEnds condition), and the connection was a shareable connection (the ShareableConnection condition), the connection closes and returns to the pool.

When the application calls close() on a connection, it is returning the connection to the pool of free connections; it is **not** closing the connection to the data store. When the application calls close() on a currently shared connection, the connection is *not returned* to the free pool. Only after the application drops the last reference to the connection, and the transaction is over, is the connection returned to the pool. Applications using unsharable connections must take care to close connections in a timely manner. Failure to do so can starve out the connection pool, making it impossible for any application running on the server to get a connection.

When the application calls close() on a connection enlisted in a transaction, the connection is not returned to the free pool. Because the transaction manager must also hold a reference to the connection object, the connection cannot return to the free pool until the transaction ends. Once a connection is enlisted in a transaction, you cannot use it in any other transaction by any other application until after the transaction is complete.

There is a case where an application calling close() can result in the connection to the data store closing and bypassing the connection return to the pool. This situation happens if one of the connections in the pool is considered stale. A connection is considered stale if you can no longer use it to contact the data store. For example, a connection is marked stale if the data store server is shut down. When a connection is marked as stale, the entire pool is cleaned out by default because it is very likely that all of the connections are stale for the same reason (or you can set your configuration to clean just the failing connection). This cleansing includes marking all of the currently InUse connections as stale so they are destroyed upon closing. The following transition states the behavior on a call to close() when the connection is marked as stale:

```
InUse>DoesNotExist:
close AND
markedStale AND
NoTx AND
noOtherReferences
```

This transition states that if the application calls close() on the connection and the connection is marked as stale during the pool cleansing step (markedStale), the connection object closes to the data store and is not returned to the pool.

Finally, you can close connections to the data store and remove them from the pool.

This transition states that there are three cases in which a connection is removed from the free pool and destroyed.

1. If a fatal error notification is received from the resource adapter (or data source). A fatal error notification (FatalErrorNotification) is received from the resource adaptor when something happens to the connection to make it unusable. All connections currently in the free pool are destroyed.
2. If the connection is in the free pool for longer than the unused timeout period (UnusedTimeoutExpired) and the pool size is greater than the minimum number of connections (poolSizeGTMin), the connection is removed from the free pool and destroyed. This mechanism enables the pool to shrink back to its minimum size when the demand for connections decreases.
3. If an age timeout is configured and a given connection is older than the timeout. This mechanism provides a way to recycle connections based on age.

Unshareable and shareable connections:

WebSphere Application Server supports both *unshareable* and *shareable* connections. An unshareable connection is not shared with other components in the application. The component using this connection has full control of this connection.

You can share a shareable connection with other components within the same transaction as long as each *getConnection()* request has the same connection properties. To enable connection sharing for data sources, the following connection properties must be the same:

- Java Naming and Directory Interface (JNDI) name. While not actually a connection property, this requirement simply means that you can only share connections from the same data source in the same server.
- Resource authentication
- In relational databases:
  - Isolation level (corresponds to access intent policies applied to CMP beans)
  - Readonly
  - Catalog
  - TypeMap

To enable connection sharing for resource adapters within the same transaction, the following connection properties must be the same:

- JNDI name. While not actually a connection property, this requirement simply means that you can only share connections from the same resource adapter in the same server.
- Resource authentication

In addition, the *ConnectionSpec* object used to get the connection must also be the same. For more information on sharing a connection with a CMP bean, see Sharing a connection with a CMP bean.

Java Message Service (JMS) connections cannot be shared with non-JMS connections.

Access to a resource marked as unshareable means that there is a one-to-one relationship between the connection handle a component is using and the physical connection with which the handle is associated. This access implies that every call to the getConnection() method returns a connection handle solely for the requesting user. Typically, you must choose unshareable if you might do things to the connection that could result in unexpected behavior occurring in another application that is sharing the connection (for example, unexpectedly changing the isolation level).

Marking a resource as shareable allows for greater scalability. Instead of creating new physical connections on every getConnection() invocation, the physical connection (that is, managed connection) is shared through multiple connection handles, as long as each getConnection request has the same connection properties. However, sharing a connection means that each user must not do anything to the connection that could change its behavior and disrupt a sharing partner (for example, changing the isolation level). The user also cannot code an application that assumes sharing to take place because it is up to the run time to decide whether or not to share a particular connection.

For WebSphere Application Server, all sharing of connections is relative to the current Unit of Work (UOW) boundary. Anyone within a specific transaction, when getting a connection from a specific connection pool, gets a handle to the same physical connection (if the sharing properties are the same).

Factors that determine sharing: The listing here is not an exhaustive one. The product might or might not share connections under different circumstances.

- Only connections acquired with the same resource reference (resource-ref) that specifies the res-sharing-scope as shareable are candidates for sharing. The resource reference properties of res-sharing-scope and res-auth and the IBM extension isolationLevel help determine if it is possible to share a connection. IBM extension isolationLevel is stored in IBM deployment descriptor extension file; for example: ibm-ejb-jar-ext.xmi.
- You can only share connections that are requested with the same properties.
- Connection Sharing only occurs between different component instances if they are within a transaction (container- or user-initiated transaction).
- Connection Sharing only occurs within a sharing boundary. Current sharing boundaries include *Transactions* and *LocalTransactionContainment* (LTC) boundaries.
- Connection Sharing rules within an LTC Scope:
  - For shareable connections, only *Connection Reuse* is allowed within a single component instance. Connection reuse occurs when the following actions are taken with a connection: get, use, commit/rollback, close; get, use, commit/rollback, close. Note that if you use the LTC resolution-control of *ContainerAtBoundary* then no start/commit is needed because that action is handled by the container.

    The connection returned on the second *get* is the same connection as that returned on the first *get* (if the same properties are used). Because the connection use is serial, only one connection handle to the underlying physical connection is used at a time, so true connection sharing does not take place. The term *"reuse"* is more accurate.

    More importantly, the *LocalTransactionContainment* boundary enclosing both *get* actions is not complete; no cleanUp() method is invoked on the ManagedConnection object. Therefore the second *get* action inherits all of the connection properties set during the first getConnection() call.
- Shareable connections between transactions (either container-managed transactions (CMT), bean-managed transactions (BMT), or LTC transactions) follow these caching rules:
  - In general, setting properties on shareable connections is not allowed because a user of one connection handle might not anticipate a change made by another connection handle. This limitation is part of the J2EE 1.3 standard.
  - General users of resource adapters can set the connection properties on the connection factory getConnection() call by passing them in a *ConnectionSpec*.

However, the properties set on the connection during one transaction are not guaranteed to be the same when used in the next transaction. Because it is not valid to share connections outside of a sharing scope, connection handles are moved off of the physical connection with which they are currently associated when a transaction ends. That physical connection is returned to the free connection pool. Connections are cleaned before going in the free pool. The next time the handle is used, it is automatically associated with an appropriate connection. The appropriateness is based on the security login information, connection properties, and (for the JDBC API) the *isolation level* specified in the extended resource reference, passed in on the original request that returned the current handle. Any properties set on the connection after it was retrieved are lost.

– For JDBC users, WebSphere Application Server provides an extension to enable passing the connection properties through the ConnectionSpec.

  Use caution when setting properties and sharing connections in a local transaction scope. Ensure that other components with which the connection is shared are expecting the behavior resulting from your settings.

- You cannot set the isolation level on a shareable connection for the JDBC API using a relational resource adapter in a global transaction. The product provides an extension to the resource reference to enable you to specify the isolation level. If your application requires the use of multiple isolation levels, create multiple resource references and map them to the same data source or connection factory.

Sharing a connection with a CMP bean: WebSphere Application Server allows you to share a physical connection between a CMP bean, a BMP bean, and a JDBC application to reduce the resource allocation or deadlock scenarios. There are several ways to ensure that all of these entity beans and the JDBC applications are sharing the same physical connection.

- **Sharing a connection between CMP beans or methods**

  When all CMP bean methods use the same access intent, they all share the same physical connection. A different access intent policy triggers the allocation of a different physical connection. For example, a CMP bean has two methods; method 1 is associated with `wsPessimisticUpdate` intent, whereas method 2 has `wsOptimisticUpdate` access intent. Method 1 and method 2 cannot share the same physical connection within a transaction. In other words, an XA data source is required to run in a global transaction.

  You can experience some deadlocks from a database if both methods try to access the same table. Therefore, sharing a connection is determined by the access intents that are defined in the CMP methods.

- **Sharing a connection between CMP and BMP beans**

  There are two options to ensure that both CMP and BMP beans share the same physical connection:

  – Define the same access intent on both CMP and BMP bean methods. Because both use the same access intent, they share the same physical connection. The advantage to using this option is that the backend is transparent to a BMP bean; however, this BMP is not portable because it uses the WebSphere extended API to handle the isolation level. For more information, refer to the code example in ″Example: Accessing data using IBM extended APIs to share connections between container-managed and bean-managed persistence beans″.

  – Determine the isolation level that the access intent uses on a CMP bean method, then use the corresponding isolation level that is specified on the resource reference to look up a data source and a connection. This option is more of a manual process, and the isolation level might be different from database to database. For more information refer to the isolation level and access intent mapping table: ″Access intent -- isolation levels and update locks″ and the ″Isolation level and resource reference″ section.

- **Sharing a connection between CMP and a JDBC application that is used by a servlet or a session bean**

  Determine the isolation level that the access intent uses on a CMP bean method, then use the corresponding isolation level specified on the resource reference to look up a data source and a connection. For more information refer to Access intent isolation levels and update locks and Isolation level and resource reference.

Connection sharing violations: There is a new exception, the `SharingViolation` exception, that the resource adapter can issue whenever an operation violates sharing requirements. Possible violations include changing connection attributes, security settings, or isolation levels, among others. When such a mutable operation is performed against a managed connection, the `SharingViolation` exception can occur when both of the following conditions are true:
- The number of connection handles associated with the managed connection is more than one.
- The managed connection is associated with a transaction, either local or XA.

Both the component and the J2C run time might need to detect this `SharingViolation` exception, depending on when and how the managed connection becomes unshareable. If the managed connection becomes unshareable because of an operation through the connection handle (for example, you change the isolation level), then the component needs to process the exception. If the managed connection becomes unshareable without being recognized by the application server (due to some component interaction with the connection handle), then the resource adapter can reject the creation of a connection handle by issuing the `SharingViolation` exception.

Connection handles:

A connection handle is a representation of a physical connection.

To use a backend resource (such as a relational database) in WebSphere Application Server you must get a connection to that resource. When you call the *getConnection()* method, you get a *connection handle* returned. The handle is not the physical connection. The physical connection is managed by the connection manager.

There are two significant configurations that affect how connection handles are used and how they behave. The first is the *res-sharing-scope*, which is defined by the resource-reference used to look up the DataSource or Connection Factory. This property tells the connection manager whether or not you can share this connection.

The second factor that affects connection handle behavior is the *usage pattern*. There are essentially two usage patterns. The first is called the *get/use/close* pattern. It is used within a single method and without calling another method that might get a connection from the same data source or connection factory. An application using this pattern does the following:
1. gets a connection
2. does its work
3. commits (if appropriate)
4. closes the connection.

The second usage pattern is called the *cached handle* pattern. This is where an application:
1. gets a connection
2. begins a global transaction
3. does work on the connection
4. commits a global transaction
5. does work on the connection again

A cached handle is a connection handle that is held across transaction and method boundaries by an application. Keep in mind the following considerations for using cached handles:
- Cached handle support requires some additional connection handle management across these boundaries, which can impact performance. For example, in a JDBC application, *Statements*, *PreparedStatements*, and *ResultSets* are closed implicitly after a transaction ends, but the connection remains valid.
- You are encouraged **not** to cache the connection across the transaction boundary for shareable connections; the get/use/close pattern is preferred.

- Caching of connection handles across servlet methods is limited to JDBC and Java Message Service (JMS) resources. Other non-relational resources, such as Customer Information Control System (CICS) or IMS objects, currently cannot have their connection handles cached in a servlet; you need to get, use, and close the connection handle within each method invocation. (This limitation only applies to single-threaded servlets because multithreaded servlets do not allow caching of connection handles.)

The following code segment shows the cached connection pattern.

```
Connection conn = ds.getConnection();
ut.begin();
conn.prepareStatement("....."); --> Connection runs in global transaction mode
...
ut.commit();
conn.prepareStatement(".....");   ---> Connection still valid but runs in autoCommit(True);
...
```

Unshareable connections: Some characteristics of connection handles retrieved with a *res-sharing-scope* of **unshareable** are described in the following sections.

The possible benefits of unshared connections

- Your application always maintains a direct link with a physical connection (managed connection).
- The connection always has a one-to-one relationship between the connection handle and the managed connection.
- In most cases, the connection does not close until the application closes it.
- You can use a cached unshared connection handle across multiple transactions.
- The connection can have a performance advantage in some cached handle situations. Because unshared connections do not have the overhead of moving connection handles off managed connections at the end of the transaction, there is less overhead in using a cached unshared connection.

The possible drawbacks of unshared connections

- Inefficient use of your connection resources. For example, if within a single transaction you get more than one connection (with the same properties) using the same data source or connection factory (same resource-ref) then you use multiple physical connections when you use unshareable connections.
- Wasted connections. It is important not to keep the connection handle open (that is, your application does not call the *close()* method) any longer then it is needed. As long as an unshareable connection is open, the physical connection is unavailable to any other component, even if your application is not currently using that connection. Unlike a shareable connection, an ushareable connection is not closed at the end of a transaction or servlet call.
- Deadlock considerations. Depending on how your components interact with the database within a transaction, using unshared connections can lead to deadlock in the database. For example, within a transaction, component A gets a connection to data source X and updates table 1, and then calls component B. Component B gets another connection to data source X, and updates/reads table 1 (or even worse the same row as component A). In some circumstances, depending on the particular database, its locking scheme, and the transaction isolation level, a deadlock can occur.

  In the same scenario, but with a *shared* connection, deadlock does not occur because all the work is done on the same connection. It is worth noting that when writing code that uses shared connections, you use a strategy that calls for multiple work items to be performed on the same connection, possibly within the same transaction. If you decide to use an unshareable connection, you must set the *maximum connections* property on the connection factory or data source correctly. An exception might occur for waiting connection requests if you exceed the maximum connections value, and unshareable connections are not being closed before the connection wait time-out is exceeded.

Shareable connections: Some characteristics of connection handles that are retrieved with a *res-sharing-scope* of **shareable** are described in the following sections.

The possible benefits of shared connections

- Within an instance of connection sharing, application components can share a managed connection with one or more connection handles, depending on how the handle is retrieved and which connection properties are used.
- They can more efficiently use resources. Shareable connections are not valid outside of their sharing boundary. For this reason, at the end of a sharing boundary (such as a transaction) the connection handle is no longer associated with the managed connection it was using within the sharing boundary (this applies only when using the cached handle pattern). The managed connection is returned to the free connection pool for reuse. Connection resources are not held longer than the end of the current sharing scope.

  If the cached handle pattern is used, then the next time the handle is used within a new sharing scope, the application server run time ensures that the handle is reassociated with a managed connection that is appropriate for the current sharing scope, and has the same properties with which the handle was originally retrieved. Remember that it is not appropriate to change properties on a shareable connection. If properties are changed, other components that share the same connection might experience unexpected behavior. Futhermore, when using cached handles, the value of the changed property might not be remembered across sharing scopes.

The possible drawbacks of shared connections

- Sharing within a single component (such as an enterprise bean and its related Java objects) is not always supported. The current specification allows resource adapters the choice of only allowing one active connection handle at a time.

  If a resource adapter chooses to implement this option then the following scenario results in an *invalid handle exception*: A component using shareable connections gets a connection and uses it. Without closing the connection, the component calls a utility class (Java object) that gets a connection handle to the same managed connection and uses it. Because the resource adapter only supports one active handle, the first connection handle is no longer valid. If the utility object returns without closing its handle, the first handle is not valid and triggers an exception at any attempt to use it.

  Note: This exception occurs only when calling a utility object (a Java object).

  Not all resource adapters have this limitation; it occurs only in certain implementations. The WebSphere Relational Resource Adapter (RRA) does not have this limitation. Any data source used through the RRA does not have this limitation. If you encounter a resource adapter with this limitation you can work around it by serializing your access to the managed connection. If you always close your connection handle before getting another (or close your handle before calling code that gets another handle), and before returning from a method, you can allow two pieces of code to share the same managed connection. You simply cannot use the connection for both events at the same time.
- Trying to change the *isolation level* on a shareable JDBC-based connection in a global transaction (that is supported by the RRA) causes an exception. The correct way to get connections with different transaction isolation levels is by configuring the IBM extended resource-reference.
- Closing connection handles for shareable connections by an application is NOT supported and causes errors. However, you can avoid this limitation by using the Relational Resource Adapter.

Lazy connection association optimization: In WebSphere Application Server Version 5.0, the Java 2 Platform, Enterprise Edition (J2EE) Connector (J2C) connection manager implemented *smart handle* support. This technology enables allocation of a connection handle to an application while the managed connection associated with that connection handle is used by other applications (assuming that the connection is not being used by the original application). This concept is part of the J2EE Connector Architecture (JCA) 1.5 specification. (You can find it in the JCA 1.5 specification document in the section entitled ″Lazy Connection Association Optimization.″) Smart handle support introduces use a method on the ConnectionManager object, the *LazyAssociatableConnectionManager()* method , and a new marker interface, the *DissociatableManagedConnection* class. You must configure the provider of the resource adapter to make this functionality available in your environment. (In the case of the RRA, WebSphere Application Server itself is the provider.) The following code snippet shows how to include smart handle support:

```
package javax.resource.spi;
import javax.resource.ResourceException;

interface LazyAssociatableConnectionManager { // application server
    void associateConnection(
        Object connection, ManagedConnectionFactory mcf,
        ConnectionRequestInfo info) throws ResourceException;
}

interface DissociatableManagedConnection { // resource adapter
    void dissociateConnections() throws ResourceException;
}
```

This DissociatableManagedConnection interface introduces another state to the Connection object: *inactive*. A Connection can now be active, closed, and inactive. The connection object enters the inactive state when a corresponding ManagedConnection object is cleaned up. The connection stays inactive until an application component attempts to re-use it. Then the resource adapter calls back to the connection manager to re-associate the connection with an active ManagedConnection object.

Connections and transactions:

All connection usage occurs within the scope of either a global transaction or a local transaction containment (LTC) boundary.

Connection behavior depends on your current operating scope. This article discusses some of the common characteristics you see when using connections in one of the transaction scopes.

You can only share connections within a global transaction scope (assuming other sharing rules are met). However, you can *serially reuse* connections within an LTC scope. A get/use/close connection pattern followed by another instance of get/use/close (to the same data source or connection factory) enables you to reuse the same connection. See the “Unshareable and shareable connections” on page 523 topic for more details.

JDBC AutoCommit behavior

All JDBC connections, when first obtained through a getConnection() call, contain the setting AutoCommit = TRUE by default.

- If you operate within an LTC and have its resolution-control set to *Application*, then AutoCommit remains *TRUE* unless changed by the application.
- If you operate within an LTC and have its resolution-control set to *ContainerAtBoundary*, then the application should **not** touch the AutoCommit setting. The WebSphere Application Server run time sets the AutoCommit value to *FALSE* before work begins, then commits or rolls back the work as appropriate at the end of the LTC scope.
- If you use a connection within a global transaction, the database ignores the AutoCommit setting so that the transaction service that controls the commit and rollback processing can manage the transaction. This action takes place upon first use of the connection to do work, regardless of the user changing the AutoCommit setting. After the transaction completes, the AutoCommit value returns to the value it had before the first use of the connection. So even if the AutoCommit value is set to *TRUE* before the connection is used in a global transaction, you need not set the value to *FALSE* since the value is ignored by the database. In this example, after the transaction completes, the AutoCommit value of the connection returns to *TRUE*.
- If you use multiple distinct connections within a global transaction, all work is guaranteed to commit or roll back together. This is not the case for a local transaction containment (LTC scope). Within an LTC, work done on one connection commits or rolls back independently from work done on any other connection within the LTC.

One-phase commit and two-phase commit resources: One-phase commit resources are such that work being done on a one phase connection cannot mix with other connections and ensure that the work done

on all of the connections completes or fails atomically . The product does not allow more than one one-phase commit connection in a global transaction. Futhermore, it does not allow a one-phase commit connection in a global transaction with one or more two-phase commit connections. You can coordinate only multiple two-phase commit connections within a global transaction.

WebSphere Application Server provides *last participant support* that enables a single one-phase commit resource to participate in a global transaction with one or more two-phase commit resources.

Note that any time you do multiple getConnection() calls using a resource reference that specifies res-sharing-scope=Unshareable , then you get multiple physical connections. This situation also occurs when res-sharing-scope=Shareable, but the sharing rules are broken. In either case, if you run in a global transaction, ensure the resources involved are enabled for two-phase commit (also sometimes referred to as *JTA Enabled*). Failure to do so results in an XA exception that logs the following message: `WTRN0063E: An illegal attempt to enlist a one phase capable resource with existing two phase capable resources has occurred.`

Passing client information to a database: Some databases enable you to set client information on the database connections using a backend-specific proprietary connection API. For some databases (such as DB2) you can also set the client information as a data source property. WebSphere Application Server before Version 6.0 only enables setting the client information as a data source property. This capability is somewhat limited, however, because the client information cannot be dynamically changed on the data source or the connections obtained from that data source. Also, setting the client information on the data source causes all connections created from that data source to have the same information. For example, if you set the ApplicationName as part of the data source *clientInformation*, all connections from that data source have the same application name. Because many different applications can access the same data source, this might not be desired.

With WebSphere Application Server Version 6.0, you can set the client information on some connections and not others, and you can set different client information on different database connections from the same data source. You can pass client information in one of two ways:

- Explicitly, by calling a proprietary API, *setClientInformation(Properties)* on the com.ibm.websphere.rsadapter.WSConnection.
- Implicitly, using the *WAS.clientinfo* trace string. You can enable this dynamically from the administrative console just like a normal trace. For more information about passing client information implicitly, see “Implicitly set client information” on page 531.

The API is defined on the *WSConnection* class which is part of the *com.ibm.websphere.rsadapter* package. You must cast your database connection in your applications to *com.ibm.websphere.rsadapter.WSConnection* before calling the API, as this is a WebSphere Application Server proprietary API. The API takes a properties object as an input parameter that provides the flexibility of adding new client information if and when it is introduced by the backend database, without any changes to this API itself.

```
public void setClientInformation (Properties props)throws SQLException;
```

For an example of using this API, see “Example: setClientInformation(Properties) API.”

Example: setClientInformation(Properties) API:
Usage Scenario

This API enables you to set client information on the WebSphere Application Server connection. Some of the client information is passed on to the backend database if that database supports such functionality.

Example

```
import com.ibm.websphere.rsadapter.WSConnection;
.....
try {
```

```
 InitialContext ctx = new InitialContext();
 //Perform a naming service lookup to get the DataSource object.
 DataSource ds = (javax.sql.DataSource)ctx.lookup("java:comp/jdbc/myDS");
}catch (Exception e) {System.out.println("got an exception during lookup: " + e);}

WSConnection conn = (WSConnection) ds.getConnection();
Properties props = new properties();
props.setProperty(WSConnection.CLIENT_ID, "user123");
props.setProperty(WSConnection.CLIENT_LOCATION, "127.0.0.1");
props.setProperty(WSConnection.CLIENT_ACCOUNTING_INFO, "accounting");
props.setProperty(WSConnection.CLIENT_APPLICATION_NAME, "appname");
props.setProperty(WSConnection.CLIENT_OTHER_INFO, "cool stuff");
conn.setClientInformation(props);
conn.close()
```

Parameters

props contains the client information to be passed. Possible values are:

- WSConnection.CLIENT_ACCOUNTING_INFO
- WSConnection.CLIENT_LOCATION
- WSConnection.CLIENT_ID
- WSConnection.CLIENT_APPLICATION_NAME
- WSConnection.CLIENT_OTHER_INFO
- WSConnection.OTHER_CLIENT_TYPE

Refer to the WSConnection documentation for more details on which client information is passed to the backend database. To reset the client information, call the method with a null parameter.

Exceptions

This API creates an SQL exception if the database issues an exception when setting the data.

Implicitly set client information: You can choose to *explicitly* pass the client information of application requests to database connections by calling an IBM proprietary API, setClientInformation(Properties), on the com.ibm.websphere.rsadapter.WSConnection object within your application code. In some cases, however, you might want WebSphere Application Server to handle the passing of client information to database connections. This method of setting the client information is referred to as *implicit*. You might choose the implicit method because:

- You want to keep your application free of proprietary APIs, or
- Your application uses container-managed persistence (CMP), in which case you cannot use the proprietary API to set client information on database connections.

The WebSphere Application Server trace facility provides the capability for setting client information implicitly. You can designate one of two special trace groups to enable or disable client information passing: “WAS.clientinfo trace” on page 532 or “WAS.clientinfopluslogging trace” on page 532.

Possible run-time scenarios

- Connection sharing

  In the case of connection sharing, WebSphere Application Server sets the client information on the first acquired connection handle only. If connection sharing is enabled and two or more getConnection methods are called (resulting in two handles on the same connection), only the first getConnection call causes the client information to pass to the backend database. This scenario does not apply to the explicit process of passing client information; in such cases every setClientinformation method is relayed to the database regardless of connection sharing.
- Implicit/explicit co-existence

When you use both the explicit and implicit procedures for relaying client information, some combination of the explicitly set data and implicitly set data is combined, but the explicit setting usually takes precedence. For example, if the application sets the client accounting information to ″myAccountingInfo″, the final accountingInfo string that is passed to the backend database looks something like the following sample code:

```
000325_WSRdbManagedConnectionImpl@1234_myAccountingInfo: where 000325 is the thread id,
WSRdbManagedConnectionImpl@1234 is the websphere connection instance.
```

- Client information reset

  When you configure Application Server to pass client information, it does reset client information when a connection is returned to the pool, but *only* if the WAS.clientinfo and WAS.clientinfopluslogging trace mechanisms are disabled (that is, WAS.clientinfo=all=disabled:WAS.clientinfopluslogging=all=disabled).

  In the explicit case, however, the reset operation is done only when the application issues setClientInformation(null) on the WSConnection connection.

WAS.clientinfo trace

By default, the implicit mechanism is disabled. You can turn on this mechanism dynamically, without stopping and starting your application server, or statically by setting the WebSphere Application Server trace group *WAS.clientinfo=all=enabled*.

The information implicitly collected and set on the database connection consists of the thread ID, user name, user location, and application name.

Important: User name and user location can only be implicitly collected and set on the database connection if you enable WebSphere global security.

thread ID
An eight-character hexadecimal value that identifies the Java thread that controlls the processing of the application request within WebSphere Application Server. This ID is displayed in the trace header.

user name
The name of the user that initiates the application request. This option is collected and passed to the backend database (when supported) only if WebSphere global security is enabled. Information here is collected by calling the WSSecurityHelper.getFirstCaller method.

user location
The name of the location of the user, in the form of cell:node:server. This option is collected and passed to the backend database, when appropriate, only when WebSphere global security is enabled. Information here is collected by calling the WSSecurityHelper.getFirstServer method.

application name
The name of the application running. This value is the output of the getApplication method from the J2EEName object. This value is collected regardless of the Global Security setting.

WAS.clientinfopluslogging trace

When debugging database problems, such as deadlocks, there is a set of information that is needed to help with the debugging effort. This information is typically obtained by enabling a WebSphere Relational Resource Adapter (RRA) trace, and an Enterprise JavaBean (EJB) container trace. However, there are some cases where timing is an issue when reproducing a given problem. Having too much tracing information can alter the behavior of the application, such as change the timing, and the problem might no longer occur.

Because of this situation, a new trace group is provided where only a minimum set of information is collected. This trace group is WAS.clientinfopluslogging. This function sets the client information implicitly on the connection, just like the WAS.clientinfo trace, as well as logs and traces important application activities. Those activities are:

- SQL Strings that are run (such as, select userId from tabl1 where id=? for update).
- Start, commit, and rollback of transactions.
- EJB calls (such as, Create, Remove, findByPrimaryKey, and so on).

Cache instances

An application uses a cache instance to store, retrieve, and share data objects within the dynamic cache.

Each cache instance can be configured independently for Java Naming and Directory Interface (JNDI) name, cache size, priority, and disk offload. Objects that are stored in a particular cache instance are not affected by other cache instances. This means that if you store an object named **object_1** with a value of `object_data` in *cache_instance_x*, you can also store an object with the same name, but different value in *cache_instance_y*.

Objects that are stored in a particular cache instance are available to applications on other servers by accessing a cache instance of the same name. The two servers must be within the same replication domain to share data.

There are two types of cache instances, object cache instances and servlet cache instances.

An object cache instance is a location in addition to the default shared dynamic cache where Java 2 Platform, Enterprise Edition (J2EE) applications can store, distribute, and share objects. After configuring object cache instances, you can use the DistributedMap or DistributedObjectCache interfaces in the `com.ibm.websphere.cache` package to programmatically access your cache instances. See the ″Reference: Generated API documentation″ for more information about the DistributedMap or DistributedObjectCache interfaces.

Servlet cache instances are locations in addition to the default dynamic cache where dynamic cache can store, distribute, and share the output and the side effects of an invoked servlet. By configuring a servlet cache instance, your applications have greater flexibility and better tuning of cache resources. The Java Naming and Directory Interface (JNDI) name that is specified for the cache instance in the administrative console maps to the <cache-instance> element in the `cachespec.xml` configuration file. Any <cache-entry> elements that are specified within a <cache-instance> element are created in that specific cache instance. Any <cache-entry> elements that are specified outside of a <cache-instance> element are stored in the default dynamic cache instance. See “Using servlet cache instances” on page 1431 for more information.

Resource adapter archive file

A Resource Adapter Archive (RAR) file is a Java archive (JAR) file used to package a resource adapter for the Java 2 Connector (J2C) Architecture for WebSphere Application Server.

A RAR file can contain the following:

- Enterprise information system (EIS) supplied resource adapter implementation code in the form of JAR files or other runnable components, such as dynamic link lists.
- Utility classes.
- Static documents, such as HTML files, images, and sound files.

The standard file extension of a RAR file is *.rar*.

Data access : Resources for learning

Use the following links to find relevant supplemental information about data access. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to this product but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Tuning parameters for data access resources

For better application performance, you can tune some data access resources through the WebSphere Application Server administrative console.

Tune these properties of data sources and connection pools to optimize the performance of transactions between your application and datastore.

Data source tuning

To view the administrative console page where you configure the following properties, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data sources** > *data_source* > **WebSphere Application Server connection properties**.

Enable JMS one phase optimization support

If your application does not use JMS messaging, **do not** select this option. Activating this support enables the Java Message Service (JMS) to get optimized connections from the data source. Activating this support also *prevents* JDBC applications from obtaining connections from the data source. For further explanation of JMS one phase support, refer to the article entitled ″Sharing connections to benefit from one phase commit optimization″ in this information center.

Statement cache size

Specifies the number of prepared statements that are cached per connection. (A prepared statement is a precompiled SQL statement that is stored in a prepared statement object. This object is used to efficiently run the given SQL statement multiple times.) In general, the more statements your application has, the larger the cache should be. **Be aware**, however, that specifying a larger statement cache size than needed wastes application memory and *does not* improve performance.

Determine the value for your cache size by adding the number of uniquely prepared statements, callable statements (as determined by the SQL string, concurrency, and the scroll type) for each application that uses this data source on a particular server. This value is the maximum number of possible prepared statements that are cached on a given connection over the life of the server. Additional information about this setting...

Default: For most databases the default is 10. Zero means there is no cache statement.

Connection pool tuning

To view the administrative console page where you configure the following properties, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data sources** > *data_source* > **Connection pool settings**.

Maximum connections

Specifies the maximum number of physical connections that can be created in this pool. These are the physical connections to the backend datastore. When this number is reached, no new physical connections are created; requestors must wait until a physical connection that is currently in use is returned to the pool.

For optimal performance, set the value for the connection pool lower than the value for the Web container threadpool size. Lower settings, such as 10 to 30 connections, might perform better than higher settings, such as 100. Additional information about this and related settings...

Default: 10

Minimum connections

Specifies the minimum number of physical connections to maintain. Until this number is exceeded, the pool maintenance thread does not discard physical connections.

If you set this property for a higher number of connections than your application ultimately uses at run time, you do not waste application resources. WebSphere Application Server does not create additional connections to achieve your minimum setting. Of course, if your application requires more connections than the value you set for this property, application performance diminishes as connection requests wait for fulfillment. Additional information about this and related settings...

Default: 1

Database performance tuning

Database performance tuning can dramatically affect the throughput of your application. For example, if your application requires high concurrency (multiple, simultaneous interactions with backend data), an improperly tuned database can result in a bottleneck. Database access threads accumulate in a backlog when the database is not configured to accept a sufficient number of incoming requests.

Tuning parameters vary according to the type of database you are using. ″DB2 tuning tips for z/OS″ are provided for your convenience. Because DB2 is not a WebSphere Application Server product and can change, consider these descriptions as suggestions.

Configuring data access with scripting

This topic contains the following tasks:

- “Configuring new J2C activation specs using scripting” on page 549
- “Testing data source connections using scripting” on page 552

Configuring a JDBC provider using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new JDBC provider:

1. Identify the parent ID and assign it to the node variable. The following example uses the node configuration object as the parent. You can modify this example to use the cell, cluster, server, or application configuration object as the parent.
   - Using Jacl:

     ```
     set node [$AdminConfig  getid  /Cell:mycell/Node:mynode/]
     ```

   - Using Jython:

     ```
     node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
     print node
     ```

   Example output:

   ```
   mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
   ```

2. Identify the required attributes:
   - Using Jacl:

     ```
     $AdminConfig required JDBCProvider
     ```

   - Using Jython:

     ```
     print AdminConfig.required('JDBCProvider')
     ```

   Example output:

   ```
   Attribute     Type
   name     String
   implementationClassName   String
   ```

3. Set up the required attributes and assign it to the jdbcAttrs variable. You can modify the following example to setup non-required attributes for JDBC provider.
   - Using Jacl:

     ```
     set n1 [list name JDBC1]
     set implCN [list implementationClassName myclass]
     set  jdbcAttrs [list  $n1  $implCN]
     ```

     Example output:

     ```
     {name {JDBC1}} {implementationClassName {myclass}}
     ```

   - Using Jython:

     ```
     n1 = ['name', 'JDBC1']
     implCN = ['implementationClassName', 'myclass']
     jdbcAttrs = [n1,  implCN]
     print jdbcAttrs
     ```

     Example output:

     ```
     [['name', 'JDBC1'], ['implementationClassName', 'myclass']]
     ```

4. Create a new JDBC provider using node as the parent:
   - Using Jacl:

     ```
     $AdminConfig create JDBCProvider $node $jdbcAttrs
     ```

   - Using Jython:

     ```
     AdminConfig.create('JDBCProvider', node, jdbcAttrs)
     ```

   Example output:

   ```
   JDBC1(cells/mycell/nodes/mynode|resources.xml#JDBCProvider_1)
   ```

5. Save the configuration changes. See the ″Saving configuration changes with the wsadmin tool″ article for more information.
6. In a network deployment environment only, synchronize the node. See the ″Synchronizing nodes with the wsadmin tool″ article for more information.

