3. Enable WebSphere Application Server security. When you are using Tivoli Access Manager you must configure LDAP as the user registry.
For more information, see the *Securing applications and their environment* PDF.
4. Enable the JACC provider for Tivoli Access Manager.
For more information, see the *Securing applications and their environment* PDF.

Disabling embedded Tivoli Access Manager client:

To unconfigure Tivoli Access Manager Security in WebSphere Application Server, you can use either the wsadmin command-line utility or the WebSphere Application Server administrative console.

- For details on unconfiguring the embedded Tivoli Access Manager client using the WebSphere Application Server administrative console, refer to “Disabling embedded Tivoli Access Manager client using the administrative console.”
- For details on unconfiguring the embedded Tivoli Access Manager client using the wsadmin command line utility, refer to “Disabling embedded Tivoli Access Manager client using wsadmin” on page 1585.

Disabling embedded Tivoli Access Manager client using the administrative console:

To unconfigure the JACC provider for Tivoli Access Manager, you can use the WebSphere Application Server administrative console.

Ensure that all the managed servers, including node agents, are started. Perform the following process once on the deployment management server. Information from the unconfigure operation is forwarded to managed servers, including node agents, when the server is restarted. The managed servers require their own restart for changes to take effect.

1. Restart the deployment manager process.
2. Click **Security > Secure administration, applications, and infrastructure > External authorization providers**.
3. Under Related items, click **External JACC provider**.

4. Under Additional properties, click **Tivoli Access Manager Properties**. The configuration screen for the JACC provider for Tivoli Access Manager is displayed.
5. Clear the **Enable embedded Tivoli Access Manager** option. If you want to ignore errors when unconfiguring, select the **Ignore errors during embedded Tivoli Access Manager disablement** option. Select this option only when the Tivoli Access Manager domain is in an irreparable state.
6. Click **OK**.
7. **Optional:** If you want security enabled without Tivoli Access Manager re-enable administrative security.
8. **Optional:** Synchronize all nodes.
9. Restart all WebSphere Application Server instances for the changes to take effect.

Forcing the unconfiguration of the Tivoli Access Manager JACC provider:

If you find you cannot restart WebSphere Application Server after configuring the JACC provider for Tivoli Access Manager a utility is available to clear the security configuration and return WebSphere Application Server to an operable state.

The utility removes all of the PDLoginModuleWrapper entries as well as the Tivoli Access Manager authorization table from security.xml and wsjaas.conf files. This utility effectively removes the JACC provider for Tivoli Access Manager.

1. Back up the security.xml and wsjaas.conf files.
2. Enter the following command as one continuous line.

```
app_server_root/java/jre/bin/java
-classpath "app_server_root /$WAS_HOME/plugin/com.ibm.ws.runtime_1.0.0.jar"
com.tivoli.pdas.jacc.cfg.CleanSecXML
fully_qualified_path/security.xml fully_qualified_path/wsjaas.conf
```

Authorizing access to administrative roles

You can assign users and groups to administrative roles to identify users who can perform WebSphere Application Server administrative functions.

Administrative roles enable you to control access to WebSphere Application Server administrative functions. Refer to the descriptions of these roles in rsec_adminroles.dita.

Using System Authorization Facility (SAF) authorization to control access to administrative roles:

When the com.ibm.security.SAF.authorization is set to true, SAF EJBROLE profiles are used to control access to administrative roles.

If you select **Use SAF EJBROLE profiles to enforce Java 2 Platform, Enterprise Edition (J2EE) roles** during security domain setup in the Customization dialog, the following administrative roles are defined by the customization jobs. The security domain name might be specified during security domain setup, and the configGroup represents the WebSphere Application Server configuration group name that you chose. The SAF role names are case sensitive.

```
RDEFINE EJBROLE (optionalSecurityDomainName.)administrator UACC(NONE)
RDEFINE EJBROLE (optionalSecurityDomainName.)monitor UACC(NONE)
RDEFINE EJBROLE (optionalSecurityDomainName.)configurator UACC(NONE)
RDEFINE EJBROLE (optionalSecurityDomainName.)operator UACC(NONE)
```

```
PERMIT (optionalSecurityDomainName.)administrator CLASS(EJBROLE) ID(configGroup) ACCESS(READ)
PERMIT (optionalSecurityDomainName.)monitor CLASS(EJBROLE) ID(configGroup) ACCESS(READ)
PERMIT (optionalSecurityDomainName.)configurator CLASS(EJBROLE) ID(configGroup) ACCESS(READ)
PERMIT (optionalSecurityDomainName.)operator CLASS(EJBROLE) ID(configGroup) ACCESS(READ)
```

If you decide at a later date to turn on SAF authorization, you must issue these Resource Access Control Facility (RACF) commands to enable proper WebSphere Application Server operation. You can give a user access to all administrative functions by connecting to the configuration group:

```
CONNECT mvsid GROUP(configGroup)
```

You can also assign individual users to specific roles by issuing the following RACF command:

```
PERMIT (optionalSecurityDomainName.)rolename CLASS(EJBROLE) ID(mvsid) ACCESS(READ)
```

You do not need to restart the server for SAF EJBROLE changes to take effect. However, after the SAF changes are made, you must issue the following RACF command, (or the equivalent for your security system), to refresh the security tables:

```
SETRPTS RACLIST(EJBROLE) REFRESH
```

Using WebSphere Authorization to control access to administrative roles: When `com.ibm.security.SAF.authorization` is set to `false`, WebSphere Application Server authorization and the administrative console are used to control access to administrative roles.

In the administrative console, click **Users and Groups**. Click either **Administrative User Roles** or **Administrative Group Roles**.

1. To add a user or a group, click **Add** on the Console users or Console groups panel.
2. To add a new administrator user, enter a user identity in the User field, highlight **Administrator**, and click **OK**. If there is no validation error, the specified user is displayed with the assigned security role.
3. To add a new administrative group, either enter a group name in the **Specify group** field or select **EVERYONE** or **ALL AUTHENTICATED** from the **Special subject** menu, highlight **Administrator**, and click **OK**. If no validation error occurs, the specified group or special subject is displayed with the assigned security role.
4. To remove a user or group assignment, click **Remove** on the Console Users or the Console Groups panel. On the Console Users or the Console Groups panel, select the check box of the user or group to remove and click **OK**.
5. To manage the set of users or groups to display, click **Show filter function** on the User Roles or Group Roles panel. In the **Search term(s)** box, type a value, then click **Go**. For example, `user*` displays only users with the user prefix.
6. After the modifications are complete, click **Save** to save the mappings.
7. Restart the application server for changes to take effect.

Administrative user roles settings and CORBA naming service user settings

Use the Administrative User Roles page to give users specific authority to administer application servers through tools such as the administrative console or `wsadmin` scripting. The authority requirements are only effective when global security is enabled. Use the Common Object Request Broker Architecture (CORBA) naming service users settings page to manage CORBA naming service users settings.

To view the Console Users administrative console page, complete either of the following steps:

- Click **Security > Secure administration, applications, and infrastructure > Administrative User Roles**.
- Click **Users and Groups > Administrative User Roles**.

To view the CORBA naming service groups administrative console page, click **Environment > Naming > CORBA Naming Service Groups**.

Note: When a third-party authorization such as Tivoli Access Manager or Service Access Facility (SAF) for z/OS is used, the information in this panel might not represent the data in the provider. Also, any changes to this panel might not be reflected in the provider automatically. Follow the provider's instructions to propagate any changes made here to the provider.

User (Administrative user roles):

Specifies users.

The users that are entered must exist in the configured active user registry.

Data type: String

User (CORBA naming service users):

Specifies CORBA naming service users.

The users that are entered must exist in the configured active user registry.

Data type: String

Role (Administrative user roles):

Specifies user roles.

The following administrative roles provide different degrees of authority that are needed to perform certain application server administrative functions:

Administrator

The administrator role has operator permissions, configurator permissions, and the permission that is required to access sensitive data including server password, Lightweight Third Party Authentication (LTPA) password and keys, and so on.

Operator

The operator role has monitor permissions and can change the run-time state. For example, the operator can start or stop services.

Configurator

The configurator role has monitor permissions and can change the WebSphere Application Server configuration.

Monitor

The monitor role has the least permissions. This role primarily confines the user to viewing the application server configuration and current state.

adminsecuritymanager

The adminsecuritymanager role has privileges for managing users and groups from within the administrative console and determines who has access to modify users and groups using administrative role mapping. Only the adminsecuritymanager role can map users and groups to administrative roles, and by default, AdminId is granted to the adminsecuritymanager.

iscadmins

The iscadmins role has administrator privileges for managing users and groups from within the administrative console only.

Note: To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

Data type: String

Range: Administrator, Operator, Configurator, Monitor, and iscadmins

Note: Other arbitrary administrative roles might also be visible in the administrative console collection table. Other contributors to the console might create these additional roles, which can be used for applications that are deployed to the console.

Role (CORBA naming service users):

Specifies naming service user roles.

A number of naming roles are defined to provide degrees of authority that are needed to perform certain application server naming service functions. The authorization policy is only enforced when global security is enabled. The following roles are valid: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete.

The roles now have authority levels from low to high:

CosNamingRead

You can query the application server name space by using, for example, the Java Naming and Directory Interface (JNDI) lookup method. The EVERYONE special-subject is the default policy for this role.

CosNamingWrite

You can perform write operations such as JNDI bind, rebind, or unbind, plus CosNamingRead operations.

CosNamingCreate

You can create new objects in the name space through operations such as JNDI createSubcontext and CosNamingWrite operations.

CosNamingDelete

You can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations.

Data type:

String

Range:

CosNamingRead, CosNamingWrite, CosNamingCreate and CosNamingDelete

Login status (Administrative user roles):

Specifies whether the user is active or inactive.

Administrative group roles and CORBA naming service groups

Use the Administrative Group Roles page to give groups specific authority to administer application servers through tools such as the administrative console or wsadmin scripting. The authority requirements are only effective when administrative security is enabled. Use the Common Object Request Broker Architecture (CORBA) naming service groups page to manage CORBA Naming Service groups settings.

To view the Console Groups administrative console page, complete either of the following steps:

- Click **Security > Secure administration, applications, and infrastructure > Administrative Group Roles**.
- Click **Users and Groups > Administrative Group Roles**.

To view the CORBA naming service groups administrative console page, click **Environment > Naming > CORBA Naming Service Groups**.

Group (CORBA naming service groups):

Identifies CORBA naming service groups.

In previous releases of WebSphere Application Server, there were two default groups: ALL AUTHENTICATED and EVERYONE. However, EVERYONE is now the only default group, and it provides CosNamingRead privileges only.

Data type: String
Range: EVERYONE

Role (CORBA naming service groups):

Identifies naming service group roles.

A number of naming roles are defined to provide the degrees of authority that are needed to perform certain application server naming service functions. The authorization policy is only enforced when global security is enabled.

Four name space security roles are available: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete. The roles have authority levels from low to high:

Cos Naming Read

You can query the application server name space using, for example, the Java Naming and Directory Interface (JNDI) lookup method. The EVERYONE special-subject is the default policy for this role.

Cos Naming Write

You can perform write operations such as JNDI bind, rebind, or unbind, and CosNamingRead operations. The ALL_AUTHENTICATED special-subject is the default policy for this role.

Cos Naming Create

You can create new objects in the name space through operations such as JNDI createSubcontext and CosNamingWrite operations. The ALL_AUTHENTICATED special-subject is the default policy for this role.

Cos Naming Delete

You can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations. The ALL_AUTHENTICATED special-subject is the default policy for this role.

Data type: String
Range: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete

Group (Administrative group roles):

Specifies groups.

The ALL_AUTHENTICATED and the EVERYONE groups can have the following role privileges: Administrator, Configurator, Operator, and Monitor.

Data type: String
Range: ALL_AUTHENTICATED, EVERYONE

Role (Administrative group roles):

Specifies user roles.

The following administrative roles provide different degrees of authority needed to perform certain application server administrative functions:

Administrator

The administrator role has operator permissions, configurator permissions, and the permission that

is required to access sensitive data, including server password, Lightweight Third Party Authentication (LTPA) password and keys, and so on.

Operator

The operator role has monitor permissions and can change the run-time state. For example, the operator can start or stop services.

Configurator

The configurator role has monitor permissions and can change the application server configuration.

Monitor

The monitor role has the least permissions. This role primarily confines the user to viewing the application server configuration and current state.

iscadmins

The iscadmins role has administrator privileges for managing users and groups from within the administrative console only.

Note: To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

Data type:

String

Range:

Administrator, Operator, Configurator, Monitor, and
iscadmins

Note: Other arbitrary administrative roles might also be visible in the administrative console collection table. Other contributors to the console might create these additional roles, which can be used for applications that are deployed to the console.

Assigning users to naming roles

Use this task to assign users to naming roles by using the administrative console.

The following steps are needed to assign users to naming roles. In the administrative console, click **Environment > Naming**, and click **CORBA Naming Service Users** or **CORBA Naming Service Groups**.

1. Click **Add** on the CORBA Naming Service Users or the CORBA Naming Service Groups panel.
2. To add a new naming service user, enter a user identity in the **User** field, highlight one or more naming roles, and click **OK**. If no validation errors occur, the specified user is displayed with the assigned security role.
3. To add a new naming service group, either select **Specify group** and enter a group name or select **Select from special subject** and then select **EVERYONE**. Click **OK**. If no validation errors occur, the specified group or special subject is displayed with the assigned security role.
4. To remove a user or group assignment, go to the **CORBA Naming Service Users** or **CORBA Naming Service Groups** panel. Select the check box next to the user or group that you want to remove and click **Remove**.
5. To manage the set of users or groups to display, expand the **Filter** folder on the right panel, and modify the filter text box. For example, setting the filter to user* displays only users with the user prefix.
6. After modifications are complete, click **Save** to save the mappings. Restart the server for the changes to take effect.

The default naming security policy is to grant all users read access to the CosNaming space and to grant any valid user the privilege to modify the contents of the CosNaming space. You can perform the previously mentioned steps to restrict user access to the CosNaming space. However, use caution when changing the naming security policy. Unless a Java 2 Platform, Enterprise Edition (J2EE) application has clearly specified its naming space access requirements, changing the default policy can result in unexpected org.omg.CORBA.NO_PERMISSION exceptions at runtime.

Propagating administrative role changes to Tivoli Access Manager

These steps provide an example of how to migrate the `admin-authz.xml` file.

Additions and changes to console users and groups are not automatically added to the Tivoli Access Manager object space after the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager is configured. Changes to console users and groups are saved in the `admin-authz.xml` file and this file must be migrated before any changes take effect. The JACC provider for Tivoli Access Manager includes the **migrateEAR** migration utility for incorporating console user and group changes into the Tivoli Access Manager object space.

Note: The **migrateEAR** utility is used to migrate the changes made to console users and groups after the JACC provider for Tivoli Access Manager is configured. The utility does not need to run for changes and additions to console user and groups made prior to the configuration of the JACC provider for Tivoli Access Manager because the changes made to the `admin-authz.xml` and `naming-authz.xml` files are automatically migrated at configuration time. Furthermore, the migration tool does not need to run before deploying standard Java 2 Platform, Enterprise Edition (J2EE) applications; J2EE application policy deployment is also performed automatically.

For example, if you wanted to migrate the `admin-authz.xml` file, perform the following steps:

1. Set up the environment.

Before running the `migrateEAR` utility, set up the environment by running the `setupCmdLine.bat` or `setupCmdLine.sh` file that is located in the `app_server_root/bin` directory.

Make sure that the `WAS_HOME` environment variable is set to the WebSphere Application Server installation directory.

2. Change to the `app_server_root/bin` directory where the `migrateEAR` utility is located.

3. Run the **migrateEAR** utility to migrate the data contained in the `admin-authz.xml` file. Use the parameter descriptions that are listed in “The `migrateEAR` utility for Tivoli Access Manager.”

A status message is displayed when the migration completes. Output of the utility is logged to the `pdwas_migrate.log` file, which is created in the directory where the utility is run. Check the log file after each migration. If the log file displays errors, check the last recorded transaction, correct the source of the error, and rerun the migration utility. If the migration is unsuccessful, verify that you supplied the correct values for the `-c` and `-j` options.

4. WebSphere Application Server does not require a restart for the changes to take effect.

The `migrateEAR` utility for Tivoli Access Manager

The **migrateEAR** utility migrates changes made to console users and groups in the `admin-authz.xml` and `naming-authz.xml` files into the Tivoli Access Manager object space.

Syntax

```
migrateEAR
-j fully_qualified_filename
-c pdPerm.properties_file_location
-a Tivoli_Access_Manager_administrator_ID
-p Tivoli_Access_Manager_administrator_password
-w WebSphere_Application_Server_administrator_user_name
-d user_registry_domain_suffix
[-r root_objectspace_name]
[-t ssl_timeout]
```

Parameters

-a *Tivoli_Access_Manager_administrator_ID*

The administrative user identifier. The administrative user must have the privileges required to create users, objects, and access control lists (ACLs). For example, `-a sec_master`.

This parameter is optional. When the parameter is not specified, you are prompted to supply it at run time.

-c *PdPerm.properties_file_location*

The Uniform Resource Indicator (URI) location of the `PdPerm.properties` file that is configured by the `pdwascfg` utility. When WebSphere Application Server is installed in the default location, the URI is:

-d *user_registry_domain_suffix*

The domain suffix for the user registry to use. For example, for Lightweight Directory Access Protocol (LDAP) user registries, this value is the domain suffix, such as: `"o=ibm,c=us"`

You can use the **`pdadmin user show`** command to display the distinguished name (DN) for a user.

-j *fully_qualified_pathname*

The fully qualified path and file name of the Java 2 Platform, Enterprise Edition application archive file `,admin-authz.xml` or the roles definitions file `naming-authz.xml` that is used for a naming operation authorization. Optionally, this path can also be a directory of an expanded enterprise application. For example, when WebSphere Application Server is installed in the default location, the path to the data files to migrate includes:

`profile_root/config/cells/cell_name`

-p *Tivoli_Access_Manager_administrator_password*

The password for the Tivoli Access Manager administrative user. The administrative user must have the privileges that are required to create users, objects, and access control lists (ACLs). For example, you can specify the password for the `-a sec_master` administrative user as `-p myPassword`.

When this parameter is not specified, the user is prompted to supply the password for the administrative user name.

-r *root_objectspace_name*

The space name of the root object. The value is the name of the root of the protected object namespace hierarchy that is created for WebSphere Application Server policy data.

The default value for the root object space is `WebAppServer`.

Set the Tivoli Access Manager root object space name by modifying the `amwas.amjacc.template.properties` file prior to configuring the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager for the first time. Use this option if the default object space value is not used in the configuration of the Tivoli Access Manager JACC provider for Tivoli Access Manager.

Do not change the Tivoli Access Manager object space name after the Tivoli Access Manager JACC provider is configured.

-t *ssl_timeout*

The number of minutes for the Secure Sockets Layer (SSL) timeout. This parameter is used to disconnect and reconnect the SSL context between the Tivoli Access Manager authorization server and the policy server before the default connection times out.

The default is 60 minutes. The minimum value is 10 minutes. The maximum value cannot exceed the Tivoli Access Manager `ssl-v3-timeout` value. The default value for `ssl-v3-timeout` is 120 minutes.

If you are not familiar with the administration of this value, you can safely use the default value.

-w *WebSphere_Application_Server_administrator_user_name*

The user name that is configured in the WebSphere Application Server security user registry field as the administrator. This value matches the account that you created or imported in "Creating the security administrative user" on page 1434. Access permission for this user is needed to create or update the Tivoli Access Manager protected object space.

When the WebSphere Application Server administrative user does not already exist in the protected object space, it is created or imported. In this case, a random password is generated for the user and the account is set to `not valid`. Change this password to a known value and set the account to `valid`.

A protected object and access control list (ACL) are created. The administrative user is added to the pdwas-admin group with the following ACL attributes:

- T** Traverse permission
- i** Invoke permission

WebAppServer

You can overwrite the action group name. The default name is WebAppServer. This action group name and the matching root object space can be overwritten when the migration utility is run with the **-r** option.

Comments

This utility migrates security policy information from deployment descriptors or enterprise archive files to Tivoli Access Manager for WebSphere Application Server. The script calls `com.tivoli.pdwas.migrate.Migrate` the Java class.

Before invoking the script you must run the **setupCmdLine.bat** or the **setupCmdLine.sh** commands. These files can be found in the `%WAS_HOME%/bin` directory.

The script is dependent on finding the correct environment variables for the location of prerequisite software. The script calls Java code with the following options:

-Dpdwas.lang.home

The directory that contains the native language support libraries that are provided with the JACC provider for Tivoli Access Manager. These libraries are located in a subdirectory under the JACC provider for Tivoli Access Manager installation directory. For example: `-Dpdwas.lang.home=%PDWAS_HOME%\java\nls`

-cp %CLASSPATH% com.tivoli.pdwas.migrate.Migrate

The CLASSPATH variable must be set correctly for your Java installation.

To enable a new user access to the administrative group in WebSphere Application Server, it is recommended that the user be added to the pdwas-admin group after JACC has been enabled. You can enter the administrative primary ID (adminID) in the group. This is required when the serverID is not the same as the adminID.

The following is an example of this command:

```
pdadmin> group modify pdwas-admin add adminID
```

Return codes

The utility can return the following exit status codes:

- 0** The command completed successfully.
- 1** The command failed.

Securing communications

WebSphere Application Server provides several methods to secure communication between a server and a client.

The following topics are covered in this section:

- Secure communications using Secure Sockets Layer
- Creating an SSL configuration
- Creating a keystore configuration

- Creating a self-signed certificate
- Creating a certificate authority request
- Extracting a signer certificate from a personal certificate
- Retrieving signers from a remote SSL port
- Adding a signer certificate to a keystore
- Exchanging signer certificates in a keystore
- Configuring certificate expiration monitoring
- Key management for cryptographic uses
- Creating a key set configuration
- Creating a key set group configuration

Secure communications using Secure Sockets Layer

The Secure Sockets Layer (SSL) protocol provides transport layer security including authenticity, data signing, and data encryption to ensure a secure connection between a client and server that uses WebSphere Application Server. The foundation technology for SSL is *public key cryptography*, which guarantees that when an entity encrypts data using its private key, only entities with the corresponding public key can decrypt that data.

WebSphere Application Server uses Java Secure Sockets Extension (JSSE) as the SSL implementation for secure connections. JSSE is part of the Java 2 Standard Edition (J2SE) specification and is included in the IBM implementation of the Java Runtime Extension (JRE). JSSE handles the handshake negotiation and protection capabilities that are provided by SSL to ensure secure connectivity exists across most protocols. JSSE relies on X.509 certificate-based asymmetric key pairs for secure connection protection and some data encryption. Key pairs effectively encrypt session-based secret keys that encrypt larger blocks of data. The SSL implementation manages the X.509 certificates.

Managing X.509 certificates

Secure communications for WebSphere Application Server require digitally-signed X.509 certificates. The contents of an X.509 certificate, such as its distinguished name and expiration, are either signed by a certificate authority (CA) or are self-signed. When a trusted CA signs an X.509 certificate, WebSphere Application Server identifies the certificate and freely distributes it. A certificate must be signed by a CA because the certificate represents the identity of an entity to the general public. Server-side ports that accept connections from the general public must use CA-signed certificates. Most clients or browsers already have the signer certificate that can validate the X.509 certificate so signer exchange is not necessary for a successful connection.

You can trust the identity of a self-signed X.509 certificate only when a peer in a controlled environment, such as internal network communications, accepts the signer certificate. To complete a trusted handshake, you must first send a copy of the entity certificate to every peer that connects to the entity. Self-signed certificates are less expensive than CA-signed certificates because they do not require signer exchange for a secure connection.

CA and self-signed X.509 certificates reside in Java *keystores*. JSSE provides a reference to the keystore in which a certificate resides. You can select from many types of keystores, including Java Cryptographic Extension (JCE)-based and hardware-based keystores. Typically, each JSSE configuration has two Java keystore references: a keystore and a *truststore*. The keystore reference represents a Java keystore object that holds personal certificates. The truststore reference represents a Java keystore object that holds signer certificates.

A personal certificate without a private key is an X.509 certificate that represents the entity that owns it during a handshake. Personal certificates contain both public and private keys. A signer certificate is an

X.509 certificate that represents a peer entity or itself. Signer certificates contain just the public key and verify the signature of the identity that is received during a peer-to-peer handshake.

For more information, see “Extracting a signer certificate from a personal certificate” on page 1551

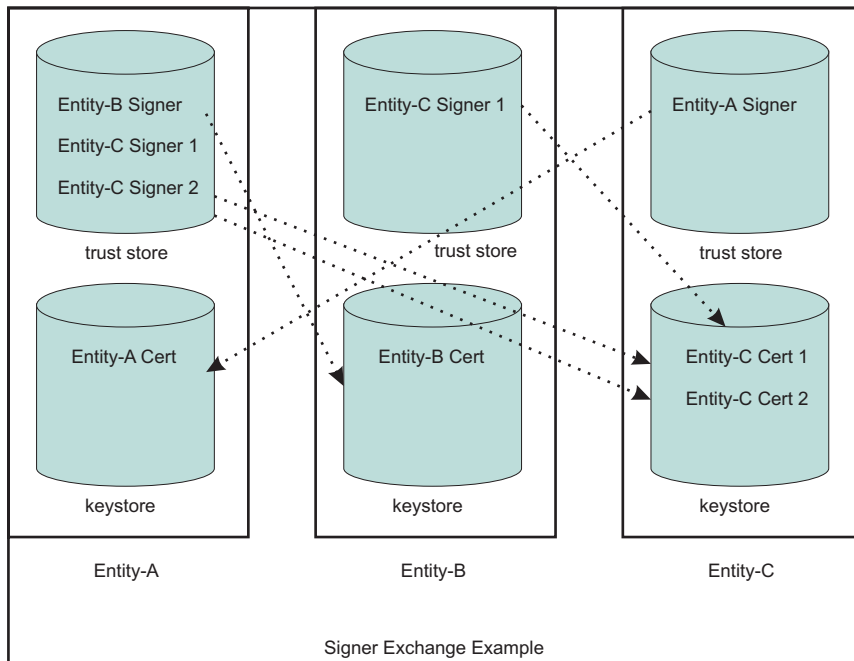

For more information about keystores, see `csec_sslkeystoreconfs.dita`.

Signer exchange

When you configure an SSL connection, you can exchange signers to establish trust in a *personal certificate* for a specific entity. Signer exchange enables you to extract the X.509 certificate from the peer keystore and add it into the truststore of another entity so that the two peer entities can connect. The signer certificate also can originate from a CA as a root signer certificate or an intermediate signer certificate. You can also extract a *signer certificate* directly from a *self-signed certificate*, which is the X.509 certificate with the public key.

Figure 1 illustrates a hypothetical keystore and truststore configuration. An SSL configuration determines which entities can connect to other entities, and the peer connections that are trusted by an SSL handshake. If you do not have the necessary signer certificate, the handshake fails because the peer cannot be trusted.

Figure 15. Signer exchange

In this example, the truststore for Entity A contains three signers. Entity A can connect to any peer as long as one of the three signers validates its personal certificate. For example, Entity A can connect to Entity B or Entity C because the signers can trust both signed personal certificates. The truststore for Entity-B contains one signer. Entity B is able to connect to Entity C only, and only when the peer endpoint is using certificate Entity-C Cert 1 as its identity. The ports that use the other personal certificate for Entity C are not trusted by Entity B. Entity C can connect to Entity A only.

In the example, the self-signed configuration seems to represent a one-to-one relationship between the signer and the certificate. However, when a CA signs a certificate, it typically signs many at a time. The advantage of using a single CA signer is that it can validate personal certificates that are generated by the

CA for use by peers. However, if the signer is a public CA, you must be aware that the signed certificates might have been generated for another company other than your target entity. For your internal communications, private CAs and self-signed certificates are preferable to public CAs because they enable you to isolate the connections that you want to occur and prevent those that you do not want to occur.

SSL configurations

An SSL configuration comprises a set of configuration attributes that you can associate with an *endpoint* or set of endpoints in the WebSphere Application Server topology. The SSL configuration enables you to create an SSLContext object, which is the fundamental JSSE object that the server uses to obtain SSL socket factories. You can manage the following configuration attributes:

- An alias for the SSLContext object
- A handshake protocol version
- A keystore reference
- A truststore reference
- A key manager
- One or more trust managers
- A security level selection of a cipher suite grouping or a specific cipher suite list
- A certificate alias choice for client and server connections

To understand the specifics of each SSL configuration attribute, see “Secure Sockets Layer configurations” on page 1463.

Selecting SSL configurations

In previous releases of WebSphere Application Server, you can reference an SSL configuration only by selecting the SSL configuration alias directly. Each secure endpoint was denoted by an alias attribute that references a valid SSL configuration within a repertoire of SSL configurations. When you made a single configuration change, you had to re-configure many alias references across the various processes. Although the current release still supports direct selection, this approach is no longer recommended.

The current release provides improved capabilities for managing SSL configurations and more flexibility when you select SSL configurations. In this release, you can select from the following approaches:

Programmatic selection

You can set an SSL configuration on the running thread prior to an outbound connection. WebSphere Application Server ensures that most system protocols, including Internet Inter-ORB Protocol (IIOP), Java Message Service (JMS), Hyper Text Transfer Protocol (HTTP), and Lightweight Directory Access Protocol (LDAP), accept the configuration. See “Example: Programmatically specifying an outbound SSL configuration using JSSEHelper API” on page 1515

Dynamic selection

You can associate an SSL configuration dynamically with a specific target host, port, or outbound protocol by using a predefined selection criteria. When it establishes the connection, WebSphere Application Server checks to see if the target host and port match a predefined criteria that includes the domain portion of the host. Additionally, you can predefine the protocol for a specific outbound SSL configuration and certificate alias selection. See “Dynamic outbound selection of Secure Sockets Layer configurations” on page 1473 for more information.

Direct selection

You can select an SSL configuration by using a specific alias, as in past releases. This method of selection is maintained for backwards compatibility because many applications and processes rely on alias references.

Scope selection

You can associate an SSL configuration and its certificate alias, which is located in the keystore

associated with that SSL configuration, with a WebSphere Application Server management scope. This approach is recommended to manage SSL configurations centrally. You can manage endpoints more efficiently because they are located in one topology view of the cell. The inheritance relationship between scopes reduces the number of SSL configuration assignments that you must set.

Each time you associate an SSL configuration with a cell scope, the node scope within the cell automatically inherits the configuration properties. However, when you assign an SSL configuration to a node, the node configuration overrides the configuration that the node inherits from the cell. Similarly, all of the application servers for a node automatically inherit the SSL configuration for that node unless you override these assignments. Unless you override a specific configuration, the topology relies on the rules of inheritance from the cell level down to the endpoint level for each application server.

The topology view displays an inbound tree and outbound tree. You can make different SSL configuration selections for each side of the SSL connection based on what that server connects to as an outbound connection and what the server connects to as an inbound connection. See “Central management of Secure Sockets Layer configurations” on page 1474 for more information.

The runtime uses an order of precedence for determining which SSL configuration to choose because you have many ways to select SSL configurations. Consider the following order of precedence when you select a configuration approach:

1. Programmatic selection. If an application sets an SSL configuration on the running thread using the `com.ibm.websphere.ssl.JSSEHelper` application programming interface (API), the SSL configuration is guaranteed the highest precedence.
2. Dynamic selection criteria for outbound host and port or protocol.
3. Direct selection.
4. Scope selection. Scope inheritance guarantees that the endpoint that you select is associated with an SSL configuration and is inherited by every scope beneath it that does not override this selection.

Default self-signed certificate configuration

By default, WebSphere Application Server creates a unique self-signed certificate for each node. WebSphere Application Server no longer relies on the default or dummy certificate that is shipped with the product. The `key.p12` default keystore and the `trust.p12` truststore are stored in the configuration repository within the node directory.

All of the nodes put their signer certificates in this common truststore (`trust.p12`). Additionally, after you federate a node, the default SSL configuration is automatically modified to point to the common truststore, which is located in the cell directory. The node can now communicate with all other servers in the cell.

All default SSL configurations contain a keystore with the name suffix `DefaultKeyStore` and a truststore with the name suffix `DefaultTrustStore`. These default suffixes instruct the WebSphere Application Server runtime to add the signer of the personal certificate to the common truststore. If a keystore name does not end with `DefaultKeyStore`, the keystore signer certificates are not added to the common truststore when you federate the server. You can change the default SSL configuration, but you must ensure that the correct trust is established for administrative connections, among others.

For more information, see “Default self-signed certificate configuration” on page 1480 and “Web server plug-in default configuration” on page 1490.

Certificate expiration monitoring

Certificate monitoring ensures that the self-signed certificate for each node is not allowed to expire. The certificate expiration monitoring function issues a warning before certificates and signers are set to expire. Those certificates and signers that are located in keystores managed by the WebSphere Application

Server configuration can be monitored. You can configure the expiration monitor to automatically replace a self-signed certificate with a new self-signed certificate that is based upon the same data that is used for the initial creation. The monitor also can automatically replace old signers with the signers from the new self-signed certificates in keystores that are managed by WebSphere Application Server. The existing signer exchanges that occurred by the runtime during federation and by administration are preserved. For more information, see “Certificate expiration monitoring” on page 1489.

WebSphere Application Server clients: signer-exchange requirements

A new self-signed certificate is generated for each node during its initial startup. To ensure trust, clients must be given these generated signers to establish a connection. Several enhancements in the current release make this process simpler. You can gain access to the signer certificates of various nodes to which the client must connect with any one of the following options (for more information, see “Secure installation for client signer retrieval” on page 1484):

- A signer exchange prompt enables you to import signer certificates that are not yet present in the truststores during a connection to a server. By default, this prompt is enabled for administrative connections and can be enabled for any client SSL configuration. When this prompt is enabled, any connection that is made to a server where the signer is not already present offers the signer of the server along with the certificate information and a Secure Hash Algorithm (SHA) digest of the certificate for verification. The user is given a choice whether to accept these credentials. If the credentials are accepted, the signer is added to the truststore of the client until the signer is explicitly removed. The signer exchange prompt does not occur again when connecting to the same server unless the personal certificate changes.
Attention: It is unsafe to trust a signer exchange prompt without verifying the SHA digest. An unverified prompt can originate from a browser when a certificate is not trusted.
- You can run a retrieveSigners administrative script from a client prior to making connections to servers. To download signers, no administrative authority is required. To upload signers, you must have Administrator role authority. The script downloads all of the signers from a specified server truststore into the specified client truststore and can be called to download only a specific alias from a truststore. You can also call the script to upload signers to server truststores. When you select the CellDefaultTrustStore truststore as the specified server truststore and common truststore for a cell, all of the signers for that cell are downloaded to the specified client truststore, which is typically ClientDefaultTrustStore. For more information, see `rxml_retrievesigners.dita`.
- You can physically distribute to clients the trust.p12 common truststore that is located in the cell directory of the configuration repository. When doing this distribution, however, you must ensure that the correct password has been specified in the `ssl.client.props` client SSL configuration file. The default password for this truststore is `WebAS`. Change the default password prior to distribution. Physical distribution is not as effective as the previous options. When changes are made to the personal certificates on the server, automated exchange can fail.

Dynamic SSL configuration changes

The SSL runtime for WebSphere Application Server maintains listeners for most SSL connections. A change to the SSL configuration causes the inbound connection listeners to create a new SSLContext object. Existing connections continue to use the current SSLContext object. Outbound connections automatically use the new configuration properties when they are attempted.

Make dynamic changes to the SSL configuration during off-peak hours to reduce the possibility of timing-related problems and to prevent the possibility of the server starting again. If you enable the runtime to accept dynamic changes, then change the SSL configuration and save the `security.xml` file. Your changes take effect when the new `security.xml` file reaches each node.

Note: If configuration changes cause SSL handshake failures, administrative connectivity failures also can occur, which can lead to outages. In this case, you must re-configure the SSL connections then perform manual node synchronization to correct the problem. You must carefully complete any

dynamic changes. It is highly recommended that you perform changes to SSL configurations on a test environment prior to making the same changes to a production system. For more information, see “Dynamic configuration updates” on page 1491.

Built-in certificate management

Certificate management that is comparable to iKeyMan functionality is now integrated into the keystore management panels of the administrative console. Use built-in certificate management to manage personal certificates, certificate requests, and signer certificates that are located in keystores. Additionally, you can remotely manage keystores. For example, you can manage a file-based keystore that is located outside the configuration repository on any node from the deployment manager. You also can remotely manage hardware cryptographic keystores from the deployment manager.

With built-in certificate management, you can replace a self-signed certificate along with all of the signer certificates scattered across many truststores and retrieve a signer from a remote port by connecting to the remote SSL host and port and intercepting the signer during the handshake. The certificate is first validated according to the certificate SHA digest, then the administrator must accept the validated certificate before it can be placed into a truststore.

When you make a certificate request, you can send it to a certificate authority (CA). When the certificate is returned, you can accept it within the administrative console. For more information, see “Certificate management” on page 1494.

Tip: Although iKeyMan functionality still ships with WebSphere Application Server, configure keystores from the administrative console using the built-in certificate management functionality. iKeyMan is still an option when it is not convenient to use the administrative console. For more information, see `csec_sslikeymancertman.dita`.

AdminTask configuration management

The SSL configuration management panels in the administrative console rely primarily on administrative tasks, which are maintained and enhanced to support the administrative console function. You can use `wsadmin` commands from a Java console prompt to automate the management of keystores, SSL configurations, certificates, and so on.

Secure Sockets Layer configurations

Secure Sockets Layer (SSL) configurations contain attributes that enable you to control the behavior of both client and server SSL endpoints. You can identify SSL configurations by their user-assigned names or aliases, and assign them to specific management scopes. The scope that an SSL configuration inherits depends upon whether you create it using a cell, node, server, or endpoint link in the configuration topology.

When you create an SSL configuration, you can set the following SSL connection attributes:

- Keystore
- Default client certificate for outbound connections
- Default server certificate for inbound connections
- Truststore
- Key manager for selecting a certificate
- Trust manager or managers for establishing trust during the handshake
- Handshaking protocol
- Ciphers for negotiating the handshake
- Client authentication support and requirements

You can manage an SSL configuration using any of the following methods:

- Central management selection
- Direct reference selection
- Dynamic outbound connection selection
- Programmatic selection

You can view an SSL configuration in the topology at the point where it was created and at all of the scopes below that point. If you want the entire cell to view an SSL configuration, you must create the configuration at the cell level in the topology. Using the administrative console, you can manage all of the SSL configurations for WebSphere Application Server. From the administrative console, click **Security > SSL certificates and key management > Manage endpoint security configurations > Inbound | Outbound > SSL_configuration**. Using the `ssl.client.props` properties file, you can manage client SSL configurations. The `ssl.client.props` file is located in the `${USER_INSTALL_ROOT}/properties` directory for each profile. For more information about configuring this file, see the “`ssl.client.props` client configuration file” on page 1525.

SSL configuration in the security.xml file

In the `security.xml` file, you can define specific attributes to configure an SSL configuration repertoire entry at a specific management scope. The scope determines the point at which other levels in the cell topology can see the configuration, as shown in the following example:

```
<repertoire xmi:id="SSLConfig_1" alias="NodeDefaultSSLSettings"
managementScope="ManagementScope_1" type="JSSE">
<setting xmi:id="SecureSocketLayer_1" clientAuthentication="false"
clientAuthenticationSupported="false" securityLevel="HIGH" enabledCiphers=""
jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS" keyStore="KeyStore_1"
trustStore="KeyStore_2" trustManager="TrustManager_1" keyManager="KeyManager_1"
clientKeyAlias="default" serverKeyAlias="default"/>
</repertoire>
```

The SSL configuration attributes that display in the previous code are described in Table 1.

Table 29. `security.xml` Attributes

security.xml attribute	Description	Default	Associated SSL property
xmi:id	The xmi:id attribute represents the unique identifier for this XML entry and determines how the SSL configuration is linked to other XML objects, such as SSLConfigGroup. This system-defined value must be unique.	The administrative configuration service defines the default value.	None. This value is used only for XML associations.
alias	The alias attribute defines the name of the SSL configuration. Direct selection uses the alias attribute and the node is not prefixed to the alias. Rather, the management scope takes care of ensuring that the name is unique within the scope.	The default is CellDefaultSSLSettings.	com.ibm.ssl.alias
managementScope	The managementScope attribute defines the management scope for the SSL configuration and determines the visibility of the SSL configuration at runtime.	The default scope is the cell.	The managementScope attribute is not mapped to an SSL property. However, it confirms whether or not the SSL configuration is associated with a process.

Table 29. security.xml Attributes (continued)

security.xml attribute	Description	Default	Associated SSL property
type	<p>The type attribute defines the Java Secure Socket Extension (JSSE) or System Secure Sockets Layer (SSSL) configuration option. JSSE is the SSL configuration type for most secure communications within WebSphere Application Server.</p> <p>Both JSSE and SSSL are valid options. The z/OS daemon still uses SSSL in this release.</p>	The default is JSSE.	com.ibm.ssl.sslType
clientAuthentication	The clientAuthentication attribute determines whether SSL client authentication is required.	The default is false.	com.ibm.ssl.clientAuthentication
clientAuthenticationSupported	<p>The clientAuthenticationSupported attribute determines whether SSL client authentication is supported. The client does not have to supply a client certificate if it does not have a client certificate.</p> <p>Attention: When you set the clientAuthentication attribute to true, you override the value that is set for the clientAuthenticationSupported attribute.</p>	The default is false.	com.ibm.ssl.client.AuthenticationSupported
securityLevel	The securityLevel attribute determines the cipher suite group. Valid values include HIGH (128-bit ciphers), MEDIUM (40-bit ciphers), LOW (for all ciphers without encryption), and CUSTOM (if the cipher suite group is customized. When you set the enabledCiphers attribute with a specific list of ciphers, the system ignores this attribute.	The default is HIGH.	com.ibm.ssl.securityLevel
enabledCiphers	You can set the enabledCiphers attribute to specify a unique list of cipher suites. Separate each cipher suite in the list with a space.	The default is the securityLevel attribute for cipher suite selection.	com.ibm.ssl.enabledCipherSuites
jsseProvider	The jsseProvider attribute defines a specific JSSE provider.	The default is IBMJSSE2.	com.ibm.ssl.contextProvider

Table 29. *security.xml* Attributes (continued)

security.xml attribute	Description	Default	Associated SSL property
sslProtocol	The sslProtocol attribute defines the SSL handshake protocol. Valid options include: SSLv2 (client-side only), SSLv3, SSL, SSL_TLS, TLSv1, and TLS values. The SSL option includes SSLv2 and SSLv3 values. The TLS option includes the TLSv1 value. SSL_TLS, which is the most interoperable protocol, includes all these values and defaults to a Transport Layer Security (TLS) handshake.	The default is SSL_TLS.	com.ibm.ssl.protocol
keyStore	The keyStore attribute defines the keystore and attributes of the keyStore instance that the SSL configuration uses for key selection.	The default is CellDefaultKeyStore.	For more information, see Keystore configurations.
trustStore	The trustStore attribute defines the key store that the SSL configuration uses for certificate signing verification.	The default is CellDefaultTrustStore.	A trustStore is a logical JSSE term. It signifies a key store that contains signer certificates. Signer certificates validate certificates that are sent to WebSphere Application Server during an SSL handshake.
keyManager	The keyManager attribute defines the key manager that WebSphere Application Server uses to select keys from a key store. A JSSE key manager controls the javax.net.ssl.X509KeyManager interface. A custom key manager controls the javax.net.ssl.X509KeyManager and the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interfaces. The com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface provides more information from WebSphere Application Server.	The default is IbmX509.	com.ibm.ssl.keyManager defines a well-known key manager and accepts the algorithm and algorithm provider formats, for example IbmX509 and IbmX509 IBMJSSE2. com.ibm.ssl.customKeyManager defines a custom key manager and takes precedence over the other keyManager properties. This class must implement javax.net.ssl.X509KeyManager and can implement com.ibm.wsspi.ssl.KeyManagerExtendedInfo. For more information, see csec_sslx509certIDkeyman.dita
trustManager	The trustManager determines which trust manager or list of trust managers to use for determining whether to trust the peer side of the connection. A JSSE trust manager implements the javax.net.ssl.X509TrustManager interface. A custom trust manager might also implement com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface to get more information from the WebSphere Application Server environment.	The default is IbmX509. You can specify the IbmPKIX trust manager for certificate revocation list (CRL) verification when the certificate contains a CRL distribution point.	com.ibm.ssl.trustManager defines a well-known trust manager, which is required for most handshake situations. com.ibm.ssl.trustManager performs certificate expiration checking and signature validation. You can define com.ibm.ssl.customTrustManagers with additional custom trust managers that are called during an SSL handshake. Separate additional trust managers with the vertical bar () character. For more information, see csec_sslx509certtrustdecisions.dita

Trust manager control of X.509 certificate trust decisions:

The role of the trust manager is to validate the Secure Sockets Layer (SSL) certificate that is sent by the peer, which includes verifying the signature and checking the expiration date of the certificate. A Java Secure Socket Extension (JSSE) trust manager determines if the remote peer can be trusted during an SSL handshake.

WebSphere Application Server has the ability to call multiple trust managers during an SSL connection. The default trust manager does the standard certificate validation; custom trust manager plug-ins run customized validation such as host name verification. For more information, see “Example: Developing a custom trust manager for custom SSL trust decisions” on page 1506

When a trust manager is configured in a server-side SSL configuration, the server calls the `isClientTrusted` method. When a trust manager is configured in a client-side SSL configuration, the client calls the `isServerTrusted` method. The peer certificate chain is passed to these methods. If the trust manager chooses not to trust the peer information, it might produce an exception to force a handshake failure.

Optionally, WebSphere Application Server provides the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface so that additional information can be passed to the trust manager. For more information, see the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface.

Default IbmX509 trust manager

The default IbmX509 trust manager, which is used in the following code sample, establishes trust by performing standard certificate validation.

```
<trustManagers xmi:id="TrustManager_1132357815717" name="IbmX509" provider="IBMJSSE2"
algorithm="IbmX509" managementScope="ManagementScope_1132357815717"/>
```

The trust manager provides a signer certificate to verify the peer certificate that is sent during the handshake. The signers who are added to the truststore for the SSL configuration must be trustworthy. If you do not trust the signers or do not want to allow others to connect to your servers, consider removing default root certificates from certificate authorities (CA). You might also remove any self-signed certificates if you cannot verify their origination.

Default IbmPKIX trust manager

You can use the default IbmPKIX trust manager to replace the IbmX509 trust manager, which is shown in the following code sample:

```
<trustManagers xmi:id="TrustManager_1132357815719" name="IbmPKIX" provider="IBMJSSE2"
algorithm="IbmPKIX" trustManagerClass="" managementScope="ManagementScope_1132357815717">
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1132357815717"
name="com.ibm.security.enableCRLDP" value="true" type="boolean"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1132357815718"
name="com.ibm.jsse2.checkRevocation" value="true" type="boolean"/>
</trustManagers>
```

In addition to its role of standard certificate verification, the IbmPKIX trust manager checks for certificates that contain certificate revocation list (CRL) distribution points. This process is known as *extended CRL checking*. When you select a trust manager, its associated properties are automatically set as Java System properties so that the IBM CertPath and IBMJSSE2 providers are aware that CRL checking is enabled.

Custom trust manager

You can define a custom trust manager to perform additional trust checking, which is based upon the needs of the environment. For example, in one environment, you might enable connections from the same Transmission Control Protocol (TCP) subnet only. The `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface provides extended information about the connection that is not provided by the standard Java Secure Sockets Extension (JSSE) `javax.net.ssl.X509TrustManager` interface. The configured `trustManagerClass` attribute determines which class is instantiated by the runtime, as shown in the following code sample:

```
<trustManagers xmi:id="TrustManager_1132357815718" name="CustomTrustManager"
trustManagerClass="com.ibm.ws.ssl.core.CustomTrustManager"
managementScope="ManagementScope_1132357815717"/>
```

The `trustManagerClass` attribute must implement the `javax.net.ssl.X509TrustManager` interface and, optionally, can implement the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface.

Disabling the default trust manager

In some cases, you might not want to perform the standard certificate verification that is provided by the `IbmX509` and `IbmPKIX` default trust managers. For example, you might be working with an internal automated test infrastructure that is not concerned with SSL client or server authentication, integrity, or confidentiality. The following sample code shows a basic custom trust manager such as `com.ibm.ws.ssl.core.CustomTrustManager` whose property is set to `true`.

```
com.ibm.ssl.skipDefaultTrustManagerWhenCustomDefined=true
```

You can set this property in the global properties at the top of the `ssl.client.props` file for clients or in the `security.xml` custom properties file for servers. You must configure a custom trust manager when you disable the default trust manager to prevent the server from calling the default trust manager even though it is configured. Disabling the default trust manager is not a common practice. Be sure to test the system with the disabled default trust manager in a test environment first. For more information on setting up a custom trust manager, see “Creating a custom trust manager configuration” on page 1503

Key manager control of X.509 certificate identities:

The role of a Java Secure Socket Extension (JSSE) key manager is to retrieve the certificate that is used to identify the client or server during a Secure Sockets Layer (SSL) handshake.

WebSphere Application Server provides a default key manager that can select a certificate from a keystore when you define the following SSL configuration properties:

com.ibm.ssl.keyStoreClientAlias

Defines the alias that is chosen from the keystore for the client side of a connection. This alias must be present in the keystore.

com.ibm.ssl.keyStoreServerAlias

Defines the alias that is chosen from the keystore for the server side of a connection. This alias must be present in the keystore.

These two properties are set automatically when you use the administrative console because the default key manager is already configured.

With WebSphere Application Server, you can configure only one key manager at a time for a given SSL configuration. If you want custom certificate selection logic on the client side, you must write a new custom key manager. The custom key manager could provide function that prompts the user to choose a certificate dynamically. Also, you can implement an extended interface so that a key manager can provide information during connection time. For more information on the extended interface, see the `com.ibm.wsspi.ssl.KeyManagerExtendedInfo` interface. For more information on custom key manager development, see `rsec_ssldevcustomkeymgr.dita`.

Default IbmX509 key manager

The default `IbmX509` key manager chooses a certificate to serve as the identity for an SSL handshake. The key manager is called to enable client authentication on either side of the SSL handshake; frequently on the server-side, and less frequently on the client side according to client and server requirements. If a keystore is not configured on the client-side and SSL client authentication is enabled, the key manager cannot select a certificate to send to the server. Therefore, the handshake fails.

The following sample code shows the key manager configuration in the `security.xml` file for an `IbmX509` key manager.

```
<keyManagers xmi:id="KeyManager_1" name="IbmX509"
provider="IBMJSSE2" algorithm="IbmX509" keyManagerClass=""
managementScope="ManagementScope_1"/>
```

You do not specify the `keyManagerClass` class because the key manager is provided by the IBMJSSE2 provider. However, you can specify whether the key manager is a custom class implementation, in which case you must specify the `keyManager` class, or an algorithm name that WebSphere Application Server can start from the Java security provider framework.

Custom key manager

The following sample code shows the key manager configuration in the `security.xml` file for a custom class.

```
<keyManagers xmi:id="KeyManager_2" name="CustomKeyManager"
keyManagerClass="com.ibm.ws.ssl.core.CustomKeyManager"
managementScope="ManagementScope_1"/>
```

The custom class must implement the `javax.net.ssl.X509KeyManager` interface and, optionally, implement the `com.ibm.wsspi.ssl.KeyManagerExtendedInfo` interface to retrieve additional WebSphere Application Server information. This interface replaces the function of the default key manager because you can configure only one key manager at a time. Therefore, the custom key manager has sole responsibility for selecting the alias to use from the configured keystore. The benefit of a custom key manager is its ability, on the client side, to prompt for an alias. This process enables the user to decide which certificate to use in situations where the user knows the client certificate identity. For more information, see `tsec_sslcreatecuskeymgr.dita`.

Keystore configurations

Use keystore configurations to define how the runtime for WebSphere Application Server loads and manages keystore types for Secure Sockets Layer (SSL) configurations.

By default, the `java.security.Security.getAlgorithms("KeyStore")` attribute does not display a predefined list of keystore types in the administrative console. Instead, WebSphere Application Server retrieves all of the `KeyStore` types that can be referenced by the `java.security.KeyStore` object, including hardware cryptographic, z/OS platform, i5/OS platform, IBM Java Cryptography Extension (IBMJCE), and Java-based content management system (CMS)-provider keystores. If you specify a keystore provider in the `java.security` file or add it to the provider list programmatically, WebSphere Application Server also retrieves custom keystores. The retrieval list depends upon the `java.security` configuration for that platform and process.

IBMJCE file-based keystores (JCEKS, JKS, and PKCS12)

A typical IBMJCE file-based keystore configuration is shown in the following sample code:

```
<keyStores xmi:id="KeyStore_1" name="NodeDefaultKeyStore"
password="{xor}349dkckdd=" provider="IBMJCE"
location="{USER_INSTALL_ROOT}/config/cells/myhostNode01Cell
/nodes/myhostNode01/key.p12" type="PKCS12" fileBased="true"
hostList="" initializeAtStartup="true" readOnly="false"
managementScope="ManagementScope_1"/>
```

For more information about default keystore configurations, see `csec_ssldefselfsigncertconf.dita`.

Table 1 describes the attributes that are used in the sample code.

Table 30. keystore configurations

Attribute name	Default	Description
xmi:id	Varies	A value that issued to reference the keystore from another area in the configuration, for example, from an SSL configuration. Make this value unique within the security.xml file.
name	For JSSE keystore: CellDefaultKeyStore. For JSSE truststore: CellDefaultTrustStore.	A name that is used to identify the keystore by sight. The name can determine if the keystore is a default keystore based upon whether the name ends with DefaultKeyStore or DefaultTrustStore.
password	The default keystore password is WebAS. It is recommended that this be changed as soon as possible. See "Updating default key store passwords using scripting" on page 1592 for more information.	The password that is used to access the keystore name is also the default that is used to store keys within the keystore.
provider	The default provider is IBMJCE.	The Java provider that implements the type attribute (for example, PKCS12 type). The provider can be left unspecified and the first provider that implements the keystore type specified is used.
location	The default varies, but typically references a key.p12 file or a trust.p12 file in the node or cell directories of the configuration repository. These files are PKCS12 type keystores.	The keystore location reference. If the keystore is file-based, the location can reference any path in the file system of the node where the keystore is located. However, if the location is outside of the configuration repository, and you want to manage the keystore remotely from the administrative console or from the wsadmin utility, then specify the hostList attribute that contains the host name of the node where it resides.
type	The default Java crypto device keystore type is PKCS12.	This type specifies the keystore. Valid types can be those returned by the <code>java.security.Security.getAlgorithms("KeyStore")</code> attribute. These types include the following keystore types, and availability depends on the process and platform <code>java.security</code> configuration: <ul style="list-style-type: none"> • JKS • JCEKS • PKCS12 • PKCS11 (Java crypto device) • CMSKS • IBMi5OSKeyStore • JCERACFKS • JCE4758KS (z/OS crypto device)
fileBased	The default is true.	This option is required for default keystores. It indicates a file-system keystore so you can use a <code>FileInputStream</code> or <code>FileOutputStream</code> for loading and storing the keystore.

Table 30. keystore configurations (continued)

Attribute name	Default	Description
hostList	The hostList attribute is used to specify a remote hostname so that the keystore can be remotely managed. There are no remotely managed keystores by default. All default keystores are managed locally in the configuration repository and synchronized out to each of the nodes.	The option manages a keystore remotely. You can set the host name of a valid node for a keystore. When you use either the administrative console or the wsadmin utility to manage certificates for this keystore, an MBean call is made to the node where the keystore exists for the approved operation. You can specify multiple hosts, although synchronization of the keystore operations are not guaranteed. For example, one of the hosts that is listed might be down when a specific operation is performed. Therefore, use multiple hosts in this list.
initializeAtStartup	The default is true.	This option informs the runtime to initialize the keystore during startup. This option can be important for hardware cryptographic device acceleration.
readOnly	The default is false.	This option informs the configuration that you cannot write to this keystore. That is, certain update operations on the keystore cannot be attempted and are not allowed. An example of a read-only keystore type is JCERACFKS on the z/OS platform. This type is read-only from the WebSphere certificate management standpoint, but you can also update it using the keystore management facility for RACF.
managementScope	The default scope is the node scope for a base Application Server environment and the cell scope for a Network Deployment environment.	This option references a particular management scope in which you can see this keystore. For example, if a hardware cryptographic device is physically located on a specific node, then create the keystore from a link to that node in the topology view under Security > Security Communications > SSL configurations . You can also use management scope to isolate a keystore reference. In some cases, you might need to allow only a specific application server to reference the keystore; the management scope is for that specific server.

z/OS keystores

WebSphere Application Server supports IBMJCE file-based keystores, Java Cryptography Extension Key Stores (JCEKS), Java Key Stores (JKS), and Public Key Cryptography Standards 12 (PKCS12), and z/OS-specific keystores. The IBMJCE file-based keystore support on z/OS is fully compatible with and similar to the support on the distributed platform.

The z/OS platform offers three additional keystores types that can be used for WebSphere Application Server on z/OS:

- JCE4758KS keystores are file-based keystores. Keys and certificates can be in this file or directly in Integrated Cryptographic Services Facility (ICSF).
- JCERACFKS is a Resource Access Control Facility (RACF)-based keystore that is used to support keys and certificates that are contained in a RACF keystore. Key material stored in ICSF are not supported with this keystore type.
- JCE4758RACFKS keystores are RACF-based keystores that are used to support keys and certificates that are contained in a RACF keystore along with keys that are stored in ICSF using the ICSF option with RACF RACDCERT.

The JCERACFKS and JCE4758RACFKS keystores use unique keystore names and are specified as keystore_type:key_name:racfid. The keystore_type must be either JCERACFKS or JCE4758RACFKS, for example, JCERACFKS:myKeyRing:USER01. If the keystore name matches the RACF keyring format and points to a valid RACF keyring, Java uses the specified RACF keyring as its keystore. If the keyring format is used, and the specified keystore type is anything other than JCERACFKS or JCE4758KS, Java attempts to interpret the keystore name as the name of a JKS keystore file. The JCE4758KS will use the normal file-based keystore name.

An IBMJCE provider can only support the JCERACFKS keystore in the set of z/OS-specific keystores that are listed previously. The IBMJCE provider cannot use the JCE4758KS or JCE4758RACFKS keystore material since it is specific to the hardware.

An IBMJCECCA provider can support software key materials for the JCERACFKS, JKS, and JCEKS keystores, and take advantage of the hardware acceleration.

A new keystore class, JceRACFKeyStore, has been added to the IBMJCE and IBMJCE4758 providers. Use this class when you retrieve certificates and keys from a keyring because this keystore allows WebSphere Application Server to read from a keyring. However, if the server attempts to write data to the keyring, an IOException is thrown. While the RACFInputStream works with any keystore, it is possible that data stored in RACF could be inadvertently written to an Hierarchical File System (HFS) file if the server uses a keystore other than the JceRACFKeyStore class.

RACFInputStream can access keys and certificates that are stored in a Service Authorization Facility (SAF) keyring implementation using either of the following methods:

- Use RACFInputStream directly to pass in a newly-created instance to the JceRACFKeyStore class
- Use URLStreamHandler to call RACFInputStream, then pass the instance to the JceRACFKeyStore class

For more information, see rsec_racfkeyringsetup.dita.

All JAVA RACF services, including the JceRACFKeyStore and RACFInputStream, use the R_datalib (IRRSDL00) service to retrieve certificates from RACF. However, to use this service, you must obtain authorization for R_datalib before you use any JAVA RACF classes. For more information on how to setup the necessary authorizations, see *OS/390 Security Server Callable Services guide*.

CMS keystores

You can set some provider-specific attributes in CMS keystores.

If the CMSKS provider supports the createStashFileForCMS attribute, and you set the attribute to true for CMSKS keystores, WebSphere Application Server creates an .sth file in the keystore location that is referenced by the attribute. The .sth extension is appended to the keystore name. For example, if the CMSKS keystore is available for a plug-in configuration and you set createStashFileForCMS to true, the stash file that is represented in the following sample code is created in the \${USER_INSTALL_ROOT}\profiles\AppSrv01/config/cells/myhostCell01/nodes/myhostNode01/servers/webserver1/plugin-key.sth path.

```
<keyStores xmi:id="KeyStore_1132071489571" name="CMSKeyStore"
password="{xor}HRYNFAtRbxEw0zpvbhw6MzM=" provider="IBMCMSProvider"
location="${USER_INSTALL_ROOT}\profiles\AppSrv01/config/cells/myhostCell01
/nodes/myhostNode01/servers/webserver1/plugin-key.kdb" type="CMSKS"
fileBased="true" createStashFileForCMS="true"
managementScope="ManagementScope_1132071489569"/>
```

When you create a CMS keystore, the CMS provider is IBMi50SJSSSEProvider, and the CMS type is IBMi50SKeyStore, as shown in the following sample code:

```
<keyStores xmi:id="KeyStore_1132071489571" name="CMSKeyStore"
password="{xor}HRYNFAtRbxEw0zpvbhw6MzM=" provider="IBMi50SJSSEProvider"
location="{USER_INSTALL_ROOT}\profiles\AppSrv01/config/cells/myhostCell01
/nodes/myhostNode01/servers/webserver1/plugin-key.kdb" type="IBMi50SKeyStore"
fileBased="true" createStashFileForCMS="true"
managementScope="ManagementScope_1132071489569"/>
```

Hardware cryptographic keystores

For cryptographic device configuration, see “Key management for cryptographic uses” on page 1566 and “Configuring a hardware cryptographic keystore” on page 1533

You can add a slot either as the custom property, `com.ibm.ssl.keyStoreSlot`, or as the configuration attribute, `slot="0"`. The custom property is read before the attribute for backwards compatibility.

In certain environments, you can use the hardware cryptographic card for hardware acceleration. Either set the `useForAcceleration` attribute to `true` or set the `com.ibm.ssl.keyStoreUseForAcceleration` custom property. When you set the attribute to `true`, you are not required to configure a password. However, you cannot use the device to store keys. For more information on configuring a hardware cryptographic keystore, see [Configuring hardware cryptographic keystore configurations](#).

Default key store passwords:

When WebSphere Application Server starts for the first time as a standalone application server or as a network deployment, each server creates a key store and trust store for the default SSL configuration. When WebSphere Application Server creates these files, they use a default password (WebAS). Because the default password is well known, it is important that you change the password to protect the security of the key store files and the SSL configuration.

You can change the keystore passwords of:

- A single keystore or multiple key stores using a command task
- Multiple keystores using a command task
- A single keystore, using the administrative console

Dynamic outbound selection of Secure Sockets Layer configurations

WebSphere Application Server provides dynamic outbound selection that enables you to choose a specific Secure Sockets Layer (SSL) configuration and certificate alias for each outbound protocol, target host, target port, or any combination of these attributes. You can specify the dynamic selection information for outbound connections from a pure client or from a server that is acting as a client.

Before the SSL runtime for WebSphere Application Server starts an outbound connection, the runtime attempts to match the outbound protocol, target host, and target port attributes with the dynamic outbound selection information that is associated with an SSL configuration and certificate alias in the configuration.

The runtime caches both selection misses and selection hits, so the impact on performance can be minimal. However, a relationship exists between the amount of dynamic outbound selection information and its impact on the initial connection performance.

Dynamic selection information for outbound administrative SOAP connections

The default dynamic outbound selection configuration specifies that all outbound administrative SOAP connections use the same SSL configuration and certificate alias within the entire cell.

The management scope of the SSL configuration is at the cell level so every process in the cell sees this configuration. When an administrative SOAP client makes an outbound connection, the client provides protocol, target host, and target port information to the SSL runtime, as shown in the following sample code:

```
<dynamicSSLConfigSelections xmi:id="DynamicSSLConfigSelection_1"
name="AdminSSLOutbound" description="Uses the AdminSSL configuration
for all outbound SOAP calls." dynamicSelectionInfo="ADMIN_SOAP,*,*"
certificateAlias="default" sslConfig="SSLConfig_2"
managementScope="ManagementScope_1"/>
```

The SSL runtime checks the configuration and confirms that `certificateAlias="default"` and `sslConfig="SSLConfig_2"` for the `ADMIN_SOAP` protocol when you enable client certificate authentication.

Note: The configured target host and port are represented by the `*` character because both the host and the port attributes can be any value.

Target information during outbound connections

The dynamic outbound selection configurations are only effective when the outbound protocol uses the JSSEHelper application programming interface (API) when you select an SSL configuration with a specified connectionInfo hash map. This hash map must contain the following properties:

com.ibm.ssl.direction

The value for outbound connections is `OUTBOUND`.

com.ibm.ssl.remoteHost

The format should match what the protocol provides. Typically this is the canonical Domain Name Space (DNS), but it also could be the IP address.

com.ibm.ssl.remotePort

The port is target port.

com.ibm.ssl.endPointName

The value for an outbound connection must be one of the following protocol strings:

- IIOP
- HTTP
- SIP
- LDAP
- ADMIN_SOAP
- BUS_TO_BUS
- BUS_CLIENT
- BUS_TO_WEBSphere_MQ

Central management of Secure Sockets Layer configurations

By default, Secure Sockets Layer (SSL) configurations for servers are managed from a central location in the topology view in the administrative console. You can associate an SSL configuration and certificate alias with a management scope. This method is the most efficient method to manipulate and modify configurations when the server topology changes.

In prior releases, SSL configurations are managed in the `server.xml` file for each process. You have to edit individual `server.xml` documents to modify individual SSL configuration aliases in the configuration topology. In this release of WebSphere Application Server, management control of SSL configurations offers more flexibility and options. You can make coarse-grained changes using the cell-scope and fine-grained changes using a particular endpoint name, as defined in the `serverindex.xml` file for a specific application server process.

Because SSL configuration associations manifest inheritance behaviors, you can simplify the number of associations by referencing only the highest level management scope that needs a unique configuration. Obviously, the security environment influences issues such as SSL configuration uniqueness, and SSL configuration and certificate alias placement in the topology.

To configure the inbound and outbound topologies, which must be done separately in the administrative console, click **Security > SSL certificates and key management > Manage endpoint security configurations > Inbound | Outbound**.

The topology view provides the scoping mechanism. The SSL configuration inherits its visibility, which is its display in the topology, at the scope where you created the configuration and at all the scopes beneath this parent scope. When you create an SSL configuration at a specific node, the configuration can be seen by that node agent and by every application server that is part of that node. Any application server or node that is not part of this particular node cannot see this SSL configuration. You can configure different certificate aliases and SSL configurations for inbound versus outbound connections.

Default centrally managed SSL configuration

While it is easier to manage SSL configurations centrally in the topology view of the administrative console, you can also use wsadmin scripting within AdminTasks. You can manage SSL configuration associations in the configuration element of the `security.xml` file.

The `sslConfigGroup` configuration object is the mechanism that is used to associate a connection direction and management scope with a specific SSL configuration and certificate alias. The default `sslConfigGroups` cell attribute has a predefined inbound and outbound cell-scoped configuration that each endpoint in the cell inherits. Because rules of precedence must guide you when you select SSL configurations, see `csec_sslsecurecom.dita` before you modify your configurations.

```
<sslConfigGroups xmi:id="SSLConfigGroup_1"
name="myhostCell01" direction="inbound" certificateAlias="default"
sslConfig="SSLConfig_1" managementScope="ManagementScope_1"/>
<sslConfigGroups xmi:id="SSLConfigGroup_2" name="myhostCell01"
direction="outbound" certificateAlias="default" sslConfig="SSLConfig_1"
managementScope="ManagementScope_1"/>

<managementScopes xmi:id="ManagementScope_1"
scopeName="(cell):myhostCell01" scopeType="cell"/>
```

In the previous sample code, the `sslConfigGroups` attribute references the cell management scope. For this example, the following list shows the precedence order for selecting management scopes, from the highest order of precedence to the lowest. Each time an endpoint scope is defined, it uses the specified SSL configuration and certificate alias. However, you can use a more dynamic or direct technique for selecting an SSL configuration such as dynamic outbound, programmatic selection, or direct selection.

For more information, see `csec_ssldynoutboundconfigs.dita`.

Endpoint scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01:
(node):myhostNode01:(server):server1:(endpoint):ENDPOINT_NAME_IN_SERVERINDEX"
scopeType="endpoint"/>
```

Cluster scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01:
(node):myhostNode01:(server):server1:(endpoint):ENDPOINT_NAME_IN_SERVERINDEX"
scopeType="endpoint"/>
```

Server scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01:
(node):myhostNode01:(server):server1" scopeType="server"/>
```

Node scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell101:
(node):myhostNode01" scopeType="node"/>
```

Nodegroup scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell101:
(nodegroup):DefaultNodeGroup" scopeType="nodegroup"/>
```

Cell scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell101"
scopeType="cell"/>
```

Secure Sockets Layer node, application server, and cluster isolation

Secure Sockets Layer (SSL) enables you to ensure that any client that attempts to connect to a server during the handshake first performs server authentication. You can isolate communications between servers that must not communicate with each other over secure ports using SSL configurations at the node, application server, and cluster scopes.

Before you attempt to isolate communications controlled by WebSphere Application Server, you must have a good understanding of the deployment topology and application environment. To isolate a node, application server, or cluster, you must be able to control the signers that are contained in the trust stores that are associated with the SSL configuration. When the client does not contain the server signer, it cannot establish a connection to the server. If you use self-signed certificates, the server that created the personal certificate controls the signer, although you do have to manage the self-signed certificates. If you obtain certificates from a certificate authority (CA), you must obtain multiple CA signers because all of the servers can connect to each other if they share the same signer.

Authenticating only the server-side of a connection is not adequate protection when you need to isolate a server. Any client can obtain a signer certificate for the server and add it to its trust store. SSL client authentication must also be enabled between servers so that the server can control its connections by deciding which client certificates it can trust. For more information, see `tsec_sslclientauthinbound.dita`, which applies as well to enabling SSL client authentication at the cell level.

Isolation also requires that you use centrally managed SSL configurations for all or most endpoints in the cell. Centrally managed configurations can be scoped, unlike direct or end point configuration selection, and they enable you to create SSL configurations, key stores, and trust stores at a particular scope. Because of the inheritance hierarchy of WebSphere Application Server cells, if you select only the properties that you need for an SSL configuration, only these properties are defined at your selected scope or lower. For example, if you configure at the node scope, your configuration applies to the application server and individual end point scopes below the node scope. For more information, see `tsec_sslassocconfigscope.dita`, `tsec_sslselconfigdirect.dita`, and `tsec_sslassocconfigout.dita`

When you configure the key stores, which contain cryptographic keys, you must work at the same scope at which you define the SSL configuration and not at a higher scope. For example, if you create a key store that contains a certificate whose host name is part of the distinguished name (DN), then store that keystore in the node directory of the configuration repository. If you decide to create a certificate for the application server, then store that keystore on the application server in the application server directory.

When you configure the trust stores, which control trust decisions on the server, you must consider how much you want to isolate the application servers. You cannot isolate the application servers from the node agents or the deployment manager. However, you can configure the SOAP connector end points with the same personal certificate or to share trust. Naming persistence requires IIOp connections when they pass through the deployment manager. Because application servers always connect to the node agents when the server starts, the IIOp protocol requires that WebSphere Application Server establish trust between the application servers and the node agents.

Establishing node SSL isolation

By default, WebSphere Application Server uses a single self-signed certificate for each node so you can isolate nodes easily. A common trust store, which is located in the cell directory of the configuration repository, contains all of the signers for each node that is federated into the cell. After federation, each cell process trusts all of the other cell processes because every SSL configuration references the common trust store.

You can modify the default configuration so that each node has its own trust store, and every application server on the node trusts only the node agent that uses the same personal certificate. You must also add the signer to the node trust store so that WebSphere Application Server can establish trust with the deployment manager. To isolate the node, ensure that the following conditions are met:

- The deployment manager must initiate connections to any process
- The node agent must initiate connections to the deployment manager and its own application servers
- The application servers must initiate connections to the applications servers on the same node, to its own node agent, and the deployment manager

Figure 1 shows Node Agent A contains a key.p12 keystore and a trust.p12 trust store at the node level of the configuration repository for node A.

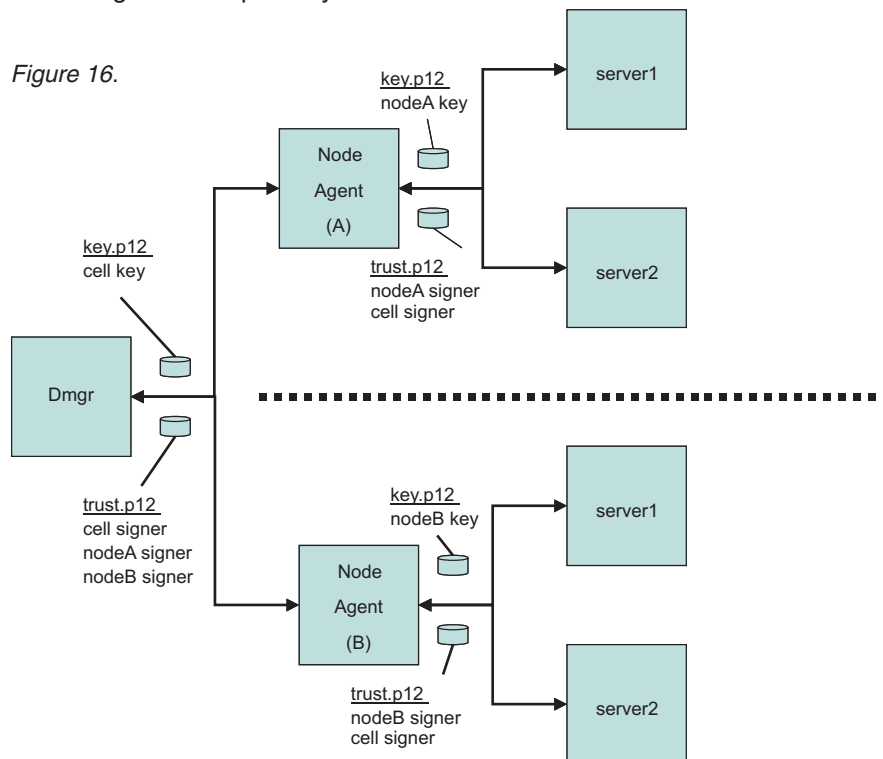

Figure 1: SSL Node Isolation

When you associate an SSL configuration with this keystore and truststore, you break the link with the cell-scoped trust store. To isolate the node completely, repeat this process for each node in the cell. WebSphere Application Server SSL configurations override the cell scope and use the node scope instead so that each process at this scope uses the SSL configuration and certificate alias that you selected at this scope. You establish proper administrative trust by ensuring that nodeA signer is in the common trust store and the cell signer is in the nodeA trust store. The same logic applies to node B as well. For more information, see `tsec_sslassocconfigscope.dita`.

Establishing application server SSL isolation

Isolating application server processes from one another is more challenging than isolating nodes. You must consider the following application design and topology conditions:

- An application server process might need to communicate with the node agent and deployment manager
- Isolating application server processes from each other might disable single sign-on capabilities for horizontal propagation

If you configure outbound SSL configurations dynamically, you can accommodate these conditions. When you define a specific outbound protocol, target host, and port for each different SSL configuration, you can override the scoped configuration.

Figure 2 shows how you might isolate an application server completely, although in practice this approach would be more complicated.

Figure 17.

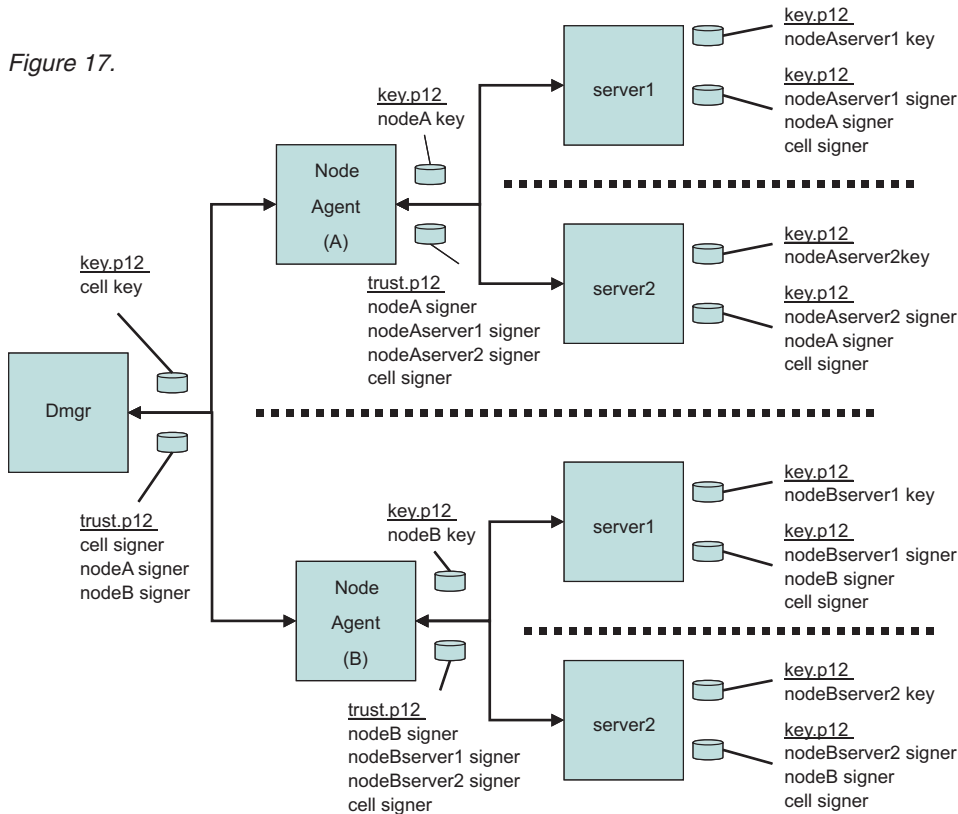

Figure 2: SSL Application Server Isolation

The dynamic configuration enables server1 on Node A to communicate with server 1 on Node B only over IIOIP. The dynamic outbound rule is IIOIP,nodeBhostname,*. For more information, see tsec_sslssoconfigout.dita

Establishing cluster SSL isolation

You can configure application servers into clusters instead of scoping them centrally at the node or dynamically at the server to establish cluster SSL isolation. While clustered servers can communicate with each other, application servers outside of the cluster cannot communicate with the cluster, thus isolating the clustered servers. For example, you might need to separate applications from different departments

while maintaining a basic level of trust among the clustered servers. Using the dynamic outbound SSL configuration method described for servers above, you can easily extend the isolated cluster as needed.

Figure 3 shows a sample cluster configuration where cluster 1 contains a key.p12 with its own self-signed certificate, and a trust.p12 that is located in the config/cells/<cellname>/clusters/<clustername> directory.

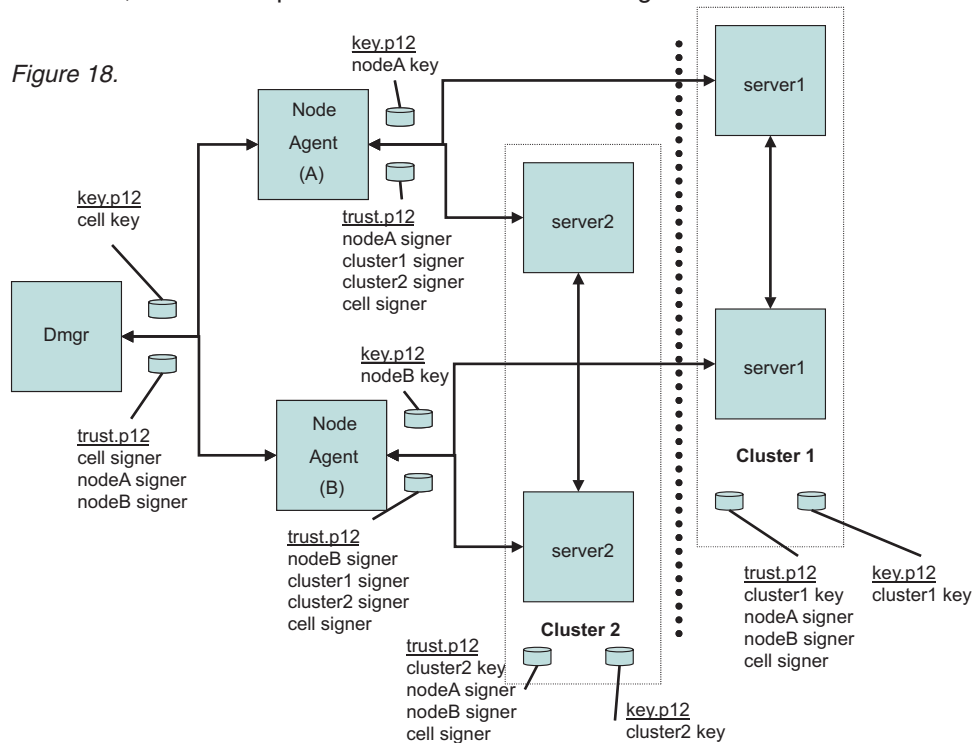

Figure 3: SSL Cluster Isolation

In the example, cluster1 might contain web applications, and cluster2 might contain EJB applications. Considering the various protocols, you decide to enable IIOP traffic between the two clusters. Your task is to define a dynamic outbound SSL configuration at the cluster1 scope with the following properties:

```
IIOP,nodeAhostname,9403|IIOP,nodeAhostname,9404|IIOP,nodeBhostname,9403|IIOP,nodeBhostname,9404
```

You must create another SSL configuration at the cluster1 scope that contains a new trust.p12 file with the cluster2 signer. Consequently, outbound IIOP requests go either to nodeAhostname ports 9403 and 9404 or to nodeBhostname ports 9403 and 9404. The IIOP SSL port numbers on these two application server processes in cluster2 identify the ports.

As you review Figure 3, notice the following features of the cluster isolation configuration:

- The trust.p12 for cluster1 contains signers that allow communications with itself (cluster1 signer), between both node agents (nodeAsigner and nodeBsigner), and with the deployment manager (cell signer).
- The trust.p12 for cluster2 contains signers that allow communications with itself (cluster2 signer), between both node agents (nodeAsigner and nodeBsigner), and with the deployment manager (cell signer).
- Node agent A and Node agent B can communicate with themselves, the deployment manager, and both clusters.

For more information, see tsec_sslasocconfigout.dita.

Although this article presents an overview of isolation methods from an SSL perspective, you must also ensure that non-SSL ports are closed or applications require the confidentiality constraint in the deployment descriptor. For example, you can set the CSlv2 inbound transport panel to require SSL and disable the channel ports that are not secure from the server ports configuration.

Also, you must enable SSL client authentication for SSL to enforce the isolation requirements on both sides of a connection. Without mutual SSL client authentication, a client can easily obtain a signer for the server programmatically and thus bypass the goal of isolation. With SSL client authentication, the server would require the client's signer for the connection to succeed. For HTTP/S protocol, the client is typically a browser, a Web Service, or a URL connection. For the IIOP/S protocol, the client is typically another application server or a Java client. WebSphere Application Server must know the clients to determine if SSL client authentication enablement is possible. Any applications that are available through a public protocol must not enable SSL client authentication because the client may fail to obtain a certificate to authenticate to the server.

Note: It is beyond the scope of this article to describe all of the factors you must consider to achieve complete isolation.

Default self-signed certificate configuration

When a WebSphere Application Server process starts for the first time, the Secure Sockets Layer (SSL) runtime initializes the default keystores and truststores that are specified in the SSL configuration.

Default keystore and truststore properties

WebSphere Application Server creates the key.p12 default keystore file and the trust.p12 default truststore file during profile creation. A default, self-signed certificate is also created in the key.p12 file at this time. The signer or public key is extracted from the key.p12 file and added to the trust.p12 file. If the files do not exist during process startup, they are recreated during startup.

You can easily identify keystore and truststore defaults because of their suffixes: DefaultKeyStore and DefaultTrustStore. Also, in the SSL configuration, you must set the fileBased attribute to true so that the runtime uses the default keystores and truststores only.

On a base application server, default key and truststores are stored in the node directory of the configuration repository. For example, the default key.p12 and trust.p12 stores are created with the AppSrv01 profile name, the myhostNode01Cell name, and the myhostNode01 node name. The key and truststores are located in the following directories:

```
C:\WebSphere\AppServer\profiles\AppSrv01\config\cells\myhostNode01Cell\nodes\myhostNode01\key.p12  
C:\WebSphere\AppServer\profiles\AppSrv01\config\cells\myhostNode01Cell\nodes\myhostNode01\trust.p12
```

The default password is WebAS for all default keystores generated by WebSphere Application Server. Change the default password after the initial configuration for a more secure environment.

Default self-signed certificate

The default self-signed certificate is created during profile creation for both the server and client for that profile.

Use caution since the new self-signed certificates created must have the signers added to the common truststore. This should be done through the administrative console.

If you want to set up SSL client authentication between the client and server, you must perform a signer exchange. The certificate properties below that exist in the ssl.client.props file do not exist in the server configuration. However, you can use these values in the server configuration by adding them as custom

security properties in the administrative console. The certificate properties appear in the `ssl.client.props` file, but do not appear in the server configuration. However, you can modify these values in the server configuration by adding them as custom properties in the administrative console.

Click **Security > Secure administration, applications, and infrastructure > Custom properties** to change the following properties:

```
com.ibm.ssl.defaultCertReqAlias=default_alias
com.ibm.ssl.defaultCertReqSubjectDN=cn=${hostname},o=IBM,c=US
com.ibm.ssl.defaultCertReqDays=365
com.ibm.ssl.defaultCertReqKeySize=1024
```

If a `default_alias` value already exists, the runtime appends `_#`, where the number sign (#) is a number that increments until it is unique in the keystore. `${hostname}` is a variable that is resolved to the host name where it was originally created. The default expiration date of self-signed certificates is one year from their creation date.

The runtime monitors the expiration dates of self-signed certificates using the Certificate Expiration Monitor. These self-signed certificates are automatically replaced along with the signer certificates when they are within the expiration threshold, which is typically 30 days before expiration. You can increase the default key size beyond 1024 bits only when the Java Runtime Environment policy files are unrestricted, that is, not exported. For more information, see `csec_sslcertmonitoring.dita`.

Default keystore and truststore configurations for new deployment manager processes

Default SSL configurations

The following sample code shows the default SSL configurations for a deployment manager:

```
<repertoire xmi:id="SSLConfig_1" alias="CellDefaultSSLSettings"
managementScope="ManagementScope_1">
<setting xmi:id="SecureSocketLayer_1" clientAuthentication="false"
securityLevel="HIGH" enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS"
keyStore="KeyStore_1" trustStore="KeyStore_2" trustManager="TrustManager_1"
keyManager="KeyManager_1"/>
</repertoire>

<repertoire xmi:id="SSLConfig_2" alias="AdminSoapSSLSettings"
managementScope="ManagementScope_1">
<setting xmi:id="SecureSocketLayer_2" clientAuthentication="false" securityLevel="HIGH"
enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS" keyStore="KeyStore_1"
trustStore="KeyStore_2" trustManager="TrustManager_1" keyManager="KeyManager_1"/>
</repertoire>
```

Note: The keystore and truststore reference `KeyStore_1` and `KeyStore_2`, respectively. By default, all of the SOAP connector secure communications use `AdminSoapSSLSettings` and all other secure communications use `CellDefaultSSLSettings`. For more information on how you can create and manage new configurations centrally, see `csec_sslcentralmanconfigs.dita`.

Default keystores and truststores

In the following sample code, the keystores and truststores for a deployment manager are referenced by the previous SSL configurations:

```
<keyStores xmi:id="KeyStore_1" name="CellDefaultKeyStore"
password="{xor}123skfkdkid=" provider="IBMJCE" location="{USER_INSTALL_ROOT}
/config/cells/myhostCell01/key.p12" type="PKCS12" fileBased="true" hostList=""
initializeAtStartup="true" managementScope="ManagementScope_2"/>

<keyStores xmi:id="KeyStore_2" name="CellDefaultTrustStore"
password="{xor}123skfkdkid=" provider="IBMJCE" location="{USER_INSTALL_ROOT}
/config/cells/myhostCell01/trust.p12" type="PKCS12" fileBased="true" hostList=""
```

```

initializeAtStartup="true" managementScope="ManagementScope_2"/>
<managementScopes xmi:id="ManagementScope_2" scopeName="(cell):myhostCell01"
scopeType="cell"/>

```

Note: In the sample code, the default key and truststores are located in the cell directory of the configuration repository. Because the scopeType management scope is set to the cell level, every process in the cell can see the key and truststores. If the physical location of the keystore is lower in the node directories hierarchy, the keystore is not visible to other nodes.

The trust.p12 truststore for the deployment manager is referred to as common because it can be seen by all of the processes. In fact, when a base application server is federated into a network deployment environment, the SSL configurations for nodes whose truststores end in DefaultTrustStore automatically change and point to the CellDefaultTrustStore common truststore. For every keystore that ends in DefaultKeyStore, the signer from the self-signed certificate is added to the common truststore. After federation, all of the default SSL configurations reference the common truststore and trusted secure communications are established for all of the server processes.

Clients that need to communicate with servers in the cell can run the retrieveSigners script that references the CellDefaultTrustStore. The script obtains all of the signers for the cell, including the self-signed certificate for the deployment manager. For more information, see csec_sslsecinstallclientsignret.dita.

Default key and truststore configurations for a Network Deployment cell with one federated node

When the key.p12 file is defined in the configuration repository, the deployment manager can locally manage the keystore and synchronize to the node that owns it. The key.p12 file physically exists in the myhostNode01 directory of the repository, which makes it available to that node and the deployment manager only.

After federation, the NodeDefaultTrustStore is not referenced by default SSL configurations. However, the truststore remains in the configuration code if you decide that a node must not trust other servers in the same cell; thus, it must not use the common CellDefaultTrustStore truststore. If you switch back to the node-specific truststore, you can add the signers from only the nodes you want to trust to obtain a higher level of isolation, even within the same cell. See “Secure Sockets Layer node, application server, and cluster isolation” on page 1476 for information about how to obtain a higher level of SSL isolation among processes within the same cell.

Default SSL configurations

The following sample code shows the CellDefaultSSLSettings and AdminSoapSSLSettings SSL configurations for the deployment manager, and the NodeDefaultSSLSettings SSL configuration for the federated node:

```

<repertoire xmi:id="SSLConfig_1" alias="CellDefaultSSLSettings"
managementScope="ManagementScope_1">
<setting xmi:id="SecureSocketLayer_1" clientAuthentication="false" securityLevel="HIGH"
enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS" keyStore="KeyStore_1"
trustStore="KeyStore_2" trustManager="TrustManager_1" keyManager="KeyManager_1"/>
</repertoire>

```

```

<repertoire xmi:id="SSLConfig_2" alias="AdminSoapSSLSettings"
managementScope="ManagementScope_1">
<setting xmi:id="SecureSocketLayer_2" clientAuthentication="false" securityLevel="HIGH"
enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS" keyStore="KeyStore_1"
trustStore="KeyStore_2" trustManager="TrustManager_1" keyManager="KeyManager_1"/>
</repertoire>

```

```

<repertoire xmi:id="SSLConfig_1128545825854" alias="NodeDefaultSSLSettings"
managementScope="ManagementScope_1128545825854">

```

```
<setting xmi:id="SecureSocketLayer_1128545825854" clientAuthentication="false"
securityLevel="HIGH" enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS"
keyStore="KeyStore_1128545825854" trustStore="KeyStore_2"
trustManager="TrustManager_1128545825854" keyManager="KeyManager_1128545825854"/>
</repertoire>
```

Note: In the sample code, the cell is configured for dynamic selection. When the node is federated, all of the Simple Object Access Protocol (SOAP) connector communications use the AdminSoapSSLSettings property. For more information about protocol, host, and port specific associations with SSL configurations, see csec_ssldynoutboundconfigs.dita.

Default key and truststores

The following sample code shows the default key and truststores configurations:

```
<keyStores xmi:id="KeyStore_1" name="CellDefaultKeyStore"
password="{xor}123skfkdidd=" provider="IBMJCE" location="{USER_INSTALL_ROOT}
/config/cells/myhostCell01/key.p12" type="PKCS12" fileBased="true" hostList=""
initializeAtStartup="true" managementScope="ManagementScope_1"/>

<keyStores xmi:id="KeyStore_2" name="CellDefaultTrustStore"
password="{xor}123skfkdidd=" provider="IBMJCE" location="{USER_INSTALL_ROOT}
/config/cells/myhostCell01/trust.p12" type="PKCS12" fileBased="true" hostList=""
initializeAtStartup="true" managementScope="ManagementScope_1"/>

<keyStores xmi:id="KeyStore_1128545825854" name="NodeDefaultKeyStore"
password="{xor}349dkckdd=" provider="IBMJCE" location="{USER_INSTALL_ROOT}/config
/cells/myhostCell01/nodes/myhostNode01/key.p12" type="PKCS12" fileBased="true"
hostList="" initializeAtStartup="true" managementScope="ManagementScope_1128545825854"/>

<keyStores xmi:id="KeyStore_1128545825874" name="NodeDefaultTrustStore"
password="{xor}349dkckdd=" provider="IBMJCE" location="{USER_INSTALL_ROOT}/config
/cells/myhostCell01/nodes/myhostNode01/trust.p12" type="PKCS12" fileBased="true"
hostList="" initializeAtStartup="true" managementScope="ManagementScope_1128545825854"/>
```

Default management scopes

The management scope for a federated node is node-specific. In general, configuration objects that are scoped for a particular node can reference only that scope. WebSphere Application Server only uses the default key and truststores in the nodes to which they are scoped.

Configuration objects can maintain their uniqueness even when multiple node configurations are located in the same security.xml file. The following sample code shows how the management scope also can define the NodeDefaultKeyStore and NodeDefaultTrustStore keystores that are added from multiple nodes.

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01"
scopeType="cell"/>
<managementScopes xmi:id="ManagementScope_1128545825854" scopeName="(cell):myhostCell01:
(node):myhostNode01" scopeType="node"/>
```

Contents of the default truststore

After federation, the CellDefaultTrustStore () common truststore contains two signers: the deployment manager signer and the federated node signer. In the following sample code, the deployment manager and node host are the same:

```
keytool -list -keystore c:\WebSphere\AppServer\profile\AppSrv01\config\cells
\myhostCell01\trust.p12 -storepass myhostCell01 -storetype PKCS12 -v
```

```
Alias name: default_signer
Entry type: trustedCertEntry
```

```
Owner: CN=myhost.austin.ibm.com, O=IBM, C=US
Issuer: CN=myhost.austin.ibm.com, O=IBM, C=US
```

```
Valid from: 10/5/05 3:34 PM until: 10/5/06 3:34 PM
Certificate fingerprints:
    SHA1: 91:A1:A9:2D:F2:7D:70:0F:04:06:73:A3:B4:A4:9C:56:9D:A8:A3:BA
*****
*****
Alias name: default
Entry type: trustedCertEntry

Owner: CN=myhost.austin.ibm.com, O=IBM, C=US
Issuer: CN=myhost.austin.ibm.com, O=IBM, C=US
Valid from: 10/18/05 4:06 PM until: 10/18/06 4:06 PM
Certificate fingerprint:
    SHA1: 33:6E:9E:10:65:04:CE:7A:6C:C3:B1:79:8B:9A:05:49:AC:E5:67:F3
```

In cases where nodes are federated from remote hosts, the CN contains the host name of the remote hosts. This node configuration enables a custom trust manager to perform host name verification using the remote certificates that it receives during the connection. The custom trust manager must implement the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface to gain access to the remote host name from the runtime. For more information, see `rsec_ssldevcustomtrustmgr.dita`.

Secure installation for client signer retrieval:

Each profile in the WebSphere Application Server environment contains a unique self-signed certificate that was created when the profile was created. This certificate replaces the default dummy certificate that ships with WebSphere Application Server in releases prior to version 6.1. When a profile is federated to a deployment manager, the signer for that self-signed certificate is added to the common truststore for the cell.

transition: Beginning with version 6.1, clients and servers that are not within the same cell require more complex Secure Sockets Layer (SSL) configurations than do servers that are within the same cell and that use the default self-signed certificate configuration.

By default, clients do not trust servers from different profiles in the WebSphere Application Server environment. That is, they do not contain the signer for these servers. There are some things that you can do to assist in establishing this trust:

1. Enable the signer exchange prompt to except the signer during the connection attempt.
2. Run the **retrieveSigners** utility to download the signers from that system prior to making the connection.
3. Copy the `trust.p12` file from the `/config/cells/<cell_name>/nodes/<node_name>` directory of the server profile to the `/etc` directory of the client. Update the SSL configuration to reflect the new file name and password, if they are different. Copying the file provides the client with a `trust.p12` that contains all signers from servers in that cell. Also, you might need to perform this step for back-level clients that are still using the `DummyClientTrustFile.jks` file. In this case, you might need to change the `sas.client.props` or `soap.client.props` file to reflect the new truststore, truststore password, and truststore type (PKCS12).

For clients to perform an in-band signer exchange, you must specify the `ssl.client.props` file as a `com.ibm.SSL.ConfigURL` property in the SSL configuration. For managed clients, this is done automatically. Signers are designated either as in-band during the connection or out-of-band during runtime. You must also set the `com.ibm.ssl.enableSignerExchangePrompt` attribute to `true`.

Tip: You can configure a certificate expiration monitor to replace server certificates that are about to expire. For more information about how clients can retrieve the new signer from the configuration, see `csec_sslcertmonitoring.dita`.

Using the signer exchange prompt to retrieve signers from a client

When the client does not already have a signer to connect to a process, you can enable the signer exchange prompt if you want to be able to accept the signer during the connection attempt. The prompt displays once for each unique certificate and for each node. After the signer for the node is added, the signer remains in the client truststore. The following sample code shows the signer exchange prompt retrieving a signer from a client:

```
C:\WASX_e0540.11\AppServer\profiles\AppSrv01\bin\serverStatus -all
ADMU0116I: Tool information is being logged in file
           C:\WASX_e0540.11\AppServer\profiles\AppSrv01\logs\serverStatus.log
ADMU0128I: Starting tool with the AppSrv01 profile
ADMU0503I: Retrieving server status for all servers
ADMU0505I: Servers found in configuration:
ADMU0506I: Server name: dmgr
```

*** SSL SIGNER EXCHANGE PROMPT ***

```
SSL signer from target host 192.168.1.5 is not found in truststore
C:\WebSphere\AppServer\profiles\AppSrv01\etc\trust.p12.
```

Here is the signer information (verify the digest value matches what is displayed at the server):

```
Subject DN:   CN=myhost.austin.ibm.com, O=IBM, C=US
Issuer DN:    CN=myhost.austin.ibm.com, O=IBM, C=US
Serial number: 1128544457
Expires:      Thu Oct 05 15:34:17 CDT 2006
SHA-1 Digest: 91:A1:A9:2D:F2:7D:70:0F:04:06:73:A3:B4:A4:9C:56:9D:A8:A3:BA
MD5 Digest:   88:72:C5:88:00:1C:A7:FA:D6:EB:04:88:AC:A1:C9:13
```

Add signer to the truststore now? (y/n) y

A retry of the request may need to occur.

```
ADMU0508I: The Deployment Manager "dmgr" is STARTED
```

To automate this process, see `rxml_retrievesigners.dita`.

When a prompt occurs to accept the signer, a socket timeout can occur and the connection might be broken. For this reason, the message **A retry of the request may need to occur.** displays after answering the prompt. The message informs the user to resubmit the request. This problem should not happen frequently, and it might be more prevalent for some protocols than others.

Verify the displayed SHA-1 digest, which is the signature of the certificate that is sent by the server. If you look at the certificate on the server, verify that the same SHA-1 digest displays.

You can disable the prompt when you do not want it to display by running the **retrieveSigners** utility to retrieve all of the signers for a particular cell. You can download or upload the signers from any remote keystore to any local keystore by referencing a common truststore with this client script. For more information, see `csec_ssldefselfsigncertconf.dita`.

Using the retrieveSigners utility to download signers for a client

You can run the **retrieveSigners** utility to retrieve all of the signers from the remote keystore for a specified client keystore.

The typical remote keystore to reference is `CellDefaultTrustStore`.

The truststore contains the signers that enable the client to connect to its processes. The **retrieveSigners** utility can point to any keystore in the target configuration, within the scope of the target process, and can download the signers (certificate entries only) to any client keystore in the `ssl.client.props` file.

The following sample code shows the **retrieveSigners** utility in a deployment manager environment.

```
C:\WASX_e0540.11\AppServer\profiles\AppSrv01\bin\retrieveSigners.bat CellDefaultTrustStore
ClientDefaultTrustStore -autoAcceptBootstrapSigner
```

```
CWPKI0308I: Adding signer alias "CN=myhost.austin.ibm.com, O=IBM, C=US" to
local keystore "ClientDefaultTrustStore" with the following SHA
digest: 91:A1:A9:2D:F2:7D:70:0F:04:06:73:A3:B4:A4:9C:56:9D:A8:A3:BA
```

```
CWPKI0308I: Adding signer alias "default" to local keystore
"ClientDefaultTrustStore" with the following SHA digest:
40:20:CF:BE:B4:B2:9C:F0:96:4D:EE:E5:14:92:9E:37:8D:51:A5:47
```

Use the **-autoAcceptBootstrapSigner** option to enable WebSphere Application Server automatically to retrieve and accept the signer for administrative connections. The SHA-1 digest is printed while the signer is added so you can verify the digest after the operation is complete.

Obtaining signers for clients and servers from a previous release

When a client from a release prior to version 6.1 connects to the current release, the client must obtain signers for a successful handshake. Clients using previous releases of WebSphere Application Server cannot obtain signers as easily as in the current release. You can copy the deployment manager *common* truststore to your back-level client or server, and then re-configure the SSL configuration to directly reference that truststore. This common truststore of type PKCS12 is located in the `/config/cells/<cell_name>/nodes/<node_name>` directory in the configuration repository and has a default password of WebAS.

To collect all of the signers for the cell in a single `trust.p12` keystore file, complete following steps:

1. Copy the `trust.p12` keystore file on the server and replicate it on the client. The client references the file directly from the `sas.client.props` and `soap.client.props` files that specify the SSL properties for previous releases.
2. Change the client-side keystore password so that it matches the default cell name that is associated with the copied keystore.
3. Change the default keystore type for the `trust.p12` file to PKCS12 in the client configuration.

The following two code samples show you a before and an after view of the changes to make.

Default SSL configuration of `sas.client.props` for a previous release

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.keyStore=file:///
C:\SERV1_601_0208/AppServer/profiles/AppSrv01/etc/DummyClientKeyFile.jks
com.ibm.ssl.keyStorePassword={xor}CDo9Hgw\=
com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.trustStore=file:///
C:\SERV1_601_0208/AppServer/profiles/AppSrv01/etc/DummyClientTrustFile.jks
com.ibm.ssl.trustStorePassword={xor}CDo9Hgw\=
com.ibm.ssl.trustStoreType=JKS
```

SSL configuration changes that are required to common truststore file in the `/etc` directory of the client

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.keyStore=file:///
C:\SERV1_601_0208/AppServer/profiles/AppSrv01/etc/DummyClientKeyFile.jks
com.ibm.ssl.keyStorePassword={xor}CDo9Hgw\=
com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.trustStore=file:///
C:\SERV1_601_0208/AppServer/profiles/AppSrv01/etc/trust.p12
com.ibm.ssl.trustStorePassword=myhostNode01Cell
com.ibm.ssl.trustStoreType=PKCS12
```

You can also make these changes in the `soap.client.props` file and specify the `key.p12` file in place of the `DummyClientKeyFile.jks` file. However, you must also change the `keyStorePassword` and `keyStoreType` values to match those in the default `key.p12` file.

In releases of WebSphere Application Server prior to version 6.1, you must edit the SSL configuration on the server to replace the common truststore. The `trust.p12` file, which is used by the server, also must contain the default dummy certificate signer for connections among servers at previous release levels. You might need to manually extract the default certificate from the `DummyServerKeyFile.jks` file and then import the certificate into the `trust.p12` file that you added to the configuration.

retrieveSigners command: The **retrieveSigners** command creates a new client self-signed certificate, keystore, and SSL configuration in the `ssl.client.props` file. Using this command you can optionally extract the signer to a file.

For more information about where to run this command, see the [Using command tools](#) article.

Syntax

The command syntax is as follows:

```
retrieveSigners <remoteKeyStoreName> <localKeyStoreName> [options]
```

where the `<remoteKeyStoreName>` and `<localKeyStoreName>` parameters are required. The optional parameters include the following:

```
[-remoteAlias aliasFromRemoteStore]  
[-localAlias storeAsAlias]  
[-listRemoteKeyStoreNames] [-listLocalKeyStoreNames]  
[-autoAcceptBootstrapSigner] [-uploadSigners] [-host host]  
[-port port] [-conntype RMI|SOAP] [-user user]  
[-password password]  
[-trace] [-logfile filename]  
[-replaceLog] [-quiet] [-help]
```

Parameters

The following parameters are available for the **retrieveSigners** command:

-remoteKeyStoreName

The name of a truststore that is located in the server configuration from which to retrieve the signers. This will typically be the `CellDefaultTrustStore` file for an managed environment or the `NodeDefaultTrustStore` file for an unmanaged environment.

-localKeyStoreName

The name of the truststore that is located in the `ssl.client.props` file for the profile to which the retrieved signers is added. This will typically be the `ClientDefaultTrustStore` file for either a managed or unmanaged environment.

-remoteAlias <aliasFromRemoteStore>

Specifies one alias from the remote truststore that you want to retrieve. Otherwise, all signers from the remote truststore will be retrieved.

-localAlias <storeAsAlias>

Determines the name of the alias stored in the local truststore. This option is only valid if you specify the `-remoteAlias` option. If you do not specify the `-localAlias` option, the alias name from the remote truststore will be used, if possible. If an alias clash occurs, the alias name will be used and it will have an incremented number appended to the end of it until it finds a unique alias.

-listRemoteKeyStoreNames

Sends a remote request to the server to list all keystores that you can specify for the

remoteKeyStoreName parameter. Use this command when you are unsure of the name of the remote truststore that you want to download the signers from.

-listLocalKeyStoreNames

Lists the keystores located in the ssl.client.props file that you can specify for the localKeyStoreName parameter. This truststore will receive the signers from the server. Use this parameter when you are unsure of the name of the local truststore that you want to retrieve the signers into. The default name of the truststore is ClientDefaultTrustStore and is located in the ssl.client.props file.

-autoAcceptBootstrapSigner

Automatically adds a signer in order to make a secure connection to the server. The purpose of the option is to allow automation of the command so that you do not need to accept the signer. After the signer is added to the local truststore, a SHA hash will print so that you can verify the certificate.

-uploadSigners

Converts the signer download into a signer upload. The signers from the localKeyStoreName parameter will be sent to the remoteKeyStoreName parameter instead.

-host <host>

Specifies the target host from which the signers will be retrieved.

-port <port>

Specifies the target administrative port to which to connect. You must specify the port based on the -conntype parameter. If the conntype is SOAP, the default port is 8879. This can vary for different servers. If the conntype is RMI, the default port is 2809. This can vary for different servers.

-conntype <RMI|Soap>

Determines the administrative connector type that is used for the MBean call to retrieve the signers.

-user <user>

When global security is enabled, you can specify this option to supply the user name that will be authenticated for the MBean operation. This must be an identity with administrator authority. If you do not specify this parameter when global security is enabled, you will be prompted for credentials by default.

-password <password>

When global security is enabled, you can specify this option to supply the password that will be authenticated for the MBean operation. The password goes along with the -user parameter.

-trace

When specified, this enables tracing of the trace specification necessary to debug this component. By default, the trace will appear in the profiles/*profile_name*/log/retrieveSigners.log. file.

-logfile <filename>

Overrides the default trace file. By default, the trace will appear in the profiles/*profile_name*/log/retrieveSigners.log. file.

-replacelog

Causes the existing trace file to be replaced when the command is executed.

-quite

Suppresses most messages from printing out on the console.

-help

Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax:

- The following example lists remote and local keystores:

```
retrieveSigners.bat -listRemoteKeyStoreNames -listLocalKeyStoreNames -conntype RMI -port 2809 [Windows]
```

```
retrieveSigners.sh -listRemoteKeyStoreNames -listLocalKeyStoreNames -conntype RMI -port 2809 [Unix]
```

Example output

```
CWPKI0306I: The following remote keystores exist on the specified server:  
    CMSKeyStore, NodeLTPAKeys, NodeDefaultTrustStore, NodeDefaultKeyStore  
CWPKI0307I: The following local keystores exist on the client:  
    ClientDefaultKeyStore, ClientDefaultTrustStore
```

- The following example retrieves all signers from NodeDefaultTrustStore:

```
retrieveSigners.bat NodeDefault TrustStore ClientDefaultTrustStore -autoAcceptBootstrapSigner  
-conntype RMI -port 2809 [Windows]
```

```
retrieveSigners.sh NodeDefault TrustStore ClientDefaultTrustStore -autoAcceptBootstrapSigner  
-conntype RMI -port 2809 [Unix]
```

Example output

```
CWPKI0308I: Adding signer alias "CN=BIRKT40.austin.ibm.com, O=IBM, C=US" to  
    local keystore "ClientDefaultTrustStore" with the following SHA  
    digest: 40:20:CF:BE:B4:B2:9C:F0:96:4D:EE:E5:14:92:9E:37:8D:51:A5:47
```

Certificate expiration monitoring:

The certificate expiration monitor administrative task cycles through all the keystores that are configured in the security.xml file and reports on any certificates that expire within a specified threshold, which is typically within 30 days.

The default self-signed certificate on each node expires 365 days after creation. You can modify the certificate validity period by changing the default value for the com.ibm.ssl.defaultCertReqDays=365 property in the ssl.client.props global property area for clients. You can also specify this property as a security custom property on the administrative console. Click **Security > Secure administration, applications, and infrastructure > Custom properties**.

The certificate expiration monitor task runs under the deployment manager process.

You can configure this monitor task to run according to a particular schedule. The schedule produces the next start date that persists in the configuration and, when the date is reached, WebSphere Application Server starts the monitor to check all of the keystores for certificates that meet the expiration threshold. You can start the task manually to run at any time.

The following security.xml configuration object specifies when the monitor task starts, determines the certificate expiration threshold, and indicates whether you are notified in an e-mail using Simple Mail Transfer Protocol (SMTP) or in a message log.

```
<wsCertificateExpirationMonitor xmi:id="WSCertificateExpirationMonitor_1"  
name="Certificate Expiration Monitor" daysBeforeNotification="30"  
isEnabled="true" autoReplace="true" deleteOld="true"  
wsNotification="WSNotification_1" wsSchedule="WSSchedule_2"  
nextStartDate="1134358204849"/>
```

The expiration monitor automatically replaces only self-signed certificates that meet the expiration threshold criteria. To replace all of the signers from the old certificate with the signer that belongs to the new certificate in all the keystores in the configuration for that cell, set the autoReplace attribute to true. When the deleteOld attribute is true, the old personal certificate and old signers also are deleted from the keystores. The isEnabled attribute determines whether the expiration monitor task runs based upon the nextStartDate attribute that is derived from the schedule. The nextStartDate attribute is derived from the schedule in milliseconds since 1970, and is identical to the System.currentTimeMillis(). If the nextStartDate has already passed when an expiration monitor process begins, and the expiration monitor is enabled, the task is started, but a new nextStartDate value is established based on the schedule.

The following sample code shows the frequency attribute as the number of days between each run.

```
<wsSchedules xmi:id="WSSchedule_2" name="ExpirationMonitorSchedule"
frequency="30" dayOfWeek="1" hour="21" minute="30"/>
```

The dayOfWeek attribute adjusts the schedule to run on a specified day of the week, which is always the same day regardless of whether the frequency is set to 30 or 31 days. Based on 24-hour clock, the hour and minute attributes determine when the expiration monitor is started on the specified day.

The following sample code shows the notification configuration, which notifies you after the expiration monitor runs.

```
<wsNotifications xmi:id="WSNotification_1" name="MessageLog" logToSystemOut="true" emailList=""/
```

For expiration monitor notifications, you can select message log, e-mail using SMTP server, or both methods of notification. When you configure the e-mail option, use the format user@domain@smtpserver. If you do not specify an SMTP server, WebSphere Application Server defaults to the same domain as the e-mail address. For example, if you configure joeuser@ibm.com, WebSphere Application Server attempts to call smtp-server.ibm.com. To specify multiple e-mail addresses using scripting, you must add a pipe (|) character between entries. When you specify the logToSystemOut attribute, the expiration monitor results are sent to the message log for the environment, which is typically the SystemOut.log file.

Web server plug-in default configuration:

When you create a new Web server definition, WebSphere Application Server associates the Web server plug-in with a Certificate Management Services (CMS) keystore for a specific node. The keystore contains all of the signers for the current cell with the self-signed certificate, which belongs to the node. The plug-in can communicate securely to WebSphere Application Server, even when the plug-in is configured with Secure Sockets Layer (SSL) client authentication enabled.

When you set the Web server definition to webserver1 on node myhostNode01, WebSphere Application Server creates the keystore configuration. The keystore is scoped to the webserver1 server, which makes it visible to this server only. Other processes cannot use this keystore definition.

The following sample code from the security.xml file shows the configuration entries for the Web server plug-in.

```
<keyStores xmi:id="KeyStore_1132357815719" name="CMSKeyStore"
password="{xor}HRYNFAtRbxEw0zpvbhw6MzM=" provider="IBMCMSProvider"
location="C:\WASX_e0540.11\AppServer\profiles\AppSrv01/config/cells
/myhostCell01/nodes/myhostNode01/servers/webserver1/plugin-key.kdb"
type="CMSKS" fileBased="true" createStashFileForCMS="true"
managementScope="ManagementScope_1132357815718"/>
<managementScopes xmi:id="ManagementScope_1132357815718" scopeName="
(cell):myhostCell01:(node):myhostNode01:(Server):webserver1" scopeType="server"/>
```

The following sample code shows how the CMS keystore and stash file are generated in the security.xml file.

```
C:\WebSphere\AppServer\profiles\Dmgr01\config\cells\myhostCell01\nodes
\myhostNode01\servers\webserver1\plugin-key.kdb
C:\WebSphere\AppServer\profiles\Dmgr01\config\cells\myhostCell01
\nodes\myhostNode01\servers\webserver1\plugin-key.sth
```

The default password for the keystore is WebAS. You can change the default keystore password by using either the administrative console or the appropriate **AdminTask** command. The following sample code shows the **AdminTask** command that you can use to create this CMS keystore.

```
$AdminTask createCMSKeyStore /config/cells/myhostCell01/nodes/myhostNode01
/servers/webserver1/plugin-key.kdb myhost.austin.ibm.com
```

Note the following characteristics of the previous example:

- You can create only one CMSKeyStore entry for each management scope. If a CMS keystore already exists for scope (cell):myhostCell01:(node):myhostNode01:(server):webserver1, then you cannot create another CMSKeyStore entry
- The Uniform Resource Identifier (URI) for the keystore name is /config/cells/myhostCell01/nodes/myhostNode01/servers/webserver1/plugin-key.kdb
- The host name in the plug-in location is myhost.austin.ibm.com. WebSphere Application Server uses this name to create a self-signed certificate, if a self-signed certificate does not already exist for that particular node. If a self-signed certificate already exists for the node, then the certificate is put into the CMS keystore and all the signers from the cell are added, by default.

When additional nodes are federated, the signers for these nodes are not automatically added to each Web server for the CMS keystore. For the Web server plug-in to be able to communicate with a newly federated node, you must manually exchange signers with the CMSKeyStore keystore. Use the administrative console keystore certificate management function to exchange signers. For more information, see “Extracting a signer certificate from a personal certificate” on page 1551.

Dynamic configuration updates

During the Secure Sockets Layer (SSL) runtime, dynamic configuration updates affect both inbound and outbound SSL endpoints. For inbound SSL endpoints, the changes that are implemented by the SSL channel are only affected by dynamic changes. For outbound SSL endpoints, all outbound connections inherit the new configuration changes.

In this release, dynamic update functionality provides you with greater flexibility and efficiency. You can change SSL configurations without restarting WebSphere Application Server for the changes to take effect.

To make dynamic changes, in the administrative console click **Security > SSL certificates and key management**, then select the **Dynamically update the runtime when SSL configuration changes occur** check box. You must save your changes and then synchronize the security.xml file with remote systems. A remote system must be able to confirm that dynamicallyUpdateSSLConfig=true is in the security.xml file.

The SSL runtime reloads the modified SSL configuration and creates a new SSLEngine for the modified connections that are associated with inbound endpoints. New outbound connections use the new configuration while existing connections continue to use the old SSLEngine object and are not affected.

Tip: Make dynamic changes to the SSL configuration during off-peak hours. Synchronization delays can negatively affect connections when you update SSL configurations during peak hours.

You can turn on and off the dynamicallyUpdateSSLConfig attribute in the security.xml file to ensure successful updates by doing the following actions:

1. Set dynamicallyUpdateSSLConfig=On.
2. Save the updated configuration.
3. Synchronize the security.xml file with remote systems.
4. Set the dynamicallyUpdateSSLConfig attribute to Off.

You must verify that all of the nodes receive the changes before turning off the dynamicallyUpdateSSLConfig attribute. Test the changes in a test environment before updating the production environment.

Tip: Some SSL changes, especially administrative SSL changes, can cause server outages if you fail to test them first. When a change prevents trust between two endpoints, the endpoints cannot communicate with each other. Additionally, if administrative SSL connection updates cause system outages, you might need to disable the nodes after you make corrective changes using the deployment manager. From the command line, you can manually synchronize the server to retrieve the new SSL changes, then restart the nodes.

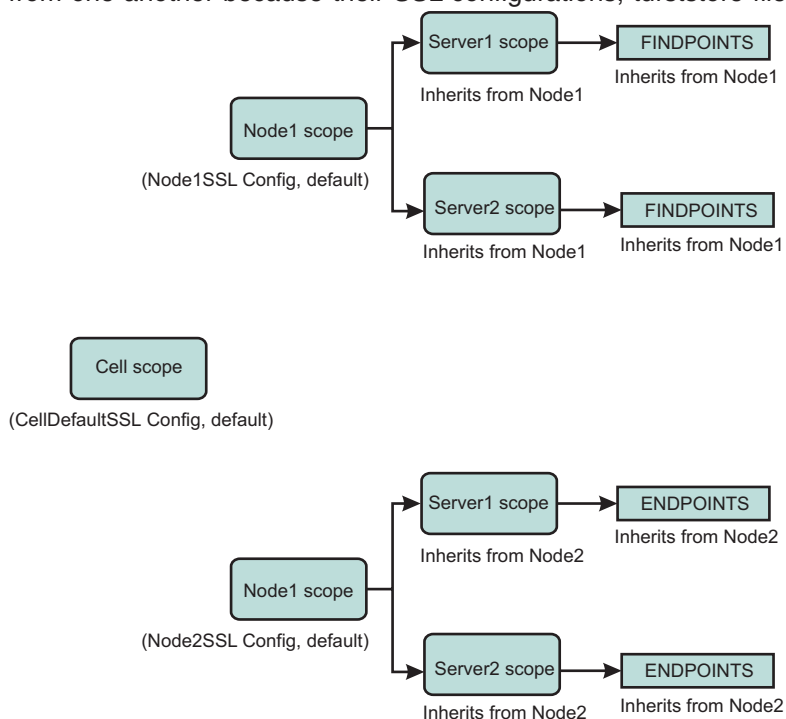

Restriction: In this release, the Object Request Broker (ORB) inbound SSL socket factory and the Admin SOAP inbound SSL socket factory are not affected by dynamic configuration changes. SSL socket factories cannot be bound to a port again without affecting the existing connections, with the exception of the SSL channel. You must restart the server to make a change to the SSL configuration for these two inbound protocols. Outbound configurations can still be changed dynamically. These changes are affected because the sockets are created during each new outbound connection.

Management scope configurations

Inbound and outbound management scopes represent opposing directions during the connection handshake process. To view inbound and outbound management scopes, use the topology tree view in the administrative console. You can define Secure Sockets Layer (SSL) configurations to distinguish the connection requirements for each direction inbound or outbound).

When expanded, the topology tree represents inbound and outbound connections for each management scope, cell, node group, node, server, cluster, and endpoint. Inbound endpoints require a server certificate. The SSL configuration specifies the server certificate for server authentication. Outbound endpoints require validated signers. Outbound endpoints connect to one or more target servers; inbound endpoints receive requests from one or more clients. The set of peer endpoints for outbound connections is typically a subset of the set of peer endpoints for inbound connections, which means you must define different requirements for inbound and outbound connections.

The following figure shows an example of two nodes: Node1 and Node2. These two nodes are isolated from one another because their SSL configurations, truststore files, and keystore files are different.

DynamicOutbound. AdminSoapSSLConfig,default ->ADMIN_SOAP
(to allow admin communications to use the same SSL configuration)

In the example of two nodes, note that Node1 cannot communicate with Node2, but each of the two nodes must be able to communicate with the deployment manager and its administrative functions. With dynamic outbound selection, you can choose an SSL configuration and a certificate alias that reference a common truststore. When a process requires the ADMIN_SOAP protocol for an outbound connection, the server uses this single SSL configuration. Because all of the scopes under the cell level inherit this configuration,

all outbound connections can communicate with the deployment manager. For more information, see “Dynamic outbound selection of Secure Sockets Layer configurations” on page 1473.

Another way to accomplish this same result is to associate the SSL configuration with the ADMIN_SOAP endpoint for each individual process, deployment manager, Node1, Node2, Node1Server1, Node1Server2, Node2Server1, and Node2Server2. However, it is recommended that you use dynamic outbound selection because it is more efficient when defining a basic SSL configuration, its keystores, and its truststores at the cell scope. The example shows how to apply the node scope association, but the same principles apply for node groups, clusters, servers, and endpoints.

Note: If your topology includes clusters that span nodes or if your applications need to communicate between nodes, the configuration that is shown in the example does not work.

Certificate management using iKeyman

Starting in WebSphere Application Server Version 6.1, you can manage your certificates from the administrative console. When using versions of WebSphere Application Server prior to Version 6.1, use iKeyman for certificate management. iKeyman is a key management utility.

WebSphere Application Server certificate management requires that you define the keystores in your WebSphere Application Server configuration. With iKeyman, you need access to the keystore file only. You can read a keystore file with personal certificates and signers that is created in iKeyman can be read into the WebSphere Application Server configuration by using the **createKeyStore** command.

The majority of certificate management functions are the same between WebSphere Application Server and iKeyman, especially for personal certificates and signer certificates. However, certificate requests are special. The underlying behavior is different in the two certificate management schemes. Because of the different behavior, when a certificate request is generated from iKeyman, the process must be completed in iKeyman. For example, a certificate that is generated by a certificate request that originated in iKeyman must be received in iKeyman as well.

The same is true for WebSphere Application Server. For example, when a certificate is generated from a certificate request that originated in WebSphere Application Server, the certificate must be received in WebSphere Application Server.

You can perform the following certificate operations using iKeyman:

Types of certificates	Functions	Description
Personal certificates	Create a self-signed certificate	Creates a self-signed certificate and stores it in a keystore.
	List personal certificates	Lists all the personal certificates in a keystore.
	Get information about a personal certificate	Gets information about a personal certificate.
	Delete a personal certificate	Deletes a personal certificate from a keystore.
	Import a certificate	Imports a certificate from a keystore to a keystore.
	Export a certificate	Exports a certificate from a keystore to another keystore.
	Extract a certificate	Extracts the signer part of a personal certificate to a file.
Signer certificates	Receive a certificate	Reads a certificate that comes from a certificate authority (CA) into a keystore.
	Add a signer certificate	Adds a signer certificate from a file to a keystore.
	List signer certificates	Lists all the signer certificates in a keystore.

Types of certificates	Functions	Description
	Get information about a signer certificate	Gets information about a signer certificate.
	Delete a signer certificate	Deletes a signer certificate from a keystore.
	Extract a signer certificate	Extracts a signer certificate from a keystore, and stores the certificate in a file.
Certificate requests	Create a certificate request	Creates a certificate request that can be sent to a CA.
	List certificate requests	Lists the certificate requests in a keystore.
	Get information about a certificate request	Gets information about a certificate request.
	Delete a certificate request	Deletes a certificate request from a keystore.
	Extract a certificate request	Extracts a certificate request to a file.

Certificate management

You can manage certificate operations that involve personal certificates, signer certificates, and personal certificate requests on the administrative console.

Types of certificates

WebSphere Application Server uses the certificates that reside in keystores to establish trust for a Secure Sockets Layer (SSL) connection. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *SSL_configuration_name* > Key stores and certificates**, then select an existing or create a new keystore. After selecting a keystore, and depending on the type of certificate you need, choose one of the following types of certificates under Related Items:

- Personal certificate
- Signer certificate
- Personal certificate request

The following table describes the certificate operations that you can perform on the administrative console:

Types of certificates	Functions	Description
Personal certificates	Create a self-signed certificate	Creates a self-signed certificate and stores it in a keystore.
	List personal certificates	Lists all the personal certificates in a keystore.
	Get information about a personal certificate	Gets information about a personal certificate.
	Delete a personal certificate	Deletes a personal certificate from a keystore.
	Import a certificate	Imports a certificate from a keystore to a keystore.
	Export a certificate	Exports a certificate from a keystore to another keystore.
	Extract a certificate	Extracts the signer part of a personal certificate to a file.
	Exchange signer certificates	Exchange signer part of a personal certificate between key store.
	Receive a certificate	Reads a certificate that comes from a certificate authority (CA) into a keystore.

Types of certificates	Functions	Description
Signer certificates	Replace a certificate	Replaces all occurrences of a personal certificate alias in the WebSphere Application Server configuration with another certificate. Also, replaces all occurrences of the personal certificates signer with the new personal certificate signer.
	Add a signer certificate	Adds a signer certificate from a file to a keystore.
	List signer certificates	Lists all the signer certificates in a keystore.
	Get information about a signer certificate	Gets information about a signer certificate.
	Delete a signer certificate	Deletes a signer certificate from a keystore.
	Extract a signer certificate	Extracts a signer certificate from a keystore, and stores the certificate in a file.
Certificate requests	Retrieve a signer from a port	Retrieves a signer certificate from a port, and stores it in a key store.
	Create a certificate request	Creates a certificate request that can be sent to a CA.
	List certificate requests	Lists the certificate requests in a keystore.
	Get information about a certificate request	Gets information about a certificate request.
	Delete a certificate request	Deletes a certificate request from a keystore.
	Extract a certificate request	Extracts a certificate request to a file.

Personal certificates

The following table lists the operations that you can perform on personal certificates, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate on the console:

Function	AdminTask object	Administrative console
Create a self-signed certificate	createSelfSignedCertificate	Security > Secure Communications > Key store and certificates > key store > Create a Self-Signed Certificate
List personal certificates	listPersonalCertificates	Security > Secure Communications > Key store and certificates > key store > personal certificates
Get information about a personal certificate	getPersonalCertificate	Security > Secure Communications > Key store and certificates > key store > personal certificates > alias
Delete a personal certificate	deletePersonalCertificate	Security > Secure Communications > Key store and certificates > key store > personal certificates > delete
Import a certificate	importCertificate	Security > Secure Communications > Key store and certificates > key store > personal certificates > import
Export a certificate	exportCertificate	Security > Secure Communications > Key store and certificates > key store > personal certificates > export
Extract a certificate	extractCertificate	Security > Secure Communications > Key store and certificates > key store > personal certificates > extract
Exchange signer certificates	exchangeSignerCertificates	Security > Secure Communications > Key store and certificates > Exchange signers

Signer certificates

The following table lists the operations that you can perform with signer certificates, the AdminTask object that you can use to perform the operation, and how to navigate to the certificate on the console:

Function	AdminTask object	Administrative console
Add a signer certificate	addSignerCertificate	Security > Secure communications > Key store and certificates > key store > signer certificates > Add
List signer certificates	listSignerCertificates	Security > Secure communications > Key store and certificates > key store > signer certificates
Get information about a signer certificate	getSignerCertificate	Security > Secure communications > Key store and certificates > key store > signer certificates > alias
Delete a signer certificate	deleteSignerCertificate	Security > Secure communications > Key store and certificates > key store > signer certificate > delete
Extract a signer certificate to a file	extractSignerCertificate	Security > Secure communications > Key store and certificates > key store > signer certificates > extract
Retrieve a signer certificate from a port	retrieveSignerFromPort	Security > Secure communications > Key store and certificates > key store > signer certificates > retrieve from port

Personal certificate requests

The following table lists the operations that you can perform on personal certificate requests, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate request on the console:

Function	AdminTask object	Administrative console
Create a personal certificate request	createCertificateRequest	Security > Secure communications > Key store and certificates > key store > Personal certificate Requests > Add
List personal certificate requests	listCertificateRequests	Security > Secure communications > Key store and certificates > key store > Personal certificate requests
Get information about a personal certificate request	getCertificateRequest	Security > Secure communications > Key store and certificates > key store > Personal certificate requests > alias
Delete a personal certificate request	deleteCertificateRequest	Security > Secure communications > Key store and certificates > key store > Personal certificate requests > delete
Extract a personal certificate request to a file	extractCertificateRequest	Security > Secure communications > Key store and certificates > key store > Personal certificate requests > Extract

Creating a Secure Sockets Layer configuration

Secure Sockets Layer (SSL) configurations contain the attributes that you need to control the behavior of client and server SSL endpoints. You create SSL configurations with unique names within specific management scopes on the inbound and outbound tree in the configuration topology. This task shows you how to define SSL configurations, including quality of protection and trust and key manager settings.

You must decide at which scope you need to define an SSL configuration, for instance, the cell, node group, node, server, cluster, or endpoint scope, from the least specific to the most specific scope. When you define an SSL configuration at the node scope, for example, only those processes within that node can load the SSL configuration; however, any processes at the endpoint in the cell can use an SSL configuration at the cell scope, which is higher in the topology.

You must also decide which scope to associate with the new SSL configuration, according to the processes that the configuration affects. For example, an SSL configuration for a hardware cryptographic device might require a keystore that is available only on a specific node, or you might need an SSL configuration for a connection to a particular SSL host and port. For more information, see “Dynamic outbound selection of Secure Sockets Layer configurations” on page 1473.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations**.
2. Select an SSL configuration link on either the Inbound or Outbound tree, depending on the process you are configuring.
 - If the scope is already associated with a configuration and alias, the SSL configuration alias and certificate alias are noted in parentheses.
 - If the parenthetical information is not included, then the scope is not associated. Instead, the scope inherits the configuration properties of the first scope above it that is associated with an SSL configuration and certificate alias.

The cell scope must be associated with an SSL configuration because it is at the top of the topology and represents the default SSL configuration for the inbound or outbound connection.

3. Click **SSL configurations** under Related Items. You can view and select any of the SSL configurations that are configured at this scope. You can also view and select these configuration at every scope that is lower on the topology.
4. Click **New** to display the SSL configuration panel. You cannot select links under Additional Properties until you type a configuration name and click **Apply**.
5. Type an SSL configuration name. This field is required. The configuration name is the SSL configuration alias. Make the alias name unique within the list of SSL configuration aliases that are already created at the selected scope. The new SSL configuration uses this alias for other configuration tasks.
6. Select a truststore name from the drop-down list. A truststore name refers to a specific truststore that holds signer certificates that validate the trust of certificates sent by remote connections during an SSL handshake. If there is no truststore in the list, see “Creating a keystore configuration” on page 1532 to create a new truststore, which is a keystore whose role is to establish trust during the connection.
7. Select a keystore name from the drop-down list. A keystore contains the personal certificates that represent a signer identity and the private key that WebSphere Application Server uses to encrypt and sign data.
 - If you change the keystore name, click **Get certificate aliases** to refresh the list of certificates from which you can choose a default alias. WebSphere Application Server uses a server alias for inbound connections and a client alias for outbound connections.
 - If there is no keystore in the list, see “Creating a keystore configuration” on page 1532 to create a new keystore.
8. Choose a default server certificate alias for inbound connections. Select the default only when you have not specified an SSL configuration alias elsewhere and have not selected a certificate alias. A centrally managed SSL configuration tree can override the default alias. For more information, see “Central management of Secure Sockets Layer configurations” on page 1474.
9. Choose a default client certificate alias for outbound connections. Select the default only when the server SSL configuration specifies an SSL client authentication.

10. Review the identified management scope for the SSL configuration. Make the management scope in this field identical to the link you selected in Step 2. If you want to change the scope, you must click a different link in the topology tree and continue at Step 3.
11. Click **Apply** if you intend to configure Additional Properties. If not, go to Step 24.
12. Click **Quality of protection (QoP) settings** under Additional Properties. QoP settings define the strength of the SSL encryption, the integrity of the signer, and the authenticity of the certificate.
13. Select a client authentication setting to establish an SSL configuration for inbound connections and for clients to send their certificates, if appropriate.
 - If you select **None**, the server does not request that a client send a certificate during the handshake.
 - If you select **Supported**, the server requests that a client send a certificate. However, if the client does not have a certificate, the handshake might still succeed.
 - If you select **Required**, the server requests that a client send a certificate. However, if the client does not have a certificate, the handshake fails.

Important: The signer certificate that represents the client must be in the truststore that you select for the SSL configuration. By default, servers within the same cell trust each other because they use the common truststore, `trust.p12`, that is located in the cell directory of the configuration repository. However, if you use keystores and truststores that you create, perform a signer exchange before you select either **Supported** or **Required**.

14. Select a protocol for the SSL handshake.
 - The default protocol, `SSL_TLS`, supports client protocols `TLSv1`, `SSLv3`, and `SSLv2`.
 - The `TLSv1` protocol supports `TLS` and `TLSv1`. The SSL server connection must support this protocol for the handshake to proceed.
 - The `SSLv3` protocol supports `SSL` and `SSLv3`. The SSL server connection must support this protocol for the handshake to proceed.

Important: Do not use the `SSLv2` protocol for the SSL server connection. Use it only when necessary on the client side.

15. Select one of the following options:
 - A predefined Java Secure Socket Extension (JSSE) provider. The `IBMJSSE2` provider is recommended for use on all platforms which support it. It is required for use by the channel framework SSL channel. When Federal Information Processing Standard (FIPS) is enabled, `IBMJSSE2` is used in combination with the `IBMJCEFIPS` crypto provider.
 - A custom JSSE provider. Type a provider name in the **Custom provider** field.

`IBMJSSE` is the only predefined JSSE provider that is supported on the i5/OS platform.

16. Select from among the following cipher suite groups:
 - **Strong:** WebSphere Application Server can perform 128-bit confidentiality algorithms for encryption and support integrity signing algorithms. However, a strong cipher suite can affect the performance of the connection.
 - **Medium:** WebSphere Application Server can perform 40-bit encryption algorithms for encryption and support integrity signing algorithms.
 - **Weak:** WebSphere Application Server can support integrity signing algorithms but not to perform encryption. Select this option with care because passwords and other sensitive information that cross the network are visible to an Internet Protocol (IP) sniffer.
 - **Custom:** you can select specific ciphers. Any time you change the ciphers that are listed from a specific cipher suite group, the group name changes to `Custom`.
17. Click **Update selected ciphers** to view a list of the available ciphers for each cipher strength.
18. Click **OK** to return to the new SSL configuration panel.
19. Click **Trust and key managers** under Additional Properties.

20. Select a default trust manager for the primary SSL handshake trust decision.
 - Choose **lbmPKIX** when you require certificate revocation list (CRL) checking using CRL distribution points in the certificates.
 - Choose **lbmX509** when you do not require CRL checking but do need increased performance. You can configure a custom trust manager to perform CRL checking, if necessary.
21. Define a custom trust manager, if appropriate. You can define a custom trust manager that runs with the default trust manager you select. The custom trust manager must implement the JSSE `javax.net.ssl.X509TrustManager` interface and, optionally, the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface to obtain product-specific information.
 - a. Click **Security > SSL certificate and key management > Manage endpoint security configurations > SSL_configuration > Trust and key managers > Trust managers > New**.
 - b. Type a unique trust manager name.
 - c. Select the **Custom** option.
 - d. Type a class name.
 - e. Click **OK**. When you return to the Trust and key managers panel, the new custom trust manager displays in the **Additional ordered trust managers** field. Use the left and right list boxes to add and remove custom trust managers.
22. Select a key manager for the SSL configuration. By default, `lbmX509` is the only key manager unless you create a custom key manager.

Important: If you choose to implement your own key manager, you can affect the alias selection behavior because the key manager is responsible for selecting the certificate alias from the keystore. The custom key manager might not interpret the SSL configuration as the WebSphere Application Server key manager `lbmX509` does. To define a custom key manager, click **Security > Secure communications > SSL configurations > SSL_configuration > Trust and key managers > Key managers > New**.

23. Click **OK** to save the trust and key manager settings and return to the new SSL configuration panel.
24. Click **Save** to save the new SSL configuration.

Important: You can override the default trust manager when you configure at least one custom trust manager and set the `com.ibm.ssl.skipDefaultTrustManagerWhenCustomDefined` property to `true`. Click **Custom Property** on the SSL configuration panel. However, if you change the default, you leave all the trust decisions to the custom trust manager, which is not recommended for production environments. In test environments, use a dummy trust manager to avoid certificate validation. Remember that these environment are not secure.

In this release of WebSphere Application Server, you can associate SSL configurations with protocols using one of the following methods:

- Set the SSL configuration on the thread programmatically
- Associate the SSL configuration with an outbound protocol, and target host and port. For more information, see “Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint” on page 1514
- Associate the SSL configuration directly using the alias. For more information, see `tsec_sslselconfigdirect.dita`
- Manage the SSL configurations centrally by associating them with SSL configuration groups or zones that are scoped for endpoints. For more information, see “Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes” on page 1517

SSL certificate and key management

Use this page to configure security for Secure Socket Layer (SSL) and key management, certificates, and notifications. The SSL protocol provides secure communications between remote server processes or

endpoints. SSL security can be used for establishing communications inbound to and outbound from an endpoint. To establish secure communications, a certificate and an SSL configuration must be specified for the endpoint.

To view this administrative console page, click **Security > SSL certificate and key management**.

Configuration settings:

Specifies the following administrative console tasks:

- Manage endpoint security configurations
- Manage certificate expiration

Use Federal Information Processing Standard (FIPS) algorithms:

Specifies the Federal Information Processing Standard (FIPS)-compliant Java cryptography engine is enabled.

- Does not affect the SSL cryptography that is performed by the application server for z/OS System Secure Sockets Layer (SSSL).
- Does not change the JSSE provider if this cell includes any Application Server versions before the application server for z/OS Version 6.0.x.

When you select the **Use the Federal Information Processing Standard (FIPS)** option, the Lightweight Third Party Authentication (LTPA) implementation uses IBMJCEFIPS. IBMJCEFIPS supports the Federal Information Processing Standard (FIPS)-approved cryptographic algorithms for Data Encryption Standard (DES), Triple DES, and Advanced Encryption Standard (AES). Although the LTPA keys are backwards compatible with prior releases of the application server, the LTPA token is not compatible with prior releases. In prior releases, the application server did not generate the LTPA token using a FIPS-approved algorithm.

The IBMJSSE2 JSSE provider does not perform cryptographic functions directly, and therefore does not need to be FIPS-approved. Instead, the IBMJSSE2 JSSE provider uses the JCE framework for cryptographic functions and uses IBMJCEFIPS when FIPS mode is enabled.

Default: Disabled

Dynamically update the runtime when SSL configuration changes occur:

Specifies that all of the SSL-related attributes that change must be read from the configuration dynamically after they have been saved, then reused for new connections. To avoid customer impact, it is recommended that changes to production servers be made during off-peak periods.

Default: Disabled

When this option is selected, the configuration is updated each time you configure an SSL communication.

SSL configurations for selected scopes

Use this page to display Secure Socket Layer (SSL) configurations for selected scopes, such as a cell, node, server, or cluster. From this page you can navigate to configuration panels for the following: SSL configurations, dynamic inbound and outbound endpoint SSL configurations, key stores, key sets, key set groups, key managers, and trust managers.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration**.

Name:

Specifies the SSL configuration scope, which is derived from the selected object in the hierarchy.

Data type: Text

Direction:

Specifies the direction for which the SSLConfig applies. Inbound refers to any listener port. Outbound refers to outbound end point connections.

Data type: Text

Inherited SSL configuration name:

Specifies the name of the SSL configuration that is inherited from a higher level scope

This field displays for server and nodegroups within the object hierarchy.

This field does not display for the top-level cell.

Data type: Text

Inherited certificate alias:

Specifies the certificate alias that is inherited from a higher-level scope.

This field displays for server and node groups within the object hierarchy.

This field does not display for the top-level cell.

Data type: Text

Override inherited values:

Specifies the SSL configuration to be used for this scope and any lower scopes that have not already designated an SSL configuration.

This field displays for server and node groups within the object hierarchy.

This field does not display for the top-level cell.

Default: Disabled

SSL configuration:

Specifies the SSL configuration that is used by requests at this scope.

Data type: Text

Update certificate alias list:

Specifies the certificate aliases contained in the key store for this SSL configuration can be selected from the **Certificate alias in key store** list. You must update the certificate list after choosing a different SSL configuration alias. If you do not update the list, you will save a certificate alias that is not contained in the SSL configuration.

Manage certificates:

Specifies to open the keystore panel for the key store in this SSL configuration, which enables you to manage personal certificates, signers, and certificate requests.

Certificate alias in key store:

Specifies the certificate to use in the key store.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the key store, the key manager might not consistently select the same certificate.

Data type: Text

SSL configurations collection

Use this page to define a list of Secure Sockets Layer (SSL) configurations.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **SSL configurations**.

Button	Resulting action
New JSSE configuration	The Java Secure Socket Extension (JSSE) repertoire is for Java-based SSL communications. You can define a new JSSE configuration that can be used to create an SSLContext, URLStreamHandler, SSLSocketFactory, SSLServerSocketFactory, and so on, using the com.ibm.websphere.ssl.JSSEHelper API.
New SSSL configuration	The System Secure Sockets Layer (SSSL) repertoire is used for HTTPS and Internet InterORB Protocol (IIOP) communication, which are used by the native transports. If you want to use the administrative console after security is enabled, you must define and select a System SSL type repertoire for HTTP. You must define a System SSL repertoire and select if IIOP security requires or supports SSL transport, or if a secure Remote Method Invocation (RMI) connector is selected for administrative requests.
Delete	Deletes an existing JSSE configuration (administrator only). Be careful that any references to the SSL configuration have been removed prior to deleting this SSL configuration.

Name:

Specifies the unique name of the SSL configuration in the management scope.

SSL configuration settings

Use this page to define Secure Sockets Layer (SSL) configuration properties.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration_name**. Under **Related items** click **SSL configurations > New**.

Name:

Specifies the unique name of the SSL configuration within the management scope in which it resides. For ways to programmatically access the properties that are configured for this SSL configuration, see the `com.ibm.websphere.ssl.JSSEHelper` application programming interface (API).

Data type: Text

Keyring name:

Specifies the name of the keyring for the System SSL configuration. This field implies the keystore and trust store.

This field applies to System SSL repertoires only

Creating a custom trust manager configuration

You can create a custom trust manager configuration at any management scope and associate the new trust manager with a Secure Sockets Layer (SSL) configuration.

You must develop, package, and locate a Java Archive JAR file for a custom key manager in the `was.install.root/lib/ext` directory on WebSphere Application Server. For more information, see “Example: Developing a custom trust manager for custom SSL trust decisions” on page 1506.

Complete the following steps in the administrative console:

1. Decide whether you want to create the custom trust manager at the cell scope or below the cell scope at the node, server, or cluster, for example.

Important: When you create a custom trust manager at a level below the cell scope, you can associate it only with a Secure Sockets Layer (SSL) configuration at the same scope or higher. An SSL configuration at a scope lower than the trust manager does not see the trust manager configuration.

- To create a custom trust manager at the cell scope, click **Security > SSL certificate and key management > Trust managers**. Every SSL configuration in the cell can select the trust manager at the cell scope.
 - To create a custom trust manager at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Trust managers**.
2. Click **New** to create a new custom trust manager.
 3. Type a unique trust manager name.
 4. Select the **Custom** implementation setting. The custom setting enables you to define a Java class with an implementation of the `javax.net.ssl.X509TrustManager` Java interface and, optionally, the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` WebSphere Application Server interface.

Note: The standard implementation setting applies only when the trust manager is already defined in the Java security provider list as a provider and an algorithm, which is not the case for a custom trust manager.

5. Type a class name, for example, `com.ibm.test.CustomTrustManager`.
6. Select one of the following actions:
 - Click **Apply**, then click **Custom properties** under Additional Properties to add custom properties to the new custom trust manager. When you are finished adding custom properties, click **OK** and **Save**, then go to the next step.
 - Click **OK** and **Save**, then go to the next step.
7. Click **SSL certificate and key management** in the page navigation at the top of the panel.

8. Select one of the following actions:
 - Click **SSL configurations** under Related Items for a cell-scoped SSL configuration.
 - Click **Manage endpoint security configurations** to select an SSL configuration at a lower scope.
9. Click the link for the existing SSL configuration that you want to associate with the new custom trust manager. You can create a new SSL configuration instead of associating the custom trust manager with an existing configuration. For more information, see “Creating a Secure Sockets Layer configuration” on page 1496.
10. Click **Trust and Key managers** under Additional Properties. If the new custom trust manager is not listed in the **Additional ordered trust managers** list, verify that you selected an SSL configuration scope that is at the same level or below the scope that you selected in Step 8.
11. Click **Add**. This action adds the new trust manager to the list of custom trust managers.
12. Click **OK** and **Save**.

You have created a custom trust manager configuration that references a JAR file in the install directory of WebSphere Application Server and associates it with an SSL configuration during the connection handshake.

You can create a custom trust manager for a pure client. For more information, see “Commands for the TrustManagerCommands group of the AdminTask object” on page 1739.

Trust and key managers settings:

Use this page to specify trust and key managers for the selected SSL configuration.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > SSL_configuration_name**. Under **Related items** click **SSL configurations > SSL_configuration_name | New JSSE configuration**. Under **Additional Properties** click **Trust and key managers**.

Attention: The application server checks the default trust managers first before checking the additional ordered trust managers in descending order.

Default trust manager:

Specifies the default trust manager, which is typically the IbmX509 trust manager by the IBMJSSE2 provider. The other default trust manager is IbmPKIX, which can be selected when certificate revocation checks must be made using the X509Certificate CRL distribution list. The IbmPKIX trust manager does not perform as well as the IbmX509 trust manager.

Data type:	Text
Default:	ibmX509TrustManager

Additional ordered trust managers:

Specifies additional trust managers that are used in the order shown for this SSL configuration.

Add:

Specifies to add the selection to the **Additional ordered trust managers** right-hand list.

Remove:

Specifies to remove the selection from the **Additional ordered trust managers** right-hand list.

Key manager:

Specifies the key manager that runs for this SSL configuration.

Data type: Text
Default: IbmX509KeyManager

Trust managers collection:

Use this page to define the implementation settings for the trust manager. A trust manager is a class that is invoked during an Secure Sockets Layer (SSL) handshake to make trust decisions about the remote end point. A default trust manager is used to validate the signature and expiration of the certificate. Custom trust managers can be plugged in to perform an extended certificate and host name check.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Trust managers**.

Button	Resulting action
New	Adds a new trust manager that can be selected by an SSL configuration. A trust manager is invoked during an SSL handshake and can decide whether the handshake should be accepted based on the information it knows about the remote certificate and host.
Delete	Deletes an existing trust manager. Make sure the trust manager is not referenced by any SSL configuration before you delete it.

Name:

Specifies the name of the trust manager. This name is used as a selection in the SSL configuration panel.

Class name:

Specifies a class that implements the javax.net.ssl.X509TrustManager interface. Optionally, the class can implement the com.ibm.wsspi.ssl.TrustMangerExtendedInfo interface to get extended information about the connection. The class can use the information to verify the host name and so on.

Algorithm:

Specifies the algorithm name of the trust manager that is implemented by the selected provider.

Trust managers settings:

This page enables you to view and set definitions for trust manager implementation settings. A trust manager is a class that gets invoked during a Secure Sockets Layer (SSL) handshake to make trust decisions about the remote end point. A default trust manager is used to validate the signature and expiration of the certificate. Custom trust managers can be plugged in to perform an extended certificate and hostname check.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items click **Trust managers > New** .

Name:

Specifies the name of the trust manager.

Data type: Text
Default: ibmX509TrustManager

Standard:

Specifies that the trust manager selection is available from a Java provider that is installed in the java.security file. This provider might be shipped by the Java Secure Sockets Extension (JSSE) or might be a custom provider that implements the javax.net.ssl.X509TrustManager interface.

Default: Enabled

Provider:

Specifies the provider name that has an implementation of the javax.net.ssl.X509TrustManager interface. This provider is typically set to IBMJSSE2.

Enabled when **Standard** is selected.

Default IBMJCE

Algorithm:

Specifies the algorithm name of the trust manager implemented by the selected provider.

Enabled when **Standard** is selected.

Default ibmX509 or IbmPKIX
Range ibmX509, IbmPKIX

Custom:

Specifies that the trust manager selection is based on a custom implementation class that implements the javax.net.ssl.X509TrustManager interface and optionally the com.ibm.wsspi.ssl.TrustManagerExctendedInfo interface to obtain additional connection information that is not otherwise available.

Default: Disabled

Class name:

Specifies a class that implements the javax.net.ssl.X509TrustManager interface. Optionally, the class can implement the com.ibm.wsspi.ssl.TrustMangerExtendedInfo interface to get extended information about the connection. The class can use the information to verify the host name and so on.

Enabled when **Custom** is selected.

Data type: Text

Example: Developing a custom trust manager for custom SSL trust decisions:

The following example is of a sample custom trust manager. The custom trust manager makes no trust decisions but instead uses the information in the X.509 certificate that it references to make decisions.

After you build and package the custom trust manager, configure it either from the `ssl.client.props` file for a pure client or the `SSLConfiguration TrustManager` link in the administrative console. See “Trust manager control of X.509 certificate trust decisions” on page 1466 for more information about trust managers.

Note: This example should only be used as a sample, and is not supported.