Attention: If you modify the class path or native library path of a JDBC provider: After saving your changes (and synchronizing the node in a network deployment environment), you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

Configuring new data sources using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new data source:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newjdbc [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/]
     ```
   - Using Jython:
     ```
     newjdbc = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/')
     print newjdbc
     ```

   Example output:
   ```
   JDBC1(cells/mycell/nodes/mynode|resources.xml#JDBCProvider_1)
   ```
2. Obtain the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required DataSource
     ```
   - Using Jython:
     ```
     print AdminConfig.required('DataSource')
     ```

   Example output:
   ```
   Attribute   Type
   name    String
   ```
3. Setting up required attributes:
   - Using Jacl:
     ```
     set name [list name DS1]
     set dsAttrs [list $name]
     ```
   - Using Jython:
     ```
     name = ['name', 'DS1']
     dsAttrs = [name]
     ```
4. Create a data source:
   - Using Jacl:
     ```
     set newds [$AdminConfig create DataSource $newjdbc $dsAttrs]
     ```
   - Using Jython:
     ```
     newds = AdminConfig.create('DataSource', newjdbc, dsAttrs)
     print newds
     ```

   Example output:
   ```
   DS1(cells/mycell/nodes/mynode|resources.xml#DataSource_1)
   ```
5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new connection pools using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new connection pool:

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/]
     ```
   - Using Jython:
     ```
     newds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/')
     ```

   Example output:
   ```
   DS1(cells/mycell/nodes/mynode|resources.xml$DataSource_1)
   ```
2. Creating connection pool:
   - Using Jacl:
     ```
     $AdminConfig create ConnectionPool $newds {}
     ```
   - Using Jython:
     ```
     print AdminConfig.create('ConnectionPool', newds, [])
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode|resources.xml#ConnectionPool_1)
   ```
3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new data source custom properties using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new data source custom property:g

1. Identify the parent ID:
   - Using Jacl:
     ```
     set newds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/]
     ```
   - Using Jython:
     ```
     newds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/')
     print newds
     ```

   Example output:
   ```
   DS1(cells/mycell/nodes/mynode|resources.xml$DataSource_1)
   ```
2. Get the J2EE resource property set:
   - Using Jacl:
     ```
     set propSet [$AdminConfig showAttribute $newds propertySet]
     ```
   - Using Jython:
     ```
     propSet = AdminConfig.showAttribute(newds, 'propertySet')
     print propSet
     ```

   Example output:
   ```
   (cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_8)
   ```
3. Get required attribute:
   - Using Jacl:

```
$AdminConfig required J2EEResourceProperty
```

- Using Jython:

```
print AdminConfig.required('J2EEResourceProperty')
```

Example output:

```
Attribute     Type
name         String
```

4. Set up attributes:
   - Using Jacl:

     ```
     set name [list name RP4]
     set rpAttrs [list $name]
     ```

   - Using Jython:

     ```
     name = ['name', 'RP4']
     rpAttrs = [name]
     ```

5. Create a J2EE resource property:
   - Using Jacl:

     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:

   ```
   RP4(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_8)
   ```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new J2CAuthentication data entries using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new J2CAuthentication data entry:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set security [$AdminConfig getid /Cell:mycell/Security:/]
     ```

   - Using Jython:

     ```
     security = AdminConfig.getid('/Cell:mycell/Security:/')
     print security
     ```

   Example output:

   ```
   (cells/mycell|security.xml#Security_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required JAASAuthData
     ```

   - Using Jython:

     ```
     print AdminConfig.required('JAASAuthData')
     ```

   Example output:

   ```
   Attribute       Type
   alias           String
   userId          String
   password        String
   ```

3. Set up required attributes:

- Using Jacl:

```
set alias [list alias myAlias]
set userid [list userId myid]
set password [list password secret]
set jaasAttrs [list $alias $userid $password]
```

  Example output:

```
{alias myAlias} {userId myid} {password secret}
```

- Using Jython:

```
alias = ['alias', 'myAlias']
userid = ['userId', 'myid']
password = ['password', 'secret']
jaasAttrs = [alias, userid, password]
print jaasAttrs
```

  Example output:

```
[['alias', 'myAlias'], ['userId', 'myid'], ['password', 'secret']]
```

4. Create JAAS auth data:
   - Using Jacl:

```
$AdminConfig create JAASAuthData $security $jaasAttrs
```

   - Using Jython:

```
print AdminConfig.create('JAASAuthData', security, jaasAttrs)
```

   Example output:

```
(cells/mycell|security.xml#JAASAuthData_2)
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new WAS40 data sources using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new WAS40 data source:

1. Identify the parent ID:
   - Using Jacl:

```
set newjdbc [$AdminConfig getid "/JDBCProvider:Cloudscape JDBC Provider/"]
```

   - Using Jython:

```
newjdbc = AdminConfig.getid('/JDBCProvider:Cloudscape JDBC Provider/')
print newjdbc
```

   Example output:

```
JDBC1(cells/mycell/nodes/mynode|resources.xml$JDBCProvider_1)
```

2. Get required attributes:
   - Using Jacl:

```
$AdminConfig required WAS40DataSource
```

   - Using Jython:

```
print AdminConfig.required('WAS40DataSource')
```

   Example output:

```
Attribute    Type
name    String
```

3. Set up required attributes:
   - Using Jacl:

```
set name [list name was4DS1]
set ds4Attrs [list $name]
```

- Using Jython:

```
name = ['name', 'was4DS1']
ds4Attrs = [name]
```

4. Create WAS40DataSource:
   - Using Jacl:

     ```
     set new40ds [$AdminConfig create WAS40DataSource $newjdbc $ds4Attrs]
     ```

   - Using Jython:

     ```
     new40ds = AdminConfig.create('WAS40DataSource', newjdbc, ds4Attrs)
     print new40ds
     ```

   Example output:

   ```
   was4DS1(cells/mycell/nodes/mynode|resources.xml#WAS40DataSource_1)
   ```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new WAS40 connection pools using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new WAS40 connection pool:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set new40ds [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/JDBCProvider:
      JDBC1/WAS40DataSource:was4DS1/]
     ```

   - Using Jython:

     ```
     new40ds = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/JDBCProvider:
      JDBC1/WAS40DataSource:was4DS1/') print new40ds
     ```

   Example output:

   ```
   was4DS1(cells/mycell/nodes/mynodes:resources.xml$WAS40DataSource_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required WAS40ConnectionPool
     ```

   - Using Jython:

     ```
     print AdminConfig.required('WAS40ConnectionPool')
     ```

   Example output:

   ```
   Attribute       Type
   minimumPoolSize     Integer
   maximumPoolSize     Integer
   connectionTimeout   Integer
   idleTimeout        Integer
   orphanTimeout       Integer
   statementCacheSize  Integer
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set mps [list minimumPoolSize 5]
     set minps [list minimumPoolSize 5]
     set maxps [list maximumPoolSize 30]
     set conn [list connectionTimeout 10]
     set idle [list idleTimeout 5]
     ```

```
set orphan [list orphanTimeout 5]
set scs [list statementCacheSize 5]
set 40cpAttrs [list $minps $maxps $conn $idle $orphan $scs]
```

Example output:

```
{minimumPoolSize 5} {maximumPoolSize 30}
{connectionTimeout 10} {idleTimeout 5}
{orphanTimeout 5} {statementCacheSize 5}
```

- Using Jython:

```
minps = ['minimumPoolSize', 5]
maxps = ['maximumPoolSize', 30]
conn = ['connectionTimeout', 10]
idle = ['idleTimeout', 5]
orphan = ['orphanTimeout', 5]
scs = ['statementCacheSize', 5]
cpAttrs = [minps, maxps, conn, idle, orphan, scs]
print cpAttrs
```

Example output:

```
[[minimumPoolSize, 5], [maximumPoolSize, 30],
[connectionTimeout, 10], [idleTimeout, 5],
[orphanTimeout, 5], [statementCacheSize, 5]]
```

4. Create was40 connection pool:
   - Using Jacl:

     ```
     $AdminConfig create WAS40ConnectionPool $new40ds $40cpAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('WAS40ConnectionPool', new40ds, 40cpAttrs)
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode:resources.xml#WAS40ConnectionPool_1)
   ```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new WAS40 custom properties using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new WAS40 custom properties:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set new40ds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/]
     ```

   - Using Jython:

     ```
     new40ds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/')
     print new40ds
     ```

   Example output:

   ```
   was4DS1(cells/mycell/nodes/mynodes|resources.xml$WAS40DataSource_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     set propSet [$AdminConfig showAttribute $newds propertySet]
     ```

   - Using Jython:

     ```
     propSet = AdminConfig.showAttribute(newds, 'propertySet')
     print propSet
     ```

   Example output:

```
(cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_9)
```

3. Get required attribute:
   - Using Jacl:
     ```
     $AdminConfig required J2EEResourceProperty
     ```
   - Using Jython:
     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:
   ```
   Attribute    Type
   name         String
   ```
4. Set up required attributes:
   - Using Jacl:
     ```
     set name [list name RP5]
     set rpAttrs [list $name]
     ```
   - Using Jython:
     ```
     name = ['name', 'RP5']
     rpAttrs = [name]
     ```
5. Create J2EE Resource Property:
   - Using Jacl:
     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:
   ```
   RP5(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_9)
   ```
6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new J2C resource adapters using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new J2C resource adapter:

1. Identify the parent ID and assign it to the node variable. The following example uses the node configuration object as the parent. You can modify this example to use the cell, cluster, server, or application configuration object as the parent.
   - Using Jacl:
     ```
     set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
     ```
   - Using Jython:
     ```
     node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
     print node
     ```

   Example output:
   ```
   mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
   ```
2. Identify the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required J2CResourceAdapter
     ```
   - Using Jython:
     ```
     print AdminConfig.required('J2CResourceAdapter')
     ```

   Example output:

```
Attribute     Type
name          String
```

3. Set up the required attributes:
   - Using Jacl:
     ```
     set rarFile /currentScript/cicseci.rar
     set option  [list  -rar.name  RAR1]
     ```
   - Using Jython:
     ```
     rarFile = '/currentScript/cicseci.rar'
     option  = '[-rar.name  RAR1]'
     ```
4. Create a resource adapter:
   - Using Jacl:
     ```
     set newra [$AdminConfig installResourceAdapter $rarFile mynode $option]
     ```
   - Using Jython:
     ```
     newra = AdminConfig.installResourceAdapter(rarFile, 'mynode', option)
     print newra
     ```

   Example output:

   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```
5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring custom properties for J2C resource adapters using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new custom property for a J2C resource adapters:

1. Identify the parent ID and assign it to the newra variable.
   - Using Jacl:
     ```
     set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
     ```
   - Using Jython:
     ```
     newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
     print newra
     ```

   Example output:

   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```
2. Get the J2EE resource property set:
   - Using Jacl:
     ```
     set propSet [$AdminConfig showAttribute $newra propertySet]
     ```
   - Using Jython:
     ```
     propSet = AdminConfig.showAttribute(newra, 'propertySet')
     print propSet
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode|resources.xml#PropertySet_8)
   ```
3. Identify the required attributes:
   - Using Jacl:
     ```
     $AdminConfig required J2EEResourceProperty
     ```
   - Using Jython:
     ```
     print AdminConfig.required('J2EEResourceProperty')
     ```

   Example output:

```
Attribute     Type
name          String
```

4. Set up the required attributes:
   - Using Jacl:
     ```
     set name [list name RP4]
     set rpAttrs [list $name]
     ```
   - Using Jython:
     ```
     name = ['name', 'RP4']
     rpAttrs = [name]
     ```
5. Create a J2EE resource property:
   - Using Jacl:
     ```
     $AdminConfig create J2EEResourceProperty $propSet $rpAttrs
     ```
   - Using Jython:
     ```
     print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
     ```

   Example output:
   ```
   RP4(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_8)
   ```
6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new J2C connection factories using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new J2C connection factory:

1. Identify the parent ID and assign it to the newra variable.
   - Using Jacl:
     ```
     set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
     ```
   - Using Jython:
     ```
     newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
     print newra
     ```

   Example output:
   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```
2. There are two ways to configure a new J2C connection factory. Perform one of the following:
   - Using the AdminTask object:
     a. List the connection factory interfaces:
        - Using Jacl:
          ```
          $AdminTask listConnectionFactoryInterfaces $newra
          ```
        - Using Jacl:
          ```
          AdminTask.listConnectionFactoryInterfaces(newra)
          ```

        Example output:
        ```
        javax.sql.DataSource
        ```
     b. Create a J2CConnectionFactory:
        - Using Jacl:
          ```
          $AdminTask createJ2CConnectionFactory $newra { -name cf1 -jndiName eis/cf1
            -connectionFactoryInterface avax.sql.DataSource
          ```
        - Using Jacl:

```
AdminTask.createJ2CConnectionFactory(newra, '['-name', 'cf1', '-jndiName', 'eis/cf1',
  '-connectionFactoryInterface', 'avax.sql.DataSource']')
```

- Using the AdminConfig object:
  a. Identify the required attributes:
     – Using Jacl:

       ```
       $AdminConfig required J2CConnectionFactory
       ```

     – Using Jython:

       ```
       print AdminConfig.required('J2CConnectionFactory')
       ```

       Example output:

       ```
       Attribute Type
       connectionDefinition ConnectionDefinition@
       ```

  b. If your resource adapter is JCA1.5 and you have multiple connection definitions defined, it is required that you specify the ConnectionDefinition attribute. If your resource adapter is JCA1.5 and you have only one connection definition defined, it will be picked up automatically. If your resource adapter is JCA1.0, you do not need to specify the ConnectionDefinition attribute. Perform the following command to list the connection definitions defined by the resource adapter:
     – Using Jacl:

       ```
       $AdminConfig list ConnectionDefinition $newra
       ```

     – Using Jython:

       ```
       print AdminConfig.list('ConnectionDefinition', $newra)
       ```

  c. Set up the required attributes:
     – Using Jacl:

       ```
       set name [list name J2CCF1]
       set j2ccfAttrs [list $name]
       set jname [list jndiName eis/j2ccf1]
       ```

     – Using Jython:

       ```
       name = ['name', 'J2CCF1']
       j2ccfAttrs = [name]
       jname = ['jndiName', eis/j2ccf1]
       ```

  d. If you are specifying the ConnectionDefinition attribute, also set up the following:
     – Using Jacl:

       ```
       set cdattr [list connectionDefinition $cd]
       ```

     – Using Jython:

       ```
       cdattr = ['connectionDefinition', $cd]
       ```

  e. Create a J2C connection factory:
     – Using Jacl:

       ```
       $AdminConfig create J2CConnectionFactory $newra $j2ccfAttrs
       ```

     – Using Jython:

       ```
       print AdminConfig.create('J2CConnectionFactory', newra, j2ccfAttrs)
       ```

       Example output:

       ```
       J2CCF1(cells/mycell/nodes/mynode|resources.xml#J2CConnectionFactory_1)
       ```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new J2C authentication data entries using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new J2C authentication data entry:

1. Identify the parent ID and assign it to the security variable.
   - Using Jacl:

     ```
     set security [$AdminConfig getid /Security:mysecurity/]
     ```
   - Using Jython:

     ```
     security = AdminConfig.getid('/Security:mysecurity/')
     ```
2. Identify the required attributes:
   - Using Jacl:

     ```
     $AdminConfig required JAASAuthData
     ```
   - Using Jython:

     ```
     print AdminConfig.required('JAASAuthData')
     ```

   Example output:

   ```
   Attribute     Type
   alias         String
   userId          String
   password          String
   ```
3. Set up the required attributes:
   - Using Jacl:

     ```
     set alias [list alias myAlias]
     set userid [list userId myid]
     set password [list password secret]
     set jaasAttrs [list $alias $userid $password]
     ```

     Example output:

     ```
     {alias myAlias} {userId myid} {password secret}
     ```
   - Using Jython:

     ```
     alias = ['alias', 'myAlias']
     userid = ['userId', 'myid']
     password = ['password', 'secret']
     jaasAttrs = [alias, userid, password]
     ```

     Example output:

     ```
     [[alias, myAlias], [userId, myid], [password, secret]]
     ```
4. Create JAAS authentication data:
   - Using Jacl:

     ```
     $AdminConfig create JAASAuthData $security $jaasAttrs
     ```
   - Using Jython:

     ```
     print AdminConfig.create('JAASAuthData', security, jaasAttrs)
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode|resources.xml#JAASAuthData_2)
   ```
5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new J2C activation specs using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a J2C activation specs:

1. Identify the parent ID and assign it to the `newra` variable.
   - Using Jacl:

     ```
     set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
     ```
   - Using Jython:

     ```
     newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
     print newra
     ```

     Example output:

     ```
     RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
     ```
2. There are two ways to configure a new J2C administrative object. Perform one of the following:
   - Using the AdminTask object:
     a. List the administrative object interfaces:

        Using Jacl:

        ```
        $AdminTask listMessageListenerTypes $newra
        ```

        Using Jython:

        ```
        AdminTask.listMessageListenerTypes(newra)
        ```

        Example output:

        ```
        javax.jms.MessageListener
        ```

     b. Create a J2C administrative object:

        Using Jacl:

        ```
        $AdminTask createJ2CActivationSpec $newra { -name ac1 -jndiName eis/ac1
          -message ListenerType javax.jms.MessageListener}
        ```

        Using Jython:

        ```
        AdminTask.createJ2CActivationSpec(newra, ['-name', 'ao1', '-jndiName', 'eis/ao1',
          '-message', 'ListenerType', 'javax.jms.MessageListener'])
        ```
   - Using the AdminConfig object:
     a. Using Jacl:

        ```
        $AdminConfig required J2CActivationSpec
        ```

        Using Jython:

        ```
        print AdminConfig.required('J2CActivationSpec')
        ```

        Example output:

        ```
        Attribute Type
        activationSpec ActivationSpec@
        ```

     b. If your resource adapter is JCA V1.5 and you have multiple activation specs defined, it is required that you specify the activation spec attribute. If your resource adapter is JCA V1.5 and you have only one activation spec defined, it will be picked up automatically. If your resource adapter is JCA V1.0, you do not need to specify the activationSpec attribute. Perform the following command to list the activation specs defined by the resource adapter:

        Using Jacl:

        ```
        $AdminConfig list ActivationSpec $newra
        ```

        Using Jython:

        ```
        print AdminConfig.list('ActivationSpec', $newra)
        ```

     c. Set the administrative object that you need to a variable:

        Using Jacl:

```
set ac ActivationSpecID
set name [list name J2CAC1]
set jname [jndiName eis/j2cac1]
set j2cacAttrs [list $name $jname]
```

Using Jython:

```
ac = ActivationSpecID
name = ['name', 'J2CAC1']
jname = ['jndiName', 'eis/j2cac1']
j2cacAttrs = [name, jname]
```

d. If you are specifying the ActivationSpec attribute, also set up the following:

Using Jacl:

```
set cdcttr [list activationSpec $ac]
```

Using Jython:

```
cdattr = ['activationSpec', ac]
```

e. Create a J2C activation spec object:

Using Jacl:

```
$AdminConfig create J2CActivationSpec $newra $j2cacAttrs
```

Using Jython:

```
print AdminConfig.create('J2CActivationSpec', newra,j2cacAttrs)
```

Example output:

```
J2CAC1(cells/mycell/nodes/mynode|resources.xml#J2CActivationSpec_1)
```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new J2C administrative objects using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a J2C administrative object:

1. Identify the parent ID and assign it to the `newra` variable.
   - Using Jacl:

     ```
     set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
     ```

   - Using Jython:

     ```
     newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
     print newra
     ```

   Example output:

   ```
   RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
   ```

2. There are two ways to configure a new J2C administrative object. Perform one of the following:
   - Using the AdminTask object:
     a. List the administrative object interfaces:

        Using Jacl:

        ```
        $AdminTask listAdminObjectInterfaces $newra
        ```

        Using Jython:

        ```
        AdminTask.listAdminObjectInterfaces(newra)
        ```

        Example output:

        ```
        com.ibm.test.message.FVTMessageProvider
        ```

     b. Create a J2C administrative object:

Using Jacl:

```
$AdminTask createJ2CAdminObject $newra { -name ao1 -jndiName eis/ao1
 -adminObjectInterface com.ibm.test.message.FVTMessageProvider }
```

Using Jython:

```
AdminTask.createJ2CAdminObject(newra, ['-name', 'ao1', '-jndiName', 'eis/ao1',
 '-adminObjectInterface', 'com.ibm.test.message.FVTMessageProvider'])
```

- Using the AdminConfig object:
  a. Using Jacl:

```
$AdminConfig required J2CAdminObject
```

Using Jython:

```
print AdminConfig.required('J2CAdminObject')
```

Example output:

```
Attribute Type
adminObject AdminObject@
```

  b. If your resource adapter is JCA V1.5 and you have multiple administrative objects defined, it is required that you specify the administrative object attribute. If your resource adapter is JCA V1.5 and you have only one administrative object defined, it will be picked up automatically. If your resource adapter is JCA V1.0, you do not need to specify the administrative object attribute. Perform the following command to list the administrative objects defined by the resource adapter:

Using Jacl:

```
$AdminConfig list AdminObject $newra
```

Using Jython:

```
print AdminConfig.list('AdminObject', $newra)
```

  c. Set the administrative objects that you need to a variable:

Using Jacl:

```
set ao AdminObjectId
set name [list name J2CAO1]
set jname [jndiName eis/j2cao1]
set j2caoAttrs [list $name $jname]
```

Using Jython:

```
ao = AdminObjectId
name = ['name', 'J2CAO1']
set jname = ['jndiName', eis/j2cao1]
j2caoAttrs = [name, jname]
```

  d. If you are specifying the AdminObject attribute, also set up the following:

Using Jacl:

```
set cdattr [list adminObject $ao]
```

Using Jython:

```
cdattr = ['adminObject', ao]
```

  e. Create a J2C administrative object:

Using Jacl:

```
$AdminConfig create J2CAdminObject $newra $j2caoAttrs
```

Using Jython:

```
print AdminConfig.create('J2CAdminObject', newra, j2caoAttrs)
```

Example output:

```
J2CAO1(cells/mycell/nodes/mynode|resources.xml#J2CAdminObject_1)
```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Testing data source connections using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to test a data source to ensure a connection to the database.

1. Identify the DataSourceCfgHelper MBean and assign it to the dshelper variable.
   - Using Jacl:

     ```
     set ds [$AdminConfig getid /DataSource:DS1/]
     $AdminControl testConnection $ds
     ```

   - Using Jython:

     ```
     ds = AdminConfig.getid('/DataSource:DS1/')
     AdminControl.testConnection(ds)
     ```

   Example output:

   ```
   WASX7217I: Connection to provided datasource was successful.
   ```

2. Test the connection. The following example invokes the testConnectionToDataSource operation on the MBean, passing in the classname, userid, password, database name, JDBC driver class path, language, and country.
   - Using Jacl:

     ```
     $AdminControl invoke $dshelper testConnectionToDataSource "COM.ibm.db2.jdbc.DB2XADataSource
      db2admin db2admin {{databaseName sample}} /sqllib/java/db2java.zip en US"
     ```

   - Using Jython:

     ```
     print AdminControl.invoke(dshelper, 'testConnectionToDataSource',  'COM.ibm.db2.jdbc.DB2XADataSource
      dbuser1 dbpwd1 "{{databaseName jtest1}}" /sqllib/java12/db \"\" \"\"\"')
     ```

   Example output:

   ```
   WASX7217I: Connection to provided data source was successful.
   ```

Deploying data access applications

Before installing a data access application into the WebSphere Application Server environment, you must first ensure that the appropriate database objects are available. This action includes creating and configuring any databases or tables required, setting necessary configuration parameters to handle expected load, and configuring any necessary JDBC providers and data source objects for servlets, enterprise beans, and client applications to use.

1. If your database configuration does not already exist:
   a. Create a database to hold the data.
   b. Create tables required by your application.
      If your application uses entity enterprise beans to access the data
      You can create the tables using the data definition language (DDL) generated from the enterprise bean configuration. For more information, see Recreating database tables from the exported table data definition language.
      If your application does not use entity beans
      You must use your database server interfaces to create the tables.
   c. See Minimum required properties for vendor-specific data sources for certain vendors' database requirements.
2. If your enterprise application contains a Web application or an EJB application that uses connection pooling to access a relational database, see "Creating and configuring a JDBC provider and data source" on page 561.

3. If your application requires access to a non-relational database, you need to configure a resource adapter and a connection factory rather than a JDBC provider and a data source.
4. If your enterprise application contains an application client that accesses a relational database, see Configuring data access for application clients.
5. Consider the security of lookups with component managed authentication. See Security of lookups with component managed authentication for more information.

Relationship of assembly and administrative console data access settings

This article provides miscellaneous tips for using supported databases. See also the related links.

Always consult the product documentation for a list of the database brands and versions that are supported by your particular WebSphere Application Server version, edition, and FixPak.

Notes about various databases

- When using local DB2 databases for data access by session clients on AIX Version 4.3.3 or later versions, in some cases you cannot establish multiple connections for session clients. This is because AIX , by default, does not permit 32-bit applications to attach to more than 11 shared memory segments per process. Of these 11 shared segments, a maximum of 10 can be used for local DB2 connections. To use EXTSHM with DB2 and avoid stale connections when there are large numbers of session clients, do the following:
  - In DB2 client environment (that is the WebSphere Application Server run time environment in this case):

    ```
    export EXTSHM=ON
    ```
  - In DB2 UDB Server environment:

    ```
    export EXTSHM=ON
    db2set DB2ENVLIST=EXTSHM
    ```
- When using Sybase 11.x, you might encounter the following error when HttpSession persistence is enabled:

  ```
  DBPortability W Could not create database table: "sessions"
  com.sybase.jdbc2.jdbc.SybSQLException: The 'CREATE TABLE' command is not
  allowed within a multi-statement transaction in the 'database_name' database
  ```

  where *database_name* is the name of the database for holding sessions.

  If you encounter the error, issue the following commands at the Sybase command line:

  ```
  use database_name
  go
  sp_dboption db,"ddl in tran ",true
  go
  ```
- Sybase 12.0 does not support local transaction modes with a JTA enabled data source. To use a connection from a JTA enabled data source in a local transaction, install Sybase patch EBF9422.

Additional administrative tasks for specific databases

For your convenience, this article provides instructions for enabling some popular database drivers, and performing other administrative tasks often required to provide data access to applications running on WebSphere Application Server. These tasks are performed outside of the WebSphere Application Server administrative tools, often using the database product tools. Always refer to the documentation accompanying your database driver as the authoritative and complete source of driver information.

See the Supported hardware, software, and APIs for the latest information about supported databases, drivers, and operating systems.

- **Enabling JDBC 2.0**

  Ensure that your operating system environment is set up to support JDBC 2.0. This action is required to use data sources created through WebSphere Application Server.

The following steps make it possible to find the appropriate JDBC 2.0 driver for use with WebSphere Application Server administration:

- **Enabling JDBC 2.0 with DB2 on Windows NT systems**

  To enable JDBC 2.0 use on Windows NT systems:
  - For DB2 Version 7.2
    1. Stop the DB2 JDBC Applet Server service.
    2. Run the following batch file:

       ```
       SQLLIB\java12\usejdbc2.bat
       ```
    3. Stop WebSphere Application Server (if it is running) and start it again.
  - For DB2 Version 8.1
    - JDBC 2.0 is supported by default, there are no additional steps for you to perform.

  Perform the steps once for each system.

- **Determining the level of the JDBC API in use for DB2 on Windows NT systems**

  To determine the JDBC level in use on your system:
  - For DB2 Version 7.2
    - If JDBC 2.0 is in use, this file exists:

      ```
      SQLLIB\java12\inuse
      ```
    - If JDBC 1.0 is in use, this file exists:

      ```
      SQLLIB\java11\inuse
      ```

      or no *java11* directory exists.
  - For DB2 Version 8.1
    - Go to directory *SQLLIB\samples\java*, compile and run the class *db2JDBCVersion.java*.

- **Enabling JDBC 2.0 with DB2 on UNIX systems**
  - For DB2 Version 7.2
    - Before starting WebSphere Application Server, call *$INSTHOME/sqllib/java12/usejdbc2* to use JDBC 2.0. For convenience, you might want to put this in your root user's startup script. For example, on AIX, add the following to the root user's *.profile*:

      ```
      if [ -f /usr/lpp/db2_07_01/java12/usejdbc2 ] ; then
          . /usr/lpp/db2_07_01/java12/usejdbc2
      fi
      ```
  - For DB2 Version 8.1
    - JDBC 2.0 is supported by default, there are no additional steps for you to perform.

- **Determining the level of the JDBC API in use for DB2 on UNIX systems**
  - For DB2 Version 7.2
    - To determine if you are using JDBC 2.0, you can echo *$CLASSPATH*. If it contains

      ```
      $INSTHOME/sqllib/java12/db2java.zip
      ```

      then JDBC 2.0 is in use.

      If it contains

      ```
      $INSTHOME/sqllib/java/db2java.zip
      ```

      then JDBC 1.0 is in use.
  - For DB2 Version 8.1
    - Go to directory *sqllib/samples/java*, compile and run the class *db2JDBCVersion.java*.

- **Sourcing the db2profile script on UNIX systems**

  Before starting WebSphere Application Server to host applications requiring data access, source the *db2profile*:

  ```
  . ~db2inst1/sqllib/db2profile
  ```

  where *db2inst1* is the user created during DB2 installation.

- **Using Java Transaction API drivers**

  Instructions are available for using Java Transaction API (JTA) drivers on particular operating systems. See your operating system documentation for more information.

The goal of this section is to provide information about the steps that make DB2 work well with applications utilizing XA classes -- that is, those whose *dataSourceClasses* implement *javax.sql.XADataSource*.

- **Using Java Transaction API drivers for DB2 on Windows NT systems**

  To enable JTA drivers for DB2 on Windows NT systems, follow these steps:

  1. Bind the necessary packages to the database. From the **DB2 Command Line Processor** window, issue the following commands:

     ```
     db2=> connect to mydb2jta
     db2=> bind db2home\bnd\@db2cli.lst
     db2=> bind db2home\bnd\@db2ubind.lst
     db2=> disconnect mydb2jta
     ```

     where *mydb2jta* is the name of the database to enable for the JTA, and *db2home* is the DB2 root installation directory path (for example, *D:\ProgramFiles\SQLLIB\bnd\@db2cli.lst*).
  2. Specify the following settings when you use an IBM WebSphere Application Server administrative client (such as the administrative console) to configure a JDBC driver:
     - **Server class path** = `%DB2_ROOT%/Sqllib/java/db2java.zip`
     - **Implementation class name** = `COM.ibm.db2.jdbc.DB2XADataSource`

- **Using Java Transaction API drivers for DB2 on UNIX systems**

  To enable JTA drivers on UNIX systems, follow these steps:

  1. Stop all DB2 services.
  2. Stop the IBM WebSphere Application Server administrative service.
  3. Stop any other processes that use the *db2java.zip* file.
  4. Make sure that you already enabled JDBC 2.0.
  5. Start the DB2 services.
  6. Bind the necessary packages to the database. From the DB2 command-line process or window, issue the following commands:

     ```
     db2=> connect to mydb2jta
     db2=> bind db2home\bnd\@db2cli.lst
     db2=> bind db2home\bnd\@db2ubind.lst
     db2=> disconnect mydb2jta
     ```
  7. Specify the following settings when you use an IBM WebSphere Application Server administrative client (such as the administrative console) to configure a JDBC driver:
     - **Server class path** = `$INSTHOME/sqllib/java12/db2java.zip`

       For example, if *$INSTHOME* is `/home/test`, the path will be `/home/test/sqllib/java12/db2java.zip`
     - **Implementation class name** = `COM.ibm.db2.jdbc.DB2XADataSource`

- **For Oracle 8.1.7 two phase commit support**

  You can use the Oracle 8.1.7 thin driver for JTA two-phase support with the following restrictions:

  - The thin driver that comes shipped with 8.1.7 might or might not work. Future patches from Oracle might work as well, but are not tested. The driver that was available from the Oracle Technology Network Web site as of February 20, 2001 does work and is the recommended driver. Later versions on this Web site are expected to work, but are not tested.

    To obtain the driver from the Oracle support Web site, visit:

    `http://technet.oracle.com/`

    You need to be a registered user for the Oracle Technology Network to get the driver from this site. Contact Oracle for access. After you have access download the 8.1.7 driver for the platforms you use and follow the instructions for installing the new driver.
  - You must use the 8.1.7 driver with 8.1.7 databases, 8.1.6 databases do not support the recover() and forget() methods and other problems are encountered running with 8.1.6. Oracle does not support JTA with 8.1.6.
  - For Oracle, you can only use JTA with container-managed persistence (CMP) beans.
  - For the bean to create the table, you must start the bean with the JTA set to *false*. After the bean creates the table, you can set the JTA back to *true*.
  - Configure an entity bean that accesses Oracle with JTA set to *true* as follows:

- Click **deployment descriptor properties** > **Transactions** > Remote tab. Set the Transaction Attribute to *TX_REQUIRED*.
- Click **Isolation** > Remote tab. Set the Isolation Level to *TRANSACTION_READ_COMMITTED*.

– Configure a session bean that is used with an entity bean that accesses Oracle with JTA set to *true* as follows:
- Click **deployment descriptor properties** > **Transactions** > Remote tab. Set the Transaction Attribute to *TX_BEAN_MANAGED*.
- Click **Isolation** > Remote tab. Set the Isolation Level to *TRANSACTION_READ_COMMITTED*.

- **Using Java Transaction API drivers for Sybase products on AIX systems**

  To enable Java Transaction API (JTA) drivers for use with Sybase products on the AIX operating system, follow these steps:
  1. Enable the Data Transaction Manager (DTM) by issuing these commands (one per line) at a command prompt:
     ```
     isql -Usa -Ppassword -Sservername
     sp_configure "enable DTM", 1
     go
     ```
  2. Stop the Sybase Adaptive Server database and start it again.
  3. Grant the appropriate role authorization to the enterprise bean user at a command prompt:
     ```
     isql -Usa -Ppassword -Sservername
     grant role dtm_tm_role to EJB
     go
     ```

- **Notes about Sybase Java Transaction API drivers**

  Do not use a Sybase Java Transaction API (JTA) connection in an enterprise bean method with an unspecified transaction context. A Sybase JTA connection does not support the local transaction mode. The implication is that you must use the Sybase JTA connection in a global transaction context.

  Related concepts

  "Data sources" on page 514
  Installed applications uses a *data source* to access the data from the database.

  Related reference

  "Data access : Resources for learning" on page 533

Recreating database tables from the exported table data definition language:

When the WebSphere Application Server deployment tooling deploys an EJB jar file containing container-managed persistence (CMP) enterprise beans, it selects the target database and creates a corresponding `Table.ddl` file. This file contains the SQL statement necessary to generate the database table for your CMP beans. You must then run the `ddl` file on your database server to create the tables.

Following is an example of how to use such a `Table.ddl` file for DB2, on Windows and z/OS:

1. To create your tables using SPUFI, extract the `Table.ddl` file located in your EJB JAR, and save it to a temporary directory on your work station.
2. Transfer this `Table.ddl` file to a data set on your z/OS system.
3. Specify the data set as the input data set to SPUFI.

Installing J2EE Connector resource adapters

1. Click **Resources**.
2. Click **Resource Adapters**.
3. Select the *scope* at which you want to define this resource adapter. (This scope becomes the scope of your connection factory.) You can choose cell, node, cluster, or server. For more information, see ″Administrative console scope settings″.

4. Click **Install RAR**. The Install RAR button opens a dialog that enables you to install a J2EE Connector Architecture (JCA) connector and create a resource adapter for it. You can also use the **New** button, but the New button creates only a new resource adapter (the JCA connector must already be installed on the system).

   Note: When installing a RAR file using this dialog, the scope you define on the Resource Adapters page has no effect on where the RAR file is installed. You can install RAR files only at the *node* level. The node on which the file is installed is determined by the scope on the **Install RAR** page. (The scope you set on the Resource Adapters page determines the scope of the new resource adapters, which you can install at the server, node, or cell level.)
5. Browse to find the appropriate RAR file.
   - If your RAR file is located on your local workstation, select **Local path** and browse to find the file.
   - If your RAR file is located on your server, select **Server path** and specify the fully qualified path to the file.
6. Click **Next**.
7. Enter the resource adapter name and any other properties needed under *General Properties*. If you install a J2C Resource Adapter that includes *Native path* elements, consider the following: If you have more than one native path element, and one of the native libraries (native library A) is dependent on another library (native library B), then you must copy native library B to a *system* directory. Because of limitations on Windows NT and most Unix platforms, an attempt to load a native library does not look in the current directory.
8. Click **OK**.

Installing resource adapters within applications:

1. Assemble an application with resource adapter archive (RAR) modules in it. See Assembling applications.
2. Install the application following the steps in Installing a new application. In the **Map modules to servers** step, specify target servers or clusters for each RAR file. Be sure to map all other modules that use the resource adapters defined in the RAR modules to the same targets. Also, specify the Web servers as targets that serve as routers for requests to this application. The plug-in configuration file (`plugin-cfg.xml`) for each Web server is generated based on the applications that are routed through it.

   Note: When installing a RAR file onto a server, WebSphere Application Server looks for the manifest (MANIFEST.MF) for the connector module. It looks first in the *connectorModule.jar* file for the RAR file and loads the manifest from the *_connectorModule.jar* file. If the class path entry is in the manifest from the *connectorModule.jar* file, then the RAR uses that class path.

   To ensure that the installed connector module finds the classes and resources that it needs, check the **Class path** setting for the RAR using the console. For more information, see “Resource Adapter settings” on page 559 and “WebSphere relational resource adapter settings” on page 505
3. Click **Finish** > **Save** to save the changes.
4. Create connection factories for the newly installed application.
   a. Open the administrative console.
   b. Click **Applications** > **Enterprise Applications** > *application name*.
   c. Click **Connector Modules** in the Related Items section of the page.
   d. Click *filename.rar*.
   e. Click **Resource adapter** in the Additional Properties section of the page.
   f. Click **J2C Connection Factories** in the Additional Properties section of the page.
   g. Click on an existing connection factory to update it, or **New** to create a new one.

If you install a J2C Resource Adapter that includes *Native path* elements, consider the following: If you have more than one native path element, and one of the native libraries (native library A) is dependent on another library (native library B), then you must copy native library B to a *system* directory. Because of limitations on Windows NT and most Unix platforms, an attempt to load a native library does not look in the current directory.

After you create and save the connection factories, you can modify the resource references defined in various modules of the application and specify the Java Naming and Directory Interface (JNDI) names of the connection factories wherever appropriate.

Note: A given native library can only be loaded one time for each instance of the Java virtual machine (JVM). Because each application has its own classloader, separate applications with embedded RAR files cannot both use the same native library. The second application receives an exception when it tries to load the library.

If any application deployed on the application server uses an embedded RAR file that includes native path elements, then you must always ensure that you shut down the application server cleanly, with no outstanding transactions. If the application server does not shut down cleanly it performs *recovery* upon server restart and loads any required RAR files and native libraries. On completion of recovery, do not attempt any application-related work. Shut down the server and restart it. No further recovery is attempted by the application server on this restart, and normal application processing can proceed.

Resource Adapters collection:

This page contains the list of installed and configured resource adapters and is used to install new resource adapters, create additional configurations of installed resource adapters or delete resource adapter configurations.

A resource adapter is an implementation of the J2EE Connector Architecture (JCA) Specification that provides access for applications to resources outside of the server or provides access for an enterprise information system (EIS) to applications on the server. It can provide application access to resources such as DB2, CICS, SAP and PeopleSoft. It can provide an EIS with the ability to communicate with message-driven beans that are configured on the server. Some resource adapters are provided by IBM; however, third party vendors can provide their own resource adapters. A resource adapter implementation is provided in a resource adapter archive file; this file has an extension of *.rar*. A resource adapter can be provided as a standalone adapter or as part of an application, in which case it is referred to as an embedded adapter. Use this panel to install a standalone resource adapter archive file. Embedded adapters are installed as part of the application installation. This panel can be used to work with either kind of adapter.

To view this administrative console page, click **Resources** >**Resource Adapters**.

Scope:

Specifies the level to which this resource adapter is visible. For general information, see *Administrative console scope settings* in the Related Reference section.

Some considerations that you should keep in mind for this particular panel are:

- Changing the scope enables you to see which resource adapter definitions exist at that level.
- Changing the scope **does not** have any effect on installation. Installations are always done under a scope of **node**, no matter what you set the scope to.
- When you create a new resource adapter from this panel, you must change the scope to what you want it to be **before** clicking **New**.

Name:

Specifies the name of the resource adapter.

A string with no spaces meant to be a meaningful text identifier for the resource adapter.

Data type String

Resource Adapter settings:

Use this page to specify settings for a Resource Adapter.

A resource adapter is an implementation of the J2EE Connector Architecture (JCA) Specification that provides access for applications to resources outside of the server or provides access for an enterprise information system (EIS) to applications on the server. It can provide application access to resources such as DB2, CICS, SAP and PeopleSoft. It can provide an EIS with the ability to communicate with message driven beans that are configured on the server. Some resource adapters are provided by IBM; however, third party vendors can provide their own resource adapters. A resource adapter implementation is provided in a resource adapter archive file; this file has an extension of *.rar*. A resource adapter can be provided as a standalone adapter or as part of an application, in which case it is referred to as an embedded adapter. Use this panel to install a standalone resource adapter archive file. Embedded adapters are installed as part of the application installation.

To view this administrative console page, click **Resources** >**Resource Adapters** > *resource_adapter*.

Scope:

Specifies the level to which this resource definition is visible. For general information, see *Administrative console scope settings* in the Related Reference section.

The Scope field is a read only string field that shows where the particular definition for a resource adapter is located. This is set either when the resource adapter is installed (which can only be at the node level) or when a new resource adapter definition is added.

Name:

Specifies the name of the resource adapter definition.

This property is required.

A string with no spaces meant to be a meaningful text identifier for the resource adapter.

Data type String

Description:

Specifies a text description of the resource adapter.

A free-form text string to describe the resource adapter and its purpose.

Data type String

Archive path:

Specifies the path to the RAR file containing the module for this resource adapter.

This property is required.

Data type String

Class path:

Specifies a list of paths or JAR file names which together form the location for the resource adapter classes.

This includes any additional libraries needed by the resource adapter. The resource adapter code base itself is automatically added to the class path, but if anything outside the RAR is needed it can be specified here.

Data type String

Native path:

Specifies a list of paths which forms the location for the resource adapter native libraries.

The resource adapter code base itself is automatically added to the class path, but if anything outside the RAR is needed it can be specified here.

Data type String

ThreadPool Alias:

Specifies the name of a thread pool that is configured in the server that is used by the resource adapter's Work Manager.

If there is no thread pool configured in the server with this name, the default configured thread pool instance, named *Default*, is used. This property is only necessary if this resource adapter uses Work Manager.

Data type String

Pretesting pooled connections to ensure validity

When a database fails, pooled connections that are not valid might exist in the free pool. This scenario is likely to occur when you have a failingConnectionOnly purge policy, which mandates that only failing connections be removed from the pool. Whether the remaining connections in the pool are valid varies with the cause of the failure. Connection pretesting is a way to test connections from the free pool before giving them to the client.

If your application uses pooled connections, you can enable the PreTest Connections feature in the administrative console to help prevent your application from obtaining connections that are no longer valid.

The feature is particularly useful for routine database outages. Because these outages are usually scheduled for periods of low use, connections to the database are likely to be in the free pool rather than in active use. Active connections are not pretested; pretesting impedes performance during normal operation. Pretesting ensures that users do not waste time trying to resume connections that became bad before the outage.

1. In the administrative console, click **Resources** > **JDBC providers**.
2. Select a provider and click **Data Sources** under Additional properties.

3. Select a data source and click **WebSphere Application Server data source properties** under Additional properties.
4. Select the **PreTest Connections** check box.
5. Type a value for the PreTest Connection Retry Interval, which is measured in seconds. This property determines the frequency with which a new connection request is made after a pretest operation fails.
6. Type a valid SQL statement for the PreTest SQL String. Use a reliable SQL command, with minimal performance impact; this statement is processed each time a connection is obtained from the free pool.

   For example, you might specify SELECT COUNT(*) from TESTTABLE. (For an Oracle database, use SELECT USER FROM DUAL.)

Creating and configuring a JDBC provider and data source

This topic outlines the process for configuring access to a relational database, and provides links to more detailed instruction.

Determine which version of data source you need. If you are using the Enterprise JavaBean (EJB) 1.0 specification or the Java Servlet 2.2 specification, you need the Version 4.0 data source. If you are using more advanced releases of these specifications, you need the current version data source (which is designated in WebSphere Application Server simply as ″Data source,″ with no associated version number).

Next, determine which JDBC provider is appropriate for your data source version, database configuration, and application requirements. The topic “Vendor-specific data sources minimum required settings” is a comprehensive source for this information. It includes a summary table and detailed listings.

1. Create a JDBC provider.

   From the administrative console, see Creating a JDBC provider using the administrative console.

   OR

   Using the wsadmin scripting client, see “Configuring a JDBC provider using scripting” on page 537.

   OR

   Using the Java Management Extensions (JMX) API, see Creating a JDBC provider and data source using the Java Management Extensions API.
2. Create a data source.

   From the administrative console, see Creating a data source using the administrative console.

   OR

   Using the wsadmin scripting client, see “Configuring new data sources using scripting” on page 538. (For V4 data sources, see “Configuring new WAS40 data sources using scripting” on page 541.)

   OR

   Using the JMX API, see Creating a JDBC provider and data source using the Java Management Extensions API.
3. Bind the resource reference. See ″Binding to a data source″ in the information center.
4. Test the connection (for non-container-managed persistence usage). See Test connection.

   Note: When you save the data source configuration, it is saved in a *resource.xml* file. In most environments, you should not need to modify the **jdbc-resource-provider-templates.xml** file. However, if updating the file becomes necessary, observe the special considerations that are discussed in ″J2EE Connector Architecture migration tips″.

Vendor-specific data sources minimum required settings: Use this table as an at-a-glance reference of JDBC providers that can be defined for use with WebSphere Application Server Version 6.x, to establish data sources for transacting with relational databases. A list that contains detailed requirements for creating data sources with these providers follows the table. (The list also contains information about JDBC providers that are *deprecated* in WebSphere Application Server Version 6.x.)

Database type	JDBC Provider	Transaction support	Version and other considerations
DB2 on Windows, UNIX, or workstation-based LINUX	DB2 Universal JDBC Provider	One phase only	
	DB2 Universal JDBC Provider (XA)	One and two phase	The XA implementation is *not* supported in WebSphere Application Server run on workstation-based LINUX
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	
DB2 UDB for iSeries	DB2 UDB for iSeries (Native)	One phase only	Recommended for use with WebSphere Application Server **run on iSeries**
	DB2 UDB for iSeries (Native XA)	One and two phase	Recommended for use with WebSphere Application Server **run on iSeries**
	DB2 UDB for iSeries (Toolbox)	One phase only	
	DB2 UDB for iSeries (Toolbox XA)	One and two phase	
	DB2 Universal JDBC Provider (XA)	One and two phase	**-***Only* for use with WebSphere Application Server **run on z/OS** **-**Only driver type 4 is supported **-**Does *not* support Version 4 data sources
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect driver (available from DB2)
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect driver (available from DB2)

Database type	JDBC Provider	Transaction support	Version and other considerations
DB2 on z/OS	DB2 for z/OS Local JDBC Provider (RRS)	One and two phase	*Only* for use with WebSphere Application Server **run on z/OS**
	DB2 Universal JDBC Provider	One phase only	
	DB2 Universal JDBC Provider (XA)	One and two phase	**-**Only driver type 4 is supported in WebSphere Application Server **run on z/OS** **-**Does *not* support Version 4 data sources in WebSphere Application Server **run on z/OS**
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect program (available from DB2)
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect program (available from DB2)
Cloudscape	Cloudscape JDBC Provider	One phase only	**-** Not for use in clustering environment: Cloudscape is accessible from a single JVM only **-** Does not support Version 4 data sources
	Cloudscape JDBC Provider (XA)	One and two phase	**-** Not for use in clustering environment: Cloudscape is accessible from a single JVM only **-** Does not support Version 4 data sources
	Cloudscape Network Server using Universal JDBC driver	One phase only	Does not support Version 4 data sources
Informix	Informix JDBC Driver	One phase only	
	Informix JDBC Driver (XA)	One and two phase	
Sybase	Sybase JDBC Driver	One phase only	
	Sybase JDBC Driver (XA)	One and two phase	

Database type	JDBC Provider	Transaction support	Version and other considerations
Oracle	Oracle JDBC Driver	One phase only	
	Oracle JDBC Driver (XA)	One and two phase	
MS SQL Server	DataDirect ConnectJDBC type 4 driver for MS SQL Server	One phase only	Only for use with the corresponding driver from DataDirect Technologies
	DataDirect ConnectJDBC type 4 driver for MS SQL Server (XA)	One and two phase	Only for use with the corresponding driver from DataDirect Technologies
	WebSphere embedded ConnectJDBC driver for MS SQL Server	One phase only	- Not available for Application Server on z/OS - Cannot be used outside of WebSphere Application Server environment
	WebSphere embedded ConnectJDBC driver for MS SQL Server (XA)	One and two phase	- Not available for Application Server on z/OS - Cannot be used outside of WebSphere Application Server environment

Detailed data source requirements per JDBC provider and platform

The following list contains the requirements for creating data sources with every JDBC provider type that is supported in WebSphere Application Server Version 6.x. Specific fields are designated for the user and password properties. Inclusion of a property in the list does not imply that you should add it to the data source custom properties list. Rather, inclusion in the list means that a value is *typically* required for that field.

Important: After you determine the type of JDBC provider that suits your application and environment, ensure that you acquire the corresponding JDBC driver at a release level supported by this version of WebSphere Application Server. Consult the Supported hardware and software Web page at the http://www.ibm.com/software/webservers/appserv/doc/latest/prereq.html IBM Web address.

Use these links to find your provider and data source information:
- DB2 on z/OS, connecting to Application Server on z/OS
- “DB2 UDB for iSeries, connecting to Application Server on z/OS” on page 567
- Cloudscape
- Informix
- Sybase
- Oracle
- MS SQL Server

DB2 on z/OS, connecting to Application Server on z/OS

1. **DB2 for zOS Local JDBC Provider (RRS)**

   The DB2 for zOS Local JDBC Provider (RRS) is for use with the DB2 for 390 and z/OS Legacy JDBC Driver. It can be used only with WebSphere Application Server for z/OS. This provider supports the creation of WebSphere Application Server for z/OS v5.0 and v4.0 data sources. It also uses z/OS Resource Recovery Services (RRS) to coordinate transactions across multiple resource managers using two-phase commit processing.

The DB2 for zOS Local JDBC Provider (RRS) allows applications to use both JDBC and Structured Query Language in Java (SQLJ) access to DB2 databases. Use of SQLJ with Container Managed Persistence (CMP) is not supported under this provider.

To use this provider, the legacy DB2 for z/OS JDBC Driver must be installed and configured to the WebSphere Application Server. Refer to the topic "Using a DB2 for z/OS Local JDBC Provider (RRS) with WebSphere Application Server for z/OS" on page 582.

The following configuration information is provided in a template for the DB2 for zOS Local JDBC Driver Provider (RRS), and is automatically filled in when you select this provider.

Data source implementation:

`com.ibm.db2.jcc.DB2ConnectionPoolDataSource`

This DB2 data source allows WebSphere Application Server for z/OS to perform connection pooling. Note that when you configure the data source, you must specify a name for the data source definition.

This provider requires JDBC driver files:

- `db2j2classes.zip`, which are DB2 for z/OS Legacy JDBC driver files. They can be retrieved using the following class path:

  `${DB2390_JDBC_DRIVER_PATH}/classes/db2j2classes.zip`
- The native files (`.so` type files) required by the DB2 for OS/390 and z/OS Legacy JDBC driver, retrievable from the following library path:

  `${DB2390_JDBC_DRIVER_PATH}/lib`

The driver requires DataStoreHelper class:

`com.ibm.websphere.rsadapter.DB2DataStoreHelper`

It also requires a valid authentication alias. When res-auth = CONTAINER is used, however, it is permissible to not specify any authentication alias. In this case, the user identity associated with a connection created by the data source is the user identity associated with the current thread at the time a connection request is made.

This driver requires the following properties:

- **databaseName** The location name of the target database, used when establishing connections using this data source.

2. **DB2 Universal JDBC Provider**

   The DB2 Universal JDBC Driver is an architecture-neutral JDBC driver for distributed and local DB2 access. Because the Universal Driver architecture is independent of any particular JDBC driver connectivity or target platform, it allows both Java connectivity (Type 4) or Java Native Interface (JNI) based connectivity (Type 2) in a single driver instance to DB2.

   Note: To use this provider, you must have the DB2 Universal JDBC Driver for DB2 Version 7 or DB2 Version 8 installed and configured for WebSphere Application Server for z/OS. Refer to the topic "Using a DB2 Universal JDBC Driver Provider with WebSphere Application Server for z/OS" on page 585.

   The DB2 Universal JDBC Provider allows applications to use both JDBC and Structured Query Language in Java (SQLJ) access to DB2 databases. SQLJ use with CMP is also supported.

   It supports the following data source:

   `com.ibm.db2.jcc.DB2ConnectionPoolDataSource`

   Note that when you configure the data source, you must specify a name for the data source definition. This data source implementation class performs one-phase commit processing when you specify driver Type 4 in WebSphere Application Server for z/OS. When you specify driver Type 2, Application Server for z/OS uses RRS to coordinate transaction processing, and two-phase commit processing is performed for global transactions. The provider requires JDBC driver files:

   - `db2jcc.jar` This is the DB2 Universal JDBC Driver jar file. After the DB2 installation, this jar file is located in DB2's install directory. The fully-qualified path of this jar must be specified as the value of the DB2UNIVERSAL_JDBC_DRIVER_PATH environment variable. Class path:

     `${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar`

- db2jcc_License_cu.jar This is the DB2 Universal JDBC driver license file that allows access to DB2 Universal databases under Cloudscape and workstations. It is not used for WebSphere Application Server for z/OS, but is included to make the provider definition common between WebSphere Application Server for z/OS and WebSphere Application Server Distributed. Class path:

  ```
  ${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_License_cu.jar
  ```
- db2jcc_License_cisuz.jar This is the DB2 Universal JDBC Driver license file that allows access to DB2 Universal databases under Cloudscape, workstations, and z/OS. After you install DB2, this jar file appears in the same DB2 directory as db2jcc.jar. Class path:

  ```
  ${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_License_cisuz.jar
  ```
- The native files (.so type files) required by the DB2 Universal JDBC Driver in WebSphere Application Server for z/OS. Use the following library path:

  ```
  ${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}
  ```

The DB2 Universal JDBC driver requires **DataStoreHelper** class:

```
com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper
```

This driver also requires a valid authentication alias if the driverType property (see properties below) is set to 4. If the driverType property is set to 2, a component-managed authentication alias must be specified to use the datasource with res-auth APPLICATION. In the case where driverType 2 is specified and the datasource is used with res-auth CONTAINER, you can specify a container-managed authentication alias; however, it is not required. If you do not specify a container-managed alias, the user identity associated with a connection created by the datasource will be the user identity associated with the current thread at the time the connection is obtained.

It requires the following properties:

- **databaseName** This is an actual database name if the **driverType** is set to **4**, or a locally cataloged database name if the **driverType** is set to **2**.
- **driverType** The JDBC connectivity type of a data source. *There are two permitted values: 2 and 4*. If you want to use Universal JDBC Type 2 driver, set this value to 2. If you want to use Universal JDBC Type 4 driver, set this value to 4.
- **serverName** The TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.
- **portNumber** The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.

3. **DB2 Universal JDBC Provider (XA)**

   This provider is the XA DB2 Universal JDBC provider that uses the DB2 Universal JDBC driver to provide access to DB2 databases. The Universal JDBC driver supports Java communication-based connectivity (driver Type 4), which allows distributed access to DB2. The driver also supports Java Native Interface (JNI) based connectivity (driver type 2), which allows local access to DB2. For XA capabilities, however, driver type 2 is not supported by the DB2 Universal JDBC Driver on WebSphere Application Server for z/OS. Therefore driver type 2 should *not* be used when defining an XA data source under this provider.

   Note: To use this provider, you must have the DB2 Universal JDBC Driver for DB2 Version 7 or DB2 Version 8 installed and configured for WebSphere Application Server for z/OS, or you must have the z/OS Application Connectivity to DB2 for z/OS feature installed and configured for WebSphere Application Server for z/OS. Refer to the topic “Using a DB2 Universal JDBC Driver Provider with WebSphere Application Server for z/OS” on page 585.

   The DB2 Universal JDBC Provider (XA) allows applications to use both JDBC and Structured Query Language in Java (SQLJ) access to DB2 databases. SQLJ use with CMP is also supported.

   This provider does not support the creation of Version 4.0 data sources.

   The DB2 Universal JDBC Provider (XA) supports the two phase data source:

   com.ibm.db2.jcc.DB2XADataSource

   Note that when you configure the data source, you must specify a name for the data source definition.

It requires JDBC driver files:

- `db2jcc.jar` This is the DB2 Universal JDBC Driver jar file. After the DB2 installation, this jar file is located in DB2's install directory. The fully-qualified path of this jar must be specified as the value of the DB2UNIVERSAL_JDBC_DRIVER_PATH environment variable:

  `${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar`
- `db2jcc_License_cu.jar` This is the DB2 Universal JDBC driver license file that allows access to DB2 Universal databases under Cloudscape and workstations. It is not used for WebSphere Application Server for z/OS, but is included to make the provider definition common between WebSphere Application Server for z/OS and WebSphere Application Server Distributed. Class path:

  `${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_License_cu.jar`
- `db2jcc_License_cisuz.jar` This is the DB2 Universal JDBC Driver license file that allows access to DB2 Universal databases under Cloudscape, workstations, and z/OS. After you install DB2, this jar file appears in the same DB2 directory as db2jcc.jar. Class path:

  `${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_License_cisuz.jar`
- The native files (`.so` type files) required by the DB2 Universal JDBC Driver in WebSphere Application Server for z/OS. Use the following library path:

  `${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}`

  (In cases that do not require native files, set the DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH to null.)

The driver requires **`DataStoreHelper`** class:

`com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper`

It also requires a valid authentication alias.

The DB2 Universal JDBC driver requires the following properties:

- **databaseName** This is a locally cataloged database name.
- **driverType** This is the JDBC connectivity type of a data source. *If you are running a version of DB2 prior to DB2 V8.1 FP6, you are restricted to using only the type 2 driver.*
- **serverName** The TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.
- **portNumber** The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.

For more information on DB2 for z/OS, visit the DB2 Web site at: http://www.ibm.com/software/data/db2/.

DB2 UDB for iSeries, connecting to Application Server on z/OS

In the rare case that you need to connect to DB2 UDB on iSeries to provide JDBC connectivity for an application run on WebSphere Application Server for z/OS, you can use the iSeries Toolbox driver for Java, the iSeries Toolbox XA-compliant driver for Java, or the DB2 JDBC Universal Driver XA.

1. **DB2 UDB for iSeries (Toolbox)**

   This JDBC driver, also known as iSeries Toolbox driver for Java, is provided in the DB2 for iSeries database server. Use this driver for remote DB2 connections on iSeries. We recommend you use this driver instead of the IBM Developer Kit for Java JDBC Driver to access remote DB2 UDB for iSeries systems.

   DB2 UDB for iSeries (Toolbox) supports one phase data source:

   `com.ibm.as400.access.AS400JDBCConnectionPoolDataSource`

   Requires JDBC driver files: **`jt400.jar`**

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

   Requires an authentication alias.

   Requires properties:

- **serverName** The name of the server from which the data source obtains connections. Example: *myserver.mydomain.com*.

2. **DB2 UDB for iSeries (Toolbox XA)**

   This XA compliant JDBC driver, also known as iSeries Toolbox XA-compliant driver for Java, is provided in the DB2 for iSeries database server. Use this driver for remote DB2 connections on iSeries. We recommend you use this driver instead of the IBM Developer Kit for Java JDBC Driver to access remote DB2 UDB for iSeries systems.

   DB2 UDB for iSeries (Toolbox XA) supports two phase data source:

   com.ibm.as400.access.AS400JDBCXADataSource

   Requires JDBC driver files: **jt400.jar**

   Requires **DataStoreHelper** class:

   `com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

   Requires an authentication alias.

   Requires properties:
   - **serverName** The name of the server from which the data source obtains connections. Example: *myserver.mydomain.com*.

3. **DB2 Universal JDBC Provider (XA)**

   This provider is the XA DB2 Universal JDBC provider that uses the DB2 Universal JDBC driver to provide access to DB2 databases. The Universal JDBC driver supports Java communication-based connectivity (driver Type 4), which allows distributed access to DB2. If you are running WebSphere Application Server for z/OS and connecting to DB2 UDB for iSeries, you *cannot* use Java Native Interface (JNI) based connectivity (driver type 2) with this provider.

   Note: To use this provider, you must have the DB2 Universal JDBC Driver for DB2 Version 7 or DB2 Version 8 installed and configured for WebSphere Application Server for z/OS, or you must have the z/OS Application Connectivity to DB2 for z/OS feature installed and configured for WebSphere Application Server for z/OS. Refer to the topic “Using a DB2 Universal JDBC Driver Provider with WebSphere Application Server for z/OS” on page 585.

   The DB2 Universal JDBC Provider (XA) allows applications to use both JDBC and Structured Query Language in Java (SQLJ) access to DB2 databases. SQLJ use with CMP is also supported.

   This provider does not support the creation of Version 4.0 data sources.

   The DB2 Universal JDBC Provider (XA) supports the two phase data source:

   com.ibm.db2.jcc.DB2XADataSource

   Note that when you configure the data source, you must specify a name for the data source definition.

   It requires JDBC driver files:
   - `db2jcc.jar` This is the DB2 Universal JDBC Driver jar file. After the DB2 installation, this jar file is located in DB2’s install directory. The fully-qualified path of this jar must be specified as the value of the DB2UNIVERSAL_JDBC_DRIVER_PATH environment variable:

     `${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar`
   - `db2jcc_License_cu.jar` This is the DB2 Universal JDBC driver license file that allows access to DB2 Universal databases under Cloudscape and workstations. It is not used for WebSphere Application Server for z/OS, but is included to make the provider definition common between WebSphere Application Server for z/OS and WebSphere Application Server Distributed. Class path:

     `${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_License_cu.jar`
   - `db2jcc_License_cisuz.jar` This is the DB2 Universal JDBC Driver license file that allows access to DB2 Universal databases under Cloudscape, workstations, and z/OS. After you install DB2, this jar file appears in the same DB2 directory as db2jcc.jar. Class path:

     `${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_License_cisuz.jar`
   - The native files (`.so` type files) required by the DB2 Universal JDBC Driver in WebSphere Application Server for z/OS. Use the following library path:

     `${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}`

(In cases that do not require native files, set the DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH to null.)

The driver requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper`

It also requires a valid authentication alias.

The DB2 Universal JDBC driver requires the following properties:

- **databaseName** This is a locally cataloged database name.
- **driverType** This is the JDBC connectivity type of a data source. Set this property to type 4 if you are running WebSphere Application Server for z/OS and connecting to DB2 UDB for iSeries.
- **serverName** The TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.
- **portNumber** The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.

For more information on DB2 for iSeries, visit the DB2 Web site at: http://www.ibm.com/software/data/db2/.

Cloudscape

1. **Cloudscape JDBC Provider**

   The Cloudscape JDBC Provider provides the JDBC access to the Cloudscape database. This Cloudscape JDBC driver used the embedded framework. You cannot use any Version 4.0 data sources with Cloudscape.

   Cloudscape JDBC Provider supports one phase data source:

   com.ibm.db2j.jdbc.DB2jConnectionPoolDataSource

   Requires JDBC driver files: **db2j.jar.**

   Requires **DataStoreHelper** class:

   `com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper`

   Does not require a valid authentication alias.

   Requires properties:

   - **databaseName** The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, Application Server uses the default location of `WAS_HOME./cloudscape` (or the equivalent default for a UNIX or LINUX environment).
     - Example database path name for Windows: `c:\`*`temp\sampleDB`*
     - Example database path name for UNIX or LINUX: */`*`tmp/sampleDB`*

     If no database currently exists for the path name you want to specify, simply append `;create=true` to the path name to create a database dynamically. (For example: `c:\`*`temp\sampleDB`*`;create=true`)

2. **Cloudscape JDBC Provider (XA)**

   The Cloudscape JDBC Provider (XA) provides the XA-compliant JDBC access to the Cloudscape database. This Cloudscape JDBC driver uses the embedded framework. You cannot use any Version 4.0 data sources with Cloudscape.

   Cloudscape JDBC Provider (XA) supports two phase data source:

   com.ibm.db2j.jdbc.DB2jXADataSource

   Requires JDBC driver files: **db2j.jar**

   Requires **DataStoreHelper** class:

   `com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper`

   Does not require a valid authentication alias.

   Requires properties:

   - **databaseName** The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, Application Server uses the default location of `WAS_HOME./cloudscape` (or the equivalent default for a UNIX or LINUX environment).

– Example database path name for Windows: `c:\temp\sampleDB`
– Example database path name for UNIX or LINUX: `/tmp/sampleDB`

If no database currently exists for the path name you want to specify, simply append `;create=true` to the path name to create a database dynamically. (For example: `c:\temp\sampleDB;create=true`)

3. **Cloudscape Network Server using Universal JDBC driver**

This Cloudscape driver takes advantage of the Network Server support that the DB2 universal Type 4 JDBC driver provides. You cannot use any Version 4.0 data sources with Cloudscape.

Cloudscape uses the DB2 Universal Driver when using the Network Server. It supports one phase data source:

com.ibm.db2.jcc.DB2ConnectionPoolDataSource

Requires JDBC driver files:

- **db2jcc.jar** If you install and run DB2, you must use the **db2jcc.jar** file that comes with DB2. To do that, the classpath in the JDBC template for Cloudscape network server is set to be:

```
<classpath>${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar</classpath>

<classpath>${CLOUDSCAPE_JDBC_DRIVER_PATH}/db2j.jar</classpath>

<classpath>${CLOUDSCAPE51_JDBC_DRIVER_PATH}/db2j.jar</classpath>

<classpath>${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar</classpath>
```

  which means that the db2jcc.jar from DB2 always takes precedence. Note that this also means that you must set the DB2 environment variable **DB2UNIVERSAL_JDBC_DRIVER_PATH** in WebSphere when you set up your DB2 datasource. This is instead of hard coding the path of the db2jcc.jar for DB2 datasources.
- **db2jcc_license_cu.jar** This file is the DB2 Universal JDBC license file that provides access to the Cloudscape databases using the **Network Server** framework. Use this file to gain access to the database. This file ships with WebSphere and is located in **${UNIVERSAL_JDBC_DRIVER_PATH}**.

  Note: **UNIVERSAL_JDBC_DRIVER_PATH** is a WebSphere environment variable that is already defined to the location in Websphere Application Server where the license jar file above is located, and will only be used if the **DB2UNIVERSAL_JDBC_DRIVER_PATH** is not set. DB2 users should ensure that **DB2UNIVERSAL_JDBC_DRIVER_PATH** is set to avoid loading multiple versions of the db2jcc.jar file.

  Note: **DB2UNIVERSAL_JDBC_DRIVER_PATH** is a WebSphere environment variable that you must set to point to the location of db2jcc.jar file (that comes with DB2). This variable is set only if you create a db2 provider.

  Note: Cloudscape requires only db2jcc_license_c.jar; however, WebSphere Application Server uses db2jcc_license_cu.jar because this works for both DB2 UDB and Cloudscape.

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.CloudscapeNetworkServerDataStoreHelper`

Note: The administrative console incorrectly lists the DB2UniversalDataStoreHelper as the default value for the **DataStoreHelper** class. You must change the default value to `com.ibm.websphere.rsadapter.CloudscapeNetworkServerDataStoreHelper`. Also change the custom properties, using the instructions in the customer property section.

Requires a valid authentication alias.

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, Application Server uses the default location of `WAS_HOME./cloudscape` (or the equivalent default for a UNIX or LINUX environment).
  – Example database path name for Windows: `c:\temp\sampleDB`
  – Example database path name for UNIX or LINUX: `/tmp/sampleDB`

If no database currently exists for the path name you want to specify, simply append `;create=true` to the path name to create a database dynamically. (For example: `c:\temp\sampleDB;create=true`)
- **driverType** Only the Type 4 driver is allowed.
- **serverName** The TCP/IP address or the host name for the Distributed Relational Database Architecture (DRDA) server.
- **portNumber** The TCP/IP port number where the DRDA server resides. The default value is port ***1527***.
- **retrieveMessagesfromServerOnGetMessage** This property is required by WebSphere Application Server, not the database. The default value is ***false***. You must set the value of this property to ***true***, to enable text retrieval using the **`SQLException.getMessage()`** method.

See the Cloudscape setup instructions for more information on configuring the Cloudscape Network Server.

For more information on IBM Cloudscape, visit the Cloudscape Web site at: http://www.ibm.com/software/data/cloudscape/

Informix

1. **Informix JDBC Driver**

   The Informix JDBC Driver is a Type 4 JDBC driver that provides JDBC access to the Informix database.

   Informix JDBC Driver supports one phase data source:

   `com.informix.jdbcx.IfxConnectionPoolDataSource`

   Requires JDBC driver files:

   `ifxjdbc.jar`
   `ifxjdbcx.jar`

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.InformixDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:
   - **serverName** The name of the Informix instance on the server. Example: *ol_myserver*.
   - **portNumber** The port on which the instances listen. Example: *1526*.
   - **ifxIFXHOST** Either the IP address or the host name of the machine that is running the Informix database to which you want to connect. Example: *myserver.mydomain.com*.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
   - **informixLockModeWait** Although not required, this property enables you to set the number of seconds that Informix software waits for a lock. By default, Informix code throws an exception if it cannot immediately acquire a lock. Example: *2*.

2. **Informix JDBC Driver (XA)**

   The Informix JDBC Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Informix database.

   Informix JDBC Driver (XA) supports two phase data source:

   `com.informix.jdbcx.IfxXADataSource`

   Requires JDBC driver files:

   `ifxjdbc.jar`
   `ifxjdbcx.jar`

   Requires **`DataStoreHelper`** class:

   `com.ibm.websphere.rsadapter.InformixDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:
   - **serverName** The name of the Informix instance on the server. Example: *ol_myserver*.
   - **portNumber** The port on which the instances listen. Example: *1526*.

- **ifxIFXHOST** Either the IP address or the host name of the machine that is running the Informix database to which you want to connect. Example: *myserver.mydomain.com*.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
- **informixLockModeWait** Although not required, this property enables you to set the number of seconds that Informix software waits for a lock. By default, Informix code throws an exception if it cannot immediately acquire a lock. Example: *2*.

For more information on Informix, visit the Informix Web site at: http://www.ibm.com/software/data/informix/

Sybase

1. **Sybase JDBC Driver**

   The Sybase JDBC Driver is a Type 4 JDBC driver that provides JDBC access to the Sybase database.

   Sybase JDBC Driver supports one phase data source:

   com.sybase.jdbc2.jdbc.SybConnectionPoolDataSource

   Requires JDBC driver files: **jconn2.jar**.

   Requires **DataStoreHelper** class:

   `com.ibm.websphere.rsadapter.SybaseDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:
   - **serverName** The name of the database server. Example: *myserver.mydomain.com*.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
   - **portNumber** The TCP/IP port number through which all communications to the server take place. Example: *4100*.
   - **connectionProperties** A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true`(Type: java.lang.String)
2. **Sybase JDBC Driver (XA)**

   The Sybase JDBC Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Sybase database.

   Sybase JDBC Driver (XA) supports two phase data source:

   com.sybase.jdbc2.jdbc.SybXADataSource

   Requires JDBC driver files: **jconn2.jar**.

   Requires **DataStoreHelper** class:

   `com.ibm.websphere.rsadapter.SybaseDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:
   - **serverName** The name of the database server. Example: *myserver.mydomain.com*
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
   - **portNumber** The TCP/IP port number through which all communications to the server take place. Example: *4100*.
   - **connectionProperties** A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true`(Type: java.lang.String)

For more information on Sybase, visit the Sybase Web site at: http://www.sybase.com/

Oracle

1. **Oracle JDBC Driver**

   The Oracle JDBC Driver provides JDBC access to the Oracle database. This JDBC driver supports both Type 2 JDBC access and Type 4 JDBC access.

   Oracle JDBC Driver supports one phase data source:

oracle.jdbc.pool.OracleConnectionPoolDataSource

Requires JDBC driver files: **ojdbc14.jar**. (Note: If you require Oracle trace, use **ojdbc14_g.jar**.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.OracleDataStoreHelper`

(Note: If you are running Oracle10g, use `com.ibm.websphere.rsadapter.Oracle10gDataStoreHelper`.

Requires a valid authentication alias.

Requires properties:

- **URL** The URL that indicates the database from which the data source obtains connections. Example: *jdbc:oracle:thin:@myServer:1521:myDatabase*, where *myServer* is the server name, *1521* is the port it is using for communication, and *myDatabase* is the database name.

2. **Oracle JDBC Driver (XA)**

   The Oracle JDBC Driver (XA) provides XA-compliant JDBC access to the Oracle database. This JDBC driver supports both Type 2 JDBC access and Type 4 JDBC access.

   Oracle JDBC Driver (XA) supports two phase data source:

   oracle.jdbc.xa.client.OracleXADataSource

   Requires JDBC driver files: **ojdbc14.jar**. (Note: If you require Oracle trace, use **ojdbc14_g.jar**.)

   Requires **DataStoreHelper** class:

   `com.ibm.websphere.rsadapter.OracleDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:

   - **URL** The URL that indicates the database from which the data source obtains connections. Example: *jdbc:oracle:thin:@myServer:1521:myDatabase*, where *myServer* is the server name, *1521* is the port it is using for communication, and *myDatabase* is the database name.

For more information on Oracle, visit the Oracle Web site at: http://www.oracle.com/

MS SQL Server

1. **DataDirect ConnectJDBC type 4 driver for MS SQL Server**

   DataDirect ConnectJDBC type 4 driver for MS SQL Server is a Type 4 JDBC driver that provides JDBC access to the MS SQL Server database. This provider is for use only with the Connect JDBC driver purchased from DataDirect Technologies.

   This JDBC provider supports this data source:

   com.ddtek.jdbcx.sqlserver.SQLServerDataSource

   Requires JDBC driver files:

   sqlserver.jar,
   base.jar and **util.jar**

   (The **spy.jar** file is optional. You need this file to enable spy logging. The **spy.jar** file is not in the same directory as the other three jar files. Instead, it is located in the `../spy/` directory.)

   Requires **DataStoreHelper** class:

   `com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper`

   Requires a valid authentication alias.

   Requires properties:

   - **serverName** The name of the server in which MS SQL Server resides. Example: *myserver.mydomain.com*
   - **portNumber** The TCP/IP port that MS SQL Server uses for communication. Port 1433 is the default.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

2. **DataDirect ConnectJDBC type 4 driver for MS SQL Server (XA)**

DataDirect ConnectJDBC type 4 driver for MS SQL Server (XA) is a Type 4 JDBC driver which provides XA-compliant JDBC access to the MS SQL Server database. This provider is for use only with the Connect JDBC driver purchased from DataDirect Technologies.

This JDBC provider supports this data source:

com.ddtek.jdbcx.sqlserver.SQLServerDataSource.

Requires JDBC driver files:

sqlserver.jar,
base.jar and **util.jar.**

(The **spy.jar** file is optional. You need this file to enable spy logging. The **spy.jar** file is not in the same directory as the other three jar files. Instead, it is located in the **../**spy/ directory.)

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper

Requires a valid authentication alias.

Requires properties:

- **serverName** The name of the server in which MS SQL Server resides. Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that MS SQL Server uses for communication. Port 1433 is the default.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

For more information on the DataDirect ConnectJDBC driver, visit the DataDirect Web site at: http://www.datadirect-technologies.com/

3. **DataDirect SequeLink type 3 JDBC driver for MS SQL Server** -- Deprecated

   Because this JDBC provider is deprecated in WebSphere Application Server Version 6.0, it is no longer an available option in the administrative console. In its place, use one of the Connect JDBC providers, which are described previously in this section.

   DataDirect SequeLink type 3 JDBC driver for MS SQL Server is a type 3 JDBC driver that provides JDBC access to MS SQL Server via SequeLink server.

   This JDBC provider supports this data source:

   com.ddtek.jdbcx.sequelink.SequeLinkDataSource

   Requires JDBC driver files:

   sljc.jar and
   spy-sl.jar

   (The JDBC driver shipped with WebSphere Application Server requires the **sljc.jar** and the **spy-sl.jar** files. The JDBC driver purchased from DataDirect requires the **sljc.jar** and the **spy.jar** files. The **spy.jar** and **spy-sl.jar** files are optional. You need these files to enable spy logging.)

   Requires **DataStoreHelper** class:

   com.ibm.websphere.rsadapter.SequeLinkDataStoreHelper

   Requires a valid authentication alias.

   Requires properties:

   - **serverName** The name of the server in which SequeLink Server resides. Example: *myserver.mydomain.com*
   - **portNumber** The TCP/IP port that SequeLink Server uses for communication. By default, SequeLink Server uses port 19996.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

4. **DataDirect SequeLink type 3 JDBC driver for MS SQL Server (XA)** -- Deprecated

   Because this JDBC provider is deprecated in WebSphere Application Server Version 6.0, it is no longer an available option in the administrative console. In its place, use one of the Connect JDBC providers, which are described previously in this section.

   DataDirect SequeLink type 3 JDBC driver for MS SQL Server (XA) is a type 3 JDBC driver that provides XA-compliant JDBC access to MS SQL Server via the SequeLink server.

This JDBC provider supports this data source:

com.ddtek.jdbcx.sequelink.SequeLinkDataSource

Requires JDBC driver files:

sljc.jar and
spy-sl.jar

(The JDBC driver shipped with WebSphere Application Server requires the **sljc.jar** and the **spy-sl.jar** files. The JDBC driver purchased from DataDirect requires the **sljc.jar** and the **spy.jar** files. The **spy.jar** and **spy-sl.jar** files are optional. You need these files to enable spy logging.)

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.SequeLinkDataStoreHelper

Requires a valid authentication alias.

Requires properties:

- **serverName** The name of the server in which SequeLink Server resides. Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that SequeLink Server uses for communication. By default, SequeLink Server uses port 19996.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

Both of the WebSphere-embedded SequeLink JDBC drivers require installation of SequeLink Server on all machines running MS SQL Server. See the readme.html file found in the DataDirect folder on the WebSphere Application Server CD for instructions on how to install SequeLink Server. (Only install SequeLink Server from the WebSphere Application Server CD if you are using the SequeLink JDBC driver embedded in WebSphere. Otherwise, install a copy of SequeLink Server purchased from DataDirect Technologies.)

From the following FTP site, you can download the latest patches and upgrades for the version of SequeLink Server that is used with the WebSphere-embedded SequeLink JDBC driver:

ftp://ftp.software.ibm.com/software/websphere/info/tools/DataDirect/datadirect.htm

For more information on the DataDirect SequeLink type 3 JDBC driver, visit the DataDirect Web site at:

http://www.datadirect-technologies.com/

5. **Microsoft JDBC driver for MSSQLServer 2000** -- Deprecated

   Because this JDBC provider is deprecated in WebSphere Application Server Version 6.0, it is no longer an available option in the administrative console. In its place, use one of the Connect JDBC providers, which are described previously in this section.

   Microsoft JDBC driver for MSSQLServer 2000 is a type 4 JDBC driver that provides JDBC access to the MS SQL Server database.

   This JDBC provider supports this data source:

   com.microsoft.jdbcx.sqlserver.SQLServerDataSource

   Requires JDBC driver files:

   mssqlserver.jar,
   msbase.jar and **msutil.jar**

   (The **spy.jar** file is optional. You need it to enable spy logging. However, Microsoft does not ship the **spy.jar** file. Contact Microsoft about this issue.)

   Requires **DataStoreHelper** class:

   com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper

   Requires a valid authentication alias.

   Requires properties:

   - **serverName** The name of the server in which MS SQL Server resides. Example: *myserver.mydomain.com*
   - **portNumber** The TCP/IP port that MS SQL Server uses for communication. Port 1433 is the default.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

6. **Microsoft JDBC driver for MSSQLServer 2000 (XA)** -- Deprecated

   Because this JDBC provider is deprecated in WebSphere Application Server Version 6.0, it is no longer an available option in the administrative console. In its place, use one of the Connect JDBC providers, which are described previously in this section.

   Microsoft JDBC driver for MSSQLServer 2000 (XA) is a type 4 JDBC driver that provides XA-compliant JDBC access to the MS SQL Server database.

   This JDBC provider supports this data source:

   com.microsoft.jdbcx.sqlserver.SQLServerDataSource

   Requires JDBC driver files:

   mssqlserver.jar,
   msbase.jar and **msutil.jar**

   (The **spy.jar** file is optional. You need it to enable spy logging. However, Microsoft does not ship the **spy.jar** file. Contact Microsoft about this issue.)

   Requires **DataStoreHelper** class:

   com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper

   Requires a valid authentication alias.

   Requires properties:
   - **serverName** The name of the server in which MS SQL Server resides. Example: *myserver.mydomain.com*
   - **portNumber** The TCP/IP port that MS SQL Server uses for communication. Port 1433 is the default.
   - **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

For more information on the Microsoft JDBC driver, visit the Microsoft Web site at:

http://www.microsoft.com/sql

Creating and configuring a JDBC provider using the administrative console:

An application installed on WebSphere Application Server accesses a relational database through a JDBC provider, which is essentially a system-level software driver. For at-a-glance information on which provider type is appropriate for your database configuration and application requirements, see the JDBC provider table.

You can easily establish a JDBC provider from the administrative console.

1. Open the administrative console.
2. Click **Resources** > **JDBC Providers**.
3. Select the *scope* of your definition. (This scope becomes the scope of your data source.) You can choose cell, node, cluster, or server. For more information, see Administrative console scope settings.
4. Click **New**.

   Note: If Java script is disabled for your browser, you do not see the three drop-down lists that are described in the next three steps (for database type, provider type, and implementation type) . Instead, you see a single drop-down box that lists *all* JDBC provider choices simultaneously (inclusive of every database, provider, and implementation type).
5. Use the first drop-down list to select the database type of the JDBC provider you need to create. If the list of supported JDBC provider types does not include the JDBC provider that you want to use, select the **User-Defined JDBC Provider**. Then consult the JDBC provider vendor's documentation for information on specific properties required for data sources associated with this provider, and skip to step eight of this list.
6. From the second drop-down list, select your JDBC provider type.
7. From the third drop-down list, select the implementation type necessary for your application. If your application does not require that connections support two-phase commit transactions, choose

Connection Pool Data Source. Choose **XA Data Source**, however, if your application requires connections that support two-phase commit transactions. Applications using this data source configuration have the benefit of container-managed transaction recovery.

8. Click **Next** to view the general property settings page for your JDBC provider.
9. Ensure that all required properties have valid values. For more information, see JDBC Provider settings.
10. Click **Apply** to view the page with your new JDBC provider settings. Note that two active data source links now appear under the **Additional Properties** heading on this page. To set up a data source, click the link that corresponds to the type required by your application, the Version 4 data source or the later version data source. (For more information, refer to the section entitled ″Choice of data source″ in the “Data sources” on page 514 topic.)
11. Click **OK** to return to the JDBC providers page, where your new JDBC provider appears in the list.

    Attention: If you modify the class path or native library path of a JDBC provider: After clicking **OK**, you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

For detailed information on creating a data source for association with your JDBC provider, see “Creating and configuring a data source using the administrative console” on page 589.

JDBC Provider collection:

Use this page to view a JDBC provider.

To view this administrative console page, click **Resources** > **JDBC Providers** in the console navigation tree.

Notice the *Scope* of your JDBC provider. If you pick anything other than the default of *Node* the provider might not be available in other scope contexts. New items created in this view are created within the selected scope.

Name:

Specifies a text identifier for this provider.

For example, this field can be *DB2 JDBC Provider (XA)*.

Data type String

Description:

Specifies a text string describing this provider.

Data type String

JDBC provider settings:

Use this page to create or modify JDBC provider settings.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider*.

Important: If you use this page to *modify* the class path or native library path of an existing JDBC provider: After you apply and save the new settings, you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

Name:

Specifies the name of the resource provider.

Data type String

Description:

Specifies a text description for the resource provider.

Data type String

Class path:

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

For example, */usr/lpp/db2/db2710/classes/db2j2classes.zip*

Class path entries are separated by using the ENTER key and must not contain path separator characters (such as ';' or ':'). Class paths contain variable (symbolic) names which you can substitute using a variable map. Check the driver installation notes for the specific required JAR file names.

Data type String

Native Library Path:

Specifies a list of paths that forms the location for the resource provider native libraries.

Native path entries are separated by using the ENTER key and must not contain path separator characters (such as ';' or ':'). Native paths can contain variable (symbolic) names which you can substitute using a variable map.

Data type String

Implementation class name:

Specifies the Java class name of the JDBC driver implementation.

This class is available in the driver file mentioned in the class path description above. For example, *COM.ibm.db2.jdbc.DB2XADataSource*.

Note: If you modify the implementation class name of the JDBC provider after you have created the provider, you might disconnect the provider from the template used to create it. As a result, data sources created from this JDBC provider do not have an associated template; you must manually configure a working data source through setting custom properties.

Data type String

New JDBC Provider:

Use this page to create a new JDBC provider.

To view this administrative console page, click **Resources** >**JDBC Providers** > **New**.

Step 1: Select the database type:

Choose a supported database type.

If the list of supported database types does not include the type that you want to use, select **User-Defined**. You might need to consult the documentation for the database for more information on specific properties that database requires.

Data type Drop-down list

Step 2: Select the JDBC provider type:

Choose a supported JDBC Provider type.

Only JDBC provider types that are appropriate for the database type you selected in step 1 will appear in the list. For at-a-glance information on which provider type is appropriate for your database configuration and application requirements, see the JDBC provider table.

Data type Drop-down list

Step 3: Select the implementation type:

Choose a supported implementation type.

Only the implementation types supported by the JDBC provider you selected in step 2 will appear in the list.

Note: If two choices appear on the implementation type list, select **Connection Pool DataSource** if your application runs in a single phase or local transaction. Otherwise, choose **XA DataSource** to run in a global transaction.

Data type Drop-down list

JDBC provider summary:

Database type	JDBC Provider	Transaction support	Version and other considerations
DB2 on Windows, UNIX, or workstation-based LINUX	DB2 Universal JDBC Provider	One phase only	
	DB2 Universal JDBC Provider (XA)	One and two phase	The XA implementation is *not* supported in WebSphere Application Server run on workstation-based LINUX
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	

Database type	JDBC Provider	Transaction support	Version and other considerations
DB2 UDB for iSeries	DB2 UDB for iSeries (Native)	One phase only	Recommended for use with WebSphere Application Server **run on iSeries**
	DB2 UDB for iSeries (Native XA)	One and two phase	Recommended for use with WebSphere Application Server **run on iSeries**
	DB2 UDB for iSeries (Toolbox)	One phase only	
	DB2 UDB for iSeries (Toolbox XA)	One and two phase	
	DB2 Universal JDBC Provider (XA)	One and two phase	**-***Only* for use with WebSphere Application Server **run on z/OS** **-**Only driver type 4 is supported **-**Does *not* support Version 4 data sources
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect driver (available from DB2)
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect driver (available from DB2)

Database type	JDBC Provider	Transaction support	Version and other considerations
DB2 on z/OS	DB2 for z/OS Local JDBC Provider (RRS)	One and two phase	*Only* for use with WebSphere Application Server **run on z/OS**
	DB2 Universal JDBC Provider	One phase only	
	DB2 Universal JDBC Provider (XA)	One and two phase	**-**Only driver type 4 is supported in WebSphere Application Server **run on z/OS** **-**Does *not* support Version 4 data sources in WebSphere Application Server **run on z/OS**
	DB2 legacy CLI-based Type 2 JDBC Provider	One phase only	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect program (available from DB2)
	DB2 legacy CLI-based Type 2 JDBC Provider (XA)	One and two phase	**-***Only* for use with WebSphere Application Server run on Windows, UNIX, or workstation-based LINUX **-** Requires the DB2 Connect program (available from DB2)
Cloudscape	Cloudscape JDBC Provider	One phase only	**-** Not for use in clustering environment: Cloudscape is accessible from a single JVM only **-** Does not support Version 4 data sources
	Cloudscape JDBC Provider (XA)	One and two phase	**-** Not for use in clustering environment: Cloudscape is accessible from a single JVM only **-** Does not support Version 4 data sources
	Cloudscape Network Server using Universal JDBC driver	One phase only	Does not support Version 4 data sources
Informix	Informix JDBC Driver	One phase only	
	Informix JDBC Driver (XA)	One and two phase	
Sybase	Sybase JDBC Driver	One phase only	
	Sybase JDBC Driver (XA)	One and two phase	

Database type	JDBC Provider	Transaction support	Version and other considerations
Oracle	Oracle JDBC Driver	One phase only	
	Oracle JDBC Driver (XA)	One and two phase	
MS SQL Server	DataDirect ConnectJDBC type 4 driver for MS SQL Server	One phase only	Only for use with the corresponding driver from DataDirect Technologies
	DataDirect ConnectJDBC type 4 driver for MS SQL Server (XA)	One and two phase	Only for use with the corresponding driver from DataDirect Technologies
	WebSphere embedded ConnectJDBC driver for MS SQL Server	One phase only	- Not available for Application Server on z/OS - Cannot be used outside of WebSphere Application Server environment
	WebSphere embedded ConnectJDBC driver for MS SQL Server (XA)	One and two phase	- Not available for Application Server on z/OS - Cannot be used outside of WebSphere Application Server environment

Using a DB2 for z/OS Local JDBC Provider (RRS) with WebSphere Application Server for z/OS:

Setting up a JDBC provider for DB2 for z/OS and creation of a data source in WebSphere Application Server for z/OS is complicated by the fact that the JDBC driver must locate and load the DSNJDBC_JDBCProfile.ser file. DB2 for z/OS Version 7 has enhanced the mechanism by which the JDBC driver locates and loads this file to accommodate WebSphere Application Server for z/OS.

The steps to install a JDBC provider using this new support are:
- Update the PROCs for the servant address spaces to include the DB2 libraries. (optional)
- Create/update the db2sqljjdbc.properties file to indicate the location of the DSNJDBC_JDBCProfile.ser file.
- Create/update WebSphere environment variables so the WebSphere server can locate the DB2 home directory and the JDBC driver can locate the db2sqljjdbc.properties file.
- Define J2C Authentication Aliases to provide userid with password to be used when connecting to DB2k.
- Define the DB2 for z/OS Local JDBC Provider (RRS) for data access.
- Define a data source specifying the aliases for component and container connections. (optional)

1. Update the PROCs for the servant address spaces to include the DB2 libraries. (optional)

   Installations have the option of placing the DB2 libraries in the linklist or //STEPLIB DD concatenation for the WebSphere address spaces that will use JDBC. In some installations a combination of techniques are used. If your installation does not have SDSNEXIT, SDSNLOAD and SDSNLOD2 in the linklist, then you must update the //STEPLIB DD concatenation for the servant address space with the missing libraries.

   Consider the following example:

   The system on which WebSphere for z/OS Version 5 is active has multiple DB2 subsystems of different versions. There are the JUDY and DBP3 subsystems, where DBP3 is the default DB2 subsystem from a linklist perspective. The p5serv1 server uses the JUDY subsystem, hence the servant address space associated with the p5srv1 server must specify the appropriate DB2 libraries in the //STEPLIB DD concatenation.

On this system, the servant address space uses procedure P5NCASR, which includes member P5NCASRZ, which contains the //STEPLIB DD concatenation. The last three lines in the following are the updates, in gray area, which that were made for JDBC access to the JUDY subsystem.