```
import java.security.cert.X509Certificate;

“Trust manager control of X.509 certificate trust decisions” on page 1466

The role of the trust manager is to validate the Secure Sockets Layer (SSL) certificate that is sent by the peer, which includes verifying the signature and checking the expiration date of the certificate. A Java Secure Socket Extension (JSSE) trust manager determines if the remote peer can be trusted during an SSL handshake.

Creating a custom key manager

You can create a custom key manager configuration at any management scope and associate the new key manager with a Secure Sockets Layer (SSL) configuration.

You must develop, package, and locate a Java Archive (.JAR) file for a custom key manager in the `was.install.root/lib/ext` directory on WebSphere Application Server. For more information, see `rsec_ssldevcustomkeymgr.dita`.

Complete the following steps in the administrative console:

1. Decide whether you want to create the custom key manager at the cell scope or below the cell scope at the node, server, or cluster, for example.

Important: When you create a custom key manager at a level below the cell scope, you can associate it only with a Secure Sockets Layer (SSL) configuration at the same scope or higher. An SSL configuration at a scope lower than the key manager does not see the key manager configuration.

- To create a custom key manager at the cell scope, click **Security > SSL certificate and key management > Key managers**. Every SSL configuration in the cell can select the key manager at the cell scope.
 - To create a custom key manager at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration > Key managers**.
2. Click **New** to create a new key manager.
 3. Type a unique key manager name.
 4. Select the **Custom** implementation setting. With the custom setting, you can define a Java class that has an implementation on the Java interface `javax.net.ssl.X509KeyManager` and, optionally, the `com.ibm.wsspi.ssl.KeyManagerExtendedInfo` WebSphere Application Server interface. The standard implementation setting applies only when the key manager is already defined in the Java security provider list as a provider and an algorithm, which is not the case for a custom key manager. The typical standard key manager is `algorithm = IbmX509`, `provider = IBMJSSE2`.
 5. Type a class name. For example, `com.ibm.test.CustomKeyManager`.
 6. Select one of the following actions:
 - Click **Apply**, then click **Custom properties** under Additional Properties to add custom properties to the new custom key manager. When you are finished adding custom properties, click **OK** and **Save**, then go to the next step.
 - Click **OK** and **Save**, then go to the next step.
 7. Click **SSL certificate and key management** in the page navigation at the top of the panel.
 8. Select one of the following actions:
 - Click **SSL configurations** under Related Items for a cell-scoped SSL configuration.
 - Click **Manage endpoint security configurations** to select an SSL configuration at a lower scope.

9. Click the link for the existing SSL configuration that you want to associate with the new custom key manager. You can create a new SSL configuration instead of associating the custom key manager with an existing configuration. For more information, see “Creating a Secure Sockets Layer configuration” on page 1496.
10. Click **Trust and Key managers** under Additional Properties.
11. Select the new custom key manager in the **Key manager** drop-down list. If the new custom key manager is not listed, verify that you selected an SSL configuration scope that is at the same level or below the scope that you selected in Step 8.
12. Click **OK** and **Save**.

You have created a custom key manager configuration that references a JAR file in the installation directory of WebSphere Application Server and associates the custom configuration with an SSL configuration during the connection handshake.

You can create a custom key manager for a pure client. For more information, see “Commands for the keyManagerCommands group of the AdminTask object” on page 1743.

Example: Developing a custom key manager for custom Secure Sockets Layer key selection:

The following example is of a sample custom key manager. This simple key manager provides the alias if it is set, and defers to the custom key manager if it is not set. Additional code can be added, for example, to prompt for a key that is given to the issuers that are provided.

After you build and package a custom key manager, you can configure it from either the `ssl.client.props` file for a pure client or by using the SSLConfiguration KeyManager link in the administrative console. See “Key manager control of X.509 certificate identities” on page 1468 for more information about key managers.

Because only one key manager can be configured at a time for any given Secure Sockets Layer (SSL) configuration, the certificate selections on the server side might not work as they would when the default `ibmX509` key manager is specified. When a custom key manager is configured, it is up to the owner of that key manager to ensure that the selection of the alias from the SSL configuration supplied is set properly when `chooseClientAlias` or `chooseServerAlias` are called. Look for the `com.ibm.ssl.keyStoreClientAlias` and `com.ibm.ssl.keyStoreServerAlias` SSL properties.

Note: This example should only be used as a sample, and is not supported.

Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint

After you create a Secure Sockets Layer (SSL) configuration, you must associate a secure outbound management scope with the new configuration. In this release, you can associate one SSL configuration

with one remote secure endpoint and a different SSL configuration to another remote secure endpoint. Both endpoints can use the same outbound protocol, if appropriate. This task describes how to create the association dynamically.

Dynamic outbound selection requires that you provide only the outbound protocol name, the target host, and the target port so that WebSphere Application Server can make a connection between the SSL configuration and the outbound protocol or remote secure endpoint. The dynamic outbound selection method takes precedence over other selection methods, such as central management and direct selection, but is second to the programmatic method, that is, setting an SSL configuration on the running thread. For more information about the selection types and precedence rules, see “Secure communications using Secure Sockets Layer” on page 1458.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Outbound**.
2. Select the management scope that you want to associate with an SSL configuration on the topology tree.
3. Under Related Items, click **Dynamic outbound endpoint SSL configurations**. The default dynamic outbound configuration name, the target protocol, host, and port connection information, and the SSL configuration name display.
4. Click **New** to create a new dynamic outbound configuration.
5. Type a dynamic outbound configuration name. Use a name that is descriptive of the purpose of the dynamic selection configuration.
6. Optionally, type a dynamic selection configuration description.
7. Type the connection information that you want to associate with the configuration that is displayed in the SSL configuration drop-down list. The connection information must be in the format *protocol name, target host, target port*. You can substitute an asterisk (*) for any value, as in the following examples:
 - *,*,443
 - *,www.ibm.com,443
 - HTTP,.austin.ibm.com,*where 443 is a port, www.ibm.com is a host, HTTP is a protocol, and .austin.ibm.com is a target host. You can add multiple connections, but each additional connection can affect outbound performance.
8. Click **Add** to add the new connection to the set of SSL configuration connections. To remove a connection, select it and click **Remove**.
9. Select an SSL configuration from the list.
10. Click **Get certificate aliases** to refresh the certificate aliases that are contained in the associated key store.
11. Choose a certificate alias from the list.
12. Click **OK** and **Save**.

WebSphere Application Server is ready to connect one or more SSL configurations to one or more remote secure endpoints.

You can return to the outbound tree and select another management scope to associate with the same or a new outbound configuration.

Example: Programmatically specifying an outbound SSL configuration using JSSEHelper API:

WebSphere Application Server provides a way to specify programmatically which Secure Sockets Layer (SSL) configurations to use prior to making an outbound connection. The `com.ibm.websphere.ssl.JSSEHelper` interface provides a complete set of application programming interfaces (APIs) for handling SSL configurations.

You must perform the following steps for your application when using the JSSEHelper API to establish an SSL properties object on the thread for use by the runtime. Some of these APIs have Java 2 Security permission requirements. See the JSSEHelper API documentation for more information about the permissions required by your application.

1. Obtain an instance of the JSSEHelper API by typing the following command:

```
com.ibm.websphere.ssl.JSSEHelper jsseHelper
= com.ibm.websphere.ssl.JSSEHelper.getInstance();
```

2. Obtain SSL properties from the WebSphere Application Server configuration or use those provided by your application. You can obtain these properties in several ways:

- By direction selection of an alias name, within the same management scope or higher as in the following example:

```
try
{
    String alias = "NodeAServer1SSLSettings";
    // As specified in the WebSphere SSL configuration
    Properties sslProps = jsseHelper.getProperties(alias);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
    e.printStackTrace(); // handle exception
}
```

- By using the `getProperties` API for programmatic, direction, dynamic outbound, or management scope selection (based on precedence rules and inheritance). The SSL runtime uses the `getProperties` API to determine which SSL configuration to use for a particular protocol. This decision is based on both the input (`sslAlias` and `connectionInfo`) and the management scope from which the property is called. The `getProperties` API makes decisions in the following order:
 - a. The API checks the thread to see if properties already exist.
 - b. The API checks for a dynamic outbound configuration that matches the `ENDPOINT_NAME`, `REMOTE_HOST`, and or `REMOTE_PORT`.
 - c. The API checks to see if the optional `sslAlias` property is specified. You can configure any protocol as direct or centrally managed. When a protocol is configured as direct, the `sslAlias` parameter is `null`. When a protocol is configured as centrally managed, the `sslAlias` parameter is also `null`.
 - d. If no selection has been made, the API chooses the dynamic outbound configuration based on the management scope it was called from. If the dynamic outbound configuration is not defined in the same scope, it then searches the hierarchy to locate one.

The last choice is the cell-scoped SSL configuration (in Network Deployment) or the node-scoped SSL configuration (in Base Application Server). The `com.ibm.websphere.ssl.SSLConfigChangeListener` parameter is notified when the SSL configuration that is chosen by a call to the `getProperties` API changes. The protocol can then call the API again to obtain the new properties as in the following example:

```
try
{
    String sslAlias = null; // The sslAlias is not specified directly at this time.
    String host = "myhost.austin.ibm.com"; // the target host
    String port = "443"; // the target port

    HashMap connectionInfo = new HashMap();
    connectionInfo.put(JSSEHelper.CONNECTION_INFO_DIRECTION,
        JSSEHelper.DIRECTION_OUTBOUND);
    connectionInfo.put(JSSEHelper.CONNECTION_INFO_REMOTE_HOST, host);
    connectionInfo.put(JSSEHelper.CONNECTION_INFO_REMOTE_PORT,
```

```

    Integer.toString(port));
connectionInfo.put(JSSEHelper.CONNECTION_INFO_ENDPOINT_NAME,
    JSSEHelper.ENDPOINT_IIOB);

    java.util.Properties props = jsseHelper.getProperties(sslAlias,
        connectionInfo, null);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
    e.printStackTrace(); // handle exception
}

```

- By creating your own SSL properties and then passing them to the runtime, as in the following example:

```

try
{
    // This is the recommended "minimum" set of SSL properties. The trustStore can
    // be the same as the keyStore.
    Properties sslProps = new Properties();
    sslProps.setProperty("com.ibm.ssl.trustStore", "some value");
    sslProps.setProperty("com.ibm.ssl.trustStorePassword", "some value");
    sslProps.setProperty("com.ibm.ssl.trustStoreType", "some value");
    sslProps.setProperty("com.ibm.ssl.keyStore", "some value");
    sslProps.setProperty("com.ibm.ssl.keyStorePassword", "some value");
    sslProps.setProperty("com.ibm.ssl.keyStoreType", "some value");

    jsseHelper.setSSLPropertiesOnThread(sslProps);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
    e.printStackTrace(); // handle exception
}

```

3. Use the `JSSEHelper.setSSLPropertiesOnThread(props)` API to set the `Properties` object on the thread so that the runtime picks it up and uses the same `JSSEHelper.getProperties` API. You can also obtain properties from the thread after they are set with the `jsseHelper.getSSLPropertiesOnThread()` API, as in the following example:

```

try
{
    Properties sslProps = jsseHelper.getProperties(null,
        connectionInfo, null); jsseHelper.setSSLPropertiesOnThread(sslProps);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
    e.printStackTrace(); // handle exception
}

```

4. When the connection is completed, you must clear the SSL properties from the thread by passing the `null` value to the `setPropertiesOnThread` API, as in the following example:

```

try
{
    jsseHelper.setSSLPropertiesOnThread(null);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
    e.printStackTrace(); // handle exception
}

```

Select the approach that best fits your connection situation when you specify programmatically which Secure Sockets Layer (SSL) configurations to use prior to making an outbound connection.

Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes:

After you create a Secure Sockets Layer (SSL) configuration, you must associate a secure inbound or outbound management scope with the new configuration. You can manage the association centrally so

that you can easily make changes that affect all the scopes that are lower on the topology and that are associated with the configuration. Beginning with WebSphere Application Server version 6.1, the recommended and the default configuration method is centrally managed SSL configurations.

You can simplify the number of associations that you need to make for an SSL configuration by associating the configuration with the highest level management scope requiring a unique configuration. SSL configuration associations manifest inheritance behaviors. Because of the inheritance behaviors, all of the scopes that are lower on the topology inherit this SSL configuration. For example, an association you make at the cell level affects nodes, servers, clusters, and endpoints. For more information, see “Central management of Secure Sockets Layer configurations” on page 1474.

A precedence rule determines which SSL configuration association is used at a particular scope. The highest precedence is given to endpoints on the topology. If you establish an association at the endpoint, this association overrides any prior association that you made higher up on the management scope topology.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management**.
2. Select the **Dynamically update the runtime when SSL configuration changes** check box if you want changes that you make to an existing SSL configuration to occur dynamically. All outbound SSL communications honor the dynamic SSL changes. Protocols that do not use the channel frameworks SSL channel for inbound communications, including Object Request Broker (ORB) and administrative SOAP protocols, do not honor dynamic updates. For more information, see “Dynamic configuration updates” on page 1491.
3. Click **Manage endpoint security configurations**.
4. Select either the inbound or the outbound tree. After finishing the selected tree, you can return to this step to repeat the following steps for the other tree.
5. Click the link for the selected cell, node, node group, server, cluster, or endpoint on the topology tree. If the scope already has an associated SSL configuration and alias, these objects display in parentheses immediately following the scope name, for example: Node01(NodeDefaultSSLSettings,default). If the deployment manager has federated a node, the node scope SSL configuration overrides the cell scope configuration above it in the topology.
6. Decide whether to override the inherited values that display in the read-only fields. Read-only fields include the management scope name, the direction, and the inherited SSL configuration name and certificate alias.
 - If you are satisfied with these values, do not override them.
 - If you want to override the inherited values, select the **Override inherited values** check box.
7. Select an SSL configuration from the list.
8. Click **Update certificate alias list**. The certificate alias list comes from the key store that is referenced by the new SSL configuration.
9. Click **Manage certificates** if you want to manage the personal certificates that are contained in the key store that is referenced in the SSL configuration.
10. Click **Update certificate alias list** to refresh the list of aliases.
11. Select a certificate alias in the key store to represent the identity of the endpoint.
12. Click **OK** to save your changes.
13. Click **Manage endpoint security configurations and trust zones** to return to the topology tree.
14. Configure the opposite direction on the topology tree using the steps in this task. You can also select additional scopes to associate with the SSL configuration, as needed.

Each SSL configuration at the selected scope and at scopes beneath it on the topology tree have the same SSL configuration properties. The following SSL configuration methods override the centrally managed configurations that you associate in the tree view:

- Direct selection at the endpoint
- Dynamic outbound SSL configuration associations
- Programmatic specifications

At any management scope, you can configure the following objects: dynamic outbound endpoint SSL configurations, key stores, key sets, key set groups, key managers, and trust managers. Like SSL configurations, these objects are scoped automatically so that they are not visible higher up in the tree nor are they loaded during runtime by processes that are higher up in the tree.

Selecting an SSL configuration alias directly from an endpoint configuration:

You can associate a secure outbound endpoint with a new Secure Sockets Layer (SSL) configuration directly. If you are migrating from a release prior to version 6.1, WebSphere Application Server still supports configurations that were selected directly at an endpoint. Direct selection always overrides centrally managed configurations and preserves migrated configurations.

Select an SSL configuration alias directly at the following endpoints:

- **Security > Secure administration, applications, and infrastructure > RMI/IOP security > CSiv2 outbound transport**
- **Security > Secure administration, applications, and infrastructure > RMI/IOP security > CSiv2 inbound transport**
- **System administration > Deployment manager > Transport Chain > WCInboundAdminSecure > SSL inbound channel (SSL_1)**
- **System administration > Deployment manager > Administration Services > JMX connectors > SOAPConnector > Custom Properties > sslConfig**
- **System administration > Node agents > nodeagent > Administration Services > JMX connectors > SOAPConnector > Custom Properties > sslConfig**
- **Servers > Application servers > server1 > Messaging engine inbound transports > InboundSecureMessaging > SSL inbound channel (SIB_SSL_JFAP)**
- **Servers > Application servers > server1 > WebSphere MQ link inbound transports > InboundSecureMQLink > SSL inbound channel (SIB_SSL_MQFAP)**
- **Servers > Application servers > server1 > SIP Container Settings > SIP container transport chains > SIPInboundDefaultSecure > SSL inbound channel (SSL_5)**
- **Servers > Application servers > server1 > Web Container Settings > Web container transport chains > WCInboundAdminSecure > SSL inbound channel (SSL_1)**
- **Servers > Application servers > server1 > Web Container Settings > Web container transport chains > WCInboundDefaultSecure > SSL inbound channel (SSL_2)**

Attention: Keep in mind that central management of SSL configurations can be a more efficient strategy because multiple configurations can be contained within a single SSLConfigGroup. If you need to convert configuration references that are already directly managed to centrally managed configurations, modify each endpoint individually. For more information on specific wsadmin commands, see “Commands for the SSLConfigGroupCommands group of the AdminTask object” on page 1747.

Complete the following steps in the administrative console:

Note: These steps provide an example to follow when you directly select any of the endpoints listed above.

1. Click **Security > Secure administration, applications, and infrastructure > RMI/IOP security > CSiv2 outbound transport**.
2. Click **Use specific SSL alias**. When you identify a specific SSL alias, you override the centrally managed scope associations.

3. Select an SSL configuration alias from the drop-down list.
4. Click **OK**.
5. Repeat these steps for additional protocols or endpoints, if desired.

By associating the endpoint directly, you have overridden a centrally managed SSL configuration.

If you decide to use management scopes instead of endpoints to associate an SSL configuration, follow the steps above, but click **Centrally managed** instead of **Use specific SSL alias**, then click **Manage endpoint security configurations**. The console is redirected to **Security > SSL certificate and key management > Manage endpoint security configurations**.

Enabling Secure Sockets Layer client authentication for a specific inbound endpoint:

When you establish a Secure Sockets Layer (SSL) configuration, you can enable client authentication for a specific inbound endpoint.

The endpoint configuration must already exist in the SSL topology.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound > SSL_configuration**. If you want to enable SSL client authentication for all processes, define an SSL configuration for the new endpoint at the node or cell level so that it is visible to all processes on the same node or on the entire cell. For more information, see “Creating a Secure Sockets Layer configuration” on page 1496.
2. Select **Override inherited values**. The SSL configuration is used for the current scope and any lower scopes that have not already designated an SSL configuration. This field displays for server and node groups within the object hierarchy and does not display for the top-level node or cell.
3. Select an SSL configuration from the drop-down list.
4. Click **Update certificate alias list**.
5. Select a **Certificate alias** from the drop-down list.
6. Click **OK** to save the configuration.

You can repeat the previous steps for each endpoint that uses the same SSL configuration to enable client authentication for the inbound endpoints.

CSlv2 Protocol Exception:

The Common Secure Interoperability Version 2 (CSlv2) secure endpoints, used for Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) security, cannot override inherited values. While the rest of the SSL properties are effective for CSlv2 when they are selected at the centrally-managed Secure Communications panel, the client authentication selection is controlled by the CSlv2 protocol configuration.

To enable SSL client certificate authentication for the CSlv2 protocol, you must use the CSlv2 inbound and outbound authentication panels. For SSL client authentication to occur between two servers, you must enable (support or require) SSL client certificate authentication for both the inbound and the outbound policies.

WebSphere Application Server can either request (support) clients to provide signer certificates for the SSL handshake, or the server can require clients to provide a valid signer certificates for the SSL handshake, which is a more secure method. However, when the server requires certificates, the server must obtain a signer for each client that connects to the server, which involves more server-side management.

The client certificate should not be used for the identity when it is used from server-to-server. However, when a pure client sends the client certificate it is used for the identity unless a message level identity is specified, such as a user ID or a password.

Do the following to enable client certificate authentication for the CSiv2 protocol for server-to-server:

1. **Click Security > Secure administration, applications, and infrastructure.**
2. Expand the **RMI/IIOP** security section.
3. Click **CSiv2 inbound authentication**.
4. Under Client authentication, select either **supported** or **required**. When you select required, only one SSL port is opened (CSV2_SSL_MUTUALAUTH_LISTENER_ADDRESS). When you select supported, two SSL ports are opened (both CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS and CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS).
If there are two ports, the client can select either based on the security configuration policy of the port.
5. Click **OK** to save.
6. If you want server-to-server SSL client authentication, then complete the remaining steps. If you don't complete the remaining steps, only pure clients are enabled to send client certificates.
7. Expand the **RMI/IIOP** security section.
8. Click **CSiv2 outbound authentication**.
9. Under Client authentication, select either **supported** or **required**.

The SSL configuration for the inbound secure endpoints for which you enable SSL client certificate authentication must have the signer certificate from any client that attempts to open a connection to that inbound secure endpoint. You must collect those signers and then add them to the trust store associated with the inbound secure endpoints SSL configuration.

Manage endpoint security configurations:

Use this page to select a Secure Socket Layer (SSL) configuration from the Local Topology hierarchy, which includes cells, nodes, node groups, servers, and clusters.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations**.

Local topology:

The Local topology represents the hierarchy of nodes, node groups, clusters, servers, and end points within the cell that comprise a centralized SSL configuration.

The topology acts as a hierarchical tree in terms of inheritance. For example, if an SSL configuration has been associated with a specific node, then all servers within that node will inherit that SSL configuration selection, provided the servers are not associated with an SSL configuration at the server scope. Centralized management of SSL is the default configuration; however, it can be overridden at various locations to directly select a specific SSL alias as in previous releases for backwards compatibility.

Scope	Description
Inbound/Outbound	Specifies the topology tree in terms of connection direction. For example, the inbound tree represents all server endpoints that receive connections at the various servers within the cell. The outbound tree represents the client side of connections from the various servers within the cell.

Scope	Description
Nodes	Specifies the nodes that are part of the cell. The list of nodes is updated anytime a node gets federated into the cell.
Servers	Specifies the servers that are part of a specific node. You can enable a specific server to have an SSL configuration associated with it so that resources within the same server can use the associated SSL configuration.
Clusters	Specifies the clusters that are part of the cell. When an SSL configuration is associated with a cluster, all servers within the cluster will use the same SSL configuration unless specified at a lower level in the topology.
Nodegroups	Specifies the node groups that are part of the cell. When an SSL configuration is associated with a node group, all nodes within that node group may use the same SSL configuration unless one is specified at a lower scope in the topology or the specific end point has chosen a direct alias reference.
Secure port and transport	Specifies an endpoint name to associate with an SSL configuration when more specific SSL settings are needed at this level. You could select an alias directly at the endpoint panel; however, when you use Secure port and transport , you can maintain more centralized control of the SSL configuration and make changes more easily.

Dynamic inbound and outbound endpoint SSL configurations collection:

Use this page to manage dynamic endpoint Secure Sockets Layer (SSL) configurations, which represent associations between Secure Socket Layer (SSL) configurations and their target protocol, host, and port.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Dynamic [inbound | outbound] endpoint SSL configurations**.

When an outbound connection is attempted, this association is checked ahead of the SSL configuration scope association. Based on the target protocol,host,port, the outbound SSL configuration used can be different from the default specified in the SSL scope configuration.

Button	Resulting action
New	Adds a new dynamic outbound selection criteria. The outbound connection selects an SSL configuration based upon connection information, including DNS host name and domain, port, and protocol type. When an outbound connection is being made, the dynamic outbound selection criteria are queried for a match, and if found the SSL configuration associated is used.
Delete	Deletes an existing dynamic outbound endpoint SSL configuration.

Name:

Specifies the unique name of the dynamic endpoint configuration.

Connection information:

Specifies the set of target protocol, host, port for the outbound request in the form *protocol,host,port*.

SSL Configuration:

Specifies the SSL configuration that is used by requests at this scope when a match occurs for the given selection criteria.

Dynamic outbound endpoint SSL configuration settings:

Use this page to set properties for dynamic outbound endpoint SSL configurations, which represent associations between SSL configurations and their target protocol, host, and port.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Dynamic [inbound | outbound] endpoint SSL configurations > New**.

When an outbound connection is attempted, this association is checked ahead of the Secure Sockets Layer (SSL) configuration scope association. This means based on the target protocol,host,port, the outbound SSL configuration used can be different than the default specified in the SSL scope configuration.

Name:

Specifies the unique name of the dynamic endpoint configuration.

Data type: Text

Description:

Specifies text that describes the purpose of this dynamic selection criteria.

Data type: Text

Add connection information:

Specifies select information in the form protocol,host,port for the outbound connection. Multiple selection criteria can be entered. An asterisk (*) can be used to mean all protocols, hosts, or ports. You can use an * for any field.

Data type: Text

An example of selection criteria is *,www.ibm.com,*, which means that any time the target host is www.ibm.com, you must use the SSL configuration specified here. Another example selection criteria is IIOP,*,*, which means that any outbound IIOP request uses the SSL configuration that is specified in the SSL configuration field. When there is a conflict between two selection criteria, the application server uses the first match. The list of valid protocols you can use include: IIOP, HTTP, JMS, LDAP, SIP, ADMIN_SOAP, or ADMIN_IIOP.

Add:

Specifies to add the selected information from the **Add select information** menu to the right-hand list.

Remove:

Specifies to remove the selection from the right-hand list.

SSL Configuration:

Specifies the SSL configuration to be used by requests at this scope when a match occurs for the given selection criteria.

Data type: Text

Get certificate alias:

When selected, the keystore within the selected SSL configuration is queried for a list of personal certificates from which to choose.

Certificate alias:

Specifies the certificate alias that is used as the identity for the connection.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the keystore, the key manager might not consistently select the same certificate.

Data type: Text
Default: (none)

Quality of protection (QoP) settings

Use this page to specify security level, ciphers, and mutual authentication settings for the Secure Socket Layer (SSL) configuration.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound *SSL_configuration_name*}**. Under **Related Items**, click **SSL configurations > {*SSL_configuration_name* | New JSSE configuration}**. Under **Additional Properties**, click **Quality of protection (QoP) settings**.

Client authentication:

Specifies the whether SSL client authentication should be requested if the SSL connection is used for the server side of the connection.

If None is selected, the server does not request that a client certificate be sent during the handshake. If Supported is selected, the server requests that a client certificate be sent. If the client does not have a certificate, the handshake might still succeed. If Required is selected, the server requests that a client certificate be sent. If the client does not have a certificate, the handshake fails.

Data type: Text
Default: None

Protocol:

Specifies the Secure Sockets Layer (SSL) handshake protocol. This protocol is typically SSL_TLS, which supports all handshake protocols except for SSLv2 on the server side. When United States Federal Information Processing standard (FIPS) option is enabled, Transport Layer Security (TLS) is automatically used regardless of this setting.

Data type: text
Default: SSL_TLS

Cipher suite groups:

Specifies the various cipher suite groups that can be chosen depending upon your security needs. The stronger the cipher suite strength, the better the security; however, this can result in performance consequences.

Data type: Text
Default: Strong

Update selected ciphers:

When selected, the cipher suites that are contained within the selected Cipher suite group are added to the list of **Selected ciphers**. Any change to this list changes the Cipher suite group to custom.

Selected ciphers:

Specifies the ciphers that are effective when the configuration is saved. These ciphers are used to negotiate with the remote side of the connection during the handshake. A common cipher needs to be selected or the handshake fails.

Data type: Text

Add:

Specifies to add the selected cipher to the **Selected ciphers** list.

Remove:

Specifies to remove the selected cipher from the **Selected ciphers** list.

ssl.client.props client configuration file

Use the `ssl.client.props` file to configure Secure Sockets Layer (SSL) for clients. In previous releases of WebSphere Application Server, SSL properties were specified in the `sas.client.props` or `soap.client.props` files or as system properties. By consolidating the configurations, WebSphere Application Server enables you to manage security in a manner that is comparable to server-side configuration management. You can configure the `ssl.client.props` file with multiple SSL configurations.

Setting up the SSL configuration for clients

Client runtimes are dependent on the WebSphere Application Server `ssl.client.props` configurations.

Use the `setupCmdLine.bat` or `setupCmdLine.sh` script on the command line to specify the `com.ibm.SSL.ConfigURL` system property.

```
-Dcom.ibm.SSL.ConfigURL=file:C:\WebSphere\AppServer\profiles\default  
\properties\ssl.client.props
```

The `com.ibm.SSL.ConfigURL` property references a file URL that points to the `ssl.client.props` file. You can reference the `CLIENTSSL` variable on the command line of any script that uses the `setupCmdLine.bat` or `setupCmdLine.sh` file.

When you specify the `com.ibm.SSL.ConfigURL` system property, the SSL configuration is available to all protocols that use SSL. SSL configurations, which are referenced in the `ssl.client.props` file, also have aliases that you can reference. In the following sample code from the `sas.client.props` file, all of the SSL properties are replaced with a property that points to an SSL configuration in the `ssl.client.props` file:

```
com.ibm.ssl.alias=default
```

The following sample code shows a property in the `soap.client.props` file that is similar to the `com.ibm.SSL.ConfigURL` property. This property references a different SSL configuration on the client side:

```
com.ibm.ssl.alias=ADMIN_SOAP
```

In the `ssl.client.props` file, you can change the administrative SSL configuration to avoid modifying the `soap.client.props` file.

Tip: In WebSphere Application Server Version 6.1, support for SSL properties is still specified in the `sas.client.props` and `soap.client.props` files. However, consider moving the SSL configurations to the `ssl.client.props` file, because this file is the new configuration model for client SSL.

Properties of the `ssl.client.props` file

This section describes the default `ssl.client.props` file properties in detail, by sections within the file.

Global properties

Global SSL properties are process-specific properties that include Federal Information Processing Standard (FIPS) enablement, the default SSL alias, the `user.root` property for specifying the root location of the key and truststore paths, and so on.

Property	Default	Description
<code>com.ibm.ssl.defaultAlias</code>	<code>DefaultSSLSettings</code>	Specifies the default alias that is used whenever an alias is not specified by the protocol that calls the JSSEHelper API to retrieve an SSL configuration. This property is the final arbiter on the client side for determining which SSL configuration to use.
<code>com.ibm.ssl.validationEnabled</code>	<code>false</code>	When set to <code>true</code> , this property validates each SSL configuration as it is loaded. Use this property for debug purposes only, to avoid unnecessary performance overhead during production.
<code>com.ibm.ssl.performURLHostNameVerification</code>	<code>false</code>	When set to <code>true</code> , this property enforces URL host name verification. When HTTP URL connections are made to target servers, the common name (CN) from the server certificate must match the target host name. Without a match, the host name verifier rejects the connection. The default value of <code>false</code> omits this check. As a global property, it sets the default host name verifier. Any <code>javax.net.ssl.HttpURLConnection</code> object can choose to enable host name verification for that specific instance by calling the <code>setHostnameVerifier</code> method with its own <code>HostnameVerifier</code> instance.
<code>com.ibm.security.useFIPS</code>	<code>false</code>	When set to <code>true</code> , FIPS-compliant algorithms are used for SSL and other Java Cryptography Extension (JCE)-specific applications. This property is typically not enabled unless the property is required by the operating environment.
<code>user.root</code>	<code>C:\WebSphere\AppServer\profiles\default</code>	This property can be used by key and truststore location properties as a single property for specifying the root path to the key and truststores. Typically, this property is the profile root. However, you can modify this property to any root directory on the local machine that has the proper read and potentially write authority to that directory.

Property	Default	Description
profile_root of the profile	C\WebSphere\ AppServer \profiles\default	Key and truststore location properties can use this property as a single property for specifying the root path to the key and truststores. You can modify this property to any root directory on the local machine that has the proper read (and potentially write) authority to that directory.

Certificate creation properties

Use certificate creation properties to specify the default self-signed certificate values for the major attributes of a certificate. You can define the distinguished name (DN), expiration date, key size, and alias that are stored in the keystore.

Property	Default	Description
com.ibm.ssl.defaultCertReqAlias	default_alias	This property specifies the default alias to use to reference the self-signed certificate that is created in the keystore. If the alias already exists with that name, the default alias is appended with <code>_#</code> , where the number sign (#) is an integer that starts with 1 and increments until it finds a unique alias.
com.ibm.ssl.defaultCertReqSubjectDN	cn=\${hostname}, o=IBM,c=US	This property uses the property distinguished name (DN) that you set for the certificate when it is created. The <code>\${hostname}</code> variable is expanded to the host name on which it resides. You can use correctly formed DNs as specified by the X.509 certificate.
com.ibm.ssl.defaultCertReqDays	365	This property specifies the validity period for the certificate and can be as small as 1 day and as large as the maximum number of days that a certificate can be set, which is approximately 20 years.
com.ibm.ssl.defaultCertReqKeySize	1024	This property is the default key size. The valid values depend upon the Java Virtual Machine (JVM) security policy files that are installed. By default, the product JVMs ship with the export policy file that limits the key size to 1024. To get a large key size such as 2048, you can download the restricted policy files from the Web site.

SSL configuration properties

Use the SSL configuration properties section to set multiple SSL configurations. For a new SSL configuration specification, set the `com.ibm.ssl.alias` property because the parser starts a new SSL configuration with this alias name. The SSL configuration is referenced by using the alias property from another file, such as `sas.client.props` or `soap.client.props`, through the default alias property. The properties that are specified in the following table enable you to create a `javax.net.ssl.SSLContext`, among other SSL objects.

Property	Default	Description
com.ibm.ssl.alias	DefaultSSLSettings	This property is the name of this SSL configuration and must be the first property for an SSL configuration because it references the SSL configuration. If you change the name of this property after it is referenced elsewhere in the configuration, the runtime defaults to the com.ibm.ssl.defaultAlias property whenever the reference is not found. The error trust file is null or key file is null might display when you start an application using an SSL reference that is no longer valid.
com.ibm.ssl.protocol	SSL_TLS	This property is the SSL handshake protocol that is used for this SSL configuration. This property attempts Transport Layer Security (TLS) first, but accepts any remote handshake protocol, including SSLv3 and TLS. Valid values for this property include SSLv2 (client side only), SSLv3, SSL, TLS, TLSv1, and SSL_TLS.
com.ibm.ssl.securityLevel	HIGH	This property specifies the cipher group that is used for the SSL handshake. The typical selection is HIGH, which specifies 128-bit or higher ciphers. The MEDIUM selection provides 40-bit ciphers. The LOW selection provides ciphers that do not perform encryption, but do perform signing for data integrity. If you specify your own cipher list selection, uncomment the property com.ibm.ssl.enabledCipherSuites.
com.ibm.ssl.trustManager	IbmX509	This property specifies the default trust manager that you must use to validate the certificate sent by the target server. This trust manager does not perform certificate revocation list (CRL) checking. You can choose to change this to IbmPKIX for CRL checking using CRL distribution lists in the certificate, which is a standard way to perform CRL checking. When you want to perform custom CRL checking, you must implement a custom trust manager and specify the trust manager in the com.ibm.ssl.customTrustManagers property. The IbmPKIX option might affect performance because this option requires IBM CertPath for trust validation. Use IbmX509 unless CRL checking is necessary.
com.ibm.ssl.keyManager	IbmX509	This property specifies the default key manager to use for choosing the client alias from the specified keystore. This key manager uses the com.ibm.ssl.keyStoreClientAlias property to specify the keystore alias. If this property is not specified, the choice is delegated to Java Secure Socket Extension (JSSE). JSSE typically chooses the first alias that it finds.
com.ibm.ssl.contextProvider	IBMJSSE2	This property is used to choose the JSSE provider for the SSL context creation. It is recommended that you default to IBMJSSE2 when you use a Java virtual machine (JVM). The client plug-in can use the SunJSSE provider when using a Sun JVM.

Property	Default	Description
com.ibm.ssl.enableSignerExchangePrdmp		This property determines whether to display the signer exchange prompt when a signer is not present in the client truststore. The prompt displays information about the remote certificate so that WebSphere Application Server can decide whether or not to trust the signer. It is very important to validate the certificate signature (hash). This signature is the only reliable information that can guarantee that the certificate has not been modified from the original server certificate. For automated scenarios, disable this property to avoid SSL handshake exceptions. Run the retrieveSigners.bat file or the retrieveSigners.sh script, which sets up the SSL signer exchange, to download the signers from the server prior to running the client.
com.ibm.ssl.keyStoreClientAlias	default	This property is used to reference an alias from the specified keystore when the target does not request client authentication. When WebSphere Application Server creates a self-signed certificate for the SSL configuration, this property determines the alias and overrides the global com.ibm.ssl.defaultCertReqAlias property.
com.ibm.ssl.customTrustManagers	Commented out by default	This property enables you to specify one or more custom trust managers, which are separated by commas. These trust managers can be in the form of <i>algorithm provider</i> or <i>classname</i> . For example, IbmX509IIBMJSSE2 is in the <i>algorithm provider</i> format, and the com.acme.myCustomTrustManager interface is in the <i>classname</i> format. The class must implement the javax.net.ssl.X509TrustManager interface. Optionally, the class can implement the com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface. These trust managers run in addition to the default trust manager that is specified by the com.ibm.ssl.trustManager interface. These trust managers do not replace the default trust manager.
com.ibm.ssl.customKeyManager	Commented out by default	This property enables you to have one, and only one, custom key manager. The key manager replaces the default key manager that is specified in the com.ibm.ssl.keyManager property. The form of the key manager is <i>algorithm provider</i> or <i>classname</i> . See the format examples for the com.ibm.ssl.customTrustManagers property. The class must implement the javax.net.ssl.X509KeyManager interface. Optionally, the class can implement the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface. This key manager is responsible for alias selection.

Property	Default	Description
com.ibm.ssl.dynamicSelectionInfo	Commented out by default	<p>This property enables dynamic association with the SSL configuration. The syntax for a dynamic association is <i>outbound_protocol</i>, <i>target_host</i>, or <i>target_port</i>. For multiple specifications, use the vertical bar () as the delimiter. You can replace any of these values with an asterisk (*) to indicate a wildcard value. Valid <i>outbound_protocol</i> values include: IIOP, HTTP, LDAP, SIP, BUS_CLIENT, BUS_TO_WEBSPHERE_MQ, BUS_TO_BUS, and ADMIN_SOAP. When you want the dynamic selection criteria to choose the SSL configuration, uncomment the default property, and add the connection information. For example, add the following on one line</p> <pre>com.ibm.ssl.dynamicSelectionInfo=HTTP, .ibm.com,443 HTTP,.ibm.com,9443</pre> <p>. ADMIN_IIOP, and ADMIN_SOAP represent administrative uses of these protocols for the Remote Method Invocation (RMI) and SOAP connectors, respectively. In the SSL configuration alias AdminSOAPSSLSettings, you can set the value to ADMIN_SOAP,*,*, which indicates that any outbound administrative SOAP connection can use this SSL configuration. Dynamic selection takes precedence over direct alias selection in the soap.client.props file.</p>
com.ibm.ssl.enabledCipherSuites	Commented out by default	<p>This property enables you to specify a custom cipher suite list and override the group selection in the com.ibm.ssl.securityLevel property. The valid list of ciphers varies according to the provider and JVM policy files that are applied. For cipher suites, use a space as the delimiter.</p>
com.ibm.ssl.keyStoreName	ClientDefaultKeyStore	<p>This property references a keystore configuration name. If you have not already defined the keystore, the rest of the keystore properties must follow this property. After you define the keystore, you can specify this property to reference the previously specified keystore configuration. New keystore configurations in the ssl.client.props file have a unique name.</p>
com.ibm.ssl.trustStoreName	ClientDefaultTrustStore	<p>This property references a truststore configuration name. If you have not already defined the truststore, the rest of the truststore properties must follow this property. After you define the truststore, you can specify this property to reference the previously specified truststore configuration. New truststore configurations in the ssl.client.props file should have a unique name.</p>

Keystore configurations

SSL configurations reference keystore configurations whose purpose is to identify the location of certificates. Certificates represent the identity of clients that use the SSL configuration. You can specify keystore configurations with other SSL configuration properties. However, it is recommended that you specify the keystore configurations in this section of the ssl.client.props file after the com.ibm.ssl.keyStoreName property identifies the start of a new keystore configuration. After you fully define the keystore configuration, the com.ibm.ssl.keyStoreName property can reference the keystore configuration at any other point in the file.

Property	Default	Description
com.ibm.ssl.keyStoreName	ClientDefaultKeyStore	This property specifies the name of the keystore as it is referenced by the runtime. Other SSL configurations can reference this name further down in the <code>ssl.client.props</code> file to avoid duplication.
com.ibm.ssl.keyStore	<code>\${user.root}/etc/key.p12</code>	This property specifies the location of the keystore in the required format of the <code>com.ibm.ssl.keyStoreType</code> property. Typically, this property references a keystore file name. However, for cryptographic token types, this property references a Dynamic Link Library (DLL) file.
com.ibm.ssl.keyStorePassword	WebAS	This property is the default password, which is the cell name for the profile when it is created. The password is typically encoded using an {xor} algorithm. You can use iKeyman to change the password in the keystore, then change this reference. If you do not know the password and if the certificate is created for you, change the password in this property, then delete the keystore from the location where it resides. Restart the client to recreate the keystore by using the new password, but only if the keystore name ends with <code>DefaultKeyStore</code> and if the <code>fileBased</code> property is <code>true</code> . Delete both the keystore and truststore at the same time so that a proper signer exchange can occur when both are recreated together.
com.ibm.ssl.keyStoreType	PKCS12	This property is the keystore type. Use the default, PKCS12, because of its interoperability with other applications. You can specify this property as any valid keystore type that is supported by the JVM on the provider list.
com.ibm.ssl.keyStoreProvider	IBMJCE	The IBM Java Cryptography Extension property is the keystore provider for the keystore type. The provider is typically IBMJCE or IBMPKCS11Impl for cryptographic devices. For z/OS, the provider can be JCERACFKS, or JCE4758KS for cryptographic devices.
com.ibm.ssl.keyStoreFileBased	true	This property indicates to the runtime that the keystore is file-based, meaning it is located on the file system.
com.ibm.ssl.keyStoreReadOnly	false	This property indicates to the runtime whether the keystore can be modified during the runtime.

Truststore Configurations

SSL configurations reference truststore configurations, whose purpose is to contain the signer certificates for servers that are trusted by this client. You can specify these properties with other SSL configuration properties. However, it is recommended that you specify truststore configurations in this section of the `ssl.client.props` file after the `com.ibm.ssl.trustStoreName` property has identified the start of a new truststore configuration. After you fully define the truststore configuration, the `com.ibm.ssl.trustStoreName` property can reference the configuration at any other point in the file.

A truststore is a keystore that JSSE uses for trust evaluation. A truststore contains the signers that WebSphere Application Server requires before it can trust the remote connection during the handshake. If you configure the `com.ibm.ssl.trustStoreName=ClientDefaultKeyStore` property, you can reference the keystore as the truststore. Further configuration is not required for the truststore because all of the signers that are generated through signer exchanges are imported into the keystore where they are called by the runtime.

Property	Default	Description
com.ibm.ssl.trustStoreName	ClientDefaultTrustStore	This property specifies the name of the truststore as it is referenced by the runtime. Other SSL configurations can reference further down in the <code>ssl.client.props</code> file to avoid duplication.
com.ibm.ssl.trustStore	<code>\${user.root}/etc/trust.p12</code>	This property specifies the location of the truststore in the format that is required by the truststore type that is referenced by the <code>com.ibm.ssl.trustStoreType</code> property. Typically, this property references a truststore file name. However, for cryptographic token types, this property references a DLL file.
com.ibm.ssl.trustStorePassword	WebAS	This property specifies the default password, which is the cell name for the profile when it is created. The password is typically encoded using an {xor} algorithm. You can use <code>iKeyman</code> to change the password in the keystore, then change the reference in this property. If you do not know the password and if the certificate was created for you, change the password in this property, then delete the truststore from the location where it resides. Restart the client to recreate the truststore by using the new password, but only if the keystore name ends with <code>DefaultTrustStore</code> and the <code>fileBased</code> property is <code>true</code> . It is recommended that you delete the keystore and the truststore at the same time so that a proper signer exchange can occur when both are recreated together.
com.ibm.ssl.trustStoreType	PKCS12	This property is the truststore type. Use the default PKCS12 type because of its interoperability with other applications. You can specify this property as any valid truststore type that is supported by the JVM functionality on the provider list.
com.ibm.ssl.trustStoreProvider	IBMJCE	This property is the truststore provider for the truststore type. The provider is typically IBMJCE or IBMPKCS11Impl for cryptographic devices. The provider can be JCERACFKS, or JCE4758KS for cryptographic devices.
com.ibm.ssl.trustStoreFileBased	true	This property indicates to the runtime that the truststore is file-based, meaning it is located on the file system.
com.ibm.ssl.trustStoreReadOnly	false	This property indicates to the runtime whether the truststore can be modified during the runtime.

Creating a keystore configuration

A Secure Sockets Layer (SSL) configuration references keystore configurations during WebSphere Application Server runtime. Whether a keystore file was created by another keystore tool or saved from a previous configuration, the file must be part of a keystore configuration object. You can create a keystore configuration for the existing keystore object.

A keystore must already exist.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration > Key stores and certificates > New**.
2. Type a name in the **Name** field. This name uniquely identifies the keystore in the configuration.

3. Type the location of the keystore file in the **Path** field. The location can be a file name or a file URL to an existing keystore file.
4. Type the keystore password in the **Password** field. This password is for the keystore file that you specified in the **Path** field.
5. Type the keystore password again in the **Confirm Password** field to confirm the password.
6. Select a keystore type from the list. The type that you select is for the keystore file that you specified in the **Path** field.
7. Select any of the following optional selections:
 - The **Read only selection** creates a keystore configuration object but does not create a keystore file. If this option is selected, the keystore file that you specified in the **Path** field must already exist.
 - The **Initialize at startup selection** initializes the keystore during runtime.
8. Click **Apply** and **Save**.

You have created a keystore configuration object for the keystore file that you specified. This keystore can now be used in an SSL configuration.

Note: You also can use this method to add a z/OS keyring file to the configuration. The keyring file must be read only, not file-based.

You can create additional keystore configurations, as needed.

Changing a keystore password

You can change the WebSphere Application Server password from the default password value, WebAS, in the administrative console or at a Java command prompt. Because the default password is well known, it is important that you change the password after you install WebSphere Application Server to protect the security of the keystore files and the Secure Sockets Layer (SSL) configuration.

When WebSphere Application Server starts for the first time as a standalone application server or as a Network Deployment Server, each server creates a keystore and truststore for the default SSL configuration. WebSphere Application Server creates these files and assigns the default password, WebAS.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Key Stores and Certificates**.
2. Select a keystore.
3. Type the new keystore password in the **Change Password** field.
4. Type the keystore password again in the **Confirm Password** field to confirm the password.
5. Select **Apply**.

WebSphere Application Server and its keystores are protected by a unique password.

Use the new password the next time you start the WebSphere Application Server.

Configuring a hardware cryptographic keystore

You can create a hardware cryptographic keystore that WebSphere Application Server can use to provide cryptographic token support in the server configuration.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration > Key stores and certificates**.
2. Click **New**.
3. Type a name to identify the keystore. This name is used to enable hardware cryptography in the Web services security configuration.

4. Type the path for the hardware device-specific configuration file. The configuration file is a text file that contains entries in the following format: *attribute = value*. The valid values for attribute and value are described in detail in the Software Developer Kit, Java Technology Edition documentation. The two mandatory attributes are name and library, as shown in the following sample code:

```
name = FooAccelerator
library = /opt/foo/lib/libpkcs11.so
slotListIndex = 0
```

5. Type a password if the token login is required. Operations that use keys on the token require a secure login. This field is optional if the keystore is used as a cryptographic accelerator. In this case, you need to select **Enable pure acceleration for hardware cryptographic operations**.
6. Select the **PKCS11** type. z/OS does not support PKCS11 at the present time.
7. Select **Read only**.
8. Click **OK** and **Save**.

WebSphere Application Server can now provide cryptographic token support in the server configuration.

You can refer to this keystore in any server Secure Sockets Layer (SSL) configuration to achieve the following results:

- Cryptographic acceleration because the cryptographic hardware device has no persistent key storage
- Secure cryptographic hardware because a cryptographic token generates and securely stores the private key that WebSphere Application Server uses for SSL key exchange.

You can also refer to this keystore in the Web services security default bindings configuration to achieve similar results.

Managing keystore configurations remotely

You can manage keystores remotely in a Network Deployment environment on separate machines. A node server can hold the configuration for a keystore, while the actual keystore resides on another system. After you set up a remotely managed configuration, you can perform all of the certificate and keystore operations for the keystore on the remote machine from the server that contains the keystore remote configuration.

Key stores can be remotely managed only in network deployed environments.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates**.
2. Click **New**.
3. Type a name in the **Name** field. This name uniquely identifies the keystore in the configuration.
4. Type the location of the keystore file in the **Path** field. The location can be a file name or a file Uniform Resource Locator (URL) to an existing keystore file.
5. Type the keystore password in the **Password** field. This password is for the keystore file that you specified in the **Path** field.
6. Type the keystore password again in the **Confirm Password** field to confirm the password.
7. Select a keystore type from the list. The type you select is for the keystore file that you specified in the **Path** field.
8. Select the **Remotely managed** check box, and then fill in one or more hosts names of the systems where the keystore file is to be located. If you provide multiple host names, separate the host names with a pipe (|).
9. Select any of the following optional selections:

- The **Read only selection** creates a keystore configuration object but does not create a keystore file. If this option is selected, the keystore file that you specified in the **Path** field must already exist.
- The **Initialize at startup selection** initializes the keystore during run time.

10. Select **Apply** and **Save**.

A keystore configuration object is created on the server from where the command was run. The keystore file for the configuration will be created on each system that you specified in the host list.

Now, you can perform all certificate management operations on the keystore from the system where the keystore configuration resides. For example, you can perform certificate management operations, such as: creating a self-signed certificate, extracting a certificate, or extracting a signer certificate.

To manage a self-signed certificates by using the wsadmin tool, use the PersonalCertificateCommands group commands of the AdminTask object. For more information, see “Commands for the PersonalCertificateCommands group of the AdminTask object” on page 1798.

Key stores and certificates collection

Use this page to manage key store types, including cryptography, Resource Access Control Facility (RACF) , Certificate Management Services (CMS), Java, and all trust store types.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > SSL_configuration_name**. Under Related items, click **Key stores and certificates**.

Button	Resulting action
New	Adds a new key store object that can be referenced by Secure Sockets Layer (SSL) configurations or KeySets. The KeyStore management scope is based on the part of the topology tree from which it was created.
Delete	Deletes an existing key store. The key store should not be referenced by any other parts of the configuration before you delete it.
Exchange signers	Refers to exchanging signers in a key store. You can select two key stores, along with personal certificates from a selected key store, then add them as a signer to another selected key store.

Name:

Specifies the unique name that is used to identify the key store. This name is typically scoped by the ManagementScope scopeName and based upon the location of the key store. The name must be unique within the existing key store collection.

This is a user-defined name.

Path:

Specifies the location of the key store file in the format needed by the key store type. This file can be a card-specific configuration file for cryptographic devices or a filename or file URL for file-based key stores. It can be a safkeyring URL for RACF keyrings.

Key store settings

Use this page to create all keystore types, including cryptographic, Resource Access Control Facility (RACF), Certificate Management Services (CMS), Java, and all truststore types.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound *SSL_configuration_name*}**. Under Related Items, click **Key stores and certificates > New**.

Links to Personal certificates, Signer certificates, and Personal certificate requests enable you to manage certificates in a manner similar to iKeyman capabilities. A keystore can be file-based, such as CMS or Java keystore types, or it can be remotely managed.

Note: Any changes made to this panel are permanent.

Name:

Specifies the unique name to identify the keystore. The keystore is typically scoped by the ManagementScope scopeName based on the location of the keystore. The name must be unique within the existing keystore collection.

Data type: Text

Path:

Specifies the location of the keystore file in the format needed by the keystore type. This file can be a dynamic link library (DLL) for cryptographic devices or a filename or file URL for file-based keystores. It can be a safkeyring URL for RACF keyrings.

Data type: Text

Enable cryptographic operations on hardware device:

Specifies whether a hardware cryptographic device is used for cryptographic operations only. Operations that require a login are not supported when using this option.

Default: Disabled

Password [new keystore] | Change password [existing keystore]:

Specifies the password used to protect the keystore. For the default keystore (names ending in DefaultKeyStore or DefaultTrustStore), the password is the Cell name. This default password must be changed.

This field can be edited.

Data type: Text

Confirm password:

Specifies confirmation of the password to open the keystore file or device.

Data type: Text

Type:

Specifies the implementation for keystore management. This value defines the tool that operates on this keystore type.

The list of options is returned by `java.security.Security.getAlgorithms("KeyStore")`. Some options might be filtered and some might be added based on the `java.security` configuration.

Data type: Text
Default: PKCS12

Read only:

Specifies whether the keystore can be written to or not. If the keystore cannot be written to, certain operations cannot be performed, such as creating or importing certificates.

Default: Disabled

Initialize at startup:

Specifies whether the keystore needs to be initialized before it can be used for cryptographic operations. If enabled, the keystore is initialized at server startup.

Default: Disabled

Key managers collection

Use this page to define the implementation settings for key managers. A key manager is invoked during a Secure Sockets Layer (SSL) handshake to determine which certificate alias is used. The default key manager (`WSX509KeyManager`) performs alias selection. If more advanced function is desired, define a custom key manager and select it on the **Manage endpoint security configurations** panel.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *SSL_configuration_name***. Under Related items, click **Key managers**.

Button	Resulting action
New	Adds a new key manager that can be selected by an SSL configuration. A key manager is invoked during an SSL handshake to select a specific certificate alias to use from a key store.
Delete	Deletes an existing key manager. The key manager should not be referenced by any SSL configuration before you can delete it.

Name:

Specifies the name of the key manager, which you can select on the SSL configuration panel.

Class name:

Specifies the name of the key manager implementation class. This class implements `javax.net.ssl.X509KeyManager` interface and, optionally, the `com.ibm.wsspi.ssl.KeyManagerExtendedInfo` interface.

Algorithm:

Specifies the algorithm name of the key manager that is implemented by the selected provider.

Key managers settings

Use this page to define key managers implementation settings. A key manager gets invoked during an Secure Sockets Layer (SSL) handshake to determine the certificate alias to be used. The default key

manager (WSX509KeyManager) performs alias selection. If more advanced function is desired, a custom key manager can be specified here and selected in the SSL configuration.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > SSL_configuration_name**. Under Related items, click **Key managers > New**.

Name:

Specifies the name of the key manager, which you can select on the SSL configuration panel.

Data type: Text

Standard:

Specifies the key manager selection that is available from a Java provider that is installed in the java.security file. This provider might be shipped by Java Secure Sockets Extension (JSSE) or be a custom provider that implements an X509KeyManager interface.

Default: Enabled

Provider:

Specifies the provider name that has an implementation of an X509KeyManager interface. This provider is typically set to IBMJSSE2.

Data type: Text

Default: IBMJCE

Algorithm:

Specifies the algorithm name of the trust manager implemented by the selected provider.

Data type: Text

Default: IbmX509

Custom:

Specifies that the key manager selection is based on a custom implementation class that implements the javax.net.ssl.X509KeyManager interface and optionally the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface to obtain additional connection information not otherwise available.

Default: Disabled

Class name:

Specifies the name of the key manager implementation class.

Data type: Text

Creating a self-signed certificate

You can create a self-signed certificate. WebSphere Application Server uses the certificate at runtime during the handshake protocol. Self-signed certificates are located in the default keystore.

You must create a keystore before you can create a self-signed certificate.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates > [keystore]**.
2. From Additional Properties, click **Personal certificates**.
3. Click **Create a self-signed certificate**.
4. Type a certificate alias name. The alias identifies the certificate request in the keystore.
5. Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).
6. Type an organization value. This value is the O value in the certificate DN.
7. You can configure one or more of the following optional values:
 - a. **Optional:** Select a key size value. The default key size value is 1024 bits.
 - b. **Optional:** Type an organizational unit value. This organizational unit value is the OU value in the certificate DN.
 - c. **Optional:** Type a locality value. This locality value is the L value in the certificate DN.
 - d. **Optional:** Type a state or providence value. This value is the ST value in the certificate DN.
 - e. **Optional:** Type a zip code value. This zip code value is the POSTALCODE value in the certificate DN.
 - f. **Optional:** Select a country value from the list. This country value is the C= value in the certificate request DN.
8. Click **Apply**.

You have created a self-signed certificate that resides in the keystore. The SSL configuration for the WebSphere Application Server runtime uses this certificate for SSL communication. Extract the signer of the self-signed certificate to add the signer to another keystore.

To create a self-signed certificate by using the wsadmin tool, use the **createSelfSignedCertificate** command of the AdminTask object. For more information, see “Commands for the PersonalCertificateCommands group of the AdminTask object” on page 1798.

Replacing an existing self-signed certificate

Occasionally, you need to replace an existing or expired self-signed certificate with a new certificate. Certificates are referenced in the runtime configuration by the Secure Sockets Layer (SSL) Configuration object and the Dynamic SSL Configuration Selection object. You can replace a certificate with a new certificate alias reference or with a new signer certificate.

The current certificate and the certificate replacement must exist in the same keystore before you can replace a certificate.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates > [keystore]**.
2. Under Additional Properties, click **Personal certificates**.
3. Select a personal certificate. The alias list must include at least two certificates that reside in the keystore.
4. Click **Replace**.

5. Select a replacement certificate alias from the list.
6. You can delete one of the following types of certificates:
 - Select **Delete old certificate** to delete the existing certificate.
 - Select **Delete old signers** to delete the existing signer certificates.
7. Click **Apply**.

Your results depend on what you selected:

- If you selected **Delete old certificate**, the new certificate alias replaces all of the references to the certificate alias in the configuration.
- If you selected **Delete old signers**, the new signer certificate replaces all of the occurrences of the old signer certificates.
- If the new certificate alias replaces the existing alias, the WebSphere Application Server runtime checks to make sure that:
 - All of the SSL Configurations objects reference the certificate
 - The Dynamic SSL Configuration Selections objects and the SSL Configuration group objects reference the certificate.
- If you selected **Delete old signers**, the existing signer certificates are replaced.
- If you selected **Delete old certificate**, the existing certificate are deleted.

To replace a self-signed certificate by using the wsadmin tool, use the **replaceCertificate** command of the AdminTask object. For more information, see `rxml_atpersonalcert.dita`.

Creating a certificate authority request

To ensure Secure Sockets Layer (SSL) communication, servers require a personal certificate that is either self-signed or signed by a certificate authority (CA). You must first create a personal certificate request to obtain a certificate that is signed by a CA.

The keystore that contains a personal certificate request must already exist.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates > keystore**.
2. Click **Personal certificate requests > New**.
3. Type the full path of the certificate request file. The certificate request is created in this location.
4. Type an alias name in the **Key label** field. The alias identifies the certificate request in the keystore.
5. Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).
6. Type an organization value. This value is the O value in the certificate DN.
7. You can configure one or more of the following optional values:
 - a. **Optional:** Select a key size value. The default key size value is 1024 bits.
 - b. **Optional:** Type an organizational unit value. This organizational unit value is the OU value in the certificate DN.
 - c. **Optional:** Type a locality value. This locality value is the L value in the certificate DN.
 - d. **Optional:** Type a state or providence value. This value is the ST value in the certificate DN.
 - e. **Optional:** Type a zip code value. The zip code value is the POSTALCODE value in the certificate DN.
 - f. **Optional:** Select a country value from the list. This country value is the C= value in the certificate request DN.
8. Click **Apply**.

The certificate request is created in the specified file location in the keystore. The request functions as a temporary placeholder for the signed certificate until you manually receive the certificate in the keystore.

To create a certificate request using the wsadmin tool, use the **createCertificateRequest** command of the AdminTask object. For more information, see “Commands for the PersonalCertificateCommands group of the AdminTask object” on page 1798.

Note: Key store tools (such as iKeyman and keyTool) cannot receive signed certificates that are generated by certificate requests from WebSphere Application Server. Similarly, WebSphere Application Server cannot accept certificates that are generated by certificate requests from other keystore utilities.

Now you can receive the CA-signed certificate into the keystore to complete the process of generating a signed certificate for your server.

Certificate request settings

Use this page to verify the properties of a personal certificate request.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > ssl_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties, click **Personal certificate requests > certificate request**.

Key label:

Specifies the certificate alias name for the signer in the key store, which is specified in the SSL configuration.

Key size:

Specifies the size of the keys that are generated.

Requested by:

Specifies the Subject distinguished name (DN) that represents the identity of the certificate request.

Fingerprint (SHA Digest):

Specifies the SHA hash of the personal certificate, which can be used to verify that the certificate has not been altered when it is used in a remote connection.

Signature algorithm:

Specifies the algorithm used to sign the certificate.

Personal certificates collection

Use this page to manage personal certificates.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties, click **Personal certificates**.

The **Personal certificates** page lists all Personal certificates in the selected key store. You can do most certificate management operations in this panel, including creating a new self-signed certificate, deleting a

certificate, receiving one generated from a CA, replacing a certificate (simultaneous delete and create, replacing references across all key stores), extracting the signer, and importing or exporting a personal certificate.

Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA).

The Key store collection must contain at least two key store files. You must select one file in order to replace, extract, or export a key store,

Button	Resulting action
Create a self-signed certificate	Enables the application server to create a new self-signed certificate.
Delete	Specifies to delete a certificate from the key store. Be careful that the certificate alias is not referenced elsewhere in the Secure Sockets Layer configuration.
Receive a certificate from a certificate authority	Enables the application server to receive a certificate authority (CA)-generated certificate from a file to complete a certificate request.
Replace	Replaces a self-signed certificate with another self-signed certificate that contains the same information, but with a new expiration period. The signer from the old certificate that is contained in any managed key store in the cell is replaced by the signer from the new certificate.
Extract	Extracts a certificate from the key store that will be added to another key store as a trusted certificate (signer).
Import	Imports a certificate, including the private key, from a key store file.
Export	Exports a certificate, including the private key, to a specified key store file.

Alias:

Specifies the alias by which the personal certificate is referenced in the key store.

When you select an alias, the View Certificate panel opens.

Issued by:

Specifies the distinguished name of the entity by which the certificate was issued. This name is the same as the issued-to distinguished name when the personal certificate is self-signed.

Issued to:

Specifies the distinguished name of the entity to which the certificate was issued.

Serial number:

Specifies the certificate serial number that is generated by the issuer of the certificate.

Expiration:

Specifies the expiration date of the signer certificate for validation purposes.

Personal certificates settings

Use this page to create new personal certificates.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *SSL_configuration_name***. Under Related items, click **Key stores and certificates > *key store***. Under Additional Properties, click **Personal certificates > Create a self-signed certificate**.

This same help file is available when you create a new certificate or modify an existing certificate. The fields in this file are marked according to when they show on the administrative console.

Alias:

Specifies the alias for the personal certificate in the key store.

This field displays when you create a new certificate. This field is read-only when you view an existing certificate.

Data type: Text

Version:

Specifies the version of the personal certificate. Valid versions include X509 V3, X509 V2, or X509 V1. It is recommended to use X509 V3 certificates.

This field is read-only when you create or view a certificate.

Data type: Text
Default: X509 V3
Range:

Key size:

Specifies the key size of the private key that is used by the personal certificate.

This field displays when you create or view a certificate.

Data type: Integer
Default: 1024

Common name:

Specifies the common name portion of the distinguished name (DN). It is recommended that this name be the host name of the machine on which the certificate resides. In some cases, the common name is used to login during Secure Socket Layer (SSL) certificate authentication; therefore, in some cases, this name might be used as a user ID for a local operating system registry.

This field displays when you create a new certificate, but does not display when you view an existing certificate.

Data type: Text

Serial number:

Specifies the certificate serial number that is generated by the issuer of the certificate.

This field displays only when you view an existing certificate.

Validity period:

Specifies the length in days during which the certificate is valid. The default is 365 days.

This field displays when you create or view a certificate.

Data type: Text

Organization:

Specifies the organization portion of the distinguished name.

This field displays only when you create a new certificate.

Data type: Text

Organization unit:

Specifies the organization unit portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Text

Locality:

Specifies the locality portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Text

State/Province:

Specifies the state portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Text

Zip code:

Specifies the zip code portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Integer

Country or region:

Specifies the country portion of the distinguished name.

This field displays only when you create a new certificate.

Data type: Text
Default: (none)

Refer to <http://www.iso.org/iso/en/prods-services/iso3166ma/02iso-3166-code-lists/list-en1.html> for a list of ISO 3166 country codes.

Validity period:

Specifies the length, in days, when the certificate is valid. The default is 365 days.

This read-only field displays only when you view an existing certificate.

Issued to:

Specifies the distinguished name of the entity to which the certificate was issued.

This read-only field displays only when you view an existing certificate.

Issued by:

Specifies the distinguished name of the entity that issued the certificate. When the personal certificate is self-signed, this name is identical to the **Issued to** distinguished name.

This read-only field displays only when you view an existing certificate.

Fingerprint (SHA Digest):

Specifies the Secure Hash Algorithm (SHA hash) of the certificate, which can be used to verify the certificate's hash at another location, such as the client side of a connection.

This read-only field displays only when you view an existing certificate.

Signature algorithm:

Specifies the algorithm used to sign the certificate.

This read-only field displays only when you view an existing certificate.

Personal certificate requests collection

Use this page to manage personal certificate requests. Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificate requests** .

A private key is generated during the certificate request generation, but only the certificate is sent to the CA. The CA generates a new certificate, signed by the CA. This can be added in the Personal Certificates panel.

Button	Resulting action
New	Creates a personal certificate request that can be given to a certificate authority to complete.
Delete	Deletes a personal certificate request.
Extract	Extracts a personal certificate request. Only one certificate request can be selected at a time.

Note: Any changes made to this panel are permanent.

Key label:

Specifies the alias that represents the personal certificate request in the key store.

Requested by:

Specifies the Subject distinguished name (DN) that represents the identity of the certificate request.

Personal certificate requests settings

Use this page to create a new certificate request that can be extracted and sent to a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificate requests > New**.

Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA). The private key is generated during the certificate request generation, but only the certificate is sent to the CA. The CA generates a new certificate, signed by the CA.

Note: Any changes made to this panel are permanent.

File for certificate request:

Specifies the fully qualified file name from which the certificate request is exported. This portion of the certificate request can be given to the certificate authority to generate the real certificate. After the real certificate is generated, you can perform an "Receive a certificate from a certificate authority" from the personal certificate collection view.

Data type: Text

Key label:

Specifies the alias that represents the personal certificate request in the key store.

Data type: Text

Key size:

Specifies the size of the keys that are generated.

Data type: Integer
Default: 1024

Common name:

Specifies the name of the entity that the certificate represents. This common name can represent a person, company, or machine. For Web sites, the common name is frequently the DNS host name where the server resides.

Data type: Text

Organization:

Specifies the organization portion of the distinguished name.

Data type: Text

Organizational unit:

Specifies the organization unit portion of the distinguished name. This field is optional.

Data type: Text

Locality:

Specifies the locality portion of the distinguished name. This field is optional.

Data type: Text

State/Province:

Specifies the state portion of the distinguished name. This field is optional.

Data type: Text

Zip code:

Specifies the zip code portion of the distinguished name. This field is optional.

Data type: Integer

Country or region:

Specifies the country portion of the distinguished name.

Data type: Text

Default: US

Refer to <http://www.iso.org/iso/en/prods-services/iso3166ma/02iso-3166-code-lists/list-en1.html> for a list of ISO 3166 country codes.

Extract certificate request

Use this page to extract a certificate request and send it to a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificate requests > Extract**.

Key label:

Specifies the alias that represents the personal certificate request in the key store.

File for certificate request:

Specifies the filename where the extracted certificate request is placed.

Data type: Text

Receiving a certificate issued by a certificate authority

When a certificate authority (CA) receives a certificate request, it issues a new certificate that functions as a temporary placeholder for a CA-issued certificate. A keystore receives the certificate from the CA and generates a CA-signed personal certificate that WebSphere Application Server can use for Secure Sockets Layer (SSL) security.

The keystore must contain the certificate request that was created and sent to the CA. Also, the keystore must be able to access the certificate that is returned by the CA.

WebSphere Application Server can receive only those certificates that are generated by a WebSphere Application Server certificate request. It cannot receive certificates that are created with certificate requests from other keystore tools, such as **iKeyman** and **keyTool**.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates > [keystore]**.
2. Under Additional Properties, click **Personal certificates**.
3. Select a personal certificate.
4. Click **Receive a certificate from a certificate authority**.
5. Type the full path and name of the certificate file.
6. Select a data type from the list.
7. Click **Apply** and **Save**.

The keystore contains a new personal certificate that is issued by a CA. The original certificate request is changed to a personal certificate.

The SSL configuration is ready to use the new CA-signed personal certificate.

To receive a certificate by using the wsadmin tool, use the **receiveCertificate** command of the AdminTask object. For more information, see “Commands for the PersonalCertificateCommands group of the AdminTask object” on page 1798.

Export certificate to a key file:

Use this page to specify a personal certificate to export to a key file.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificates > Export**.

Certificate alias to export:

Displays the name of the certificate that you selected to export on the previous panel.

Data type: Text

Alias:

Specifies the alias that the personal certificate is referenced by in the key store.

Data type: Text

Key file name:

Specifies the key store file name into which the exported certificate is added. If the key store file name already exists, the exported certificate will be added. If the key store file name does not already exist, one will be created, and the exported certificate will be added.

Data type: Text

Type:

Specifies the type of key store file. The valid types are listed in the menu.

Data type: Text
Default: JKS

Key file password:

Specifies the password that is used to access the key store file.

Data type: Text

Confirm password:

Confirms the password entered in the previous field.

The key file password and the new alias must be specified in case a certificate already exists with the same name.

Data type: Text

Import certificate from a key file:

Use this page to specify a personal certificate to import from a key file.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *SSL_configuration_name***. Under Related items, click **Key stores and certificates > *key store***. Under Additional Properties, click **Personal certificates > Import certificates from a key file**.

Key file name:

Specifies the fully qualified path to keystore file that contains the certificate to import.

Data type: Text

Type:

Specifies the type of keystore file. The valid types are listed in the menu.

Data type: Text

Key file password:

Specifies the password that is used to access the keystore file.

Data type: Text

Certificate alias to import:

Specifies the certificate alias identified as the **Key file name** that you want to import into the current key store.

Data type: Text
Default: (none)

Imported certificate alias:

Specifies the new alias that you want the certificate to be named in the current key store.

Data type: Text

Receive certificate from CA:

Use this page to import your personal certificate from the certificate authority (CA). The imported certificate replaces the temporary certificate associated with the public/private keys in the certificate request that is stored in the key store.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items click **Key stores and certificates > *key store***. Under Additional Properties, click **Personal certificates > Receive certificate from CA**.

Certificate file name:

Specifies the filename that contains the certificate generated by the certificate authority (CA).

Data type: Text

Data type:

Specifies the format of the file that is either Base64 encoded ASCII data or Binary DER data.

Data type: Text
Default: Base64-encoded ASCII data

Replace a certificate

Use this page to specify two certificates: the first selected certificate is replaced by the second selected certificate. The replace function replaces all the old signer certificates in key stores that are managed throughout the cell with the new signer from the new certificate. The same level of trust that was established with the old certificate is maintained.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *ssl_configuration*** . Under Related items, click **Key stores and certificates > *key store*** . Under Additional Properties click **Personal certificates > Replace certificate**.

Old certificate:

Specifies the certificate that you want to replace.

Data type: Text

Replace with:

Specifies the certificate that you want to replace the old certificate.

Data type: Text
Default: (none)

Delete old certificate after replacement:

Specifies that you want to delete the old certificate and all associated signer certificates after the new certificate replaces it. If you do not replace the old personal certificate, it might be assigned a new alias name.

Default: Disabled

Delete old signers:

Specifies that you want to delete the old signer certificates that are associated with the old certificate after the new signer certificates replace them. If you do not delete the old signer certificates, they might be assigned new alias names.

Default: Disabled

Extracting a signer certificate from a personal certificate

Personal certificates contain a private key and a public key. You can extract the public key, called the *signer certificate*, to a file, then import the certificate into another keystore. The client requires the signer portion of a personal certificate for Security Socket Layer (SSL) communication.

The keystore that contains a personal certificate must already exist.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates > keystore** .
2. Under Additional Properties, click **Personal certificates**.
3. Select a personal certificate.
4. Click **Extract**.
5. Type the full path for the certificate file name. The signer certificate is written to this certificate file.
6. Select a data type from the list.
7. Click **Apply**.

The signer portion of the personal certificate is stored in the file that is provided.

This signer can now be imported into other keystores.

To extract a signer certificate from a personal certificate using the wsadmin tool, use the **extractCertificate** command of the AdminTask object. For more information, see “Commands for the PersonalCertificateCommands group of the AdminTask object” on page 1798.

Extract certificate

Use this page to extract the signer from the personal certificate. The certificate can be imported into a trust store for trust verification.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificates > Extract**.

Certificate alias to extract:

Specifies the filename that contains the extracted certificate.

Data type: Text

Certificate file name:

Specifies the fully qualified path where the certificate file will reside.

Data type: Text

Data type:

Specifies the format of the file, which is either Base64-encoded ASCII data or Binary DER data.

Data type: Text

Default: Base64-encoded ASCII data

Extract signer certificate

Use this page to extract a signer certificate that can be added elsewhere.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > Key stores and certificates > key store > Signer Certificates > Extract signer certificate**.

File name:

Specifies the fully qualified file name where the extracted signer certificate is placed.

Data type: Text

Data type:

Specifies the format of the file, which is either Base64 encoded ASCII data or Binary DER data.

Data type: Text

Retrieving signers using the retrieveSigners utility at the client

The client requires the signer certificates from the server to be able to communicate with WebSphere Application Server. Use the **retrieveSigners** command to get the signer certificate from a server.

The retrieveSigners utility is located in one of the following directories, depending on your operating system:

- On Windows operating system: *profile_root*\bin . For example: C:\WebSphere\AppServer\profiles\AppSrv01\bin
- On UNIX operating systems: *../profile_root/bin*

In this release, a Java client that does not have access to a stdin console prompt should use the retrieveSigners utility to download the signers from the remote server key store when signers are needed for a Secure Sockets Layer (SSL) handshake. For example, you might interpret the client as failing to respond if an applet client or Java Web Start Client application cannot access the stdin signer exchange prompt. Thus, you must add the WebSphere Java method call **com.ibm.wsspi.ssl.RetrieveSignersHelper.callRetrieveSigners** to your client application to retrieve the signers and to avoid running the retrieveSigners utility manually.

Use the retrieveSigners utility for situations where you cannot verify whether or not the `com.ibm.ssl.enableSignerExchangePrompt=` property is enabled or disabled when the application makes a request. Set the `com.ibm.ssl.enableSignerExchangePrompt=` property to `false` in the `ssl.client.props` file if you cannot see the console.

Alternatively, you can manually create the server key in the client truststore.

Complete the following steps, as required:

1. Use the **retrieveSigners** command to get the signer certificate from a server. You can find details about the **retrieveSigners**. parameters in “Secure installation for client signer retrieval” on page 1484.
2. If the client and server are on the same machine, you will need only the *remoteKeyStoreName* and *localKeyStoreName* parameters. The most typical key store to reference on a remote system is `CellDefaultTrustStore` on a network deployed environment and `NodeDefaultTrustStore` on an application server.
3. When retrieving signers from a remote server, add these required connection-related parameters: **-host** *host*, **-port** *port*, **-conntype** {*RMI* | *SOAP*}.
4. If the remote server has security enabled, also supply the **-user** *user* **-password** *password* parameters.
5. Use the **-autoAcceptBootstrapSigner** parameter if you want to enable automation of the signer retrieval. This parameter automatically adds to the server all the signers that are needed to make the connection.

After running, the command displays the SHI-1 digest of the signers added. The output looks similar to the following output:

```
C:\WebSphere\AppServer\profiles\AppSrv01\bin\retrieveSigners.bat
CellDefaultTrustStore ClientDefaultTrustStore
```

```
CWPKI0308I: Adding signer alias "default_signer" to local keystore
            "ClientDefaultTrustStore" with the following SHA digest:
```

See the following examples of how to call the `retrieveSigners.bat` file on the Windows operating system:

To retrieve signers on the same system, enter:

```
'profile_home'\bin\retrieveSigners.bat CellDefaultTrustStore ClientDefaultTrustStore
```

To retrieve signers on a remote system with a SOAP connection, enter:

```
'profile_home'\bin\retrieveSigners.bat CellDefaultTrustStore ClientDefaultTrustStore
-host myRemoteHost -port 8879 -conntype SOAP -autoAcceptBootstrapSigner
```

To retrieve signers on a remote system with an RMI connection, enter:

```
'profile_home'\bin\retrieveSigners.bat CellDefaultTrustStore ClientDefaultTrustStore
-host myRemoteHost -port 2809 -conntype RMI -autoAcceptBootstrapSigner
```

To retrieve signers on a remote system that has security enabled, enter:

```
'profile_home'\bin\retrieveSigners.bat CellDefaultTrustStore ClientDefaultTrustStore
-host myRemoteHost -port 8879 -conntype SOAP -user testuser -password testuserpwd
-autoAcceptBootstrapSigner
```

Changing the signer auto-exchange prompt at the client

For clients to communicate with WebSphere Application Server, clients must obtain a signer certificate from the server. Clients can use the **retrieveSigners** command to connect to a server to obtain the appropriate signer. A prompt displays that asks whether or not you want to add a signer to the truststore. If the Secure Sockets Layer (SSL) configuration uses an automated script that might hang, use the prompt to obtain the certificate.

The `com.ibm.ssl.enableSignerExchangePrompt` property in the `profile_home/properties/ssl.client.props` file controls the signer certificate prompt. By default, this property is set to `true`, meaning the prompt is enabled.

Complete the following steps to disable or enable the signer-exchange prompt at the client:

1. Open the `profile_home/properties/ssl.client.props` file using an editor.
2. Locate the section containing the SSL configuration information for the client that you are working with.
3. Change the value of the `com.ibm.ssl.enableSignerExchangePrompt` property to `false` if you do not want the signer-exchange prompt, or set it to `true` if you want to be prompted.
4. Save and close the file.

When the `com.ibm.ssl.enableSignerExchangePrompt` property is set to `false`, no prompt displays, so you can exchange signers while some administrative clients are running. When the `com.ibm.ssl.enableSignerExchangePrompt` property is set to `true`, a signer-exchange prompt displays, and you are asked to accept or reject the certificate. The prompt looks like the following example:

```
C:\WebSphere\AppServer\profiles\dmgr\bin>serverStatus -all
ADMU0116I: Tool information is being logged in file
            C:\WebSphere\AppServer\profiles\Dmgr\logs\serverStatus.log
ADMU0128I: Starting tool with the dmgr profile
ADMU0503I: Retrieving server status for all servers
ADMU0505I: Servers found in configuration:
ADMU0506I: Server name: dmgr
```

*** SSL SIGNER EXCHANGE PROMPT ***

SSL signer from target host 192.174.1.5 is not found in truststore
C:/WebSphere/AppServer/profiles/Dmgr/etc/trust.p12.

Verify that the digest value matches what is displayed at the server in the following signer information:

Subject DN: CN=hostname.austin.ibm.com, O=IBM, C=US
Issuer DN: CN=hostname.austin.ibm.com, O=IBM, C=US
Serial number: 1128544457
Expires: Thu Oct 20 15:34:17 CDT 2006
SHA-1 Digest: 91:A1:A9:2D:F2:7D:70:0F:04:06:73:A3:B4:A4:9C:56:9D:A8:A3:BA
MD5 Digest: 88:72:C5:88:00:1C:A7:FA:D6:EB:04:88:AC:A1:C9:13

Add signer to the truststore now? (y/n) y
A retry of the request might need to occur.
ADMU0508I: The Application Server "server1" is STARTED.

Clients can instigate communications for various processes using signer certificates obtained from WebSphere Application Server.

Importing a signer certificate from a truststore to a z/OS keyring

You can import a signer certificate, which is also called a certificate authority (CA) certificate, from a truststore on a non-z/OS platform server to a z/OS keyring.

To import a certificate to a z/OS keyring, complete the following steps:

1. On the non-z/OS platform server, change to the `install_root/bin` directory and start the iKeyman utility, which is called `keyman.bat` (Windows) or `keyman.sh` (UNIX). The `install_root` variable refers to the installation path for WebSphere Application Server.
2. Within the iKeyman utility, open the server truststore. The default server truststore is called the `DummyServerTrustFile.jks` file. The file is located in the `[$USER_INSTALL_ROOT]/etc/` directory. The default password is `WebAS`.
3. Extract the signer certificate from the truststore using the **ikeyman** utility. Complete the following steps to extract the signer certificate:
 - a. Select **Signer certificates** from the menu.
 - b. Select **new websphere dummy server alias**.
 - c. Select **Extract**.
 - d. Select the correct data type. The `signer_certificate` can have either a Base64-encoded ASCII data type or a Binary DER data type.
 - e. Specify the fully qualified path and the file name of the certificate.
4. From an FTP prompt on the non-z/OS platform server, type `cd bin` to change to binary mode.
5. From an FTP prompt on the non-z/OS platform server, type `put 'signer_certificate' mvs.dataset`. The `signer_certificate` variable refers to the name of the signer certificate on the non-z/OS platform server. The `mvs.dataset` variable is the data set name to which the certificate was exported. The `RACDCERT CERTAUTH ADD` command in the next step works with a Multiple Virtual Storage (MVS) data set only. You can either turn the certificate file into a binary MVS data set or use the `put` command with an Hierarchical File System (HFS) file, and then use the following command to copy the file into a MVS data set:

```
0GET file_name mvs.dataset
```
6. On the z/OS platform server, go to option 6 in the Interactive System Productivity Facility (ISPF) dialog panels and issue the following commands as a super user to add the signer certificate to the z/OS keyring:
 - a. Type `RACDCERT CERTAUTH ADD ('signer_certificate') WITHLABEL('Dummy Server CA') TRUST` The `Dummy Server CA` variable refers to the label name for the certificate authority (CA) certificate that you are importing from a non-z/OS platform server. The `keyring_name` variable refers to the name of the z/OS keyring that is used by the servers in the cell.

- b. Type `RACDCERT ID(ASCR1) CONNECT(CERTAUTH LABEL('Dummy Server CA') RING(keyring_name)`
- c. Type `RACDCERT ID(DMCR1) CONNECT(CERTAUTH LABEL('Dummy Server CA') RING(keyring_name)`
- d. Type `RACDCERT ID(DMSR1) CONNECT(CERTAUTH LABEL('Dummy Server CA') RING(keyring_name)` In the previous commands, ASCR1, DMCR1, and DMSR1 are the RACF IDs under which the started tasks for the cell run in WebSphere Application Server for z/OS. The ASCR1 value is the RACF ID for the application server control region. The DMCR1 value is the RACF ID for the deployment manager control region. The DMSR1 value is the RACF ID for the deployment manager server region.

After completing these steps, the z/OS keyring contains the signer certificates that originated on the non-z/OS platform server.

To verify that the certificates were added, use option 6 on the ISPF dialog panel and type the following command:

```
RACDCERT ID(CBSYMSR1) LISTRING(keyring_name)
```

The CBSYMSR1 value is the RACF ID for the application server region.

Note: Although iKeyman is supported for WebSphere Application Server Version 6.1, customers are encouraged to use the administrative console to export signer certificates.

Exporting a signer certificate from WebSphere Application Server for z/OS to a truststore

You can export a signer certificate, which is also called a certificate authority (CA) certificate, from WebSphere Application Server for z/OS to a truststore.

WebSphere Application Server, WebSphere Application Server Network Deployment, or WebSphere Application Server - Express can use the certificate in the truststore.

To export the certificate to a truststore, complete the following steps:

1. Export the z/OS[®] signer certificate to a data set by issuing the following Resource Access Control Facility (RACF) command as a super user using Time Sharing Option (TSO) option 6:

```
RACDCERT CERTAUTH EXPORT(LABEL('signer_certificate')) DSN('mvs.dataset')FORMAT(CERTDER)
```

The *signer_certificate* variable is the RACF label name of the certificate that is used by the cell. The *signer_certificate* can have either a Base64-encoded ASCII data type or a Binary DER data type. The *mvs.dataset* variable is the data set name to which the certificate is exported. You do not need to pre-allocate this data set because it is created by RACF.

2. From a command line on the non-z/OS platform server, type `cd` and change to the following directory:
`install_root/profiles/default/etc`
3. From an FTP prompt on the non-z/OS platform server, type `cd bin` to change to binary mode.
4. From an FTP prompt on the non-z/OS platform server, type the following command:
`get 'mvs.dataset' signer_certificate`
5. On the non-z/OS platform server, change to the `install_root/bin` directory and start the **iKeyman** utility, which is called `ikeyman.bat` for Windows or `ikeyman.sh` for UNIX.
6. Within the iKeyman utility, open the server truststore. The default server truststore is called the `DummyServerTrustFile.jks` file. The file is located in the `${USER_INSTALL_ROOT}/etc/` directory. The default password is `WebAS`. It is recommended that you create a new key file and trust file if you plan to use the certificate in a production environment.
7. Add your exported signer certificate to the server truststore using the iKeyman utility. Complete the following steps to add your exported signer certificate:
 - a. Select **Signer certificates** from the menu.
 - b. Select the correct data type. The signer certificate can have either a Base64-encoded ASCII data type or a Binary DER data type.

- c. Specify the fully qualified path and file name of the signer certificate.
8. Within the iKeyman utility, open the client truststore. The default client truststore is called the `DummyClientTrustFile.jks` file. The file is located in the `${USER_INSTALL_ROOT}/etc/` directory. The default password is `WebAS`. It is recommended that you create a new key file and trust file if you plan to use the certificate in a production environment.
9. Add your exported signer certificate to the client truststore using the iKeyman utility. Complete the following steps to add your exported signer certificate:
 - a. Select **Signer certificates** from the menu.
 - b. Select the correct data type. The signer certificate can have either a Base64-encoded ASCII data type or a Binary DER data type.
 - c. Specify the fully qualified path and file name of the signer certificate.
10. Restart the server process to use the new signer certificates.

After completing these steps, you can use the exported signer certificates with the WebSphere Application Server, WebSphere Application Server Network Deployment, or WebSphere Application Server - Express products.

Retrieving signers from a remote SSL port

To perform Secure Sockets Layer (SSL) communication with a server, WebSphere Application Server must retrieve a signer certificate from a secure remote SSL port during the handshake. After the signer certificate is retrieved, you can add the signer certificate to a keystore.

The keystore that is to contain the signer certificate must already exist.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > Key stores and certificates > keystore > Signer certificates > Retrieve from port**.
2. Click **Retrieve from port**.
3. Type the host name of the machine on which the signer resides.
4. Type the port location on the host machine on which the signer resides. The port location is not limited to ports on WebSphere Application Server. The ports can include Lightweight Directory Access Protocol (LDAP) ports or ports on any server on which an SSL port is already configured, such as `SIB_ENDPOINT_SECURE_ADDRESS`.
5. Select an SSL configuration for the outbound connection from the list.
6. Type an alias name for the certificate.
7. Click **Retrieve signer information**. A message window displays information about the retrieved signer certificate, such as: the serial number, issued-to and issued-by identities, SHA hash, and expiration date.
8. Click **Apply**. This action indicates that you accept the credentials of the signer.

The signer certificate that is retrieved from the remote port is stored in the keystore.

An SSL configuration or client process that requires an SSL connection to the server can use the retrieved and approved signer certificate.

To retrieve a signer certificate from a port using the `wsadmin` tool, use the **`retrieveSignerFromPort`** command of the `AdminTask` object. For more information, see “Commands for the `PersonalCertificateCommands` group of the `AdminTask` object” on page 1798.

Retrieve from port

Use this page to retrieve a signer certificate from a remote SSL port. The system connects to the specified remote SSL host and port and receives the signer during the handshake using a trust manager. The signer SHA hash displays for validation and, if approved by an administrator, is added to the currently selected trust store.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store > Signer certificates > Retrieve from port**.

Host:

Specifies the host name to which you connect when attempting to retrieve the signer certificate from the Secure Sockets Layer (SSL) port.

Data type: Text

Port:

Specifies the SSL port to which you connect when attempting to retrieve the signer certificate.

Data type: Text

SSL configuration for outbound connection:

Specifies the SSL configuration that is used to connect to the previously specified SSL port. This configuration is also the SSL configuration that contains the signer after retrieval. This SSL configuration does not need to have the trusted certificate for the SSL port as it is retrieved during validation and presented here.

Data type: Text
Default: DefaultSSLConfig

Alias:

Specifies the certificate alias name that you want to reference the signer in the key store, which is specified in the SSL configuration.

Data type: Text

Retrieved signer information:

Specifies the signer certificate information if it is retrieved from the remote host and port.

Serial number:

Specifies the certificate serial number that is generated by the issuer of the certificate.

Issued to:

Specifies the distinguished name of the entity to which the certificate was issued.

Issued by:

Specifies the distinguished name of the entity that issued the certificate. This name is the same as the issued-to distinguished name when the signer certificate is self-signed.

Fingerprint (SHA Digest):

Specifies the Secure Hash Algorithm (SHA hash) of the certificate, which can be used to verify the certificate's hash at another location, such as the client side of a connection.

Expiration:

Specifies the expiration date of the retrieved signer certificate for validation purposes.

Adding a signer certificate to a keystore

Signer certificates establish the trust relationship in SSL communication. You can extract the signer part of a personal certificate from a keystore, and then you can add the signer certificate to other keystores.

The keystore that you want to add the signer certificate to must already exist.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > SSL_configuration_name > Key stores and certificates.**
2. Select a keystore from the list of keystores.
3. Click **Add signers.**
4. Enter an alias for the signer certificate in the **Alias** field
5. Enter the full path to the signer certificate file in the **File name** field.
6. Select a data type from the list in the **Data type** field.
7. Click **Apply.**

When these steps are completed, the signer from the certificate file is stored in the keystore. You can see the signer in the keystore files list of signer certificates. Use the keystore to establish trust relationships for the SSL configurations.

To add a signer certificate to a keystore by using the wsadmin tool, use the **addSignerCertificate** command of the AdminTask object. For more information, see `rxml_atpersonalcert.dita`.

Add signer certificate

Use this page to add a signer certificate to the key store.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration**. Under Related items click **Key stores and certificates > key store > Signer certificates > Add.**

Alias:

Specifies the alias that the signer certificate is referenced by in the key store.

Data type: Text

File name:

Specifies the filename where the encoded signer certificate is located.

Data type: Text

Data type:

Specifies the format of the file, which is either Base64 encoded ASCII data or Binary DER data.

Data type: Text

Signer certificates collection

Use this page to manage signer certificates in key stores. Signer certificates are used by Java Secure Socket Extensions (JSSE) to validate certificates sent by the remote side of the connection during a Secure Sockets Layer (SSL) handshake. If a signer does not exist in the trust store that can validate the certificate sent, the handshake fails and generates an "unknown certificate" error.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items click **Key stores and certificates > key store > Signer certificates**.

Button	Resulting action
Add	Adds a new trusted (signer) certificate.
Delete	Deletes an existing signer certificate.
Extract	Extracts a signer certificate from a personal certificate to a file.
Retrieve from port	Makes a test connection to an SSL port and retrieves the signer from the server during the handshake. The information from the certificate will be displayed so you can decide whether to trust it based upon the MD5 and/or SHA hash.

Alias:

Specifies the alias for this signer certificate in the key store.

Issued to:

Specifies the distinguished name of the entity that requested the certificate.

Fingerprint (SHA digest):

Specifies the Secure Hash Algorithm (SHA hash) of the certificate. This can be used to verify the hash for the certificate at another location, such as the client side of a connection.

Expiration:

Specifies the expiration date of the signer certificate for validation purposes.

Signer certificate settings

Use this page to verify the general properties of the selected signer certificate.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key stores and certificates > key store > Signer certificates > signer certificate** .

Alias:

Specifies the alias for this signer certificate in the key store.

Version:

Specifies the version of the personal certificate. Valid versions include X509 V3, X509 V2, or X509 V1.

Key size:

Specifies the key size of the public key used by the signer certificate.

Serial number:

Specifies the certificate serial number that is generated by the issuer of the certificate.

Validity period:

Specifies the begin and end dates of the certificate.

Issued to:

Specifies the distinguished name of the entity that requested the certificate.

Issued by:

Specifies the distinguished name of the entity that issued the certificate. This name is the same as the issued-to distinguished name when the signer certificate is self-signed.

Fingerprint (SHA Digest):

Specifies the Secure Hash Algorithm (SHA) hash of the certificate, which can be used to verify the hash for the certificate at another location such as the client side of a connection.

Signature algorithm:

Specifies the algorithm that is used to sign the certificate.

Exchanging signer certificates

To establish trust relationships, you can exchange signer certificates between keystores. When you exchange signer certificates, you are extracting a personal certificate from one keystore and adding it to another keystore as a *signer certificate*.

To exchange signer certificates, there must be two keystores.

Complete the following steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key stores and certificates**.
2. Select two keystores from the list of keystores.
3. Click **Exchange signers**.
4. Select any of the certificates in the first personal certificates list, and click **Add**. After adding, the signer part of the selected personal certificate appears in the other (second) keystore signers list.
5. Select any of the certificates in the second personal certificates list, and click **Add**. After adding, the signer part of the selected personal certificate appears in the other (first) keystore signers list.
6. **Optional:** If you need to remove any of the certificates from either of the signers lists, highlight one or more of the certificates, and click **Remove**.
7. Click **Apply** and **Save**.

The signer certificate appears in the list for each keystore.

The extracted signer certificate is available to both keystores during the connection handshake.

Key stores and certificates exchange signers

Use this page to extract a personal certificate from one keystore and add it to another keystore as a signer certificate.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration**. Under Related items, click **Key stores and certificates > Exchange signers**.

Note: Any changes made to this panel are permanent.

[key store] personal certificates:

Specifies the personal certificates that are currently stored in the specified key store.

Press and hold the **Ctrl** key to select more than one item from the list.

Data type: Text

[key store] signers:

Specifies the trusted signer certificates that are currently stored in the specified key store and selected for the exchange.

Press and hold the **Ctrl** key to select more than one item from the list.

Data type: Text

Add:

Specifies to extract the signer from the selected personal certificate in the key store list on the left and add it to the signers list of the key store on the right.

After the certificate is added, it no longer displays in the left-hand list. The personal certificate is still in the key store, but it is no longer selectable

Remove:

Specifies to remove a selected signer from the signers list of the key store on the right. The removed certificate displays in the key store list on the left.

Configuring certificate expiration monitoring

When certificates expire, they can no longer be used by the system. WebSphere Application Server provides a utility to monitor certificates that are close to expiration or have already expired. You can schedule certificate monitoring, or you can request certificate monitoring on demand. You can also configure options for deleting expired certificates and for recreating certificates.

WebSphere Application Server notifies you when a certificate is about to expire. Complete the information required for notification messaging in “Notifications” on page 1565.

Complete the following configuration steps in the administrative console:

1. Click **Security > SSL certificate and key management > Manage certificate expiration**.

2. Type a number for the number of days threshold in the **Expiration notification threshold** field. WebSphere Application Server issues an expiration warning n number of days before expiration.
3. Select or check one or more of the following options:
 - **Expiration check notification.** Select the method from the list that you want to use to receive your notification.
 - **Automatically replace expiring self-signed certificates.** If you do not want to recreate the self-signed certificate, clear the check box.
 - **Delete expiring certificates and signers after replacement.** If you do not want to delete the expired certificates and signers, clear the check box.
 - **Enable checking.** If you do not want to have certificate monitoring enabled, clear the check box.
4. Enter the time of day when you want certificate monitoring to take place to schedule the running of the certificate expiration monitor.
5. Select one of the following options:
 - **Check by calendar.** For **Weekday**, enter the day of week that you want to run the certificate expiration monitor. For **Repeat Interval**, specify the frequency to run the certificate monitor.
 - **Check by number of days.** Enter a number for how frequently the monitor runs, in number of days.
6. Click **Apply**.

After completing the settings, a certificate expiration monitor object and a schedule are set up in the configuration. The certificate expiration monitor runs according to the configurations options that you configured.

You can generate reports that state which certificates have expired. The reports identify the notifications of certificate replacements and deletions. The report is sent according to the notification option that you specified.

Manage certificate expiration settings

Use this page to configure the certificate expiration monitor.

To view this administrative console page, click **Security > SSL certificate and key management > Manage certificate expiration**.

Attention: To see the changes to the Expiration checking fields, you must click **Apply**.

Expiration notification threshold:

Specifies a threshold number of days during which the application warns specified individuals that a certificate is about to expire. For example, when the expiration monitor is run and the threshold is 30 days, if the current date is 30 days or less from the certificate expiration date, the certificate is flagged for notification. The application server can be configured to provide certification expiration notification through either e-mail or the message log file.

Data type:	Integer
Default:	30 days

Expiration check notification:

Specifies the notification type (such as e-mail or System Out) when an expiration monitor runs.

Default:

Automatically replace expiring self-signed certificates:

Specifies a new self-signed certificate be generated using the same certificate information if the expiration notification threshold is reached. The old certificate is replaced and uses the same alias. All old signers are managed by the key store configuration are also replaced. The system only replaces self-signed certificates.

Default: Enabled

Delete expiring certificates and signers after replacement:

Specifies whether to completely remove old, self-signed certificates from the key store during a replace operation or leave them there under a renamed alias. If an old certificate is not deleted, the system renames the alias so that the new certificate can use the old alias, which might be referenced elsewhere in the configuration.

Default: Enabled

Enable checking:

Specifies the certificate monitor is active and will run as scheduled.

Scheduled time of day to check for expired certificates:

Specifies the scheduled time that the system checks for expired certificates.

You can type the scheduled time in hours and minutes, specify either A.M. or P.M., or 24-hour.

Data type Integer
Default: 0, 0
Range: 1–12, 0–59

Check by calendar:

Indicates that you want to schedule a specific day of the week on which the expiration monitor runs. For example, it might run on Sunday.

Default: Disabled

Weekday:

Specifies the day of the week on which the expiration monitor runs if **Check on a specific day** is selected.

Default: Sunday
Range: Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday

Repeat interval:

Specifies the period of time between each schedule time to check for expired certificates or the interval between schedule checks.

Default: Daily
Range: Daily, Weekly

Check by number of days:

Specifies that you want to schedule a specific number of days between each run of the expiration monitor. The day of the week on which this occurs is not counted. For example, if you set the interval to check for expired certificates every seven days, the expiration monitor runs on day eight.

Default: Disabled

Next start date:

Specifies the date for the next scheduled check. This allows the deployment manager to be stopped and restarted without resetting the date.

Notifications

Use this page to specify the generic notification definitions that are used in certificate expiration monitors.

To view this administrative console page, complete the following steps:

1. Click **Security > SSL certificate and key management**.
2. Under Configuration settings, click **Manage certificate expiration**.
3. Under Related items, click **Notifications**.

Button	Resulting action
New	Adds a notification. The notification configures how the expiration monitor notifies the administrator of certificates that will expire within the specified threshold.
Delete	Deletes an existing notification.

Notification name:

Specifies the notification name.

Message log:

Specifies that this configuration intends to log certificate expiration information to the message log file.

List of e-mail addresses:

Specifies the e-mail addresses that are sent notifications when certificates fall within the expiration threshold. You must specify the SMTP server for each e-mail address. If an e-mail address is not specified, by default the application server assumes that the SMTP server is "smtp-server." For example, if you type *name@domain*, the SMTP server will be smtp-server.domain.

Notifications settings

Use this page to set properties for new notifications used in certificate expiration monitors.

To view this administrative console page, complete the following steps:

1. Click **Security > SSL certificate and key management**.
2. Under Configuration settings, click **Manage certificate expiration**.
3. Under Related items, click **Notifications > New**.

Notification name:

Specifies the name of the notification configuration.

Data type: Text

Message log:

Specifies that this configuration will log certificate expiration information to a message log file.

Default: Disabled

Email sent to notification list:

Specifies that this configuration intends to send certificate expiration information in an e-mail to the e-mail list.

Default: Disabled

Email address to add:

Specifies the e-mail addresses that are sent notifications when certificates fall within the expiration threshold. You must specify the SMTP server for each e-mail address. If an e-mail address is not specified, by default the application server assumes that the SMTP server is "smtp-server." For example, if you type *name@domain*, the SMTP server will be smtp-server.domain.

Data type: Text (format as valid Internet mail address)

Add:

Adds the e-mail address to the right-hand list.

Remove:

Removes the e-mail address from the right-hand list.

Outgoing mail (SMTP) server:

Specifies the SMTP server to be used with the e-mail address. If none is specified, the e-mail realm will be used.

Key management for cryptographic uses

WebSphere Application Server provides a framework for managing keys (secret keys or key pairs) that applications use to perform cryptographic operations on data. The key management framework provides an application programming interface (API) for retrieving these keys. Keys are managed in keystores so the keystore type can be supported by WebSphere Application Server, provided that the keystores can store the referenced key type. You can configure keys and scope keystores so that they are visible only to particular processes, nodes, clusters, and so on.

The key management infrastructure is based on two key configuration object types: key sets and key set groups. WebSphere Application Server uses a key set to manage instances of keys of the same type. You can configure a key set to generate a single key or a key pair, depending on the key or key pair generator class. A key set group manages one or more key sets and enables you to configure and generate different key types at the same time. For example, if your application needs both a secret key and key pair for cryptographic operations, you can configure two key sets, one for the key pair and one for the secret key that the key set group manages. The key set group controls the auto-generation characteristics of the

keys, including the schedule. The framework can automatically generate keys on a scheduled basis, such as on a particular day of the week and time of day, so that key generation is done during off-peak hours.

Figure 1 shows an example of a key set group that is configured to manage two key sets: key set 1 and key set 2.

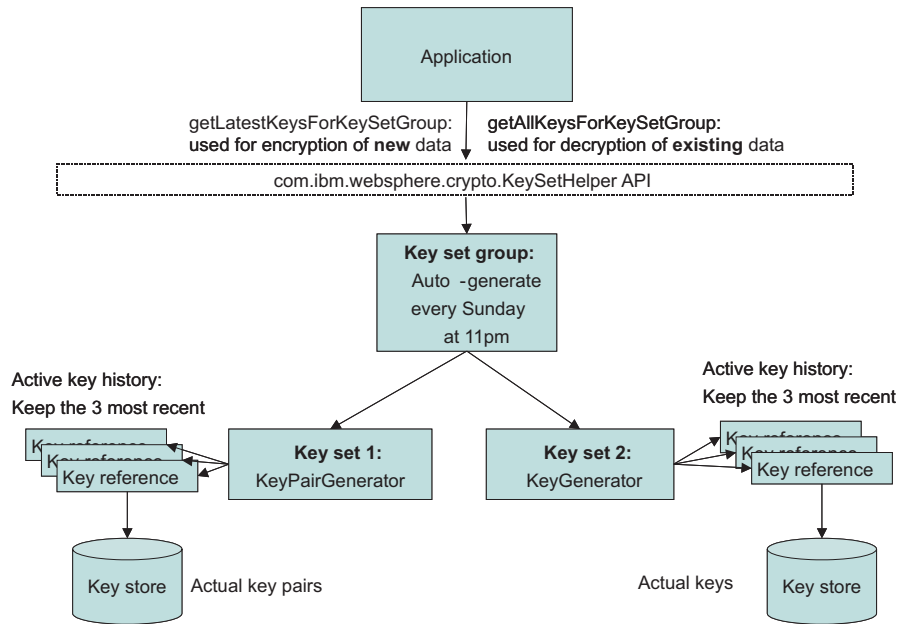

Figure 1: Key Management Infrastructure

Figure 19.

Key set 1 generates key pairs. Key set 2 generates secret keys. The application needs both types of keys for its cryptographic operations, signing and encryption, on data. The keys for each key set need to be generated in tandem. The application stores the key set group name with the encrypted data. The key set group generates a new set of keys every Sunday night at 11 P.M.. The application maintains key generation data for two weeks.

Creating a key set configuration

You can use key sets to manage multiple instances of cryptographic keys. WebSphere Application Server uses keys to encrypt or sign outbound data, and decrypt or verify inbound data during cryptographic operations.

You must have write-access to the keystore that will contain the keys after you generate them from a key set. However, if you want to generate keys outside of WebSphere Application Server, you can reference the keys from a read-only keystore that contains a secret key that you can access when you generate the keys. If you are creating a key pair using an X509Certificate and a PrivateKey object, see “Example: Developing a key or key pair generation class for automated key generation” on page 1574.

Complete the following steps in the administrative console:

1. Decide whether you want to create the key set at the cell scope or below the cell scope at the node, server, or cluster, for example:
 - To create a key set at the cell scope, click **Security > SSL certificate and key management > Key sets**.
 - To create a key set at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration > Key sets**.
2. Click **New** to create a new key set.
3. Type a key set name. For example, CellmyKey.
4. Type a key alias prefix name. For example, myKey. This field specifies the prefix for the key alias when the new key is generated and stored in the keystore. Following the prefix is the key reference version number, for example, 2, so that the full key alias name would be myKey_2. If the key reference already has a specified alias for a key that exists in the keystore, then WebSphere Application Server ignores this field.
5. Type a key password. The key password protects the key in the keystore. This password is ignored by WebSphere Application Server if you already specified a password for the key alias reference. To check for a key reference password, click **Active key history** under Additional Properties. The key reference password protects keys that are generated by a key generator class.
6. Type the password again to confirm it.
7. **Optional:** Type the key generator class name. For example, `com.ibm.ws.security.ltpa.LTPAKeyGenerator`. The class name generates keys. If the class implements `com.ibm.websphere.crypto.KeyGenerator`, then a `getKey` method returns a `java.security.Key` object that is set in the keystore using the `setKey` method without a certificate chain. If the class implements `com.ibm.websphere.crypto.KeyPairGenerator`, then a `getKeyPair` method returns a `com.ibm.websphere.crypto.KeyPair` object that contains either a `java.security.PublicKey` and `java.security.PrivateKey` or a `java.security.cert.Certificate` and a `java.security.PrivateKey` object. The key generator class and the `KeySetHelper` API specify the details of the keys that are generated.
8. **Optional:** Select **Delete key references that are beyond the maximum number of keys** if you do not want old keys saved in the keystore after WebSphere Application Server removes their references from the Active key history listing. The Active key history lists the keys that the `KeySetHelper` API is currently tracking. The number of keys in the list is equal to the number of keys that you specify in **Maximum number of keys referenced**.
9. Type a numeric value for the maximum number of keys referenced. For example, if you type 3 and select **Delete key references that are beyond the maximum number of keys**, the fourth key version generation automatically triggers WebSphere Application Server to delete the first key version from the keystore. If you choose not to delete the old keys, they do not display in the Active key history list but instead remain in the keystore where you can remove them manually.
10. Select a keystore from the drop-down list.
 - Select a JCEKS keystore if you are storing a secret key.
 - Select any keystore if you are storing a key pair with an `X509Certificate` and `PrivateKey` object.
11. **Optional:** Select **Generates key pair** if your key generator class name implements the `com.ibm.websphere.crypto.KeyPairGenerator` interface instead of the `com.ibm.websphere.crypto.KeyGenerator` interface. This option designates that the key references a key pair instead of a single key. A key pair contains both a public key and a private key. The WebSphere Application Server run time determines whether or not key pairs are stored and loaded differently than single keys.
12. **Optional:** Click **Apply** if you want to select **Active key history** under Additional Properties to add alias references or generate more keys.
 - a. Click **Active key history**.
 - b. Click **Add key alias reference** if you are not using the key generator class name to add key alias references to the keys that already exist in the keystore. Use this option to retrieve the keys from a read-only keystore without the key set generating them.

- c. Type an alias reference.
 - d. Click **Generate key** if you want to generate a key using the class name that you defined in the key sets panel. Each new key increments numerically, for example, myAlias_2.
 - e. Click **Apply**.
13. Click the key set name in the navigation path at the top of the panel.
 14. Click **OK** and **Save**.

You have created a key set that you can manage using the **Active key history** link. You can generate keys manually to associate them with specified key sets.

After you generate new keys from a key set, you can access them programmatically using the `com.ibm.websphere.crypto.KeySetHelper` API. You must have Java 2 Security permissions, if enabled, to access keys in key sets. Specify the key set name within the fine-grained permissions, as in the following code sample: `WebSphereRuntimePermission "getKeySets.keySetName".` For more information, see “Example: Retrieving the generated keys from a key set group” on page 1573. To generate multiple key types at the same time or to schedule the key generation on a specific schedule, see “Creating a key set group configuration” on page 1572.

Active key history collection

Use this page to manage key alias references.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration_name**. Under Related items, click **Key Sets > key set > Active key history**.

Button	Resulting action
Add key alias reference	Adds a reference to a key that already exists in a key store. If a key generation class is configured, the references are added automatically during generation and do not need to be added manually.
Delete	Deletes an existing key reference. This action does not delete the key in the keystore.
Generate key	Generates a key. The button is displayed only if a generator class name is specified for the key set, and the selected key store is editable.

Key alias reference:

Specifies the name of the alias as it appears in the keystore.

Add key alias reference settings

Use this page to access key alias reference information.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration_name**. Under Related items, click **Key Sets > key set > Active key history > Add key alias reference**.

Alias reference:

Specifies the name of the alias as it appears in the key store.

Data type: Text

Password:

Specifies the key password to get access to the key. This password is enforced by the keystore for that specific key. If the key does not have a password, this field can be left blank.

Data type: Text

Confirm password:

Confirms the password entered in the previous field.

Data type: Text

Key sets collection

Use this page to manage key sets, which control a set of key instances of the same type for use in cryptographic operations. The keys can either be generated using a custom class or reference keys that already exist in a keystore.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key sets**.

Button	Resulting action
New	Adds a new key set.
Delete	Deletes an existing key set. Make sure the key set is not referenced by a key set group before deleting it.

Key set name:

Specifies the key set name that is used to select the key set from a key set group and from runtime application programming interfaces (API).

Key store:

Specifies the key store that contains the keys for storage, retrieval, or both.

Key alias prefix name:

Specifies the prefix for the key alias when a new key is generated and stored in a key store. The rest of the key alias comes from the key reference version number.

For example, if the alias prefix is mykey and the key reference version is 2, the keystore references the key using alias mykey_2. If the key reference already has a specified alias for a key already existing in the keystore, this field is ignored.

Key sets settings

Use this page to set the properties for a new key set.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key sets > New**.

Key set name:

Specifies the key set name that is used to select the key set from a key set group and from runtime application programming interfaces (API).

Data type: Text

Key alias prefix name:

Specifies the prefix for the key alias when a new key is generated and stored in a keystore. The rest of the key alias comes from the key reference version number. For example, if the alias prefix is mykey and the key reference version is 2, the keystore references the key using alias mykey_2. If the key reference already has a specified alias for a key already existing in the keystore, this field is ignored.

Data type: Text

Key password:

Specifies the password used to protect the key in the keystore. If a password is specified in the key reference as well, this password is ignored. This password is used for keys that get generated by a key generator class.

Data type: Text

Confirm password:

Specifies the same password again to confirm it was entered correctly the first time.

Data type: Text

Key generator class name:

Specifies the class name that generates keys. If the class implements `com.ibm.websphere.crypto.KeyGenerator`, then a `getKey()` method should return a `java.security.Key` object that is set in the key store using the `setKey` method without a certificate chain. The key store type associated with the key set must support storing keys without certificates, such as JCEKS.

Data type: Text

If the class implements `com.ibm.websphere.crypto.KeyPairGenerator`, then a `getKeyPair()` method should return a `com.ibm.websphere.crypto.KeyPair` object containing either a `java.security.PublicKey` and `java.security.PrivateKey`, or a `java.security.cert.Certificate[]` and a `java.security.PrivateKey`. The key generator class and the caller of the `KeySetHelper` API should know the details of the keys that are generated. This framework does not need to understand the key algorithms and lengths.

Delete key references that are beyond the maximum number of keys:

Specifies that the keys are deleted from the keystore at the same time that the key reference is deleted. The server deletes the older key references as the Maximum number of keys referenced value is exceeded.

Maximum number of keys referenced:

Specifies the maximum number of key instances that are returned when keys from this key set are requested. The oldest key reference gets removed whenever a new key reference gets generated after the maximum has been reached.

Data type: Integer

Default:

3

Key store:

Specifies the key store that contains the keys for storage, retrieval, or both.

Data type:

Text

Generates key pair:

Specifies that a key references a key pair instead of a key. The key pair contains both a public key and a private key.

Creating a key set group configuration

A key set group manages one or more key sets. WebSphere Application Server uses key set groups to automatically generate cryptographic keys or multiple synchronized key sets.

Complete the following steps in the administrative console:

1. Decide whether you want to create the key set group at the cell scope or below the cell scope at the node, server, or cluster, for example.
 - To create a key set group at the cell scope, click **Security > SSL certificate and key management > Key set groups**.
 - To create a key set group at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL_configuration > Key set groups**.
2. You can choose to generate a key for an existing key set group, delete an existing key set group, or create a new key set group.
 - To generate a key for an existing key set group, select a key set group from the list of existing key set groups, and click **Generate keys**. You have generated a new key for each key set in the selected group.
 - To delete an existing key set group, select a key set group from the list of existing key set groups, and click **Delete**. You have deleted the key set group.
 - To create a new key set group, go to step 3.

CAUTION:

Do not delete the cell or node LTPAKeySetGroup, which is used by the Lightweight Third Party Authentication (LPTA) mechanism.

3. Click **New** to create a new key set group.
4. Type a key set group name. You can reference this name by using the `com.ibm.websphere.crypto.KeySetHelper` API to retrieve the managed keys from an application.
5. Select one or more key sets from the Key sets list.

Note: If the key set(s) you want is not listed, make sure that it was created at the same scope or a higher scope than where you are creating the new key set group.

6. Click **Add** to add the selected key set(s) to the new key set group.
7. Select **Automatically generate keys** to generate the new keys on a schedule. If you decide to generate keys automatically, then you must specify a scheduled time of day.
8. Specify the scheduled time to generate keys automatically in hours and minutes, A.M. or P.M., or every 24 hours.
9. You can choose to generate new keys on a specific day or at an interval.

- Select **Generate on a specific day**. Select a day of the week from the drop-down list, and type a repeat interval number for the number of days between each key generation. This choice enables you to schedule key generation when your systems are least busy.
- Select **Generate at an interval**. Type a repeat interval number for the number of days between each key generation. This choice enables you to schedule key generation more frequently than once a week.

Note: The **Next start date** is a read-only field that specifies the date for the next scheduled generation. You can stop and restart the deployment manager or base application server without resetting this date. If you do not see the next start date appear after changing the configuration, click **OK** to save it, then check that the next start date displays.

10. Click **Save**.

You have created a new key set group to manage key sets and key generation on a schedule.

After you generate new keys from a key set, you can access them programmatically using the `com.ibm.websphere.crypto.KeySetHelper` API. You must have Java 2 Security permissions, if enabled, to access keys in key sets. Specify the key set name within the fine-grained permissions, as in the following code sample: `WebSphereRuntimePermission "getKeySets.keySetName".` For more information, see “Example: Retrieving the generated keys from a key set group.”

Example: Retrieving the generated keys from a key set group

This example shows how applications can use the `com.ibm.websphere.crypto.KeySetHelper` API to retrieve managed keys from the `KeySet` or `KeySetGroup` configurations. Use the `com.ibm.websphere.crypto.KeySetHelper` API to get either the latest set of keys or the all keys in the `KeySet` or `KeySetGroup` object.

Use the latest keys when performing any new cryptographic operations. All of the other keys that are defined in the `KeySet` or `KeySetGroup` object are for the validation of previously performed cryptographic operations.

The following example uses a method that an application might use to initialize the keys in the associated `KeySetGroup` object. The application might want to store the keys in two separate maps, one for generation and one for validation. Refer to the API documentation for `KeySetHelper` API to determine which Java 2 Security requirements are required.

```
/**
 * Initializes the primary and secondary Maps used for initializing the keys.
 */
public void initializeKeySetGroupKeys() throws com.ibm.websphere.crypto.KeyException
{
    java.util.Map generationKeys = null;
    java.util.Map validationKeys = null;

    PublicKey tempPublicKey = null;
    PrivateKey tempPrivateKey = null;
    byte[] tempSharedKey = null;

    keySetGroupName = "ApplicationKeySetGroup";
    com.ibm.websphere.crypto.KeySetHelper ksh = com.ibm.websphere.crypto.KeySetHelper.getInstance();

    *   {Secret_3=javax.crypto.spec.SecretKeySpec@fffe8aa7,
    *     KeyPair_3=com.ibm.websphere.crypto.KeyPair@4da04da0}
    * }
    ***/
}
else
{
    throw new com.ibm.websphere.crypto.KeyException("Could not generateKeys.");
}
}

```

Example: Developing a key or key pair generation class for automated key generation

A class that generates keys for cryptographic operations can be created automatically. With this capability, the key management infrastructure can maintain a list of keys for a predefined key set, and applications can access these keys.

You can schedule new key generation at predefined frequencies. Remember that key generation frequency affects the security of your data. For example, for persistent data, you might schedule key generation less frequently than for real time communications, which require that the keys be generated more often as old keys expire.

When you develop a key generation class, decide if you are creating a shared key or a key pair because this decision determines the interface you must use.

If you are developing shared keys, refer to the following example, which uses the KeyGenerator class to implement the com.ibm.websphere.crypto.KeyGenerator interface. The interface returns a java.security.Key key, which is stored as a SecretKey in a JCEKS keystore type. You can use any other keystore type that supports storing secret keys.

```
package com.ibm.test;

import java.util.*;
import com.ibm.ws.ssl.core.*;
import com.ibm.ws.ssl.config.*;
import com.ibm.websphere.crypto.KeyException;

public class KeyGenerator implements com.ibm.websphere.crypto.KeyGenerator
{
    private java.util.Properties customProperties = null;
    private java.security.Key secretKey = null;

    public KeyGenerator()
    {
    }

    /**
     * <p>
     * This method is called to pass any custom properties configured with
     * the KeySet to the implementation of this interface.
     * </p>
     *
     * @param java.util.Properties
     */
    public void init (java.util.Properties customProps)
    {
        customProperties = customProps;
    }

    /**
     * <p>
     * This method is called whenever a key needs to be generated either
     * from the schedule or manually requested. The key is stored in the
     * KeyStore referenced by the configured KeySet that contains the
     * keyGenerationClass implementing this interface. The implementation of
     * this interface manages the key type. The user of the KeySet
     * must know the type that is returned by this keyGenerationClass.
     * </p>
     *
     * @return java.security.Key
     * @throws com.ibm.websphere.crypto.KeyException
     */
    public java.security.Key generateKey () throws KeyException
    {
        try
        {
            // Assume generate3DESKey is there to create the key.
            byte[] tripleDESKey = generate3DESKey();
            secretKey = new javax.crypto.spec.SecretKeySpec(tripleDESKey, 0, 24, "3DES");

            if (secretKey != null)
            {
                return secretKey;
            }
            else
            {
                throw new com.ibm.websphere.crypto.KeyException ("Key could not be generated.");
            }
        }
        catch (Exception e)
        {
            e.printStackTrace(); // handle exception
        }
    }
}
```

If you are developing a key pair, refer to the following example, which uses the KeyPairGenerator class to implement the com.ibm.websphere.crypto.KeyPairGenerator interface.

```
package com.ibm.test;

import java.util.*;
import javax.crypto.spec.SecretKeySpec;
import com.ibm.websphere.crypto.KeyException;

/**
 * <p>
 * This implementation defines the method to generate a java.security.KeyPair.
 * When a KeyGeneration class implements this method, the generateKeyPair method
 * is called and a KeyPair is stored in the keystore. The isKeyPair
 * attribute is ignored since the KeyGenerationClass is an
 * implementation of KeyPairGenerator. The isKeyPair attributes is for when
 * the keys already exist in a KeyStore, and are just read (not
 * generating them).
 * </p>
 * @author IBM Corporation
 * @version WebSphere Application Server 6.1
 * @since WebSphere Application Server 6.1
 **/
public class KeyPairGenerator implements com.ibm.websphere.crypto.KeyPairGenerator
{
    private java.util.Properties customProperties = null;

    public KeyPairGenerator()
    {
    }

    /**
     * <p>
     * This method is called to pass any custom properties configured with
     * the KeySet to the implementation of this interface.
     * </p>
     *
     * @param java.util.Properties
     **/
    public void init (java.util.Properties customProps)
    {
        customProperties = customProps;
    }

    /**
     * <p>
     * This method is called whenever a key needs to be generated either
     * from the schedule or manually requested and isKeyPair=true in the KeySet
     * configuration. The key is stored in the KeyStore referenced by
     * the configured KeySet which contains the keyGenerationClass implementing
     * this interface. The implementation of this interface manages the
     * type of the key. The user of the KeySet must know the type that
     * is returned by this keyGenerationClass.
     * </p>
     *
     * @return com.ibm.websphere.crypto.KeyPair
     * @throws com.ibm.websphere.crypto.KeyException
     **/
    public com.ibm.websphere.crypto.KeyPair generateKeyPair () throws KeyException
    {
        try
        {
            java.security.KeyPair keyPair = generateKeyPair();

            // Store as SecretKeySpec
            if (keyPair != null)
            {
                java.security.PrivateKey privKey = keyPair.getPrivate();
                java.security.PublicKey pubKey = keyPair.getPublic();

                SecretKeySpec publicKeyAsSecretKey = new SecretKeySpec
                    (pubKey.getEncoded(), "RSA_PUBLIC");
            }
        }
    }
}
```

```

        SecretKeySpec privateKeyAsSecretKey = new SecretKeySpec
            (privKey.getEncoded(), "RSA_PRIVATE");

        com.ibm.websphere.crypto.KeyPair pair = new
com.ibm.websphere.crypto.KeyPair(publicKeyAsSecretKey, privateKeyAsSecretKey);
        return pair;
    }
    else
    {
        throw new com.ibm.websphere.crypto.KeyException ("Key pair could
not be generated.");
    }
}
catch (Exception e)
{
    e.printStackTrace(); // handle exception
}
}
}
}

```

This interface returns a `com.ibm.websphere.crypto.KeyPair` key pair, which can contain either a `X509Certificate` and `PrivateKey` object or `PublicKey` and `PrivateKey` objects. If the `com.ibm.websphere.crypto.KeyPair` interface contains a `X509Certificate` and `PrivateKey` object, the certificate and private key are stored in the keystore. Consequently, they can use any `KeyStore` type.

If the `com.ibm.websphere.crypto.KeyPair` interface contains `PublicKey` and `PrivateKey` objects, you must convert the encoded values to the `SecretKeySpec` object in order to store them. The WebSphere Application Server runtime stores and retrieves the key pair as secret keys. The runtime converts the key pair back to `PublicKey` and `PrivateKey` objects when the server retrieves the pair during the handshake.

Use the following constructors to develop the `com.ibm.websphere.crypto.KeyPair` interface:

- **Public and private constructor**

```
public KeyPair(java.security.Key publicKey, java.security.Key privateKey)
```
- **Certificate and private constructor.**

```
public KeyPair(java.security.cert.Certificate[] certChain,
java.security.Key privateKey)
```

The previous example code shows the `KeyPairGenerator` class using the public and private constructor. Each call to this class generates a new and unique key pair, and this class is invoked by a `KeySet` to create a new key pair when `isKeyPair=true`. The version number in the key set increments each time it is called.

Key set groups collection

Use this page to manage groups of public, private, and shared keys. These key groups enable the application server to control multiple sets of Lightweight Third Party Authentication (LTPA) keys.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration*** . Under Related items, click **Key set groups**.

Button	Resulting action
New	Adds a key set group. A key set group combines one or more key sets together as a single key set group. It allows the generation of multiple different types of keys to occur at the same time. A single key set represents one type of key, so a key set group allows you to group the different types.
Delete	Deletes an existing key set group. You must be sure that there are no other references to this key set group before you delete it.

Button	Resulting action
Generate keys	Generates keys for key set group. The system generates keys for each key set within the key set group so that the keys remain synchronized with each other in terms of version. You must configure a valid key generation class and a key store that is writable. See the <code>com.ibm.websphere.crypto.KeySetHelper</code> application programming interfaces (APIs) to enable the use of keys that are managed by a <code>KeySetGroup</code> or <code>KeySet</code> .

Key set group name:

Specifies the name of the key set group used to reference it.

Automatically generate keys:

Specifies that the keys are to be generated automatically on a schedule.

Key set groups settings

Use this page to create new key set groups.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl_configuration** . Under Related items, click **Key set groups > New**.

Key set group name:

Specifies the name of key set group used. This name can be referenced using the `com.ibm.websphere.crypto.KeySetHelper` API to retrieve the managed keys from an application.

Data type: Text

Key sets:

Specifies a set of key instances of the same type for use in cryptographic operations.

Add:

Specifies to add the selected key set part of this key set group.

Remove:

Specifies to remove the selection from the **Key sets** list.

Automatically generate keys:

Specifies that the keys are generated automatically on a schedule. When a new key is generated, the `security.xml` is updated and saved by the runtime to track the key reference version. This can cause save conflicts when updating the same file from admin applications.

Default: Disabled

Scheduled time for generation:

Specifies the scheduled time when the system generates selected key set group or groups. You can specify the scheduled time in hours and minutes; specify either A.M. or P.M., or specify 24-hour. You can

also specify the day of the week you want the scheduled event to occur. It is recommended that you set this event to occur during a low peak time, especially for keys that are used by runtime for token validation.

Data type	Integer
Default:	0, 0
Range:	1–12, 0–59

Generate on a specific day:

Specifies whether to have the generation occur on a specific day of the week. It is best to auto-generate keys during a low peak day.

Default:	Enabled
-----------------	---------

Weekday:

Specifies the day of the week on which the expiration monitor will run if the Check on a specific day option is selected.

Default:	Sunday
Range:	Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday

Repeat interval:

Specifies the period of time between each schedule time to check for expired certificates or the interval between schedule checks.

Default:	Daily
Range:	Daily, Weekly

Generate at an interval:

Specifies to generate keys at the specified frequency regardless of the day of the week on which generation occurs.

Default:	Disabled
-----------------	----------

Next start date:

Specifies the date for the next scheduled check. This allows the deployment manager to be stopped and restarted without resetting the date.

Configuring security with scripting

You can configure security with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

If you enable security for a WebSphere Application Server cell, supply authentication information to communicate with servers.

The `sas.client.props` and the `soap.client.props` files are located in the properties directory for each WebSphere Application Server profile, `profilePath/properties`.

- The nature of the properties file updates required for running in secure mode depend on whether you connect with a Remote Method Invocation (RMI) connector, or a SOAP connector:
 - If you use a Remote Method Invocation (RMI) connector, set the following properties in the `sas.client.props` file with the appropriate values:

```
com.ibm.CORBA.loginUserId=  
com.ibm.CORBA.loginPassword=
```

Also, set the following property:

```
com.ibm.CORBA.loginSource=properties
```

The default value for this property is `prompt` in the `sas.client.props` file. If you leave the default value, a dialog box appears with a password prompt. If the script is running unattended, it appears to hang.

- If you use a SOAP connector, set the following properties in the `soap.client.props` file with the appropriate values:

```
com.ibm.SOAP.securityEnabled=true  
com.ibm.SOAP.loginUserId=  
com.ibm.SOAP.loginPassword=
```

Optionally, set the following property:

```
com.ibm.SOAP.loginSource=none
```

The default value for this property is `prompt` in the `soap.client.props` file. If you leave the default value, a dialog box appears with a password prompt. If the script is running unattended, it appears to hang.

- To specify user and password information, choose one of the following methods:
 - Specify user name and password on a command line, using the **-user** and **-password** commands. For example:

```
wsadmin.sh -conntype RMI -port 2809 -user u1 -password secret1
```
 - Specify user name and password in the `sas.client.props` file for a RMI connector or the `soap.client.props` file for a SOAP connector.

If you specify user and password information on a command line and in the `sas.client.props` file or the `soap.client.props` file, the command line information overrides the information in the props file.

Note: On UNIX system, the use of `-password` option may result in security exposure as the password information becomes visible to the system status program such as `ps` command which can be invoked by other user to display all the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the `soap.client.props` file for SOAP connector or `sas.client.props` file for RMI connector. The `soap.client.props` and `sas.client.props` files are located in the properties directory of your WebSphere Application Server profile.

Enabling and disabling administrative security using scripting

You can use scripting to enable or disable administrative security.

Before starting this task, the `wsadmin` tool must be running. See the Starting the `wsadmin` scripting client article for more information.

The default profile sets up procedures so that you can enable and disable administrative security based on LocalOS registry.

- To determine if application security is enabled or disabled by looking at the value of the `appEnabled` field in the WCCM security model, use the **isAppEnabled** command, for example:
 - Using `Jacl`:

```
$AdminTask isAppSecurityEnabled {-interactive}
```

- Using Jython:

```
AdminTask.isAppSecurityEnabled ('[-interactive]')
```

This command returns a value of true if appEnabled is set to true. Otherwise, returns a value of false.

- To determine if administrative security is enabled or disabled by looking at the value of the enabled field in the WCCM security model, use the **isGlobalSecurity** command, for example:

- Using Jacl:

```
$AdminTask isGlobalSecurity {-interactive}
```

- Using Jython:

```
AdminTask.isGlobalSecurity ('[-interactive]')
```

Returns a value of true if enabled is set to true. Otherwise, returns a value of false.

- To set administrative security based on the passed in value, use the **setGlobalSecurity** command. For example:

- Using Jacl:

```
$AdminTask setGlobalSecurity {-interactive}
```

- Using Jython:

```
AdminTask.setGlobalSecurity ('[-interactive]')
```

Returns a value of true if the enabled field in the WCCM security model is successfully updated. Otherwise, returns a value of false.

- You can use the **help** command to find out the arguments that you need to provide with this call, for example:

- Using Jacl:

```
securityon help
```

Example output:

```
Syntax: securityon user password
```

- Using Jython:

```
securityon()
```

Example output:

```
Syntax: securityon(user, password)
```

- To enable administrative security based on the LocalOS registry, use the following procedure call and arguments:

- Using Jacl:

```
securityon user1 password1
```

- Using Jython:

```
securityon('user1', 'password1')
```

- To disable administrative security based on the LocalOS registry, use the following procedure call:

- Using Jacl:

```
securityoff
```

- Using Jython:

```
securityoff()
```

Enabling and disabling LTPA authentication

There are sample scripts located in the <WAS_ROOT>/bin directory on how to enable and disable LTPA authentication. The scripts are:

- LTPA_LDAPSecurityProcs.py (python script)
- LTPA_LDAPSecurityProcs.jacl (jacl script)

Note: The scripts hard code the type of LDAP server and base distinguished name (baseDN). The LDAP server type is hardcoded as IBM_DIRECTORY_SERVER and the baseDN is hardcoded as o=ibm,cn=us.

Enabling and disabling Java 2 security using scripting

You can enable or disable Java 2 security with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

Perform the following steps to enable or disable Java 2 security:

1. Identify the security configuration object and assign it to the security variable:

- Using Jacl:

```
set security [$AdminConfig list Security]
```
- Using Jython:

```
security = AdminConfig.list('Security')  
print security
```

Example output:

```
(cells/mycell|security.xml#Security_1)
```

2. Modify the enforceJava2Security attribute to enable or disable Java 2 security. For example:

- To enable Java 2 security:
 - Using Jacl:

```
$AdminConfig modify $security {{enforceJava2Security true}}
```
 - Using Jython:

```
AdminConfig.modify(security, [['enforceJava2Security', 'true']])
```
- To disable Java 2 security:
 - Using Jacl:

```
$AdminConfig modify $security {{enforceJava2Security false}}
```
 - Using Jython:

```
AdminConfig.modify(security, [['enforceJava2Security', 'false']])
```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Propagating security policy of installed applications to a JACC provider using wsadmin scripting

It is possible that you have applications installed prior to enabling the Java Authorization Contract for Containers (JACC)-based authorization. You can start with default authorization and then move to an external provider-based authorization using JACC later.

Also, during application installation or modification you might have had problems propagating the security policy information to the JACC provider. For example, network problems might occur, the JACC provider might not be available, and so on. For these cases, the security policy of the previously installed applications does not exist in the JACC provider to make the access decisions. One choice is to reinstall the applications involved. However, you can avoid reinstalling by using the wsadmin scripting tool. Use this tool to propagate information to the JACC provider independent of the application installation process. The tool eliminates the need for reinstalling the applications.

The tool uses the SecurityAdmin MBean to propagate the policy information in the deployment descriptor of any installed application to the JACC provider. You can invoke this tool using wsadmin at the base application server for base and deployment manager level for Network Deployment. Note that the SecurityAdmin MBean is available only when the server is running.

Use propagatePolicyToJACCProvider(String appNames) to propagate the policy information in the deployment descriptor of the enterprise archive (EAR) files to the JACC provider. If the RoleConfigurationFactory and the RoleConfiguration interfaces are implemented by the JACC provider, the authorization table information in the binding file of the EAR files is also propagated to the provider. See the *Securing applications and their environment* PDF for more information about these interfaces.

The appNames String contains the list of application names, delimited by a colon (:), whose policy information must be stored in the provider. If a null value is passed, the policy information of the deployed applications is propagated to the provider.

Also, be aware of the following items:

- Before migrating applications to the Tivoli Access Manager JACC provider, create or import the users and groups that are in the applications to Tivoli Access Manager.
- Depending on the application or the number of applications that are propagated, you might have to increase the request time-out period either in the soap.client.props file in the directory *profile_root/properties* (if using SOAP) or in the sas.client.props file (if using RMI) for the command to complete. You can set the request time-out value to 0 to avoid the timeout problem, and change it back to the original value after the command is run.

1. Configure your JACC provider in WebSphere Application Server.
See the *Securing applications and their environment* PDF for more information.
2. Restart the server.
3. Enter the following commands:

```
//use the SecurityAdmin MBean at the Deployment Manager or the unmanaged base
//application server connect to the appropriate process (Deployment Manager or
//base application server)
wsadmin -user serverID -password serverPWD
// To get the SecurityAdmin MBean for Deployment Manager
wsadmin> set secadm [$AdminControl queryNames type=SecurityAdmin,process=dmgr,*]
// or to get the SecurityAdmin MBean for a unmanaged base application server
//(replace the process name to match your configuration)
wsadmin> set secadm [$AdminControl queryNames
    type=SecurityAdmin,process=server1,*]
// to propagate specific applications security policy information
wsadmin>set appNames [list app1:app2]
// or to propagate all applications installed
wsadmin>set appNames [list null]

// Run the command to propagate
wsadmin>$AdminControl invoke $secadm propagatePolicyToJACCProvider $appNames
```

Configuring the JACC provider for Tivoli Access Manager using the wsadmin utility

You can use the wsadmin utility to configure Tivoli Access Manager security for WebSphere Application Server.

Verify that all the managed servers, including node agents, are started. The following configuration is performed once on the deployment manager server. The configuration parameters are forwarded to managed servers, including node agents, when a synchronization is performed. The managed servers require their own restart for the configuration changes to take effect.

1. Start WebSphere Application Server.
2. Start the **wsadmin** command-line utility.

Run the **wsadmin** command from the *app_server_root/bin* directory.

- At the **wsadmin** prompt, enter the following command:

```
$AdminTask configureTAM -interactive
```

You are prompted to enter the following information:

Option	Description
WebSphere Application Server node name	Specify a single node or enter an asterisk (*) to choose all nodes including the deployment manager.
Tivoli Access Manager Policy Server	Enter the name of the Tivoli Access Manager policy server and the connection port. Use the format, <i>policy_server : port</i> . The policy server communication port is set at the time of Tivoli Access Manager configuration. The default port is 7135.
Tivoli Access Manager Authorization Server	Enter the name of the Tivoli Access Manager authorization server. Use the format <i>auth_server : port : priority</i> . The authorization server communication port is set at the time of Tivoli Access Manager configuration. The default port is 7136. More than one authorization server can be specified by separating the entries with commas. Having more than one authorization server configured is useful for failover and performance. The priority value is the order of authorization server use. For example: <i>auth_server1:7136:1,auth_server2:7137:2</i> . A priority of 1 is still required when configuring against a single authorization server.
WebSphere Application Server administrator's distinguished name	Enter the full distinguished name of the WebSphere Application Server security administrator ID, as created in the "Creating the security administrative user" topic in the <i>Securing applications and their environment</i> PDF. For example: <i>cn=wasadmin,o=organization,c=country</i>
Tivoli Access Manager user registry distinguished name suffix	For example: <i>o=organization,c=country</i>
Tivoli Access Manager administrator's user name	Enter the Tivoli Access Manager administration user ID, as created at the time of Tivoli Access Manager configuration. This ID is usually, <i>sec_master</i> .
Tivoli Access Manager administrator's user password	Enter the password for the Tivoli Access Manager administrator.
Tivoli Access Manager security domain	Enter the name of the Tivoli Access Manager security domain that is used to store users and groups. If a security domain is not already established at the time of Tivoli Access Manager configuration, click Return to accept the default.
Embedded Tivoli Access Manager listening port set	WebSphere Application Server needs to listen on a TCP/IP port for authorization database updates from the policy server. More than one process can run on a particular node and machine so a list of ports is required for the processes. Enter the ports that are used as listening ports by Tivoli Access Manager clients, separated by a comma. If you specify a range of ports, separate the lower and higher values by a colon. For example, <i>7999, 9990:9999</i> .