```
 //* P5NCASRZ
//*
//* Output DDs
//*
//CEEDUMP DD SYSOUT=*
//SYSOUT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*
//*
//*Steplib Setup
//*
//STEPLIB DD DISP=SHR,DSN=WAS500.WAS.SBBOLD2
// DD DISP=SHR,DSN=WAS500.WAS.SBBOLOAD
// DD DISP=SHR,DSN=DSN710.JUDY.SDSNEXIT
// DD DISP=SHR,DSN=DSN710.SDSNLOAD
// DD DISP=SHR,DSN=DSN710.SDSNLOD2
//*
```

2. Create/update the db2sqljjdbc.properties file to indicate the location of the DSNJDBC_JDBCProfile.ser file.

   The db2sqljjdbc.properties file contains information which the DB2 JDBC driver uses to configure itself. The following are the contents of the db2sqljjdbc.properties file created for the use of the WebSphere servers running in node *nodec* of cell *p5cell* and in particular server *p5srv1*.

   The area near the bottom under db2.connpool.max.size=100 indicates the new means by which the location of the DSNJDBC_JDBCProfile.ser file is specified using as of APAR PQ69861.

```
# >>> Start of p5nc_wscjudy_db2sqljjdbc.properties <<<
#
# Any lines starting with the pound sign '#'
# are comments. Please see the DB2 for OS/390
# Application Programming Guide and Reference
# for Java for the description of these settings.
#
#
# This DBRMLIB is specific for the DSN7 subsystem and the JDBC driver.
#
#DB2SQLJDBRMLIB=DSN710.DBRMLIB.DATA
#
# This is installation specific: the name of the DB2 subsystem to use.
#
DB2SQLJSSID=JUDY
#
# The next 5 items are default values which are coded for documentation
#
#
DB2SQLJPLANNAME=DSNJDBC
DB2SQLJJDBCPROGRAM=DSNJDBC
DB2SQLJMULTICONTEXT=YES
DB2SQLJATTACHTYPE=RRSAF
DB2CURSORHOLD=YES
#
#
# The following items are for tracing, there are no default values
#
#DB2SQLJ_TRACE_FILENAME=/tmp/p5srv1_jdbc
#DB2SQLJ_TRACE_BUFFSIZE=256
#DB2SQLJ_TRACE_WRAP=1
#
#
db2.connpool.max.size=100
#
# The following allows the JDBC driver to find and
# load the serialized profile.
#
```

```
db2.jdbc.profile.pathname=/usr/lpp/db2710/classes/DSNJDBC_JDBCProfile.ser
#
# <<< End of p5nc_wscjudy_db2sqljjdbc.properties >>>
```

The key entries in this file are:

DB2SQLJSSID
Identifies the DB2 subsystem (for example, JUDY) that should be used by the JDBC driver

db2.jdbc.profile.pathname
Identifies the serialized profile (for example, /usr/lpp/db2710/classes/DNSJDBC_JDBCProfile.ser) to be used by the JDBC dsriver. This is a new property introduced by APAR PQ69861.

Note: WebSphere for z/OS has always recommended specifying the db2sqljjdbc.properties and contents rather than assuming the defaults. While it is possible for the JDBC driver to locate the DB2 subsystem through specifying SSID in the DSNHDECP module, which resides in SDSNEXT library, rather than db2sqljjdbc.properties file, it is useful having a properties file for several reasons. Being able to specify the location of the serialized profile makes the definition of the DB2 JDBC provider less complicated.

Note: This file must be placed in the HFS in a directory that is readable by the all the servant address spaces on the z/OS image. It must be in codepage Cp1047 (for example, EBCDIC).

3. Create/update WebSphere environment variables so the WebSphere server can locate the DB2 home directory and the JDBC driver can locate the db2sqljjdbc.properties file.

   The WebSphere for z/OS configuration needs to have WebSphere and POSIX environment variables set so that the DB2 home directory and the db2sqljjdbc.properties file can be located. Click on Environment > Manage WebSphere Variables. Select the node level view and click Apply.

   There are two variables of interest.

   a. **DB2390_JDBC_DRIVER_PATH** This variable will be present but have no assigned value. Update this value to the directory in which the DB2 code resides. For example: /usr/lpp/db2/db2710
   b. **DB2SQLJPROPERTIES** This variable will not be present. Add this value to indicate the location and name of DB2 JDBCSQLJ properties file which you created for this node. For example: /shared/zWebSphere/V5/misc/p5nc_wscjudy_db2sqljjdbc.properties

   Note: These variables are set at the node level and thus are applicable to all servers in the node residing on this system. They can be set at the server level instead of or in addition to setting them at the node level.

   Note: The DB2390_JDBC_DRIVER_PATH variable could actually be set at the cell level and removed from the node level definitions if all nodes in the cell will use the same DB2 home directory.

   Note: The DB2SQLJPROPERTIES should not be set at the cell level, as it contains the specific DB2 subsystem to which the JDBC driver will use.

   Note: The /shared/zWebSphere/V5/misc/ directory is a commonly accessible directory for all systems in the sysplex. The name of the file indicates which cell (for example, p5) and node (for example, nc) that it is intended to be used. It is certainly possible to use a non-shared directory that is system specific (for example, /etc/zWebSphere/V5/misc/...)

   Note: After these updates have been made and saved, it is necessary to restart the server to have the server use the //STEPLIB DD updates from Step 1, if required, and to have the POSIX runtime environment variables refreshed with the changes made in this step. This restart can be delayed, but it must be done before the data source created in the last step can be used.

4. Define J2C Authentication Aliases to provide userid with password to be used when connecting to DB2k.

If you do not want to connect to DB2 with the servant region's userid, you must define an alias that holds a userid and password to be used on the getConnection( ) method. Click on Security > Configuration > J2C Authentication Data.

Click New and specify an alias, a userid and a password that can be passed to DB2 (or any other J2C resource), then click Apply.

Note: Add as many aliases as you require for access to DB2.

5. Define the DB2 for z/OS Local JDBC Provider (RRS) for data access.

   From the administrative console, click Resources > JDBC Providers. Select the server on which you want to install a JDBC provider and click Apply.

   Click New. In the list of JDBC providers, select **DB2 390 Local JDBC Provider (RRS)**, then click Apply.

6. Define a data source specifying the aliases for component and container connections. (optional)

   Select data source to create a data source for a J2EE 1.3 compliant application (creating a data source for a J2EE 1.2 compliant application is left as an exercise for the reader).

   Click New. Scroll down on the Data Sources panel, and specify for your data source:

   - A Name
   - A JNDI name
   - The database name, which is the location of the DB2 subsystem that manages the data you want to access
   - A Component-managed Authentication Alias (optional)
   - A Container-managed Authentication Alias (optional)

   Indicate if you want this data source to be used for container managed persistence, then click Apply. Save all of your changes to the master configuration.

   Now you are ready to install an application and test your data source.

Using a DB2 Universal JDBC Driver Provider with WebSphere Application Server for z/OS:

Verify that DB2 Universal JDBC Driver on z/OS and all the files required by WebSphere Application Server for z/OS are installed and available in an HFS directory before you continue with this configuration.

To use DB2 Universal JDBC Driver with WebSphere Application Server for z/OS, one of the following versions of the driver must be installed. Refer to the APARs and DB2 product information for details on installation.

- The DB2 Universal JDBC Driver in DB2 UDB for z/OS Version 8. This version supports both driver Types 2 and 4.
- The DB2 Universal JDBC Driver Provider by APAR PQ80841 on DB2 UDB for OS/390 and z/OS Version 7. This version supports both driver Types 2 and 4.
- The z/OS Application Connectivity to DB2 for z/OS feature that provides DB2 Universal JDBC Driver Type 4 connectivity. This version supports only driver Type 4 connectivity to DB2 databases. If this driver is installed, only the DB2 Universal JDBC Driver Provider (XA) can be used on WebSphere Application Server for z/OS to access remote DB2 databases.

Remember: Because DB2 constantly augments its support for WebSphere Application Server, consult DB2 service updates to see if the product offers an upgraded version of the driver that you need.

To use a DB2 Universal JDBC Driver with WebSphere Application Server for z/OS, you must:

- Configure the DB2 Universal JDBC Driver.
- Define a DB2 Universal JDBC Driver provider for WebSphere Application Server for z/OS.
- Define a DB2 Universal JDBC Driver provider data source.

1. Configure the DB2 Universal JDBC Driver for WebSphere Application Server for z/OS
   a. Define a DB2 Universal JDBC Driver provider

      Before you create a JDBC provider for the DB2 Universal JDBC Driver for z/OS, WebSphere Application Server for z/OS must know the location of the installed DB2 Universal JDBC Driver and license file, and the location of any native files that might be required by the DB2 Universal JDBC Driver. To do this, from the WebSphere Application Server for z/OS Administrative Console, go to Environment > Manage WebSphere Variables, and update the values of the following environment variables:

      1) **DB2UNIVERSAL_JDBC_DRIVER_PATH**

         Specify the fully-qualified path of the directory that contains the DB2 Universal JDBC Driver. This must be the directory that contains the db2jcc.jar and the db2jcc_license_cisuz.jar.

         Example: If the fully-qualified path of the db2jcc.jar is /usr/lpp/db2810/jcc/classes/db2jcc.jar, specify /usr/lpp/db2810/jcc/classes as the value of the variable.

      2) **DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH**

         Specify the fully-qualified directory path of the directory that contains the DB2 Universal JDBC Driver native files, if necessary. This is the directory that contains the driver files that have a .so file type. If the driver version you are using does not require native files, leave this value at null.

         Example: If the fully-qualified path of the directory containing the native files is /usr/lpp/db2810/jcc/lib, specify /usr/lpp/db2810/jcc/lib as the value of the variable.

   b. Bind the required DB2 packages

      As with any application that executes SQL statements in DB2 for z/OS, the Universal JDBC driver must first bind with DB2 the packages that represent the SQL statements to be executed. The Universal JDBC Driver does not use the same packages used by the legacy JDBC driver, and uses a different process for binding its packages.

      The specific details of the bind utility and bind process are described by the README provided with the installed DB2 Universal JDBC Driver. Refer to this README for details on how to setup and perform the required binding.

      Also note that the utility requires the server name (or IP address), the port number, and the database name (the database location on z/OS) for the target DB2. To get this information, issue a DB2 **-DISPLAY DDF** command on the target DB2 system. This displays the IPADDR (IP address), the SQL DOMAIN (server name), the TCPPORT number, and the LOCATION (database name/location) for you to use as input to the utility.

      You must perform the bind process for each target DB2 that will be accessed using the DB2 Universal JDBC Driver.

   c. Set up to handle in-doubt transactions

      You must perform this setup once for each target DB2 for z/OS Version 7 location that is accessed using the DB2 Universal JDBC Driver Type 4 XA support.

      Because DB2 for z/OS Version 7 does not implement J2EE XA support, the Type 4 driver XA processing uses DB2 V7 two-phase commit protocol and a table in each location (database) to store a list of global transactions that are in doubt (finished but not committed).

      This table must be set up at each DB2 V7 location that is accessed. To do this, use the In-Doubt Utility, which is included as part of the installed DB2 Universal JDBC Driver. Use this utility to create the SYSIBM.INDOUBT Table that stores information about In-Doubt Global Transactions. This utility also binds the package T4XAIndbtPkg, which contains the SQL statements to insert and delete from the SYSIBM.INDOUBT Table. The T4XAIndbtPkg package is written with SQLJ.

      This installation process requires that the target DB2 subsystem be configured with DDF enabled for incoming TCP/IP connections.

      1) To enable DDF on the target DB2, issue the DB2 **-START DDF** command on that system.
      2) This utility requires the server name (or IP address) and the port number for the target DB2 V7. To obtain this information, issue a DB2 **-DISPLAY DDF** command on the target DB2 V7

system. This displays the IPADDR (IP address), the SQL DOMAIN (server name), and the TCPPORT number that can be used as input to the utility.

To find more detailed information about the In-Doubt utility, refer to the *DB2 Universal Database for z/OS Version 7 Application Programming Guide and Reference for Java™* publication. (You can download it from the Library section of the DB2 Universal Database for z/OS Version 7 product information Web pages.) Within this publication, search for discussion about the utility under **DB2T4XAIndoubtUtil**, which is the official name of the In-Doubt utility.

Note: The previously described setup for in-doubt transactions is ***not*** a requirement for DB2 FOR z/OS Version 8 servers because DB2 FOR z/OS Version 8 natively supports XA commands over DRDA and manages the In-Doubt Global Transactions internally.

d. Define a db2.jcc.propertiesFile

A db2.jcc.propertiesFile for use by DB2 Universal JDBC Driver Type 2 processing under WebSphere Application Server for z/OS can be created and specified as input to the driver. This runtime properties file is for use in specifying various runtime options that the DB2 Universal JDBC Driver uses for Type 2 connectivity. These options are specified as properties in the form of parameter=value. Refer to the README file packaged with the installed DB2 Universal JDBC Driver for a detailed description of each of the properties.

This file is not required; however, if it is not provided, universal driver default processing is performed.

Of specific interest is the db2.jcc.ssid property. This property specifies the DB2 subsystem identifier (not location name), to be used by the DB2 Universal JDBC Driver Type 2 processing as the local subsystem name to which it should connect. If this property is not provided, the driver uses the subsystem identifier that it finds in the DSNHDECP load module. If the installation wants to use the DSNHDECP load module to specify the subsystem identifier, this load module must be included in a steplib dataset in the servant region PROCs associated with each server that will use the DB2 identified by the subsystem ID. Refer to the README file packaged with the universal driver for more information on using this load module. If that DSNHDECP load module does not accurately reflect the desired subsystem, or if multiple subsystems might be using a generic DSNHDECP, the db2.jcc.ssid property must be specified.

Although the db2.jcc.propertiesFile is not required, if you choose to define the file, you must specify the fully qualified-hfs-filename. To do this, specify the file as a JVM System property as follows:

- **db2.jcc.propertiesFile = <fully-qualified-hfs-filename>**

Because the driver-general properties are typically specific to a driver load (for example, server) versus to all servers using the JDBC provider, it is best that this JVM property be set at the server level. To define the **db2.jcc.propertiesFile=** property to the server level using the WebSphere Application Server for z/OS Administrative Console:

1) Under the WebSphere Application Server for z/OS Administrative Console, go to Servers > Application Servers, then click the server to which you want to add the JVM property.
2) From the selected server page, go to Process Definition > Servant.
3) On the Servant page, scroll down to the Additional Properties at the bottom of the page, then click Java Virtual Machine.
4) On the Java Virtual Machine page, scroll down to Additional Properties at the bottom of the page, then click Custom Properties.
5) On the Custom Properties page, scroll down to New to configure a new JVM property for the selected server. The name of the property is **db2.jcc.propertiesFile**. The value of the property is the fully-qualified-hfs-filename that you created and initialized with the DB2 Universal JDBC Driver properties. These are the properties that you want the Type 2 driver to use for the selected server
6) Click OK.
7) Click Save to save the new JVM property.

2. Define the DB2 Universal JDBC Driver provider.

After the DB2 Universal JDBC Driver is configured for WebSphere Application Server for z/OS, configure either a DB2 Universal JDBC Driver provider, which is non-XA, or a DB2 Universal JDBC Driver provider (XA), which supports XA. In doing so, it is important to note that if you use both the DB2 Legacy JDBC Driver and the DB2 Universal JDBC Driver under WebSphere Application Server for z/OS, you must ensure that DB2 JDBC providers associated with these two drivers are not located on the same server. (Refer to Provider Coexistence Considerations).

IBM suggests that you define your DB2 Universal JDBC Driver providers at a server level to reduce the chance of conflict with the DB2 for zOS Local JDBC Provider (RRS) that uses the DB2 Legacy JDBC Driver. Likewise, any DB2 for z/OS Local JDBC Provider you have defined must be defined at the server level to avoid conflict.

To define a DB2 Universal JDBC Driver provider:

a. From the WebSphere Application Server for z/OS Administrative Console, click Resources > JDBC Providers.
b. On the JDBC Provider page, set the JDBC Provider scope to the server upon which you want to install the new provider.
c. Click Apply.
d. Click New. The JDBC Providers page is displayed.
e. Make your selections from the three drop-down lists for either a non-XA or an XA implementation of the DB2 Univeral JDBC Driver provider:

   Non-XA implementation

   1) For database type, select DB2
   2) For provider type, select DB2 Universal JDBC Driver provider
   3) For implementation type, select Connection pool data source

   This provider supports driver Types 2 and 4. It does not support J2EE XA transaction processing. In the case of driverType 2 processing, RRS is used to coordinate transaction processing and manage global transaction using two-phase commit. In the case of driverType 4, one-phase commit processing is used to manage transactions.

   Note: Do not select this provider if your installation has the z/OS Application Connectivity to DB2 for z/OS feature defined to WebSphere Application Server for z/OS. This feature provides only universal driver type 4 XA connectivity, which is not supported by the non-XA DB2 Universal JDBC Driver provider.

   XA implementation

   1) For database type, select DB2
   2) For provider type, select DB2 Universal JDBC Driver provider
   3) For implementation type, select XA data source

   This provider supports only driverType 4. It uses J2EE XA to manage global transactions across multiple resource managers and to perform two-phase commit processing.

f. A configuration view of the selected provider displays, showing the default name of the provider, the classpath, the native library path, and the datasource implementation classname used by the provider. With the exception of the provider name, typically none of the information changes. If you choose, you can type your name for the provider in the Name field.
g. When the provider definition is complete, click Apply.
h. Finally, click Save to save the new JDBC provider.

3. Defining a DB2 Universal JDBC Driver provider data source

   To specify a data source for the defined DB2 Universal JDBC Driver provider:

   a. From the WebSphere Application Server for z/OS Administrative Console, click Resources > JDBC Providers. On the JDBC Providers page that displays, select the DB2 Universal JDBC Driver provider that requires the definition of a data source.

b. On the DB2 Universal JDBC Driver Provider page that displays, in the Additional Properties section at the bottom of the page, make a choice as follows:
   - Choose **Data Sources** if you want to define a data source for a DB2 Universal JDBC Driver provider (XA). In this case, Data Sources (Version 4) is not supported.
   - Choose **Data Sources** or **Data Sources (Version 4)** if you want to define a data source for a DB2 Universal JDBC Driver provider. This choice depends on the type of data source you want to define.

c. On the Data Sources page that displays, click New.

d. On the New page, supply values for these important properties (your security implementation, of course, does not require all of the alias types):
   - Name
   - JNDI name
   - Indicate if you want this data source to be used for container managed persistence.
   - Component-managed Authentication Alias (optional)
   - Container-managed Authentication Alias (optional)
   - Mapping-Configuration alias (optional)
   - Database name, which is the location name of the target database used when establishing connections with this data source
   - Driver type, which is the JDBC connectivity type used by the data source

     If you want to use a driverType 4, set the value to 4. If you want to use a driverType 2 , set the value to 2. If the data source is for the DB2 Universal JDBC Driver provider (XA), specify only driverType 4. Specification of driverType 2 in the case of the DB2 Universal JDBC Driver provider (XA) is not supported.
   - Server name, which is the TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server.

     This property is required only if driverType is set to 4. This property is not used if driverType is set to 2.
   - Port number, which is the TCP/IP port number where the DRDA server resides.

     Provide a value for this property only if driverType is set to 4. This property is not used if driverType is set to 2.

   Note: If you set the driverType property for the data source to 4, an appropriate managed Authentication Alias must be specified. If you set the driverType property for the data source to 2 and no managed Authentication Alias is specified, the user identity currently associated with the thread at the time of a getConnection request is used as the identity associated with the connection.

e. Click Apply. A link to Custom Properties is now available on this page.

f. Click the Custom Properties link if you want to define additional settings for your data source.

g. After specifying the properties, click **Save** to save the new data source.

Creating and configuring a data source using the administrative console:

After you create a JDBC provider, you must create a data source to access the backend data store. Application components use the data source to access connection instances to your database; a connection pool is associated with each data source. The product supports two different versions of data source:

- Version 4.0, for use with the Enterprise JavaBeans (EJB) 1.0 specification and the Java Servlet 2.2 specification
- The latest standard version for use with more advanced releases of these specifications

1. Open the administrative console.

2. Click **Resources** > **JDBC Providers**.
3. Choose the JDBC resource provider under which you want to create your data source. The detail page for this provider is displayed.
4. Under Additional Properties, click the **Data Sources** link that is appropriate for your application. The Data sources or Data sources (Version 4) page is displayed.
5. Click **New** to display the Data source settings page.
6. Verify that all the required properties have valid values.

   For data sources of the latest standard version:

   a. Select a DataStoreHelper class name from the list entitled DataStoreHelpers provided by WebSphere Application Server, or leave the default selection as is. If you want to use a data store helper other than those available in the drop-down list, click **Specify a user-defined DataStoreHelper**. Type a fully qualified class name in the field that is provided.

   b. The next section of properties varies according to the database selection, provider type, and implementation that you chose for your JDBC provider. These properties are either required or highly recommended for your data source. Provide valid values for these settings if you do not want to accept the default values.

   c. Click **Component-managed Authentication Alias** if your database requires a user ID and password for a connection. This alias is used only when the application resource reference is using `res-auth = Application`.

      Important:(For components with `res-auth=Container`) Both the Container-managed Authentication Alias and Mapping-Configuration Alias settings are deprecated. They are superseded by the specification of a login configuration on the resource-reference mapping at deployment time. You must now use this login setting to define the aliases at deployment.

   d. If you chose XA Data Source as the implementation type of your JDBC provider, you need to specify the alias used during transaction recovery processing. An additional section entitled Authentication Alias for XA Recovery is available. Select either **Use Application Authentication Alias** to use the same value that you chose for component-managed authentication, or select **Specify:** to choose a different alias from the drop-down list.
7. Click **Apply** to view a page with your new data source settings. Additional properties and Related items sections are now available on this page. Additional properties contains the Connection pool, Custom properties, and WebSphere Application Server data source properties choices. (If you are using a Version 4 data source, however, you see only the first two choices.)

   a. Click on the first link to define settings that affect the behavior of the Java 2 Connector (J2C) connection pool manager.

   a. Go to the Custom properties page to view and modify additional properties that the database vendor might require for the connection of its product to an application server.

   b. Use the WebSphere Application Server data source properties page to input settings that exclusively affect the WebSphere Application Server connection to the database.

   c. The Related items section (applicable only to later version data sources, not Version 4 data sources) contains the J2C Authentication data entries choice. Here, you can specify a list of user IDs and passwords for J2C security to use.
8. Click **Save**.
9. Return to the data source page to confirm that your new data source is displayed in the list.

You are now ready to install the application for which you configured the data sources. During installation, you can bind resource references to these data sources.

Data source collection:

Use this page to create or modify a data source.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data sources**.

Note: If you are using the Enterprise JavaBean (EJB) 1.0 specification and the Java Servlet 2.2 specification, you must use the **Data sources (Version 4)** console page.

Name:

Specifies the display name of this data source.

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for this data source.

Data type String

Description:

Specifies a text description of the data source.

Data type String

Category:

Specifies a string that you can use to classify or group a data source.

Data type String

Data source settings:

Use this page to create a data source for association with your JDBC provider. Think of the data source as a pooled set of connections necessary for conducting transactions between your application and database.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data sources** > **New** (if you are creating a new data source) or > *data_source* (if you are viewing an established data source).

Note: If your application uses an Enterprise JavaBean (EJB) 1.1 or a Java Servlet 2.2 module, you must use the **Data sources (Version 4)** > *data_source* console page.

Name:

Specifies the display name for the data source.

Valid characters for this name include letters and numbers, but NOT most of the special characters. For example you can set this field to *Test Data Source*. But any name starting with a period (•) or containing special characters (\ / , : ; ″ * ? < > | = + & % ’ `) is not a valid name.

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information on objects and the search tools required to locate those objects.

There are many naming and directory service implementations, and the interfaces to them vary. JNDI provides a common interface that is used to access the various naming and directory services.

For example, you can use the name *jdbc/markSection*.

If you leave this field blank a JNDI name is generated from the name of the data source. For example, a data source name of markSection generates a JNDI name of *jdbc/markSection*.

After you set this value, save it, and restart the server, you can see this string when you run the dump name space tool.

Data type String

Container-managed persistence:

Specifies if this data source is used for container-managed persistence of enterprise beans.

If this field is checked, a CMP Connector Factory that corresponds to this data source is created for the relational resource adapter.

Data type Checkbox
Default Enabled (The field is checked.)

Description:

Specifies a text description for the resource.

Data type String

Category:

Specifies a category string you can use to classify or group the resource.

Data type String

Data store helper class name:

Specifies the name of the DataStoreHelper implementation class that extends the capabilities of your selected JDBC driver implementation class to perform database-specific functions.

WebSphere Application Server provides a set of DataStoreHelper implementation classes for each of the JDBC provider drivers it supports. These implementation classes are in the package com.ibm.websphere.rsadapter. For example, if your JDBC provider is DB2, then your default DataStoreHelper class is com.ibm.websphere.rsadapter.DB2DataStoreHelper. The administrative console page you are viewing, however, might make multiple DataStoreHelper class names available to you in a

drop-down list; be sure to select the one required by your database configuration. Otherwise, your application might not work correctly. If you want to use a DataStoreHelper other than those displayed in the drop-down list, select **Specify a user-defined DataStoreHelper** and type a fully qualified class name. Refer to the Information Center topic ″Example: Developing your own DataStoreHelper class.″

Data type Drop-down list or string (if **user-defined DataStoreHelper** is selected)

Important data source properties: These properties are specific to the data source that corresponds to your selected JDBC provider. They are either required by the data source, or are especially useful for the data source. You can find a complete list of the properties required for all supported JDBC providers in the topic ″Vendor-specific data sources minimum required settings″ in the Information Center.

Component-managed Authentication Alias:

This alias is used for database authentication at run time.

The **Component-managed Authentication Alias** is only used when the application resource reference is using *res-auth = Application*.

If your database (for example, Cloudscape) does not support *user ID* and *password*, then do not set the alias in the component-managed authentication alias or container-managed authentication alias fields. Otherwise, you see the warning message in the system log to indicate that the user and password are not valid properties. (This message is only a warning message; the data source is still created successfully.)

If you do not set an alias (component-managed or otherwise), and your database requires the user ID and password to get a connection, then you receive an exception during run time.

Data type Drop-down list

Container-managed Authentication Alias (deprecated):

Specifies authentication data (a string path converted to userid and password) for container-managed sign-on to the resource.

Note: Beginning with WebSphere Application Server Version 6.0, the container-managed authentication alias is superseded by the specification of a login configuration on the resource-reference mapping at deployment time, for components with *res-auth=Container*.

Choose from aliases defined under **Security**>**JAAS Configuration**> **J2C Authentication Data**.

To define a new alias not already appearing in the pick list:
- Click **Apply** to expose Related Items.
- Click **J2C Authentication Data Entries**.
- Define an alias.
- Click the connection factory name at the top of the *J2C Authentication Data Entries* page to return to the connection factory page.
- Select the alias.

Data type Drop-down list

Mapping-Configuration Alias (deprecated):

Allows users to select from the **Security** > **JAAS Configuration** > **Application Logins Configuration** list.

Note: Beginning with WebSphere Application Server Version 6.0, the Mapping-Configuration Alias is superseded by the specification of a login configuration on the resource-reference mapping at deployment time, for components with *res-auth=Container*.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations.

Data type Drop-down list

Authentication Alias for XA Recovery:

This optional field is used to specify the authentication alias that should be used during XA recovery processing.

If the resource adapter does not support XA transactions, then this field will not be displayed. The default value will come from the selected alias for application authentication (if specified).

Use Component-managed Authentication Alias
Selecting this radio button specifies that the alias set for Component-managed Authentication is used at XA recovery time.

Data type Radio button

Specify:
Selecting this radio button enables you to choose an authentication alias from a drop-down list of configured aliases.

Data type Radio button

WebSphere Application Server data source properties collection:

Use this page to view the WebSphere Application Server data source properties. These properties apply to the WebSphere Application Server connection, rather than to the database connection.

To view this administrative console page, click **Resources** >**JDBC Providers** > *JDBC_provider* > **Data sources** > *data_source* > **WebSphere Application Server connection properties**.

Statement Cache Size:

Specifies the number of free statements that are cached per connection.

The WebSphere Application Server data source optimizes the processing of prepared statements. A prepared statement is a precompiled SQL statement that is stored in a prepared statement object. This object is used to efficiently execute the given SQL statement multiple times.

If the cache is not large enough, useful entries are discarded to make room for new entries. To determine the largest value for your cache size to avoid any cache discards, add the number of uniquely prepared statements and callable statements (as determined by the *sql* string, concurrency, and the scroll type) for each application that uses this data source on a particular server. This value is the maximum number of possible prepared statements that are cached on a given connection over the life of the server. Setting the cache size to this value means you never have cache discards. In general, the more statements your application has, the larger the cache should be. For example, if the application has 5 SQL statements, set the statement cache size to 5, so that each connection has 5 statements.

In test applications, tuning the statement cache improved throughput by 10-20%. However, because of potential resource limitations, this might not always be possible.

Data type	Integer
Default	Depends on the database. Most are 10. Informix Version 7.3, 9.2, or 9.3 without latest fix must be 0. A default of 0 means there is no cache statement.

Enable Multithreaded Access Detection: If checked, the application server detects the existence of access by multiple threads.

Enable WebSphere Connection Pooling: If checked, the application server sets up connect pools for this datasource.

Enable Database Reauthentication: If checked, there is not be an exact match on connections retrieved out of the WebSphere Application Server connection pool (that is, connection pool search criteria do not include user name and password). Instead, the reauthentication of connection is done in the *doConnectionSetupPerTransaction()* of the DataStoreHelper class. Note that WebSphere Application Server runtime does NOT provide connection reauthentication implementation. Therefore, when this box is checked you MUST extend the DataStoreHelper class to provide implementation of the *doConnectionSetupPerTransaction()* method where the reauthentication takes place. Failure to do that results in wrong connections being handed out to users. For more information, refer to the API documentation for *com.ibm.websphere.rsadapter.DataStoreHelper#doConnectionSetupPerTransaction(...)*.

Connection reauthentication can help improve performance by reducing the overhead of opening and closing connections, particularly for applications that always request connections with different user names and passwords.

Enable JMS One Phase Optimization Support: If checked, the application server allows JMS to get optimized connections from this data source. This property prevents JDBC applications from sharing connections with CMP applications.

PreTest Connections: If checked, the application server tries to connect to this data source before it attempts to send data to or receive data from this data source. If you select this property, you can specify how often, in seconds, the application server retries to make a connection if the initial attempt fails.

PreTest Connection Retry Interval: When **PreTest Connection** is checked, use this property to specify how long, in seconds, the application server waits before retrying to make a connection if the initial attempt fails.

PreTest SQL String:

Specifies the string of data that the application server sends to the database to test the connection.

Data type	Integer

Data sources (Version 4):

Use this page to view the settings of a Version 4.0 style data source.

These Version 4.0 data sources use the WebSphere Application Server Version 4.0 Connection Manager architecture. All EJB 1.1 modules must use a Version 4.0 data source.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data sources (Version 4)**.

Name:

Specifies a text identifier of the data source.

Data type String

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name of the data source.

Data type String

Description:

Specifies a text description of the data source.

Data type String

Category:

Specifies a text string that you can use to classify or group the data source.

Data type String

Data source (Version 4) settings:

Use this page to create a Version 4.0 style data source. This data source uses the WebSphere Application Server Version 4.0 connection manager architecture. All of your EJB1.x modules must use this data source.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data Sources (Version 4)** > *data_source*.

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the cell level, all users in that cell can look up and use that data source, which is unique within that cell. However, resource property settings are local to each server in the cell. For example, if you define *max connections* to 10, then each server in that cell can have 10 connections.

Cell The most general scope. Resources defined at the cell scope are visible from all nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the node scope override any duplicates defined at the cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server

The most specific scope for defining resources. Resources defined at the server scope override any duplicate resource definitions defined at the cell scope or parent node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type String

Name:

Specifies the display name for the resource.

For example, you can set this field to *Test Data Source*.

Data type String

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information on objects and the search tools required to locate those objects.

There are many naming and directory service implementations, and the interfaces to them vary. JNDI provides a common interface that is used to access the various naming and directory services.

For example, you can use the name *jdbc/markSection*.

If you leave this field blank a JNDI name is generated from the name of the data source. For example, a data source name of markSection generates a JNDI name of *jdbc/markSection*.

After you set this value, save it, and restart the server, you can see this string when you run the dump name space tool.

Data type String

Description:

Specifies a text description for the resource.

Data type String

Category:

Specifies a category string that you can use to classify or group the resource.

Data type String

Database Name:

Specifies the name of the database that this data source accesses.

For example, you can call the database *SAMPLE*.

Data type String

Default User ID:

Specifies the user name to use for connecting to the database.

For example, you can use the ID *db2admin*.

Data type String

Default Password:

Specifies the password used for connecting to the database.

For example, you can use the password *db2admin*.

Data type String

Custom properties:

Use this page to view and configure the custom properties of a J2EE resource provider.

You can configure custom property collections for numerous resource types. According to the resource type with which a collection is associated, your ability to add, delete, and modify individual properties and settings varies. Begin the configuration process by clicking on the *Required* field to sort those column values in descending order. All of the required (true) values are then sorted at the beginning of the page. Be sure to set all required properties.

Name:

Specifies the property name.

You must ensure that the resource provider has the setting for this name.

Data type String

Value:

Specifies the property value.

Data type Variable; see “Custom property settings” on page 599 for more information.

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type String

Required:

Specifies whether this property is required for the resource provider.

Data type Boolean or Check box

Custom property settings:

Use this page to view and set custom properties that might be required for resource providers and resource factories.

According to the resource type with which a property collection is associated, your ability to modify individual property settings varies. Therefore, consider the following descriptions as a general reference for custom property settings. (The administrative console page that you are using to configure your custom property may only allow you to modify a subset of the following settings.)

Required:

Specifies properties that are required for this resource.

Data type Check box

Name:

Specifies the name associated with this property (PortNumber, ConnectionURL, etc).

Data type String

Value:

Specifies the value associated with this property in this property set.

Data type Determined by the **Type** setting, which you select from a drop-down list. If the type is `java.lang.String` then the value is of type String; if the type is `java.lang.Integer`, then the value is of type Integer; and so on.

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type String

Type:

Specifies the fully qualified Java data type of this property .

There are specific types that are valid:
- java.lang.Boolean
- java.lang.String
- java.lang.Integer

- java.lang.Double
- java.lang.Byte
- java.lang.Short
- java.lang.Long
- java.lang.Float
- java.lang.Character

Data type Drop-down list

Custom Properties (Version 4) collection:

Use this page to view properties for a Version 4.0 data source.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data Sources (Version 4)** > *data_source* > **Custom Properties**

Name:

Specifies the name of the custom property

Data type String

Value:

Specifies the value of the custom property.

Data type Integer

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type String

Required:

Specifies properties that are required for this resource.

Data type String

Custom property (Version 4) settings:

Use this page to add properties for a Version 4.0 data source.

To view this administrative console page, click **Resources** >**JDBC Providers**> *JDBC_provider* > **Data Sources (Version 4)** > *data_source* > **Custom Properties** > *custom_property*.

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the cell level, all users in that cell can look up and use that data source, which is unique within that cell. However, resource property settings are local to each server in the cell. For example, if you define *max connections* to 10, then each server in that cell can have 10 connections.

Cell The most general scope. Resources defined at the cell scope are visible from all nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the node scope override any duplicates defined at the cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server
The most specific scope for defining resources. Resources defined at the server scope override any duplicate resource definitions defined at the cell scope or parent node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type String

Required:

Specifies properties that are required for this resource.

Data type Check box

Name:

Specifies the name associated with this property (PortNumber, ConnectionURL, etc).

Data type String

Value:

Specifies the value associated with this property in this property set.

Data type Integer

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type String

Type:

Specifies the fully qualified Java type of this property (java.lang.Integer, java.lang.Byte).

Data type String

Creating a data source for a clustered environment:

Use these steps to define a data source on multiple nodes that comprise a cluster.

The first part of this task defines a JDBC provider with a cluster scope setting. Be aware that all members of your cluster must run at least Version 6 of WebSphere Application Server to use this scope setting for the cluster. (See Administrative console scope settings for more information about scope settings in general.)

The cluster scope has precedence over the node and cell scopes. Create a data source for a cluster if you want the data source to:

- Be available for all the members of this cluster to use
- Override any resource factories that have the same JNDI name that is defined within the cell scope

1. Open the administrative console.
2. Click **Resources** > **JDBC Providers**. In the Scope section, note that the default scope setting is at the *node* level.
3. Click **Browse Clusters**. The JDBC providers > Select a Cluster Scope panel is displayed.
4. Select the cluster for which you want to define a data source, and click **OK**. The JDBC providers panel is displayed again.
5. Click **Apply**.
6. Click **New** to create a new JDBC provider at the cluster level. The class path for your new JDBC provider is already filled in; part of that class path is specified using a symbolic variable, for example: *${DB2390_JDBC_DRIVER_PATH}/classes/db2j2classes.zip*. Leave it at the default.
7. Finish creating the JDBC provider.
8. Click **Environment**.
9. Click **WebSphere Variables**.
10. For each node, select the symbolic variable used in the class path of your JDBC provider, and provide a value that is appropriate for the selected node. For example, if the class path of your JDBC provider uses the symbolic variable *${DB2390_JDBC_DRIVER_PATH}*, you might supply the value `/usr/lpp/db2` on one node and `/usr/lpp/db2710` on another node, depending on where your DB2 390 installation is located.
11. Click **DB2_JDBC_DRIVER_PATH** (this already exists by default). Here provide the path (in the *value* field) where *db2java.zip* exists on the selected node.
12. Click **Apply** and save the changes.

    Note: This variable must be defined on each node within the cluster.

You are now ready to configure your data source. For guidance, refer to “Creating and configuring a data source using the administrative console” on page 589.

Creating and configuring a JDBC provider and data source using the Java Management Extensions API:

If your application requires access to a JDBC connection pool from a J2EE 1.3 or 1.4 level WebSphere Application Server component, you can create the necessary JDBC provider and data source objects using the Java Management Extensions (JMX) API exclusively. Alternatively, you can use the JMX API in combination with the WSadmin - scripting tool.

Note: Use the JMX API to create only data sources for which the product does *not* provide a template. For every JDBC provider WebSphere Application Server supports, the product provides a corresponding data source template. You can create supported providers and associated data sources through the administrative console, or by using the WSadmin - scripting tool. For a

complete list of supported JDBC providers (and therefore a complete list of data sources that must be created using a template), refer to the topic “Vendor-specific data sources minimum required settings” on page 561.

These steps outline the general procedure for using the JMX API to create a JDBC provider and data source, on WebSphere Application Server running on Windows platforms:

1. Put the appropriate JAR files in your classpath.

   You need two JAR files in your classpath -- `wsexception.jar` and `wasjmx.jar`. The following command is an example for setting your classpath:

   ```
   export CLASSPATH=$CLASSPATH:/WebSphere/V5R1M0/AppServer/lib/
    wsexception.jar:/WebSphere/V5R1M0/AppServer/lib/wasjmx.jar
   ```

2. Look up the host and get an administration client handle.
3. Get a configuration service handle.
4. Update the `resource.xml` file using the configuration service as desired.
   a. Add a JDBC provider.
   b. Add the data source.
   c. Add the connection factory. This step is necessary only for data sources that must support container-managed persistence.
5. Reload the `resource.xml` file to bind the newly created data source into the JNDI namespace. Perform this step if you want to use the newly created data source right away without restarting the application server.
   a. Locate the DataSourceConfigHelper MBean using the name.
   b. Put together the signature and parameters for the call.
   c. Invoke the reload() call.
6. **Attention:** If you modify the class path or native library path of an existing JDBC provider, you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

Example: Using the Java Management Extensions API to create a JDBC driver and data source for container-managed persistence:

```
//
// "This program may be used, executed, copied, modified and distributed without royalty for the
// purpose of developing, using, marketing, or distributing."
//

Example: Creating a JDBC provider and data source using Java Management Extensions API and the scripting tool: The following code is a JACL (WSadmin - scripting tool) script used to create a data source. Use this script to create only data sources for which the product does *not* provide a template. For every JDBC provider WebSphere Application Server supports, the product provides a corresponding data source template. See the topic ″J2EE Connector Architecture migration tips″ for instructions on how to use the `createUsingTemplate` command to establish these data sources. For a complete list of supported JDBC providers (and therefore a complete list of data sources that must be created using a template), refer to the topic “Vendor-specific data sources minimum required settings” on page 561.