Option	Description
Defer	Set to <i>yes</i> , this option defers the configuration of the management server until the next restart. Set to <i>no</i> , configuration of the management server occurs immediately. Managed servers are configured on their next restart.

- When all information is entered, select **F** to save the configuration properties or **C** to cancel from the configuration process and discard entered information.

Now enable the JACC provider for Tivoli Access Manager- Enabling the JACC provider for Tivoli Access Manager topic in the *Securing applications and their environment* PDF.

Disabling embedded Tivoli Access Manager client using wsadmin

Follow these steps to unconfigure the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager.

In a Network Deployment architecture, ensure that all the managed servers, including node agents, are started. Perform the following process once on the deployment management server. Details of the unconfiguration are forwarded to managed servers, including node agents, when a synchronization is performed. The managed servers require their own reboot for the configuration changes to take effect.

- Restart the deployment manager process.
- Start the wsadmin command-line utility. The wsadmin command is found in the *install_dir/bin* directory
- From the **wsadmin** prompt, enter the following command:

```
WSADMIN>$AdminTask unconfigureTAM -interactive
```

You are prompted to enter the following information:

Option	Description
WebSphere Application Server node name	Enter an asterisk (*) to select all nodes.
Tivoli Access Manager administrator user name	Enter the Tivoli Access Manager administration user ID, as created at the time of Tivoli Access Manager configuration. This name is usually, <i>sec_master</i> .
Tivoli Access Manager administrator user password	Enter the password for the Tivoli Access Manager administrator.
Force	Enter <i>yes</i> , if you want to ignore errors when unconfiguring the JACC provider for Tivoli Access Manager. Enter this option as <i>yes</i> only when the Tivoli Access Manager domain is in an irreparable state.
Defer	Enter <i>no</i> , to force the unconfiguration of the connected server. Enter <i>No</i> for the unconfiguration to proceed correctly.

- When all information is entered, enter **F** to save the properties or **C** to cancel from the unconfiguration process and discard the entered information.
- Optional:** Synchronize all nodes.
- Restart all WebSphere Application Server instances for the changes to take effect.

Creating an SSL configuration at the node scope using scripting

An Secure Socket Layer (SSL) configuration references many other configuration objects. To help you make valid selections for the new SSL configuration before you create it, view information about existing configuration objects. Information about existing objects is also useful when you create a node scoped SSL configuration using the **createSSLConfig** command of the AdminTask object.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

To use the information in this task effectively, familiarize yourself with the instructions in the Creating a Secure Sockets Layer configuration topic in the *Securing applications and their environment* PDF. Perform the following task to create an Secure Socket Layer (SSL) configuration at the node scope:

1. List the existing configuration objects. Perform any of the following:
 - List some of the configuration objects that you may need when you create a new SSL configuration. For example, you want to see which management scopes have already been defined. If the one you need does not exist you will need to create it.

– Using Jacl:

```
$AdminTask listManagementScopes {-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02}
```

– Using Jython:

```
AdminTask.listManagementScopes ('[-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02]')
```

This shows an existing cell scope and existing node scope that you can use. If you want to create a different scope, use the **createManagementScope** command of the AdminTask object to define a different one. The valid scope parameters are cell, nodegroup, node, server, cluster, and endpoint. See the Central management of Secure Sockets Layer configurations topic in the *Securing applications and their environment* PDF for more information on scope definitions.

- List the key stores that exist in the configuration including key stores and trust stores.

– Using Jacl:

```
$AdminTask listKeyStores
```

– Using Jython:

```
AdminTask.listKeyStores()
```

Example output:

```
CellDefaultKeyStore(cells/BIRKT40Cell102|security.xml#KeyStore_1)
CellDefaultTrustStore(cells/BIRKT40Cell102|security.xml#KeyStore_2)
CellLTPAKeys(cells/BIRKT40Cell102|security.xml#KeyStore_3)
```

The previous example only lists the key stores for the default management scope which is also known as the cell scope. To obtain key stores for other scopes, specify the scopeName parameter, for example:

– Using Jacl:

```
$AdminTask listKeyStores {-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02 }
```

– Using Jython:

```
$AdminTask listKeyStores ('[-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02]')
```

Example output:

```
CellDefaultKeyStore(cells/BIRKT40Cell102|security.xml#KeyStore_1)
CellDefaultTrustStore(cells/BIRKT40Cell102|security.xml#KeyStore_2)
CellLTPAKeys(cells/BIRKT40Cell102|security.xml#KeyStore_3)
NodeDefaultKeyStore(cells/BIRKT40Cell102|security.xml#KeyStore_1134610924357)
NodeDefaultTrustStore(cells/BIRKT40Cell102|security.xml#KeyStore_1134610924377)
```

- List specific trust or key managers. Be sure to display the object name for the trust managers. You will need the object name for the SSL configuration because you can specify multiple trust manager instances.

- Using Jacl:

```
$AdminTask listTrustManagers {-scopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 -displayObjectName true }
```
- Using Jython:

```
AdminTask.listTrustManagers ('[-scopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 -displayObjectName true]')
```

Example output:

```

IbmX509(cells/BIRKT40Cell02|security.xml#TrustManager_1)
IbmPKIX(cells/BIRKT40Cell02|security.xml#TrustManager_2)
IbmX509(cells/BIRKT40Cell02|security.xml#TrustManager_1134610924357)
IbmPKIX(cells/BIRKT40Cell02|security.xml#TrustManager_1134610924377)

```

2. Create the node-scoped SSL configuration in interactive mode. Now that we have the information we need to choose from, we need to decide if these objects are sufficient or if we need to create new ones. For now, we will reuse what we've already got in the configuration and save creating new instances to task documents specific to those objects.

- Using Jacl:

```
$AdminTask createSSLConfig -interactive
```
- Using Jython:

```
AdminTask.createSSLConfig ('[-interactive]')
```

Example output:

Create a SSL Configuration.

```

*SSL Configuration Alias (alias): BIRKT40Node02SSLConfig
Management Scope Name (scopeName): (cell):BIRKT40Cell02:(node):BIRKT40Node02
Client Key Alias (clientKeyAlias): default
Server Key Alias (serverKeyAlias): default
SSL Type (type): [JSSE]
Client Authentication (clientAuthentication): [false]
Security Level of the SSL Configuration (securityLevel): [HIGH]
Enabled Ciphers SSL Configuration (enabledCiphers):
JSSE Provider (jsseProvider): [IBMJSSE2]
Client Authentication Support (clientAuthenticationSupported): [false]
SSL Protocol (sslProtocol): [SSL_TLS]
Trust Manager Object Names (trustManagerObjectNames): (cells/BIRKT40Cell02|security.xml#TrustManager_1)
*Trust Store Name (trustStoreName): NodeDefaultTrustStore
Trust Store Scope (trustStoreScopeName): (cell):BIRKT40Cell02:(node):BIRKT40Node02
*Key Store Name (keyStoreName): NodeDefaultKeyStore
Key Store Scope Name (keyStoreScopeName): (cell):BIRKT40Cell02:(node):BIRKT40Node02
Key Manager Name (keyManagerName): IbmX509
Key Manager Scope Name (keyManagerScopeName): (cell):BIRKT40Cell02:(node):BIRKT40Node02

```

Create SSL Configuration

F (Finish)
C (Cancel)

```

Select [F, C]: [F] F
WASX7278I: Generated command line: $AdminTask createSSLConfig {-alias BIRKT40Node02SSLConfig -scopeName
(cell):BIRKT40Cell02:(node):BIRKT40Node02 -clientKeyAlias default -serverKeyAlias default
-trustManagerObjectNames (cells/BIRKT40Cell02|security.xml#TrustManager_1) -trustStoreName
NodeDefaultTrustStore -trustStoreScopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 -keyStoreName
NodeDefaultKeyStore -keyStoreScopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 -keyManagerName
IbmX509 -keyManagerScopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 }

```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

The name of the SSL configuration object that you created, for example, (cells/BIRKT40Cell02|security.xml#SSLConfig_1136652770753), appears in the security.xml file.

Example security.xml file output:

```
<repertoire xmi:id="SSLConfig_1136652770753" alias="BIRKT40Node02SSLConfig" type="JSSE"
managementScope="ManagementScope_1134610924357">
<setting xmi:id="SecureSocketLayer_1136652770924" clientKeyAlias="default" serverKeyAlias="default"
clientAuthentication="false" securityLevel="HIGH" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS"
keyStore="KeyStore_1134610924357" trustStore="KeyStore_1134610924377" trustManager="TrustManager_1"
keyManager="KeyManager_1134610924357"/>
</repertoire>
```

Once you create the SSL configuration object, the next step is to use it. There are several different ways that you can associate SSL configurations with protocols, for example:

- Set the SSL configuration on the thread programmatically.
- Associate the SSL configuration with an outbound protocol or a target host and port.
- Directly associating the SSL configuration using the alias.
- Centrally managing the SSL configurations by associating them with SSL configuration groups or zones so that they are used based upon the group from where the end point exists.

Creating self-signed certificates using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

You can create self-signed certificates using the scripting and the AdminTask object. You can run the commands in interactive or batch mode. Interactive mode provides a way to discover the flags that you need to run the task in batch mode.

Certificates reside inside of key stores. To run the commands, you will need the name of the key store to be supplied. Use the **listKeyStore** command of the AdminTask object to get a list of key stores. If you need a new key store, use the **createKeyStore** command of the AdminTask object.

To create a personal key store, use the following examples:

- Interactive mode:
 - Using Jacl:
`$AdminTask createSelfSignedCertificate -interactive`
 - Using Jython:
`AdminTask.createSelfSignedCertificate ('[-interactive]')`

Example output:

```
*Key Store Name (keyStoreName): keyStore
Key Store Scope Name (keyStoreScope):
*Certificate Alias (certificateAlias): newCert
"Certificate Version" (certificateVersion): 3
*Key Size (certificateSize): [1024]
*Common Name (certificateCommonName): localhost
*Organization (certificateOrganization): workgroup
Organizational Unit (certificateOrganizationalUnit): testing
certLocality (certificateLocality): austin
State (certificateState): Texas
Zip (certificateZip): 78757
Country (certificateCountry): [US]
Validity Period (certificateValidDays): [365]
Create Self-Signed Certificate
```

```
F (Finish)
C (Cancel)
```

```
Select [F, C]: [F]
```

```
WASX7278I: Generated command line: $AdminTask createSelfSignedCertificate
```

```
{-keyStoreName keyStore -certificateAlias newCert -certificateVersion 3
-certificateCommonName localhost -certificateOrganization ibm
-certificateOrganizationalUnit testing -certificateLocality austin
-certificateState Texas -certificateZip 78757 }
true
```

At the end of the output, the batch mode parameters are provided.

- Batch mode:

- Using Jacl:

```
$AdminTask createSelfSignedCertificate {-keyStoreName keyStore
-certificateAlias newCert -certificateVersion 3 -certificateCommonName localhost
-certificateOrganization ibm -certificateOrganizationalUnit testing
-certificateLocality austin -certificateState Texas -certificateZip 78757 }
```

- Using Jython:

```
AdminTask.createSelfSignedCertificate ('[-keyStoreName keyStore
-certificateAlias newCert -certificateVersion 3 -certificateCommonName localhost
-certificateOrganization ibm -certificateOrganizationalUnit testing
-certificateLocality austin -certificateState Texas -certificateZip 78757]')
```

Automating SSL configurations using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

SSL configuration is needed for WebSphere to perform SSL connections with other servers. A SSL configuration can be configured through the Admin Console. But if an automated way to create a SSL configuration is desired then AdminTask should be used.

AdminTask can be used in a interactive mode and batch mode. For automation the batch mode options should be used. AdminTask batch mode can be called in a JACL or Python script. Interactive mode will step through all the parameter the task needs, requires ones are marked with a '*'. Before the interactive task executes the task it echoes the batch mode syntax of the task to the screen. This can be helpful when writing batch mode scripts.

There attributes needed to create an ssl configurations:

- A key store
- Default client certificate alias
- Default server certificate alias
- Trust store
- The handshake protocol
- The ciphers needed during handshake
- Supporting client authentication or not

If automating the creation of a SSL Configuration it may be needed to create some of the attribute values needed like the key store, trust store, key manager, and trust managers.

- To create a SSL configuration the createSSLConfig AdminTask can be used. To make changes to the SSL configurations use the modifySSLConfig AdminTask.

- Interactive mode:

Interactive mode steps you through all attributes and tell you the default value of the attribute if there is one. The default value is in '[' on the prompt line. The actual flag used in batch mode is in '(' on each prompt line. If you are using the default value then the flag will not show up on the batch command line.

Using Jacl:

```
$AdminTask createSSLConfig -interactive
```

- Using Jython:

```
AdminTask.createSSLConfig ('[interactive]')
```

Example output:

```
*SSL Configuration Alias (alias): testSSLConfig
Management Scope Name (scopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
Client Key Alias (clientKeyAlias): clientCert
Server Key Alias (serverKeyAlias): serverCert
SSL Type (type): [JSSE]
Client Authentication (clientAuthentication): [false]
Security Level of the SSL Configuration (securityLevel): [HIGH] HIGH
Enabled Ciphers SSL Configuration (enabledCiphers):
JSSE Provider (jsseProvider): [IBMJSSE2]
Client Authentication Support (clientAuthenticationSupported): [false]
SSL Protocol (sslProtocol): [SSL_TLS] SSL_TLS
Trust Manager Object Names (trustManagerObjectNames):
*Trust Store Name (trustStoreName): testTrustStore
Trust Store Scope (trustStoreScopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
*Key Store Name (keyStoreName): testKeyStore
Key Store Scope Name (keyStoreScopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
Key Manager Name (keyManagerName): IbmX509
Key Manager Scope Name (keyManagerScopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
```

Create SSL Configuration

```
F (Finish)
C (Cancel)
```

```
Select [F, C]: [F]
```

```
WASX7278I: Generated command line: $AdminTask createSSLConfig {-alias testSSLConfig
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01 -clientKeyAlias clientCert
-serverKeyAlias serverCert -trustStoreName testTrustStore
-trustStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyStoreName testKeyStore -keyStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyManagerName IbmX509 -keyManagerScopeName (cell):HOSTNode01Cell:(node):HOSTNode01 }
(cells/HOSTNode01Cell|security.xml#SSLConfig_1137687301834)
```

At the end of the output, the batch mode parameters are provided.

– Batch mode:

Using Jacl:

```
$AdminTask createSSLConfig {-alias testSSLConfig
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01 -clientKeyAlias clientCert
-serverKeyAlias serverCert -trustStoreName testTrustStore
-trustStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyStoreName testKeyStore -keyStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyManagerName IbmX509 -keyManagerScopeName (cell):HOSTNode01Cell:(node):HOSTNode01}
```

– Using Jython:

```
AdminTask.createSSLConfig ('[-alias testSSLConfig
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01 -clientKeyAlias clientCert
-serverKeyAlias serverCert -trustStoreName testTrustStore
-trustStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyStoreName testKeyStore -keyStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyManagerName IbmX509 -keyManagerScopeName (cell):HOSTNode01Cell:(node):HOSTNode01]')
```

Example output:

```
(cells/HOSTNode01Cell|security.xml#SSLConfig_1137687301834)
```

- **Key Stores and Trust Stores** The key store and trust store may already exist or a new one may need to be created. To create a new key store or trust store use the `createKeyStore` AdminTask. It will create a key store file and store the configuration object in the system configuration. A trust store is just a key store that usually only has signer certificates in it. To create a key store enter:

– Using Jacl:

```
$AdminTask createKeyStore {-keyStoreName testKeyStore -keyStoreType PKCS12
-keyStoreLocation $(USER_INSTALL_ROOT)\testKeyStore.p12 -keyStorePassword abcd
-keyStorePasswordVerify abcd -keyStoreIsFileBased true -keyStoreReadOnly false}
```

- Using Jython:

```
AdminTask.createKeyStore ('[-keyStoreName testKeyStore -keyStoreType PKCS12
-keyStoreLocation $(USER_INSTALL_ROOT)\testKeyStore.p12 -keyStorePassword abcd
-keyStorePasswordVerify abcd -keyStoreIsFileBased true -keyStoreReadOnly false]')
```

To populate the key store with certificates see “Managing Certificates using AdminConsole and Admin Task” The key store and trust store are required to create a SSL configuration. Use the ‘-keyStoreName’ and ‘-trustStoreName’ flags on the createSSLConfig. There scopes can be added with the ‘-keyStoreScope’ flag and ‘-trustStoreScope’ flags.

- Key Manager Key manager are used to determine how a certificate is selected. The IbmX509 key manager is in the security configuration by default. If a different key manager is needed then use createKeyManager AdminTask to create it. To create a key manager enter:

- Using Jacl:

```
$AdminTask createKeyManager {-name testKeyManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm }
```

- Using Jython:

```
AdminTask.createKeyManager ('[-name testKeyManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm]')
```

To supply a key manager on the createSSLConfig AdminTask use the ‘-keyManagerName’ along with the ‘-keyManagerScope’ flag.

- Trust Manager Trust managers are use to determine how trust is established during ssl communication. The IbmX509 and IbmPKIX are trust managers are in the security configuration by default. If a different or additional trust manager is needed then use the createTrustManger AdminTask to create it. To create a trust manager enter:

- Using Jacl:

```
$AdminTask createTrustManager {-name testTrustManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm }
```

- Using Jython:

```
AdminTask.createTrustManager ('[-name testTrustManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm]')
```

The SSL Configuration can have multiple trust managers. To supply multiple trust managers give a comma separated list of the trust managers configuration IDs with the -trustManagerObjectNames flag. When you create a trust manager the configuration object ID is returned. To get a list of trust managers object IDs use the **listTrustManagers** command of the AdminTask object with the -displayObjectName true flag. For example:

```
wsadmin>$AdminTask listTrustManagers -interactive
List Trust Managers
```

List trust managers.

Management Scope Name (scopeName):

Display list in ObjectName Format (displayObjectName): [false] true

List Trust Managers

F (Finish)

C (Cancel)

Select [F, C]: [F]

Inside generate script command

```
WASX7278I: Generated command line: $AdminTask listTrustManagers {-displayObjectName true }
IbmX509(cells/IBM-0AF8DABCF16Node01Cell|security.xml#TrustManager_IBM-0AF8DABCF16Node01_1)
IbmPKIX(cells/IBM-0AF8DABCF16Node01Cell|security.xml#TrustManager_IBM-0AF8DABCF16Node01_2)
```

Updating default key store passwords using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

When you install WebSphere Application Server, each server creates a key store and trust store for the default SSL configuration with the default password WebAS. To protect the security of the key store files and the SSL configuration, you must change the password. The following examples update the default password:

- Change multiple key stores passwords. The **changeMultipleKeyStorePasswords** command updates all of the key stores that have the same password. For example:

- Using Jacl:

```
$AdminTask changeMultipleKeyStorePasswords {-keyStorePassword WebAS  
-newKeyStorePassword secretPwd -newKeyStorePasswordVerify secretPwd}
```

- Using Jython:

```
AdminTask.changeMultipleKeyStorePasswords ['{-keyStorePassword WebAS  
-newKeyStorePassword secretPwd -newKeyStorePasswordVerify secretPwd}']
```

- Change the password of a single key store. The **changeKeyStorePassword** command updates the password of an individual key store. For example:

- Using Jacl:

```
$AdminTask changeKeyStorePassword {-keyStoreName testKS  
-keyStoreScope (cell):localhost:(server):server1  
-keyStorePassword WebAS -newKeyStorePassword secretPwd  
-newKeyStorePasswordVerify secretPwd}
```

- Using Jython:

```
AdminTask.changeKeyStorePassword (['-keyStoreName testKS  
-keyStoreScope (cell):localhost:(server):server1  
-keyStorePassword WebAS -newKeyStorePassword secretPwd  
-newKeyStorePasswordVerify secretPwd'])
```

Commands for the IdMgrConfig group of the AdminTask object

Use the commands in the IdMgrConfig group to configure the virtual member manager. The commands for this group do not require a target object. To see the additional commands related to the virtual member manager, see the Commands for the IdMgrRepositoryConfig group of the AdminTask object and the Commands for the IdMgrRealmConfig group of the AdminTask object articles.

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the IdMgrConfig group of the AdminTask object:

Table 31.

Command name:	Description:	Parameters and return values:	Examples:
<p>createIdMgr Supported EntityType</p>	<p>The createIdMgr Supported EntityType command creates a supported entity type configuration. To validate the result, check for duplicate entity type names.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name of the supported entity type. (String, required) - defaultParent The default parent node for the supported entity type. (String, required) - rdnProperties The RDN attribute name for the supported entity type in the entity domain name. Separate the RDN properties with semicolons (;). (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createIdMgrSupported EntityType {-name <i>entity1</i> -defaultParent <i>node1</i>}</pre> • Using Jython string: <pre>AdminTask.createIdMgrSupported EntityType ('[-name <i>entity1</i> -defaultParent <i>node1</i>']')</pre> • Using Jython list: <pre>AdminTask.createIdMgrSupported EntityType (['-name', '<i>entity1</i>', '-defaultParent', '<i>node1</i>'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createIdMgrSupported EntityType {-interactive}</pre> • Using Jython string: <pre>AdminTask.createIdMgrSupported EntityType ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.createIdMgrSupported EntityType (['-interactive'])</pre>

Table 31. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>deleteIdMgr Supported EntityType</p>	<p>The deleteIdMgr Supported EntityType command deletes the supported entity type configuration that you specify.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name of the supported entity type. The value of this parameter must be one of the supported entity types. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrSupported EntityType {-name <i>entity1</i>} • Using Jython string: AdminTask.deleteIdMgrSupported EntityType ('[-name <i>entity1</i>']') • Using Jython list: AdminTask.deleteIdMgrSupportedEntityType (['-name', '<i>entity1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrSupportedEntityType {-interactive} • Using Jython string: AdminTask.deleteIdMgrSupportedEntityType ('[-interactive]') • Using Jython list: AdminTask.deleteIdMgrSupportedEntityType (['-interactive'])
<p>getIdMgr Supported EntityType</p>	<p>The getIdMgr Supported EntityType command returns the configuration of the supported entity type that you specify.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name of the supported entity type. The value of this parameter must be one of the supported entity types. (String, required) • Returns: A hash map that has the parameters of the createIdMgrSupportedEntityType command as keys. Since the rdnProperties parameter has multiple values, its values are returned in a list. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrSupported EntityType {-name <i>entity1</i>} • Using Jython string: AdminTask.getIdMgrSupported EntityType ('[-name <i>entity1</i>']') • Using Jython list: AdminTask.getIdMgrSupportedEntityType (['-name', '<i>entity1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrSupportedEntityType {-interactive} • Using Jython string: AdminTask.getIdMgrSupportedEntityType ('[-interactive]') • Using Jython list: AdminTask.getIdMgrSupportedEntityType (['-interactive'])

Table 31. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr Supported EntityTypes	The listIdMgr Supported EntityTypes command lists all of the supported entity types that are configured.	<ul style="list-style-type: none"> • Parameters: None • Returns: A list that contains the names of the supported entity types. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgr SupportedEntityTypes • Using Jython string: AdminTask.listIdMgr SupportedEntityTypes() • Using Jython list: AdminTask.listIdMgr SupportedEntityTypes() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrSupported EntityTypes {-interactive} • Using Jython string: AdminTask.listIdMgrSupported EntityTypes (['-interactive']) • Using Jython list: AdminTask.listIdMgrSupported EntityTypes (['-interactive'])
resetId MgrConfig	The resetId MgrConfig command resets the current configuration to the last configuration that was saved.	<ul style="list-style-type: none"> • Parameters: None • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask resetIdMgrConfig • Using Jython string: AdminTask.resetIdMgrConfig() • Using Jython list: AdminTask.resetIdMgrConfig() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask resetIdMgrConfig {-interactive} • Using Jython string: AdminTask.resetIdMgrConfig (['-interactive']) • Using Jython list: AdminTask.resetIdMgrConfig (['-interactive'])

Table 31. (continued)

Command name:	Description:	Parameters and return values:	Examples:
showId MgrConfig	The showId MgrConfig command returns the current configuration XML in string format.	<ul style="list-style-type: none"> • Parameters: None • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask showIdMgrConfig • Using Jython string: AdminTask.showIdMgrConfig() • Using Jython list: AdminTask.showIdMgrConfig() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask showIdMgrConfig {-interactive} • Using Jython string: AdminTask.showIdMgrConfig (['-interactive']) • Using Jython list: AdminTask.showIdMgrConfig (['-interactive'])
updateIdMgr Supported EntityType	The updateIdMgr Supported EntityType command updates the configuration that you specify for a supported entity type.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name of the supported entity type. The value of this parameter must be one of the supported entity types. (String, required) - defaultParent The default parent node for the supported entity type. (String, optional) - rdnProperties The RDN attribute name for the supported entity type in the entity domain name. To reset all the values of the rdnProperties parameter, specify a blank string (""). (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrSupported EntityType {-name <i>entity1</i>} • Using Jython string: AdminTask.updateIdMgrSupported EntityType ('[-name <i>entity1</i>']) • Using Jython list: AdminTask.updateIdMgrSupported EntityType (['-name', '<i>entity1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrSupported EntityType {-interactive} • Using Jython string: AdminTask.updateIdMgrSupported EntityType ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrSupported EntityType (['-interactive'])

Commands for the IdMgrRepositoryConfig group of the AdminTask object

Use the commands in the IdMgrRepositoryConfig to configure the virtual member manager. The commands for this group do not require a target object. To see the additional commands related to the virtual member manager, see the “Commands for the IdMgrConfig group of the AdminTask object” on page 1592 and the “Commands for the IdMgrRealmConfig group of the AdminTask object” on page 1686 articles.

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the IdMgrRepositoryConfig group of the AdminTask object:

Table 32.

Command name:	Description:	Parameters and return values:	Examples:
addIdMgrLDAPBackupServer	The addIdMgrLDAPBackupServer command adds or updates backup LDAP servers.	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) - primary_host The host name for the primary LDAP server. (String, required) - host The host name for the LDAP server. (String, required) - port The port number for the LDAP server. (Integer, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask addIdMgrLDAPBackupServer {-id <i>id1</i> -primary_host <i>myprimaryhost</i> -host <i>myhost.ibm.com</i>}</pre> Using Jython string: <pre>AdminTask.addIdMgrLDAPBackupServer ('[-id <i>id1</i> -primary_host <i>myprimaryhost</i> -host <i>myhost.ibm.com</i>']')</pre> Using Jython list: <pre>AdminTask.addIdMgrLDAPBackupServer (['-id', '<i>id1</i>', '-primary_host', '<i>myprimaryhost</i>', '-host', '<i>myhost.ibm.com</i>'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask addIdMgrLDAPBackupServer {-interactive}</pre> Using Jython string: <pre>AdminTask.addIdMgrLDAPBackupServer ('[-interactive]')</pre> Using Jython list: <pre>AdminTask.addIdMgrLDAPBackupServer (['-interactive'])</pre>

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>addIdMgr LDAPEntity Type</p>	<p>The addIdMgr LDAPEntity Type command adds an LDAP entity type definition.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - name The name of the entity type. (String, required) - searchFilter The search filter that you want to use to search the entity type. (String, optional) - objectClasses One or more object classes for the entity type. (String, required) - objectClassesForCreate The object class to use when an entity type is created. If the value of this parameter is the same as the objectClass parameter, you do not need to specify this parameter. (String, optional) - searchBases The search base or bases to use while searching the entity type. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask addIdMgrLDAPEntity Type {-id <i>id1</i> -name <i>name1</i> -objectClasses <i>objectclass</i>}</code> • Using Jython string: <code>AdminTask.addIdMgrLDAPEntity Type ('[-id <i>id1</i> -name <i>name1</i> -objectClasses <i>objectclass</i>']')</code> • Using Jython list: <code>AdminTask.addIdMgrLDAPEntity Type (['-id', '<i>id1</i>', '-name', '<i>name1</i>', '-objectClasses', '<i>objectclass</i>'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask addIdMgrLDAPEntityType {-interactive}</code> • Using Jython string: <code>AdminTask.addIdMgrLDAPEntityType ('[-interactive]')</code> • Using Jython list: <code>AdminTask.addIdMgrLDAPEntityType (['-interactive'])</code>

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>addId MgrLDAP EntityType RDNAttr</p>	<p>The addId MgrLDAP EntityType RDNAttr command adds RDN attribute configuration to an LDAP entity type definition.</p>	<ul style="list-style-type: none"> • Parameters: <li style="padding-left: 20px;">- id The ID of the repository. (String, required) <li style="padding-left: 20px;">- entityTypeName The name of the entity type. (String, required) <li style="padding-left: 20px;">- name The attribute name that is used to build the relative distinguished name (RDN) for the entity type. (String, required) <li style="padding-left: 20px;">- objectClass The object class to use for the entity type for the relative distinguished name (RDN) attribute name that you specify. Use this parameter to map one entity type to multiple structural object classes. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addIdMgrLDAPEntityTypeRDNAttr {-id <i>id1</i> -entityTypeName <i>entitytype</i> -name <i>name1</i>} • Using Jython string: AdminTask.addIdMgrLDAPEntityTypeRDNAttr ('[-id <i>id1</i> -entityTypeName <i>entitytype</i> -name <i>name1</i>]') • Using Jython list: AdminTask.addIdMgrLDAPEntityTypeRDNAttr (['-id', '<i>id1</i>', '-entityTypeName', '<i>entitytype</i>', '-name', '<i>name1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addIdMgrLDAPEntityTypeRDNAttr {-interactive} • Using Jython string: AdminTask.addIdMgrLDAPEntityTypeRDNAttr ('[-interactive]') • Using Jython list: AdminTask.addIdMgrLDAPEntityTypeRDNAttr (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>addIdMgr LDAPGroup Dynamic Member Attr</p>	<p>The addIdMgr LDAPGroup Dynamic Member Attr command adds a dynamic member attribute configuration to an LDAP group configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - name The name of the LDAP attribute that is used as the group member attribute. For example, member or uniqueMember. (String, required) - objectClass The group object class that contains the member attribute. For example, groupOfNames or groupOfUniqueNames. If you do not define this parameter, the member attribute applies to all group object classes. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addIdMgrLDAPGroup DynamicMemberAttr {-id <i>id1</i> -name <i>name1</i> -objectClass <i>objectclass</i>} • Using Jython string: AdminTask.addIdMgrLDAPGroup DynamicMemberAttr ('[-id <i>id1</i> -name <i>name1</i> -objectClass <i>objectclass</i>']') • Using Jython list: AdminTask.addIdMgrLDAPGroup DynamicMemberAttr (['-id', '<i>id1</i>', '-name', '<i>name1</i>', '-objectClass', '<i>objectclass</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addIdMgrLDAPGroup DynamicMemberAttr {-interactive} • Using Jython string: AdminTask.addIdMgrLDAPGroup DynamicMemberAttr ('[-interactive]') • Using Jython list: AdminTask.addIdMgrLDAPGroup DynamicMemberAttr (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- scope</p> <p>The scope of the member attribute. The valid values for this parameter include the following:</p> <ul style="list-style-type: none"> • direct - The member attribute only contains direct members, therefore, this value refers to the member directly contained by the group and not contained through the nested group. For example, if Group1 contains Group2 and Group2 contains User1, then Group2 is a direct member of Group1 but User1 is not a direct member of Group1. Both member and uniqueMember are direct member attributes. • nested - The member attribute that contains the direct members and the nested members. 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> • all - The member attribute that contains the direct members, the nested members, and the dynamic members. For example, the <code>ibm-allMembers</code> attribute which is supported by the IBM Tivoli Directory Server. (String, optional) - dummyMember Indicates that if you create a group without specifying a member, a dummy member will be filled in to avoid creating an exception about missing a mandatory attribute. (String, optional) • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>addIdMgr LDAPGroup MemberAttr</p>	<p>The addIdMgr LDAPGroup MemberAttr command adds a member attribute configuration to an LDAP group configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - name The name of the LDAP attribute that is used as the group member attribute. For example, member or uniqueMember. (String, required) - objectClass The group object class that contains the member attribute. For example, groupOfNames or groupOfUniqueNames. If you do not define this parameter, the member attribute applies to all group object classes. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addIdMgrLDAPGroup MemberAttr {-id <i>id1</i> -name <i>name1</i>} • Using Jython string: AdminTask.addIdMgrLDAPGroup MemberAttr ('[-id <i>id1</i> -name <i>name1</i>]') • Using Jython list: AdminTask.addIdMgrLDAPGroup MemberAttr (['-id', '<i>id1</i>', '-name', '<i>name1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addIdMgrLDAPGroup MemberAttr {-interactive} • Using Jython string: AdminTask.addIdMgrLDAPGroup MemberAttr ('[-interactive]') • Using Jython list: AdminTask.addIdMgrLDAPGroup MemberAttr (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- scope</p> <p>The scope of the member attribute. The valid values for this parameter include the following:</p> <ul style="list-style-type: none"> • direct - The member attribute only contains direct members, therefore, this value refers to the member directly contained by the group and not contained through the nested group. For example, if Group1 contains Group2 and Group2 contains User1, then Group2 is a direct member of Group1 but User1 is not a direct member of Group1. Both member and uniqueMember are direct member attributes. • nested - The member attribute that contains the direct members and the nested members. 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> • all - The member attribute that contains the direct members, the nested members, and the dynamic members. For example, the <code>ibm-allMembers</code> attribute which is supported by the IBM Tivoli Directory Server. (String, optional) - dummyMember Indicates that if you create a group without specifying a member, a dummy member will be filled in to avoid creating an exception about missing a mandatory attribute. (String, optional) • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>addId MgrLDAP Server</p>	<p>The addId MgrLDAP Server command adds an LDAP server to the LDAP repository ID that you specify.</p> <p>If the value of the <code>sslEnabled</code> parameter is set to <code>true</code>, the addIdMgrLDAPServer command operation will fail while trying to validate the connection. To workaround this problem, perform the following steps:</p> <ol style="list-style-type: none"> 1. Start WebSphere Application Server. 2. Start the <code>wsadmin</code> tool without specifying the <code>-conntype none</code> option. 	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - host The host name for the primary LDAP server. (String, required) - port The port number for the LDAP server. (Integer, optional) - bindDN The binding distinguished name for the LDAP server. (String, optional) - bindPassword The binding password. (String, optional) - authentication Indicates the authentication method to use. The default value is <code>simple</code>. Valid values include: <code>none</code> or <code>strong</code>. (String, optional) - referral The LDAP referral. The default value is <code>ignore</code>. Valid values include: <code>follow</code>, <code>throw</code>, or <code>false</code>. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask addIdMgrLDAPServer {-id <i>id1</i> -host <i>myhost.ibm.com</i>}</code> • Using Jython string: <code>AdminTask.addIdMgrLDAPServer ('[-id <i>id1</i> -host <i>myhost.ibm.com</i>]')</code> • Using Jython list: <code>AdminTask.addIdMgrLDAPServer (['-id', '<i>id1</i>', '-host', '<i>myhost.ibm.com</i>'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask addIdMgrLDAPServer {-interactive}</code> • Using Jython string: <code>AdminTask.addIdMgrLDAPServer ('[-interactive]')</code> • Using Jython list: <code>AdminTask.addIdMgrLDAPServer (['-interactive'])</code>

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- derefAliases Controls how aliases are dereferenced. The default value is always. Valid values include:</p> <ul style="list-style-type: none"> • never - never deference aliases • finding - deferences aliases only during name resolution • searching - deferences aliases only after name resolution <p>(String, optional)</p> <p>- sslEnabled Indicates to enable SSL or not. The default value is false. (Boolean, optional)</p> <p>- connectionPool The connection pool. The default value is false. (Boolean, optional)</p> <p>- connectTimeout The connection timeout in seconds. The default value is 0. (Integer, optional)</p>	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- ldapServerType The type of LDAP server being used. The default value is IDS51. (String, optional)</p> <p>- sslConfiguration The SSL configuration. (String, optional)</p> <p>-</p> <p>certificateMapMode Specifies whether to map X.509 certificates into a LDAP directory by exact distinguished name or by certificate filter. The default value is exactdn. To use the certificate filter for the mapping, specify certificatefilter. (String, optional)</p> <p>- certificateFilter If certificateMapMode has the value certificatefilter, then this property specifies the LDAP filter which maps attributes in the client certificate to entries in LDAP. (String, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>addIdMgr Repository BaseEntry</p>	<p>The addIdMgr Repository BaseEntry command adds a base entry to the specified repository.</p>	<ul style="list-style-type: none"> • Parameters: <li style="padding-left: 20px;">- id The ID of the repository. (String, required) <li style="padding-left: 20px;">- name The distinguished name of a base entry. (String, required) <li style="padding-left: 20px;">- nameInRepository The distinguished name in the repository that uniquely identifies the base entry name. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addIdMgrRepository BaseEntry {-id <i>id1</i> -name <i>name1</i>} • Using Jython string: AdminTask.addIdMgrRepository BaseEntry ('[-id <i>id1</i> -name <i>name1</i>]') • Using Jython list: AdminTask.addIdMgrRepository BaseEntry (['-id', '<i>id1</i>', '-name', '<i>name1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addIdMgrRepository BaseEntry {-interactive} • Using Jython string: AdminTask.addIdMgrRepository BaseEntry ('[-interactive]') • Using Jython list: AdminTask.addIdMgrRepository BaseEntry (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>createId MgrDB Repository</p>	<p>The createId MgrDB Repository command creates a database repository configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - dataSourceName The name of the data source. The default value is jdbc/wimDS. (String, required) - databaseType The type of the database. The default value is DB2. (String, required) - dbURL The URL of the database. (String, required) - dbAdminId The database administrator ID. (String, required if database type is not Cloudscape.) - dbAdminPassword The database administrator password. (String, required if database type is not Cloudscape.) - adapterClassName The default value is com.ibm.ws.wim.adapter.db.DBAdapter. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createIdMgrDB Repository {-id <i>id1</i> -dataSourceName <i>datasource name</i> -databaseType <i>DB2</i>} • Using Jython string: AdminTask.createIdMgrDB Repository ('[-id <i>id1</i> -dataSourceName <i>datasource name</i> -databaseType <i>DB2</i>']') • Using Jython list: AdminTask.createIdMgrDB Repository (['-id', '<i>id1</i>', '-dataSourceName', '<i>datasource name</i>', '-databaseType', '<i>DB2</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createIdMgrDB Repository {-interactive} • Using Jython string: AdminTask.createIdMgrDB Repository ('[-interactive]') • Using Jython list: AdminTask.createIdMgrDB Repository (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - JDBCClass The JDBC driver class name. (String, optional) - supportSorting Indicates if sorting is supported or not. The default value is false. (Boolean, optional) - supportTransaction Indicates if transactions are supported or not. The default value is false. (Boolean, optional) - isExtIdUnique Specifies if the external ID is unique. The default value is true. (Boolean, optional) - supportExternalName Indicates if external names are supported or not. The default value is false. (Boolean, optional) 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - entityRetrievalLimit Indicates the value of the retrieval limit on database entries. The default value is 200. (Integer, optional) - saltLength The salt length in bits. The default value is 12. (Integer, optional) - encryptionKey The default value is rZ15ws0e1y9yHk3zCs3sTMv/ho8fY17s. (String, optional) <ul style="list-style-type: none"> • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>createId MgrFile Repository</p>	<p>The createId MgrFile Repository command creates a file repository configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - messageDigestAlgorithm The message digest algorithm that will be used for hashing the password. The default value is SHA-1. Valid values include the following: SHA-245, SHA-384, or SHA-512. (String, required) - adapterClassName The default value is com.ibm.ws.wim.adapter.file.was.FileAdapter. (String, optional) - supportPaging Indicates if paging is supported or not. The default value is false. (Boolean, optional) - supportSorting Indicates if sorting is supported or not. The default value is false. (Boolean, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createIdMgrFile Repository {-id <i>id1</i> -messageDigestAlgorithm <i>SHA-245</i>} • Using Jython string: AdminTask.createIdMgrFile Repository ('[-id <i>id1</i> -messageDigestAlgorithm <i>SHA-245</i>]') • Using Jython list: AdminTask.createIdMgrFile Repository (['-id', '<i>id1</i>', '-messageDigestAlgorithm', '<i>SHA-245</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createIdMgrFile Repository {-interactive} • Using Jython string: AdminTask.createIdMgrFile Repository ('[-interactive]') • Using Jython list: AdminTask.createIdMgrFile Repository (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - supportTransaction Indicates if transaction is supported or not. The default value is false. (Boolean, optional) - isExtIdUnique Specifies if the external ID is unique or not. The default value is true. (Boolean, optional) - supportExternalName Indicates if external names are supported or not. The default value is false. (Boolean, optional) - baseDirectory The base directory where the fill will be created in order to store the data. The default is to be dynamically built during run time using user.install.root and cell name. (String, optional) - fileName The file name of the repository. The default value is fileRegistry.xml. (String, optional) 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> <li data-bbox="769 306 1011 562"> - saltLength The salt length of the randomly generated salt for password hashing. The default value is 12. (Integer, optional) <li data-bbox="769 573 954 602"> <ul style="list-style-type: none"> <li data-bbox="769 573 954 602">• Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>createId MgrLDAP Repository</p>	<p>The create IdMgrLDAP Repository command creates an LDAP repository configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The unique identifier for the repository. (String, required) - ldapServerType The type of LDAP server that is being used. The default value is <code>IDS51</code>. (String, required) - adapterClassName The default value is <code>com.ibm.ws.wim.adapter.db.DBAdapter</code>. (String, optional) - supportSorting Indicates if sorting is supported or not. The default value is <code>false</code>. (Boolean, optional) - supportPaging Indicates if paging is supported or not. The default value is <code>false</code>. (Boolean, optional) - supportTransaction Indicates if transactions are supported or not. The default value is <code>false</code>. (Boolean, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createIdMgrLDAP Repository {-id <i>id1</i> -ldapServerType <i>IDS51</i>}</code> • Using Jython string: <code>AdminTask.createIdMgrLDAP Repository ('[-id <i>id1</i> -ldapServerType <i>IDS51</i>']')</code> • Using Jython list: <code>AdminTask.createIdMgrLDAP Repository (['-id', '<i>id1</i>', '-ldapServerType', '<i>IDS51</i>'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createIdMgrLDAP Repository {-interactive}</code> • Using Jython string: <code>AdminTask.createIdMgrLDAP Repository ('[-interactive]')</code> • Using Jython list: <code>AdminTask.createIdMgrLDAP Repository (['-interactive'])</code>

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
deleteIdMgr LDAPGroup Dynamic MemberAttr	The deleteIdMgr LDAPGroup Dynamic MemberAttr command deletes a dynamic member attribute configuration from an LDAP group configuration.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) - name The name of the LDAP attribute that is used as the group member attribute. For example, memberURL. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteIdMgrLDAPGroupDynamicMemberAttr {-id <i>id1</i> -name <i>name1</i>}</pre> • Using Jython string: <pre>AdminTask.deleteIdMgrLDAPGroupDynamicMemberAttr ('[-id <i>id1</i> -name <i>name1</i>']')</pre> • Using Jython list: <pre>AdminTask.deleteIdMgrLDAPGroupDynamicMemberAttr (['-id', '<i>id1</i>', '-name', '<i>name1</i>'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteIdMgrLDAPGroupDynamicMemberAttr {-interactive}</pre> • Using Jython string: <pre>AdminTask.deleteIdMgrLDAPGroupDynamicMemberAttr ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.deleteIdMgrLDAPGroupDynamicMemberAttr (['-interactive'])</pre>

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
deleteld MgrLDAP Server	The deleteld MgrLDAP Server command deletes the configuration for the LDAP server that you specify from the LDAP repository ID that you specify.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) - host The host name for the primary LDAP server. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrLDAP Server {-id <i>id1</i> -host <i>myhost.ibm.com</i>} • Using Jython string: AdminTask.deleteIdMgrLDAP Server ('[-id <i>id1</i> -host <i>myhost.ibm.com</i>']') • Using Jython list: AdminTask.deleteIdMgrLDAP Server (['-id', '<i>id1</i>', '-host', '<i>myhost.ibm.com</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrLDAP Server {-interactive} • Using Jython string: AdminTask.deleteIdMgrLDAP Server ('[-interactive]') • Using Jython list: AdminTask.deleteIdMgrLDAP Server (['-interactive'])
deleteldMgr Repository	The deleteldMgr Repository command deletes a repository that you specify.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. Valid values include existing repository IDs. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgr Repository {-id <i>id1</i>} • Using Jython string: AdminTask.deleteIdMgr Repository ('[-id <i>id1</i>']') • Using Jython list: AdminTask.deleteIdMgr Repository (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrRepository {-interactive} • Using Jython string: AdminTask.deleteIdMgrRepository ('[-interactive]') • Using Jython list: AdminTask.deleteIdMgrRepository (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>deleteIdMgr Repository BaseEntry</p>	<p>The deleteIdMgr Repository BaseEntry command deletes a base entry from the specified repository.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) - name The distinguished name of a base entry. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrRepository BaseEntry {-id <i>id1</i> -name <i>name1</i>} • Using Jython string: AdminTask.deleteIdMgrRepository BaseEntry ('[-id <i>id1</i> -name <i>name1</i>']') • Using Jython list: AdminTask.deleteIdMgrRepository BaseEntry (['-id', '<i>id1</i>', '-name', '<i>name1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrRepository BaseEntry {-interactive} • Using Jython string: AdminTask.deleteIdMgrRepository BaseEntry ('[-interactive]') • Using Jython list: AdminTask.deleteIdMgrRepository BaseEntry (['-interactive'])
<p>getIdMgr LDAPAttr Cache</p>	<p>The getIdMgr LDAPAttr Cache command returns the LDAP attribute cache configuration.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map with the parameters of the setIdMgr LDAPAttr Cache command as keys. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPAttr Cache {-id <i>id1</i>} • Using Jython string: AdminTask.getIdMgrLDAPAttr Cache ('[-id <i>id1</i>']') • Using Jython list: AdminTask.getIdMgrLDAPAttr Cache (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPAttrCache {-interactive} • Using Jython string: AdminTask.getIdMgrLDAPAttrCache ('[-interactive]') • Using Jython list: AdminTask.getIdMgrLDAPAttrCache (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getIdMgr LDAP ContextPool	The getIdMgr LDAP Context Pool command returns the LDAP context pool configuration.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map that includes the parameters of the setIdMgrLDAPContextPool command as the keys. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPContextPool {-id <i>id1</i>} • Using Jython string: AdminTask.getIdMgrLDAPContextPool ('[-id <i>id1</i>']') • Using Jython list: AdminTask.getIdMgrLDAPContextPool (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPContextPool {-interactive} • Using Jython string: AdminTask.getIdMgrLDAPContextPool ('[-interactive]') • Using Jython list: AdminTask.getIdMgrLDAPContextPool (['-interactive'])
getIdMgr LDAP EntityType	The getIdMgr LDAP EntityType command returns the LDAP entity type configuration data.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) - name The name of the entity type. (String, required) • Returns: A hash map with the keys the same as the property name of the addIdMgrLDAPEntityType command. Multi-valued parameters are returned as list. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPEntityType {-id <i>id1</i> -name <i>name1</i>} • Using Jython string: AdminTask.getIdMgrLDAPEntityType ('[-id <i>id1</i> -name <i>name1</i>]') • Using Jython list: AdminTask.getIdMgrLDAPEntityType (['-id', '<i>id1</i>', '-name', '<i>name1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPEntityType {-interactive} • Using Jython string: AdminTask.getIdMgrLDAPEntityType ('[-interactive]') • Using Jython list: AdminTask.getIdMgrLDAPEntityType (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>getIdMgr LDAPEntity TypeRDNAttr</p>	<p>The getIdMgr LDAPEntity TypeRDNAttr command returns the relative distinguished name (RDN) attribute configuration for an LDAP entity type definition.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) - entityTypeName The name of the entity name. (String, required) • Returns: A hash map with the RDN attribute names as the key. If the object class is set, the value of the key will be set to the value of the object class. Otherwise, the value will be null. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrLDAPEntity TypeRDNAttr {-id id1 -entityTypeName name1}</pre> • Using Jython string: <pre>AdminTask.getIdMgrLDAPEntity TypeRDNAttr ('[-id id1 -entityTypeName name1]')</pre> • Using Jython list: <pre>AdminTask.getIdMgrLDAPEntity TypeRDNAttr (['-id', 'id1', '-entityTypeName', 'name1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrLDAPEntity TypeRDNAttr {-interactive}</pre> • Using Jython string: <pre>AdminTask.getIdMgrLDAPEntity TypeRDNAttr ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getIdMgrLDAPEntity TypeRDNAttr (['-interactive'])</pre>
<p>getIdMgr LDAPGroupConfig</p>	<p>The getIdMgr LDAPGroupConfig command returns the LDAP group configuration.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map that contains the parameters of the setIdMgr LDAPGroupConfig command as the keys. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrLDAPGroup Config {-id id1}</pre> • Using Jython string: <pre>AdminTask.getIdMgrLDAPGroup Config ('[-id id1]')</pre> • Using Jython list: <pre>AdminTask.getIdMgrLDAPGroup Config (['-id', 'id1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrLDAPGroup Config {-interactive}</pre> • Using Jython string: <pre>AdminTask.getIdMgrLDAPGroup Config ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getIdMgrLDAPGroup Config (['-interactive'])</pre>

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getIdMgr LDAPGroup Dynamic Member Attrs	The getIdMgr LDAPGroup Dynamic Member Attrs command returns the dynamic member attribute configuration from the LDAP group configuration.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map list that contains the parameters of the addIdMgr LDAPGroup Dynamic MemberAttr command as the keys. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPGroupDynamicMemberAttrs {-id <i>id1</i>} • Using Jython string: AdminTask.getIdMgrLDAPGroupDynamicMemberAttrs ('[-id <i>id1</i>']') • Using Jython list: AdminTask.getIdMgrLDAPGroupDynamicMemberAttrs (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPGroupDynamicMemberAttrs {-interactive} • Using Jython string: AdminTask.getIdMgrLDAPGroupDynamicMemberAttrs ('[-interactive]') • Using Jython list: AdminTask.getIdMgrLDAPGroupDynamicMemberAttrs (['-interactive'])
getIdMgr LDAPGroup MemberAttrs	The getIdMgr LDAPGroup MemberAttrs command returns the member attribute configuration for the LDAP group configuration.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map list that contains the parameters of the addIdMgr LDAPGroup MemberAttr command as the keys. 	<p>Batch mode example usage:</p> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPGroupMemberAttrs {-interactive} • Using Jython string: AdminTask.getIdMgrLDAPGroupMemberAttrs ('[-interactive]') • Using Jython list: AdminTask.getIdMgrLDAPGroupMemberAttrs (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getIdMgr LDAPSearch ResultCache	The getIdMgr LDAPSearch ResultCache command returns the LDAP search result cache configuration.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map with the parameters of the setIdMgr LDAPSearch ResultCache command as the keys. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPSearchResultCache {-id <i>id1</i>} • Using Jython string: AdminTask.getIdMgrLDAPSearchResultCache ('[-id <i>id1</i>']') • Using Jython list: AdminTask.getIdMgrLDAPSearchResultCache (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPSearchResultCache {-interactive} • Using Jython string: AdminTask.getIdMgrLDAPSearchResultCache ('[-interactive]') • Using Jython list: AdminTask.getIdMgrLDAPSearchResultCache (['-interactive'])
getIdMgr LDAPServer	The getIdMgr LDAPServer command returns the configuration for the LDAP server that you specify for the LDAP repository ID that you specify.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) - host The host name for the primary LDAP server. (String, required) • Returns: A hash map with the keys the same as the parameter names for the addIdMgr LDAPServer command. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPServer {-id <i>id1</i> -host <i>myhost.ibm.com</i>} • Using Jython string: AdminTask.getIdMgrLDAPServer ('[-id <i>id1</i> -host <i>myhost.ibm.com</i>]') • Using Jython list: AdminTask.getIdMgrLDAPServer (['-id', '<i>id1</i>', '-host', '<i>myhost.ibm.com</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPServer {-interactive} • Using Jython string: AdminTask.getIdMgrLDAPServer ('[-interactive]') • Using Jython list: AdminTask.getIdMgrLDAPServer (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getIdMgr Repository	<p>The getIdMgr Repository command returns the configuration of the specified repository.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map. The keys will vary depending on the type of repository. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrRepository {-id <i>id1</i>} • Using Jython string: AdminTask.getIdMgrRepository ('[-id <i>id1</i>']') • Using Jython list: AdminTask.getIdMgrRepository (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrRepository {-interactive} • Using Jython string: AdminTask.getIdMgrRepository ('[-interactive]') • Using Jython list: AdminTask.getIdMgrRepository (['-interactive'])
listIdMgr Custom Properties	<p>The listIdMgr Custom Properties command returns a list of custom properties for the repository that you specify.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map that contains keys as the custom property names and values as custom property values. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrCustomProperties {-id <i>id1</i>} • Using Jython string: AdminTask.listIdMgrCustomProperties ('[-id <i>id1</i>']') • Using Jython list: AdminTask.listIdMgrCustomProperties (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrCustomProperties {-interactive} • Using Jython string: AdminTask.listIdMgrCustomProperties ('[-interactive]') • Using Jython list: AdminTask.listIdMgrCustomProperties (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr LDAPBackupServers	The listIdMgr LDAPBackupServers command returns a list of the backup LDAP server or servers.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) - primary_host The host name for the primary LDAP server. (String, required) • Returns: A list of hash maps. The hash maps contains the names of the backup servers as the key and the port numbers as the value. Returning all the data in a hash map does not maintain the order of backup servers. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAPBackupServer {-id <i>id1</i> -primary_host <i>hostname</i>} • Using Jython string: AdminTask.listIdMgrLDAPBackupServer ('[-id <i>id1</i> -primary_host <i>hostname</i>]') • Using Jython list: AdminTask.listIdMgrLDAPBackupServer (['-id', '<i>id1</i>', '-primary_host', '<i>hostname</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAPBackupServer {-interactive} • Using Jython string: AdminTask.listIdMgrLDAPBackupServer ('[-interactive]') • Using Jython list: AdminTask.listIdMgrLDAPBackupServer (['-interactive'])
listIdMgr LDAPEntityTypeTypes	The listIdMgr LDAPEntityTypeTypes command lists the name of all of the configured LDAP entity type definitions.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A list that contains the names of the configured LDAP entity types. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAPEntityType {-id <i>id1</i>} • Using Jython string: AdminTask.listIdMgrLDAPEntityType ('[-id <i>id1</i>]') • Using Jython list: AdminTask.listIdMgrLDAPEntityType (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAPEntityType {-interactive} • Using Jython string: AdminTask.listIdMgrLDAPEntityType ('[-interactive]') • Using Jython list: AdminTask.listIdMgrLDAPEntityType (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr LDAP Servers	The listIdMgr LDAP Servers command lists all of the configured primary LDAP servers.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A list that contains the primary LDAP server names. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAP Servers {-id <i>id1</i>} • Using Jython string: AdminTask.listIdMgrLDAP Servers ('[-id <i>id1</i>']') • Using Jython list: AdminTask.listIdMgrLDAP Servers (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAP Servers {-interactive} • Using Jython string: AdminTask.listIdMgrLDAP Servers ('[-interactive]') • Using Jython list: AdminTask.listIdMgrLDAP Servers (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr Repositories	<p>The listIdMgr Repositories command lists names and types of all configured repositories.</p>	<ul style="list-style-type: none"> • Parameters: None • Returns: A hash map with key as the name of the repository and value as another hash map that includes the following keys: <ul style="list-style-type: none"> – repositoryType - The type of repository. For example, File, LDAP, DB, and so on. – specificRepositoryType - The specific type of repository. For example, LDAP, IDS51, NDS, and so on. – host - The host name where the repository resides. For File, it is LocalHost and for DB it is dataSourceName. <p>This command will not return the Property Extension and Entry Mapping repository data.</p>	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listIdMgrRepositories</pre> • Using Jython string: <pre>AdminTask.listIdMgrRepositories()</pre> • Using Jython list: <pre>AdminTask.listIdMgrRepositories()</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listIdMgrRepositories {-interactive}</pre> • Using Jython string: <pre>AdminTask.listIdMgrRepositories (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.listIdMgrRepositories (['-interactive'])</pre>

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr Repository BaseEntries	The listIdMgr Repository BaseEntries command lists the base entries for a specified repository.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map that contains base entry name as key and nameInRepository as value. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRepository BaseEntries {-id <i>id1</i>} • Using Jython string: AdminTask.listIdMgrRepository BaseEntries ('[-id <i>id1</i>']') • Using Jython list: AdminTask.listIdMgrRepository BaseEntries (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRepository BaseEntries {-interactive} • Using Jython string: AdminTask.listIdMgrRepository BaseEntries ('[-interactive]') • Using Jython list: AdminTask.listIdMgrRepository BaseEntries (['-interactive'])
listIdMgr Supported DBTypes	The listIdMgr Supported DBTypes command returns a list of supported database types.	<ul style="list-style-type: none"> • Parameters: None • Returns: A list of supported database types. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrSupportedDBTypes • Using Jython string: AdminTask.listIdMgrSupportedDBTypes () • Using Jython list: AdminTask.listIdMgrSupportedDBTypes () <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrSupported DBTypes {-interactive} • Using Jython string: AdminTask.listIdMgrSupported DBTypes ('[-interactive]') • Using Jython list: AdminTask.listIdMgrSupported DBTypes (['-interactive'])

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr rSupported Message Digest Algorithms	The listIdMgr Supported Message Digest Algorithms command returns a list of supported message digest algorithms.	<ul style="list-style-type: none"> • Parameters: None • Returns: A list of supported message digest algorithms. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrSupported MessageDigestAlgorithms • Using Jython string: AdminTask.listIdMgrSupported MessageDigestAlgorithms () • Using Jython list: AdminTask.listIdMgrSupported MessageDigestAlgorithms () <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrSupportedMessageDigestAlgorithms {-interactive} • Using Jython string: AdminTask.listIdMgrSupportedMessageDigestAlgorithms ('[-interactive]') • Using Jython list: AdminTask.listIdMgrSupportedMessageDigestAlgorithms (['-interactive'])
listIdMgr Supported LDAPServerTypes	The listIdMgr Supported LDAP ServerTypes command returns a list of supported LDAP server types.	<ul style="list-style-type: none"> • Parameters: None • Returns: A list of supported LDAP server types. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrSupported LDAPServerTypes • Using Jython string: AdminTask.listIdMgrSupported LDAPServerTypes () • Using Jython list: AdminTask.listIdMgrSupported LDAPServerTypes () <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrSupported LDAPServerTypes {-interactive} • Using Jython string: AdminTask.listIdMgrSupported LDAPServerTypes ('[-interactive]') • Using Jython list: AdminTask.listIdMgrSupported LDAPServerTypes (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
removeIdMgr LDAPBackupServer	The removeIdMgr LDAPBackupServer command removes the backup LDAP server or servers.	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - primary_host The host name for the primary LDAP server. (String, required) - host The name of the backup host name. Use an asterisk (*) if you want to remove all backup servers. (String, required) - port The port number of the LDAP server. (Integer, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask removeIdMgrLDAPBackupServer {-id id1 -primary_host myprimaryhost.ibm.com -host myhost.ibm.com}</code> • Using Jython string: <code>AdminTask.removeIdMgrLDAPBackupServer ('[-id id1 -primary_host myprimaryhost.ibm.com -host myhost.ibm.com]')</code> • Using Jython list: <code>AdminTask.removeIdMgrLDAPBackupServer (['-id', 'id1', '-primary_host', 'myprimaryhost.ibm.com', '-host', 'myhost.ibm.com'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask removeIdMgrLDAPBackupServer {-interactive}</code> • Using Jython string: <code>AdminTask.removeIdMgrLDAPBackupServer (['-interactive'])</code> • Using Jython list: <code>AdminTask.removeIdMgrLDAPBackupServer (['-interactive'])</code>

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>setIdMgr Custom Property</p>	<p>The setIdMgr Custom Property command adds the custom properties to a repository configuration.</p>	<ul style="list-style-type: none"> • Parameters: <li style="padding-left: 20px;">- id The ID of the repository. Valid values include the existing repository IDs. (String, required) <li style="padding-left: 20px;">- name The name of the additional property for the repository that are not defined OOTB. (String, required) <li style="padding-left: 20px;">- value If this parameter is an empty string, the property will be deleted from the repository configuration. If this parameter is not an empty string and name does not exist, it will be added. If name is an empty string, all the custom properties will be deleted. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrCustomProperty {-id <i>id1</i> -name <i>name1</i> -value <i>value</i>} • Using Jython string: AdminTask.setIdMgrCustomProperty ('[-id <i>id1</i> -name <i>name1</i> -value <i>value</i>']') • Using Jython list: AdminTask.setIdMgrCustomProperty (['-id', '<i>id1</i>', '-name', '<i>name1</i>', '-value', '<i>value</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrCustomProperty {-interactive} • Using Jython string: AdminTask.setIdMgrCustomProperty ('[-interactive]') • Using Jython list: AdminTask.setIdMgrCustomProperty (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
setIdMgr LDAPA ttrCache	<p>The setIdMgr LDAPA ttrCache command configures the LDAP attribute cache configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - cachesDiskOffLoad (String, optional) - enabled Indicates if you want to enable attribute caching. The default value is true. (Boolean, optional) - cacheSize The maximum size of the attribute cache defined by the number of attribute objects that are permitted in the attribute cache. The minimum value of this parameter is 100. The default value is 4000. (Integer, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPAttr Cache {-id <i>id1</i>} • Using Jython string: AdminTask.setIdMgrLDAPAttr Cache ('[-id <i>id1</i>']') • Using Jython list: AdminTask.setIdMgrLDAPAttr Cache (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPAttr Cache {-interactive} • Using Jython string: AdminTask.setIdMgrLDAPAttr Cache ('[-interactive]') • Using Jython list: AdminTask.setIdMgrLDAPAttr Cache (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- cacheTimeout The amount of time in seconds before the cached entries that are located in the attributes cache can be not valid. The minimum value of this parameter is 0. The attribute objects that are cached will remain in the attributes cache until the virtual member manager changes the attribute objects. The default value is 1200. (Integer, optional)</p> <p>- attributeSizeLimit An integer that represents the maximum number of attribute object values that can cache in the attributes cache.</p> <p>Some attributes, for example, the member attribute, contain many values. The attributeSizeLimit parameter prevents the attributes cache to cache large attributes. The default value is 2000. (Integer, optional)</p>	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- serverTTLAttribute</p> <p>The name of the ttl attribute that is supported by the LDAP server. The attributes cache uses the value of this attribute to determine when the cached entries in the attributes cache will time out.</p> <p>The ttl attribute contains the time, in seconds, that any information from the entry should be kept by a client before it is considered stale and a new copy is fetched. A value of 0 implies that the object will not be cached.</p> <p>For more information about this attribute, go to:</p> <p>http://www.ietf.org/proceedings/98aug/I-D/draft-ietf-asid-ldap-cache-01.txt.</p> <p>The ttl attribute is not supported by all LDAP servers. If this attribute is supported by an LDAP server, you can set the value of the serverTTLAttribute parameter to the name of the ttl attribute in order to allow the value of the ttl attribute to determine when cached entries will time out. The time out value for different entries in attributes cache can be different.</p>	<p>Chapter 16. Security 1639</p>

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>For example, if the value of the serverTTLAttribute parameter is ttl and the attributes cache retrieves attributes of a user from an LDAP server, it will also retrieve the value of the ttl attribute of this user. If the value is 200, the WMM uses this value to set the time out for the attributes of the user in the attributes cache instead of using the value of cacheTimeout. You can set different ttl attribute values for different users. (String, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>setIdMgrLDAPContextPool</p>	<p>The setIdMgr LDAPContextPool command sets up the LDAP context pool configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - enabled By default, the context pool is enabled. If you set this parameter to false, the context pool is disabled. When the context pool is disabled, new context instances will be created for each request. The default value is true. (Boolean, optional) - initPoolSize The number of context instances that the the virtual member manager LDAP adapter creates when it creates the pool. The valid range for this parameter is 1 to 50. The default value is 1. (Integer, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPContextPool {-id <i>id1</i>} • Using Jython string: AdminTask.setIdMgrLDAPContextPool ('[-id <i>id1</i>']') • Using Jython list: AdminTask.setIdMgrLDAPContextPool (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPContextPool {-interactive} • Using Jython string: AdminTask.setIdMgrLDAPContextPool ('[-interactive]') • Using Jython list: AdminTask.setIdMgrLDAPContextPool (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- maxPoolSize</p> <p>The maximum number of context instances that the context pool will maintain. Context instances that are in use and those that are idle contribute to this number. When the pool size reaches this number, new context instances cannot be created for new requests. The new request is blocked until a context instance is released by another request or is removed. The request checks periodically if there are context instances available in the pool according to the amount of time that you specify using the poolWaitTime parameter.</p> <p>The minimum value for this parameter is 0. There is no maximum value. Setting the value of this parameter to 0 means that there is no maximum size and a request for a pooled context instance will use an existing pooled idle context instance or a newly created pooled context instance. The default value is 20. (Integer, optional)</p>	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- prefPoolSize</p> <p>The preferred number of context instances that the context pool will maintain. Context instances that are in use and those that are idle contribute to this number. When there is a request for the use of a pooled context instance and the pool size is less than the preferred size, the context pool creates and uses a new pooled context instance regardless of whether an idle connection is available. When a request finishes with a pooled context instance and the pool size is greater than the preferred size, the context pool closes and removes the pooled context instance from the pool.</p> <p>The valid range for this parameter is from 0 to 100. Setting the value of this parameter to 0 means that there is no preferred size and a request for a pooled context instance results in a newly created context instance only if no idle ones are available. The default value is 3.(Integer, optional)</p>	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- poolTimeOut An integer that represents the number of milliseconds that an idle context instance may remain in the pool without being closed and removed from the pool. When a context instance is requested from the pool, if this context already exists in the pool for more than the time defined by poolTimeout, this connection will be closed no matter this context instance is stale or active. A new context instance will be created and put back to the pool after it has been released from the request.</p> <p>The minimum value for this parameter is 0. There is no maximum value. Setting the value of this parameter to 0 means that the context instances in the pool will remain in the pool until they are staled. The context pool catches the communication exception and recreates a new context instance. The default value is 0.(Integer, optional)</p>	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- poolWaitTime The time interval in milliseconds that the request waits until the context pool rechecks if there are idle context instances available in the pool when the number of context instances reaches the maximum pool size. If no idle context instance, the request will continue waiting for the same period of time until next checking.</p> <p>The minimum value for the poolWaitout parameter is 0. There is no maximum value. A value of 0 for this parameter means that the context pool will not check if idle context exists. The request will be notified when a context instance releases from other requests. The default value is 3000.(Integer, optional)</p> <ul style="list-style-type: none"> Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>setIdMgr LDAPGroupConfig</p>	<p>The setIdMgr LDAPGroupConfig command sets up the LDAP group configuration.</p>	<ul style="list-style-type: none"> • Parameters: <li style="padding-left: 20px;">- id The ID of the repository. (String, required) <li style="padding-left: 20px;">- updateGroupMembership Updates the group membership if the member is deleted or renamed. Some LDAP servers, for example, Domino server, do not clean up the membership of the user when a user is deleted or renamed. If you choose these LDAP server types in the <code>ldapServerType</code> property, the value of this parameter is set to true. Use this parameter to change the value. The default value is false. (Boolean, optional) <li style="padding-left: 20px;">- name The name of the membership attribute. For example, <code>memberOf</code> in an active directory server and <code>ibm-allGroups</code> in IDS. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask setIdMgrLDAPGroupConfig {-id id1}</code> • Using Jython string: <code>AdminTask.setIdMgrLDAPGroupConfig ('[-id id1]')</code> • Using Jython list: <code>AdminTask.setIdMgrLDAPGroupConfig (['-id', 'id1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask setIdMgrLDAPGroupConfig {-interactive}</code> • Using Jython string: <code>AdminTask.setIdMgrLDAPGroupConfig ('[-interactive]')</code> • Using Jython list: <code>AdminTask.setIdMgrLDAPGroupConfig (['-interactive'])</code>

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- scope</p> <p>The scope of the membership attribute. The following are the possible values for this parameter:</p> <ul style="list-style-type: none"> • direct - The membership attribute only contains direct groups. Direct groups contain the member and are not contained through a nested group. For example, if group1 contains group2, group2 contains user1, then group2 is a direct group of user1, but group1 is not a direct group of user1. • nested - The membership attribute contains both direct groups and nested groups. • all - The membership attribute contains direct groups, nested groups, and dynamic members. <p>The default value is <code>direct</code>. (String, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>setIdMgr LDAPSearch ResultCache</p>	<p>The setIdMgr LDAPSearch ResultCache command sets up the LDAP search result cache configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - cachesDiskOffLoad Loads the attributes caches and the search results onto hard disk. By default, when the number of cache entries reaches the maximum size of the cache, cache entries are evicted to allow new entries to enter the caches. If you enable this parameter, the evicted cache entries will be copied to disk for future access. The default value is false. (Boolean, optional) - enabled Enables the search results cache. The default value is true. (Boolean, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPSearch ResultCache {-id <i>id1</i>} • Using Jython string: AdminTask.setIdMgrLDAPSearch ResultCache (['-id <i>id1</i>']) • Using Jython list: AdminTask.setIdMgrLDAPSearch ResultCache (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPSearch ResultCache {-interactive} • Using Jython string: AdminTask.setIdMgrLDAPSearch ResultCache (['-interactive']) • Using Jython list: AdminTask.setIdMgrLDAPSearch ResultCache (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- cacheSize The maximum size of the search results cache. The number of naming enumeration objects that can be put into the search results cache. The minimum value of this parameter is 100. The default value is 2000. (Integer, optional)</p> <p>- cacheTimeOut The amount of time in seconds before the cached entries in the search results cache can be not valid. The minimum value for this parameter is 0. A value of 0 means that the cached naming enumeration objects will stay in the search results cache until there are configuration changes. The default value is 600. (Integer, optional)</p>	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- searchResultSizeLimit The maximum number of entries contained in the naming enumeration object that can be cached in the search results cache. For example, if the results from a search contains 2000 users, the search results will not cache in the search results cache if the value of the of this property is set to 1000. The default value is 1000. (Integer, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>setIdMgr Entry Mapping Repository</p>	<p>The setIdMgr Entry Mapping Repository command sets or updates an entry mapping repository configuration.</p>	<ul style="list-style-type: none"> • Parameters: - dataSourceName The name of the data source. The default value is jdbc/wimDS. The parameter is required if the property extension is not set. The parameter is not required if the command is used to update the existing configuration. (String) - databaseType The type of the database. The default value is DB2. The parameter is required if the property extension is not set. The parameter is not required if the command is used to update the existing configuration. (String) - dbURL The URL of the database. The parameter is required if the property extension is not set. The parameter is not required if the command is used to update the existing configuration. (String) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrEntry MappingRepository {-dbAdminId <i>dbid1</i> -dbAdminPassword <i>pw1</i>} • Using Jython string: AdminTask.setIdMgrEntry MappingRepository ('[-dbAdminId <i>dbid1</i> -dbAdminPassword <i>pw1</i>]') • Using Jython list: AdminTask.setIdMgrEntry MappingRepository (['-dbAdminId', '<i>dbid1</i>', '-dbAdmin Password', '<i>pw1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrEntryMapping Repository {-interactive} • Using Jython string: AdminTask.setIdMgrEntryMapping Repository ('[-interactive]') • Using Jython list: AdminTask.setIdMgrEntryMapping Repository (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>updateIdMgr LDAPGroup Dynamic MemberAttr</p>	<p>The updateIdMgr LDAPGroup Dynamic MemberAttr command updates a dynamic member attribute configuration to an LDAP group configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - name The name of the LDAP attribute that is used as the group member attribute. For example, memberURL. (String, required) - objectClass The group object class that contains the dynamic member attribute. For example groupOfURLs. If you do not define this parameter, the dynamic member attribute will apply to all group object classes. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAPGroup DynamicMemberAttr {-id <i>id1</i> -name <i>name1</i> -objectClass <i>groupOfURLs</i>} • Using Jython string: AdminTask.updateIdMgrLDAPGroup DynamicMemberAttr ('[-id <i>id1</i> -name <i>name1</i> -objectClass <i>groupOfURLs</i>]') • Using Jython list: AdminTask.updateIdMgrLDAPGroup DynamicMemberAttr (['-id', '<i>id1</i>', '-name', '<i>name1</i>', '-objectClass', '<i>groupOfURLs</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAPGroup DynamicMemberAttr {-interactive} • Using Jython string: AdminTask.updateIdMgrLDAPGroup DynamicMemberAttr ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrLDAPGroup DynamicMemberAttr (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgr LDAPGroup MemberAttr	<p>The updateIdMgr LDAPGroup MemberAttr command updates a member attribute configuration of an LDAP group configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - name The name of the LDAP attribute that is used as the group member attribute. For example, member or uniqueMember. (String, required) - objectClass The group object class that contains the member attribute. For example, groupOfNames or groupOfUniqueNames. If you do not define this parameter, the member attribute applies to all group object classes. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAPGroupMemberAttr {-id <i>id1</i> -name <i>name1</i>} • Using Jython string: AdminTask.updateIdMgrLDAPGroupMemberAttr ('[-id <i>id1</i> -name <i>name1</i>]') • Using Jython list: AdminTask.updateIdMgrLDAPGroupMemberAttr (['-id', '<i>id1</i>', '-name', '<i>name1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAPGroupMemberAttr {-interactive} • Using Jython string: AdminTask.updateIdMgrLDAPGroupMemberAttr ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrLDAPGroupMemberAttr (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- scope The scope of the member attribute. The following are the valid values:</p> <ul style="list-style-type: none"> • direct - The member attribute only contains direct members whereby the member is directly contained by the group and not contained in a nested group. For example, if group1 contains group2, group2 contains user1, then group2 is a direct member of group1 but user1 is not a direct member of group1. Both member and uniqueMember are direct member attributes. • nested - The member attribute contains both direct members and nested members. 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> • all - The member attribute contains direct members, nested members and dynamic members. One example is the <code>ibm-allMembers</code> attribute that IBM Tivoli Directory Server supports. <p>The default value is <code>direct</code>. (String, optional)</p> <p>- dummyMember When you create a group without specifying a member, a dummy member will be filled in automatically to avoid receiving an exception that indicates that there is a mandatory attribute missing. (String, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateId MgrLDAP Repository	The updateId MgrLDAP Repository command updates an LDAP repository configuration.	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - ldapServerType The type of LDAP server that is being used. The default value is IDS51. (String, optional) - adapterClassName The default value is com.ibm.ws.wim.adapter.ldap.LdapAdapter. (String, optional) - certificateMapMode Specifies whether to map X.509 certificates into a LDAP directory by exact distinguished name or by certificate filter. The default value is exactdn. To use the certificate filter for the mapping, specify certificatefilter. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAP Repository {-id <i>id1</i>} • Using Jython string: AdminTask.updateIdMgrLDAP Repository ('[-id <i>id1</i>']') • Using Jython list: AdminTask.updateIdMgrLDAP Repository (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAP Repository {-interactive} • Using Jython string: AdminTask.updateIdMgrLDAP Repository ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrLDAP Repository (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- certificateFilter If certificateMapMode has the value certificatefilter, then this property specifies the LDAP filter which maps attributes in the client certificate to entries in LDAP. (String, optional)</p> <p>- isExtIdUnique Specifies if the external ID is unique. The default value is true. (Boolean, optional)</p> <p>- loginProperties Indicates the property name used for login. (String , optional)</p> <p>-</p> <p>primaryServerQueryTimeInterval Indicates the polling interval for testing the primary server availability. The value of this parameter is specified in minutes. The default value is 15. (Integer, optional)</p>	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - returnToPrimaryServer Indicates to return to the primary LDAP server when it is available. The default value is true. (Boolean, optional) - supportAsyncMode Indicates if the async mode is supported or not. The default value is false. (Boolean, optional) - supportSorting Indicates if sorting is supported or not. The default value is false. (Boolean, optional) - supportPaging Indicates if paging is supported or not. The default value is false. (Boolean, optional) - supportTransaction Indicates if transactions are supported or not. The default value is false. (Boolean, optional) 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - supportExternalName Indicates if external names are supported or not. The default value is <code>false</code>. (Boolean, optional) - sslConfiguration The SSL configuration. (String, optional) - translateRDN Indicates to translate RDN or not. The default value is <code>false</code>. (Boolean, optional) - searchTimeLimit The value of search time limit. (Integer, optional) - searchCountLimit The value of search count limit. (Integer, optional) - searchPageSize The value of search page size. (Integer, optional) • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgr LDAPSearch ResultCache	<p>The updateIdMgr LDAPSearch ResultCache command updates the LDAP search result cache configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - cachesDiskOffLoad Loads the attributes caches and the search results onto hard disk. By default, when the number of cache entries reaches the maximum size of the cache, cache entries are evicted to allow new entries to enter the caches. If you enable this parameter, the evicted cache entries will be copied to disk for future access. The default value is false. (Boolean, optional) - enabled Enables the search results cache. The default value is true. (Boolean, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAPSearchResultCache {-id id1} • Using Jython string: AdminTask.updateIdMgrLDAPSearchResultCache (['-id id1']) • Using Jython list: AdminTask.updateIdMgrLDAPSearchResultCache (['-id', 'id1']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAPSearchResultCache {-interactive} • Using Jython string: AdminTask.updateIdMgrLDAPSearchResultCache (['-interactive']) • Using Jython list: AdminTask.updateIdMgrLDAPSearchResultCache (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- cacheSize The maximum size of the search results cache. The number of naming enumeration objects that can be put into the search results cache. The minimum value of this parameter is 100. The default value is 2000. (Integer, optional)</p> <p>- cacheTimeOut The amount of time in seconds before the cached entries in the search results cache can be not valid. The minimum value for this parameter is 0. A value of 0 means that the cached naming enumeration objects will stay in the search results cache until there are configuration changes. The default value is 600. (Integer, optional)</p>	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- searchResultSizeLimit The maximum number of entries contained in the naming enumeration object that can be cached in the search results cache. For example, if the results from a search contains 2000 users, the search results will not cache in the search results cache if the value of the of this property is set to 1000. The default value is 1000. (Integer, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgr LDAPServer	<p>The updateIdMgr LDAPServer command updates an LDAP server configuration for the LDAP repository ID that you specify.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - host The host name for the LDAP server that contains the properties that you want to modify. (String, required) - port The port number for the LDAP server. (Integer, optional) - authentication Indicates the authentication method to use. The default value is simple. Valid values include: none or strong. (String, optional) - bindDN The binding domain name for the LDAP server. (String, optional) - bindPassword The binding password. The password is encrypted before it is stored. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrLDAPServer {-id <i>id1</i> -host <i>myhost.ibm.com</i>}</code> • Using Jython string: <code>AdminTask.updateIdMgrLDAPServer ('[-id <i>id1</i> -host <i>myhost.ibm.com</i>']')</code> • Using Jython list: <code>AdminTask.updateIdMgrLDAPServer (['-id', '<i>id1</i>', '-host', '<i>myhost.ibm.com</i>'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrLDAPServer {-interactive}</code> • Using Jython string: <code>AdminTask.updateIdMgrLDAPServer ('[-interactive]')</code> • Using Jython list: <code>AdminTask.updateIdMgrLDAPServer (['-interactive'])</code>

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>-</p> <p>certificateMapMode Specifies whether to map X.509 certificates into a LDAP directory by exact distinguished name or by certificate filter. The default value is exactdn. To use the certificate filter for the mapping, specify certificatefilter. (String, optional)</p> <p>- certificateFilter If certificateMapMode has the value certificatefilter, then this property specifies the LDAP filter which maps attributes in the client certificate to entries in LDAP. (String, optional)</p> <p>- connectTimeout The connection timeout measured in seconds. The default value is 0. (Integer, optional)</p> <p>- connectionPool The connection pool. The default value is false. (Boolean, optional)</p>	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- derefAliases Controls how aliases are dereferenced. The default value is always. Valid values include:</p> <ul style="list-style-type: none"> • never - never deference aliases • finding - deferences aliases only during name resolution • searching - deferences aliases only after name resolution <p>(String, optional)</p> <p>- ldapServerType The type of LDAP server being used. The default value is IDS51. (String, optional)</p> <p>- primary_host The host name for the primary LDAP server. (String, optional)</p> <p>- referral The LDAP referral. The default value is ignore. Valid values include: follow, throw, or false. (String, optional)</p>	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - sslConfiguration The SSL configuration. (String, optional) - sslEnabled Indicates to enable SSL or not. The default value is false. (Boolean, optional) • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgr Repository	The updateIdMgr Repository command updates the common repository configuration.	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - adapterClassName The implementation class name for the repository adapter. (String, optional) - EntityTypesNotAllowCreate The name of the entity type that should not be created in this repository. (String, optional) - EntityTypesNotAllowUpdate The name of the entity type that should not be updated in this repository. (String, optional) - EntityTypesNotAllowRead The name of the entity type that should not be read from this repository. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrRepository {-id <i>id1</i>} • Using Jython string: AdminTask.updateIdMgrRepository ('[-id <i>id1</i>']') • Using Jython list: AdminTask.updateIdMgrRepository (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrRepository {-interactive} • Using Jython string: AdminTask.updateIdMgrRepository ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrRepository (['-interactive'])

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - EntityTypesNotAllowDelete The name of the entity type that should not be deleted from this repository. (String, optional) - loginProperties (String, optional) - readOnly Indicates if this is a read only repository. The default value is false. (Boolean, optional) - repositoriesForGroups The repository ID where group data is stored. (String, optional) - supportPaging Indicates if the repository supports paging or not. (Boolean, optional) - supportSorting Indicates if the repository supports sorting or not. (Boolean, optional) 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - supportTransaction Indicates if the repository supports transaction or not. (Boolean, optional) - isExtIdUnique Specifies if the external ID is unique or not. (Boolean, optional) - supportedExternalName Indicates if the repository supports external names or not. (Boolean, optional) - supportAsyncMode Indicates if the adapter supports async mode or not. The default value is false. (Boolean, optional) <ul style="list-style-type: none"> • Returns: None 	

Table 32. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgr Repository BaseEntry	The updateIdMgr Repository BaseEntry command updates a base entry to the specified repository.	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - name The distinguished name of a base entry. (String, required) - nameInRepository The distinguished name in the repository that uniquely identifies the base entry name. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrRepositoryBaseEntry {-id <i>id1</i> name <i>name1</i>}</code> • Using Jython string: <code>AdminTask.updateIdMgrRepositoryBaseEntry ('[-id <i>id1</i> name <i>name1</i>']')</code> • Using Jython list: <code>AdminTask.updateIdMgrRepositoryBaseEntry (['-id', '<i>id1</i>', 'name', '<i>name1</i>'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrRepositoryBaseEntry {-interactive}</code> • Using Jython string: <code>AdminTask.updateIdMgrRepositoryBaseEntry ('[-interactive]')</code> • Using Jython list: <code>AdminTask.updateIdMgrRepositoryBaseEntry (['-interactive'])</code>

Commands for the IdMgrRealmConfig group of the AdminTask object

Use the commands in the IdMgrConfig group to configure the member manager realm and realms. The commands for this group do not require a target object. To see the additional commands related to the member manager, see the `Commands for the IdMgrRepositoryConfig group of the AdminTask object and the Commands for the IdMgrConfig group of the AdminTask object articles.

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the IdMgrRealmConfig group of the AdminTask object:

Table 33.

Command name:	Description:	Parameters and return values:	Examples:
addIdMgrRealmBaseEntry	<p>The addIdMgrRealmBaseEntry command adds a base entry to a specified realm configuration.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) - baseEntry The name of a base entry. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask addIdMgrRealmBaseEntry {-name realm1 -baseEntry entry1}</pre> • Using Jython string: <pre>AdminTask addIdMgrRealmBaseEntry ('[-name realm1 -baseEntry entry1]')</pre> • Using Jython list: <pre>AdminTask addIdMgrRealmBaseEntry (['-name', 'realm1', '-baseEntry', 'entry1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask addIdMgrRealmBaseEntry {-interactive}</pre> • Using Jython string: <pre>AdminTask.addIdMgrRealmBaseEntry ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.addIdMgrRealmBaseEntry (['-interactive'])</pre>

Table 33. (continued)

Command name:	Description:	Parameters and return values:	Examples:
createIdMgrRealm	<p>The createIdMgrRealm command creates a realm configuration.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) - securityUse A string that indicates if this virtual realm will be used in security now, later, or never. The default value is active. Additional values includes: inactive and nonSelectable. (String, optional) - delimiter The delimiter used for this realm. The default value is @. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createIdMgrRealm {-name realm1} • Using Jython string: AdminTask.createIdMgrRealm ('[-name realm1]') • Using Jython list: AdminTask.createIdMgrRealm (['-name', 'realm1']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createIdMgrRealm {-interactive} • Using Jython string: AdminTask.createIdMgrRealm ('[-interactive]') • Using Jython list: AdminTask.createIdMgrRealm (['-interactive'])
deleteIdMgrRealm	<p>The deleteIdMgrRealm command deletes the realm configuration that you specified.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrRealm {-name realm1} • Using Jython string: AdminTask.deleteIdMgrRealm ('[-name realm1]') • Using Jython list: AdminTask.deleteIdMgrRealm (['-name', 'realm1']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrRealm {-interactive} • Using Jython string: AdminTask.deleteIdMgrRealm ('[-interactive]') • Using Jython list: AdminTask.deleteIdMgrRealm (['-interactive'])

Table 33. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>deleteIdMgr RealmBaseEntry</p>	<p>The deleteIdMgr RealmBaseEntry command deletes a base entry from a realm configuration that you specified.</p> <p>The realm must always contain at least one base entry, thus you cannot remove every entry.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) - baseEntry The name of a base entry. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteIdMgrRealmBaseEntry {-name realm1 -baseEntry entry1}</pre> • Using Jython string: <pre>AdminTask.deleteIdMgrRealmBaseEntry (['-name realm1 -baseEntry entry1'])</pre> • Using Jython list: <pre>AdminTask.deleteIdMgrRealmBaseEntry (['-name', 'realm1', '-baseEntry', 'entry1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteIdMgrRealmBaseEntry {-interactive}</pre> • Using Jython string: <pre>AdminTask.deleteIdMgrRealmBaseEntry (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.deleteIdMgrRealmBaseEntry (['-interactive'])</pre>
<p>getIdMgrDefaultRealm</p>	<p>The getIdMgrDefaultRealm command returns the default realm name.</p>	<ul style="list-style-type: none"> • Parameters: None • Returns: The name of the default realm. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrDefaultRealm</pre> • Using Jython string: <pre>AdminTask.getIdMgrDefaultRealm()</pre> • Using Jython list: <pre>AdminTask.getIdMgrDefaultRealm()</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrDefaultRealm {-interactive}</pre> • Using Jython string: <pre>AdminTask.getIdMgrDefaultRealm (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.getIdMgrDefaultRealm (['-interactive'])</pre>

Table 33. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>getIdMgrRepositories ForRealm</p>	<p>The getIdMgrRepositories ForRealm command returns repository specific details for the repositories configured for a specified realm.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) • Returns: A hash map with the following keys: <ul style="list-style-type: none"> - id - The repository ID. - repositoryType - The type of repository, for example, File, LDAP, DB, and so on. - specificRepositoryType - The specific type of repository, for example, for LDAP, IDS51, NDS, and so on. - host - The host name where the repository resides. For example, for File, LocalHost or for DB, dataSourceName. - port - The port number. This only applies to LDAP. - name - The name of the base entry. - nameInRepository - The name in repository for the base entry. <p>This command will not return the property extension and entry mapping repository data.</p>	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrRepositories ForRealm {-name realm1}</pre> • Using Jython string: <pre>AdminTask.getIdMgrRepositories ForRealm ('[-name realm1]')</pre> • Using Jython list: <pre>AdminTask.getIdMgrRepositories ForRealm (['-name', 'realm1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrRepositories ForRealm {-interactive}</pre> • Using Jython string: <pre>AdminTask.getIdMgrRepositories ForRealm (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.getIdMgrRepositories ForRealm (['-interactive'])</pre>

Table 33. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getIdMgrRealm	The getIdMgrRealm command returns the configuration parameters for the realm that you specified.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) • Returns: A hash map that contains keys as the parameters of the createIdMgrRealm command. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrRealm {-name <i>realm1</i>} • Using Jython string: AdminTask.getIdMgrRealm ('[-name <i>realm1</i>']') • Using Jython list: AdminTask.getIdMgrRealm (['-name', '<i>realm1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrRealm {-interactive} • Using Jython string: AdminTask.getIdMgrRealm ('[-interactive]') • Using Jython list: AdminTask.getIdMgrRealm (['-interactive'])
listIdMgrRealms	The listIdMgrRealms command returns all of the names of the configured realms.	<ul style="list-style-type: none"> • Parameters: None • Returns: A list that contains the name of the configured realms. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRealms • Using Jython string: AdminTask.listIdMgrRealms() • Using Jython list: AdminTask.listIdMgrRealms() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRealms {-interactive} • Using Jython string: AdminTask.listIdMgrRealms ('[-interactive]') • Using Jython list: AdminTask.listIdMgrRealms (['-interactive'])

Table 33. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgrRealmBaseEntries	The listIdMgrRealmBaseEntries command returns all of the names of the configured realms.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) • Returns: A list of all the base entries of the specified realm. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRealmBaseEntries {-name <i>realm1</i>} • Using Jython string: AdminTask.listIdMgrRealmBaseEntries ('[-name <i>realm1</i>']') • Using Jython list: AdminTask.listIdMgrRealmBaseEntries (['-name', '<i>realm1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRealmBaseEntries {-interactive} • Using Jython string: AdminTask.listIdMgrRealmBaseEntries ('[-interactive]') • Using Jython list: AdminTask.listIdMgrRealmBaseEntries (['-interactive'])
renameIdMgrRealm	The renameIdMgrRealm command renames the name of the realm that you specified.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask renameIdMgrRealm {-name <i>realm1</i>} • Using Jython string: AdminTask.renameIdMgrRealm ('[-name <i>realm1</i>']') • Using Jython list: AdminTask.renameIdMgrRealm (['-name', '<i>realm1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask renameIdMgrRealm {-interactive} • Using Jython string: AdminTask.renameIdMgrRealm ('[-interactive]') • Using Jython list: AdminTask.renameIdMgrRealm (['-interactive'])

Table 33. (continued)

Command name:	Description:	Parameters and return values:	Examples:
setIdMgrDefaultRealm	<p>The setIdMgrDefaultRealm command sets up the default realm configuration.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name of the realm that is used as a default realm when the caller does not specify any in context. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrDefaultRealm {-name <i>realm1</i>} • Using Jython string: AdminTask.setIdMgrDefaultRealm ('[-name <i>realm1</i>']') • Using Jython list: AdminTask.setIdMgrDefaultRealm (['-name', '<i>realm1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrDefaultRealm {-interactive} • Using Jython string: AdminTask.setIdMgrDefaultRealm ('[-interactive]') • Using Jython list: AdminTask.setIdMgrDefaultRealm (['-interactive'])

Table 33. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgrRealm	<p>The updateIdMgrRealm command updates the configuration for a realm that you specify.</p>	<ul style="list-style-type: none"> • Parameters: - name The realm name. (String, required) - securityUse A string that indicates if this realm will be used in security now, later, or never. The default value is active. Additional values includes: inactive and nonSelectable. (String, optional) - delimiter The delimiter used for this realm. The default value is @. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrRealm {-name <i>realm1</i>} • Using Jython string: AdminTask.updateIdMgrRealm ('[-name <i>realm1</i>']') • Using Jython list: AdminTask.updateIdMgrRealm (['-name', '<i>realm1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrRealm {-interactive} • Using Jython string: AdminTask.updateIdMgrRealm ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrRealm (['-interactive'])

Commands for the WIMManagementCommands group of the AdminTask object

Use the commands in the WIMManagementCommands group to configure the virtual member manager. The commands for this group do not require a target object. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the WIMManagementCommands group of the AdminTask object:

Table 34.

Command name:	Description:	Parameters and return values:	Examples:
addMemberToGroup	<p>The addMemberToGroup command adds a user or a group to a group.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - memberUniqueName Specifies the unique name value for the user or group that you want to add to the specified group. This parameter maps to the <code>uniqueName</code> property in the virtual member manager. (String, required) - groupUniqueName Specifies the unique name value for the group to which you want to add the user or group that you specified in the <code>memberUniqueName</code> parameter. This parameter maps to the <code>uniqueName</code> property in virtual member manager. (String, required) • Returns: Void if the command is successful. Returns an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask addMemberToGroup {-memberUniqueName uid= meyersd,cn=users,dc=yourco, dc=com -groupUniqueName cn=admins,cn=groups, dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.addMemberToGroup (['-memberUniqueName uid=meyersd,cn=users, dc=yourco,dc=com -group UniqueName cn=admins, cn=groups,dc=yourco, dc=com']')</pre> • Using Jython list: <pre>AdminTask.addMemberToGroup (['-memberUniqueName', 'uid=meyersd,cn=users,dc= yourco,dc=com', '-group UniqueName', 'cn=admins, cn=groups,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask addMemberToGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.addMemberToGroup (['-interactive']')</pre> • Using Jython list: <pre>AdminTask.addMemberToGroup (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
createGroup	<p>The createGroup command creates a new group in the virtual member manager. After the command completes, the new group will appear in the repository. For LDAP, a group must contain a member. The <code>memberUniqueName</code> parameter is optional in this case. If you set the <code>memberUniqueName</code> parameter to the unique name of a group or a user, the group or user will be added as a member of the group.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - cn Specifies the common name for the group that you want to create. This parameter maps to the <code>cn</code> property in virtual member manager. (String, required) - description Specifies additional information about the group that you want to create. This parameter maps to the <code>description</code> property in a virtual member manager object. (String, optional) - parent Specifies the repository in which you want to create the group. This parameter maps to the <code>parent</code> property in the virtual member manager. (String, optional) - memberUniqueName Specifies the unique name value for the user or group that you want to add to the new group. This parameter maps to the <code>uniqueName</code> property in the virtual member manager. (String, optional) • Returns: The unique name of the group that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createGroup {-cn groupA -description a group of admins}</code> • Using Jython string: <code>AdminTask.createGroup (['-cn groupA -description a group of admins'])</code> • Using Jython list: <code>AdminTask.createGroup (['-cn', 'groupA', '-description', 'a group of admins'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createGroup {-interactive}</code> • Using Jython string: <code>AdminTask.createGroup (['-interactive'])</code> • Using Jython list: <code>AdminTask.createGroup (['-interactive'])</code>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
createUser	<p>The createUser command creates a new user in the default repository or a repository that the parent command parameter specifies. This command creates a person entity and a login account entity in the virtual member manager.</p>	<ul style="list-style-type: none"> • Parameters: - uid Specifies the unique ID for the user that you want to create. Virtual member manager then creates a uniqueId value and a uniqueName value for the user. This parameter maps to the uid property in the virtual member manager. (String, required) - password Specifies the password for the user. This parameter maps to the password property in the virtual member manager. (String, required) - confirmPassword Specifies the password again to validate how it was entered for the password parameter. This parameter maps to the password property in virtual member manager. (String, optional) - cn Specifies the first name or given name of the user. This parameter maps to the cn property in virtual member manager. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createUser {-uid 123 -password tempPass -confirmPassword tempPass -cn Jane -surname Doe -ibm-primaryEmail janedoe@acme.com}</pre> • Using Jython string: <pre>AdminTask.createUser ('[-uid 123 -password tempPass -confirmPassword tempPass -cn Jane -surname Doe -ibm-primaryEmail janedoe@acme.com]')</pre> • Using Jython list: <pre>AdminTask.createUser (['-uid', '123', '-password', 'tempPass', '-confirmPassword', 'tempPass', '-cn', 'Jane', '-surname', 'Doe', '-ibm-primaryEmail', 'janedoe@acme.com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createUser {-interactive}</pre> • Using Jython string: <pre>AdminTask.createUser ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.createUser (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> <li data-bbox="721 304 1029 562"> <p>- surname Specifies the last name or family name of the user. This parameter maps to the sn property in virtual member manager. (String, optional)</p> <li data-bbox="721 583 1029 842"> <p>- ibm-primaryEmail Specifies the e-mail address of the user. This parameter maps to the ibm-PrimaryEmail property in the virtual member manager. (String, optional)</p> <li data-bbox="721 863 1029 1121"> <p>- parent Specifies the repository in which you want to create the user. This parameter maps to the parent property in the virtual member manager. (String, optional)</p> <li data-bbox="721 1142 1029 1209"> <p>• Returns: The unique name of the user that you created.</p> 	

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
deleteGroup	<p>The deleteGroup command deletes a group in the virtual member manager. You cannot use this command to delete descendants. When this command completes, the group will be deleted from the repository.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the group that you want to delete. This parameter maps to the uniqueName property in virtual member manager. (String, required) • Returns: Void if the command is successful. Returns an error if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteGroup {-uniqueName cn=opera tors,cn=users,dc=yourco, dc=com}</pre> • Using Jython string: <pre>AdminTask.deleteGroup (['-uniqueName cn=ope rators,cn=users,dc=you rco,dc=com']')</pre> • Using Jython list: <pre>AdminTask.deleteGroup (['-uniqueName', 'cn =operators,cn=users,dc =yourco,dc=com']')</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.deleteGroup (['-interactive']')</pre> • Using Jython list: <pre>AdminTask.deleteGroup (['-interactive']')</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
deleteUser	<p>The deleteUser command deletes a user from the virtual member manager. This includes a person object and an account object in the non-merged repositories.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the user that you want to delete. This parameter maps to the uniqueName property in virtual member manager. (String, required) • Returns: Void if the command is successful and an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteUser {-uniqueName uid=dmey ers,cn=users,dc=yourco, dc=com}</pre> • Using Jython string: <pre>AdminTask.deleteUser ('[-uniqueName uid= dmeyers,cn=users,dc= yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.deleteUser ([-uniqueName', 'uid=dm eyers,cn=users,dc=yourco, dc=com']])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteUser {-interactive}</pre> • Using Jython string: <pre>AdminTask.deleteUser ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.deleteUser (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
duplicate MembershipOfGroup	<p>Use the duplicate MembershipOfGroup command to make a one group a member of all of the same groups as another group. For example, group A is in group B and group C. To add group D to the same groups as group A, use the duplicate MembershipOfGroup command.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - copyToName Specifies the name of the group to which you want to add the memberships of the group specified in the copyFromName parameter. (String, required) - copyFromName Specifies the name of the group from which you want to copy the group memberships for another group to use. (String, required) • Returns: Void if the command is successful. Returns an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask duplicateMembershipOfGroup {-copyToName cn=operators,cn=groups,dc=yourco,dc=com -copyFromName cn=admins,cn=groups,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.duplicateMembershipOfGroup ('[-copyToName cn=operators,cn=groups,dc=yourco,dc=com -copyFromName cn=admins,cn=groups,dc=yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.duplicateMembershipOfGroup (['-copyToName', 'cn=operators,cn=groups,dc=yourco,dc=com', '-copyFromName', 'cn=admins,cn=groups,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask duplicateMembershipOfGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.duplicateMembershipOfGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.duplicateMembershipOfGroup (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>duplicate Membership OfUser</p>	<p>Use the duplicate Membership OfUser command to make a one user a member of all of the same groups as another user. For example, user 1 is in group B and group C. To add user 2 to the same groups as user 1, use the duplicate Membership OfUser command.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - copyToName Specifies the name of the user to which you want to add the memberships of the user specified in the copyFromName parameter. (String, required) - copyFromName Specifies the name of the user from which you want to copy the group memberships for another user to use. (String, required) • Returns: Void if the command is successful. Returns an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask duplicateMembershipOfUser {-copyToName uid=meyersd,cn=users,dc=yourco,dc=com -copyFromName uid=jhart,cn=users,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.duplicateMembershipOfUser ('[-copyToName uid=meyersd,cn=users,dc=yourco,dc=com -copyFromName uid=jhart,cn=users,dc=yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.duplicateMembershipOfUser (['-copyToName', 'uid=meyersd,cn=users,dc=yourco,dc=com', '-copyFromName', 'uid=jhart,cn=users,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask duplicateMembershipOfUser {-interactive}</pre> • Using Jython string: <pre>AdminTask.duplicateMembershipOfUser ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.duplicateMembershipOfUser (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getGroup	<p>The getGroup command retrieves the common name and description of a group.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the group that you want to view. This parameter maps to the uniqueName property in virtual member manager. (String, required) • Returns: A map of common name and description properties. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getGroup {-uniqueName cn=operators, cn=groups,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.getGroup ('[-uniqueName cn=operators, cn=groups,dc=yourco, dc=com]')</pre> • Using Jython list: <pre>AdminTask.getGroup ([' -uniqueName', 'cn=opera tors,cn=groups,dc=your co,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.getGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getGroup (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getMembership OfGroup	<p>The getMembership OfGroup command retrieves the groups of which a group is a member.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the group whose group memberships you want to view. This parameter maps to the uniqueName property in virtual member manager. (String, required) • Returns: A list of unique names of each of the groups of which the group is a member. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMebmership OfGroup {-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.getMebmership OfGroup ('[-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.getMebmership OfGroup (['-uniqueName', 'uid=dmeyers,cn=users,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMembership OfGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.getMembership OfGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getMembership OfGroup (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getMembershipOfUser	<p>The getMembershipOfUser command retrieves the groups of which a user is a member.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the user whose group memberships you want to view. This parameter maps to the <code>uniqueName</code> property in virtual member manager. (String, required) • Returns: A list of unique names for each group of which the user is a member. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMembershipOfUser {-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.getMembershipOfUser ('[-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.getMembershipOfUser (['-uniqueName', 'uid=dmeyers,cn=users,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMembershipOfUser {-interactive}</pre> • Using Jython string: <pre>AdminTask.getMembershipOfUser ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getMembershipOfUser (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getMembers OfGroup	<p>The getMembers OfGroup command retrieves the members of a group.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the group whose members you want to view. This parameter maps to the uniqueName property in virtual member manager. (String, required) • Returns: The unique name of each of the members of the group and the type of each member. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMembersOfGroup {-uniqueName cn=operators,cn=groups ,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.getMembersOfGroup [('-uniqueName cn=operators,cn=groups ,dc=yourco,dc=com')]</pre> • Using Jython list: <pre>AdminTask.getMembersOfGroup [('-uniqueName', 'cn=operators,cn=groups ,dc=yourco,dc=com')]</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMembersOfGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.getMembersOfGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getMembersOfGroup (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>getUser</p>	<p>The getUser command retrieves information about a user in the virtual member manager.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the user that you want to view. This parameter maps to the uniqueName property in the virtual member manager. (String, required) • Returns: A map that contains the following properties: uniqueName, cn, sn, uid, and ibm-primaryEmail. These attributes are fixed and you cannot change them. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getUser {-user Name uid=dmeyers,cn=users,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.getUser ('[-use rName uid=dmeyers,cn=users,dc=yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.getUser (['-use rName', 'uid=dmeyers,cn=users,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getUser {-interactive}</pre> • Using Jython string: <pre>AdminTask.getUser (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.getUser (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>removeMember FromGroup</p>	<p>The removeMember FromGroup command removes a user or a group from a group.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - memberUniqueName Specifies the unique name value for the user or group that you want to remove from the specified group. This parameter maps to the <code>uniqueName</code> property in virtual member manager. (String, required) - groupUniqueName Specifies the unique name value for the group from which you want to remove the user or group that you specified with the <code>memberUniqueName</code> parameter. This parameter maps to the <code>uniqueName</code> property in virtual member manager. (String, required) • Returns: Void if the command is successful. Returns an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask removeMember FromGroup {-memberUnique Name uid=meyersd,cn= users,dc=yourco,dc=com -groupUniqueName cn= admins,cn-groups,dc= yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.removeMemberF romGroup ('[-memberUnique Name uid=meyersd,cn= users,dc=yourco,dc=com -groupUniqueName cn=a dmns,cn-groups,dc=your co,dc=com]')</pre> • Using Jython list: <pre>AdminTask.removeMemberFrom Group (['-memberUniqueName', 'uid=meyersd,cn=users, dc=yourco,dc=com', '-groupUniqueName', 'cn=admins,cn-groups,dc= yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask removeMember FromGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.removeMemberFr omGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.removeMemberFr omGroup (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
searchGroups	<p>Use the searchGroups command to find groups in the virtual member manager that match criteria that you provide. For example, you can use the searchGroups command to find all of the groups with a common name that begins with IBM. You can search for any virtual member manager property because the command is generic.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - cn The first name or given name of the user. This parameter maps to the cn property in the virtual member manager. You must set this parameter or the description parameter, but not both. (String, optional) - description Specifies information about the group. This parameter maps to the description entity in a virtual member manager object. You must set this parameter or the cn parameter, but not both. (String, optional) - timeLimit Specifies the maximum amount of time in milliseconds that the search can run. The default value is no time limit. (String, optional) - countLimit Specifies the maximum number of results that you want returned from the search. By default, all groups found in the search are returned. (String, optional) • Returns: A list of unique names of all of the groups that match the search criteria that you provided. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask searchGroups {cn *IBM*} • Using Jython string: AdminTask.searchGroups ('[cn *IBM*]') • Using Jython list: AdminTask.searchGroups (['cn', '*IBM*']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask searchGroups {-interactive} • Using Jython string: AdminTask.searchGroups ('[-interactive]') • Using Jython list: AdminTask.searchGroups (['-interactive'])

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
searchUsers	<p>Use the searchUsers command to find users in the virtual member manager that match criteria that you provide. For example, you can use the searchUsers command to find all of the telephone numbers that contain 919. You can search for any virtual member manager property because the command is generic.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - principalName Specifies the principal name of the user that is used as the logon ID for the user in the system. This parameter maps to the principalName property in virtual member manager. You must specify only one of the following parameters: principalName, uid, cn, sn, or ibm-primaryEmail. (String, optional) - uid Specifies the unique ID value for the user for whom you want to search. This parameter maps to the uid property in virtual member manager. You must specify only one of the following parameters: principalName, uid, cn, sn, or ibm-primaryEmail. (String, optional) - cn Specifies the first name or given name of the user. This parameter maps to the cn property in virtual member manager. You must specify only one of the following parameters: principalName, uid, cn, sn, or ibm-primaryEmail. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask searchUsers {-principalName */IBM/US*} • Using Jython string: AdminTask.searchUsers ('[-principalName */IBM/US*]') • Using Jython list: AdminTask.searchUsers (['-principalName', '*/IBM/US*']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask searchUsers {-interactive} • Using Jython string: AdminTask.searchUsers ('[-interactive]') • Using Jython list: AdminTask.searchUsers (['-interactive'])

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- sn Specifies the last name or family name of the user. This parameter maps to the sn property in virtual member manager. You must specify only one of the following parameters: principalName, uid, cn, sn, or ibm-primaryEmail. (String, optional)</p> <p>- ibm-primaryEmail Specifies the email address of the user. This parameter maps to the ibm-PrimaryEmail property in the virtual member manager. You must specify only one of the following parameters: principalName, uid, cn, sn, or ibm-primaryEmail. (String, optional)</p> <p>- timeLimit Specifies the maximum amount of time in milliseconds that the search can run. The default is not time limit. (String, optional)</p> <p>- countLimit Specifies the maximum number of results that you want returned from the search. By default, all users found in the search are returned. (String, optional)</p> <ul style="list-style-type: none"> • Returns: A list of unique names of all of the users that match the search criteria that you provided. 	

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateGroup	<p>The updateGroup command updates the common name or the description of a group.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the group for which you want to modify the properties. This parameter maps to the uniqueName property in virtual member manager. (String, required) - cn Specifies the new common name used for the group. This parameter maps to the cn property in virtual member manager. (String, optional) - description Specifies the new information about the group. This parameter maps to the description entity in a virtual member manager object. (String, optional) • Returns: Void if the command is successful. Returns an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateGroup {-uniqueName cn=operators,cn=groups,dc=yourco,dc=com -cn groupA} • Using Jython string: AdminTask.updateGroup ('[-uniqueName cn=operators,cn=groups,dc=yourco,dc=com -cn groupA]') • Using Jython list: AdminTask.updateGroup (['-uniqueName', 'cn=operators,cn=groups,dc=yourco,dc=com', '-cn', 'groupA']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateGroup {-interactive} • Using Jython string: AdminTask.updateGroup ('[-interactive]') • Using Jython list: AdminTask.updateGroup (['-interactive'])

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateUser	<p>The updateUser command updates the following properties: uniqueName, uid, password, cn, sn, or ibm-primaryEmail.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the user for which you want to modify the properties. This parameter maps to the uniqueName property in virtual member manager. (String, required) - uid Specifies the new unique ID value for the user. This parameter maps to the uid property in virtual member manager. (String, optional) - password Specifies the new password for the user. This parameter maps to the password property in virtual member manager. (String, optional) - confirmPassword Specifies the password again to validate how it was entered on the password parameter. This parameter maps to the password property in virtual member manager. (String, optional) - cn Specifies the new first name or given name of the user. This parameter maps to the cn property in virtual member manager. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask updateUser {-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com -uid 123}</pre> • Using Jython string: <pre>AdminTask.updateUser ('[-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com -uid 123]')</pre> • Using Jython list: <pre>AdminTask.updateUser (['-uniqueName', 'uid=dmeyers,cn=users,dc=yourco,dc=com', '-uid', '123'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask updateUser {-interactive}</pre> • Using Jython string: <pre>AdminTask.updateUser ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.updateUser (['-interactive'])</pre>

Table 34. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - surname Specifies the new last name or family name of the user. This parameter maps to the sn property in virtual member manager. (String, optional) - ibm-primaryEmail Specifies the new e-mail address of the user. This parameter maps to the mail property in virtual member manager. (String, optional) • Returns: Void if the command is successful. Returns an exception if the command fails. 	

Commands for the KeyStoreCommands group of the AdminTask object

Use the commands in the KeyStoreCommands group to create or delete key stores. The commands for this group do not require a target object. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the KeyStoreCommands group of the AdminTask object:

Table 35.

Command name:	Description:	Parameters and return values:	Examples:
<p>changeKey Store Password</p>	<p>The changeKey Store Password command changes the password on the key store.</p>	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - keyStorePassword The password that protects the key store that you want to change. (String, required) - newkeyStorePassword The new password that protects the key store. (String, required) - newkeyStorePassword Verify The new password that protects the key store. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask changeKeyStore Password {-keyStoreName testKS -keyStorePassword testpwd -newKeyStorePassword keyPWD -newKeyStorePasswordVerify keyPWD}</pre> • Using Jython string: <pre>AdminTask.changeKeyStore Password ('[-keyStoreName testKS -keyStorePassword testpwd -newKeyStorePassword keyPWD -newKeyStorePassword Verify keyPWD]')</pre> • Using Jython list: <pre>AdminTask.changeKeyStore Password (['-keyStoreName', 'testKS', '-keyStorePassword', 'testpwd', '-newKeyStorePassword', 'keyPWD', '-newKeyStorePasswordVerify', 'keyPWD'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask changeKeyStore Password {-interactive}</pre> • Using Jython string: <pre>AdminTask.changeKeyStore Password ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.changeKeyStore Password (['-interactive'])</pre>

Table 35. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>change Multiple KeyStore Passwords</p>	<p>The change Multiple KeyStore Passwords command updates all of the key stores in the configuration that have a give password and changed them to a new password. This is useful because when you create key store files on the system, they will have WebAS as a password by default.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStorePassword Specifies the name of the password that you want to change. (String, required) - newKeyStorePassword Specifies the new password that you will use to access the key store. (String, required) - newKeyStorePassword Verify Confirms the new key store password. (String, required) • Returns: A list of key store aliases that where changed 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask changeMultipleKeyStorePasswords {-keyStorePassword WebAS -newKeyStorePassword newpwd -newKeyStorePassword Verify newpwd}</pre> • Using Jython string: <pre>AdminTask.changeMultipleKeyStorePasswords ('[-keyStorePassword WebAS -newKeyStorePassword newpwd -newKeyStorePasswordVerify newpwd]')</pre> • Using Jython list: <pre>AdminTask.changeMultipleKeyStorePasswords (['-keyStorePassword', 'WebAS', '-newKeyStorePassword', 'newpwd', '-newKeyStorePasswordVerify', 'newpwd'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask changeMultipleKeyStorePasswords {-interactive}</pre> • Using Jython string: <pre>AdminTask.changeMultipleKeyStorePasswords (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.changeMultipleKeyStorePasswords (['-interactive'])</pre>

Table 35. (continued)

Command name:	Description:	Parameters and return values:	Examples:
createKeyStore	The createKeyStore command creates the key store settings in the configuration and the key store database.	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreType The implementation of the key store management. (String, required) - keyStoreLocation The location of the key store. For file based, the location is the files system path to the key store database. For hardware key store, the location is the path to the token library. (String, required) - keyStorePassword The password that protects the key store. (String, required) - keyStorePasswordVerify The password that protects the key store. (String, required) - keyStoreProvider The provider used to implement the key store. (String, optional) - isKeyStoreFileBased Set the value of this parameter to true if the key store is file based. Set the value of this parameter to false for hardware crypto key stores. (Boolean, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeyStore {-keyStoreName testKS -location c:\temp\test KeyFile.p12 keyStorePass word testpwd -keyStore PasswordVerify testpwd -isKeyStoreFileBased true -keyStoreInitAtStartup true -keyStoreReadOnly false}</pre> • Using Jython string: <pre>AdminTask.createKeyStore (['-keyStoreName testKS -location c:\temp\testKey File.p12 keyStorePass word testpwd -keyStorePass wordVerify testpwd -isKey StoreFileBased true -key StoreInitAtStartup true -keyStoreReadOnly false'])</pre> • Using Jython list: <pre>AdminTask.createKeyStore (['-keyStoreName', 'testKS', '-location', 'c:\temp\test KeyFile.p12', 'keyStorePass word', 'testpwd', '-keySto rePasswordVerify', 'testpwd', '-isKeyStoreFileBased', 'true', '-keyStoreInitAt Startup', 'true', '-key StoreReadOnly', 'false'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKey Store {-interactive}</pre> • Using Jython string: <pre>AdminTask.createKeySt ore ['-interactive']</pre> • Using Jython list: <pre>AdminTask.createKeyS tore (['-interactive'])</pre>

Table 35. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - keyStoreHostList A list of host names that indicate from where the key store is remotely managed, separated by commas. (String, optional) - keyStoreInitAtStartup Set the value of this parameter to true if the key store is initialized at startup. Otherwise, set the value of this parameter to false. (Boolean, optional) - keyStoreReadOnly Set the value of this parameter to true if you cannot write to the key store. Otherwise, set the value of this parameter to false. (Boolean, optional) - keyStoreStashFile Set the value of this parameter to true if you want to create stash files for CMS type key store. Otherwise, set the value of this parameter to false. (Boolean, optional) - scopeName The name of the scope. (String, optional) - - enableCryptoOperations Specifies if the key store object will be used for hardware cryptographic operations or not. The default value is false. (Boolean, optional) • Returns: The configuration object name of the key store object that you created. 	

Table 35. (continued)

Command name:	Description:	Parameters and return values:	Examples:
createCMSKeyStore	<p>The createCMSKeyStore command creates a CMS key store database and the key store settings in the configuration.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - cmsKeyStoreURI The URI of the CMS key store. (String, required) - pluginHostName The host name of the plug-in. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createCMSKeyStore • Using Jython: AdminTask.createCMSKeyStore() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createCMSKeyStore {-interactive} • Using Jython string: AdminTask.createCMSKeyStore ('[-interactive]') • Using Jython list: AdminTask.createCMSKeyStore (['-interactive'])
deleteKeyStore	<p>The deleteKeyStore command deletes the settings of a key store from the configuration and the key store file.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key store that you want to delete. (String, required) - scopeName The name of the scope. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeyStore {-name testKS} • Using Jython string: AdminTask.deleteKeyStore ('[-name testKS]') • Using Jython list: AdminTask.deleteKeyStore (['-name', 'testKS']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeyStore {-interactive} • Using Jython string: AdminTask.deleteKeyStore ('[-interactive]') • Using Jython list: AdminTask.deleteKeyStore (['-interactive'])

Table 35. (continued)

Command name:	Description:	Parameters and return values:	Examples:
exchangeSigners	The exchangeSigners command exchange signer certificate between key stores.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName1 The name that uniquely identifies a key store. You must specify a second key store name using the <code>keyStoreName2</code> parameter. (String, required) - keyStoreScope1 The scope name of the key store that you specified with the <code>keyStoreName1</code> parameter. (String, required) - certificateAlaisList1 A list of aliases separated by a comma. (String, optional) - keyStoreName2 The name that uniquely identifies a key store. You must specify a second key store name using the <code>keyStoreName1</code> parameter. (String, required) - keyStoreScope2 The scope name of the key store that you specified with the <code>keyStoreName2</code> parameter. (String, required) - certificateAliasList2 A list of aliases separated by a comma. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask exchangeSigners {-keyStoreName1 testKS -certificateAliasList1 testCert1 -keyStoreName2 secondKS -certificate AlaisList2 certAlis}</pre> • Using Jython string: <pre>AdminTask.exchangeSigners ('[-keyStoreName1 testKS -certificateAliasList1 testCert1 -keyStoreName2 secondKS -certificateAlais List2 certAlis]')</pre> • Using Jython list: <pre>AdminTask.exchangeSigners (['-keyStoreName1', 'testKS', '-certificateAliasList1', 'testCert1', '-keyStoreName 2', 'secondKS', '-certifica teAlaisList2', 'certAlis'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask exchangeSigners {-interactive}</pre> • Using Jython string: <pre>AdminTask.exchangeSigners ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.exchangeSigners (['-interactive'])</pre>

Table 35. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getKeyStoreInfo	The getKeyStoreInfo command displays the settings of a particular key store.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key store. (String, required) - scopeName The name of the scope. (String, optional) • Returns: The settings of the key store that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeyStore {-name testKS} • Using Jython string: AdminTask.getKeyStore ('[-name testKS]') • Using Jython list: AdminTask.getKeyStore (['-name', 'testKS']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeyStore Info {-interactive} • Using Jython string: AdminTask.getKeyStore Info ('[-interactive]') • Using Jython list: AdminTask.getKeyStore Info (['-interactive'])

Table 35. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listKeyFileAliases	<p>The listKeyFileAliases command lists the certificates in a key store file.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyFilePath The path of the key file. (String, required) - keyFilePassword The password for the key file. (String, required) - keyFileType The key file type. (String, required) • Returns: A list of certificate aliases. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listKeyFileAliases {-keyFilePaht c:\temp\testKeyFile.p12 -keyFilePassword testPwd -keyFileType PKCS12}</pre> • Using Jython string: <pre>AdminTask.listKeyFileAliases ('[-keyFilePaht c:\temp\testKeyFile.p12 -keyFilePassword testPwd -keyFileType PKCS12]')</pre> • Using Jython list: <pre>AdminTask.listKeyFileAliases (['-keyFilePaht', 'c:\temp\testKeyFile.p12', '-keyFilePassword', 'testPwd', '-keyFileType', 'PKCS12'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listKeyFileAliases {-interactive}</pre> • Using Jython string: <pre>AdminTask.listKeyFileAliases ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.listKeyFileAliases (['-interactive'])</pre>

Table 35. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listKeyStores	The listKeyStores command lists the key store for a particular scope.	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - displayObjectName Set the value of this parameter to true to list the key store configuration objects within a scope. Set the value of this parameter to false to list the strings that contain the key store name and management scope. (String, optional) - scopeName The name of the scope. (String, optional) Returns: A list of key stores. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listKeyStores</code> Using Jython: <code>AdminTask.listKeyStores()</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listKeyStores {-interactive}</code> Using Jython string: <code>AdminTask.listKeyStores ('[-interactive]')</code> Using Jython list: <code>AdminTask.listKeyStores (['-interactive'])</code>
listKeyStoresTypes	The listKeyStoresTypes command lists all valid key store types.	<ul style="list-style-type: none"> Parameters: None Returns: A list of key store types. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listKeyStoreTypes</code> Using Jython: <code>AdminTask.listKeyStoreTypes()</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listKeyStores Types {-interactive}</code> Using Jython string: <code>AdminTask.listKeyStores Types ('[-interactive]')</code> Using Jython list: <code>AdminTask.listKeyStores Types (['-interactive'])</code>

Commands for the SSLConfigCommands group of the AdminTask object

Use the commands in the SSLConfigCommands group to create and delete SSL configurations. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SSLConfigCommands group of the AdminTask object:

Table 36.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>createSSLConfig</p>	<p>The createSSLConfig command creates an SSL configuration that is based on key store and trust store settings. You can use the SSL configuration settings to make the SSL connections.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - alias The name of the alias. (String, required) - scopeName The name of the scope. (String, optional) - clientKeyAlias The certificate alias name for the client. (String, optional) - serverKeyAlias The certificate alias name for the server. (String, optional) - type The type of SSL configuration. (String, optional) - clientAuthentication Set the value of this parameter to true to request client authentication. Otherwise, set the value of this parameter to false. (Boolean, optional) - securityLevel The cipher group that you want to use. Valid values include: HIGH, MEDIUM, LOW, and CUSTOM. (String, optional) - enabledCiphers A list of ciphers used during SSL handshake. (String, optional) - jsseProvider One of the JSSE providers. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createSSLConfig {-alias testSSLCfg -clientKeyAlias key1 -serverKeyAlias key2 -trustStoreName trustKS -keyStoreName testKS -keyManagerName testKeyMgr} • Using Jython string: AdminTask.createSSLConfig ('[-alias testSSLCfg -clientKeyAlias key1 -serverKeyAlias key2 -trustStoreName trustKS -keyStoreName testKS -keyManagerName testKeyMgr]') • Using Jython list: AdminTask.createSSLConfig (['-alias', 'testSSLCfg', '-clientKeyAlias', 'key1', '-serverKeyAlias', 'key2', '-trustStoreName', 'trustKS', '-keyStoreName', 'testKS', '-keyManagerName', 'testKeyMgr']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createSSLConfig {-interactive} • Using Jython string: AdminTask.createSSLConfig ('[-interactive]') • Using Jython list: AdminTask.createSSLConfig (['-interactive'])

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<p>-</p> <p>clientAuthenticationSupported Set the value of this parameter to true to support client authentication. Otherwise, set the value of this parameter to false. (Boolean, optional)</p> <p>- sslProtocol The protocol type for the SSL handshake. Valid values include: SSL_TLS, SSL, SSLv2, SSLv3, TLS, TLSv1. (String, optional)</p> <p>-</p> <p>trustManagerObjectName A list of trust managers separated by commas. (String, optional)</p> <p>- trustStoreNames The key store that holds trust information used to validate the trust from remote connections. (String, required)</p> <p>-</p> <p>trustStoreScopeName The management scope name of the trust store. (String, optional)</p>	

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - keyStoreName The key store that holds the personal certificates that provide identity for the connection. (String, required) - keyStoreScopeName The management scope name of the key store. (String, optional) - ssslKeyRingName Specifies a system SSL (SSSL) key ring name. The value for this parameter has no affect unless the SSL configuration type is SSSL. (String, optional) • Returns: The configuration object name of the SSL configuration object that you created. 	

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createSSL Config Property	The createSSL Config Property command creates a property for an SSL configuration. Use this command to set SSL configuration settings that are different than the settings in the SSL configuration object.	None	<ul style="list-style-type: none"> • Parameters: - sslConfigAliasName The alias name of the SSL configuration. (String, required) - scopeName The name of the scope. (String, optional) - propertyName The name of the property. (String, required) - propertyValue The value of the property. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createSSLConfigProperty {-sslConfigAliasName NodeDefaultSSLSettings -scopeName (cell):localhostNode01Cell:(node):localhostNode01 -propertyName test.property -propertyValue testValue}</pre> • Using Jython string: <pre>AdminTask.createSSLConfigProperty ('[-sslConfigAliasName NodeDefaultSSLSettings -scopeName (cell):localhostNode01Cell:(node):localhostNode01 -propertyName test.property -propertyValue testValue]')</pre> • Using Jython list: <pre>AdminTask.createSSLConfigProperty (['-sslConfigAliasName', 'NodeDefaultSSLSettings', '-scopeName', '(cell):localhostNode01Cell:(node):localhostNode01', '-propertyName', 'test.property', '-propertyValue', 'testValue'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createSSLConfigProperty {-interactive}</pre> • Using Jython string: <pre>AdminTask.createSSLConfigProperty ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.createSSLConfigProperty (['-interactive'])</pre>

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteSSLConfig	<p>The deleteSSLConfig command deletes the SSL configuration object that you specify from the configuration.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - alias The name of the alias. (String, required) - scopeName The name of the scope. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteSSLConfig {-alias NodeDefaultSSL Settings -scopeName (cell):localhostNode01Cell:(node):localhostNode01}</pre> • Using Jython string: <pre>AdminTask.deleteSSLConfig (['-alias NodeDefaultSSL Settings -scopeName (cell):localhostNode01Cell:(no de):localhostNode01'])</pre> • Using Jython list: <pre>AdminTask.deleteSSLConfig (['-alias', 'NodeDefault SSLSettings', '-scopeName', '(cell):localhostNode01 Cell:(node):localhost Node01'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteSSLConfig {-interactive}</pre> • Using Jython string: <pre>AdminTask.deleteSSLConfig (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.deleteSSLConfig (['-interactive'])</pre>

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getSSLConfig	The getSSLConfig command obtains information about an SSL configuration and displays the settings.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - alias The name of the alias. (String, required) - scopeName The name of the scope. (String, optional) • Returns: Information about the SSL configuration that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getSSLConfig {-alias NodeDefaultSSL Settings -scopeName (cell):localhostNode01 Cell:(node):localhost Node01 }</pre> • Using Jython string: <pre>AdminTask.getSSLConfig (['-alias NodeDefault SSLSettings -scopeName (cell):localhostNode01 Cell:(node):localhost Node01'])</pre> • Using Jython list: <pre>AdminTask.getSSLConfig (['-alias', 'Node DefaultSSLSettings', '-scopeName', '(cell): localhostNode01Cell: (node):localhostNode01'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getSSLConfig {-interactive}</pre> • Using Jython string: <pre>AdminTask.getSSLConfig (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.getSSLConfig (['-interactive'])</pre>

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getSSLConfig Properties	The getSSLConfig Properties command obtains information about SSL configuration properties.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - alias The name of the alias. (String, required) - scopeName The name of the scope. (String, optional) • Returns: Information about SSL configuration properties. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getSSLConfig Properties {-sslConfig AliasName NodeDefault SSLSettings -scopeName (cell):localhostNode01 Cell:(node):localhostNode01}</pre> • Using Jython string: <pre>AdminTask.getSSLConfig Properties ('[-sslConfigAliasName NodeDefaultSSLSettings -scopeName (cell):localhostNode01Cell:(node):localhostNode01]')</pre> • Using Jython list: <pre>AdminTask.getSSLConfig Properties (['-sslConfigAliasName', 'NodeDefaultSSLSettings', '-scopeName', '(cell):localhostNode01Cell:(node):localhostNode01'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getSSLConfig Properties {-interactive}</pre> • Using Jython string: <pre>AdminTask.getSSLConfig Properties ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getSSLConfig Properties (['-interactive'])</pre>

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listSSLCiphers	The listSSLCiphers command lists the SSL ciphers.	None	<ul style="list-style-type: none"> • Parameters: - sslConfigAliasName The alias name of the SSL configuration. (String, required) - scopeName The name of the scope. (String, optional) - securityLevel The cipher group that you want to use. Valid values include: HIGH, MEDIUM, LOW, and CUSTOM. (String, required) - provider (String, optional) • Returns: A list of SSL ciphers. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listSSLCiphers {-sslConfigAliasName test SSLCfg -securityLevel HIGH} • Using Jython string: AdminTask.listSSLCiphers ('[-sslConfigAliasName testSSLCfg -securityLevel HIGH]') • Using Jython list: AdminTask.listSSLCiphers (['-sslConfigAliasName', 'testSSLCfg', '-securityLevel', 'HIGH']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listSSLCiphers {-interactive} • Using Jython string: AdminTask.listSSLCiphers ('[-interactive]') • Using Jython list: AdminTask.listSSLCiphers (['-interactive'])

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listSSLConfig	The listSSLConfig command lists the defined SSL configurations within a management scope.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name of the scope. (String, optional) - displayObjectName Set the value of this parameter to true to list the SSL configuration objects within the scope. Set the value of this parameter to false to list the strings that contain the SSL configuration alias and management scope. (Boolean, optional) • Returns: A list of the defined SSL configurations. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listSSLConfig {-scopeName (cell): localhostNode01Cell:(node): localhostNode01 -displayObjectName true}</pre> • Using Jython string: <pre>AdminTask.listSSLConfig (['-scopeName (cell): localhostNode01Cell:(node):localhostNode01 -displayObjectName true'])</pre> • Using Jython list: <pre>AdminTask.listSSLConfig (['-scopeName', '(cell):localhostNode01Cell:(node):localhostNode01', '-displayObjectName', 'true'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listSSLConfig {-interactive}</pre> • Using Jython string: <pre>AdminTask.listSSLConfig (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.listSSLConfig (['-interactive'])</pre>

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listSSLConfig Properties	The listSSLConfig Properties command lists the properties for a SSL configuration.	None	<ul style="list-style-type: none"> • Parameters: - • sslConfigAliasName The alias name of the SSL configuration. (String, required) - • scopeName The name of the scope. (String, optional) - • displayObjectName Set the value of this parameter to true to list the SSL configuration objects within the scope. Set the value of this parameter to false to list the strings that contain the SSL configuration alias and management scope. (Boolean, optional) • Returns: A list of properties. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listSSLConfig Property {-alias No deDefaultSSLSettings -scope Name (cell):localhostNode01 -displayObjectName true} • Using Jython string: AdminTask.listSSLConfig Property ('[-alias No deDefaultSSLSettings -scopeName (cell):localhostNode01Cell:(node):localhostNode01 -displayObjectName true]') • Using Jython list: AdminTask.listSSLConfigProperty (['-alias', 'No', 'deDefaultSSLSettings', '-scopeName', '(cell):localhostNode01Cell:(node):localhostNode01', '-displayObjectName', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listSSLConfig Properties {-interactive} • Using Jython string: AdminTask.listSSLConfig Properties ('[-interactive]') • Using Jython list: AdminTask.listSSLConfig Properties (['-interactive'])

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>modifySSLConfig</p>	<p>The modifySSLConfig command modifies the settings of an existing SSL configuration.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - alias The name of the alias. (String, required) - scopeName The name of the scope. (String, optional) - clientKeyAlias The certificate alias name for the client. (String, optional) - serverKeyAlias The certificate alias name for the server. (String, optional) - type The type of SSL configuration. (String, optional) - clientAuthentication Set the value of this parameter to true to request client authentication. Otherwise, set the value of this parameter to false. (Boolean, optional) - securityLevel The cipher group that you want to use. Valid values include: HIGH, MEDIUM, LOW, and CUSTOM. (String, optional) - enabledCiphers A list of ciphers used during SSL handshake. (String, optional) - jsseProvider One of the JSSE providers. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask modifySSLConfig {-alias test SSLCfg -clientKeyAlias tstKey1 -serverKeyAlias tstKey2 -securityLevel LOW} • Using Jython string: AdminTask.modifySSLConfig ('[-alias testSSLCfg -clientKeyAlias tstKey1 -serverKeyAlias tstKey2 -securityLevel LOW]') • Using Jython list: AdminTask.modifySSLConfig (['-alias', 'testSSLCfg', '-clientKeyAlias', 'tstKey1', '-serverKeyAlias', 'tstKey2', '-securityLevel', 'LOW']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask modifySSLConfig {-interactive} • Using Jython string: AdminTask.modifySSLConfig ('[-interactive]') • Using Jython list: AdminTask.modifySSLConfig (['-interactive'])

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<p>-</p> <p>clientAuthenticationSupported Set the value of this parameter to true to support client authentication. Otherwise, set the value of this parameter to false. (Boolean, optional)</p> <p>- sslProtocol The protocol type for the SSL handshake. Valid values include: SSL_TLS, SSL, SSLv2, SSLv3, TLS, TLSv1. (String, optional)</p> <p>-</p> <p>trustManagerObjectNames A list of trust managers separated by commas. (String, optional)</p> <p>- trustStoreName The key store that holds trust information used to validate the trust from remote connections. (String, optional)</p> <p>-</p> <p>trustStoreScopeName The management scope name of the trust store. (String, optional)</p>	

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - keyStoreName The key store that holds the personal certificates that provide identity for the connection. (String, optional) - keyStoreScopeName The management scope name of the key store. (String, optional) - sslKeyRingName Specifies a system SSL (SSSL) key ring name. The value for this parameter has no affect unless the SSL configuration type is SSSL. (String, optional) <ul style="list-style-type: none"> • Returns: None 	

Commands for the DescriptivePropCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the DescriptivePropCommands group of the AdminTask object:

Table 37.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createDescriptiveProp	The createDescriptiveProp command creates key manager settings in the configuration. Use this command during SSL handshake to determine which certificate to use.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - parentDataType (String, required) - parentClassName (String, required) - parentScopeName (String, optional) - name (String, required) - value (String, required) - type (String, required) - displayNameKey (String, required) - nlsRangeKey (String, optional) - hoverHelpKey (String, optional) - range (String, optional) - inclusive (Boolean, optional) - firstClass (Boolean, optional) Returns: The configuration object name of the key manager object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask createKeyManager {-name testKM -keyManager Class com.ibm.ws.security. ltpa.LTPAKeyPairGenerator}</pre> Using Jython string: <pre>AdminTask.createKeyManager (['[-name testKM -keyManag erClass com.ibm.ws.securi ty.ltpa.LTPAKeyPairGenera tor]'])</pre> Using Jython list: <pre>AdminTask.createKeyManager (['-name', 'testKM', '-key ManagerClass', 'com.ibm.ws .security.ltpa.LTPAKeyPair Generator'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask createDescrip tiveProp {-interactive}</pre> Using Jython string: <pre>AdminTask.createDescripti veProp ('[-interactive]')</pre> Using Jython list: <pre>AdminTask.createDescripti veProp (['-interactive'])</pre>
deleteDescriptiveProp	The deleteDescriptiveProp command deletes key manager settings from the configuration.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - parentDataType (String, required) - parentClassName (String, required) - parentScopeName (String, optional) - name (String, required) Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask deleteDescrip tiveProp {-interactive}</pre> Using Jython string: <pre>AdminTask.deleteDescrip tiveProp ('[-interactive]')</pre> Using Jython list: <pre>AdminTask.deleteDescrip tiveProp (['-interactive'])</pre>

Table 37. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getDescriptiveProp	The getDescriptiveProp command obtains information about key manager settings.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - parentDataType (String, required) - parentClassName (String, required) - parentScopeName (String, optional) - name (String, required) • Returns: Information about key manager settings. 	Interactive mode example usage: <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getDescriptiveProp {-interactive}</pre> • Using Jython string: <pre>AdminTask.getDescriptiveProp ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getDescriptiveProp (['-interactive'])</pre>
listDescriptiveProp	The listDescriptiveProp command lists the key managers within a particular management scope.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - parentDataType (String, required) - parentClassName (String, required) - parentScopeName (String, optional) - displayObjectName Set the value of this parameter to true to list the key manager objects within the scope. Set the value of this parameter to false to list the strings that contain the key manager name and management scope. (Boolean, optional) • Returns: A list of key managers. 	Interactive mode example usage: <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listDescriptiveProp {-interactive}</pre> • Using Jython string: <pre>AdminTask.listDescriptiveProp ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.listDescriptiveProp (['-interactive'])</pre>

Table 37. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifyDescriptiveProp	The modifyDescriptiveProp command modifies the settings of an existing key manager.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - parentDataType (String, required) - parentClassName (String, required) - parentScopeName (String, optional) - name (String, required) - value (String, optional) - type (String, optional) - displayNameKey (String, optional) - nlsRangeKey (String, optional) - hoverHelpKey (String, optional) - range (String, optional) - inclusive (Boolean, optional) - firstClass (Boolean, optional) Returns: None 	Interactive mode example usage: <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask modifyDescriptiveProp {-interactive}</pre> Using Jython string: <pre>AdminTask.modifyDescriptiveProp ('[-interactive]')</pre> Using Jython list: <pre>AdminTask.modifyDescriptiveProp (['-interactive'])</pre>

Commands for the TrustManagerCommands group of the AdminTask object

Use the commands in the TrustManagerCommands group to create and delete a trust manager. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the TrustManagerCommands group of the AdminTask object:

Table 38.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createTrustManager	<p>The createTrustManagerInfo command creates trust manager settings in the configuration. Use this command during SSL handshake to make trust decisions about remote endpoints.</p>	None	<ul style="list-style-type: none"> • Parameters: - name The name that uniquely identifies the trust manager. (String, required) - scopeName The name of the scope. (String, optional) - provider The provider name of the trust manager. (String, optional) - algorithm The algorithm name of the trust manager. (String, optional) - trustManagerClass Specifies a class that implements the <code>javax.net.ssl.X509TrustManager</code> interface. You cannot use this parameter with the provider or algorithm parameters. (String, optional) • Returns: The configuration object name of the trust manager object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createTrustManager {-name testTM -provider IBMJSSE2 -algorithm IbmX509}</code> • Using Jython string: <code>AdminTask.createTrustManager ('[-name testTM -provider IBMJSSE2 -algorithm IbmX509]')</code> • Using Jython list: <code>AdminTask.createTrustManager (['-name', 'testTM', '-provider', 'IBMJSSE2', '-algorithm', 'IbmX509'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createTrustManager {-interactive}</code> • Using Jython string: <code>AdminTask.createTrustManager ('[-interactive]')</code> • Using Jython list: <code>AdminTask.createTrustManager (['-interactive'])</code>

Table 38. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteTrustManager	The deleteTrustManager command deletes the trust manager settings from the configuration.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the trust manager. (String, optional) - scopeName The name of the scope. (String, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask deleteTrustManager {-name testTM} Using Jython string: AdminTask.deleteTrustManager (['-name testTM']) Using Jython list: AdminTask.deleteTrustManager (['-name', 'testTM']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask deleteTrustManager {-interactive} Using Jython string: AdminTask.deleteTrustManager (['-interactive']) Using Jython list: AdminTask.deleteTrustManager (['-interactive'])
getTrustManager	The getTrustManager command obtains the setting of a trust manager.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the trust manager. (String, optional) - scopeName The name of the scope. (String, optional) Returns: The settings of the trust manager group that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask getTrustManager {-name testTM} Using Jython string: AdminTask.getTrustManager (['-name testTM']) Using Jython list: AdminTask.getTrustManager (['-name', 'testTM']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask getTrustManager {-interactive} Using Jython string: AdminTask.getTrustManager (['-interactive']) Using Jython list: AdminTask.getTrustManager (['-interactive'])

Table 38. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listTrustManagers	The listTrustManagers command lists the trust managers within a particular management scope.	None	<ul style="list-style-type: none"> • Parameters: - scopeName The name of the scope. (String, optional) - displayObjectName Set the value of this parameter to true to list the trust manager objects within a scope. Set the value of this parameter to false to list the strings that contain the trust manager name and management scope. (Boolean, optional) • Returns: A list of trust managers that are found within the management scope that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listTrustManagers {-displayObjectName true} • Using Jython string: AdminTask.listTrustManagers ('[-displayObjectName true]') • Using Jython list: AdminTask.listTrustManagers (['-displayName', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listTrustManagers {-interactive} • Using Jython string: AdminTask.listTrustManagers ('[-interactive]') • Using Jython list: AdminTask.listTrustManagers (['-interactive'])

Table 38. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifyTrustManager	The modifyTrustManager command changes existing trust manager settings.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the trust manager. (String, required) - scopeName The name of the scope. (String, optional) - provider The provider name of the trust manager. (String, optional) - algorithm The algorithm name of the trust manager. (String, optional) - trustManagerClass Specifies a class that implements the <code>javax.net.ssl.X509TrustManager</code> interface. You cannot use this parameter with the provider or algorithm parameters. (String, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask modifyTrustManager {-name testTM -trustManagerClass test.trust.manager}</code> Using Jython string: <code>AdminTask.modifyTrustManager (['-name testTM -trustManagerClass test.trust.manager'])</code> Using Jython list: <code>AdminTask.modifyTrustManager (['-name', 'testTM', '-trustManagerClass', 'test.trust.manager'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask modifyTrustManager {-interactive}</code> Using Jython string: <code>AdminTask.modifyTrustManager (['-interactive'])</code> Using Jython list: <code>AdminTask.modifyTrustManager (['-interactive'])</code>

Commands for the keyManagerCommands group of the AdminTask object

Use the commands in the `keyManagerCommands` group to manage key managers. You can use these commands to create, modify, list, or obtain information about key managers. For more information about the `AdminTask` object, see the [Commands for the AdminTask object](#) article.