This script sets up the following sample JDBC objects:
- Creates a data source *fvtDS_1*
- Creates a 4.0 data source *fvtDS_3*
- Creates a container-managed persistence (CMP) data source linked to *fvtDS_1*

Attention: If you later modify the class path or native library path of the JDBC provider associated with your data source, you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

```
#AWE --  Set up XA DB2 data sources, both Version 4.0 and J2EE Connector architecture (JCA)-compliant data sources.

#UPDATE THESE VALUES:

Verifying a connection:

Many connection problems can be easily fixed by verifying some configuration parameters. This article provides a checklist of steps that you must complete to enable a successful connection. Click on the link for more information on a specific step.

If your connection is still not successful after completing these steps and reviewing the applicable information, check the SYSOUT of your application servant region for warning or exception messages.

1. Create the authentication data alias.
2. Create the JDBC provider.
3. Create a data source.
4. Save the data source.
5. If you created a new authentication alias, restart the server for which you need to verify connectivity.
6. Test the connection

   You can test your connection from the data source collection view or the data source details view. Access either view in the administrative console, and then select a connection from the list. Click the **Test Connection** button on the connection.

Test connection service:

WebSphere Application Server provides a test connection service for testing connections to the data sources that you configure for database access.

If the definition of your data source includes a WebSphere variable, you need to determine how your scope settings for both the variable and data source can affect the test connection results. Your next step is to choose which of the three ways you want to activate the test connection service: through the administrative console, the wsadmin tool, or a Java stand-alone program.

Verifying your scope settings

Use of a WebSphere variable in your data source definition can elicit test connection results that are incongruent with the actual run-time behavior of your data access application. In some cases, a test connection operation fails, but the data source functions normally during application run time. The reverse scenario can also occur. The cause of the potential conflict is the difference between how your application server handles WebSphere variable scope settings at run time, and how it handles those scope settings for a test connection operation. Understanding the difference helps you choose a successful configuration for your data source.

At run time, an application server resolves environment variables from the most specific scope to the broadest scope. That is, the server checks for the resolution of a variable in the server scope, then the cluster scope, then the node scope, and lastly the cell scope. When testing a connection, however, the most specific scope level at which the server checks variable definitions is determined by the scope at which the data source was created.

The test connection operation itself is performed in the JVM that corresponds with the scope of the data source. If the data source is configured at the cell scope, the test connection operation is carried out in the deployment manager process. If the data source is configured in the node scope, the test connection operation is performed in the node agent process for that node. For cluster-scoped data sources, the test connection operation is attempted in the node agent for each node that contains a cluster member. For server-scoped data sources, the test connection operation is first attempted in the server. If the server is unavailable, the test connection operation is retried in the node agent for the node that contains the application server.

Note: For any data source, regardless of scope setting, you must restart the associated JVM if you add or modify the authentication alias object.

Processing data source configurations in this way yields different, sometimes misleading, test connection results for different scope settings, as shown in the following table:

Table 5. Test connection results for different data source and environment variable combinations

Data source scope	Cell level variables	Node level variables	Server level variables
Cell level	Ok* *(See the following section)*	Fail	Fail
Node level	Ok	Ok	Fail
Server level	Ok	Ok	Ok

Contrary to expectations, these test connection failures generally do not translate into run-time failures, assuming that you are conscientious about configuring your WebSphere variables. A `variable cannot be found` exception results from attempted use of a data source that is configured with undefined variables.

Test connection success, but run-time failure

One of the scope combinations listed in the table, however, produces the reverse scenario: the test connection operation succeeds, but the data source fails at run time. This anomaly occurs in the case of a cell-scoped data source that uses a cell-scoped WebSphere variable. At run time, the cell-scoped variable is preempted by a default scope setting. In a default WebSphere Application Server installation, the supported database driver variables are defined and initialized to an empty string at the node scope. That empty setting effectively overrides any variable definition you provide at the cell scope level for a cell-scoped data source.

Because the run-time server checks the node scope for the variable before it checks the cell scope, it reads the empty string variable and accepts it as a value for the database driver class path. The incorrect

class path elicits a `classNotFound` exception when the server attempts to use the data source. To make the data source work for both test connection and run time, define the driver class path variable at the cell scope (indicating the location of the driver files on the deployment manager node), *as well as* at each node on which the data source must function. Alternatively, you can delete the node scope definitions if the database location is the same as the cell-scoped variable.

Bypassing variable lookups

You can bypass the environment variable lookups by changing the class path entries for the JDBC provider to hard-coded values. However, this strategy succeeds only if the class path is the same on all nodes where the data source must function.

Activating the test connection service

There are three ways to activate the test connection service: through the administrative console, the wsadmin tool, or a Java stand-alone program. Each process invokes the same methods on the same MBean.

Administrative console

WebSphere Application Server allows you to test a connection from the administrative console by simply pushing a button: the *Data source collection*, *Data source settings*, *Version 4 data source collection*, and *Version 4 data source settings* pages all have **Test Connection** buttons. After you define and save a data source, you can click this button to ensure that the parameters in the data source definition are correct. On the collection page, you can select several data sources and test them all at once. Note that there are certain conditions that must be met first. For more information, see Testing a connection with the administrative console.

WsAdmin tool

The wsadmin tool provides a scripting interface to a full range of WebSphere Application Server administration activities. Because the Test Connection functionality is implemented as a method on an MBean, and wsadmin can invoke MBean methods, wsadmin can be utilized to test connections to data sources. You have two options for testing a data source connection through wsadmin:

The *AdminControl* object of wsadmin has a testConnection operation that tests the configuration properties of a data source object. For information, see Testing a connection using wsadmin.

You can also test a connection by invoking the MBean operation. Use Example: Testing data source connection using wsadmin as a guide for this technique.

Java stand-alone program

Finally, you can test a connection by executing the `testConnection()` method on the `DataSourceCfgHelper` MBean. This method allows you to pass the configuration ID of the configured data source. The Java program connects to a running Java Management Extensions (JMX) server to access the MBean. In a Network Deployment installation of Application Server, you connect to the JMX server running in the deployment manager, usually running on port 8879.

The return value from this invocation is either 0, a positive number, or an exception. 0 indicates that the operation completed successfully, with no warnings. A positive number indicates that the operation completed successfully, with the number of warnings. An exception indicates that the test of the connection failed.

You can find an example of this code in Example: Test a connection using testConnection(ConfigID).

Testing a connection with the administrative console:

After you have defined and saved a data source, you can click the **Test Connection** button to ensure that the parameters in the data source definition are correct. On the collection panel, you can select multiple data sources and test them all at once. Be sure that the following conditions are met before using the Test Connection button.

1. Depending on your specific needs, a valid *Authentication Data alias* might need to exist and be supplied on the data source panels.
2. If you are testing a connection using a WebSphere Application Server Version 4.0 type of data source, ensure that the *user* and *password* information is filled in.
3. If you used a WebSphere environment entry for the classpath or other fields, such as *${DB2390_JDBC_DRIVER_PATH}/classes/db2j2classes.zip*, make sure that you assign it a value in the *WebSphere Variables* page. Note that if you add a new WebSphere environment variable, or modify it , the process (node agents and deployment manager) might need restarting.
4. Verify that the environment variables used exist in the scope of the test. For example, if the node scoped data source you defined uses *${DB2_JDBC_DRIVER_PATH}*, check that there exists a node level definition for *DB2_JDBC_DRIVER_PATH = c:\sqllib\java*(or your system dependent value).
5. Ensure that the deployment manager and node agent are up and running.
6. Click **Test Connection**.

   A Test Connection operation can have three different outcomes, each resulting in a different message being displayed in the messages panel of the page on which you press the Test Connection button.
   a. The test can complete successfully, meaning that a connection is successfully obtained to the database using the configured data source parameters. The resulting message states: Test Connection for data source *DataSourceName* on process *ProcessName* at node *NodeName* was successful.
   b. The test can complete successfully with warnings. This means that while a connection is successfully obtained to the database, warnings were issued. The resulting message states: Test Connection for data source *DataSourceName* on process *ProcessName* at node *NodeName* was successful with warning(s). View the JVM Logs for more details.

      The **View the JVM Logs** text is a hyperlink that takes you to the JVM Logs console screen for the process.
   c. The test can fail. A connection to the database with the configured parameters is not obtained. The resulting message states: Test Connection failed for data source *DataSourceName* on process *ProcessName* at node *NodeName* with the following exception: *ExceptionText*. View the JVM Logs for more details.

      Again, the text for **View the JVM Logs** is a hyperlink to the appropriate logs screen.

Testing a connection using wsadmin:

The *AdminControl* object of wsadmin has a testConnection operation that tests the configuration properties of a data source object. It takes a *configuration ID* as an argument.

Note: There is no way to pass a user ID and password to this invocation. This invocation can only be used for databases that do not require a user ID and password to make a connection (such as DB2 on a Windows machine), or for data sources that have a component-managed or container-managed authentication alias set on the data source object.

1. Invoke the getid() method for your data source.
2. Set the value of the *configuration id* to a variable.

   ```
   set myds [$AdminConfig getid /JDBCProvider:mydriver/DataSource:mydatasrc/]
   ```

   where */JDBCProvider:mydriver/DataSource:mydatasrc/* is the data source you want to test. After you have the configuration ID of the data source, you can test the connection to the database.
3. Test the connection to the database.

```
$AdminControl testConnection $myds
```

Example: Test a connection using testConnection(ConfigID): This program uses JMX to connect to a running server and invoke the *testConnection* method on the *DataSourceCfgHelper* MBean.

```
/**
 * Description
 * Resource adapter test program to make sure that the MBean interfaces work.

 }
}
```

Configuring J2EE Connector connection factories in the administrative console

1. Click **Resources**.
2. Click **Resource Adapters**.
3. Select a resource adapter under Resource Adapters.
4. Click **J2C Connection Factories** under Additional Properties .
5. Click **New**.
6. Specify *General Properties* .
7. Select the authentication preference.
8. Select aliases for **component-managed authentication**, **container-managed authentication**, or both. If none are available, or you want to define a different one, click **Apply** > **J2C Authentication Data Entries** under Related Items.

a. Click **J2C Auth Data Entries** under Related Items.
b. Click **New**.
c. Specify General Properties.
d. Click **OK**.

9. Click **OK**.
10. Click the J2C connection factory you just created.
11. Under *Additional Properties* click **Connection Pool**.
12. Change any values desired by clicking the property name.
13. Click **OK**.
14. Click **Custom Properties** under *Additional Properties*.
15. Click any property name to change its value. Note that **UserName** and **Password** if present, are overridden by the **component-managed authentication** alias you specified in a previous step.
16. Click **Save**.

Connection pool settings:

Use this page to configure connection pool settings.

This administrative console page is common to a range of resource types; for example, JDBC data sources and JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Connection Pool**. For example: click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data Sources** > *data_source* > **Connection Pool**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

This value indicates the number of seconds a request for a connection waits when there are no connections available in the free pool and no new connections can be created, usually because the maximum value of connections in the particular connection pool has been reached. For example, if Connection Timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. It usually does not make sense to retry the getConnection() method; if a longer wait time is required you should increase the Connection Timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, the administrator should review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection Timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, allowing a new physical connection to be created.

If Maximum Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Maximum Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeout` exception is issued.

For example, if the Maximum Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Maximum Connections is set to 0, the connection pool is allowed to grow infinitely. This also has the side effect of causing the Connection Timeout value to be ignored.

If multiple standalone application servers use the same data source, there is one pool for each application server. If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Data type	Integer
Default	10
Range	0 to max int

Minimum Connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the Unused Timeout thread does not discard physical connections. However, the pool does not create connections solely to ensure that the minimum connection pool size is maintained. Also, if you set a value for Aged Timeout, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example if the Minimum Connections value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Minimum Connections setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The *Reap Time* interval affects the accuracy of the *Unused Timeout* and *Aged Timeout* settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout,

until it reaches the number of connections specified in *Minimum Connections*. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the Reap Time value. See Reap Time for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting *Aged Timeout* to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the Reap Timeout value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. See Reap Time for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. JCA data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type String

Default EntirePool

Range

EntirePool
All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly
Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next getConnection() request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

Connection pool advanced settings:

Use this page to specify connection pooling related settings.

Properties-shared partitions, free pool partitions, and free pool distribution table size are properties related to reducing the time a thread needs to wait for a synchronization lock.

Partition support is always enabled. The default values of 0 should be used enabling the connection pool to pick the best values for performance. In some cases where large multiprocessor systems are used, adjusting the partition support properties might help performance.

To view this administrative console page, click **Resources** > **Resource Adapters** > *resource_adapter* > **J2C Connection Factories** > *connection_factory* > **Connection Pool** > **Advanced Connection Pool**.

Number of shared partitions:

Specifies the number of partitions that are created in each of the shared pools.

Data type	integer
Default value	0
Range	0 to max int

Number of free pool partitions:

Specifies the number of partitions that are created in each of the free pools.

Data type	integer
Default value	0
Range	0 to max int

Free pool distribution table size:

The free pool distribution table size is used for better distribution of the Subject and CRI hash values within a hash table to minimize collisions for faster retrieval of a matching free connection.

If there are many incoming requests with varying credentials, this value can help with the distribution of finding a free pool for a connection for that user. Larger values are more common for installations that have many different credentials accessing the resource. Smaller values (1) should be used if the same credentials apply to all incoming requests for the resource.

Data type	integer
Default value	0
Range	0 to max int

Surge threshold:

Specifies the number of connections created before surge protection is activated.

Surge protection is designed to prevent overloading of a data source when too many connections are created at the same time. Surge protection is controlled by two properties, *surge threshold* and *surge creation interval*.

The surge threshold property specifies the number of connections created before surge protection is activated. After you reach the specified number of connections, you enter *surge mode*.

The surge creation interval property specifies the amount of time, in seconds, between the creation of connections when in surge mode.

For example, assume the follow settings:
- maxConnections = 50
- surgeThreshold = 10
- surgeCreationInterval = 30 seconds

If the connection pool receives 15 connection requests, 10 connections are created at about the same time. The 11th connection is created 30 seconds after the first 10 connections. The 12th connection is created 30 seconds after the 11th connection. Connections continue to be created every 30 seconds until there are no more new connections needed or you reach the maxConnections value.

Surge connection support starts if the surge threshold is > -1 and the surge creation interval is > 0. The surge threshold property has a default value of -1, which indicates that it is turned off.

wsadmin examples

```
$AdminControl getAttribute $objectname surgeCreationInterval
$AdminControl setAttribute $objectname surgeCreationInterval 30
$AdminControl getAttribute $objectname surgeThreshold
$AdminControl setAttribute $objectname surgeThreshold 15
```

Data type	integer
Default value	-1
Range	-1 to max int

Surge creation interval:

Specifies the amount of time between connection creates when you are in surge protection mode.

If the number of connections specified in the surge threshold property have been made, each request for a new connection must wait to be created on the surge creation interval. This property has a default value of 20, which indicates that at least 20 seconds should pass between connections being created. Valid values for this property are any positive integer.

Data type	integer
Default value	20
Range	0 to max int

Stuck timer time:

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool appears to be stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. The stuck timer time property is the interval for the timer. This is how often the connection pool checks for stuck connections. The default value is 5 seconds.

If an attempt to change the stuck time, stuck timer time, or stuck threshold properties using the wsadmin scripting tool fails, an `IllegalState` exception occurs. The pool cannot have any active requests or active connections during this request. For the stuck connection support to start, all three stuck property values must be greater than 0 and maximum connections must be greater than 0.

Also, the stuck timer time, if it is set, must be less than the stuck time value. In fact, it is suggested that the stuck timer time should be one-quarter to one-sixth the value of stuck time so that the connection pool checks for stuck connections 4 to 6 times before a connection is declared stuck. This reduces the likelihood of false positives

wsadmin examples

```
$AdminControl getAttribute $objectname stuckTime
$AdminControl setAttribute $objectname stuckTime 30
$AdminControl getAttribute $objectname stuckTimerTime
$AdminControl setAttribute $objectname stuckTimerTime 15
$AdminControl getAttribute $objectname stuckThreshold
$AdminControl setAttribute $objectname stuckThreshold 10
```

Data type	integer
Default value	5
Range	0 to max int

Stuck time:

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool appears to be stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. The stuck time property is the interval, in seconds, allowed for a single active connection to be in use to the backend resource before it is considered to be stuck.

Data type	integer
Default value	0
Range	0 to max int

Stuck threshold:

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool appears to be stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. An application can explicitly catch this exception and continue processing. The pool will continue to periodically check for stuck connections when the number of stuck connections is past the threshold. If the number of stuck connections drops below the stuck threshold, the pool will detect this during its periodic checks and enable the pool to begin servicing requests again. The stuck threshold is the number of connections that need to be considered stuck for the pool to be in stuck mode.

Data type	integer
Default value	0
Range	0 to max int

Connection pool (Version 4) settings:

Use this page to create a connection pool for a Version 4.0 data source.

To view this administrative console page, click **Resources** > **JDBC Providers** > *JDBC_provider* > **Data Sources (Version 4)** > *data_source* > **Connection Pool**.

Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the cell level, all users in that cell can look up and use that data source, which is unique within that cell. However, resource property settings are local to each server in the cell. For example, if you define *max connections* to 10, then each server in that cell can have 10 connections.

Cell The most general scope. Resources defined at the cell scope are visible from all nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the node scope override any duplicates defined at the cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server
The most specific scope for defining resources. Resources defined at the server scope override

any duplicate resource definitions defined at the cell scope or parent node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

Data type String

Minimum Pool Size:

Specifies the minimum number of connections to maintain in the pool.

The minimum pool size can affect the performance of an application. Smaller pools require less overhead when the demand is low because fewer connections are held open to the database. When the demand is high, the first applications experience a slow response because new connections are created if all others in the pool are in use.

Data type Integer
Default 1
Range Any non-negative integer.

Maximum Pool Size:

Specifies the maximum number of connections to maintain in the pool.

If the maximum number of connections is reached and all connections are in use, additional requests for a connection wait up to the number of seconds specified as the connection timeout. The maximum pool size can affect the performance of an application. Larger pools require more overhead when demand is high because there are more connections open to the database at peak demand. These connections persist until idled out of the pool. If the maximum value is smaller, longer wait times or possible connection timeout errors during peak times can occur. Ensure that the database can support the maximum number of connections in the application server, in addition to any load that it has outside of the application server.

Data type Integer
Default 10
Range Any positive integer

Connection Timeout:

Specifies the maximum number of seconds an application waits for a connection from the pool before timing out and issuing a `ConnectionWaitTimeout` exception to the application.

Setting this value to 0 disables the connection timeout.

Data type Integer
Units Seconds
Default 180
Range Any non-negative integer

Idle Timeout:

Specifies the maximum number of seconds that an idle (unallocated) connection can remain in the pool before being removed to free resources.

Connections need to idle out of the pool because keeping connections open to the database can cause database memory problems. However, not all connections are idled out of the pool, even if they are older than the Idle Timeout setting. A connection is not idled if removing the connection would cause the pool to shrink below its minimum size. Setting this value to 0 disables the idle timeout.

Data type	Integer
Units	Seconds
Default	1800
Range	Any non-negative integer

Orphan Timeout:

Specifies the maximum number of seconds that an application can hold a connection without using it before the connection returns to the pool

If there is no activity on an allocated connection for longer than the Orphan Timeout setting, the connection is marked for orphaning. After another Orphan Timeout number of seconds, if the connection still has no activity, the connection returns to the pool. If the application tries to use the connection again, it is issued a stale connection exception. Connections that are enlisted in a transaction are not orphaned. Setting this value to 0 disables the orphan timeout.

Data type	Integer
Units	Seconds
Default	1800
Range	Any non-negative integer

Statement Cache Size:

Specifies the number of cached prepared statements to keep per connection.

The largest value you would need to set your cache size to if you do not want any cache discards is determined as follows: for each application that uses this data source on a particular server, add up the number of unique prepared statements (as determined by the *sql* string, concurrency, and the scroll type). This is the maximum number of possible prepared statements that can be cached on a given connection over the life of the server. Setting the cache size to this value means you never have cache discards. This provides better performance. However, because of potential resource limitations, this might not always be possible.

Data type	Integer
Default	10
Range	Any non-negative integer

Auto Connection Cleanup:

Specifies whether or not the connection pooling software automatically closes connections from this data source at the end of a transaction.

The default is *false*, which indicates that when a transaction completes, WebSphere Application Server closes the connection and returns it to the pool. Any use of the connection after the transaction has ended results in a stale connection exception because the connection is closed and has returned to the pool. This mechanism ensures that connections are not held indefinitely by the application. If the value is set to *true*, the connection is not returned to the pool at the end of a transaction. In this case, the application must return the connection to the pool by calling *close()*. If the application does not close the connection, the pool can run out of connections for other applications to use.

Data type	Check box
Default	False (clear)

Configuring connection factories for resource adapters within applications:

1. Click **Applications**.
2. Click **Install New Application**.
3. Browse to find the appropriate EAR file, which contains an RAR file.
4. Click **Next**.
5. Select **resource ref mapping to a J2C Connection Factory**, then click **Next**.
6. After the application installs, click **Applications**.
7. Select the application just installed.
8. Click **Connector Modules** under Related Items.
9. Select an RAR file name on the Connector Modules page.
10. Click **Resource Adapter** under Additional Properties.
11. Click **J2C Connection Factories** under Additional Properties.
12. Click **New**.
13. Specify General Properties.
14. Select a **Component-managed authentication alias** if any application components with *Application* or *Per connection factory* authentication specified in the resource reference are going to be getting connections from this connection factory using the empty-argument getConnection() method. For resources supporting XA, you can optionally specify an Authentication alias for XA recovery. If a desired alias is not available, or you want to define a different one, click **Apply** > **J2C Authentication Data Entries** under Related Items.
    a. Click **J2C Auth Data Entries** under Related Items.
    b. Click **New**.
    c. Specify General Properties.
    d. Click **OK**.
15. Click **OK**.
16. Click the J2C connection factory you just created.
17. Click **Connection Pool** under Additional Properties .
18. Change any values desired by clicking on the property name.
19. Click **OK**.
20. Click **Custom Properties** under Additional Properties.
21. Click any property name to change its value. Note that **UserName** and **Password** if present, are overridden by the **component-managed authentication** alias you specified in a previous step.
22. Click **Save**.

J2C Connection Factories collection:

Use this page to select a connection factory, which represents one set of connection configuration values.

Application components such as enterprise beans have resource reference descriptors that refer to the connection factory, not the resource adapter. The connection factory is really a configuration properties list holder. In addition to the arbitrary set of configuration properties defined by the vendor of the resource adapter, there are several standard configuration properties that apply to the connection factory. These standard properties are used by the Java 2 Connectors connection pool manager in the application server run time and are not known by the vendor-supplied resource adapter code.

To view this administrative console page, click **Resources** > **Resource Adapters** > *resource_adapter* > **J2C Connection Factories**.

Name:

Specifies a list of the connection factory display names.

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name of this connection factory.

Data type String

Description:

Specifies a text description of this connection factory.

Data type String

Category:

Specifies a string that you can use to classify or group this connection factory.

Data type String

J2C Connection Factories settings:

Use this page to specify settings for a connection factory.

To view this administrative console page, click **Resources** > **Resource Adapters** > *resource_adapter* > **J2C Connection Factories** > *connection_factory*.

Name:

Specifies a list of connection factory display names.

This is a required property.

Data type String

JNDI Name:

Specifies the JNDI name of this connection factory.

For example, the name could be *eis/myECIConnection*.

After you set this value, save it and restart the server. You can see this string when you run the *dumpNameSpace* tool. This is a required property. If you do not specify a JNDI name, it is filled in by default using the Name field.

Data type String
Default eis/*display name*

Description:

Specifies a text description of this connection factory.

Data type String

Connection Factory Interface:

Specifies the fully qualified name of the Connection Factory Interfaces supported by the resource adapter.

This is a required property. For new objects, the list of available classes is provided by the resource adapter in a drop-down list. After you create the connection factory, the field is a read only text field.

Data type Drop-down list or text

Category:

Specifies a string that you can use to classify or group this connection factory.

Data type String

Authentication Alias for XA Recovery:

This optional field is used to specify the authentication alias that should be used during XA recovery processing.

If the resource adapter does not support XA transactions, then this field will not be displayed. The default value will come from the selected alias for application authentication (if specified).

Use Component-managed Authentication Alias
Selecting this radio button specifies that the alias set for component-managed authentication is used at XA recovery time.

Data type Radio button

Specify:
Selecting this radio button enables you to choose an authentication alias from a drop-down list of configured aliases.

Data type Radio button

Component-managed Authentication Alias:

Specifies authentication data for component-managed signon to the resource.

Choose from aliases defined under **Security**>**JAAS Configuration**> **J2C Authentication Data**.

To define a new alias not already appearing in the pick list:
- Click **Apply** to expose Related Items.
- Click **J2C Authentication Data Entries**.
- Define an alias.
- Click the connection factory name at the top of the *J2C Authentication Data Entries* page to return to the connection factory page.

- Select the alias.

Data type Pick-list

Container-managed Authentication Alias (deprecated):

Specifies authentication data (a string path converted to userid and password) for container-managed signon to the resource.

Note: Beginning with WebSphere Application Server Version 6.0, the container-managed authentication alias is superseded by the specification of a login configuration on the resource-reference mapping at deployment time, for components with *res-auth=Container*.

Choose from aliases defined under **Security**>**JAAS Configuration**> **J2C Authentication Data**.

To define a new alias not already appearing in the pick list:
- Click **Apply** to expose Related Items.
- Click **J2C Authentication Data Entries**.
- Define an alias.
- Click the connection factory name at the top of the *J2C Authentication Data Entries* page to return to the connection factory page.
- Select the alias.

Data type Pick-list

Authentication Preference (deprecated):

Specifies the authentication mechanisms defined for this connection factory.

Note: Beginning with WebSphere Application Server Version 6.0, the authentication preference is superseded by the combination of the <res-auth> application component deployment descriptor setting and the specification of a login configuration on the resource-reference mapping at deployment time.

This setting specifies which of the authentication mechanisms defined for the corresponding resource adapter applies to this connection factory. Common values, depending on the capabilities of the resource adapter, are: *KERBEROS*, *BASIC_PASSWORD*, and *None*.

If None is chosen, the application component is expected to manage authentication (<res-auth>Application</res-auth>). In this case, the user ID and password are taken from one of the following:
- The component-managed authentication alias
- UserName, Password Custom Properties
- Strings passed on the getConnection method

For example, if two authentication mechanism entries are defined for a resource adapter in the *ra.xml* document:
- <authentication-mechanism-type>BasicPassword</authentication-mechanism-type>
- <authentication-mechanism-type>Kerbv5</authentication-mechanism-type>

the authentication preference specifies the mechanism to use for container-managed authentication. An exception is issued during server startup if a mechanism that is not supported by the resource adapter is selected.

Data type Pick-list
Default BASIC_PASSWORD

Mapping-Configuration Alias (deprecated):

Allows users to select from the **Security** > **JAAS Configuration** > **Application Logins Configuration** list.

Note: Beginning with WebSphere Application Server Version 6.0, the Mapping-Configuration Alias is superseded by the specification of a login configuration on the resource-reference mapping at deployment time, for components with *res-auth=Container*.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations.

Data type Pick-list

J2C Connection Factory advanced settings:

Use this page to specify settings for a connection factory.

To view this administrative console page, click **Resources** > **Resource Adapters** > *resource_adapter* > **J2C Connection Factories** > *connection_factory* > **Advanced Connection Factory Properties**.

Manage cached handles:

Specifies whether cached handles (handles held in `inst vars` in a bean) should be tracked by the container.

Data type Checkbox

Log missing transaction contexts:

Specifies whether or not the container logs that there is a missing transaction context when a connection is obtained.

Data type Checkbox

Connection factory JNDI name tips: Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information on objects and the search tools required to locate those objects. There are many naming and directory service implementations, and the interfaces to them vary.

Java Naming and Directory Interface (JNDI) provides a common interface that is used to access the various naming and directory services. After you have set this value, saved it, and restarted the server, you should be able to see this string when you invoke name space dump tool.

For WebSphere Application Server specifically, when you create a data source the default JNDI name is set to *jdbc/data_source_name*. When you create a connection factory, its default name is *eis/j2c_connection_factory_name*. You can, of course, override these values by specifying your own.

In addition, if you click the checkbox for the *Use this data source for container managed persistence (CMP)* option when you create the data source, another reference is created with the name of *eis/jndi_name_of_datasource_CMP*. For example, if a data source has a JNDI name of

jdbc/myDatasource, the CMP JNDI name is *eis/jdbc/myDatasource_CMP*. This name is used internally by CMP and is provided simply for informational purposes.

When creating a connection factory or data source, a JNDI name is given by which the connection factory or data source can be looked up by a component. Preferably an ″indirect″ name with the *java:comp/env* prefix should be used and must be used in future releases. An ″indirect″ name makes any resource-reference data associated with the application available to the connection management runtime, to better manage resources based on the res-auth, res-isolation-level, res-sharing-scope, and res-resolution-control settings.

Though you can use a direct JNDI name, this naming method is deprecated in Version 6 of WebSphere Application Server. Application Server assigns default values to the resource-reference data when you use this method. An informational message, resembling the following, is logged to document the defaults:

```
J2CA0294W: Deprecated usage of direct JNDI lookup of resource jdbc/IOPEntity.
The following default values are used: [Resource-ref settings]

 res-auth:                 1 (APPLICATION)
 res-isolation-level:      0 (TRANSACTION_NONE)
 res-sharing-scope:        true (SHAREABLE)
 loginConfigurationName:   null
 loginConfigProperties:    null
[Other attributes]

 res-resolution-control:   999 (undefined)
isCMP1_x:                 false (not CMP1.x)
isJMS:                 false (not JMS)
```

These default values can lead to unexpected behavior in your resources. For example, an application component (such as a JAAS login module) that accesses a resource with container-managed authentication data might fail to authenticate with the backend resource. Because the res-auth setting is assigned the default level of *Application*, rather than *Container*, the application server cannot find it.

This message can occur when you try using the fully qualified names of resources when looking up resources through Java Naming Directory Interface (JNDI). The J2EE programming model recommends the use of resource references and the local JNDI java:comp/env context. To correct this problem, modify the application to use the preferred J2EE programming model with resource references and the local JNDI java:comp/env context.

Security of lookups with component managed authentication

External Java clients (stand alone clients or servers from other cells) with Java Naming and Directory Interface (JNDI) access can look up a Java 2 Connector (J2C) resource such as a data source or Java Message Service (JMS) queue. However, they are not permitted to take advantage of the component managed *authentication alias* defined on the resource. This alias is a default value used when the *user* and *password* are not supplied on the getConnection() call. Therefore, if an external client needs to get a connection, it must assume responsibility for the authentication by passing it through arguments on the getConnection() call.

Any client running in the WebSphere Application Server process (such as a Servlet or an enterprise bean) within the same cell that can look up a resource in the JNDI namespace can obtain connections without explicitly providing authentication data on the getConnection() call. In this case, if the component‘s res-auth setting is **Application**, authentication is taken from the component-managed authentication alias defined on the connection factory. With res-auth set to **Container**, authentication is taken from the login configuration defined on the component‘s resource-reference. It is important to note that J2C authentication alias is per **cell**. An enterprise bean or Servlet in one application server cannot look up a resource in another server process which is in a different cell, because the alias would not be resolved.

Configuring data access for the Application Client

Configuring data access for the Application Client involves specifying the resource reference and associated database information required for data access. This specification is done as part of the assembly and deployment steps for the Application Client.

There are two tools needed to configure data sources used by J2EE application clients:

- An assembly tool such as the Application Server Toolkit (AST) or Rational Web Developer for defining the resource reference in the deployment descriptor; and
- The Application Client Resource Configuration Tool (ACRCT) for defining the connection to the database in the client deployment environment.

Data access from an application client uses the JDBC driver connection functions directly from the client side. It does not take advantage of the additional pooling support available in the WebSphere Application Server run time. Configuring data access for an application client does not require configuration of a JDBC provider and data source on the WebSphere Application Server server machine.

If you want to take advantage of the pooling and additional database functions provided by WebSphere Application Server, it is recommended that your client application utilize an enterprise bean running on the server side to perform data access.

Defining an application client resource reference using an assembly tool

1. Assemble your application client module as described in ″Assembling application clients″.
2. Create a new resource reference:
   a. In a Project Explorer view, right-click your application client module and click **Open With > Deployment Descriptor Editor**.
   b. On the **References** tab, click **Add > Resource reference > Next**.
   c. On the Resource Reference page, enter the **Name** of this resource reference. The Application Client for WebSphere Application Server run time uses this name for two purposes: to bind the object into the *java:comp/env* portion of the JNDI namespace, and to find client specific configuration information. If the code for the Application Client performs a lookup for *java:comp/env/jdbc/myDB*, the name of the resource reference should be *jdbc/myDB*.
   d. For **Type**, select *javax.sql.DataSource* for JDBC connections.
   e. For **Authentication**, select *Application* if your client application intends to provide authentication information. If the Application Client for WebSphere Application Server run time provides the authentication information (as configured by the Application Client Resource Configuration tool), select *Container*.
   f. Ignore the **Sharing scope** setting; it is unused in an application client resource reference. All Application Client resources are not shared.
   g. Click **Finish**.
   h. Close the deployment descriptor and save your changes.

The JNDI name field appears under **WebSphere Bindings** after your add the reference.

Client configuration with the ACRCT:

There are two client resources for you to configure in the Application Client Resource Configuration Tool (ACRCT) to enable data access from an application client: a data source provider and a data source.

Notes

Note: The following WebSphere objects, which can be bound into the server name space, are not supported on the client:
- Java 2 Connector (J2C) objects

- Connection manager objects

The WebSphere Application Server Client does not provide client database drivers. If your client application uses a database directly, rather than using an enterprise bean, you must provide the database drivers on the client machine. This action can involve contacting your database vendor to acquire client database driver code and licenses.

Instead of accessing the database directly, it is recommended that your client application use an enterprise bean. Accessing a database through an enterprise bean eliminates the need to have database drivers on the client machine because the database access is handled by the enterprise bean running on the WebSphere Application Server. Enterprise beans can also take advantage of the additional database functions provided by the WebSphere Application Server run time.

1. Configure a new data source provider as described in Configuring new data source providers. This provider describes the JDBC database implementation for your client application.
2. Enter the following information on the **General** tab:
   a. A **name** for this data source provider.
   b. Optional: A **description**.
   c. The **classpath** to the data source provider implementation classes or JAR files. This is optional if the implementation classes or JAR files are already in the class path configuration of the client.
   d. The name of the **implementation class**. For example, for DB2 this value is *COM.ibm.db2.jdbc.DB2DataSource*. Remember this class must implement the *javax.sql.DataSource* class. The ACRCT does not verify this class and you receive an error when you run your client application if the class does not implement *javax.sql.DataSource*.

   Use the **Custom** tab to configure non-standard properties of the data source provider. This panel enables you to enter property-value pairs. During run time the *implementation class name* is created and any custom properties added on this panel are set on the newly created data source object using reflection. Any properties configured on this panel must have an appropriate set method on the data source class. For example, assume there is a property called *use2Phase* and its value should be 1. On the custom panel you enter the value *use2Phase* into the **name** column and the value *1* into the **value** column. The Application Client for WebSphere Application Server run time then uses reflection to find a property on the data source class called, typically *setUse2Phase* and call that method passing the value of 1. See your database product documentation for valid properties on your data source implementation.
3. Click **OK**.
4. Configure a new data source as described in Configuring new data sources for application clients. This describes the client properties of the database your client application uses.
5. Enter the following information on the **General** tab:
   a. A **Name**. This field is required and identifies a name for the Application Client Resource Configuration Tool to use. This name is **not** used by your client application program.
   b. Optional: A **description**.
   c. The **JNDI name**. This field is required and must match the value entered in the **Name** field on the Add Resource Reference page of the assembly tool. In the example above, set this value to *jdbc/myDB*.
   d. Optional: The **Database Name**.
   e. Optional: Your *userid* in the **User** field.
   f. Optional: Your *password* in the **Password** field. This password does not display.
   g. Your password again to confirm in the **Re-Enter password** field. Note: The **User** and **Password** fields are used only when the **Authentication** field on the Add Resource Reference page of the assembly tool is set to *Container*.

Configuring Cloudscape Version 5.1.60x

Cloudscape provides the following two separate frameworks for running Cloudscape with WebSphere Application Server:

- Embedded: This framework is the same as the one for Cloudscape Version 5.0. To use this framework, define a Cloudscape JDBC provider. See the Cloudscape section in the minimum required settings article for more information.

  You must use the embedded framework if you are running XA. Cloudscape does not support XA on Network Server.
- Network Server: This framework was a new feature in Cloudscape Version 5.1, and removes these limitations that existed in earlier versions of Cloudscape:
  - inability to access a remote Cloudscape instance
  - only one JVM can boot up the same database instance

  The following steps describe how to configure and run the Network Server framework.

1. Start the Network Server on the machine that hosts the database instance.

   To start the Network Server, run the **startNetworkServer.bat** file, which is located in the `WAS_HOME/cloudscape/bin/networkserver` directory. On UNIX platforms, the file is **startNetwokServer.sh**.
2. Update the **db2j.properties** file, which is located in the `WAS_HOME/cloudscape` directory, if necessary.

   Cloudscape should work without any modifications to this file.

   Use the entries in the **db2j.properties** file to turn on trace, change the port number on which Network Server listens, and enable other functions of the Network Server framework. The default port number on which the Network Server listens is port 1527.

   For more information on this file, see the Cloudscape documentation at www.ibm.com/software/data/cloudscape/pubs/collateral.html.
3. Define a Cloudscape Network Server using Universal JDBC driver to connect Cloudscape with WebSphere Application Server using the Network Server framework.
4. Stop the Network Server by invoking the **stopNetworkServer.bat** file.

   You can find this file in the `WAS_HOME/cloudscape/bin/networkserver` directory. On UNIX platforms, the file is **stopNetworkServer.sh**.
5. Review additional tools available in the Network Server framework.

   Find these tools in the `WAS_HOME/cloudscape/bin/networkserver` directory. These tools are:
   - `sysinfo`
   - `cview`
   - `ij`
   - `dropSYSIBM` Use this tool to drop the SYSIBM schema and its contents.
6. Create a SYSIBM schema.

   If you do not create the SYSIBM schema, you cannot see the datatypes when you create tables using the `cview` graphical user interface. The **db2j.drda.loadSYSIBM** property in the **db2j.properties** file controls whether the schema is created on the first connection to the database. The **db2j.drda.loadSYSIBM** property default value is true.

   Note: When you run ij, surround the dbname by double quotation marks (″ ″) if it includes the full path name; for example: ij> connect ’″c:temp;create=true″’

   This is ’ ″ ″ ’ without spaces.

Cloudscape Version 5.1.60x post installation instructions:

After installing Cloudscape Version 5.1.60x, you must complete the following steps before you can access the database.

If you are running a WebSphere Application Server Network Deployment configuration, you must ensure the correct server or scope is set before completing these steps.

1. Upgrade or migrate any existing database instances.
   a. Backup an existing database.

      You must complete a backup in case you have to access the previous version of Cloudscape. After you migrate a database, you cannot access your old database unless you perform a backup.
   b. Migrate an existing database by doing the following:
      - Set the ***connectionAttributes*** custom property to **upgrade=true**.

        The data source is located in the WebSphere Application Server administrative console under the JDBC providers.
      - If you are using the cview interface, located in the WAS_HOME/cloudscape51/bin/embedded directory, click **yes** when you see the *upgrade database* prompt.

        Note: Ensure you migrate **defaultDB**, which is located in the WAS_HOME/bin/DefaultDB directory.
2. Set or change the class path definitions in any existing JDBC providers, which are defined to use Cloudscape. Cloudscape JAR files will not load when WebSphere Application Server is active.

   Use the WebSphere Application Server environment variable **${CLOUDSCAPE_JDBC_DRIVER_PATH}\db2j.jar** to point to the new version of Cloudscape.

   The **CLOUDSCAPE_JDBC_DRIVER_PATH** environment variable is defined in WebSphere Application Server with a value of WAS_HOME/cloudscape/lib.

   In a Network Deployment configuration, you must ensure the correct server or scope is set for this variable to take effect. Typically the scope is the server on which you are running Cloudscape.
3. If the application server is running Cloudscape as a persistent store for UDDI in previous versions, additional steps are necessary.

   The server SystemOut log might issue this message:

   ```
   The data source class name com.ibm.db2j.jdbc.db2jConnectionPoolDataSource could not be found.
   ```

   This is because the Cloudscape JAR file has moved to from its location in version 5.x to a new location in version 5.1x.

   To correct this situation, do the following:
   a. Upgrade the database to Cloudscape 5.1.60x.
   b. Rerun the install script, ***or*** edit the class path field in the data source.

DB2 tuning parameters

DB2 has many parameters that you can configure to optimize database performance. For complete DB2 tuning information, refer to the *DB2 UDB Administration Guide: Performance* document.

DB2 logging

- **Description:** DB2 has corresponding log files for each database that provides services to administrators, including viewing database access and the number of connections. For systems with multiple hard disk drives, you can gain large performance improvements by setting the log files for each database on a different hard drive from the database files.
- **How to view or set:** At a DB2 command prompt, issue the command: `db2 update db cfg for [database_name] using newlogpath [fully_qualified_path]`.
- **Default value:** Logs reside on the same disk as the database.
- **Recommended value:** Use a separate high-speed drive, preferably performance enhanced through a redundant array of independent disk (RAID) configuration.

DB2 configuration advisor

Located in the DB2 Control Center, this advisor calculates and displays recommended values for the DB2 buffer pool size, the database, and the database manager configuration parameters, with the option of applying these values. See more information about the advisor in the online help facility within the Control Center.

Number of connections to DB2 - MaxAppls and MaxAgents

When configuring the data source settings for the databases, confirm the DB2 MaxAppls setting is greater than the maximum number of connections for the data source. If you are planning to establish clones, set the MaxAppls value as the maximum number of connections multiplied by the number of clones. The same relationship applies to the session manager number of connections. The MaxAppls setting must be equal to or greater than the number of connections. If you are using the same database for session and data sources, set the MaxAppls value as the sum of the number of connection settings for the session manager and the data sources.

For example, MaxAppls = (number of connections set for the data source + number of connections in the session manager) multiplied by the number of clones.

After calculating the MaxAppls settings for the WebSphere Application Server database and each of the application databases, verify that the MaxAgents setting for DB2 is equal to or greater than the sum of all of the MaxAppls values. For example, MaxAgents = sum of MaxAppls for all databases.

DB2 buffpage

- **Description:** Improves database system performance. Buffpage is a database configuration parameter. A buffer pool is a memory storage area where database pages containing table rows or index entries are temporarily read and changed. Data is accessed much faster from memory than from disk.
- **How to view or set:** To view the current value of buffpage for database *x*, issue the DB2 command `get db cfg for x` and look for the value **BUFFPAGE**. To set **BUFFPAGE** to a value of *n*, issue the DB2 command `update db cfg for x` using **BUFFPAGE *n*** and set **NPAGES** to -1 as follows:

  ```
  db2   <-- go to DB2 command mode, otherwise the following "select" does not work as is
      connect to x    <-- (where x is the particular DB2 database name)
      select * from syscat.bufferpools
         (and note the name of the default, perhaps: IBMDEFAULTBP)
         (if NPAGES is already -1, there is no need to issue following command)
      alter bufferpool IBMDEFAULTBP size -1
      (re-issue the above "select" and NPAGES now equals -1)
  ```

  You can collect a snapshot of the database while the application is running and calculate the buffer pool hit ratio as follows:

  1. Collect the snapshot:
     a. Issue the **update monitor switches using bufferpool on** command.
     b. Make sure that bufferpool monitoring is on by issuing the **get monitor switches** command.
     c. Clear the monitor counters with the **reset monitor all** command.
  2. Run the application.
  3. Issue the **get snapshot for all databases** command before all applications disconnect from the database, otherwise statistics are lost.
  4. Issue the **update monitor switches using bufferpool off** command.
  5. Calculate the hit ratio by looking at the following database snapshot statistics:
     – Buffer pool data logical reads
     – Buffer pool data physical reads
     – Buffer pool index logical reads
     – Buffer pool index physical reads
- **Default value:** 250
- **Recommended value:** Continue increasing the value until the snapshot shows a satisfactory hit rate.

The buffer pool hit ratio indicates the percentage of time that the database manager did not need to load a page from disk to service a page request. That is, the page is already in the buffer pool. The greater the buffer pool hit ratio, the lower the frequency of disk input and output. Calculate the buffer pool hit ratio as follows:

- P = buffer pool data physical reads + buffer pool index physical reads
- L = buffer pool data logical reads + buffer pool index logical reads
- Hit ratio = (1-(P/L)) * 100%

DB2 query optimization level

- **Description:** Sets the amount of work and resources that DB2 puts into optimizing the access plan. When a database query runs in DB2, various methods are used to calculate the most efficient access plan. The range is from 0 to 9. An optimization level of 9 causes DB2 to devote a lot of time and all of its available statistics to optimizing the access plan.
- **How to view or set:** The optimization level is set on individual databases and can be set with either the command line or with the DB2 Control Center. Static SQL statements use the optimization level that is specified on the **prep** and **bind** commands. If the optimization level is not specified, DB2 uses the default optimization as specified by the dft_queryopt setting. Dynamic SQL statements use the optimization class that is specified by the current query optimization special register, which is set using the SQL Set statement. For example, the following statement sets the optimization class to 1:

  ```
  Set current query optimization = 1
  ```

  If the current query optimization register is not set, dynamic statements are bound using the default query optimization class.
- **Default value:** 5
- **Recommended value:** Set the optimization level for the needs of the application. Use high levels only when there are very complicated queries.

DB2 reorgchk
- **Description:** Obtains the current statistics for data and rebinding. Use this parameter because SQL statement performance can deteriorate after many updates, deletes or inserts.
- **How to view or set:** Use the DB2 **reorgchk update statistics on table all** command to perform the **runstats** operation on all user and system tables for the database to which you are currently connected. Rebind packages using the **bind** command. If statistics are available, issue the **db2 -v "select tbname, nleaf, nlevels, stats_time from sysibm.sysindexes"** command on DB2 CLP. If no statistic updates exist, nleaf and nlevels are -1, and stats_time has an empty entry (for example: "-"). If the runstats command was previously run, the real-time stamp from completion of the runstats operation also displays under stats_time. If you think the time shown for the previous runstats operation is too old, run the runstats command again.
- **Default value:** None
- **Recommended value:** None

DB2 locktimeout
- **Description:** Specifies the number of seconds that an application waits to obtain a lock. Setting this property helps avoid global deadlocks for applications.
- **How to view or set:** To view the current value of the lock timeout property for database *xxxxxx*, issue the DB2 **get db cfg for *xxxxxx*** command and look for the value, LOCKTIMEOUT. To set LOCKTIMEOUT to a value of *n*, issue the DB2 **update db cfg for *xxxxxx*** command using **LOCKTIMEOUT *n***, where *xxxxxx* is the name of the application database and *n* is a value between 0 and 30 000 inclusive.
- **Default value:** -1, meaning lock timeout detection is turned off. In this situation, an application waits for a lock if one is not available at the time of the request, until either of the following events occurs:
  - The lock is granted
  - A deadlock occurs
- **Recommended value:** If your database access pattern tends toward a majority of writes, set this value so that it gives you early warning when a timeout occurs. A setting of 30 seconds suits this purpose. If your pattern tends toward a majority of reads, either accept the default lock timeout value, or set the property to a value greater than 30 seconds.

DB2 maxlocks
- **Description:** Specifies the percentage of the lock list that is reached when the database manager performs escalation, from row to table, for the locks held by the application. Although the escalation process does not take much time, locking entire tables versus individual rows decreases concurrency, and potentially decreases overall database performance for subsequent attempts to access the affected tables.

- **How to view or set:** To view the current value of the maxlocks property for database *xxxxxx*, issue the DB2 **get db cfg for *xxxxxx*** command and look for the MAXLOCKS value. To set MAXLOCKS to a value of *n*, issue the DB2 **update db cfg for *xxxxxx*** command using **MAXLOCKS *n***, where *xxxxxx* is the name of the application database and *n* is a value between 1 and 100 inclusive.
- **Default value:** Refer to the current database information for property default values per operating system.
- **Recommended value:** If lock escalations are causing performance concerns, you might need to increase the value of this parameter or the locklist parameter, which is described in the following paragraph. You can use the database system monitor to determine if lock escalations are occurring.

DB2 locklist
- **Description:** Specifies the amount of storage that is allocated to the lock list.
- **How to view or set:** To view the current value of the locklist property for database *xxxxxx*, issue the DB2 **get db cfg for *xxxxxx*** command and look for the LOCKLIST value . To set LOCKLIST to a value of *n*, issue the DB2 **update db cfg for *xxxxxx*** command using **LOCKLIST *n***, where *xxxxxx* is the name of the application database and *n* is a value between 4 and 60 000 inclusive.
- **Default value:** Refer to the current database information for property default values per operating system.
- **Recommended value:** If lock escalations are causing performance concerns, you might need to increase the value of this parameter or the maxlocks parameter, which is described in the previous paragraph. You can use the database system monitor to determine if lock escalations are occurring. Refer to the *DB2 Administration Guide: Performance* document for more details.

Connector modules collection

Use this page to view established connector modules, which are resource adaptor (RAR) files that have been packaged into deployable components compliant with the J2EE Connector Architecture (JCA).

To view this administrative console page, click **Applications** >**Enterprise Applications** > *application* > **Connector Modules**.

You must generate a connector module for every resource adapter (RAR file) in the application. You do this through an assembly tool, which creates an instance of the connector module object for the RAR file. To learn more about the process, see the topic ″Assembling resource adapter (connector) modules″ in the Information Center.

Remove: Removes a module from the deployed application. The module is deleted from the application in the WebSphere Application Server configuration repository and also from all the nodes where the application is installed and running (or expected to run). If the application is running on a node when the module file is deleted from the node as a result of configuration synchronization then the application is stopped, the module file is deleted from the node's file system, and then the application is restarted.

Update: Opens a wizard that helps you update a module in an application. If a module has the same URI as a module already existing in the application, the new module replaces the existing module. If the new module does not exist in the application, it is added to the deployed application. If the application is running on a node when the module file is updated on the same node as a result of configuration synchronization, then the application is stopped, the module file is updated on the node's file system, and the application is restarted. If the application is running on a node when a new module file is *added* (that is, established for the first time) as a result of configuration synchronization, then the newly added module is started *without* stopping and restarting the running application.

Remove File: Deletes a file from a module of a deployed application. The file is also deleted from all the nodes where the module is installed after configuration is synchronized with nodes. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and then the application is restarted.

URI:

Specifies the logical path to the resource that will be serviced by the product.

Name:

Specifies the display name of the connector module.

Connector module settings:

Use this page to view the settings of connector modules, which are resource adapter (RAR) files that have been packaged into deployable components compliant with the J2EE Connector Architecture (JCA).

To view this administrative console page, click **Applications** > **Enterprise Applications** > *application* > **Connector Modules** > *connector_module*.

The following field descriptions refer to properties that are set when you create connector modules using an assembly tool. To learn more about the process, see the topic ″Assembling resource adapter (connector) modules″ in the Information Center.

Remove: Removes a module from the deployed application. The module is deleted from the application in the WebSphere Application Server configuration repository and also from all the nodes where the application is installed and running (or expected to run). If the application is running on a node when the module file is deleted from the node as a result of configuration synchronization then the application is stopped, the module file is deleted from the node's file system, and then the application is restarted.

Update: Opens a wizard that helps you update module in an application. If a module has the same URI as a module already existing in the application, the new module replaces the existing module. If the new module does not exist in the application, it is added to the deployed application. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and then the application is restarted.

Remove File: Deletes a file from a module of a deployed application. The file is also deleted from all the nodes where the module is installed after configuration is synchronized with nodes. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and then the application is restarted.

Uri:

Specifies the logical path to the resource that is serviced by WebSphere Application Server.

Data type String

Name:

Specifies the display name of the connector module.

Data type String

altDD:

Specifies the alternate DD of the connector module.

The alternate DD URI for a given module.

Data type String

Starting weight:

Specifies the startup priority of the connector module over others.

When your application contains multiple modules, the starting weight you specify determines this module's startup priority over other modules during server startup. Modules with lower startup order are started first.

Data type String

Messaging resources

Using asynchronous messaging

These topics describe how to use asynchronous messaging with WebSphere Application Server, to enable enterprise applications to use JMS resources and message-driven beans.

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. This JMS support is provided by one or more JMS providers, and associated services and resources, that you configure for use by enterprise applications. You can deploy EJB 2.1 applications that use the JMS 1.1 interfaces and EJB 2.0 applications that use the JMS 1.0.2 interfaces.

You can use the WebSphere administrative console to administer the WebSphere Application Server support for asynchronous messaging. For example, you can configure messaging providers and their resources, and can control the activity of messaging services.

For more information about implementing WebSphere enterprise applications that use asynchronous messaging, see the following topics:

- Learning about messaging with WebSphere
- Installing a messaging provider
- Using the default messaging provider
- "Maintaining Version 5 default messaging resources" on page 670
- "Using JMS resources of WebSphere MQ" on page 704
- "Using JMS resources of a generic provider" on page 770
- "Administering support for message-driven beans" on page 779
- ″Programming to use asynchronous messaging″
- ″Troubleshooting WebSphere messaging″

Learning about messaging with WebSphere Application Server

Use this topic to learn about the use of asynchronous messaging for enterprise applications with WebSphere Application Server.

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) and Java Connector Architecture (JCA) programming interfaces. These interfaces provide a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests, as messages.

Besides using the programming interfaces directly to explicitly poll for messages, WebSphere Application Server also supports the use of message-driven beans as asynchronous message consumers. A

message-driven bean is invoked by the EJB container when a message arrives at the destination that it is configured to listen on, without an application having to explicitly poll the destination.

To handle non-JMS requests inbound to WebSphere Application Server from enterprise information systems, message-driven beans use a Java Connector Architecture (JCA) 1.5 resource adapter written for that purpose. In the JCA 1.5 specification, such message-driven beans are commonly called message endpoints or simply endpoints.

Message-driven beans that implement the javax.jms.MessageListener interface can be used for JMS messaging. For JMS messaging, message-driven beans can use a JMS provider that has a JCA 1.5 resource adapter, such as the default messaging provider that is part of WebSphere Application Server version 6.

With a JCA 1.5 resource adapter, you deploy EJB 2.1 message-driven beans as JCA resources to use a J2C activation specification. If a JMS provider does not have a JCA 1.5 resource adapter, such as the V5 Default Messaging and WebSphere MQ, you must configure JMS message-driven beans against a listener port (as in WebSphere Application Server version 5).

You can use the WebSphere administrative console to administer the WebSphere Application Server support for asynchronous messaging. For example, you can configure JCA resource adapters, J2C activation specifications, JMS providers, and JMS resources, and can control the activity of messaging services.

To learn more about WebSphere messaging support, see the following topics:

JMS providers

This topic provides an overview of the support for JMS providers by WebSphere Application Server.

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

The service integration technologies of IBM WebSphere Application Server can act as a messaging system when you have configured a service integration bus that is accessed through the default messaging provider. This support is installed as part of WebSphere Application Server, administered through the administrative console, and is fully integrated with the WebSphere Application Server runtime.

WebSphere Application Server also includes support for the following JMS providers:

WebSphere MQ
: Provided for use with supported versions of WebSphere MQ.

Generic
: Provided for use with any 3rd party messaging system. If you want to use message-driven beans, the messaging system must support ASF.

For backwards compatibility with earlier releases, WebSphere Application Server also includes support for the V5 default messaging provider which enables you to configure resources for use with the WebSphere Application Server version 5 Embedded Messaging system. The V5 default messaging provider can also be used with a service integration bus.

WebSphere applications can use messaging resources provided by any of these JMS providers. However the choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you may already have a messaging infrastructure based on WebSphere

MQ. In this case you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

Styles of messaging in applications

This topic describes the ways that applications can use point-to-point and publish/subscribe messaging.

Applications can use the following styles of asynchronous messaging:

Point-to-Point
: Point-to-point applications use queues to pass messages between each other. The applications are called point-to-point, because a client sends a message to a specific queue and the message is picked up and processed by a server listening to that queue. It is common for a client to have all its messages delivered to one queue. Like any generic mailbox, a queue can contain a mixture of messages of different types.

Publish/subscribe
: Publish/subscribe systems provide named collection points for messages, called topics. To send messages, applications publish messages to topics. To receive messages, applications subscribe to topics; when a message is published to a topic, it is automatically sent to all the applications that are subscribers of that topic. By using a topic as an intermediary, message publishers are kept independent of subscribers.

Both styles of messaging can be used in the same application.

Applications can use asynchronous messaging in the following ways:

One-way
: An application sends a message, and does not want a response. This pattern of use is often referred to as a datagram.

Request / response
: An application sends a request to another application and expects to receive a response in return.

One-way and forward
: An application sends a request to another application, which sends a message to yet another application.

These messaging techniques can be combined to produce a variety of asynchronous messaging scenarios.

For more information about how such messaging scenarios are used by WebSphere enterprise applications, see the following topics:

- An overview of asynchronous messaging with JMS
- An overview of asynchronous messaging with message-driven beans

For more information about these messaging techniques and the Java Message Service (JMS), see Sun's Java Message Service (JMS) specification documentation (http://developer.java.sun.com/developer/technicalArticles/Networking/messaging/).

For more information about message-driven bean and inbound messaging support, see Sun's Enterprise JavaBeans specification (http://java.sun.com/products/ejb/docs.html).

For information about JCA inbound messaging processing, see Sun's J2EE Connector Architecture specification (http://java.sun.com/j2ee/connector/download.html).

Using JMS interfaces to explicitly poll for messages

This topic provides an overview of applications that use JMS interfaces to explicitly poll for messages on a destination then retrieve messages for processing by business logic beans (enterprise beans).

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interfaces. JMS provides a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests, as JMS messages.

The base support for asynchronous messaging using JMS, shown in the following figure, provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This enables WebSphere J2EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics).

Applications can use both point-to-point and publish/subscribe messaging (referred to as “messaging domains” in the JMS specification), while supporting the different semantics of each domain.

WebSphere Application Server supports applications that use JMS 1.1 domain-independent interfaces (referred to as the “common interfaces” in the JMS specification). With JMS 1.1, the preferred approach for implementing applications is to use the common interfaces. The JMS 1.1 common interfaces provide a simpler programming model than domain-specific interfaces. Also, applications can create both queues and topics in the same session and coordinate their use in the same transaction.

The common interfaces are also parents of domain-specific interfaces. These domain-specific interfaces (provided for JMS 1.0.2 in WebSphere Application Server version 5) are supported only to provide inter-operation and backward compatibility with applications that have already been implemented to use those interfaces.

A WebSphere application can use the JMS interfaces to explicitly poll a JMS destination to retrieve an incoming message, then pass the message to a business logic bean. The business logic bean uses standard JMS calls to process the message; for example, to extract data or to send the message on to another JMS destination.

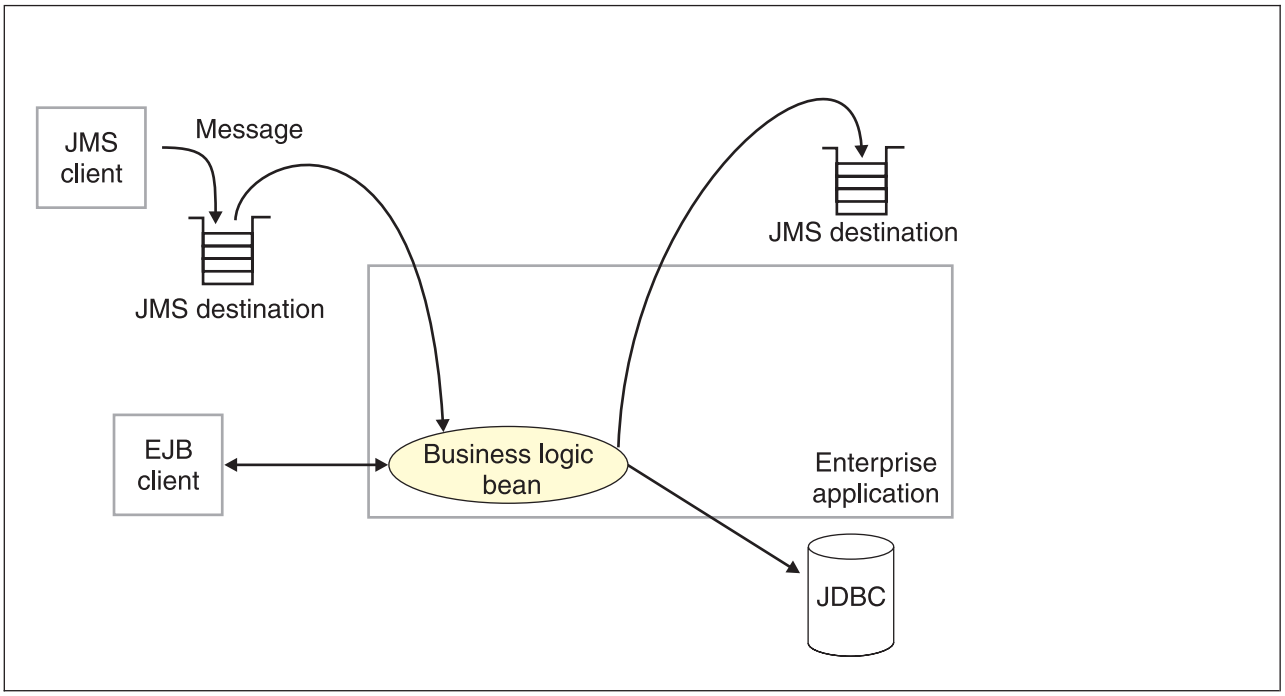

Figure 3. Asynchronous messaging using JMS. This figure shows an enterprise application polling a JMS destination to retrieve an incoming message, which it processes with a business logic bean. The business logic bean uses standard JMS calls to process the message; for example, to extract data or to send the message on to another JMS destination. For more information, see the text that accompanies this figure.

WebSphere applications can use standard JMS calls to process messages, including any responses or outbound messaging. Responses can be handled by an enterprise bean acting as a sender bean, or handled in the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of functionality for asynchronous messaging is called bean-managed messaging, and gives an enterprise bean complete control over the messaging infrastructure; for example, for connection and session pool management. The application server has no role in bean-managed messaging.

WebSphere applications can also use message-driven beans, as described in related topics.

For more details about JMS, see Sun's Java Message Service (JMS) specification documentation.

Using message-driven beans to automatically retrieve messages

WebSphere Application Server supports the use of message-driven beans as asynchronous message consumers.

Messaging with message-driven beans is shown in the figure Messaging with message-driven beans.

A client sends messages to the destination (or endpoint) for which the message-driven bean is deployed as the message listener. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination. The message-driven bean implements some business logic to process incoming messages on the destination.

Message-driven beans can be configured as listeners on a Java Connector Architecture (JCA) 1.5 resource adapter or against a listener port (as in WebSphere Application Server version 5). With a JCA 1.5 resource adapter, message-driven beans can handle generic message types, not just JMS messages. This makes message-driven beans suitable for handling generic requests inbound to WebSphere Application Server from enterprise information systems through the resource adapter. In the JCA 1.5 specification, such message-driven beans are commonly called message endpoints or simply endpoints.

All message-driven beans must implement the MessageDrivenBean interface. For JMS messaging, a message-driven bean must also implement the message listener interface, javax.jms.MessageListener.

A message driven bean can be registered with the EJB timer service for time-based event notifications if it implements the javax.ejb.TimedObject interface in addition to the message listener interface.

You are recommended to develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean, to provide clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.

Messages arriving at a destination being processed by a message-driven bean have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see ″Enterprise bean component security″ in the information center.

For JMS messaging, message-driven beans can use a JMS provider that has a JCA 1.5 resource adapter, such as the default messaging provider that is part of WebSphere Application Server version 6. With a JCA 1.5 resource adapter, you deploy EJB 2.1 message-driven beans as JCA 1.5-compliant resources, to use a J2C activation specification. If the JMS provider does not have a JCA 1.5 resource adapter, such as the V5 Default Messaging and WebSphere MQ, you must configure JMS message-driven beans against a listener port (as in WebSphere Application Server version 5).

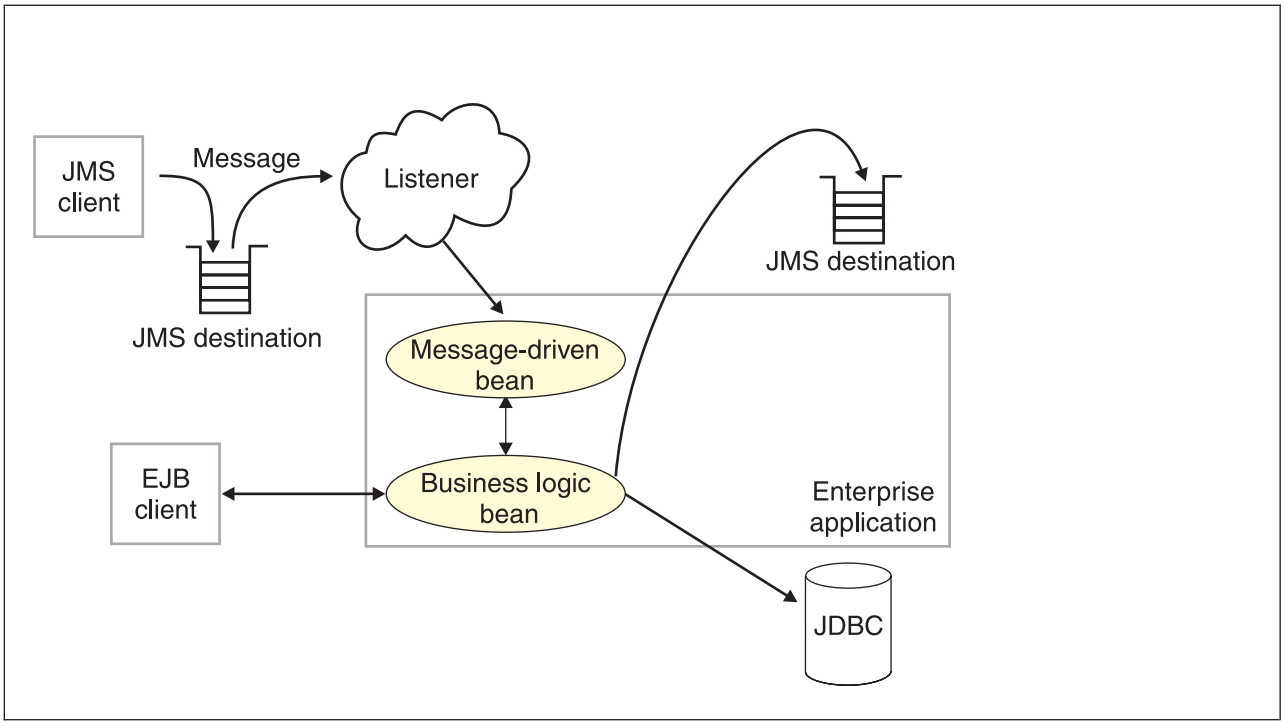

Figure 4. Messaging with message-driven beans. This figure shows an incoming message being passed automatically to the onMessage() method of a message-driven bean that is deployed as a listener for the destination. The message-driven bean processes the message, in this case passing the message on to a business logic bean for business processing. For more information, see the text that accompanies this figure.

Message-driven beans - JCA components:

This topic provides an overview of the administrative components that you configure for message-driven beans as listeners on a Java Connector Architecture (JCA) 1.5 resource adapter.

Components for a JCA resource adapter

To handle non-JMS requests inbound to WebSphere Application Server from enterprise information systems, message-driven beans use a Java Connector Architecture (JCA) 1.5 resource adapter written by a third party for that purpose.

With a Java Connector Architecture (JCA) 1.5 resource adapter, a message-driven bean acts as a listener on a specific endpoint. In the JCA 1.5 specification, such message-driven beans are commonly called message endpoints or simply endpoints.

Each application configuring one or more message-driven beans must specify the resource adapter that sends messages to the endpoint. To specify the resource adapter, you configure the message-driven bean to use an activation specification that has been configured by the administrator for the resource adapter.

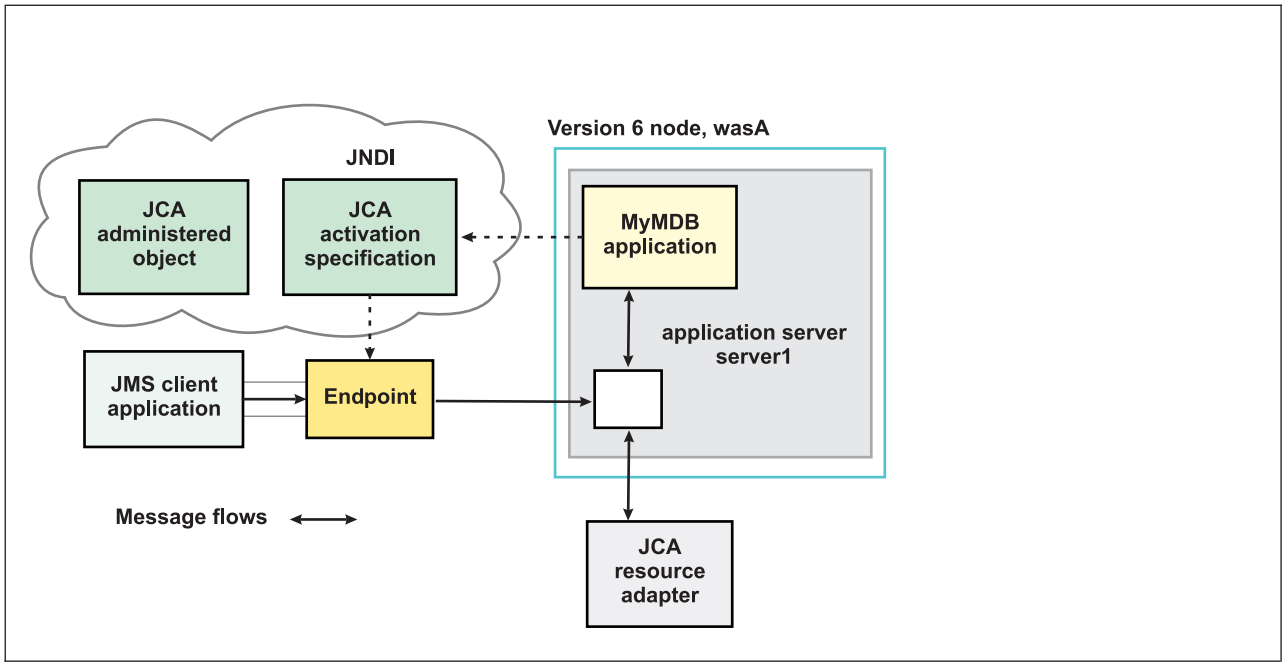

Figure 5. Message-driven bean components for a JCA resource adapter. This figure shows the main components of WebSphere support for message-driven beans for use with an external JCA resource adapter.

The administrator creates a J2C activation specification for the appropriate resource adapter to provide information to the deployer about the configuration properties of an endpoint instance (message-driven bean) related to the processing of the inbound messages. Properties specified on an activation specification can be overridden by appropriately named activation-configuration properties in the deployment descriptor of an associated EJB 2.1 message-driven bean.

When a deployed message-driven bean is installed, it is associated with an activation specification for an endpoint. When a message arrives on the endpoint, the message is passed to a new instance of a message-driven bean for processing.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with JNDI names that are then available for applications to use. Some messaging styles may need applications to use special administered objects for sending and synchronously receiving messages (through connection objects using programming interfaces specific to a messaging style). Administered objects can also be used to perform transformations on an asynchronously-received message in a way that is specific to a message provider. Administered objects can be accessed by a component by using either a message destination reference (preferred) or a resource environment reference.

JMS components used with a JCA messaging provider

Message-driven beans that implement the javax.jms.MessageListener interface can be used for JMS messaging. For JMS messaging, message-driven beans can use a JCA-based messaging provider such as the SIB JMS Resource Adapter (which is the default messaging provider listed under JMS providers) that is part of WebSphere Application Server and configure message-driven beans to use a JCA activation specification.

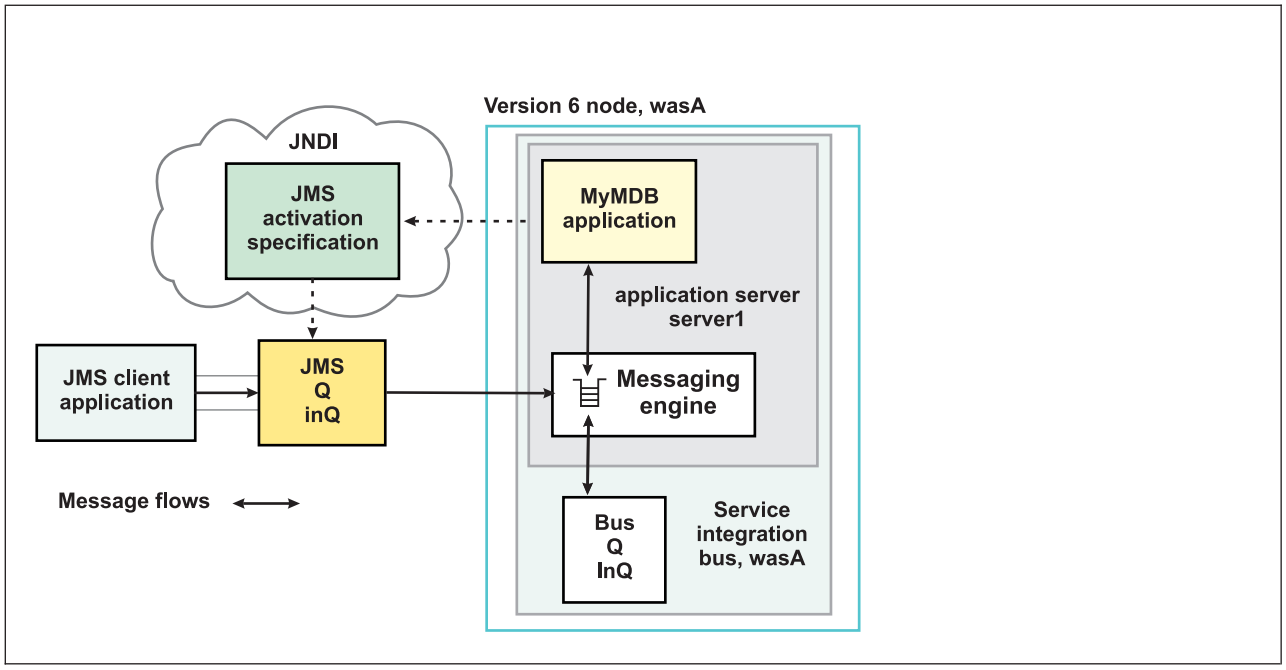

Figure 6. Message-driven bean components for the default messaging provider. This figure shows the main components of WebSphere support for message-driven beans for use with the default messaging provider.

With the SIB JMS Resource Adapter, a message-driven bean acts as a listener on a specific JMS destination.

The administrator creates a JMS activation specification (which, the WebSphere administrative console shows on the panel **Resources** → **JMS providers** → **Default messaging** → **JMS activation specifications**) to provide information to the deployer about the configuration properties of a message-driven bean related to the processing of the inbound messages. WebSphere provides additional support for JCA activation specifications that are JMS-based and shows the JMS-specific panel rather than the generic JCA activation specification panel. For example, a JMS activation specification specifies the name of the service integration bus to connect to, and includes information about the message acknowledgement modes, message selectors, destination types, and whether or not durable subscriptions are shared across connections with members of a server cluster. Properties specified on an activation specification can be overridden by appropriately named activation-configuration properties in the deployment descriptor of an associated EJB 2.1 message-driven bean.

The administrator also creates other administered objects that configure the JMS destination and the associated resources of a service integration bus that are used to implement messaging with that JMS destination. For more information about JMS resources and service integration, see .

″Learning about the default messaging provider″ in the information center.

J2C activation specification configuration and use:

This topic provides an overview about the configuration and use of J2C activation specifications, used in the deployment of message-driven beans for JCA 1.5 resources.

J2C activation specifications are part of the configuration of inbound messaging support that can be part of a JCA 1.5 resource adapter. Each JCA 1.5 resource adapter that supports inbound messaging defines one or more `messagelistener` types in its deployment descriptor (ra.xml). The messagelistener type is the interface that the resource adapter uses to communicate inbound messages to the message endpoint. A message-driven bean (MDB) is a message endpoint and implements one of the messagelistener-type interfaces provided by the resource adapter. By allowing multiple message listener types, a resource

adapter can support a variety of different protocols. For example, the interface javax.jms.MessageListener, is a type of message listener that supports JMS messaging. For each messagelistener-type that a resource adapter implements, the resource adapter defines an associated activation specification (`activationspec` in the ra.xml). The activation specification is used to set configuration properties for a particular use of the inbound support for the receiving endpoint.

When an application containing a message-driven bean is deployed, the deployer must select a resource adapter that supports the same messagelistener type that the message-driven bean implements. As part of the message-driven bean deployment, the deployer needs to specify the properties to set on the J2C activation specification. Later, during application startup, a J2C activation specification instance is created, and these properties are set and used to activate the endpoint (that is, to configure the resource adapter's inbound support for the specific message-driven bean).

J2C activation specification configuration options and precedence:
Resource adapter scoped configuration

A J2C activation specification configuration instance can be created and modified under an installed resource adapter at the cell, node, or server scope. This activation specification configuration is created based on a particular message listener type for the given resource adapter. Valid properties available for configuration are determined by introspection of the ActivationSpec class instance provided with the resource adapter. When created, an ActivationSpec class instance is referenced by its JNDI name. This activation specification configuration is needed during the deployment of a message-driven bean for the resource adapter.

Configuring a J2C activation specification instance at the cell, node, or server level offers two distinct advantages:

- The activation specification configuration information can be share among multiple message-driven beans across multiple applications.
- Updates to the configuration properties can be made without the need to redeploy the application.

Application-based configuration

Applications with message-driven beans have the option of specifying all, some, or none of the properties needed by the ActivationSpec class. These properties, specified as activation-config properties in the application's deployment descriptor, are configured when the application is assembled. To change any of these properties requires redeploying the application. These properties are unique to this applications use and are not shared with other message-driven beans. Any properties defined in the application's deployment descriptor take precedence over those defined by the resource adapter-scoped definition. This allows application developers to choose the best defaults for their applications.

To deploy and activate a message-driven bean with respect to application specification configuration properties would be as follows:

1. Use JNDI to look up a J2C activation specification configuration instance, which is based on its resource adapter-scoped definition.
2. Set the properties needed by the ActivationSpec class to the values defined by the cell, node, or server definition. If any of the properties are also defined as activation-config properties of the application, use the value defined by the activation-config property.
3. During application startup, the server activates the MDB endpoint by calling the resource adapter and passing a configured instance of the ActivationSpec.
4. Note that a resource adapter can specify in its deployment descriptor if a given ActivationSpec property is required. If it is required, and it is not supplied either by the cell, node or server definition, or an activation-config property from the applications deployment descriptor, then an exception is raised as part of the sequence to activate the message-driven bean.

WebSphere activation specification optional binding properties:

J2C authentication alias

If you provide values for user name and password as custom properties on an activation specification, you may not want to have those values exposed in clear text for security reasons. WebSphere security allows you to securely define an authentication alias for such cases. Configuration of activation specifications, both as an administrative object and during application deployment enable you to use the authentication alias instead of providing the user name and password.

If you set the authentication alias field, then you should not set the user name and password custom properties fields. Also, authentication alias properties set as part of application deployment take precedence over properties set on an activation specification administrative object.

Only the authentication alias is ever written to file in an unencrypted form, even for purposes of transaction recovery logging. The security service is used to protect the real user name and password.

During application startup, when the activation specification is being initialized as part of endpoint activation, the server uses the authentication alias to retrieve the real user name and password from security then set it on the activation specification instance.

Destination JNDI name

For resource adapters that support JMS you need to associate javax.jms.Destinations with an activation specification, such that the resource adapter can service messages from the JMS destination. In this case, the administrator configures a J2C Administered Object which implements the javax.jms.Destination interface and binds it into JNDI.

You can configure a J2C Administered Object to use an ActivationSpec class that implements a setDestination(javax.jms.Destination) method. In this case, you can specify the destination JNDI name (that is, the JNDI name for the J2C Administered object that implements the javax.jms.Destination).

A destination JNDI name set as part of application deployment take precedence over properties set on an activation specification administrative object.

During application startup, when the activation specification is being initialized as part of endpoint activation, the server uses the destination JNDI name to look up the destination administered object then set it on the activation specification instance.

Message-driven beans - transaction support: Message-driven beans can handle messages on destinations (or endpoints) within the scope of a transaction.

Destination transaction handling

If transaction handling is specified for a destination, the message-driven bean starts a global transaction *before* it reads any incoming message from that destination. When the message-driven bean processing has finished, it commits or rolls back the transaction (using JTA transaction control).

All messages retrieved from a specific destination have the same transactional behavior.

If messages are queued to be sent within a global transaction they are sent when the transaction is committed. If the processing of a message causes the transaction to be rolled back, then the message that caused the bean instance to be invoked is left on the JMS destination.

Inbound resource adapter transaction handling

A message-driven bean can be set up to either have Bean or Container transaction handling. The resource adapter owner must tell the message-driven bean developer how to set up the message-driven bean for transaction handling.

WebSphere Application Server cloning and WebSphere MQ clustering

This topic provides a summary of information about using WebSphere Application Server horizontal cloning with WebSphere MQ server clustering support. It describes a scenario that shows how the message listener service can be configured to take advantage of WebSphere MQ server clustering and provides some information about how to resolve potential runtime failures in the clustering scenario. The information in this topic is based on the scenario shown in the figure WebSphere Application Server horizontal cloning with WebSphere MQ clustered queues.

Note: WebSphere MQ server clustering is only available with the full WebSphere MQ product installed as a JMS provider.

Each JMS listener is used to retrieve messages from a destination defined to the server. In the following information the listener configurations are the same for each WebSphere application server. Each application server host contains a WebSphere application server and an WebSphere MQ server. If a host is only used to distribute messages, it only contains an WebSphere MQ server. There can be many servers defined in the configuration, although for simplicity the information in this topic is based on a scenario containing only three servers as shown in "WebSphere Application Server cloning and WebSphere MQ clustering."

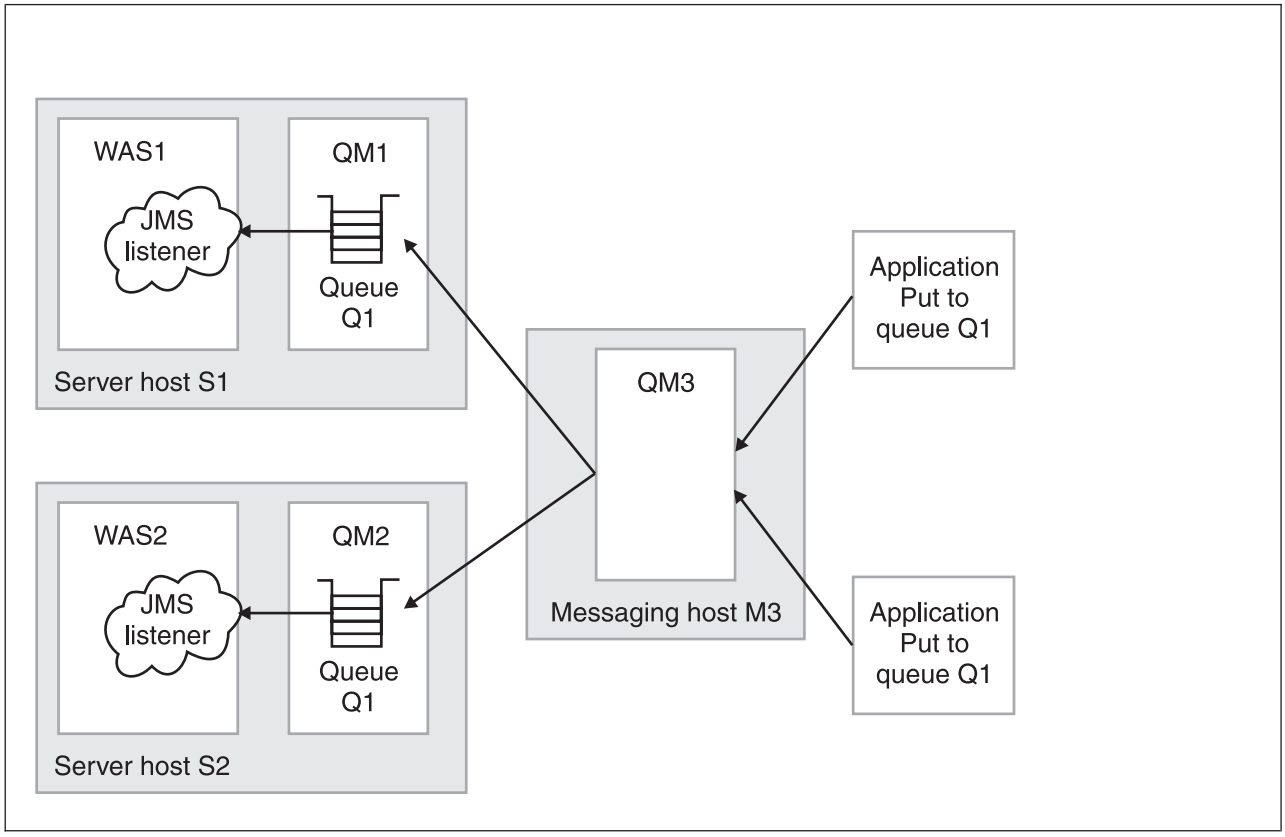

Figure 7. WebSphere Application Server horizontal cloning with WebSphere MQ clustered queues. This figure shows two WebSphere Application Server hosts, with horizontal clustering, and a messaging host used to distribute messages for WebSphere MQ server clustering. For more information, see the text that accompanies this figure.

The scenario shown in "WebSphere Application Server cloning and WebSphere MQ clustering" comprises the following three hosts:

- Server host S1 contains the following servers:
  WebSphere MQ server.
  The server is defined to have a queue manager, QM1, and a local queue, Q1. The queue

manager belongs to a cluster. The queue is populated by the WebSphere MQ server located on host M3. Applications can add messages directly to the queue, Q1, but would not be subjected to the control of the WebSphere MQ cluster.

WebSphere Application Server

This contains a cloned application server, WAS1, which is configured with a JMS listener. The listener is configured to retrieve messages from JMS destination Q1.

- Server host S2 contains the following servers:

  WebSphere MQ server.

  The server is defined to have a queue manager, QM2, and a local queue, Q1. The queue manager belongs to the same cluster as QM1 on host S1. As with QM1, the queue is populated by the WebSphere MQ server located on host M3. Applications can add messages directly to the queue, Q1, but would not be subjected to the control of the MQ cluster.

  WebSphere Application Server

  This contains a cloned application server, WAS2 (identical to WAS1 on host S1), which is configured with a JMS listener. The listener is configured to retrieve messages from JMS destination Q1.

- Messaging host M3 contains the following servers:

  WebSphere MQ server.

  The server is defined to have a queue manager, QM3, which also belongs to the same cluster as QM1 and QM2. Applications add messages to the queue manager and queue Q1. The cluster to which this queue manager belongs causes messages to be distributed to all other queue managers in the cluster which have queue Q1 defined.

  Note: Queue Q1 is not defined as a local queue on this host. If the queue was defined locally, then messages would remain on the server for local processing; messages would not be distributed by the queue manager cluster control to the other queue managers in the cluster that do have the queue defined.

  This host does not have a WebSphere application server defined. All message retrieval processing is performed by the other two application servers on hosts S1 and S2.

Recovery scenarios

There are several failure scenarios that could occur with the clustering configuration; for example:

- WAS server failures.

  In this scenario the failure of any single WebSphere application server results in the messages for the specified destination remaining on the queue, until the server is restarted.

- WebSphere MQ Queue Manager failures.

  There are two different failures to consider:

  1. Failure of a queue manager on the same host as a WebSphere application server (for example, failure of QM2 on host S2). In this case messages are delivered to the other available application servers, until the WebSphere MQ server is back online, when messages are processed as expected.
  2. Failure of the messaging host M3 and its queue manager, QM3. In this case, the result of an outage is more significant because no messages are delivered to the other queue managers in the cluster. In a fully-deployed and scaled production system, host M3 would not be designed to be a single point of failure, and additional messaging servers would be added to the cluster configuration.

Asynchronous messaging - security considerations

This topic describes considerations that you should be aware of if you want to use security for asynchronous messaging with WebSphere Application Server.

Security for messaging operates as a part of the WebSphere Application Server global security, and is enabled only when global security is enabled.

When global security is enabled, JMS connections made to the JMS provider are authenticated, and access to JMS resources owned by the JMS provider are controlled by access authorizations. Also, all requests to create new connections to the JMS provider must provide a user ID and password for authentication. The user ID and password do not need to be provided by the application. If authentication is successful, then the JMS connection is created; if the authentication fails then the connection request is ended.

Standard J2C authentication is used for a request to create a new connection to the JMS provider. If your resource authentication (res-auth) is set to Application, set the alias in the Component-managed Authentication Alias. If the application that tries to create a connection to the JMS provider specifies a user ID and password, those values are used to authenticate the creation request. If the application does not specify a user ID and password, the values defined by the Component-managed Authentication Alias are used. If the connection factory is not configured with a Component-managed Authentication Alias, then you receive a runtime JMS exception when an attempt is made to connect to the JMS provider.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with the version 5 default messaging provider or WebSphere MQ. For example, the default Windows NT user ID, **Administrator**, is not valid for use, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider or WebSphere MQ connection factory must specify a user ID no longer than 12 characters.
2. If you want to use Bindings transport mode for JMS connections to WebSphere MQ, you set the property **Transport type**=BINDINGS on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
   - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error `MQJMS2013 invalid security authentication supplied for MQQueueManager` error.
   - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Authorization to access messages stored by the default messaging provider is controlled by authorization to access the service integration bus destinations on which the messages are stored. For information about authorizing permissions for individual bus destinations, see ″Administering destination permissions″ in the information center.

Installing and configuring a JMS provider

This topic describes the different ways that you can use JMS providers with WebSphere Application Server. A JMS provider enables use of the Java Message Service (JMS) and other message resources in WebSphere Application Server.

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

The service integration technologies of IBM WebSphere Application Server can act as a messaging system when you have configured a service integration bus that is accessed through the default messaging provider. This support is installed as part of WebSphere Application Server, administered through the administrative console, and is fully integrated with the WebSphere Application Server runtime.

WebSphere Application Server also includes support for the following JMS providers:

WebSphere MQ
Provided for use with supported versions of WebSphere MQ.

Generic
Provided for use with any 3rd party messaging system. If you want to use message-driven beans, the messaging system must support ASF.

For more information about the support for JMS providers, see "JMS providers" on page 644.

For more information about installing and using JMS providers, see the following topics:

- Installing the default messaging provider
- Using WebSphere MQ as a JMS provider. Installing WebSphere MQ as a JMS provider.

  Note:
  - You can install WebSphere MQ in addition to the default messaging provider. The preferred solution for publish/subscribe messaging with WebSphere MQ as a JMS provider is a full message broker such as WebSphere MQ Event Broker.
  - If you install WebSphere MQ as a JMS provider, you can use the WebSphere administrative console to administer the JMS resources provided by WebSphere MQ, such as queue connection factories. However, you cannot administer MQ security, which is administered through WebSphere MQ.

  For more information about scenarios and considerations for using WebSphere MQ with IBM WebSphere Application Server, see the White Papers and Red books provided by WebSphere MQ; for example, through the WebSphere MQ library Web page at http://www-3.ibm.com/software/ts/mqseries/library/
- Installing another JMS provider, which must conform to the JMS specification and, to use message-driven beans, support the ASF function. If you want to use a JMS provider other than the default messaging provider or WebSphere MQ, you should complete the following steps:
  1. Installing and configuring the JMS provider and its resources by using the tools and information provided with the product.
  2. Defining the JMS provider to WebSphere Application Server as a generic messaging provider.

  Note: You can use the WebSphere administrative console to administer JMS connection factories and destinations (within WebSphere Application Server) for a generic provider, but cannot administer the JMS provider or its resources outside of WebSphere Application Server.

Installing the default messaging provider

Use this task to install the default messaging provider of IBM WebSphere Application Server.

The default messaging provider is installed as a fully-integrated component of WebSphere Application Server, and needs no separate installation steps. However, ensure that there is enough space in the file systems where you want to store messaging data.

You can use the WebSphere administrative console to define JMS resources for the default messaging provider.

For more information about the default messaging provider, see Using the default messaging provider.

Configuring messaging with scripting

This topic contains the following tasks:

- "Configuring the message listener service using scripting" on page 657
- "Configuring new JMS providers using scripting" on page 658

Configuring the message listener service using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure the message listener service for an application server:

1. Identify the application server and assign it to the server variable:
   - Using Jacl:
     ```
     set server [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
     ```
   - Using Jython:
     ```
     server = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
     print server
     ```

   Example output:

   ```
   server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
   ```
2. Identify the message listener service belonging to the server and assign it to the mls variable:
   - Using Jacl:
     ```
     set mls [$AdminConfig list MessageListenerService $server]
     ```
   - Using Jython:
     ```
     mls = AdminConfig.list('MessageListenerService', server)
     print mls
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode/servers/server1|server.xml#MessageListenerService_1)
   ```
3. Modify various attributes with one of the following examples:
   - This example command changes the thread pool attributes:
     - Using Jacl:
       ```
       $AdminConfig modify $mls {{threadPool {{inactivityTimeout 4000} {isGrowable true}
       {maximumSize 100} {minimumSize 25}}}}
       ```
     - Using Jython:
       ```
       AdminConfig.modify(mls, [['threadPool', [['inactivityTimeout', 4000], ['isGrowable',  'true'],
         ['maximumSize', 100], ['minimumSize', 25]]]])
       ```
   - This example modifies the property of the first listener port:
     - Using Jacl:
       ```
       set lports [$AdminConfig showAttribute $mls listenerPorts]
       set lport [lindex $lports 0]
       $AdminConfig modify $lport {{maxRetries 2}}
       ```
     - Using Jython:

```
lports = AdminConfig.showAttribute(mls, 'listenerPorts')
cleanLports = lports[1:len(lports)-1]
lport = cleanLports.split(" ")[0]
AdminConfig.modify(lport, [['maxRetries', 2]])
```