The following commands are available for the `keyManagerCommands` group of the `AdminTask` object:

Table 39.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createKeyManager	<p>The createKeyManager command creates the key manager settings in the configuration. Use this command during SSL handshake to determine which certificate alias to use.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key manager. (String, required) - scopeName The name of the scope. (String, optional) - provider The provider name of the key manager. (String, optional) - algorithm The algorithm name of the key manager. (String, optional) - keyManagerClass The name of the key manager implementation class. You can not use this parameter with the provider or the algorithm parameter. (String, optional) • Returns: The configuration object name of the key manager object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeyManager {-name testKM -keyManagerClass com.ibm.ws.security.ltpa.LTPAKeyPairGenerator}</pre> • Using Jython string: <pre>AdminTask.createKeyManager ('[-name testKM -keyManagerClass com.ibm.ws.security.ltpa.LTPAKeyPairGenerator]')</pre> • Using Jython list: <pre>AdminTask.createKeyManager (['-name', 'testKM', '-keyManagerClass', 'com.ibm.ws.security.ltpa.LTPAKeyPairGenerator'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeyManager {-interactive}</pre> • Using Jython string: <pre>AdminTask.createKeyManager ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.createKeyManager (['-interactive'])</pre>

Table 39. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteKeyManager	The deleteKeyManager command deletes the key manager settings from the configuration.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key manager. (String, optional) - scopeName The name of the scope. (String, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask deleteKeyMa nager {-name testKM} Using Jython string: AdminTask.deleteKeyMa nager ('[-name testKM]') Using Jython list: AdminTask.deleteKeyMa nager (['-name', 'testKM']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask deleteKeyM anager {-interactive} Using Jython string: AdminTask.deleteKeyMa nager ('[-interactive]') Using Jython list: AdminTask.deleteKeyM anager (['-interactive'])
getKeyManager	The getKeyManager command obtains the settings of a key manager.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key manager. (String, optional) - scopeName The name of the scope. (String, optional) Returns: The settings of the key manager that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask getKeyMana ger {-name testKM} Using Jython string: AdminTask.getKeyMana ger ('[-name testKM]') Using Jython list: AdminTask.getKeyMana ger (['-name', 'testKM']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask getKeyManag er {-interactive} Using Jython string: AdminTask.getKeyManag er ('[-interactive]') Using Jython list: AdminTask.getKeyManag er (['-interactive'])

Table 39. (continued)

listKeyManagers	The listKeyManagers command lists the key managers within a particular management scope.	None	<ul style="list-style-type: none"> • Parameters: - scopeName The name of the scope. (String, optional) - - displayObjectName Set the value of this parameter to true to list the key manager objects within the scope. Set the value of this parameter to false to list the strings that contain the key manager name and the management scope. (Boolean, optional) • Returns: A list of key managers. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeyManagers • Using Jython: AdminTask.listKeyManagers() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeyManagers {-interactive} • Using Jython string: AdminTask.listKeyManagers ('[-interactive]') • Using Jython list: AdminTask.listKeyManagers (['-interactive'])

Table 39. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifyKeyManagers	The modifyKeyManagers command changes existing key manager settings.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key manager. (String, required) - scopeName The name of the scope. (String, optional) - provider The provider name of the key manager. (String, optional) - algorithm The algorithm name of the key manager. (String, optional) - keyManagerClass The name of the key manager implementation class. You can not use this parameter with the provider or the algorithm parameter. (String, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask modifyKeyManagers {-name testKM -provider IBMJSSE2 -algorithm IbmX509} Using Jython string: AdminTask.modifyKeyManagers ('[-name testKM -provider IBMJSSE2 -algorithm IbmX509]') Using Jython list: AdminTask.modifyKeyManagers (['-name', 'testKM', '-provider', 'IBMJSSE2', '-algorithm', 'IbmX509']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask modifyKeyManagers {-interactive} Using Jython string: AdminTask.modifyKeyManagers ('[-interactive]') Using Jython list: AdminTask.modifyKeyManagers (['-interactive'])

Commands for the SSLConfigGroupCommands group of the AdminTask object

Use the commands in the SSLConfigGroupCommands group to create or delete a SSL configuration group. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SSLConfigGroupCommands group of the AdminTask object:

Table 40.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createSSLConfigGroup	<p>The createSSLConfigGroup command creates a SSL configuration group.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the SSL configuration group. (String, required) - direction The direction to which the SSL configuration applies. Valid values include inbound or outbound. (String, required) - certificateAlias (String, required) - scopeName The name of the scope. (String, optional) - sslConfigAliasName The alias that uniquely identifies the SSL configurations in the group. (String, required) - sslConfigScopeName The scope that uniquely identifies the SSL configurations in the group. (String, optional) • Returns: The configuration object name of the SSL configuration group object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createSSLConfigGroup { -name testSSLCfgGrp -direction inbound -certificateAlias alias1 -sslConfigAliasName testSSLCfg}</pre> • Using Jython string: <pre>AdminTask.createSSLConfigGroup ['(-name testSSLCfgGrp -direction inbound -certificateAlias alias1 -sslConfigAliasName testSSLCfg)']</pre> • Using Jython list: <pre>AdminTask.createSSLConfigGroup [['-name', 'testSSLCfgGrp', '-direction', 'inbound', '-certificateAlias', 'alias1', '-sslConfigAliasName', 'testSSLCfg']]</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createSSLConfigGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.createSSLConfigGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.createSSLConfigGroup (['-interactive'])</pre>

Table 40. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteSSLConfigGroup	The deleteSSLConfigGroup command deletes a SSL configuration group from the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the SSL configuration group. (String, required) - direction The direction to which the SSL configuration applies. Valid values include inbound or outbound. (String, required) - scopeName The name of the scope. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteSSLConfigGroup {-name createSSLCfgGrp -direction inbound} • Using Jython string: AdminTask.deleteSSLConfigGroup [('-name createSSLCfgGrp -direction inbound)'] • Using Jython list: AdminTask.deleteSSLConfigGroup [('-name', 'createSSLCfgGrp', '-direction', 'inbound)'] <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteSSLConfigGroup {-interactive} • Using Jython string: AdminTask.deleteSSLConfigGroup ('[-interactive]') • Using Jython list: AdminTask.deleteSSLConfigGroup (['-interactive'])

Table 40. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getSSLConfigGroup	The getSSLConfigGroup command returns information about a SSL configuration setting.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the SSL configuration group. (String, required) - direction The direction to which the SSL configuration applies. Valid values include inbound or outbound. (String, required) - scopeName The name of the scope. (String, optional) • Returns: The settings of the SSL configuration group that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getSSLConfig Group {-name createSSLCfgGrp -direction inbound} • Using Jython string: AdminTask.getSSLConfig Group ['-name createSSLCfgGrp -direction inbound'] • Using Jython list: AdminTask.getSSLConfig Group [('-name', 'createSSLCfgGrp', '-direction', 'inbound')] <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getSSLConfig Group {-interactive} • Using Jython string: AdminTask.getSSLConfig Group ('[-interactive]') • Using Jython list: AdminTask.getSSLConfig Group (['-interactive'])

Table 40. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listSSLConfigGroups	<p>The listSSLConfigGroups command lists the SSL configuration groups within a scope and a direction.</p>	None	<ul style="list-style-type: none"> • Parameters: <li style="padding-left: 20px;">- direction The direction to which the SSL configuration applies. Valid values include inbound or outbound. (String, optional) <li style="padding-left: 20px;">- scopeName The name of the scope. (String, optional) <li style="padding-left: 20px;">- <li style="padding-left: 20px;">- displayObjectName If you set this parameter to true, the command returns a list of all of the SSL configuration group objects within the scope. If you set this parameter to false, the command returns a list of strings that contain the SSL configuration name and management scope. (Boolean, optional) • Returns: A list of SSL configuration groups. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask -listSSLConfigGroups {-displayObjectName true}</code> • Using Jython string: <code>AdminTask.listSSLConfigGroups [('-displayObjectName true)']</code> • Using Jython list: <code>AdminTask.listSSLConfigGroups [('-displayObjectName' 'true')]</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask listSSLConfigGroups {-interactive}</code> • Using Jython string: <code>AdminTask.listSSLConfigGroups ('[-interactive]')</code> • Using Jython list: <code>AdminTask.listSSLConfigGroups (['-interactive'])</code>

Table 40. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifySSLConfigGroup	The modifySSLConfigGroup command modifies the setting of an existing SSL configuration group.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the SSL configuration group. (String, required) - direction The direction to which the SSL configuration applies. Valid values include inbound or outbound. (String, required) - certificateAlias (String, optional) - scopeName The name of the scope. (String, optional) - sslConfigAliasName The alias that uniquely identifies the SSL configurations in the group. (String, optional) - sslConfigScopeName The scope that uniquely identifies the SSL configurations in the group. (String, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask modifySSLConfig Group {-name createSSLCfg Grp -direction inbound -certificateAlias alias2} Using Jython string: AdminTask.modifySSLConfig Group ['(-name createSSL CfgGrp -direction inbound -certificateAlias alias2)'] Using Jython list: AdminTask.modifySSLConfig Group [('-name', 'create SSLCfgGrp', '-direction', 'inbound', '-certificate Alias', 'alias2')] <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask modifySSLConf igGroup {-interactive} Using Jython string: AdminTask.modifySSLConf igGroup ('[-interactive]') Using Jython list: AdminTask.modifySSLConf igGroup (['-interactive'])

Commands for the DynamicSSLConfigSelections group of the AdminTask object

Use the commands in the DynamicSSLConfigSelections group to create or delete a dynamic SSL configuration selection. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the DynamicSSLConfigSelections group of the AdminTask object:

Table 41.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>createDynamic SSLConfig Selection</p>	<p>The createDynamic SSLConfig Selection command creates the configuration settings for the dynamic SSL configuration selection.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - dynSSLConfigSelectionName The name that uniquely identifies the dynamic SSL configuration selection. (String, required) - scopeName The name of the scope. (String, optional) - dynSSLConfigSelectionDescription The description of the dynamic SSL configuration selection. (String, optional) - dynSSLConfigSelectionInfo The information for the dynamic SSL configuration selection. (String, required) - sslConfigName The name of the SSL configuration. (String, required) - sslConfigScope The scope of the SSL configuration. (String, optional) - certificateAlias The alias name to identify the certificate. (String, required) • Returns: The configuration object name of the dynamic SSL configuration selection object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createDynamicSSLConfigSelection</code> • Using Jython: <code>AdminTask.createDynamicSSLConfigSelection()</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createDynamicSSLConfigSelection {-interactive}</code> • Using Jython string: <code>AdminTask.createDynamicSSLConfigSelection (['-interactive'])</code> • Using Jython list: <code>AdminTask.createDynamicSSLConfigSelection (['-interactive'])</code>

Table 41. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>deleteDynamic SSLConfig Selection</p>	<p>The deleteDynamic SSLConfig Selection command deletes the dynamic SSL configuration selection from the configuration.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: None • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteDynamic SSLConfigSelection</pre> • Using Jython: <pre>AdminTask.deleteDynamic SSLConfigSelection()</pre> • <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteDynamic SSLConfigSelection {-interactive}</pre> • Using Jython string: <pre>AdminTask.deleteDynamicSSLConfigSelection ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.deleteDynamic SSLConfigSelection (['-interactive'])</pre>
<p>getDynamic SSLConfig Selection</p>	<p>The getDynamic SSLConfig Selection command obtains information about a particular dynamic SSL configuration selection.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: None • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getDynamicSSLConfigSelection</pre> • Using Jython: <pre>AdminTask.getDynamicSSLConfigSelection()</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getDynamicSSLConfigSelection {-interactive}</pre> • Using Jython string: <pre>AdminTask.getDynamicSSLConfigSelection ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getDynamicSSLConfigSelection (['-interactive'])</pre>

Table 41. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listDynamic SSLConfig Selections	The listDynamic SSLConfig Selections command lists the configuration objects name for a dynamic SSL configuration selection.	None	<ul style="list-style-type: none"> Parameters: None Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listDynamic SSLConfigSelection Using Jython: AdminTask.listDynamic SSLConfigSelection() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listDynamicSSL ConfigSelections {-interactive} Using Jython string: AdminTask.listDynamicSSL ConfigSelections ('[-interactive]') Using Jython list: AdminTask.listDynamicSSL ConfigSelections (['-interactive'])

Commands for the ManagementScopeCommands group of the AdminTask object

Use the commands in the ManagementScopeCommands group to create or delete a management scope. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the ManagementScopeCommands group of the AdminTask object:

Table 42.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createManagementScope	The createManagementScope command creates a management scope setting in the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name that uniquely identifies the management scope. (String, required) - scopeType The type of the management scope. Valid types include cell, node, nodegroup, cluster, server, and endpoint. (String, optional) • Returns: The configuration object name of the management scope object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createManagementScope {-name (cell):localhostNode01Cell -scopeType cell} • Using Jython string: AdminTask.createManagementScope [('-name (cell):localhostNode01Cell -scopeType cell)'] • Using Jython list: AdminTask.createManagementScope [('-name', '(cell):localhostNode01Cell', '-scopeType', 'cell')] <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createManagementScope {-interactive} • Using Jython string: AdminTask.createManagementScope ('[-interactive]') • Using Jython list: AdminTask.createManagementScope (['-interactive'])

Table 42. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteManagementScope	The deleteManagementScope command deletes a management object from the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name that uniquely identifies the management scope. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteManagementScope {-scopeName (cell):localhostNode01Cell} • Using Jython string: AdminTask.deleteManagementScope ('[-scopeName (cell):localhostNode01Cell]') • Using Jython list: AdminTask.deleteManagementScope (['-scopeName', '(cell):localhostNode01Cell']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteManagementScope {-interactive} • Using Jython string: AdminTask.deleteManagementScope ('[-interactive]') • Using Jython list: AdminTask.deleteManagementScope (['-interactive'])

Table 42. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getManagementScope	The getManagementScope command displays the setting of a management scope object.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name that uniquely identifies the management scope. (String, required) • Returns: The settings of the management scope object. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getManagementScope {-scopeName (cell):localhostNode01Cell} • Using Jython string: AdminTask.getManagementScope ('[-scopeName (cell):localhostNode01Cell]') • Using Jython list: AdminTask.getManagementScope (['-scopeName', '(cell):localhostNode01Cell']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getManagementScope {-interactive} • Using Jython string: AdminTask.getManagementScope ('[-interactive]') • Using Jython list: AdminTask.getManagementScope (['-interactive'])

Table 42. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listManagementScopes	The listManagementScopes command lists the management scopes in the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - displayObjectName Set the value to true to display the object names of the management scope. (Boolean, optional) • Returns: A list that contains all of the management scope names. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listManagementScopes { -name testKM -provider IBMJSSE2 -algorithm IbmX509}</pre> • Using Jython string: <pre>AdminTask.listManagementScopes ('[-name testKM -provider IBMJSSE2 -algorithm IbmX509]')</pre> • Using Jython list: <pre>AdminTask.listManagementScopes (['-name', 'testKM', '-provider', 'IBMJSSE2', '-algorithm', 'IbmX509'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listManagementScopes {-interactive}</pre> • Using Jython string: <pre>AdminTask.listManagementScopes ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.listManagementScopes (['-interactive'])</pre>

Commands for the WSCertExpMonitorCommands group of the AdminTask object

Use the commands in the WSCertExpMonitorCommands group to start or update the certificate expiration monitor. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the WSCertExpMonitorCommands group of the AdminTask object:

Table 43.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createWSCert ExpMonitor	The createWSCert ExpMonitor command creates the certificate expiration monitor settings in the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the certificate expiration monitor. (String, required) - autoReplace Set the value of this parameter to true if you want to replace a certificate within a certificate expiration date. If not, set the value of this parameter to false. (Boolean, required) - deleteOld Set the value of this parameter to true if you want to delete an old certificate during certificate expiration monitoring. If not, set the value of this parameter to false. (Boolean, required) - daysBeforeNotification The number of days before a certificate expires that you want to be notified of the expiration. (Integer, required) - wsScheduleName The name of the scheduler to use for certificate expiration. (String, required) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createWSCert ExpMonitor {-name test CertMon -autoReplace true -deleteOld true -daysBeforeNotification 30 -wsScheduleName testSchedule -wsNotificationName testNotifier -isEnabled false} • Using Jython string: AdminTask.createWSCert ExpMonitor ('[-name testCertMon -autoReplace true -deleteOld true -daysBeforeNotification 30 -wsScheduleName testSchedule -wsNotificationName testNotifier -isEnabled false]') • Using Jython list: AdminTask.createWSCert ExpMonitor (['-name', 'testCertMon', '-autoReplace', 'true', '-deleteOld', 'true', '-daysBeforeNotification', '30', '-wsScheduleName', 'testSchedule', '-wsNotificationName', 'testNotifier', '-isEnabled', 'false']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createWSCert ExpMonitor {-interactive} • Using Jython string: AdminTask.createWSCert ExpMonitor ('[-interactive]') • Using Jython list: AdminTask.createWSCert ExpMonitor (['-interactive'])

Table 43. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - wsNotificationName The name of the notifier to use for certificate expiration. (String, required) - isEnabled Set the value of this parameter to true if the certificate expiration monitor is enabled. If not, set the value of this parameter to false. (Boolean, optional) • Returns: The configuration object name of the certificate expiration monitor object that you created. 	
deleteWSCertExpMonitor	The deleteWSCertExpMonitor command deletes the settings of a scheduler from the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the certificate expiration monitor. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteWSCertExpMonitor {-name testCertMon} • Using Jython string: AdminTask.deleteWSCertExpMonitor ('[-name testCertMon]') • Using Jython list: AdminTask.deleteWSCertExpMonitor (['-name', 'testCertMon']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteWSCertExpMonitor {-interactive} • Using Jython string: AdminTask.deleteWSCertExpMonitor ('[-interactive]') • Using Jython list: AdminTask.deleteWSCertExpMonitor (['-interactive'])

Table 43. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getWSCertExpMonitor	The getWSCertExpMonitor command displays the settings of a particular scheduler.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the certificate expiration monitor. (String, required) • Returns: The settings of the scheduler that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getWSCertExpMonitor {-name testCertMon} • Using Jython string: AdminTask getWSCertExpMonitor ('[-name testCertMon]') • Using Jython list: AdminTask getWSCertExpMonitor (['-name', 'testCertMon']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getWSCertExpMonitor {-interactive} • Using Jython string: AdminTask.getWSCertExpMonitor ('[-interactive]') • Using Jython list: AdminTask.getWSCertExpMonitor (['-interactive'])

Table 43. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listWSCertExpMonitor	The listWSCertExpMonitor command lists the scheduler in the configuration.	None	<ul style="list-style-type: none"> • Parameters: - displayObjectNames If you set the value of this parameter to true, the command returns the certificate expiration monitor configuration object. If you set the value of this parameter to false, the command returns the name of the certificate expiration monitor. (Boolean, optional) • Returns: The scheduler in the configuration. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listWSCertExpMonitor {-displayObjectName false} • Using Jython string: AdminTask.listWSCertExpMonitor ('[-displayObjectName false]') • Using Jython list: AdminTask.listWSCertExpMonitor (['-displayObjectName', 'false']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listWSCertExpMonitor {-interactive} • Using Jython string: AdminTask.listWSCertExpMonitor ('[-interactive]') • Using Jython list: AdminTask.listWSCertExpMonitor (['-interactive'])

Table 43. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>modifyWSCert ExpMonitor</p>	<p>The modifyWSCert ExpMonitor command changes the setting of an existing scheduler.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - name The name that uniquely identifies the certificate expiration monitor. (String, required) - autoReplace Set the value of this parameter to true if you want to replace a certificate within a certificate expiration date. If not, set the value of this parameter to false. (Boolean, required) - deleteOld Set the value of this parameter to true if you want to delete an old certificate during certificate expiration monitoring. If not, set the value of this parameter to false. (Boolean, required) - daysBeforeNotification The number of days before a certificate expires that you want to be notified of the expiration. (Integer, required) - wsScheduleName The name of the scheduler to use for certificate expiration. (String, required) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask modifyWSCert ExpMonitor {-name testCertMon -autoReplace false -deleteOld false -daysBeforeNotification 20 -isEnabled true} • Using Jython string: AdminTask.modifyWSCert ExpMonitor ('[-name testCertMon -autoReplace false -deleteOld false -daysBeforeNotification 20 -isEnabled true]') • Using Jython list: AdminTask.modifyWSCert ExpMonitor (['-name', 'testCertMon', '-autoReplace', 'false', '-deleteOld', 'false', '-daysBeforeNotification', '20', '-isEnabled', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask modifyWSCert ExpMonitor {-interactive} • Using Jython string: AdminTask.modifyWSCert ExpMonitor ('[-interactive]') • Using Jython list: AdminTask.modifyWSCert ExpMonitor (['-interactive'])

Table 43. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - wsNotificationName The name of the notifier to use for certificate expiration. (String, required) - isEnabled Set the value of this parameter to true if the certificate expiration monitor is enabled. If not, set the value of this parameter to false. (Boolean, optional) <ul style="list-style-type: none"> • Returns: None 	
startCertificateExpMonitor	The startCertificateExpMonitor command performs certificate monitoring. This command visits all key stores and checks to see if they are within certificate expiration range.	None	<ul style="list-style-type: none"> • Parameters: None • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask startCertificateExpMonitor</code> • Using Jython: <code>AdminTask.startCertificateExpMonitor()</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask startCertificateExpMonitor {-interactive}</code> • Using Jython string: <code>AdminTask.startCertificateExpMonitor ('[-interactive]')</code> • Using Jython list: <code>AdminTask.startCertificateExpMonitor (['-interactive'])</code>

Commands for the KeySetGroupCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the KeySetGroupCommands group of the AdminTask object:

Table 44.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createKeySetGroup	<p>The createKeySetGroup command creates the key set group settings in the configuration. Use this command to manage groups of public, private, and shared keys.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set group. (String, required) - scopeName The name of the scope. (String, optional) - autoGenerate Set the value of this parameter to true if you want to automatically generate keys. If not, set the value to false. (Boolean, optional) - wsScheduleName The name of the scheduler to use to perform key generation. (String, required) - keySetObjectNames A list of key set configuration names separated by colons (:). (String, required) • Returns: The configuration object name of the key set group object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeySetGroup {-name keySetGrp -autoGenerate true -wsScheduleName testSchedule -keySetObjectNames testKeySet(cells/localhostNode01Cell security.xml#KeySet_1130354347825)}</pre> • Using Jython string: <pre>AdminTask.createKeySetGroup(['-name keySetGrp -autoGenerate true -wsScheduleName testSchedule -keySetObjectNames testKeySet(cells/localhostNode01Cell security.xml#KeySet_1130354347825)'])</pre> • Using Jython list: <pre>AdminTask.createKeySetGroup(['-name', 'keySetGrp', '-autoGenerate', 'true', '-wsScheduleName', 'testSchedule', '-keySetObjectNames', 'testKeySet(cells/localhostNode01Cell security.xml#KeySet_1130354347825)'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeySetGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.createKeySetGroup(['-interactive'])</pre> • Using Jython list: <pre>AdminTask.createKeySetGroup(['-interactive'])</pre>

Table 44. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteKeySetGroup	The deleteKeySetGroup command deletes the settings of a key set group from the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set group. (String, required) - scopeName The name of the scope. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeySet Group {-name keySetGrp } • Using Jython string: AdminTask.deleteKeySet Group ('[-name keySetGrp]') • Using Jython list: AdminTask.deleteKeySet Group (['-name', 'key SetGrp']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKey SetGroup {-interactive} • Using Jython string: AdminTask.deleteKeySet Group ('[-interactive]') • Using Jython list: AdminTask.deleteKeySet Group (['-interactive'])

Table 44. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
generateKeys ForKey SetGroup	<p>The generateKeys ForKey SetGroup command generates keys for all of the keys in the key sets that make up the key set group.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keySetGroupName The name of the key set group. (String, required) - keySetGroupScope The scope of the key set group. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask generateKey ForKeySetGroup {-keySetGroupName keySetGrp}</pre> • Using Jython string: <pre>AdminTask.generateKey ForKeySetGroup ('[-keySetGroupName keySetGrp]')</pre> • Using Jython list: <pre>AdminTask.generateKey ForKeySetGroup (['-keySetGroupName', 'keySetGrp'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask generateKeys ForKeySetGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.generateKeys ForKeySetGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.generateKeys ForKeySetGroup (['-interactive'])</pre>

Table 44. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getKeySetGroups	<p>The getKeySetGroups command displays the settings of a particular key set group.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set group. (String, required) - scopeName The name of the scope. (String, optional) • Returns: The settings of the specified key set group. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeySetGroup { -name keySetGrp } • Using Jython string: AdminTask.getKeySetGroup ('[-name keySetGrp]') • Using Jython list: AdminTask.getKeySetGroup (['-name', 'keySetGrp']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeySetGroups {-interactive} • Using Jython string: AdminTask.getKeySetGroups (['-interactive']) • Using Jython list: AdminTask.getKeySetGroups (['-interactive'])

Table 44. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listKeySetGroups	<p>The listKeySetGroups command lists the key set groups for a particular scope.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name of the scope. (String, optional) - displayObjectNames If you set the value of this parameter to true, the command returns a list of all of the key set group objects within a scope. If you set the value of this parameter to false, the command returns a list of strings that contain the key set group name and management scope. (Boolean, optional) • Returns: A list of key set groups. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeySetGroup {-displayObjectName true} • Using Jython string: AdminTask.listKeySetGroup ('[-displayObjectName true]') • Using Jython list: AdminTask.listKeySetGroup (['-displayObjectName', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeySetGroups {-interactive} • Using Jython string: AdminTask.listKeySetGroups ('[-interactive]') • Using Jython list: AdminTask.listKeySetGroups (['-interactive'])

Table 44. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifyKeySetGroup	The modifyKeySetGroup command changes the settings of an existing key set group.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set group. (String, required) - scopeName The name of the scope. (String, optional) - autoGenerate Set the value of this parameter to true if you want to automatically generate keys. If not, set the value to false. (Boolean, optional) - wsScheduleName The name of the scheduler to use to perform key generation. Commands for the KeySetCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the KeySetCommands group of the AdminTask object:

Table 45.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createKeySet	<p>The createKeySet command creates the key set settings in the configuration. Use this command to control key instances that have the same type.</p>	None	<ul style="list-style-type: none"> • Parameters: - name The name that uniquely identifies the key set. (String, required) - scopeName The name of the scope. (String, optional) - aliasPrefix The prefix for the key alias when a new key generates. (String, required) - password The password that protects the key in the key store. (String, required) - - maxKeyReferences The maximum number of key references returned keys from this key set. (Integer, required) - deleteOldKeys Set the value of this parameter to true to delete old keys when new keys are generated. Otherwise, set the value of this parameter to false. (Boolean, optional) - - keyGenerationClass The class that is used to generate new keys in the key set. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createKeySet {-name testKeySet -alias Prefix test -password pwd -maxKeyReferences 2 -deleteOldKeys true -keyStoreName testKeyStore -isKeyPair false} • Using Jython string: AdminTask.createKeySet('[-name testKeySet -alias Prefix test -password pwd -maxKeyReferences 2 -deleteOldKeys true -keyStoreName testKeyStore -isKeyPair false]') • Using Jython list: AdminTask.createKeySet(['-name', 'testKeySet', '-aliasPrefix', 'test', '-password', 'pwd', '-maxKeyReferences', '2', '-deleteOldKeys', 'true', '-keyStoreName', 'testKeyStore', '-isKeyPair', 'false']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createKeySet {-interactive} • Using Jython string: AdminTask.createKeySet('[-interactive]') • Using Jython list: AdminTask.createKeySet(['-interactive'])

Table 45. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - keyStoreName The key store that contains the keys. (String, required) - - keyStoreScopeName The management scope where the key store is located. (String, optional) - isKeyPair Set the value of this parameter to true if the keys in the key set are key pairs. Otherwise, set the value of this parameter to false. (Boolean, optional) • Returns: The configuration object name of the key set object that you created. 	
deleteKeySet	The deleteKeySet command deletes the settings of a key set from the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set. (String, required) - scopeName The name of the scope. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeySet {-name testKeySet} • Using Jython string: AdminTask.deleteKeySet (['-name testKeySet']) • Using Jython list: AdminTask.deleteKeySet (['-name', 'testKeySet']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeySet {-interactive} • Using Jython string: AdminTask.deleteKeySet (['-interactive']) • Using Jython list: AdminTask.deleteKeySet (['-interactive'])

Table 45. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>generateKey ForKeySet</p>	<p>The generateKeyForKeySet command generates keys for the keys in the key set.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keySetName The name of the key set. Otherwise, set the value of this parameter to false. (Boolean, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask generateKeyForKeySet { -keySetName testKeySet } • Using Jython string: AdminTask.generateKeyForKeySet ('[-keySetName testKeySet]') • Using Jython list: AdminTask.generateKeyForKeySet (['-keySetName', 'testKeySet']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask generateKeyForKeySet {-interactive} • Using Jython string: AdminTask.generateKeyForKeySet ('[-interactive]') • Using Jython list: AdminTask.generateKeyForKeySet (['-interactive'])
<p>getKeySet</p>	<p>The getKeySet command displays the settings of a particular key set.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set. (String, required) - scopeName The name of the scope. (String, optional) • Returns: The settings of the specified key set group. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeySet {-name testKeySet} • Using Jython string: AdminTask.getKeySet ('[-name testKeySet]') • Using Jython list: AdminTask.getKeySet (['-name', 'testKeySet']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeySet {-interactive} • Using Jython string: AdminTask.getKeySet ('[-interactive]') • Using Jython list: AdminTask.getKeySet (['-interactive'])

Table 45. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listKeySets	The listKeySets command lists the key sets in a particular scope.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name of the scope. (String, optional) - displayObjectNames Set the value of this parameter to true to list the key set configuration objects within the scope. Set the value of this parameter to false if you want to list the strings that contain the key set group name and management scope. (Boolean, optional) • Returns: The key sets for the scope that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeySets {-displayObjectName true} • Using Jython string: AdminTask.listKeySets (['-displayObjectName true']) • Using Jython list: AdminTask.listKeySets (['-displayObjectName', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeySets {-interactive} • Using Jython string: AdminTask.listKeySets (['-interactive']) • Using Jython list: AdminTask.listKeySets (['-interactive'])

Table 45. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifyKeySet	The modifyKeySet command changes the settings of an existing key set.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set. (String, required) - scopeName The name of the scope. (String, optional) - aliasPrefix The prefix for the key alias when a new key generates. (String, optional) - password The password that protects the key in the key store. (String, optional) - maxKeyReferences The maximum number of key references returned keys from this key set. (Integer, optional) - deleteOldKeys Set the value of this parameter to true to delete old keys when new keys are generated. Otherwise, set the value of this parameter to false. (Boolean, optional) - keyGenerationClass The class that is used to generate new keys in the key set. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask modifyKeySet {-name testKeySet -maxKeyReferences 3 -deleteOldKeys false} • Using Jython string: AdminTask.modifyKeySet ('[-name testKeySet -maxKeyReferences 3 -deleteOldKeys false]') • Using Jython list: AdminTask.modifyKeySet (['-name', 'testKeySet', '-maxKeyReferences', '3', '-deleteOldKeys', 'false']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask modifyKeySet {-interactive} • Using Jython string: AdminTask.modifyKeySet ('[-interactive]') • Using Jython list: AdminTask.modifyKeySet (['-interactive'])

Table 45. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - keyStoreName The key store that contains the keys. (String, optional) - - keyStoreScopeName The management scope where the key store is located. (String, optional) - isKeyPair Set the value of this parameter to true if the keys in the key set are key pairs. Otherwise, set the value of this parameter to false. (Boolean, optional) <ul style="list-style-type: none"> • Returns: None 	

Commands for the KeyReferenceCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the KeyReferenceCommands group of the AdminTask object:

Table 46.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createKeyReference	<p>The createKeyReference command creates the key reference setting in the configuration for key set objects.</p>	None	<ul style="list-style-type: none"> • Parameters: - keySetName The name that uniquely identifies the key set to which the key reference belongs. (String, required) - keySetScope The management scope of the key set. (String, optional) - keyAlias The alias name that identifies the key for the key set that you specify. (String, required) - keyPassword The password used for encrypting the key. (String, optional) - keyPasswordVerify The password used for encrypting the key. (String, optional) - version The version of the key reference. (String, optional) - keyReferenceSaveConfig Set the value of this parameter to true to save the key reference to the configuration. Otherwise, set the value to false. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createKeyReference {-keySetName testKeySet -keyAlias testKey -password testPWD -passwordVerify testPWD -keyReferenceSaveConfig true} • Using Jython string: AdminTask.createKeyReference (['-keySetName testKeySet -keyAlias testKey -password testPWD -passwordVerify testPWD -keyReferenceSaveConfig true']) • Using Jython list: AdminTask.createKeyReference (['-keySetName', 'testKeySet', '-keyAlias', 'testKey', '-password', 'testPWD', '-passwordVerify', 'testPWD', '-keyReferenceSaveConfig', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createKeyReference {-interactive} • Using Jython string: AdminTask.createKeyReference (['-interactive']) • Using Jython list: AdminTask.createKeyReference (['-interactive'])

Table 46. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> Returns: The configuration object name of the key reference scope object that you created. 	
deleteKeyReference	<p>The deleteKeyReference command deletes a key reference object from the key set object in the configuration.</p>	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - keySetName The name that uniquely identifies the key set to which the key reference belongs. (String, required) - keySetScope The management scope of the key set. (String, optional) - keyAlias The alias name that identifies the key for the key set that you specify. (String, required) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask deleteKeyReference { -keySetName testKeySet -keyAlias testKey }</pre> Using Jython string: <pre>AdminTask.deleteKeyReference (['-keySetName testKeySet -keyAlias testKey'])</pre> Using Jython list: <pre>AdminTask.deleteKeyReference (['-keySetName', 'testKeySet', '-keyAlias', 'testKey'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask deleteKeyReference {-interactive}</pre> Using Jython string: <pre>AdminTask.deleteKeyReference (['-interactive'])</pre> Using Jython list: <pre>AdminTask.deleteKeyReference (['-interactive'])</pre>

Table 46. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getKeyReference	The getKeyReference command displays the setting of a key reference object.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keySetName The name that uniquely identifies the key set to which the key reference belongs. (String, required) - keySetScope The management scope of the key set. (String, optional) - keyAlias The alias name that identifies the key for the key set that you specify. (String, required) • Returns: The settings of the key reference object. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeyReference { -keySetName test KeySet -keyAlias testKey } • Using Jython string: AdminTask.getKeyReference ('[-keySetName test KeySet -keyAlias testKey]') • Using Jython list: AdminTask.getKeyReference (['-keySetName', 'testKeySet', '-keyAlias', 'testKey']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeyReference {-interactive} • Using Jython string: AdminTask.getKeyReference ('[-interactive]') • Using Jython list: AdminTask.getKeyReference (['-interactive'])

Table 46. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listKeyReferences	The listKeyReferences command lists the key references for a particular key set in the configuration.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - keySetName The name that uniquely identifies the key set to which the key reference belongs. (String, required) - keySetScope The management scope of the key set. (String, optional) Returns: The configuration object name of the key reference scope object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listKeyReferences { -keySetName testKeySet } Using Jython string: AdminTask.listKeyReferences ('[-keySetName testKeySet]') Using Jython list: AdminTask.listKeyReferences (['-keySetName', 'testKeySet']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listKeyReferences {-interactive} Using Jython string: AdminTask.listKeyReferences ('[-interactive]') Using Jython list: AdminTask.listKeyReferences (['-interactive'])

Commands for the securityEnablement group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the securityEnablement group of the AdminTask object:

Table 47.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
GlobalSettings		None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - secureApps Enables application security. The default value is true. (Boolean, required) - secureLocalResources Enables Java 2 Security. The default value is true. (Boolean, required) - ltpaPassword Defines the LTPA password. Valid values include the password used by LTPA. (String, required) - userRegistryType Defines the type of user registry to use. Valid values include: Embedded, LDAP, LocalOS, or Custom. (String, required) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask GlobalSettings {-interactive} • Using Jython string: AdminTask.GlobalSettings ('[-interactive]') • Using Jython list: AdminTask.GlobalSettings (['-interactive'])

Table 47. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>CustomRegistry</p>	<p>The CustomRegistry command checks that the specified name for the primary administrator does not already exist in the custom registry.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - primaryAdminName Represents a name of the primary administrator. The value must be a valid administrator name. (String, required) - serverUserName Represents the user name used to connect to internal security routines. The value must be a valid user name. (String, required) - customRegistryClass Represents the class name of the custom user registry implementation of the UserRegistry. The value must be a valid class name for a custom registry. (String, required) - customProperties Custom user registry properties. An array or name-value properties. (String, required) - customName The custom user registry property name. (String, required) - customValue The custom user registry property value that is associated with the property name. (String, required) • Returns: A value of true if the primary administrator does not already exist in the custom registry. Otherwise, returns a value of false. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask CustomRegistry {-interactive}</code> • Using Jython string: <code>AdminTask.CustomRegistry ('[-interactive]')</code> • Using Jython list: <code>AdminTask.CustomRegistry (['-interactive'])</code>

Table 47. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
EmbeddedRegistry	<p>The EmbeddedRegistry command checks that the specified name for the primary administrator does not already exist in the WIM file-based registry. Returns true if it does not; false, otherwise.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - primaryAdminName This string represents a name of the primary administrator. The value must be a valid administrator name. (String, required) - adminPassword The password associated with the primary administrator. The value must be a valid administrator password. (String, required) - serverUserName This string represents the user name used to connect to internal security routines. The value must be a valid user name. (String, required) • Returns: A value of true if the specified name for the primary administrator does not already exist in the WIM file-based registry. Otherwise, returns a value of false. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask EmbeddedRegistry {-interactive} • Using Jython string: AdminTask.EmbeddedRegistry ('[-interactive]') • Using Jython list: AdminTask.EmbeddedRegistry (['-interactive'])

Table 47. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
LDAPRegistry	<p>The LDAPRegistry command checks, after all the inputs for the LDAP registry have been defined, that a connection can be made successfully to the LDAP server. An SSL connection test to LDAP is also supported using this command.</p>	None	<ul style="list-style-type: none"> • Parameters: - IdapServerType The type of LDAP user registry to be connected to WebSphere Application Server. Valid values include: IBM Tivoli Directory Server, SecureWay, Sun ONE, Domino, Active Directory, eDirectory, Custom. (String, required) - IdapHostname The host name for the LDAP server. (String, required) - IdapPort The port to connect to the LDAP server. (Integer, required) - IdapBaseDN The base distinguished name of the directory service, the starting point for searches. (String, required) - IdapBindDN The bind distinguished name, used to bind to the directory server. (String, required) 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask LDAPRegistry {-interactive} • Using Jython string: AdminTask.LDAPRegistry ('[-interactive]') • Using Jython list: AdminTask.LDAPRegistry (['-interactive'])

Table 47. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - IdapBindPassword The password for the application server, used to bind to the directory service (String, required) - IdapServerUserName The user ID that is used to run WebSphere Application Server for security purposes. (String, required) • Returns: A value of true if the connection was successful. Otherwise, returns a value of false. 	
LocalOSRegistry	The LocalOSRegistry command checks that the specified name for the primary administrator does not already exist in the LocalOS registry.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - primaryAdminName This string represents a name of the primary administrator. The value must be a valid administrator name. (String, required) - serverUserName This string represents the user name used to connect to internal security routines. The value must be a valid user name. (String, required) • Returns: A value of true if the specified name for the primary administrator does not already exist in the LocalOS registry. Otherwise, returns a value of false. 	Interactive mode example usage: <ul style="list-style-type: none"> • Using Jacl: \$AdminTask LocalOSRegistry {-interactive} • Using Jython string: AdminTask.LocalOSRegistry ('[-interactive]') • Using Jython list: AdminTask.LocalOSRegistry (['-interactive'])

Table 47. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
CurrentSettings	The CurrentSettings command returns a string that represents all of the existing settings set by the wizard that will be read from the workspace instead of from the configuration repository of the security.xml file.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - currentWizardSettings A properties object that contains all the current settings selected through the wizard. (Properties, required) Returns: A string of security settings as name-value pairs. 	Interactive mode example usage: <ul style="list-style-type: none"> Using Jacl: \$AdminTask CurrentSettings {-interactive} Using Jython string: AdminTask.CurrentSettings ('[-interactive]') Using Jython list: AdminTask.CurrentSettings (['-interactive'])

Commands for the CertificateRequestCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the CertificateRequestCommands group of the AdminTask object:

Table 48.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>createCertificateRequest</p>	<p>The createCertificateRequest command creates a certificate request that is associated with a particular key store.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - certificateVersion The certificate version. (String, required) - certificateSize (Integer, required) - certificateCommonName (String, required) - certificateOrganization (String, optional) - certificateOrganizationUnit (String, optional) - certificateLocality (String, optional) - certificateState The state code for the certificate. (String, optional) - certificateZip The zip code for the certificate. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createCertificateRequest {-keyStoreName testKeyStore -certificateAlias certReq -certificateSize 1024 -certificateCommonName localhost -certificateOrganization testing -certificateRequestFilePath c:\temp\testCertReq.arm} • Using Jython string: AdminTask.createCertificateRequest ('[-keyStoreName testKeyStore -certificateAlias certReq -certificateSize 1024 -certificateCommonName localhost -certificateOrganization testing -certificateRequestFilePath c:\temp\testCertReq.arm] • Using Jython list: AdminTask.createCertificateRequest (['-keyStoreName', 'testKeyStore', '-certificateAlias', 'certReq', '-certificateSize', '1024', '-certificateCommonName', 'localhost', '-certificateOrganization', 'testing', '-certificateRequestFilePath', 'c:\temp\testCertReq.arm']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createCertificateRequest {-interactive} • Using Jython string: AdminTask.createCertificateRequest ('[-interactive]') • Using Jython list: AdminTask.createCertificateRequest (['-interactive'])

Table 48. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - certificateCountry The country for the certificate. (String, optional) - certificateValidDays The amount of time in days for which the certificate is valid. (Integer, optional) - - certificateRequestFilePath The file location of the certificate request that can be sent to a certificate authority. (String, required) • Returns: The configuration object name of the key store object that you created. 	
deleteCertificate Request	The deleteCertificateRequest command deletes a certificate request from a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask deleteCertificateRequest {-interactive}</code> • Using Jython string: <code>AdminTask.deleteCertificateRequest ('[-interactive]')</code> • Using Jython list: <code>AdminTask.deleteCertificateRequest (['-interactive'])</code>

Table 48. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
extractCertificateRequest	The extractCertificateRequest command extracts a certificate request to a file.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - certificateRequestFilePath The file location of the certificate request that can be sent to a certificate authority. (String, required) • Returns: A certificate request file is created that contains the extracted certificate. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask extractCertificateRequest {-interactive}</code> • Using Jython string: <code>AdminTask.extractCertificateRequest ('[-interactive]')</code> • Using Jython list: <code>AdminTask.extractCertificateRequest (['-interactive'])</code>

Table 48. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getCertificateRequest	The getCertificateRequest command obtains information about a particular certificate request in a key store.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) Returns: Information about the certificate request. 	Interactive mode example usage: <ul style="list-style-type: none"> Using Jacl: \$AdminTask getCertificateRequest {-interactive} Using Jython string: AdminTask.getCertificateRequest ('[-interactive]') Using Jython list: AdminTask.getCertificateRequest (['-interactive'])
listCertificateRequest	The listCertificateRequest command lists all the certificate requests associated with a particular key store.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) Returns: An attribute list for each certificate request in a key store. 	Interactive mode example usage: <ul style="list-style-type: none"> Using Jacl: \$AdminTask listCertificateRequest {-interactive} Using Jython string: AdminTask.listCertificateRequest ('[-interactive]') Using Jython list: AdminTask.listCertificateRequest (['-interactive'])

Commands for the SignerCertificateCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SignerCertificateCommands group of the AdminTask object:

Table 49.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
addSignerCertificate	The addSignerCertificate command adds a signer certificate from a certificate file to a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, optional) - certificateFilePath The full path name of the file that contains the signer certificate. (String, required) - certificateAlias The alias name of the signer certificate in the key store. (String, required) - base64Encoded Set the value of this parameter to true if the certificate is ascii base 64 encoded. Set the value of this parameter to false if the certificate is binary. (String, required) • Returns: The configuration object name of the key store object that you created. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addSignerCertificate {-interactive} • Using Jython string: AdminTask.addSignerCertificate ('[-interactive]') • Using Jython list: AdminTask.addSignerCertificate (['-interactive'])

Table 49. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteSignerCertificate	The deleteSignerCertificate command deletes a signer certificate from a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, optional) - certificateAlias The alias name of the signer certificate in the key store. (String, required) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteSignerCertificate {-interactive} • Using Jython string: AdminTask.deleteSignerCertificate ('[-interactive]') • Using Jython list: AdminTask.deleteSignerCertificate (['-interactive'])

Table 49. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
extractSignerCertificate	The extractSignerCertificate command extracts a signer certificate from a key store to a file.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, optional) - certificateAlias The alias name of the signer certificate in the key store. (String, required) - certificateFilePath The full path name of the file that contains the signer certificate. (String, required) - base64Encoded Set the value of this parameter to true if the certificate is ascii base 64 encoded. Set the value of this parameter to false if the certificate is binary. (String, required) • Returns: The certificate file is created and contains the signer certificate. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask extractSignerCertificate {-interactive} • Using Jython string: AdminTask.extractSignerCertificate ('[-interactive]') • Using Jython list: AdminTask.extractSignerCertificate (['-interactive'])

Table 49. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getSignerCertificate	The getSignerCertificate command obtains information about a signer certificate from a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, optional) - certificateAlias The alias name of the signer certificate in the key store. (String, required) • Returns: Information about a signer certificate. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getSignerCertificate {-interactive} • Using Jython string: AdminTask.getSignerCertificate ('[-interactive]') • Using Jython list: AdminTask.getSignerCertificate (['-interactive'])
listSignerCertificates	The listSignerCertificates command lists all signer certificates in a particular key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, optional) • Returns: A list of signer certificate aliases. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listSignerCertificates {-interactive} • Using Jython string: AdminTask.listSignerCertificates ('[-interactive]') • Using Jython list: AdminTask.listSignerCertificates (['-interactive'])

Table 49. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
retrieveSignerFromPort	The retrieveSignerFromPort command retrieves a signer from a remote host and stores the signer in a key store.	None	<ul style="list-style-type: none"> • Parameters: - host The host name of the system from where the signer certificate will be retrieved. (String, required) - port The port of the remote system from where the signer certificate will be retrieved. (Integer, required) - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, required) - sslConfigName The name of the SSL configuration object. (String, optional) - sslConfigScopeName The management scope where the SSL configuration object is located. (String, optional) • Returns: The signer certificate is created in the key store file. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask retrieveSignerFromPort {-host serverHost -port 443 -keyStoreName testKeyStore -certificateAlias serverHostSigner} • Using Jython string: AdminTask.retrieveSignerFromPort ('[-host serverHost -port 443 -keyStoreName testKeyStore -certificateAlias serverHostSigner]') • Using Jython list: AdminTask.retrieveSignerFromPort (['-host', 'serverHost', '-port', '443', '-keyStoreName', 'testKeyStore', '-certificateAlias', 'serverHostSigner']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask retrieveSignerFromPort {-interactive} • Using Jython string: AdminTask.retrieveSignerFromPort ('[-interactive]') • Using Jython list: AdminTask.retrieveSignerFromPort (['-interactive'])

Table 49. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
retrieveSigner InfoFromPort	The retrieveSigner InfoFromPort command retrieves signer information from a port on a remote host.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - host The host name of the system from where the signer certificate will be retrieved. (String, required) - port The port of the remote system from where the signer certificate will be retrieved. (Integer, required) - sslConfigName The name of the SSL configuration object. (String, optional) - sslConfigScopeName The management scope where the SSL configuration object is located. (String, optional) Returns: Information about the signer certificate from the remote host port. 	Interactive mode example usage: <ul style="list-style-type: none"> Using Jacl: \$AdminTask retrieveSigner InfoFromPort {-interactive} Using Jython string: AdminTask.retrieveSigner InfoFromPort (['-interactive']) Using Jython list: AdminTask.retrieveSigner InfoFromPort (['-interactive'])

Commands for the PersonalCertificateCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the personalCertificateCommands group of the AdminTask object:

Table 50.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>createSelfSignedCertificate</p>	<p>The createSelfSignedCertificate command creates a personal certificate in a key store.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - certificateVersion The version of the certificate. (String, required) - certificateSize The size of the certificate. (Integer, required) - certificateCommonName The common name of the certificate. (String, required) - certificateOrganization The organization of the certificate. (String, optional) - certificateOrganizationUnit The organizational unit of the certificate. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createSelfSignedCertificate {-keyStoreName testKeyStore -certificateAlias default -certificateCommonName localhost -certificateOrganization ibm} • Using Jython string: AdminTask.createSelfSignedCertificate (['-keyStoreName testKeyStore -certificateAlias default -certificateCommonName localhost -certificateOrganization ibm']) • Using Jython list: AdminTask.createSelfSignedCertificate (['-keyStoreName', 'testKeyStore', '-certificateAlias', 'default', '-certificateCommonName', 'localhost', '-certificateOrganization', 'ibm']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createSelfSignedCertificate {-interactive} • Using Jython string: AdminTask.createSelfSignedCertificate (['-interactive']) • Using Jython list: AdminTask.createSelfSignedCertificate (['-interactive'])

Table 50. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - certificateLocality The locality of the certificate. (String, optional) - certificateState The state of the certificate. (String, optional) - certificateZip The zip code of the certificate. (String, optional) - certificateCountry The country of the certificate. (String, optional) - certificateValidDays The amount of time in days for which the certificate is valid. (Integer, optional) • Returns: None 	
deleteCertificate	The deleteCertificate command deletes a personal certificate from a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteCertificate {-interactive} • Using Jython string: AdminTask.deleteCertificate ('[-interactive]') • Using Jython list: AdminTask.deleteCertificate (['-interactive'])

Table 50. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
exportCertificate	<p>The exportCertificate command exports a personal certificate from one key store to another.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - - keyStorePassword The password to the key store. (String, required) - keyFilePath The full path to a key store file that is located in a file system. The store from where a certificate will be imported or exported. (String, required) - keyFilePassword The password to the key store file. (String, required) - keyFileType The type of the key file. (String, required) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - aliasInKeyStore (String, optional) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask exportCertificate {-interactive}</code> • Using Jython string: <code>AdminTask.exportCertificate ('[-interactive]')</code> • Using Jython list: <code>AdminTask.exportCertificate (['-interactive'])</code>

Table 50. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
extractCertificate	<p>The extractCertificate command extracts the signer part of a personal certificate to a file.</p>	None	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - certificateRequestFilePath The full path of the request file that contains the certificate. (String, required) - base64Encoded Set the value of this parameter to true if the certificate is ascii base 64 encoded. Set the value of this parameter to false if the certificate is binary. (Boolean, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask extractCertificate {-keyStoreName testKeyStore -certificateFilePath c:\temp\CertFile.arm -certificateAlias testCertificate} • Using Jython string: AdminTask.extractCertificate (['-keyStoreName testKeyStore -certificateFilePath c:\temp\CertFile.arm -certificateAlias testCertificate']) • Using Jython list: AdminTask.extractCertificate (['-keyStoreName', 'testKeyStore', '-certificateFilePath', 'c:\temp\CertFile.arm', '-certificateAlias', 'testCertificate']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask extractCertificate {-interactive} • Using Jython string: AdminTask.extractCertificate (['-interactive']) • Using Jython list: AdminTask.extractCertificate (['-interactive'])

Table 50. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getCertificate	The getCertificate command obtains information about a particular personal certificate in a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) • Returns: Information about the certificate request. 	Interactive mode example usage: <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getCertificate {-interactive} • Using Jython string: AdminTask.getCertificate ('[-interactive]') • Using Jython list: AdminTask.getCertificate (['-interactive'])

Table 50. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
importCertificate	The importCertificate command imports a personal certificate from a key store.	None	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - keyFilePath The full path to a key store file that is located in a file system. The store from where a certificate will be imported or exported. (String, required) - keyFilePassword The password to the key store file. (String, required) - keyFileType The type of the key file. (String, required) - - certificateAliasFromKeyFile The certificate alias in the key file from which the certificate is being imported. (String, required) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask importCertificate {-interactive} • Using Jython string: AdminTask.importCertificate ('[-interactive]') • Using Jython list: AdminTask.importCertificate (['-interactive'])

Table 50. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listPersonalCertificates	<p>The listPersonalCertificates command lists the personal certificates in a particular key store.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) • Returns: A list of attributes for each personal certificate in a key store. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listPersonalCertificates {-interactive} • Using Jython string: AdminTask.listPersonalCertificates ('[-interactive]') • Using Jython list: AdminTask.listPersonalCertificates (['-interactive'])

Table 50. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
receiveCertificate	<p>The receiveCertificate command receives a signer certificate from a file to a personal certificate.</p>	None	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - certificateFilePath The full path of the file that contains the certificate. (String, required) - base64Encoded Set the value of this parameter to true if the certificate is ascii base 64 encoded. Set the value of this parameter to false if the certificate is binary. (Boolean, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask receiveCertificate {-keyStoreName testKeyStore -certificateFilePath c:\temp\CertFile.arm} • Using Jython string: AdminTask.receiveCertificate (['-keyStoreName testKeyStore -certificateFilePath c:\temp\CertFile.arm']) • Using Jython list: AdminTask.receiveCertificate (['-keyStoreName', 'testKeyStore', '-certificateFilePath', 'c:\temp\CertFile.arm']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask receiveCertificate {-interactive} • Using Jython string: AdminTask.receiveCertificate (['-interactive']) • Using Jython list: AdminTask.receiveCertificate (['-interactive'])

Table 50. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
replaceCertificate	<p>The replaceCertificate command replaces a personal certificate with a new one. Replaces all signer certificates from the personal certificate.</p>	None	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - replacementCertificateAlias The alias of the certificate that is used to replace a different certificate. (String, required) - deleteOldCert Set the value of this parameter to true if you want to delete the old signer certificates during certificate replacement. Otherwise, set the value of this parameter to false. (Boolean, optional) - deleteOldSigners Set the value of this parameter to true if you want to delete the old certificates during certificate replacement. Otherwise, set the value of this parameter to false. (Boolean, optional) <ul style="list-style-type: none"> • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask replaceCertificate {-keyStoreName testKeyStore -certificateAlias default -replacementCertificateAlias replaceCert -deleteOldCert true -deleteOldSigners true} • Using Jython string: AdminTask.replaceCertificate ('[-keyStoreName testKeyStore -certificateAlias default -replacementCertificateAlias replaceCert -deleteOldCert true -deleteOldSigners true]') • Using Jython list: AdminTask.replaceCertificate (['-keyStoreName', 'testKeyStore', '-certificateAlias', 'default', '-replacementCertificateAlias', 'replaceCert', '-deleteOldCert', 'true', '-deleteOldSigners', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask replaceCertificate {-interactive} • Using Jython string: AdminTask.replaceCertificate ('[-interactive]') • Using Jython list: AdminTask.replaceCertificate (['-interactive'])

Commands for the SPNEGO TAI group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SPNEGO TAI group of the AdminTask object:

Command name:	Description:	Target object:	Parameters and return values:	Examples:
addSpnegoTAIProperties	The addSpnegoTAIProperties command adds properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.	None	<ul style="list-style-type: none"> Parameters: - spnId This is the SPN identifier for the group of custom properties that are to be defined with this command. If you do not specify this parameter, an unused SPN identifier is assigned. (String, optional) - host Specifies the host name portion in the SPN used by the SPNEGO TAI to establish a Kerberos secure context. (String, required) - filter Defines the filtering criteria used by the class specified with the above attribute. If no filter is specified, all HTTP requests are subject to SPNEGO authentication. (String, optional) - filterClass Specifies the name of the Java class used by the SPNEGO TAI to select which HTTP requests will be subject to SPNEGO authentication. If no filter class is specified, the default filter class, <code>com.ibm.ws.security.spnego.HTTPHeaderFilter</code>, is used. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask addSpnegoTAIProperties -host myhost.ibm.com -filter user-agent%=IE 6</code> Using Jython string: <code>AdminTask.addSpnegoTAIProperties (['-host myhost.ibm.com -filter user-agent%=IE 6'])</code> Using Jython list: <code>AdminTask.addSpnegoTAIProperties (['-host', 'myhost.ibm.com', '-filter', 'user-agent%=IE', '6'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask addSpnegoTAIProperties -interactive</code> Using Jython string: <code>AdminTask.addSpnegoTAIProperties (['-interactive'])</code> Using Jython list: <code>AdminTask.addSpnegoTAIProperties ['-interactive'])</code>

			<p>- noSpnegoPage Specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application if it does not support SPNEGO authentication. (String, optional).</p> <p>If you do not specify the noSpnegoPage attribute then the default is used:</p> <pre>"<html><head><title> SPNEGO authentication is not supported. </title></head>" + "<body>SPNEGO authe ntication is not supported on this client.</body> </html>";</pre> <p>- ntlmTokenPage Specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application when the SPNEGO token received by the interceptor after the challenge-response handshake contains a NT LAN manager (NTLM) token instead of the expected SPNEGO token. (String, optional).</p> <p>If you do not specify the ntlmTokenPage attribute then the default is used:</p> <pre>"<html><head><title> An NTLM Token was received.</title> </head>" + "<body>Your bro wser configuration is correct, but you have not logged into a supported Windows Domain." + "<p>Please login to the application using the normal login page.</html>";</pre>	
--	--	--	--	--

			<p>- trimUserName</p> <p>Specifies whether (true) or not (false) the SPNEGO TAI is to remove the suffix of the principal user name, starting from the @ that precedes the Kerberos realm name. If this attribute is set to true, the suffix of the principal user name is removed. If this attribute is set to false, the suffix of the principal name is retained. The default value used is true. (String, optional)</p> <ul style="list-style-type: none">• Returns: None	
--	--	--	---	--

<p>createKrb ConfigFile</p>	<p>The createKrb ConfigFile command creates the Kerberos configuration file for use with the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - krbPath Provides the fully qualified file system location of the Kerberos configuration (krb5.ini or krb5.conf) file. (String, required) - realm Provides the Kerberos realm name. The value of this attribute is used by the SPNEGO TAI to form the Kerberos service principal name for each of the hosts specified with the property <code>com.ibm.ws.security.spnego.SPN<id>.hostname</code> (String, required) - kdcHost Provides the host name of the Kerberos Key Distribution Center (KDC). (String, required) - kdcPort Provides the port number of the KDC. The default value, if not specified, is 88. (String, optional) - dns Provides the default domain name service (DNS) that is used to produce a fully qualified host name. (String, required) - keytabPath Provides the file system location of the Kerberos keytab file. (String, required) - encryption Identifies the list of supported encryption types, separated by a space. The specified value is used for the <code>default_tkt_encytypes</code> and <code>default_tgs_encytypes</code>. The default encryption types, if not specified, are <code>des-cbc-md5</code> and <code>rc4-hmac</code>. (String, optional) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createKrbConfigFile -interactive</code> • Using Jython string: <code>AdminTask.createKrbConfigFile ('[-interactive]')</code> • Using Jython list: <code>AdminTask.createKrbConfigFile ['-interactive']</code>
---------------------------------	---	-------------	--	---

deleteSpnegoTAIProperties	The deleteSpnegoTAIProperties command deletes properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - spnId The SPN identifier for the group of custom properties that are to be deleted with this command. If you do not specify this parameter, all SPNEGO TAI custom properties are deleted. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask deleteSpnegoTAIProperties {-spnId 2}</code> • Using Jython string: <code>AdminTask.deleteSpnegoTAIProperties ('[-spnId 2]')</code> • Using Jython list: <code>AdminTask.deleteSpnegoTAIProperties (['-spnId', '2'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask deleteSpnegoTAIProperties -interactive</code> • Using Jython string: <code>AdminTask.deleteSpnegoTAIProperties (['-interactive'])</code> • Using Jython list: <code>AdminTask.deleteSpnegoTAIProperties ['-interactive'])</code>
---------------------------	---	------	---	---

<p>modifySpnegoTAIProperties</p>	<p>The modifySpnegoTAIProperties command modifies the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - spnId The SPN identifier for the group of custom properties that are to be defined with this command. (String, required) - host Specifies the host name portion in the SPN used by the SPNEGO TAI to establish a Kerberos secure context. (String, optional) - filter Defines the filtering criteria used by the class specified with the above attribute. (String, optional) - filterClass Specifies the name of the Java class used by the SPNEGO TAI to select which HTTP requests will be subject to SPNEGO authentication. If no class is specified, all HTTP requests will be subject to SPNEGO authentication. (String, optional) - noSpnegoPage Specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application if it does not support SPNEGO authentication. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask modifySpnegoTAI PROPERTIES -spnId 1 -filter host==myhost.company.com</code> • Using Jython string: <code>AdminTask.modifySpnegoTAI PROPERTIES (['-spnId 1 -filter host==myhost.com pany.com']')</code> • Using Jython list: <code>AdminTask.modifySpnegoTAI PROPERTIES (['-spnId', '1', '-filter', 'host==my host.company.com']')</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask modifySpnegoTAI Properties -interactive</code> • Using Jython string: <code>AdminTask.modifySpnegoTAI Properties (['-interactive']')</code> • Using Jython list: <code>AdminTask.modifySpnegoTAI Properties ['-interactive']</code>
----------------------------------	---	-------------	---	--

			<p>- ntlmTokenPage Specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application when the SPNEGO token received by the interceptor after the challenge-response handshake contains a NT LAN manager (NTLM) token instead of the expected SPNEGO token. (String, optional)</p> <p>- trimUserName Specifies whether (true) or not (false) the SPNEGO TAI is to remove the suffix of the principal user name, starting from the "@" that precedes the Kerberos realm name. If this attribute is set to true, the suffix of the principal user name is removed. If this attribute is set to false, the suffix of the principal name is retained. The default value used is true. (String, optional)</p> <ul style="list-style-type: none"> • Returns: None 	
--	--	--	--	--

showSpnegoTAI Properties	The showSpnegoTAI Properties command displays the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - spnId The service principal name (SPN) identifier for the group of custom properties that are to be displayed with this command. If you do not specify this parameter, all SPNEGO TAI custom properties are displayed. (String, optional) Returns: A list of properties. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask showSpnegoTAI Properties -spnId 1</code> Using Jython string: <code>AdminTask.showSpnegoTAI Properties (['-spnId 1'])</code> Using Jython list: <code>AdminTask.showSpnegoTAI Properties (['-spnId', '1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask showSpnegoTAI Properties -interactive</code> Using Jython string: <code>AdminTask.showSpnegoTAI Properties (['-interactive'])</code> Using Jython list: <code>AdminTask.showSpnegoTAI Properties ['-interactive'])</code>
--------------------------	---	------	---	---

Commands for the AuthorizationGroupCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the AuthorizationGroupCommands group of the AdminTask object:

Command name:	Description:	Target object:	Parameters and return values:	Examples:
---------------	--------------	----------------	-------------------------------	-----------

<p>addResourceToAuthorizationGroup</p>	<p>The addResourceToAuthorizationGroup command adds a resource instance to an existing authorization group. A resource instance cannot belong to more than one authorization group.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. (String, required) - resourceName The name of the resource instance that you want to add to an authorization group. (String, required) <p>The resourceName parameter should be in the following format: ResourceType= ResourceName</p> <p>where ResourceType is one of the following values: Application, Server, ServerCluster, Node, NodeGroup</p> <p>ResourceName is the name of the resource instance, for example, server1.</p> <p>The following are example uses of the resourceName parameter:</p> <ul style="list-style-type: none"> - Node=node1:Server=server1 <p>This example uniquely identifies server1. node1 is required if another server1 exists on a different node.</p> <ul style="list-style-type: none"> - Application=app1 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask addResourceToAuthorizationGroup {-authorizationGroupName groupName -resourceName Application=app1}</code> • Using Jython string: <code>AdminTask.addResourceToAuthorizationGroup(['-authorizationGroupName groupName -resourceName Application=app1'])</code> • Using Jython list: <code>AdminTask.addResourceToAuthorizationGroup(['-authorizationGroupName', 'groupName', '-resourceName', 'Application=app1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask addResourceToAuthorizationGroup {-interactive}</code> • Using Jython string: <code>AdminTask.addResourceToAuthorizationGroup (['-interactive'])</code> • Using Jython list: <code>AdminTask.addResourceToAuthorizationGroup (['-interactive'])</code>
			<ul style="list-style-type: none"> • Returns: None 	

<p>createAuthorizationGroup</p>	<p>The createAuthorizationGroup command creates a new authorization group. When you create a new authorization group, no members are associated with it. Also, no user to administrative role mapping for the authorization table is associated with the authorization group.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group that you want to create. (String, required) • Returns: The configuration ID of the authorization group that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createAuthorizationGroup {-authorizationGroupName <i>groupName</i>}</pre> • Using Jython string: <pre>AdminTask.createAuthorizationGroup(['-authorizationGroupName <i>groupName</i>'])</pre> • Using Jython list: <pre>AdminTask.createAuthorizationGroup(['-authorizationGroupName', '<i>groupName</i>'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createAuthorizationGroup -interactive</pre> • Using Jython string: <pre>AdminTask.createAuthorizationGroup(['-interactive'])</pre> • Using Jython list: <pre>AdminTask.createAuthorizationGroup(['-interactive'])</pre>
---------------------------------	--	-------------	--	--

deleteAuthorizationGroup	The deletes an existing authorization group. When you delete an authorization group, the authorization table that corresponds is also deleted.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - authorizationGroup Name The name of the authorization group that you want to delete. (String, required) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask deleteAuthorizationGroup {-authorizationGroupName groupName}</code> Using Jython string: <code>AdminTask.deleteAuthorizationGroup('[-authorizationGroupName groupName]')</code> Using Jython list: <code>AdminTask.deleteAuthorizationGroup(['-authorizationGroupName', 'groupName'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask deleteAuthorizationGroup {-interactive}</code> Using Jython string: <code>AdminTask.deleteAuthorizationGroup ('[-interactive]')</code> Using Jython list: <code>AdminTask.deleteAuthorizationGroup (['-interactive'])</code>
	The command lists the existing authorization groups.	None	<ul style="list-style-type: none"> Parameters: None Returns: A list of short names of all existing authorization groups. (String []) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroups</code> Using Jython: <code>AdminTask.listAuthorizationGroups()</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroups {-interactive}</code> Using Jython string: <code>AdminTask.listAuthorizationGroups ('[-interactive]')</code> Using Jython list: <code>AdminTask.listAuthorizationGroups (['-interactive'])</code>

<p>listAuthorizationGroupsForGroupID</p>	<p>The listAuthorizationGroupsForGroupID command lists all of the authorization groups to which a given user group has access. This command lists the authorization groups and the granted roles for each authorization group. The group ID can be a short name or a fully qualified domain name if the LDAP user registry is being used. This command will list cell as a group if the user has cell level access.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - groupid The ID of the user group. (String, required) • Returns: The map of the authorization group and granted roles. (Map[String=String[]]) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listAuthorizationGroupsForGroupID {-groupid <i>userGroupName</i>}</pre> • Using Jython string: <pre>AdminTask.listAuthorizationGroupsForGroupID(['-groupid <i>userGroupName</i>'])</pre> • Using Jython list: <pre>AdminTask.listAuthorizationGroupsForGroupID(['-groupid', '<i>userGroupName</i>'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listAuthorizationGroupsForGroupID {-interactive}</pre> • Using Jython string: <pre>AdminTask.listAuthorizationGroupsForGroupID ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.listAuthorizationGroupsForGroupID (['-interactive'])</pre>
--	--	-------------	---	---

listAuthorizationGroupsForUser ID	The listAuthorizationGroupsForUser ID command lists all of the authorization groups to which a given user has access. This command lists the authorization groups and the granted roles for each authorization group. The user ID and the group ID can be a short name or a fully qualified domain name if the LDAP user registry is being used. This command will list cell as a group if the user has cell level access.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - userid The ID of the user. (String, required) Returns: The map of the authorization group and granted roles. (Map[String=String[]]) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroupsForUserID{-userid userName}</code> Using Jython string: <code>AdminTask.listAuthorizationGroupsForUserID(['-userid userName'])</code> Using Jython list: <code>AdminTask.listAuthorizationGroupsForUserID(['-userid', 'userName'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroupsForUserID {-interactive}</code> Using Jython string: <code>AdminTask.listAuthorizationGroupsForUserID (['-interactive'])</code> Using Jython list: <code>AdminTask.listAuthorizationGroupsForUserID (['-interactive'])</code>
-----------------------------------	---	------	--	---

listAuthorizationGroupsOfResource	The listAuthorizationGroupsOfResource command lists authorization groups for a given resource. If the value of the <code>traverseContainedObjects</code> parameter is false, only the authorization group of the resource is returned. If the value of the <code>traverseContainedObjects</code> parameter is true, it returns the authorization group of the resource and the authorization groups of all the parent resources in the containment tree.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - resourceName The name of the resource. (String, required) The <code>resourceName</code> parameter must be in the following format: ResourceType=ResourceName where <code>ResourceType</code> can be any one of the following values: Application, Server, ServerCluster, Node, or NodeGroup. <code>ResourceName</code> is the name of the resource instance, for example, <code>server1</code>. The following are examples of the <code>resourceName</code> parameter: Node=node1: Server=server This example uniquely identifies <code>server1</code>. The name of the node is required if a server on a different node uses the same server name. Application=app1 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroupsOfResource {-resourceName Application=app1}</code> Using Jython string: <code>AdminTask.listAuthorizationGroupsOfResource(['-resourceName Application=app1'])</code> Using Jython list: <code>AdminTask.listAuthorizationGroupsOfResource(['-resourceName', 'Application=app1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroupsOfResource {-interactive}</code> Using Jython string: <code>AdminTask.listAuthorizationGroupsOfResource(['-interactive'])</code> Using Jython list: <code>AdminTask.listAuthorizationGroupsOfResource(['-interactive'])</code>
-----------------------------------	---	------	---	--

			<p>- traverseContainedResources</p> <p>Finds the authorization groups of all the parent resources by traversing the resource containment tree upwards. The default value is false. (Boolean, optional)</p> <ul style="list-style-type: none"> Returns: The short names of all of the authorization groups for which the resource belongs. If you do not specify the <code>traverseContainedResources</code> parameter, the result of this command will only contain one value because a resource instance can only belong to one authorization group. (String[]) 	
listResourcesOfAuthorizationGroup	The listResourcesOfAuthorizationGroup command lists all of the resources within the given authorization group.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. (String, required) Returns: The configuration IDs of all of the resource instances within the authorization group. (String[]) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listResourcesOfAuthorizationGroup {-authorizationGroupName groupName} Using Jython string: AdminTask.listResourcesOfAuthorizationGroup(['-authorizationGroupName groupName']) Using Jython list: AdminTask.listResourcesOfAuthorizationGroup(['-authorizationGroupName', 'groupName']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listResourcesOfAuthorizationGroup {-interactive} Using Jython string: AdminTask.listResourcesOfAuthorizationGroup(['-interactive']) Using Jython list: AdminTask.listResourcesOfAuthorizationGroup(['-interactive'])

listResourcesForGroupID	<p>The listResourcesForGroupID command lists all the objects that a given group has access to. This command lists the resources and the granted roles for each resource. The resources that this command returns include the resources from the authorization groups to which the user group is granted roles and the resources that are descendants of the resources with in authorization groups to which the user group is granted access to any role. The group ID can be a short name or fully qualified domain name if a LDAP user registry is used.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - groupid The ID of the user group. (String, required) • Returns: The map of the granted role and resources. (Map[String=String[]]) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask listResourcesForGroupID {-groupid <i>userGroup</i> <i>groupName</i>}</code> • Using Jython string: <code>AdminTask.listResourcesForGroupID(['-groupid <i>userGroup</i> <i>groupName</i>'])</code> • Using Jython list: <code>AdminTask.listResourcesForGroupID(['-groupid', 'userGroupName'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask listResourcesForGroupID {-interactive}</code> • Using Jython string: <code>AdminTask.listResourcesForGroupID ('[-interactive]')</code> • Using Jython list: <code>AdminTask.listResourcesForGroupID (['-interactive'])</code>
-------------------------	---	------	--	--

listResourcesForUserID	<p>The listResourcesForUserID command lists all the objects that a given user has access to. This command lists the resources and the granted roles for each resource. The resources that this command returns include the resources from the authorization groups to which the user is granted roles and the resources that are descendants of the resources with in authorization groups to which the user is granted access to any role. The user ID can be a short name or fully qualified domain name if a LDAP user registry is used.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - userid The ID of the user. (String, required). • Returns: The map of granted role and resources. (Map[String=String[]]) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask listResourcesForUserID {-userid userName }</code> • Using Jython string: <code>AdminTask.listResourcesForUserID('[-userid userName]')</code> • Using Jython list: <code>AdminTask.listResourcesForUserID(['-userid', 'userName'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask listResourcesForUserID {-interactive}</code> • Using Jython string: <code>AdminTask.listResourcesForUserID ('[-interactive]')</code> • Using Jython list: <code>AdminTask.listResourcesForUserID (['-interactive'])</code> <p>Example output:</p> <pre>{deployer=[], operator=[], administrator=[cells/IBM-LP16L31HVE8Cell107/clusters/C1 cluster.xml, cells/IBM-LP16L31HVE8Cell107/nodes/IBM-LP16L31HVE8Node05/servers/cm1 server.xml], monitor=[], configurator=[]}</pre>
------------------------	--	------	--	---