- This example adds a listener port:
  - Using Jacl:

```
set new [$AdminConfig create ListenerPort $mls {{name my} {destinationJNDIName di}
 {connectionFactoryJNDIName jndi/fs}}]
$AdminConfig create StateManageable $new {{initialState START}}
```

  - Using Jython:

```
new = AdminConfig.create('ListenerPort', mls, [['name', 'my'], ['destinationJNDIName', 'di'],
 ['connectionFactoryJNDIName', 'jndi/fsi']])
print new
print AdminConfig.create('StateManageable', new, [['initialState', 'START']])
```

  Example output:

```
my(cells/mycell/nodes/mynode/servers/server1:server.xml#ListenerPort_1079471940692)
(cells/mycell/nodes/mynode/servers/server1:server.xml#StateManageable_107947182623)
```

4. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
5. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new JMS providers using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new JMS provider:

1. Identify the parent ID:
   - Using Jacl:

```
set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
```

   - Using Jython:

```
node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
print node
```

   Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

2. Get required attributes:
   - Using Jacl:

```
$AdminConfig required JMSProvider
```

   - Using Jython:

```
print AdminConfig.required('JMSProvider')
```

   Example output:

```
Attribute        Type
name     String
externalInitialContextFactory    String
externalProviderURL               String
```

3. Set up required attributes:
   - Using Jacl:

```
set name [list name JMSP1]
set extICF [list externalInitialContextFactory  "Put the external initial context factory here"]
set extPURL [list externalProviderURL "Put the external provider URL here"]
set jmspAttrs [list $name $extICF $extPURL]
```

   - Using Jython:

```
name = ['name', 'JMSP1']
extICF = ['externalInitialContextFactory',  "Put the external initial context factory here"]
extPURL = ['externalProviderURL', "Put the external provider URL here"]
jmspAttrs = [name, extICF, extPURL]
print jmspAttrs
```

Example output:

```
{name JMSP1} {externalInitialContextFactory {Put the external initial context factory here }}
{externalProviderURL {Put the external provider URL here}}
```

4. Create the JMS provider:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig create JMSProvider $node $jmspAttrs]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.create('JMSProvider', node, jmspAttrs)
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new JMS destinations using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new JMS destination:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:myNode/JMSProvider:JMSP1]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required GenericJMSDestination
     ```

   - Using Jython:

     ```
     print AdminConfig.required('GenericJMSDestination')
     ```

   Example output:

   ```
   Attribute       Type
   name       String
   jndiName    String
   externalJNDIName  String
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name JMSD1]
     set jndi [list jndiName jms/JMSDestination1]
     set extJndi [list externalJNDIName jms/extJMSD1]
     set jmsdAttrs [list $name $jndi $extJndi]
     ```

   - Using Jython:

```
name = ['name', 'JMSD1']
jndi = ['jndiName', 'jms/JMSDestination1']
extJndi = ['externalJNDIName', 'jms/extJMSD1']
jmsdAttrs = [name, jndi, extJndi]
print jmsdAttrs
```

Example output:

```
{name JMSD1} {jndiName jms/JMSDestination1} {externalJNDIName jms/extJMSD1}
```

4. Create generic JMS destination:
   - Using Jacl:

     ```
     $AdminConfig create GenericJMSDestination $newjmsp  $jmsdAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('GenericJMSDestination', newjmsp,  jmsdAttrs)
     ```

   Example output:

   ```
   JMSD1(cells/mycell/nodes/mynode|resources.xml#GenericJMSDestination_1)
   ```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new JMS connections using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new JMS connection:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:myNode/JMSProvider:JMSP1]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required GenericJMSConnectionFactory
     ```

   - Using Jython:

     ```
     print AdminConfig.required('GenericJMSConnectionFactory')
     ```

   Example output:

   ```
   Attribute       Type
   name       String
   jndiName    String
   externalJNDIName  String
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name JMSCF1]
     set jndi [list jndiName jms/JMSConnFact1]
     set extJndi [list externalJNDIName jms/extJMSCF1]
     set jmscfAttrs [list $name $jndi $extJndi]
     ```

     Example output:

     ```
     {name JMSCF1} {jndiName jms/JMSConnFact1} {externalJNDIName jms/extJMSCF1}
     ```

- Using Jython:

```
name = ['name', 'JMSCF1']
jndi = ['jndiName', 'jms/JMSConnFact1']
extJndi = ['externalJNDIName', 'jms/extJMSCF1']
jmscfAttrs = [name, jndi, extJndi]
print jmscfAttrs
```

  Example output:

```
[[name, JMSCF1], [jndiName, jms/JMSConnFact1], [externalJNDIName, jms/extJMSCF1]]
```

4. Create generic JMS connection factory:
   - Using Jacl:

```
$AdminConfig create GenericJMSConnectionFactory $newjmsp $jmscfAttrs
```

   - Using Jython:

```
print AdminConfig.create('GenericJMSConnectionFactory', newjmsp, jmscfAttrs)
```

   Example output:

```
JMSCF1(cells/mycell/nodes/mynode|resources.xml#GenericJMSConnectionFactory_1)
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new WebSphere queue connection factories using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new WebSphere queue connection factory:

1. Identify the parent ID:
   - Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

   - Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
print newjmsp
```

   Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

2. Get required attributes:
   - Using Jacl:

```
$AdminConfig required WASQueueConnectionFactory
```

   - Using Jython:

```
print AdminConfig.required('WASQueueConnectionFactory')
```

   Example output:

```
Attribute       Type
name       String
jndiName    String
```

3. Set up required attributes:
   - Using Jacl:

```
set name [list name WASQCF]
set jndi [list jndiName jms/WASQCF]
set mqcfAttrs [list $name $jndi]
```

   Example output:

```
{name WASQCF} {jndiName jms/WASQCF}
```

   - Using Jython:

```
name = ['name', 'WASQCF']
jndi = ['jndiName', 'jms/WASQCF']
mqcfAttrs = [name, jndi]
print mqcfAttrs
```

Example output:

```
[[name, WASQCF], [jndiName, jms/WASQCF]]
```

4. Create was queue connection factories:
   - Using Jacl:

     ```
     $AdminConfig create WASQueueConnectionFactory $newjmsp $mqcfAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('WASQueueConnectionFactory', newjmsp, mqcfAttrs)
     ```

   Example output:

   ```
   WASQCF(cells/mycell/nodes/mynode|resources.xml#WASQueueConnectionFactory_1)
   ```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new WebSphere topic connection factories using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new WebSphere topic connection factory:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required WASTopicConnectionFactory
     ```

   - Using Jython:

     ```
     print AdminConfig.required('WASTopicConnectionFactory')
     ```

   Example output:

   ```
   Attribute            Type
   name                 String
   jndiName             String
   port                 ENUM(DIRECT, QUEUED)
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name WASTCF]
     set jndi [list jndiName jms/WASTCF]
     set port [list port QUEUED]
     set mtcfAttrs [list $name $jndi $port]
     ```

     Example output:

     ```
     {name WASTCF} {jndiName jms/WASTCF} {port QUEUED}
     ```

   - Using Jython:

```
name = ['name', 'WASTCF']
jndi = ['jndiName', 'jms/WASTCF']
port = ['port', 'QUEUED']
mtcfAttrs = [name, jndi, port]
print mtcfAttrs
```

Example output:

```
[[name, WASTCF], [jndiName, jms/WASTCF], [port, QUEUED]]
```

4. Create was topic connection factories:
   - Using Jacl:

     ```
     $AdminConfig create WASTopicConnectionFactory $newjmsp $mtcfAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('WASTopicConnectionFactory', newjmsp, mtcfAttrs)
     ```

   Example output:

   ```
   WASTCF(cells/mycell/nodes/mynode|resources.xml#WASTopicConnectionFactory_1)
   ```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new WebSphere queues using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new WebSphere queue:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required WASQueue
     ```

   - Using Jython:

     ```
     print AdminConfig.required('WASQueue')
     ```

   Example output:

   ```
   Attribute       Type
   name       String
   jndiName    String
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name WASQ1]
     set jndi [list jndiName jms/WASQ1]
     set wqAttrs [list $name $jndi]
     ```

     Example output:

     ```
     {name WASQ1} {jndiName jms/WASQ1}
     ```

   - Using Jython:

```
name = ['name', 'WASQ1']
jndi = ['jndiName', 'jms/WASQ1']
wqAttrs = [name, jndi]
print wqAttrs
```

Example output:

```
[[name, WASQ1], [jndiName, jms/WASQ1]]
```

4. Create was queue:
   - Using Jacl:

     ```
     $AdminConfig create WASQueue $newjmsp $wqAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('WASQueue', newjmsp, wqAttrs)
     ```

   Example output:

   ```
   WASQ1(cells/mycell/nodes/mynode|resources.xml#WASQueue_1)
   ```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new WebSphere topics using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new WebSphere topic:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required WASTopic
     ```

   - Using Jython:

     ```
     print AdminConfig.required('WASTopic')
     ```

   Example output:

   ```
   Attribute       Type
   name       String
   jndiName    String
   topic        String
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name WAST1]
     set jndi [list jndiName jms/WAST1]
     set topic [list topic "Put your topic here"]
     set wtAttrs [list $name $jndi $topic]
     ```

     Example output:

     ```
     {name WAST1} {jndiName jms/WAST1} {topic {Put your topic here}}
     ```

   - Using Jython:

```
name = ['name', 'WAST1']
jndi = ['jndiName', 'jms/WAST1']
topic = ['topic', "Put your topic here"]
wtAttrs = [name, jndi, topic]
print wtAttrs
```

Example output:

```
[[name, WAST1], [jndiName, jms/WAST1], [topic, "Put your topic here"]]
```

4. Create was topic:
   - Using Jacl:

     ```
     $AdminConfig create WASTopic $newjmsp $wtAttrs
     ```

   - Using Jython:

     ```
     print AdminConfig.create('WASTopic', newjmsp, wtAttrs)
     ```

   Example output:

   ```
   WAST1(cells/mycell/nodes/mynode|resources.xml#WASTopic_1)
   ```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new MQ queue connection factories using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new MQ queue connection factory:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required MQQueueConnectionFactory
     ```

   - Using Jython:

     ```
     print AdminConfig.required('MQQueueConnectionFactory')
     ```

   Example output:

   ```
   Attribute       Type
   name       String
   jndiName    String
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name MQQCF]
     set jndi [list jndiName jms/MQQCF]
     set mqqcfAttrs [list $name $jndi]
     ```

     Example output:

     ```
     {name MQQCF} {jndiName jms/MQQCF}
     ```

   - Using Jython:

```
name = ['name', 'MQQCF']
jndi = ['jndiName', 'jms/MQQCF']
mqqcfAttrs = [name, jndi]
print mqqcfAttrs
```

Example output:

```
[[name, MQQCF], [jndiName, jms/MQQCF]]
```

4. Set up a template:
   - Using Jacl:

     ```
     set template [lindex [$AdminConfig listTemplates MQQueueConnectionFactory] 0]
     ```

   - Using Jython:

     ```
     import java
     lineseparator = java.lang.System.getProperty('line.separator')
     template = AdminConfig.listTemplates('MQQueueConnectionFactory').split(lineseparator)[0]
     print template
     ```

   Example output:

   ```
   Example non-XA WMQ QueueConnectionFactory(templates/
   system:JMS-resource-provider-templates.xml
   #MQQueueConnectionFactory_3)
   ```

5. Create MQ queue connection factory:
   - Using Jacl:

     ```
     $AdminConfig createUsingTemplate MQQueueConnectionFactory $newjmsp $mqqcfAttrs $template
     ```

   - Using Jython:

     ```
     print AdminConfig.createUsingTemplate('MQQueueConnectionFactory', newjmsp, mqqcfAttrs, template)
     ```

   Example output:

   ```
   MQQCF(cells/mycell/nodes/mynode:resources.xml#MQQueueConnectionFactory_1)
   ```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new MQ topic connection factories using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new MQ topic connection factory:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```

   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode:resources.xml#JMSProvider_1)
   ```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required MQTopicConnectionFactory
     ```

   - Using Jython:

     ```
     print AdminConfig.required('MQTopicConnectionFactory')
     ```

   Example output:

```
Attribute       Type
name       String
jndiName    String
```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name MQTCF]
     set jndi [list jndiName jms/MQTCF]
     set mqtcfAttrs [list $name $jndi]
     ```

     Example output:

     ```
     {name MQTCF} {jndiName jms/MQTCF}
     ```

   - Using Jython:

     ```
     name = ['name', 'MQTCF']
     jndi = ['jndiName', 'jms/MQTCF']
     mqtcfAttrs = [name, jndi]
     print mqtcfAttrs
     ```

     Example output:

     ```
     [[name, MQTCF], [jndiName, jms/MQTCF]]
     ```

4. Set up a template:
   - Using Jacl:

     ```
     set template [lindex [$AdminConfig listTemplates MQTopicConnectionFactory] 0]
     ```

   - Using Jython:

     ```
     import java
     lineseparator = java.lang.System.getProperty('line.separator')
     template = AdminConfig.listTemplates('MQTopicConnectionFactory').split(lineseparator)[0]
     print template
     ```

   Example output:

   ```
   Example non-XA WMQ TopicConnectionFactory(templates/system:
   JMS-resource-provider-templates.xml
   #MQTopicConnectionFactory_5)
   ```

5. Create mq topic connection factory:
   - Using Jacl:

     ```
     $AdminConfig create MQTopicConnectionFactory $newjmsp $mqtcfAttrs $template
     ```

   - Using Jython:

     ```
     print AdminConfig.create('MQTopicConnectionFactory', newjmsp, mqtcfAttrs, template)
     ```

   Example output:

   ```
   MQTCF(cells/mycell/nodes/mynode:resources.xml#MQTopicConnectionFactory_1)
   ```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new MQ queues using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new MQ queue:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```

   - Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required MQQueue
     ```

   - Using Jython:

     ```
     print AdminConfig.required('MQQueue')
     ```

   Example output:

   ```
   Attribute       Type
   name       String
   jndiName    String
   baseQueueName  String
   ```

3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name MQQ]
     set jndi [list jndiName jms/MQQ]
     set baseQN [list baseQueueName "Put the base queue name here"]
     set mqqAttrs [list $name $jndi $baseQN]
     ```

     Example output:

     ```
     {name MQQ} {jndiName jms/MQQ} {baseQueueName {Put the base queue name here}}
     ```

   - Using Jython:

     ```
     name = ['name', 'MQQ']
     jndi = ['jndiName', 'jms/MQQ']
     baseQN = ['baseQueueName', "Put the base queue name here"]
     mqqAttrs = [name, jndi, baseQN]
     print mqqAttrs
     ```

     Example output:

     ```
     [[name, MQQ], [jndiName, jms/MQQ], [baseQueueName, "Put the base queue name here"]]
     ```

4. Set up a template:
   - Using Jacl:

     ```
     set template [lindex [$AdminConfig listTemplates MQQueue] 0]
     ```

   - Using Jython:

     ```
     import java
     lineseparator = java.lang.System.getProperty('line.separator')
     template = AdminConfig.listTemplates('MQQueue').split(lineseparator)[0]
     print template
     ```

   Example output:

   ```
   Example.JMS.WMQ.Q1(templates/system:JMS-resource-provider-
   templates.xml#MQQueue_1)
   ```

5. Create MQ queue factory:
   - Using Jacl:

     ```
     $AdminConfig create MQQueue $newjmsp $mqqAttrs $template
     ```

   - Using Jython:

     ```
     print AdminConfig.create('MQQueue', newjmsp, mqqAttrs, template)
     ```

   Example output:

   ```
   MQQ(cells/mycell/nodes/mynode|resources.xml#MQQueue_1)
   ```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new MQ topics using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to configure a new MQ topic:

1. Identify the parent ID:
   - Using Jacl:

     ```
     set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
     ```
   - Using Jython:

     ```
     newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
     print newjmsp
     ```

   Example output:

   ```
   JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
   ```
2. Get required attributes:
   - Using Jacl:

     ```
     $AdminConfig required MQTopic
     ```
   - Using Jython:

     ```
     print AdminConfig.required('MQTopic')
     ```

   Example output:

   ```
   Attribute            Type
   name                 String
   jndiName             String
   baseTopicName        String
   ```
3. Set up required attributes:
   - Using Jacl:

     ```
     set name [list name MQT]
     set jndi [list jndiName jms/MQT]
     set baseTN [list baseTopicName "Put the base topic name here"]
     set mqtAttrs [list $name $jndi $baseTN]
     ```

     Example output:

     ```
     {name MQT} {jndiName jms/MQT} {baseTopicName {Put the base topic name here}}
     ```
   - Using Jython:

     ```
     name = ['name', 'MQT']
     jndi = ['jndiName', 'jms/MQT']
     baseTN = ['baseTopicName', "Put the base topic name here"]
     mqtAttrs = [name, jndi, baseTN]
     print mqtAttrs
     ```

     Example output:

     ```
     [[name, MQT], [jndiName, jms/MQT], [baseTopicName, "Put the base topic name here"]]
     ```
4. Create MQ topic factory:
   - Using Jacl:

     ```
     $AdminConfig create MQTopic $newjmsp $mqtAttrs
     ```
   - Using Jython:

     ```
     print AdminConfig.create('MQTopic', newjmsp, mqtAttrs)
     ```

   Example output:

   ```
   MQT(cells/mycell/nodes/mynode|resources.xml#MQTopic_1)
   ```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Maintaining Version 5 default messaging resources

This topic is the entry-point into a set of topics about maintaining messaging resources provided for WebSphere Application Server version 5 applications by the default messaging provider.

WebSphere application server version 5 applications can use JMS resources provided by the default messaging provider of WebSphere application server version 6. You can use the WebSphere administrative console to manage the JMS connection factories and destinations for WebSphere Application Server version 5 applications. Such JMS resources are maintained as V5 Default Messaging resources.

In a deployment manager cell, you can use V5 Default Messaging resources to maintain Version 5 default messaging resources for both version 6 and version 5 nodes in the cell.

- V5 Default Messaging configured against a version 6 node provides a JMS transport to a messaging engine of a service integration bus that supports the version 6 default messaging provider. The messaging engine emulates the service of a version 5 JMS server.
- V5 Default Messaging configured against a version 5 node provides a JMS transport to a version 5 JMS server.

You can also use the administrative console to manage a JMS server on a Version 5 node.

For more information about maintaining Version 5 default messaging resources, see the following topics:
- "Listing version 5 default messaging resources"
- "Configuring Version 5 default JMS resources" on page 693
- "Managing Version 5 JMS servers in a deployment manager cell" on page 696
- "Configuring authorization security for a Version 5 default messaging provider" on page 697
- "Tuning JMS destinations" on page 701

Listing version 5 default messaging resources

Complete this task to display administrative lists of JMS resources for use by WebSphere application server version 5 applications.

You can use the WebSphere administrative console to display lists of the following types of JMS resources for use by WebSphere application server version 5 applications. You can use the panels displayed to select JMS resources to configure, administer, create, or delete (where appropriate).

To display administrative lists of Version 5 default JMS resources, complete the following general steps:

1. Start the WebSphere administrative console.
2. Display the version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **V5 Default Messaging**.
3. **Optional:** Change the **Scope** setting to the level at which the JMS queue connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
4. In the content pane, under Additional Resources, click the link for the type of JMS resource. This displays a list of any existing resources of the selected type. For more information about the settings panels displayed for resources, see the related reference topics.

JMS provider settings:

Use this panel to view the configuration properties of the selected JMS provider. *You cannot change these properties.*

To view this page, use the administrative console to complete one of the following steps:

- In the navigation pane, click **Resources** → **JMS Providers** → **WebSphere MQ**.
- In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
- In the navigation pane, click **Resources** → **JMS Providers** → **Generic** → *provider_name*.

If you want to browse or change JMS resources of the JMS provider, complete the following steps:

1. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications.
2. Under Additional Properties, click the link for the type of resource . For more information about the administrative console panels for the types of JMS resources, see the related topics.

Scope:

The level to which this resource definition is visible; the cell, node, or server level.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

When JMS resources are created for this messaging provider, they are always created into the provider scope selected in this panel. To browse or change resources in other scopes, select the required level option, then click **Apply**, before clicking the link for the type of resource.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell.

Cell The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

Node The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

Server
The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

Data type String

Name:

The name by which the JMS provider is known for administrative purposes.

Data type String
Default WebSphereJMSProvider

Description:

A description of the JMS provider, for administrative purposes within IBM WebSphere Application Server.

Data type String

Classpath:

The Java classpath for WebSphere MQ as a JMS provider. The list of paths or JAR file names that together form the location for the JMS provider classes.

[JMS Providers > WebSphere MQ and JMS Providers > Generic only]

Data type String
Default **[WebSphere MQ]** $MQJMS_LIB_ROOT

Native Library Path:

The native library path for WebSphere MQ as a JMS provider. An optional path to any native libraries needed by the JMS provider.

[JMS Providers > WebSphere MQ and JMS Providers > Generic only]

Data type String
Default **[WebSphere MQ]** $MQJMS_LIB_ROOT

The Native Library Path property is set to the directory where the WebSphere MQ Java feature is installed.

External initial context factory:

The Java classname of the initial context factory for the JMS provider.

[JMS Providers > Generic only]

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Data type String
Default Null

External provider URL:

The JMS provider URL for external JNDI lookups.

[JMS Providers > Generic only]

For example, an LDAP URL for a messaging provider has the form: `ldap://hostname.company.com/contextName`.

Data type String
Default Null

Version 5 JMS server collection:

On a WebSphere Application Server Version 5 node, a JMS server provides the functions of the JMS provider. Use this panel to list JMS servers on WebSphere Application Server Version 5 nodes within the administration domain, or to select a JMS server to view or change its configuration properties.

There can be at most one JMS server on each Version 5 node in the administration domain, and any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

To view this page, use the administrative console to complete the following step:
1. In the navigation pane, select **Servers** → **Version 5 JMS Servers**.

To browse or change the properties of a JMS server, select its name in the list displayed.

To act on one or more of the JMS servers listed, click the check box next to the server name, then use the buttons provided.

version 5 JMS server settings:

The JMS functions on a version 5 node within a deployment manager cell are served by a JMS server. Use this panel to view or change the configuration properties of the selected JMS server.

JMS servers are supported only to aid migration of WebSphere Application Server version 5 nodes to WebSphere Application Server version 6.

You can use this panel to configure a general set of JMS server properties, which add to the default values of properties configured automatically for the version 5 default messaging provider.

Before you set any of the values on this panel, configure the JMS Server for each node by using the WebSphere Application Server ISPF Customization Dialog.

Name:

The name by which the JMS server is known for administrative purposes within IBM WebSphere Application Server.

This name should not be changed.

Data type	String
Units	Not applicable
Default	WebSphere Internal JMS Server
Range	Not applicable

Description:

A description of the JMS server, for administrative purposes within IBM WebSphere Application Server.

This string should not be changed.

Data type	String
Default	WebSphere Internal JMS Server

Queue Names:

The names of the queues hosted by this JMS server. Each queue name must be added on a separate line.

Each queue listed in this field must have a separate queue administrative object with the same administrative name. To make a queue available to applications, define a WebSphere queue and add its name to this field on the JMS Server panel for the host on which you want the queue to be hosted.

Data type String
Units Queue name
Range Each entry in this field is a queue name of up to 45 characters, which must match exactly (including use of upper- and lowercase characters) the WebSphere queue administrative object defined for the queue.

Initial State:

The state that you want the JMS server to have when it is next restarted.

Data type Enum
Default Started
Range
Started
The JMS server is started automatically.
Stopped
The JMS server is not started automatically. If any deployed enterprise applications are to use JMS server functions provided by the JMS server, the system administrator must start the JMS server manually or select the Started value of this property then restart the JMS server.

To restart a JMS server on a version 5 node, stop then restart that JMS server.

Version 5 WebSphere Queue connection factory collection:

Use this panel to list JMS queue connection factories for point-to-point messaging, for use by WebSphere Application Server version 5 applications. These configuration properties control how connections are created between the JMS provider and the default messaging system that it uses.

This panel shows a list of the JMS queue connection factories with a summary of their configuration properties.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere queue connection factories**. This displays a list of any existing JMS queue connection factories.

To define a new JMS queue connection factory, click **New**.

To browse or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check box next to the name of the connection factory, then use the buttons provided.

Version 5 WebSphere queue connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server version 5 applications.

A WebSphere queue connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server version 5 applications.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. Under Additional Resources, click **WebSphere queue connection factories**. This displays a list of any existing JMS queue connection factories.
4. Click the name of the JMS queue connection factory that you want to work with.

A queue connection factory for the embedded WebSphere JMS provider has the following properties:

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String
Default Null

JNDI name:

The JNDI name that is used to bind the JMS connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Default	Null
Range	Pull-down list of Version 5 nodes in the WebSphere administrative domain.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere queue connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security** → **JAAS Configuration** → **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type Enum
Default Null
Range
ClientContainer
The client container maps authentication aliases.
WSLogin
The WSLogin module maps authentication aliases.
DefaultPrincipalMapping
The JAAS configuration maps an authentication alias to its userid and password.

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to `DIRECT` this property does not apply, and always adopts non-XA coordination.

Data type Checkbox
Default Selected (enabled for XA coordination)

Range	**Selected** The connection factory is enabled for XA-coordination of messages **Cleared** The connection factory is not enabled for XA coordination of messages
Recommended	Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to a range of resource types; for example, JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Session pools**. For example: click **Resources** → **JMS Providers** → **V5 Default Messaging** → **WebSphere queue connection factories** → *connection_factory* → **Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached . For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a ConnectionWaitTimeoutException. It usually does not make sense to retry the getConnection() method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher

value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a ConnectionWaitTimeoutException is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the Web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. JCA data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type String

Default FailingConnectionOnly

Range

EntirePool
All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly
Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Version 5 WebSphere topic connection factory collection:

Use this panel to list JMS topic connection factories for publish/subscribe messaging, for use by WebSphere Application Server version 5 applications. These configuration properties control how connections are created between the JMS provider and the default messaging system that it uses.

This panel shows a list of JMS topic connection factories with a summary of their configuration properties.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere topic connection factories**. This displays a list of any existing JMS topic connection factories.

To define a new JMS topic connection factory, click **New**.

To view or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check box next to the name of the connection factory, then use the buttons provided.

WebSphere topic connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS topic connection factory for publish/subscribe messaging by WebSphere Application Server version 5 applications.

A WebSphere topic connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server version 5 applications.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. Under Additional Resources, click **WebSphere topic connection factories**. This displays a list of any existing JMS topic connection factories.
4. Click the name of the JMS topic connection factory that you want to work with.

A JMS topic connection factory for use with the Version 5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String
Default Null

JNDI name:

The JNDI name that is used to bind the topic connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this topic connection factory, for your IBM WebSphere Application Server administrative records.

Data type String

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type Enum
Default Null
Range Pull-down list of nodes in the WebSphere administrative domain.

Port:

Which of the two ports that connections use to connect to the JMS server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for non-persistent, non-transactional, non-durable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish/subscribe support. Therefore, any topic connection factory configured with **Port** set to `Direct` cannot be used with message-driven beans.

Data type Enum
Units Not applicable
Default QUEUED
Range
QUEUED
The listener port used for full-function JMS-compliant, publish/subscribe support.
DIRECT
The listener port used for direct TCP/IP connection (non-transactional, non-persistent, and non-durable subscriptions only) for publish/subscribe support.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security** → **JAAS Configuration** → **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type Enum
Default Null
Range
ClientContainer
The client container maps authentication aliases.
WSLogin
The WSLogin module maps authentication aliases.
DefaultPrincipalMapping
The JAAS configuration maps an authentication alias to its userid and password.

Clone Support:

Select this checkbox to enable clone support to allow the same durable subscription across topic clones.

Data type Enum
Default Cleared
Range
Selected
Clone support is enabled.
Cleared
Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

Client ID:

The JMS client identifier used for connections to the queue manager.

Data type String
Range A valid JMS client ID

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to `DIRECT` this property does not apply, and always adopts non-XA coordination.

Data type Checkbox
Default Selected (enabled for XA coordination)
Range
Selected
The connection factory is enabled for XA-coordination of messages
Cleared
The connection factory is not enabled for XA coordination of messages

Recommended	Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Version 5 WebSphere queue destination collection:

Use this panel to list JMS queue for point-to-point messaging for use by WebSphere Application Server version 5 applications.

This panel shows a list of the JMS queue destinations with a summary of their configuration properties.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere queue destinations**. This displays a list of any existing JMS queue destinations.

To define a new JMS queue destination, click **New**.

To view or change the properties of a queue destination, select its name in the list displayed.

To act on one or more of the queue destinations listed, click the check box next to the name of the queue, then use the buttons provided.

Version 5 WebSphere queue destination settings:

Use this panel to view or change the configuration properties of the selected JMS queue destination for point-to-point messaging by WebSphere Application Server version 5 applications.

A queue destination is used to configure a JMS queue of the default messaging provider for use by WebSphere Application Server version 5 applications. Connections to the queue are created by the associated V5 Default Messaging WebSphere queue connection factory.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere queue destinations**. This displays a list of any existing JMS queue destinations.
4. Click the name of the JMS queue destination that you want to work with.

A JMS queue for use with the internal WebSphere JMS provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

To enable applications to use this queue, you must add the queue name to the Queue Names field on the panel for the JMS server that hosts the queue.

Data type String

JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes

Data type String
Default Null

Category:

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type Enum
Default APPLICATION DEFINED
Range
APPLICATION DEFINED
Messages on the destination have their persistence defined by the application that put them onto the queue.
NON PERSISTENT
Messages on the destination are not persistent.
PERSISTENT
Messages on the destination are persistent. When a persistent message is put to a queue, all of the message data is written to the messaging log (under the *embedded_messaging_install*\log directory) to make recovery of the message possible.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type Enum
Default APPLICATION DEFINED

Range

APPLICATION DEFINED
The priority of messages on this destination is defined by the application that put them onto the destination.

QUEUE DEFINED
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

SPECIFIED
The priority of messages on this destination is defined by the **Specified priority** property.*If you select this option, you must define a priority on the **Specified priority** property.*

Specified priority:

If the **Priority** property is set to `Specified`, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Default 0
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type Enum
Default APPLICATION DEFINED
Range

APPLICATION DEFINED
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

UNLIMITED
Messages on this queue have no expiry timeout, so those messages never expire.

SPECIFIED
The expiry timeout for messages on this queue is defined by the **Specified expiry** property.*If you select this option, you must define a timeout on the **Specified expiry** property.*

Specified expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type Integer
Units Milliseconds
Default 0

Range	Greater than or equal to 0 • 0 indicates that messages never timeout • Other values are an integer number of milliseconds

Version 5 WebSphere topic destination collection:

Use this panel to list JMS topic destinations for publish/subscribe messaging with the default messaging provider on a Version 5 node in the deployment manager cell.

This panel shows a list of JMS topic destinations with a summary of their configuration properties.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere topic destinations**. This displays a list of any existing JMS topic destinations.

To define a new JMS topic connection factory, click **New**.

To browse or change the properties of a topic destination, select its name in the list displayed.

To act on one or more of the topic destinations listed, click the check box next to the name of the topic, then use the buttons provided.

Version 5 WebSphere topic destination settings:

Use this panel to browse or change the configuration properties of the selected JMS topic destination for publish/subscribe messaging by WebSphere application server version 5 applications.

A WebSphere topic destination is used to configure the properties of a JMS topic for the default messaging provider on a Version 5 node in the deployment manager cell. Connections to the topic are created by the associated topic connection factory.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. Under Additional Resources, click **WebSphere topic destinations**. This displays a list of any existing JMS topic destinations.
4. Click the name of the JMS topic destination that you want to work with.

A JMS topic destination for use with the Version 5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI name:

The JNDI name that is used to bind the topic into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this topic, for your IBM WebSphere Application Server administrative records.

Data type String

Topic:

The name of the topic as defined to the JMS provider.

Data type String
Default Null
Range The topic value can be dot notation and include wildcard characters.

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type Enum
Default APPLICATION DEFINED
Range
APPLICATION DEFINED
Messages on the destination have their persistence defined by the application that put them onto the queue.
NON-PERSISTENT
Messages on the destination are not persistent.
PERSISTENT
Messages on the destination are persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type Enum
Units Not applicable
Default APPLICATION DEFINED
Range
APPLICATION DEFINED
The priority of messages on this destination is defined by the application that put them onto the destination.
QUEUE DEFINED
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
SPECIFIED
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified priority:

If the **Priority** property is set to `Specified`, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Default 0
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type Enum
Units Not applicable
Default APPLICATION DEFINED
Range

APPLICATION DEFINED
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

UNLIMITED
Messages on this queue have no expiry timeout, so those messages never expire.

SPECIFIED
The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*

Specified expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type Integer
Units Milliseconds
Default 0
Range Greater than or equal to 0
- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Configuring Version 5 default JMS resources

Use the following tasks to configure the JMS connection factories and destinations WebSphere application server version 5 applications.

You only need to complete these tasks if you have WebSphere application server version 5 applications that need to use JMS resources provided by the default messaging provider. Such JMS resources are maintained as V5 Default Messaging resources.

In a deployment manager cell, you can use V5 Default Messaging resources to maintain Version 5 default messaging resources for both version 6 and version 5 nodes in the cell.

Configuring a Version 5 queue connection factory:

Use this task to browse or change the properties of a JMS queue connection factory for point-to-point messaging with the default messaging provider on a Version 5 node in the deployment manager cell. This task contains an optional step for you to create a new JMS queue connection factory.

To configure a JMS queue connection factory for use by WebSphere application server version 5 applications, use the administrative console to complete the following steps:

1. Display the version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **Optional:** Change the **Scope** setting to the level at which the JMS queue connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, under Additional Properties, click **WebSphere queue connection factories** This displays any existing JMS queue connection factories for the Version 5 messaging provider in the content pane.

4. To browse or change an existing JMS queue connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this JMS queue connection factory is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the JMS queue connection factory into the name space.
   c. Click **Apply**. This defines the JMS queue connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the queue connection factory, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 JMS topic connection factory:

Use this task to browse or change a JMS topic connection factory for publish/subscribe messaging by WebSphere application server version 5 applications.

To configure a JMS topic connection factory for use by WebSphere application server version 5 applications, use the administrative console to complete the following steps:

1. Display the version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **Optional:** Change the **Scope** setting to the level at which the JMS topic connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, under Additional Properties, click **WebSphere topic connection factories** This displays any existing JMS topic connection factories for the Version 5 messaging provider in the content pane.
4. To browse or change an existing JMS topic connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the JMS topic connection factory into the name space.
   c. Click **Apply**. This defines the JMS topic connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the topic connection factory, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 WebSphere queue destination:

Use this task to browse or change the properties of a JMS queue destination for point-to-point messaging by WebSphere Application Server version 5 applications. This task contains an optional step for you to create a new topic destination.

To optimize performance, configure the topic destination properties to best fit your applications. For more information, see “Performance considerations for WebSphere Version 5 queue destinations” on page 702.

To configure a JMS queue destination for use by WebSphere application server version 5 applications, use the administrative console to complete the following steps:

1. Display the version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **Optional:** Change the **Scope** setting to the level at which the JMS destination is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, under Additional Properties, click **WebSphere queue destinations** This displays any existing queue destinations for the Version 5 default messaging provider in the content pane.
4. To browse or change an existing JMS queue destination, click its name in the list. Otherwise, to create a new queue destination, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this queue destination is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the queue destination into the name space.
   c. Click **Apply**. This defines the queue destination to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the queue destination, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To make a queue destination available to applications, you need to host the queue on a JMS server. To add a new queue to a JMS server or to change an existing queue on a JMS server, you define the administrative name of the queue to the JMS server, as described in Managing Version 5 JMS servers in a deployment manager cell.
9. To have the changed configuration take effect, stop then restart the application server.

Configuring a version 5 WebSphere topic destination:

Use this task to browse or change the properties of a JMS topic destination for publish/subscribe messaging by WebSphere application server version 5 applications.. This task contains an optional step for you to create a new topic destination.

To optimize performance, configure the topic destination properties to best fit your applications. For more information, see “Performance considerations for WebSphere Version 5 topic destinations” on page 702.

To configure a JMS topic destination for use WebSphere application server version 5 applications, use the administrative console to complete the following steps:

1. Display the version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS Providers** → **V5 Default Messaging**.
2. **Optional:** Change the **Scope** setting to the level at which the JMS destination is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.

3. In the content pane, under Additional Properties, click **WebSphere topic destinations** This displays any existing JMS topic destinations for the Version 5 default messaging provider in the content pane.
4. To browse or change an existing JMS topic destination, click its name in the list. Otherwise, to create a new topic destination, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this topic destination is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the topic destination into the name space.

      Topic The name of the topic in the default messaging provider, to which messages are sent.
   c. Click **Apply**. This defines the topic destination to WebSphere Application Server, and enables you to browse or change additional properties.
5. **Optional:** Change properties for the topic destination, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Managing Version 5 JMS servers in a deployment manager cell

Use this task to manage JMS servers on WebSphere Application Server version 5 nodes in a deployment manager cell.

The use of JMS servers is only intended to support migration from WebSphere Application Server version 5 nodes to WebSphere Application Server version 6.

In a WebSphere Application Server deployment manager cell, each Version 5 node can have at most one JMS server, and any Version 5 application server within the cell can use JMS resources served by any of those JMS servers. Applications on WebSphere Application Server version 6 can also use JMS resources served by any of those JMS servers.

You can use the WebSphere administrative console to display a list of all version 5 JMS servers, to show and control their runtime status. You can also configure a general set of JMS server properties, which add to the default values of properties configured automatically for the version 5 default messaging provider.

Note: In general, the default values of properties for the version 5 default messaging provider are adequate for JMS servers. However, if you are running high messaging loads, you may need to change some WebSphere MQ properties; for example, WebSphere MQ properties for log file locations, file pages, and buffer pages. For more information about configuring WebSphere MQ properties, see the *WebSphere MQ System Administration* book, SC33-1873, which is available from the IBM Publications Center or from the WebSphere MQ collection kit, SK2T-0730.

To manage a version 5 JMS server, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers** → **JMS Servers** This displays a table of the JMS servers, showing their runtime status.
2. **Optional:** If you want to change the runtime status of a JMS server, complete the following steps:
   a. In the table of JMS servers, select the JMS servers that you want to act on.
      - To act on one or more specific JMS servers, select the check box next to the JMS server name.
      - To act on all JMS servers, select the check box next to the JMS servers title of the table.
   b. Click one of the actions displayed to change the status of the JMS servers; for example, click **Stop** to stop a JMS server.

The status of the JMS servers that you have acted on is updated to show the result of your actions.

3. **Optional:** If you want to change the properties of a JMS server, complete the following steps:
   a. Click the name of the server
   b. Set one or more of the following configuration properties:

      Initial state
      If you want the JMS server to be started automatically when the application server is next started, set this property to `Started`.

      Number of threads
      Set the number of concurrent threads to be used by the publish/subscribe matching engine. The number of concurrent threads should only be set to a small number.
4. **Optional:** If you want the JMS server to host a new JMS queue, add the queue name to the Queue Names field.

   The name must match the name of a JMS Queue administrative object, including the use of upper- and lowercase.
5. **Optional:** If you want to stop the JMS server hosting a JMS queue, remove the queue name from the Queue Names field.
6. Click **OK**.
7. Save your changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the JMS server.

Configuring authorization security for a Version 5 default messaging provider

Use this task to configure authorization security for the default messaging provider on a WebSphere Application Server version 5 node in a deployment manager cell.

To configure authorization security for the version 5 default messaging provider complete the following steps.

Note: Security for the version 5 default messaging provider is enabled when you enable global security for WebSphere Application Server on the version 5 node. For more information about enabling global security, see Managing secured applications.

1. Configure authorization settings to access JMS resources owned by the embedded WebSphere JMS provider. Authorization to access JMS resources owned by the embedded WebSphere JMS provider is controlled by settings in the *wempspath*/*wempsname*/`config/integral-jms-authorizations.xml` file.

   The settings grant or deny authenticated userids access to internal JMS provider resources (queues or topics). As supplied, the integral-jms-authorisations.xml file grants the following permissions:
   - Read and write permissions to all queues.
   - Pub, sub, and persist to all topics.

   To configure authorization settings, edit the integral-jms-authorisations.xml file according to the information in this topic and in that file.
2. Edit the queue-admin-userids element to create a list of userids with administrative access to all queues. Administrative access is needed to create queues and perform other administrative activities on queues. For example, consider the following queue-admin-userids section:

   ```
   <queue-admin-userids>
       <userid>adminid1</userid>
       <userid>adminid2</userid>
   </queue-admin-userids>
   ```

   In this example the userids adminid1 and adminid2 are defined to have administrative access to all queues.
3. Edit the queue-default-permissions element to define the default queue access permissions. These permissions are used for queues for which you do not define specific permissions (in queue sections). If this section is not specified, then access permissions exist only for those queues for which you have specifically created queue elements.

For example, consider the following queue-default-permissions element:

```
<queue-default-permissions>
  <permission>write</permission>
</queue-default-permissions>
```

In this example the default access permission for all queues is **write**. This can be overridden for a specific queue by creating a queue element that sets its access permission to **read**.

4. If you want to define specific access permissions for a queue, create a queue element, then define the following elements:

   For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
  </public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
  <authorize>
    <userid>useridrw</userid>
    <permission>read</permission>
    <permission>write</permission>
  </authorize>
</queue>
```

   In this example for the queue q1, the userid useridr has read permission, the userid useridw has write permission, the userid useridrw has both read and write permissions, and all other userids have no access permissions (<public></public>).

5. Edit topic elements to define the access permissions for publish/subscribe topic destinations.

   For topics, you can grant and deny access permissions. Full permission inheritance is supported on topics. If you do not define specific access permissions for a userid on a specific topic then permissions are inherited first from the public permissions on that topic then from the parent topic. The inheritance of access permissions continues until the root topic from which the root permissions are assumed.

   a. If you want to define default access permissions for the root topic, edit a topic element with an empty name element. If you omit such a topic section, topics have no default topic permissions other than those defined by specific topic elements. For example, consider the following topic element for the root topic:

```
 <topic>
    <name></name>
    <public>
      <permission>+pub</permission>
    </public>
  </topic>
```

      In this example, the default access permission for all topics is set to publish. This can be overridden by other topic elements for specific topic names.

   b. If you want to define access permissions for a specific topic, create a topic element with the name for the topic then define the access permissions in the public and authorize elements of the topic element. For example, consider the following topic section:

```
  <topic>
    <name>a/b/c</name>
    <public>
      <permission>+sub</permission>
    </public>
    <authorize>
```

```
      <userid>useridpub</userid>
      <permission>+pub</permission>
    </authorize>
  </topic>
```

In this example, the subscribe permission is granted to anyone accessing any topic whose name starts with `a/b/c`. Also, the userid useridpub is granted publish permission for any topic whose name starts with `a/b/c`.

6. Save the integral-jms-authorizations.xml file.

If the dynamic update setting is selected, changes to the integral-jms-authorizations.xml file become active when the changed file is saved, so there is no need to stop and restarted the JMS server. If the dynamic update setting is not selected, you need to stop and restart the JMS server to make changes active.

Dynamic updating is available, by ensuring proper tagging in the integral-jms-authorizations.xml file `<dyanmic-update>true</dynamic-update>`.

Authorization settings for Version 5 default JMS resources:

Use the integral-jms-authorisations.xml file to view or change the authorization settings for Java Message Service (JMS) resources owned by the default messaging provider on WebSphere Application Server version 5 nodes.

Authorization to access default JMS resources owned by the default messaging provider on WebSphere Application Server nodes is controlled by the following settings in the *wempspath*/*wempsname*/config/integral-jms-authorizations.xml file.

This structure of the settings in integral-jms-authorisations.xml is shown in the following example. Descriptions of these settings are provided after the example. To configure authorization settings, follow the instructions provided in Configuring authorization security for the Version 5 JMS providers

```
<integral-jms-authorizations>

  <dynamic-update>true</dynamic-update>

  <queue-admin-userids>
    <userid>adminid1</userid>
    <userid>adminid2</userid>
  </queue-admin-userids>

  <queue-default-permissions>
    <permission>write</permission>
  </queue-default-permissions>

  <queue>
    <name>q1</name>
    <public>
    </public>
    <authorize>
      <userid>useridr</userid>
      <permission>read</permission>
    </authorize>
    <authorize>
      <userid>useridw</userid>
      <permission>write</permission>
    </authorize>
  </queue>

  <queue>
    <name>q2</name>
    <public>
      <permission>write</permission>
    </public>
```

```
    <authorize>
      <userid>useridr</userid>
      <permission>read</permission>
    </authorize>
  </queue>

  <topic>
    <name></name>
    <public>
      <permission>+pub</permission>
    </public>
  </topic>

  <topic>
    <name>a/b/c</name>
    <public>
      <permission>+sub</permission>
    </public>
    <authorize>
      <userid>useridpub</userid>
      <permission>+pub</permission>
    </authorize>
  </topic>

</integral-jms-authorizations>
```

dynamic-update: Controls whether or not the JMS Server checks dynamically for updates to this file.
true (Default) Enables dynamic update support.
false Disables dynamic update checking and improves authorization performance.

queue-admin-userids: This element lists those userids with administrative access to all Version 5 default queue destinations. Administrative access is needed to create queues and perform other administrative activities on queues. You define each userid within a separate userid sub element:
<userid>*adminid***</userid>**
Where *adminid* is a user ID that can be authenticated by IBM WebSphere Application Server.

queue-default-permissions: This element defines the default queue access permissions that are assumed if no permissions are specified for a specific queue name. These permissions are used for queues for which you do not define specific permissions (in queue elements). If this element is not specified, then no access permissions exist unless explicitly authorized for individual queues.

You define the default permission within a separate permission sub element:
<permission>*read-write***</permission>**
Where *read-write* is one of the following keywords:
read By default, userids have read access to Version 5 default queue destinations.
write By default, userids have write access to Version 5 default queue destinations.

queue: This element contains the following authorization settings for a single queue destination:
name The name of the queue.
public The default public access permissions for the queue. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the queue.

You define each default permission within a separate permission element.
authorize
The access permissions for a specific userid. Within each authorize element, you define the following elements:
userid The userid that you want to assign a specific access permission.
permission
An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain the keyword read or write to define the access permission.

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
  </public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
  <authorize>
    <userid>useridrw</userid>
    <permission>read</permission>
    <permission>write</permission>
  </authorize>
</queue>
```

topic: This element contains the following authorization settings for a single topic destination:

Each topic element has the following sub elements:

name The name of the topic, without wildcards or other substitution characters.

public The default public access permissions for the topic. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the topic.

You define each default permission within a separate permission element.

authorize

The access permissions for a specific userid. Within each authorize element, you define the following elements:

userid The userid that you want to assign a specific access permission.

permission

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain one of the following keywords to define the access permission:

+pub Grant publish permission

+sub Grant subscribe permission

+persist

Grant persist permission

-pub Deny publish permission

-sub Deny subscribe permission

-persist

Deny persist permission

Tuning JMS destinations

Use this task to configure the properties of a JMS destination to optimize performance of applications that use the WebSphere Application version 5 default messaging provider or WebSphere MQ as a JMS provider.

To optimize performance, configure destination properties to best fit your applications. You should also consider queue attributes of the JMS server that are associated with the queue name. For more information, see the following topics:

• “Performance considerations for WebSphere Version 5 queue destinations” on page 702

- “Performance considerations for WebSphere Version 5 topic destinations”
- “Performance considerations for WebSphere MQ queue destinations”
- “Performance considerations for WebSphere MQ topic destinations” on page 703

Performance considerations for WebSphere Version 5 queue destinations: To optimize performance, configure the queue destination properties to best fit your applications. For example, setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued. To ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for your application usage.

For queue destinations configured on a WebSphere Application Server version 5 node, you should also consider queue attributes of the internal JMS server that are associated with the queue name. Inappropriate queue attributes can reduce the performance of WebSphere operations.

BOQNAME
: The excessive backout requeue name. This can be set to a local queue name that can hold the messages which were rolled back by the WebSphere applications. This queue name can be a system dead letter queue.

BOTHRESH
: The backout threshold and can be set to a number once the threshold is reached, the message will be moved to the queue name specified in BOQNAME.

For more information about using these properties, see:

- “Handling poison messages” in the *WebSphere MQ Using Java* book
- The *WebSphere MQ Script (MQSC) Command Reference* book

Performance considerations for WebSphere Version 5 topic destinations: To optimize performance, configure the JMS destination properties to best fit your applications. For example, setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued.

For JMS destinations configured on a WebSphere Application Server version 5 node, ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for your application usage.

- Ensure the queue attribute, INDXTYPE is set to MSGID for the following system queues:
  - SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE
  - SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE
- Ensure the queue attribute, INDXTYPE is set to CORRELID for the following system queues:
  - SYSTEM.JMS.ND.SUBSCRIBER.QUEUE
  - SYSTEM.JMS.D.SUBSCRIBER.QUEUE

For more information about using these properties, see:

- The *WebSphere MQ Using Java* book
- The *WebSphere MQ Script (MQSC) Command Reference* book

Performance considerations for WebSphere MQ queue destinations: To optimize performance, configure the queue destination properties to best fit your applications. For example, setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued. To ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for your application usage.

You should also consider queue attributes of the internal JMS server that are associated with the queue name. Inappropriate queue attributes can reduce the performance of WebSphere operations.

You should also consider the queue attributes associated with the queue name you created with WebSphere MQ. Inappropriate queue attributes can reduce the performance of WebSphere operations. You can use WebSphere MQ commands to change queue attributes for the queue name.

BOQNAME
The excessive backout requeue name. This can be set to a local queue name that can hold the messages which were rolled back by the WebSphere applications. This queue name can be a system dead letter queue.

BOTHRESH
The backout threshold and can be set to a number once the threshold is reached, the message will be moved to the queue name specified in BOQNAME.

INDXTYPE
Set this to MSGID. This causes an index of message identifiers to be maintained, which can improve WebSphere MQ retrieval of messages.

DEFSOPT
Set this to SHARED (for shared input from the queue).

SHARE
This must be specified (so that multiple applications can get messages from this queue).

For more information about using these properties, see:

- For BOQNAME and BOTHRESH, see “Handling poison messages” in the *WebSphere MQ Using Java* book
- The *WebSphere MQ Script (MQSC) Command Reference* book

Performance considerations for WebSphere MQ topic destinations: To optimize performance, configure the topic destination properties to best fit your applications. For example, setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued. To ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for your application usage.

- Ensure the queue attribute, INDXTYPE is set to MSGID for the following system queues:
  - SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE
  - SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE
- Ensure the queue attribute, INDXTYPE is set to CORRELID for the following system queues:
  - SYSTEM.JMS.ND.SUBSCRIBER.QUEUE
  - SYSTEM.JMS.D.SUBSCRIBER.QUEUE

- The *WebSphere MQ Script (MQSC) Command Reference* book

JMS components on version 5 nodes

To provide messaging support on a WebSphere Application Server version 5 node, there is at most one JMS server and some number of JMS resources configured for the default messaging JMS provider on that node.

A JMS server on a version 5 node serves the JMS resources (connection factories and destinations) for that node. The JMS server is managed as a separate process to application servers on the same node. Any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

A connection factory encapsulates the configuration properties used to create connections with the JMS provider, to enable applications to access JMS destinations.

The main components of JMS support on a version 5 node are shown in the figure The main components of WebSphere JMS support.

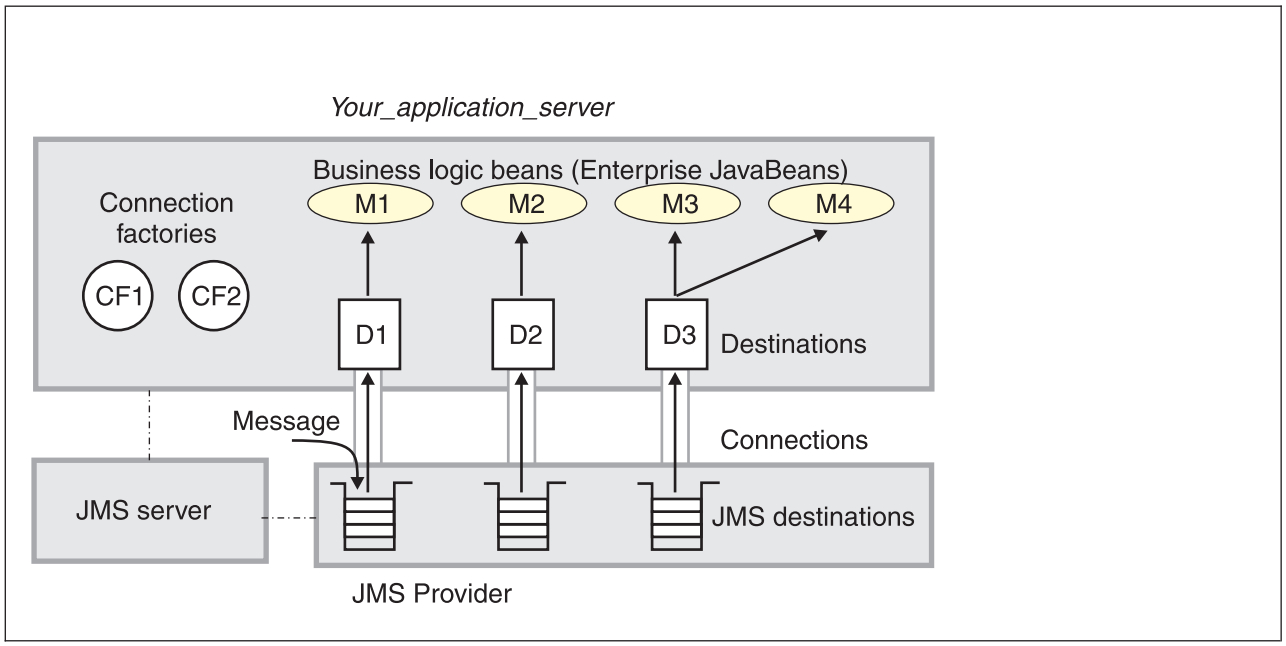

Figure 8. The main JMS components on a version 5 node. This figure shows the main JMS components on a version 5 node, from JMS provider through a connection to a destination, then to a WebSphere enterprise application (acting as a JMS client) that processes the message retrieved from the destination. For more information, see the text that accompanies this figure.

Using JMS resources of WebSphere MQ

This topic is the entry-point into a set of topics about enabling WebSphere applications to use JMS resources provided by WebSphere MQ.

You can install WebSphere MQ as a JMS provider to WebSphere Application Server. WebSphere applications can use the JMS 1.1 interfaces or JMS 1.0.2 interfaces to access JMS resources provided by WebSphere MQ, in addition to JMS resources provided by the default messaging provider (or a generic messaging provider).

You can use the WebSphere administrative console to administer the JMS connection factories and destinations provided by WebSphere MQ.

In a mixed-version WebSphere Application Server deployment manager cell, you can administer WebSphere MQ resources on both Version 6 and Version 5 nodes. For Version 5 nodes, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.

For more information about using WebSphere MQ as a messaging provider to WebSphere Application Server, see the following topics:

- “Installing WebSphere MQ as a JMS provider” on page 705
- “Listing JMS resources for WebSphere MQ” on page 705
- “Configuring JMS resources for the WebSphere MQ messaging provider” on page 765

Installing WebSphere MQ as a JMS provider

Use this task to install and configure WebSphere MQ with support for the Java Message Service (JMS), for use as a JMS provider to WebSphere Application Server.

To install and configure WebSphere MQ for use as a JMS provider to IBM WebSphere Application Server, complete the following steps:

1. Install a supported version of WebSphere MQ, with the required MQ features, as described in the installation instructions provided with WebSphere MQ.

   To identify the a supported version of WebSphere MQ, see the Supported hardware and software Web page at http://www.ibm.com/software/webservers/appserv/doc/latest/prereq.html.

   For information about installing WebSphere MQ, or migrating to a supported version of WebSphere MQ from an earlier version, see the appropriate WebSphere MQ *Quick Beginnings* book, as listed above.

   (RHEL 3.0 and SLES 8) After you install WebSphere MQ on any of the following platforms, but before you try to accept the license, apply the fix located at: http://l3.hursley.ibm.com/cgi-bin/ViewPRB.pl?1812. Otherwise, you may see a segmentation fault error when attempting to run the `mqlicense.sh -accept` command to accept the WebSphere MQ license agreement. Also, export the following variable: `LD_ASSUME_KERNEL=2.4.19`

   - Red Hat Enterprise Linux (RHEL) 3.0 on Intel or s390
   - SUSE Linux Enterprise Server (SLES) 8 on Intel

   If request metrics is enabled when using WebSphere MQ V5.3, an exception is issued and request metrics functions fail. If you use WebSphere MQ V5.3 plus CSD08, no exception is issued; however, request metrics still fails to record the Java Message Service (JMS) type request information. The solution is to apply the interim fix for WebSphere MQ V5.3 plus CSD08: Put the JAR files in the /opt/IBM/WebSphere/AppServer/lib/WMQ/java/lib directory and in the external websphere_mq_install_root/java/lib directories. For more information about this issue, see the Technote 1192026; for example, at http://www-1.ibm.com/support/docview.wss?rs=0&q1;=1192026&uid;=swg21192026.
2. If you want to use WebSphere MQ - Publish/Subscribe support, you need to provide a Publish/Subscribe broker.

   For example, you can do this by using either WebSphere MQ Event Broker or WebSphere MQ Integrator (formerly MQSeries Integrator). For more information about these products, see the following Web sites:
   - WebSphere MQ Event Broker Web site at http://www-4.ibm.com/software/ts/mqseries/platforms/#eventb
   - WebSphere MQ Integrator Web site at http://www-4.ibm.com/software/ts/mqseries/platforms/#integrator
3. Follow the WebSphere MQ instructions for verifying your installation setup.
4. If you want to install IBM WebSphere Application Server on the same host as WebSphere MQ, and have not yet done so, install and customize WebSphere Application Server.
5. Set the MQJMS_LIB_ROOT environment variable to the directory where WebSphereMQ\Java\lib is installed. IBM WebSphere Application Server uses the MQJMS_LIB_ROOT to locate the WebSphere MQ libraries for the WebSphere MQ JMS Provider.

This task has installed WebSphere MQ for use as a JMS provider for WebSphere Application Server.

You can configure JMS resources to be provided by WebSphere MQ, by using the WebSphere administrative console to define WebSphere MQ resources.

Listing JMS resources for WebSphere MQ

Use this task with the WebSphere administrative console to list the JMS resources provided by WebSphere MQ as a messaging provider.

You can use the WebSphere administrative console to display lists of the following types of JMS resources provided by WebSphere MQ. You can use the panels displayed to select JMS resources to administer, or to create or delete JMS resources (where appropriate).

To display administrative lists of JMS resources for WebSphere MQ, complete the following general steps:

1. Start the WebSphere administrative console.
2. In the navigation pane, click **Resources** → **JMS Providers** → **WebSphere MQ**
3. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If the scope is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
4. In the content pane, under Additional Resources, click the link for the type of JMS resource. This displays a list of any existing resources of the selected type. For more information about the settings panels displayed for resources, see the related reference topics.

WebSphere MQ connection factory collection:

The unified JMS connection factories configured in the WebSphere MQ messaging provider, for both point-to-point and publish/subscribe messaging.

This panel shows a list of the WebSphere MQ unified JMS connection factories with a summary of their configuration properties. In a deployment manager cell, these connection factories are not available for Version 5 nodes.

This type of connection factory is sometimes called a “unified” or “domain-independent” JMS connection factory, and supports the JMS 1.1 domain-independent interfaces (referred to as the ″common interfaces″ in the JMS specification). This enables applications to use the same, common, interfaces for both point-to-point and publish/subscribe messaging. A unified JMS connection factory also supports the domain-specific (queue and topic) interfaces, as used in JMS 1.0.2, so applications can still use those interfaces.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. In the content pane, ensure that the scope is set to cell scope or to node or server scope for a Version 6 node.
3. In the content pane, under Additional Resources, click **WebSphere MQ connection factories**. This displays a list of any existing JMS queue connection factories.

To define a new connection factory, click **New**.

To view or change the properties of a queue connection factory, click its name in the list displayed.

To act on one or more of the connection factories listed, select the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere MQ connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with WebSphere MQ as a JMS provider. These configuration properties control how connections are created to associated JMS queues and topics.

This type of connection factory is sometimes called a “unified” or “domain-independent” JMS connection factory, and supports the JMS 1.1 domain-independent interfaces (referred to as the ″common interfaces″ in the JMS specification). This enables applications to use the same, common, interfaces for both

point-to-point and publish/subscribe messaging. A unified JMS connection factory also supports the domain-specific (queue and topic) interfaces, as used in JMS 1.0.2, so applications can still use those interfaces.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, expand **Resources** → **JMS Providers** → **WebSphere MQ**.
2. In the content pane, ensure that the scope is set to cell scope, or to node or server scope for a Version 6 node.
3. In the content pane, under Additional Resources, click **WebSphere MQ connection factories**.
4. Click the name of the JMS connection factory that you want to work with.

A unified JMS connection factory for the WebSphere MQ JMS provider has the following properties.

Note:
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the WebSphere MQ *Using Java* book. and the *WebSphere MQ System Administration* book, SC33-1873, which are available from the WebSphere MQ messaging platform-specific books Web page at http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