<p>mapGroupsToAdminRole</p>	<p>The mapGroupsToAdminRole command maps group IDs in an administrative roles in an authorization group. The name of the authorization group that you provide determines which authorization table will be used. If you do not specify an authorization group name, the mapping is done to the cell level authorization table. The group ID can be a short name or a fully qualified domain name if the LDAP user registry is used.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - authorizationGroup Name The name of the authorization group. If you do not specify this parameters, the cell level authorization group is assumed. (String, optional) - roleName The name of the administrative role. (String, required) - groupids The list of group IDs that will mapped to the administrative role. (String[], required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask mapGroupsToAdminRole {-authorizationGroupName group Name - roleName administrator -groupids group1}</pre> • Using Jython string: <pre>AdminTask.mapGroupsToAdminRole ('[-authorizationGroupName group Name -roleName administrator -groupids group1]')</pre> • Using Jython list: <pre>AdminTask.mapGroupsToAdminRole (['-authorizationGroupName', 'groupName', '-roleName', 'administrator', '-groupids', 'group1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask mapGroupsToAdminRole {-interactive}</pre> • Using Jython string: <pre>AdminTask.mapGroupsToAdminRole ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.mapGroupsToAdminRole (['-interactive'])</pre>
-----------------------------	--	-------------	--	---

mapUsersToAdminRole	<p>The mapUsersToAdminRole command maps user IDs to one or more administrative roles in the authorization group. The name of the authorization group that you provide determines the authorization table. If you do not specify the name of the authorization group, the mapping is done to the cell level authorization table. The user ID can be a short name or fully qualified domain name in case LDAP user registry is used.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. If you do not specify this parameter, the cell level authorization group is assumed. (String, optional) - roleName The name of the administrative role. (String, required) - userids The list of user IDs that will be mapped to the administrative role (String[], required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask mapUsersToAdminRole {-authorizationGroupName group Name - roleName administrator -userids user1}</pre> • Using Jython string: <pre>AdminTask.mapUsersToAdminRole ('[-authorizationGroupName groupName -roleName administ rator -userids user1]')</pre> • Using Jython list: <pre>AdminTask.mapUsersToAdminRole (['-authorizationGroupName', 'groupName', '-roleName', 'administrator', '-userids', 'user1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask mapUsersToAdmin Role {-interactive}</pre> • Using Jython string: <pre>AdminTask.mapUsersToAdmin Role ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.mapUsersToAdmin Role (['-interactive'])</pre>
---------------------	---	------	--	--

<p>removeGroupsFromAdminRole</p>	<p>The removeGroupsFromAdminRole command removes previously mapped group IDs from administrative roles in the authorization group. The name of the authorization group that you provide determines which authorization table is involved. If you do not specify an authorization group name, the group IDs are removed from the cell level authorization table. The group ID can be a short name or fully qualified domain name if a LDAP user registry is used.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. If you do not specify this parameter, the cell level authorization group is assumed. (String, optional) - roleName The name of the administrative role. (String, required) - userids A list of group IDs that you want to remove from the administrative role. (String[], required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask removeGroupsFromAdminRole {-authorizationGroupName groupName - roleName administrator -groupids group1}</code> • Using Jython string: <code>AdminTask.removeGroupsFromAdminRole('[-authorizationGroupName groupName -roleName administrator -groupids group1]')</code> • Using Jython list: <code>AdminTask.removeGroupsFromAdminRole(['-authorizationGroupName', 'groupName', '-roleName', 'administrator', '-groupids', 'group1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask removeGroupsFromAdminRole {-interactive}</code> • Using Jython string: <code>AdminTask.removeGroupsFromAdminRole ('[-interactive]')</code> • Using Jython list: <code>AdminTask.removeGroupsFromAdminRole (['-interactive'])</code>
----------------------------------	---	-------------	--	---

<p>remove Resource From AuthorizationGroup</p>	<p>The removeResourceFromAuthorizationGroup command removes resources from an existing authorization group. If you do not specify the authorization group, it will be determined and the resource will be removed from that authorization group.</p>	<p>None</p>	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - authorizationGroup Name The name of the authorization group. (String, optional) - resourceName The name of the resource instance that you want to remove from the authorization group. (String, required) <p>The resourceName parameter must be in the following format:</p> <pre>ResourceType= ResourceName</pre> <p>where the ResourceType can be any of the following: Application, Server, ServerCluster, Node, or NodeGroup.</p> <p>The ResourceName is the name of the resource instance, for example, server1.</p> <p>The following are examples of the resourceName parameter:</p> <pre>Node=node1: Server=server1</pre> <p>This example uniquely identifies server1. node1 is required if the name of the server exists on multiple nodes.</p> <pre>Application=app1</pre> Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask removeResourceFromAuthorizationGroup {-authorizationGroupName groupName -resourceName Application=app1}</pre> Using Jython string: <pre>AdminTask.removeResourceFromAuthorizationGroup(['-authorizationGroupName groupName -resourceName Application=app1'])</pre> Using Jython list: <pre>AdminTask.removeResourceFromAuthorizationGroup(['-authorizationGroupName', 'groupName', '-resourceName', 'Application=app1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask removeResourceFromAuthorizationGroup {-interactive}</pre> Using Jython string: <pre>AdminTask.removeResourceFromAuthorizationGroup (['-interactive'])</pre> Using Jython list: <pre>AdminTask.removeResourceFromAuthorizationGroup (['-interactive'])</pre>
--	---	-------------	--	--

removeUsersFromAdminRole	The removeUsersFromAdminRole command removes previously mapped user IDs from administrative roles in the authorization group. The name of the authorization group that you provide determines which authorization table is involved. If you do not specify an authorization group name, the user ID from the cell level authorization table will be used. The user ID can be a short name or a fully qualified domain name if a LDAP user registry is used.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. If you do not specify this parameter, the cell level authorization group is assumed. (String, optional) - roleName The name of the administrative role. (String, required) - userids A list of user IDs that you want to remove from the administrative role. (String[], required) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask removeUsersFromAdminRole {-authorizationGroupName groupName - roleName administrator -userids user1}</code> Using Jython string: <code>AdminTask.removeUsersFromAdminRole('[-authorizationGroupName groupName -roleName administrator -userids user1]')</code> Using Jython list: <code>AdminTask.removeUsersFromAdminRole(['-authorizationGroupName', 'groupName', '-roleName', 'administrator', '-userids', 'user1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask removeUsersFromAdminRole {-interactive}</code> Using Jython string: <code>AdminTask.removeUsersFromAdminRole ('[-interactive]')</code> Using Jython list: <code>AdminTask.removeUsersFromAdminRole (['-interactive'])</code>
--------------------------	--	------	---	---

Commands for the ChannelFrameworkManagement group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the ChannelFrameworkManagement group of the AdminTask object:

Command name:	Description:	Target object:	Parameters and return values:	Examples:
---------------	--------------	----------------	-------------------------------	-----------

<p>createChain</p>	<p>The createChain command creates a new chain of transport channels that are based on a chain template.</p>	<p>The instance of the transport service under which the new chain is created. (ObjectName, required)</p>	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - template The chain template on which to base the new chain. (ObjectName, required) - name The name of the new chain. (String, required) - endPoint The name of the end point to be used by the instance of the TCP inbound channel in the new chain if the chain is an inbound chain. (ObjectName, optional) Returns: The object name of the channel chain that was created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask createChain (cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1) {-template WebContainer(templates/chains webcontainer-chains.xml#Chain_1) -name trialChain1} \$AdminTask createChain (cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1) {-template WebContainer(templates/chains webcontainer-chains.xml#Chain_1) -name trialChain1 -endPoint (cells/rohitbuildCell01/nodes/rohitbuildCellManager01 serverindex.xml#EndPoint_3) }</pre> Using Jython string: <pre>AdminTask.createChain('cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1', '[-template "WebContainer(templates/chains webcontainer-chains.xml#Chain_1)" -name trialChain]')</pre> <pre>AdminTask.createChain('cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1', '[-template "WebContainer(templates/chains webcontainer-chains.xml#Chain_1)" -name trialChain -endPoint "(cells/rohitbuildCell01/nodes/rohitbuildCellManager01 serverindex.xml#EndPoint_3)"]')</pre> Using Jython list: <pre>AdminTask.createChain('cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1', ['-template', "WebContainer(templates/chains webcontainer-chains.xml#Chain_1)", '-name', 'trialChain']) AdminTask.createChain('cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1', ['-template', "WebContainer(templates/chains webcontainer-chains.xml#Chain_1)", '-name', 'trialChain', '-endPoint', "(cells/rohitbuildCell01/nodes/rohitbuildCellManager01 serverindex.xml#EndPoint_3)"]])</pre>
<p>1830</p>	<p>Administering applications and their environment</p>			

				<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask createChain {-interactive} Using Jython string: AdminTask.createChain ('[-interactive]') Using Jython list: AdminTask.createChain (['-interactive'])
deleteChain	The deleteChain command deletes an existing chain and, optionally, the transport channels in the chain.	The chain to be deleted. (Object name, required)	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - deleteChannels If the value of this attribute is true, non-shared transport channels used by the specified chain will be deleted. (Boolean, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask deleteChain trialChain1 (cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#Chain_1093554462922) \$AdminTask deleteChain trialChain1 (cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#Chain_1093554378078) {-deleteChannels true} Using Jython string: AdminTask.deleteChain('trialChain1(cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1)') AdminTask.deleteChain('trialChain1(cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1)', '[-deleteChannels true]') Using Jython list: AdminTask.deleteChain('trialChain1(cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1)') AdminTask.deleteChain('trialChain1(cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1)', ['-deleteChannels', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask deleteChain {-interactive} Using Jython string: AdminTask.deleteChain ('[-interactive]') Using Jython list: AdminTask.deleteChain (['-interactive'])

listChain Templates	<p>The listChain Templates command displays a list of templates that you can use to create chains in this configuration. All templates have a certain type of transport channel as the last transport channel in the chain.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - acceptorFilter The templates returned by this method all have a transport channel instance of the specified type as the last transport channel in the chain. (String, optional) • Returns: A list of all the chain template object names. If you specify the <code>acceptorFilter</code> parameter, the list that returns is filtered to match the filter that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listChainTemplates {} \$AdminTask listChainTemplates "-acceptorFilter WebContainer InboundChannel"</pre> • Using Jython string: <pre>AdminTask.listChainTemplates() AdminTask.listChainTemplates (['-acceptorFilter WebContainerInboundChannel'])</pre> • Using Jython list: <pre>AdminTask.listChainTemplates() AdminTask.listChainTemplates (['-acceptorFilter', 'WebContainerInboundChannel'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listChainTemplates {-interactive}</pre> • Using Jython string: <pre>AdminTask.listChainTemplates ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.listChainTemplates (['-interactive'])</pre>
---------------------	--	------	--	---

listChains	The listChains command lists all the chains that are configured under a particular instance of the transport channel service.	The instance of the transport channel service under which the chains are configured. (ObjectName, required)	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - acceptorFilter The chains that are returned by this parameter will have a transport channel instance of the type that you specify as the last transport channel in the chain. (String, optional) - endPointFilter: The chains returned by this parameter will have a TCP inbound channel using an end point with the name that you specify.(String, optional) Returns: A list of all the channel chain object names that match the specified filters. If no you do not specify any parameters, all of the channel chains that are configured under the particular instance of transport channel service are returned. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask listChains (cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328) \$AdminTask listChains (cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328) {-acceptorFilter WebContainerInboundChannel} \$AdminTask listChains (cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328) {-endPointFilter WC_adminhost}</pre> Using Jython string: <pre>AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)') AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)', '[-acceptorFilter WebContainerInboundChannel]') AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)', '[-endPointFilter WC_adminhost]')</pre> Using Jython list: <pre>AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)') AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)', ['-acceptorFilter', 'WebContainerInboundChannel']) AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)', ['-endPointFilter', 'WC_adminhost'])</pre>
------------	--	---	--	--

				<p>Interactive mode example usage:</p> <ul style="list-style-type: none">• Using Jacl: <code>\$AdminTask listChains {-interactive}</code>• Using Jython string: <code>AdminTask.listChains ('[-interactive]')</code>• Using Jython list: <code>AdminTask.listChains (['-interactive'])</code>
--	--	--	--	--

Chapter 17. Naming and directory

Using naming

Naming is used by clients of WebSphere Application Server applications most commonly to obtain references to objects related to those applications, such as Enterprise JavaBeans (EJB) homes.

The Naming service is based on the Java Naming and Directory Interface (JNDI) 1.2.1 Specification and the Object Management Group (OMG) Interoperable Naming (CosNaming) specifications Naming Service Specification, Interoperable Naming Service revised chapters and Common Object Request Broker: Architecture and Specification (CORBA).

1. Develop your application using either JNDI or CORBA CosNaming interfaces. Use these interfaces to look up server application objects that are bound into the name space and obtain references to them. Most Java developers use the JNDI interface. However, the CORBA CosNaming interface is also available for performing Naming operations on WebSphere Application Server name servers or other CosNaming name servers.
2. Assemble your application using an assembly tool. Application assembly is a packaging and configuration step that is a prerequisite to application deployment. If the application you are assembling is a client to an application running in another process, you should qualify the `jniName` values in the deployment descriptors for the objects related to the other application. Otherwise, you may need to override the names with qualified names during application deployment. If the objects have fixed qualified names configured for them, you should use them so that the `jniName` values do not depend on the other application's location within the topology of the cell.
3. **Optional:** Verify that your application is assigned the appropriate security role if administrative security is enabled. For more information on the security roles, see "Naming roles" on page 1845.
4. Deploy your application. Put your assembled application onto the application server. If the application you are assembling is a client to an application running in another server process, be sure to qualify the `jniName` values for the other application's server objects if they are not already qualified. For more information on qualified names, refer to "Lookup names support in deployment descriptors and thin clients" on page 1839.
5. **Optional:** If your application must access applications in other cells, configure foreign cell bindings for the other cells.
6. Configure name space bindings. This step is necessary in these cases:
 - Your deployed application is to be accessed by legacy client applications running on previous versions of WebSphere Application Server. In this case, you must configure additional name bindings for application objects relative to the default initial context for legacy clients. (Version 5 clients have a different initial context from legacy clients.)
 - The application requires qualified name bindings for such reasons as:
 - It will be accessed by J2EE client applications or server applications running in another server process.
 - It will be accessed by thin client applications.

In this case, you can configure name bindings as additional bindings for application objects. The qualified names for the configured bindings are *fixed*, meaning they do not contain elements of the cell topology that can change if the application is moved to another server. Objects as bound into the name space by the system can always be qualified with a topology-based name. You must explicitly configure a name binding to use as a fixed qualified name.

For more information on qualified names, refer to "Lookup names support in deployment descriptors and thin clients" on page 1839. For more information on configured name bindings, refer to "Configured name bindings" on page 1842.
7. Troubleshoot any problems that develop. If a Naming operation is failing and you need to verify whether certain name bindings exist, use the `dumpNameSpace` tool to generate a dump of the name space.

Naming

Naming is used by clients of WebSphere Application Server applications to obtain references to objects related to those applications, such as enterprise bean (EJB) homes.

These objects are bound into a mostly hierarchical structure, referred to as a *name space*. In this structure, all non-leaf objects are called *contexts*. Leaf objects can be contexts and other types of objects. Naming operations, such as lookups and binds, are performed on contexts. All naming operations begin with obtaining an *initial context*. You can view the initial context as a starting point in the name space.

The name space structure consists of a set of *name bindings*, each consisting of a name relative to a specific context and the object bound with that name. For example, the name `myApp/myEJB` consists of one non-leaf binding with the name `myApp`, which is a context. The name also includes one leaf binding with the name `myEJB`, relative to `myApp`. The object bound with the name `myEJB` in this example happens to be an EJB home reference. The whole name `myApp/myEJB` is relative to the initial context, which you can view as a starting place when performing naming operations.

You can access and manipulate the name space through a *name server*. Users of a name server are referred to as *naming clients*. Naming clients typically use the Java Naming and Directory Interface (JNDI) to perform naming operations. Naming clients can also use the Common Object Request Broker Architecture (CORBA) CosNaming interface.

You can use security to control access to the name space. For more information, see Naming roles.

Typically, objects bound to the name space are resources and objects associated with installed applications. These objects are bound by the system, and client applications perform lookup operations to obtain references to them. Occasionally, server and client applications bind objects to the name space. An application can bind objects to transient or persistent partitions, depending on requirements.

In J2EE environments, some JNDI operations are performed with `java:` URL names. Names bound under these names are bound to a completely different name space which is local to the calling process. However, some lookups on the `java:` name space may trigger indirect lookups to the name server.

Name space logical view

The name space for the entire cell is federated among all servers in the cell. Every server process contains a name server. All name servers provide the same logical view of the cell name space.

The various server roots and persistent partitions of the name space are interconnected by a system name space. You can use the system name space structure to traverse to any context in a the cell's name space. A logical view of the name space is shown in the following diagram.

Logical View of a Cell's Name Space

The bindings in the preceding diagram appear with solid arrows, labeled in bold, and dashed arrows, labeled in gray. Solid arrows represent *primary bindings*. A primary binding is formed when the associated subcontext is created. Dashed arrows show *linked bindings*. A linked binding is formed when an existing context is bound under an additional name. Linked bindings are added for convenience or interoperability with previous WebSphere Application Server versions.

A cell name space is composed of contexts which reside in servers throughout the cell. All name servers in the cell provide the same logical view of the cell name space. A name server constructs this view at startup by reading configuration information. Each name server has its own local in-memory copy of the name space and does not require another running server to function. There are, however, a few exceptions. Server roots for other servers are not replicated among all the servers. The respective server for a server root must be running to access that server root context.

In WebSphere Application Server Network Deployment cells, the cell and node persistent areas can be read even if the deployment manager and respective node agent are not running. However, the deployment manager must be running to update the cell persistent segment, and a node agent must be running to update its respective node persistent segment.

Name space partitions

There are four major partitions in a cell name space:

- System name space partition
- Server roots partition
- Cell persistent partition
- Node persistent partition

System name space partition

The system name space contains a structure of contexts based on the cell topology. The system structure supports traversal to all parts of a cell name space and to the cell root of other cells, which are configured as foreign cells. The root of this structure is the cell root. In addition to the

cell root, the system structure contains a node root for each node in the cell. You can access other contexts of interest specific to a node from the node root, such as the node persistent root and server roots for servers configured in that node.

All contexts in the system name space are read-only. You cannot add, update, or remove any bindings.

Server roots partition

Each server in a cell has a server root context. A server root is specific to a particular server. You can view the server roots for all servers in a cell as being in a transient read/write partition of the cell name space. System artifacts, such as EJB homes for server applications and resources, are bound under the server root context of the associated server. A server application can also add bindings under its server root. These bindings are transient. Therefore, the server application creates all required bindings at application startup, so they exist anytime the application is running.

A server cluster is composed of many servers that are logically equivalent. Each member of the cluster has its own server root. These server roots are not replicated across the cluster. In other words, adding a binding to the server root of one member does not propagate it to the server roots of the other cluster members. To maintain the same view across the cluster, you should create all user bindings under the server root by the server application at application startup so that the bindings are present under the server root of each cluster member. Because of Workload Management (WLM) behavior, a JNDI client outside a cluster has no control over which cluster member's server root context becomes the target of the JNDI operation. Therefore, you should execute bind operations to the server root of a cluster member from within that cluster member process only.

Server-scoped configured name bindings are relative to a server's server root.

The name of a cluster member must be unique within a cell and must be different from the cell name.

Cell persistent partition

The root context of the cell persistent partition is the cell persistent root. A binding created under the cell persistent root is saved as part of the cell configuration and continues to exist until it is explicitly removed. Applications that need to create additional persistent bindings of objects generally associated with the cell can bind these objects under the cell persistent root.

It is important to note that the cell persistent area is not designed for transient, rapidly changing bindings. The bindings are more static in nature, such as part of an application setup or configuration, and are not created at run time.

The cell persistent area can be read even if the deployment manager is not running. However, the deployment manager must be running to update the cell persistent segment. Because every server contains its own copy of the cell persistent partition, any server can look up locally objects bound in the cell persistent partition.

Cell-scoped configured name bindings are relative to a cell's cell persistent root.

Node persistent partition

The node persistent partition is similar to the cell partition except that each node has its own node persistent root. A binding created under a node persistent root is saved as part of that node configuration and continues to exist until it is explicitly removed.

Applications that need to create additional persistent bindings of objects associated with a specific node can bind those objects under that particular node's node persistent root. As with the cell persistent area, it is important to note that the node persistent area is not designed for transient, rapidly changing bindings. These bindings are more static in nature, such as part of an application setup or configuration, and are not created at run time.

The node persistent area for a node can be read from any server in the node even if the respective node agent is not running. However, the node agent must be running to update the node persistent area, or for any server outside the node to read from that node persistent partition.

Because every server in a node contains its own copy of the node persistent partition for its node, any server in the node can look up locally objects bound in that node persistent partition.

Node-scoped configured name bindings are relative to a node's node persistent root.

Initial context support

All naming operations begin with obtaining an initial context. You can view the initial context as a starting point in the name space. Use the initial context to perform naming operations, such as looking up and binding objects in the name space.

Initial contexts registered with the ORB as initial references

The server root, cell persistent root, cell root, and node root are registered with the name server's ORB and can be used as an initial context. An initial context is used by CORBA and enterprise bean applications as a starting point for name space lookups. The keys for these roots as recognized by the ORB are shown in the following table:

Root Context	Initial Reference Key
Server Root	NameServiceServerRoot
Cell Persistent Root	NameServiceCellPersistentRoot
Cell Root	NameServiceCellRoot, NameService
Node Root	NameServiceNodeRoot

A server root initial context is the server root context for the specific server you are accessing. Similarly, a node root initial context is the node root for the server being accessed.

You can use the previously mentioned keys in CORBA INS object URLs (corbaloc and corbaname) and as an argument to an ORB `resolve_initial_references` call. For examples, see CORBA and JNDI programming examples, which show how to get an initial context.

Default initial contexts

The default initial context depends on the type of client. Different categories of clients and the corresponding default initial context follow.

- **WebSphere Application Server V5 and later JNDI interface implementation**

The JNDI interface is used by EJB applications to perform name space lookups. WebSphere Application Server clients by default use the WebSphere Application Server CosNaming JNDI plug-in implementation. The default initial context for clients of this type is the server root of the server specified by the provider URL. For more details, refer to the JNDI programming examples on getting initial contexts.

- **Other JNDI implementation**

Some applications can perform name space lookups with a non-WebSphere Application Server CosNaming JNDI plug-in implementation. Assuming the key `NameService` is used to obtain the initial context, the default initial context for clients of this type is the cell root.

- **CORBA**

The standard CORBA client obtains an initial `org.omg.CosNaming.NamingContext` reference with the key `NameService`. The initial context in this case is the cell root.

Lookup names support in deployment descriptors and thin clients

Server application objects, such as EJB homes, are bound relative to the server root context for the server in which the application is installed. Other objects, such as resources, can also be bound to a specific

server root. The names used to look up these objects must be qualified so as to select the correct server root. This topic discusses what relative and qualified names are, when they can be used, and how you can construct them.

Relative names

All names are relative to a context. Therefore, a name that can be resolved from one context in the name space cannot necessarily be resolved from another context in the name space. This point is significant because the system binds objects with names relative to the server root context of the server in which the application is installed. Each server has its own server root context. The initial JNDI context is by default the server root context for the server identified by the provider URL used to obtain the initial context. (Typically, the URL consists of a host and port.) For applications running in a server process, the default initial JNDI context is the server root for that server. A relative name will resolve successfully when the initial context is obtained from the server which contains the target object, but it will not resolve successfully from an initial context obtained from another server.

If all clients of a server application run in the same server process as the application, all objects associated with that application are bound to the same initial context as the clients' initial context. In this case, only names relative to the server's server root context are required to access these server objects. Frequently, however, a server application has clients that run outside the application's server process. The initial context for these clients can be different from the server application's initial context, and lookups on the relative names for server objects may fail. These clients need to use the qualified name for the server objects. This point must be considered when setting up the `jndiName` values in a J2EE client application deployment descriptors and when constructing lookup names in thin clients. Qualified names resolve successfully from any initial context in the cell.

Qualified names

All names are relative to a context. Here, the term *qualified name* refers to names that can be resolved from any initial context in a cell. This action is accomplished by using names that navigate to the same context, the cell root. The rest of the qualified name is then relative to the cell root and uniquely identifies an object throughout the cell. All initial contexts in a server (that is, all naming contexts in a server registered with the ORB as an initial reference) contain a binding with the name **cell**, which links back to the cell root context. All qualified names begin with the string **cell/** to navigate from the current initial context back to the cell root context.

A qualified name for an object is the same throughout the cell. The name can be topology-based, or some fixed name bound under the cell persistent root. Topology-based names, described in more detail below, navigate through the system name space to reach the target object. A fixed name bound under the cell persistent root has the same qualified name throughout the cell and is independent of the topology. Creating a fixed name under the cell persistent root for a server application object requires an extra step when the server application is installed, but this step eliminates impacts to clients when the application is moved to a different location in the cell topology. The process for creating a fixed name is described later in this section.

Generally, you **must** use qualified names for EJB `jndiName` values in a J2EE client application deployment descriptors and for EJB lookup names in thin clients. The only exception is when the initial context is obtained from the server in which the target object resides. For example, a session bean which is a client to an entity bean can use a relative name if the two beans run in the same server. If the session bean and entity beans run in different servers, the `jndiName` for the entity bean must be qualified in the session bean's deployment descriptors. The same requirement may be true for resources as well, depending on the scope of the resource.

- **Topology-based names**

The system name space partition in a cell's name space reflects the cell's topology. This structure can be navigated to reach any object bound into the cell's name space. Topology-based qualified names

include elements from the topology which reflect the object's location within the cell. For a system-bound object, such as an EJB home, the form for a topology-based qualified name depends on whether the object is bound to a single server or cluster. Both forms are described below.

Single server

An object bound in a single server has a topology-based qualified name of the following form:

```
cell/nodes/nodeName/servers/serverName/relativeJndiName
```

where *nodeName* and *serverName* are the node name and server name for the server where the object is bound, and *relativeJndiName* is the unqualified name of the object; that is, the object's name relative to its server's server root context.

Server cluster

An object bound in a server cluster has a topology-based qualified name of the following form:

```
cell/clusters/clusterName/relativeJndiName
```

where *clusterName* is the name of the server cluster where the object is bound, and *relativeJndiName* is the unqualified name of the object; that is, the object's name relative to a cluster member's server root context.

- **Fixed names**

It is possible to create a fixed name for a server object so that the qualified name is independent of the cell topology. This quality is desirable when clients of the application run in other server processes or as pure clients. Fixed names have the advantage of not changing if the object is moved to another server. The *jndiName* values in deployment descriptors for a J2EE client application can reference the qualified fixed name for a server object regardless of the cell topology on which the client or server application is being installed.

Defining a cell-wide fixed name for a server application object requires an extra step after the server application is installed. That is, a binding for the object must be created under the cell persistent root. A fixed name bound under the cell persistent root can be any name, but all names under the cell persistent root must be unique within the cell because the cell persistent root is global to the entire cell.

A qualified fixed name has the form:

```
cell/persistent/fixedName
```

where *fixedName* is an arbitrary fixed name.

The binding can be created programmatically (for example, using JNDI). However, it is probably more convenient to configure a cell-scoped binding for the server object.

You must keep the programmatic or configured binding up-to-date. Configured EJB bindings are based on the location of the enterprise bean within the cell topology, and moving the EJB application to another single server or to a server cluster, for example, requires the configured binding to be updated. Similar changes affect an EJB home reference programmatically bound so that the fixed name would need to be rebound with a current reference. However, for J2EE clients, the *jndiName* value for the object, and for thin clients, the lookup name for the object, remains the same. In other words, clients that access objects by fixed names are not affected by changes to the configuration of server applications they access.

JNDI support in WebSphere Application Server

IBM WebSphere Application Server includes a name server to provide shared access to Java components, and an implementation of the `javax.naming` JNDI package which supports user access to the WebSphere Application Server name server through the JNDI naming interface.

WebSphere Application Server does **not** provide implementations for:

- `javax.naming.directory` or
- `javax.naming.ldap` packages

Also, WebSphere Application Server does **not** support interfaces defined in the `javax.naming.event` package.

However, to provide access to LDAP servers, the development kit shipped with WebSphere Application Server supports the Sun Microsystems implementation of:

- `javax.naming.ldap` and
- `com.sun.jndi.ldap.LdapCtxFactory`

WebSphere Application Server's JNDI implementation is based on version 1.2 of the JNDI interface, and was tested with Version 1.2.1 of the Sun Microsystems JNDI Service Provider Interface (SPI).

The default behavior of this JNDI implementation is adequate for most users. However, users with specific requirements can control certain aspects of JNDI behavior.

Configured name bindings

Administrators can configure bindings into the name space. A configured binding is different from a programmatic binding in that the system creates the binding every time a server is started, even if the target context is in a transient partition.

Administrators can add name bindings to the name space through the configuration. Name servers add these configured bindings to the name space view, by reading the configuration data for the bindings. Configuring bindings is an alternative to creating the bindings from a program. Configured bindings have the advantage of being created each time a server starts, even when the binding is created in a transient partition of the name space. Cell-scoped configured bindings provide a fixed qualified name for server application objects.

Scope

You can configure a binding at one of the following four scopes: cell, node, server, or cluster. Cell-scoped bindings are created under the cell persistent root context. Node-scoped bindings are created under the node persistent root context for the specified node. Server-scoped bindings are created under the server root context for the selected server. Cluster-scoped bindings are created under the server root context in each member of the selected cluster.

The scope you select for new bindings depends on how the binding is to be used. For example, if the binding is not specific to any particular node, cluster, or server, or if you do not want the binding to be associated with any specific node, cluster, or server, a cell-scoped binding is a suitable scope. Defining fixed names for enterprise beans to create fixed qualified names is just such an application. If a binding is to be used only by clients of an application running on a particular server (or cluster), or if you want to configure a binding with the same name on different servers (or clusters) which resolve to different objects, a server-scoped (or cluster-scoped) binding would be appropriate. Note that two servers or clusters can have configured bindings with the same name but resolve to different objects. At the cell scope, only one binding with a given name can exist.

Intermediate contexts

Intermediate contexts created with configured bindings are read-only. For example, if an EJB home binding is configured with the name `some/compound/name/ejbHome`, the intermediate contexts `some`, `some/compound`, and `some/compound/name` will be created as read-only contexts. You cannot add, update, or remove any read-only bindings.

The configured binding name cannot conflict with existing bindings. However, configured bindings can use the same intermediate context names. Therefore, a configured binding with the name `some/compound/name2/ejbHome2` does not conflict with the previous example name.

Configured binding types

Types of objects that you can bind follow:

EJB: EJB home installed in some server in the cell

The following data is required to configure an EJB home binding:

- JNDI name of the EJB server or server cluster where the enterprise bean is deployed
- Target root for the configured binding (scope)
- The name of the configured binding, relative to the target root.

A cell-scoped EJB binding is useful for creating a fixed lookup name for an enterprise bean so that the qualified name is not dependent on the topology.

Note: In standalone servers, an EJB binding resolving to another server cannot be configured because the name server does not read configuration data for other servers. That data is required to construct the binding.

CORBA: CORBA object available from some CosNaming name server

You can identify any CORBA object bound into some INS compliant CosNaming server with a corbaname URL. The referenced object does not have to be available until the binding is actually referenced by some application.

The following data is required in order to configure a CORBA object binding:

- The corbaname URL of the CORBA object
- An indicator if the bound object is a context or leaf node object (to set the correct CORBA binding type of context or object)
- Target root for the configured binding
- The name of the configured binding, relative to the target root

Indirect: Any object bound in WebSphere Application Server name space accessible with JNDI

Besides CORBA objects, this includes `javax.naming.Referenceable`, `javax.naming.Reference`, and `java.io.Serializable` objects. The target object itself is not bound to the name space. Only the information required to look up the object is bound. Therefore, the referenced name server does not have to be running until the binding is actually referenced by some application. The following data is required in order to configure an indirect JNDI lookup binding:

- JNDI provider URL of name server where object resides
- JNDI lookup name of object
- Target root for the configured binding (scope)
- The name of the configured binding, relative to the target root.

A cell-scoped indirect binding is useful when creating a fixed lookup name for a resource so that the qualified name is not dependent on the topology. You can also achieve this topology by widening the scope of the resource definition.

String: String constant

You can configure a binding of a string constant. The following data is required to configure a string constant binding:

- String constant value
- Target root for the configured binding (scope)
- The name of the configured binding, relative to the target root

Name space federation

Federating name spaces involves binding contexts from one name space into another name space.

For example, assume that a name space, Name Space 1, contains a context under the name `a/b`. Also assume that a second name space, Name Space 2, contains a context under the name `x/y`. (See the following illustration.) If context `x/y` in Name Space 2 is bound into context `a/b` in Name Space 1 under the name `f2`, the two name spaces are federated. Binding `f2` is a federated binding because the context associated with that binding comes from another name space. From Name Space 1, a lookup of the name

a/b/f2 returns the context bound under the name x/y in Name Space 2. Furthermore, if context x/y contains an enterprise bean (EJB) home bound under the name ejb1, the EJB home can be looked up from Name Space 1 with the lookup name a/b/f2/ejb1. Notice that the name crosses name spaces. This fact is transparent to the naming client.

In a WebSphere Application Server name space, you can create federated bindings with the following restrictions:

- Federation is limited to CosNaming name servers. A WebSphere Application Server name server is a Common Object Request Broker Architecture (CORBA) CosNaming implementation. You can create federated bindings to other CosNaming contexts. You cannot, for example, bind contexts from an LDAP name server implementation.
- If you use JNDI to federate the name space, you must use a WebSphere Application Server initial context factory to obtain the reference to the federated context. If you use some other initial context factory implementation, you might not be able to create the binding or the level of transparency might be reduced.
- A federated binding to a non-WebSphere Application Server naming context has the following functional limitations:
 - JNDI operations are restricted to the use of CORBA objects. For example, you can look up EJB homes, but you cannot look up non-CORBA objects such as data sources.
 - JNDI caching is not supported for non-WebSphere Application Server name spaces. This restriction affects the performance of lookup operations only.
 - If security is enabled, WebSphere Application Server does not support federated bindings to non-WebSphere Application Server name spaces.
- Do not federate two WebSphere Application Server stand-alone server name spaces. Incorrect behavior might result. If you want to federate WebSphere Application Server name spaces, use servers running under the Network Deployment package of WebSphere Application Server.
- When federating the name spaces of two cells running a Network Deployment package of WebSphere Application Server, the names of the cells must be different. Otherwise, incorrect behavior can result.

Naming roles

The Java 2 Platform, Enterprise Edition (J2EE) role-based authorization concept is extended to protect the CosNaming service.

CosNaming security offers increased granularity of security control over CosNaming functions. CosNaming functions are available on CosNaming servers such as the WebSphere Application Server. They affect the content of the name space. Generally two ways are acceptable in which client programs result in CosNaming calls. The first is through the Java Naming and Directory Interface (JNDI) methods. The second is CORBA clients invoking CosNaming methods directly.

The following security roles exist. However, the roles have an authority level from low to high as shown in the following list. The list also provides the security-related interface methods for each role. The interface methods that are not listed are either not supported or not relevant to security.

- **CosNamingRead.** Users who are assigned the CosNamingRead role can do queries of the name space, such as through the JNDI lookup method. The Everyone special-subject is the default policy for this role.

Table 51. CosNamingRead role packages and interface methods

Package	Interface methods
javax.naming	<ul style="list-style-type: none"> • Context.list • Context.listBindings • Context.lookup • NamingEnumeration.hasMore • NamingEnumeration.next
org.omg.CosNaming	<ul style="list-style-type: none"> • NamingContext.list • NamingContext.resolve • BindingIterator.next_one • BindingIterator.next_n • BindingIterator.destroy

- **CosNamingWrite.** Users who are assigned the CosNamingWrite role can do write operations (such as JNDI bind, rebind, or unbind) plus CosNamingRead operations. As a default policy, Subjects are not assigned this role.

Table 52. CosNamingWrite role packages and interface methods

Package	Interface methods
javax.naming	<ul style="list-style-type: none"> • Context.bind • Context.rebind • Context.rename • Context.unbind
org.omg.CosNaming	<ul style="list-style-type: none"> • NamingContext.bind • NamingContext.bind_context • NamingContext.rebind • NamingContext.rebind_context • NamingContext.unbind

- **CosNamingCreate.** Users who are assigned the CosNamingCreate role are allowed to create new objects in the name space through JNDI createSubcontext operations plus CosNamingWrite operations. As a default policy, Subjects are not assigned this role.

Table 53. CosNamingCreate role packages, interface methods

Package	Interface methods
javax.naming	Context.createSubcontext
org.omg.CosNaming	NamingContext.bind_new_context

- **CosNamingDelete.** Users who are assigned the CosNamingDelete role can destroy objects in the name space, for example by using the JNDI destroySubcontext method and CosNamingCreate operations. As a default policy, Subjects are not assigned this role.

Table 54. CosNamingDelete role packages and interface methods

Package	Interface methods
javax.naming	Context.destroySubcontext
org.omg.CosNaming	NamingContext.destroy

Important: The javax.naming package applies to the CosNaming JNDI service provider only. All of the variants of a JNDI interface method have the same role mapping.

If the caller is not authorized, the packages listed in the previous tables exhibit the following behavior:

javax.naming

This package creates the javax.naming.NoPermissionException exception, which maps NO_PERMISSION from the CosNaming method invocation to NoPermissionException.

org.omg.CosNaming

This package creates the org.omg.CORBA.NO_PERMISSION exception.

Users, groups, or the AllAuthenticated and Everyone special subjects can be added or removed to or from the naming roles from the WebSphere Application Server administrative console at any time. However, you must restart the server for the changes to take effect. A best practice is to map groups or one of the special-subjects, rather than specific users, to Naming roles because it is more flexible and easier to administer in the long run. By mapping a group to a naming role, adding or removing users to or from the group occurs outside of WebSphere Application Server and does not require a server restart for the change to take effect.

If a user is assigned a particular naming role and that user is a member of a group that is assigned a different naming role, the user is granted the most permissive access between the role that is assigned and the role the group is assigned. For example, assume that the MyUser user is assigned the CosNamingRead role. Also, assume that the MyGroup group is assigned the CosNamingCreate role. If the MyUser user is a member of the MyGroup group, the MyUser user is assigned the CosNamingCreate role because the user is a member of the MyGroup group. If the MyUser user is not a member of the MyGroup group, is assigned the CosNamingRead role.

The CosNaming authorization policy is only enforced when administrative security is enabled. When administrative security is enabled, attempts to do CosNaming operations without the proper role assignment result in a org.omg.CORBA.NO_PERMISSION exception from the CosNaming server.

In WebSphere Application Server, each CosNaming function is assigned to one role only. Therefore, users who are assigned the CosNamingCreate role cannot query the name space unless they also are assigned the CosNamingRead role. In most cases, a creator needs three roles assigned: CosNamingRead, CosNamingWrite, and CosNamingCreate. The CosNamingRead and CosNamingWrite roles assignment for the creator example in above have been included in CosNamingCreate role. In most cases, WebSphere Application Server administrators do not have to change the roles assignment for every user or group when they move to this release from a previous one.

Although the ability exists to greatly restrict access to the name space by changing the default policy, doing so might result in unexpected org.omg.CORBA.NO_PERMISSION exceptions at runtime. Typically, J2EE applications access the name space and the identity is that of the user that authenticated to WebSphere Application Server when he J2EE application is accessed. Unless the J2EE application provider clearly communicates the expected naming roles, fully consider changing the default naming authorization policy.

Foreign cell bindings

If you have applications in a cell that access other applications in another cell, you can configure a foreign cell name binding for the other cell. A *foreign cell name binding* is a context binding that resolves to the Cell Root context of the other cell. All applications in the local cell can look up objects in the foreign cell through the foreign cell binding.

Foreign cell bindings limit bootstrap address information for a foreign cell to a single location, instead of placing in the local cell's application deployment data the bootstrap address information contained in every foreign cell reference. If the bootstrap address for the foreign cell changes, you only need to update the foreign cell binding. You do not need to update the deployment data for any application in the local cell that looks up application objects in the foreign cell through the foreign cell binding.

For example, assume the foreign cell CellB has a cell-scoped EJB name space binding configured with a name in the name space of `ejb/AccountHome`. Applications running in CellB would look up the home with a JNDI name of `cell/persistent/ejb/AccountHome`. (J2EE applications would actually use a `java:comp/env` name that maps to that JNDI name through deployment descriptor data.) If you configure a foreign cell binding to CellB in the local cell, applications running in the local cell can look up `AccountHome` with a JNDI name of `cell/cells/CellB/persistent/ejb/AccountHome`. In both lookup names, the suffix `persistent/ejb/AccountHome` is relative to the Cell Root context in CellB.

The foreign cell and the local cell must have different names.

Naming and directories: Resources for learning

Additional information and guidance on naming and directories is available on various Internet sites.

Use the following links to find relevant supplemental information about naming and directories. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

The naming service provided with WebSphere Application Server Version 6 is the same as that provided for Version 5, thus information on the Version 5 naming and directories applies to Version 6.

The following links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Refer to Web resources for learning for links to information applicable to WebSphere Application Server generally, such as lists of IBM technical papers, Redbooks and samples.

Configuring name servers

Name servers add configured name space bindings to the name space view by reading the configuration data for the bindings. If you use configured bindings, you do not need to create name space bindings from a program.

You can configure a name server to provide a display name and initial state for an application server, as well as specify custom properties for the name server. To configure a name server, complete the following:

1. In the administrative console, click **Servers > Application Servers > Server Components > Name Server**.
2. Edit the fields as desired.
All of the fields are mandatory.
3. To make other changes, click **Custom Properties** and configure a custom property.
4. Click **OK** to register your changes.

Name server settings

Use this page to configure Naming Service Provider settings for the application server.

To view this administrative console page, click one of the following paths:

- **Servers > Application Servers > *server_name* > Administration > Server Components > Name Server**
- **Servers > JMS Servers > *server_name* > Administration > Server Components > Name Server**

Name

Specifies the display name for the server.

Data type String

Initial State

Specifies the execution state. The options are: *Started* and *Stopped*.

Data type String
Default Started

Configuring name space bindings

Instead of creating name space bindings from a program, you can configure name space bindings using the administrative console. Name servers add these configured bindings to the name space view by reading the configuration data for the bindings. Configured bindings are created each time a server starts, even when the binding is created in a transient partition of the name space. One major use of configured bindings is to provide fixed qualified names for server application objects.

Assemble and deploy your application onto an application server. If the application is a client to an application running in another server process, specify qualified jndiName values for the other application's server objects during assembly or deployment. For more information on qualified names, refer to "Lookup names support in deployment descriptors and thin clients" on page 1839.

A deployed application requires qualified fixed names if the application is accessed by thin client applications or by J2EE client applications or server applications running in another server process.

When you configure a name space binding, you create a qualified fixed name for a server object. A fixed name does not change if the object is moved to another server. A qualified fixed name with a cell scope has the form:

cell/persistent/*fixedName*

where *fixedName* is an arbitrary fixed name.

You can configure name space bindings, and thus qualified fixed names, for the following objects:

- A string constant value
- An enterprise bean (EJB) home installed on a server in the cell
- A CORBA object available from a CosNaming name server
- An object bound in a WebSphere Application Server name space that is accessible using a JNDI indirect lookup

To view or configure a name space binding for an object of a deployed application, complete the following:

1. Go to the Name Space Bindings page.

In the administrative console, click **Environment > Naming > Name Space Bindings**.

2. Select the desired scope.

The scope determines where in the name space the name space binding is created. It also affects which name servers contain the binding in the name space that they manage. Regardless of the scope, a name space binding is accessible from all name servers in the cell. However, the scope can affect whether the lookup can be resolved locally by a name server or whether the name server must make a remote call to another name server to resolve the binding.

Only name space bindings created with the selected scope are visible in the collection table on the page. By changing the scope, you can see and create bindings in other scopes.

- a. Select a cell, node, cluster or server scope.

If you are creating a new name space binding, refer to the table below as a guide in selecting a scope:

Scope	Description
Cell	<p>Cell-scoped bindings are created under the cell persistent root context. Select Cell if the name space binding is not specific to any particular node or server, or if you do not want the binding to be associated with any specific node, cluster or server. For example, you can use cell-scoped bindings to create fixed qualified names for enterprise beans. Fixed qualified names do not have any node, cluster or server names embedded within them.</p> <p>Cell-scoped bindings are created in the deployment manager process, and all node agent and application server processes, in the cell. Therefore all name servers in the cell can resolve those bindings locally. No remote invocations to other name servers are necessary to resolve the bindings.</p>
Node	<p>Node-scoped bindings are created under the node persistent root context for the selected node. Select Node if the name space binding is specific to a particular node, or if you want the binding to be associated with a specific node.</p> <p>Node-scoped bindings are created in the node agent and all application server processes in the selected node. Therefore, all name servers in the node can resolve those bindings locally. No remote invocations to other name servers are necessary to resolve the bindings. However, name servers in other nodes must make remote calls to the node agent in the selected node in order to resolve the bindings. For example, in order for a name server running in node <i>node1</i> to resolve the name <code>cell/nodes/node2/persistent/nodeScopedConfiguredBinding</code>, the name server must make a remote call to the node agent running in <i>node2</i>. Any name server running in <i>node2</i> can resolve that name without invoking any other name servers.</p>

Scope	Description
Server	<p>Server-scoped bindings are created under the server root context for the selected server. Select Server if a binding is to be used only by clients of an application running on a particular server, or if you want to configure a binding with the same name on different servers which resolve to different objects. Note that two servers can have configured bindings with the same name but resolve to different objects.</p> <p>Server-scoped bindings are created in the process of the selected application server. Therefore, the name server running in the selected application server can resolve those bindings locally. No remote invocations to other name servers are necessary to resolve the bindings. However, all other name servers in the cell must make remote calls to the selected server in order to resolve the bindings. For example, in order for the name server running in <i>server1</i> in node <i>node1</i> to resolve the name <code>cell/nodes/node1/servers/server2/serverScopedConfiguredBinding</code>, it must make a remote call to <i>server2</i> in <i>node1</i>. Only the name server in <i>server2</i> in <i>node1</i> can resolve that name without invoking any other name servers.</p>
Cluster	<p>Cluster-scoped bindings are created under the server root context for all members in the selected cluster. Select Cluster if the name space binding is specific to a particular cluster, or if you want the binding to be associated with a specific cluster.</p> <p>Cluster-scoped bindings are created in all member processes of the selected cluster. Therefore, the name server running in each member of the selected cluster can resolve those bindings locally. No remote invocations to other name servers are necessary to resolve the bindings. However, all other name servers in the cell must make remote calls to the node agent in the selected node in order to resolve the bindings. For example, in order for a name server running in any member of <i>cluster1</i> to resolve the name <code>cell/clusters/cluster2/clusterScopedConfiguredBinding</code>, it must make a remote call to some member in <i>cluster2</i>. Only the name servers in <i>cluster2</i> members can resolve that name without invoking any other name servers.</p> <p>Server-scoped bindings in cluster members override cluster-scoped bindings with the same binding name. However, cluster members generally should all be configured identically, and server-scoped bindings should not be required for individual cluster members.</p>

- b. Click **Apply**.
3. Create a new name space binding.
 - a. Open the New Name Space Binding wizard.
On the Name Space Bindings page, click **New**.
 - b. On the **Specify binding type** panel, select the binding type.
The name space binding can be for a constant string value, an EJB home, a CORBA CosNaming NamingContext or CORBA leaf node object, or an object that you can look up indirectly using JNDI.
 - c. On the **Specify basic properties** panel, specify the binding identifier and other properties for the binding.
For property descriptions, refer to the following:
 - “String binding settings” on page 1852
 - “EJB binding settings” on page 1853
 - “CORBA object binding settings” on page 1854
 - “Indirect lookup binding settings” on page 1855
 - d. **Optional:** On the **Other context properties** panel, specify new properties to be passed to the `javax.naming.InitialContext` constructor.
This step applies to indirect lookup bindings only.
 - e. On the **Summary** panel, verify the settings and click **Finish**.

The name of the new binding is displayed in the collection table on the Name Space Bindings page.
4. **Optional:** Edit a previously created binding.
 - a. From the collection table on the Name Space Bindings page, click the name of the binding that you want to edit.
 - b. Edit the binding properties as desired. Step 3(c) provides links to property descriptions.

c. Click **OK**.

Cell-scoped bindings are created under the cell persistent root context. Node-scoped bindings are created under the node persistent root context for the specified node. Server-scoped bindings are created under the server root context for the selected server. Cluster-scoped bindings are created under the server root context for each member of the selected cluster.

Name space binding collection

Use this page to configure a name binding of an EJB, a CORBA CosNaming NamingContext, a CORBA leaf node object, an object that you can look up using JNDI, or a constant string value.

Binding information for configured bindings is stored in the configuration and applied upon startup of the name server for each server within the scope of the binding.

To view the Name Space Bindings page, click **Environment > Naming > Name Space Bindings**.

Click the check boxes to select one or more of the bindings in your collection. Use the buttons to control the selected bindings.

When creating a new binding, select a scope before clicking **New**. The **Scope** setting filters what bindings are listed in the collection as well as sets the scope of the new binding.

Name

Shows the names given to uniquely identify these configured bindings.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the `namebindings.xml` file. This field is for information purposes only and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped or cluster-scoped, the starting context is the server's server root context.

Binding type

Shows the type of binding configured. Valid values are String, EJB, CORBA, and Indirect. This field is for information purposes only and cannot be updated.

Specify binding type settings

Use this panel to select the type of name space binding that you want.

To view this administrative console panel, click **Environment > Naming > Name Space Bindings > New**.

You can configure a name space binding for any of the following objects:

- A string constant value
- An enterprise bean (EJB) home installed on a server in the cell
- A CORBA object available from a CosNaming name server
- An object bound in a WebSphere Application Server name space that is accessible using a JNDI indirect lookup

On this panel, select a binding type and then click **Next**.

Binding type

Specifies the type of binding configured.

String	<p>Select String to configure a name space binding for a string constant value.</p> <p>To configure a String binding, you need the following information:</p> <ul style="list-style-type: none"> • The string constant value • The target root context for the configured binding (scope) • The name of the configured binding, relative to the target root context
EJB	<p>Select EJB to configure a name space binding for an EJB home installed on a server in the cell. Use a cell-scoped EJB binding to create a fixed qualified lookup name for an enterprise bean. A fixed qualified lookup name is not dependent on the cell topology.</p> <p>To configure an EJB home binding, you need the following information:</p> <ul style="list-style-type: none"> • The JNDI name of the EJB server or server cluster where the enterprise bean is deployed • The target root context for the configured binding (scope) • The name of the configured binding, relative to the target root context <p>On standalone servers, do not configure an EJB binding that resolves to another server. The name server cannot read configuration data for other servers. That data is required to construct the binding.</p>
CORBA	<p>Select CORBA to configure a name space binding for a Common Object Request Broker: Architecture and Specification (CORBA) object available from a Object Management Group (OMG) Interoperable Naming (CosNaming) name server. Identify a CORBA object bound into an INS compliant CosNaming server with a corbaname URL. The referenced object does not have to be available until the binding is actually referenced by an application.</p> <p>To configure a CORBA binding, you need the following information:</p> <ul style="list-style-type: none"> • The corbaname URL of the CORBA object • An indicator if the bound object is a context or leaf node object (to set the correct CORBA binding type of context or object) • The target root context for the configured binding • The name of the configured binding, relative to the target root context
Indirect	<p>Select Indirect to configure a name space binding for an object bound in a WebSphere Application Server name space that is accessible using a Java Naming and Directory Interface (JNDI) indirect lookup. You can select Indirect for CORBA objects as well as for <code>javax.naming.Referenceable</code>, <code>javax.naming.Reference</code>, and <code>java.io.Serializable</code> objects.</p> <p>The target object itself is not bound to the name space. Only the information required to look up the object is bound. Therefore, the referenced name server does not have to be running until the binding is actually referenced by some application.</p> <p>To configure an indirect JNDI lookup binding, you need the following information:</p> <ul style="list-style-type: none"> • The JNDI provider URL of the name server where the object resides • The JNDI lookup name of the object • The target root context for the configured binding (scope) • The name of the configured binding, relative to the target root context <p>The following information is optional:</p> <ul style="list-style-type: none"> • The JNDI initial context factory class name. The default is the WebSphere Application Server initial context factory, <code>com.ibm.websphere.naming.WsnInitialContextFactory</code>. • Additional properties to pass to the <code>javax.naming.InitialContext</code> constructor. <p>A cell-scoped indirect binding is useful when creating a fixed qualified lookup name for a bound object so that the qualified lookup name is not dependent on the cell topology.</p>

String binding settings

Use this page to view or configure a string binding.

To view this console page, click **Environment > Naming > Name Space Bindings > string_namespace_binding**. The settings on this page are similar to those on the **Specify basic properties** panel of the New Name Space Binding wizard.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the `namebindings.xml` file.

The **Scope** setting is shown only when you edit an existing binding on the console page, and is not shown when you create a new binding on the wizard panel. This setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped or cluster-scoped, the starting context is the server's server root context.

Binding type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes only and cannot be updated.

Binding identifier

Specifies the name that uniquely identifies this configured binding.

Name in name space

Specifies the name used for this binding in the name space. This name can be a simple or compound name depending on the portion of the name space where this binding is configured.

String value

Specifies the string to be bound into the name space.

EJB binding settings

Use this page to configure a new EJB binding, or to view or edit an existing EJB binding.

To view this console page, click **Environment > Naming > Name Space Bindings > *EJB_namespace_binding***. The settings on this page are similar to those on the **Specify basic properties** panel of the New Name Space Binding wizard.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the `namebindings.xml` file.

The **Scope** setting is shown only when you edit an existing binding on the console page, and is not shown when you create a new binding on the wizard panel. This setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped or cluster-scoped, the starting context is the server's server root context.

Binding type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes only and cannot be updated.

Binding identifier

Specifies the name that uniquely identifies this configured binding.

Name in name space

Specifies the name used for this binding in the name space. This name can be a simple or compound name depending on the portion of the name space where this binding is configured.

Enterprise Bean Location

Specifies whether the enterprise bean is running in a server cluster or a single server. If Single server is specified, type the node name.

Server

Specifies the name of the cluster or non-clustered server in which the enterprise bean is configured.

JNDI name

Specifies the JNDI name of the deployed enterprise bean (the bean's JNDI name that is in the enterprise bean bindings--not the java:comp name).

CORBA object binding settings

Use this page to configure a new name binding of a CORBA object binding, or to view or edit an existing CORBA object binding.

To view this console page, click **Environment > Naming > Name Space Bindings > CORBA_namespace_binding**. The settings on this page are similar to those on the **Specify basic properties** panel of the New Name Space Binding wizard.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the namebindings.xml file.

The **Scope** setting is shown only when you edit an existing binding on the console page, and is not shown when you create a new binding on the wizard panel. This setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped or cluster-scoped, the starting context is the server's server root context.

Binding type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes only and cannot be updated.

Binding identifier

Specifies the name that uniquely identifies this configured binding.

Name in name space

Specifies the name used for this binding in the name space. This name can be a simple or compound name depending on the portion of the name space where this binding is configured.

Corbaname URL

Specifies the CORBA name URL string identifying where the object is bound in a CosNaming server.

Federated context

Specifies whether the target is a CosNaming context (true) or a leaf node object (false).

true	The target object is bound with a context CORBA binding type. If the corbaname URL does not resolve to a NamingContext, an error occurs when the binding is first used (which is when the URL is first resolved).
false	The target object is bound with an object CORBA binding type.

Indirect lookup binding settings

Use this page to configure a new indirect lookup name binding, or to view or edit an existing indirect lookup binding.

To view this console page, click **Environment > Naming > Name Space Bindings > indirect_lookup_namespace_binding**. The settings on this page are similar to those on the **Specify basic properties** panel of the New Name Space Binding wizard.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the namebindings.xml file.

The **Scope** setting is shown only when you edit an existing binding on the console page, and is not shown when you create a new binding on the wizard panel. This setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped or cluster-scoped, the starting context is the server's server root context.

Binding type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes only and cannot be updated.

Binding identifier

Specifies the name that uniquely identifies this configured binding.

Name in name space

Specifies the name used for this binding in the name space. This name can be a simple or compound name depending on the portion of the name space where this binding is configured.

Provider URL

Specifies the provider URL string needed to obtain a JNDI initial context.

JNDI name

Specifies the name used to look up the target object from the initial context.

Initial context factory name

Specifies the class name of the initial context factory used to obtain a JNDI initial context.

This field is optional. If no factory is specified, the WebSphere Application Server initial context factory is used.

If the scope of the indirect lookup binding includes servers or nodes previous to version 6.1, the initial context factory name and other context factory properties are not shown on the console page.

Other context properties settings

Use this page to specify properties to be passed to the `javax.naming.InitialContext` constructor for an indirect JNDI lookup name binding. Completion of this page is optional. The properties are in addition to the basic properties specified for an indirect name space binding.

To specify new context properties and view this page, click **Environment > Naming > Name Space Bindings > New > Indirect > *indirect_binding_basic_properties* > Specify additional context properties.**

The properties are used only by version 6.1 and later nodes. The page is not shown for version 5.x or 6.0.x nodes.

To add a property to be passed to the `javax.naming.InitialContext` constructor when obtaining the initial JNDI context, specify a name and value pair to be passed to the constructor and click **Apply**. You can add multiple name-value properties. The specified properties are displayed in the collection table.

To view existing context properties, click **Environment > Naming > Name Space Bindings > *indirect_binding_name* > Other Context Properties.**

If the scope of the indirect lookup binding includes servers or nodes previous to version 6.1, the initial context factory name and other context factory properties are not shown on the console page.

Name

Specifies the name (or key) for the property.

Each property name must be unique. If the same name is specified for multiple properties, the value used is undefined.

Do not start your property names with `was.` because this prefix is reserved for properties that are predefined in WebSphere Application Server.

Value

Specifies the value paired with the specified name.

Description

Specifies information about the name-value pair.

Configuring foreign cell bindings

Configure foreign cell name bindings to enable your applications to access other applications in other cells. A *foreign cell* is a cell other than the one in which an application resides. A foreign cell name binding is a context binding that resolves to the Cell Root context of a foreign cell. All applications in the local cell can look up objects in the foreign cell through the foreign cell binding.

Configure server clusters for failover support as needed.

Migrate any version 5 or 6.0.x bootstrap addresses to use version 6.1 foreign cell bindings. Version 6.1 foreign cell bindings enable you to specify more than one bootstrap address and enhance failover support.

If applications in the local cell access applications in one or more foreign cells, configure a foreign cell binding for each foreign cell.

Administrators typically configure a foreign cell binding before they configure any applications with JNDI names that resolve through the binding. However, you can create a foreign cell binding any time before you start an application that uses the binding.

The foreign cell and the local cell must have different names.

To view or configure a foreign cell binding, use the administrative console.

1. Go to the Foreign Cell Bindings page.

In the administrative console, click **Environment > Naming > Foreign Cell Bindings**.

2. Create a new foreign cell binding.

- a. Open the New Foreign Cell Binding wizard.

On the Foreign Cell Bindings page, click **New**.

- b. On the **Specify foreign cell name** panel, specify the name of the cell that applications in the local cell will access.

- c. On the **Specify bootstrap addresses** panel, specify a host name and port for a new bootstrap address, and then click **Apply**.

Repeat this step for each bootstrap address that you need. The name of each new bootstrap address is displayed in the collection table on the Bootstrap Addresses page.

- d. On the **Summary** panel, verify the settings and click **Finish**.

The name of the new binding is displayed in the collection table on the Foreign Cell Bindings page.

3. **Optional:** Edit a previously created foreign cell binding.

- a. From the collection table on the Foreign Cell Bindings page, click the name of the binding that you want to edit.

- b. On the foreign cell binding settings page, edit the foreign cell name as desired.

- c. Edit the list of bootstrap addresses used for the foreign cell binding.

- 1) From the collection table on the Foreign Cell Bindings page, click *foreign_cell_binding_name* > **Bootstrap Addresses**.

- 2) On the foreign cell binding settings page, click **Bootstrap Addresses**. The Bootstrap Addresses page opens.

To add a new bootstrap address, click **New** and specify the host and port.

To delete a bootstrap address, click the check box next to the cell name and click **Delete**.

To edit an existing bootstrap address, click the address you want to edit. On the bootstrap address settings page, edit the host and port as desired and click **OK** to register the change.

Configurations for foreign cell bindings are created or changed as specified.

Save changes to your administrative configuration. Configure name space bindings for your applications as needed.

Migrating bootstrap addresses

WebSphere Application Server versions 5 and 6.0.x support foreign cell bindings, but support is limited to a single bootstrap address and you cannot configure foreign cell bindings in the console. The single bootstrap address used in versions 5 and 6.0.x has been deprecated, replaced in version 6.1 by a list of bootstrap addresses.

Configure server clusters for failover support as needed.

When a version 5 or 6.0.x cell is migrated to version 6.1 or later, foreign cell binding configurations initially are left unchanged to maintain compatibility with existing wsadmin scripts. All nodes in the migrated cell, including those later than version 6.0.x, continue to use the single bootstrap address setting to create bindings in the name space.

This topic describes how to migrate any version 5 or 6.0.x bootstrap addresses to use version 6.1 foreign cell bindings. Version 6.1 foreign cell bindings enable you to specify more than one bootstrap address and enhance failover support.

1. Edit your version 5.x or 6.0.x foreign cell binding scripts, replacing `bootstrapAddress` with `bootstrapAddresses`, the list property introduced in version 6.1.

The bootstrap address properties are in the context of the `ForeignCell` class. The fully qualified name for the version 5.x or 6.0.x property now deprecated is the following:

```
topology.cell:Cell/foreignCells/bootstrapAddress
```

The fully qualified name for the bootstrap address list property introduced in version 6.1 is the following:

```
topology.cell:Cell/foreignCells/bootstrapAddresses
```

Version 6.1 and later foreign cell binding scripts should use the bootstrap address list property, `bootstrapAddresses`.

2. Run the `convertScriptCompatibility` command to convert each single bootstrap address configuration to a new bootstrap address list configuration containing that single bootstrap address.

In the migrated cell, nodes still running version 5 or 6.0.x will use one of the addresses in the bootstrap address list configuration, but no particular one, to create a foreign cell binding in the name space.

Nodes running at a version later than version 6.0.x ignore the old single bootstrap address setting in preference for the bootstrap address list. If the `convertScriptCompatibility` command encounters a foreign cell binding configuration with the old single bootstrap address and the newer bootstrap address list both set, the old single bootstrap address is removed and the bootstrap address list is left unchanged.

Click **Environment > Naming > Foreign Cell Bindings > *foreign_cell_binding_name* > Bootstrap Addresses** in the console and examine the collection on the Bootstrap Addresses page to see if single bootstrap addresses migrated to the bootstrap address list.

Console foreign cell binding panels added in version 6.1 only display and update the bootstrap address list that is new in version 6.1. They do not change the single bootstrap address configuration setting. If you use the console to edit a foreign cell binding configuration that existed when the cell was initially migrated, and you have not yet run the `convertScriptCompatibility` command, the updated binding configuration contains both the original single bootstrap address and whatever list of bootstrap addresses you configure in the console. In the migrated cell, nodes still running at version 5 or 6.0.x continue to use the single bootstrap address configuration setting to bind foreign cell bindings in the name space.

Foreign cell binding collection

Use this page to manage foreign cell bindings.

If you have applications in a cell that access other applications in another cell, you can configure a foreign cell name binding for the other cell. A *foreign cell name binding* is a context binding that resolves to the Cell Root context of the other cell. All applications in the local cell can look up objects in the foreign cell through the foreign cell binding.

Foreign cell bindings limit bootstrap address information for a foreign cell to a single location, instead of placing in the local cell's application deployment data the bootstrap address information contained in every foreign cell reference. If the bootstrap address for the foreign cell changes, you only need to update the foreign cell binding. You do not need to update the deployment data for any application in the local cell that looks up application objects in the foreign cell through the foreign cell binding.

For example, assume the foreign cell CellB has a cell-scoped EJB name space binding configured with a name in the name space of `ejb/AccountHome`. Applications running in CellB would look up the home with a JNDI name of `cell/persistent/ejb/AccountHome`. (J2EE applications would actually use a `java:comp/env` name that maps to that JNDI name through deployment descriptor data.) If you configure a foreign cell binding to CellB in the local cell, applications running in the local cell can look up `AccountHome` with a JNDI name of `cell/cells/CellB/persistent/ejb/AccountHome`. In both lookup names, the suffix `persistent/ejb/AccountHome` is relative to the Cell Root context in CellB.

To view the Foreign Cell Bindings page, click **Environment > Naming > Foreign Cell Bindings**.

Click the check boxes to select one or more of the bindings in your collection. Use the buttons to control the selected bindings.

Foreign cell name

Shows the names given to uniquely identify these foreign cell bindings.

The foreign cell and the local cell must have different names.

Foreign cell binding settings

Use this page to configure a foreign cell binding.

To view this administrative console page, click **Environment > Naming > Foreign Cell Bindings > *foreign_cell_binding***. The setting on this page is similar to that on the **Specify foreign cell name** panel of the new foreign cell binding wizard.

Foreign cell name:

Specifies the name of the foreign cell. The foreign cell name must be different from the cell that contains the foreign cell binding. Otherwise, incorrect behavior might result.

Bootstrap address collection

Use this page to manage bootstrap addresses for a foreign cell binding. Multiple bootstrap addresses can enhance the failover support provided by clusters.

To view this administrative console panel, click **Environment > Naming > Foreign Cell Bindings > *foreign_cell_binding_name* > Bootstrap addresses**.

Click the check boxes to select one or more of the bootstrap addresses in your collection. Use the buttons to control the selected bootstrap addresses.

Host name

Specifies the host name of the deployment manager, node agent, server or cluster member in the foreign cell that is used for bootstrapping.

Port

Specifies the bootstrap port number for the deployment manager, node agent, server or cluster member running on the specified host.

Bootstrap address settings

Use this page to specify one or more bootstrap addresses for a foreign cell binding. Multiple bootstrap addresses can enhance the failover support provided by clusters.

Only one bootstrap address is required on the z/OS platform to enhance the failover support provided by clusters.

To view this administrative console page, click **Environment > Naming > Foreign Cell Bindings > *foreign_cell_binding_name* > Bootstrap addresses > *bootstrap_address_host_name***. This page is similar to the **Specify bootstrap addresses** panel on the new foreign cell binding wizard.

Host name:

Specifies the host name of the deployment manager, node agent, server or cluster member in the foreign cell that is used for bootstrapping.

Specify the IP address, domain name server (DNS) host name with domain name suffix, or just the DNS host name, of the bootstrap host for the deployment manager of the backup cluster.

For example, if the host name is myhost, the fully qualified DNS name can be myhost.myco.com and the IP address can be 155.123.88.201.

A single address is sufficient for high availability.

Port:

Specifies the bootstrap port number for the deployment manager, node agent, server or cluster member running on the specified host. The port value is used in conjunction with the host name.

Developing applications that use JNDI

References to EJB homes and other artifacts such as data sources are bound to the WebSphere Application Server name space. These objects can be obtained through the JNDI interface. Before you can perform any JNDI operations, you need to get an initial context. You can use the initial context to look up objects bound to the WebSphere Application Server name space.

The following examples describe how to get an initial context and how to perform lookup operations.

- Getting the default initial context
- Getting an initial context by setting the provider URL property
- Setting the provider URL property to select a different root context as the initial context
- Looking up an EJB home with JNDI
- Looking up a JavaMail session with JNDI

In these examples, the default behavior of features specific to the WebSphere Application Server JNDI Context implementation is used.

The WebSphere Application Server JNDI context implementation includes special features. JNDI caching enhances performance of repeated lookup operations on the same objects. Name syntax options offer a choice of a name syntaxes, one optimized for typical JNDI clients, and one optimized for interoperability with CosNaming applications. Most of the time, the default behavior of these features is the preferred behavior. However, sometimes you should modify the behavior for specific situations.

JNDI caching and name syntax options are associated with a `javax.naming.InitialContext` instance. To select options for these features, set properties that are recognized by the WebSphere Application Server initial context factory. To set JNDI caching or name syntax properties which will be visible to WebSphere Application Server initial context factory, do the following:

1. **Optional:** Configure JNDI caches

JNDI caching can greatly increase performance of JNDI lookup operations. By default, JNDI caching is enabled. In most situations, this default is the desired behavior. However, in specific situations, use the other JNDI cache options.

Objects are cached locally as they are looked up. Subsequent lookups on cached objects are resolved locally. However, cache contents can become stale. This situation is not usually a problem, since most objects you look up do not change frequently. If you need to look up objects which change relatively frequently, change your JNDI cache options.

JNDI clients can use several properties to control cache behavior.

You can set properties:

- From the command line by entering the actual string value. For example:

```
java -Dcom.ibm.websphere.naming.jndicache.maxentrylife=1440
```
- In a `jndi.properties` file by creating a file named `jndi.properties` as a text file with the desired properties settings. For example:

```
...
com.ibm.websphere.naming.jndicache.cacheobject=none
...
```

Include the file as the beginning of the classpath, so that the class loader loads your copy of `jndi.properties` before any other copies.

- Within a Java program by using the **PROPS.JNDI_CACHE*** Java constants, defined in the ***com.ibm.websphere.naming.PROPS*** file. The constant definitions follow:

```
public static final String JNDI_CACHE_OBJECT =
    "com.ibm.websphere.naming.jndicache.cacheobject";
public static final String JNDI_CACHE_OBJECT_NONE      = "none";
public static final String JNDI_CACHE_OBJECT_POPULATED = "populated";
public static final String JNDI_CACHE_OBJECT_CLEARED  = "cleared";
public static final String JNDI_CACHE_OBJECT_DEFAULT  =
    JNDI_CACHE_OBJECT_POPULATED;

public static final String JNDI_CACHE_NAME =
    "com.ibm.websphere.naming.jndicache.cachename";
public static final String JNDI_CACHE_NAME_DEFAULT = "providerURL";

public static final String JNDI_CACHE_MAX_LIFE =
    "com.ibm.websphere.naming.jndicache.maxcachelife";
public static final int    JNDI_CACHE_MAX_LIFE_DEFAULT = 0;

public static final String JNDI_CACHE_MAX_ENTRY_LIFE =
    "com.ibm.websphere.naming.jndicache.maxentrylife";
public static final int    JNDI_CACHE_MAX_ENTRY_LIFE_DEFAULT = 0;
```

To use the previous properties in a Java program, add the property setting to a hashtable and pass it to the `InitialContext` constructor as follows:

```
java.util.Hashtable env = new java.util.Hashtable();
...

// Disable caching
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE); ...
javax.naming.Context initialContext = new javax.naming.InitialContext(env);
```

2. **Optional:** Specify the name syntax

Most WebSphere applications use JNDI to look up EJB objects and do not need to look up objects bound by CORBA applications. Therefore, the default name syntax used for JNDI names is the most convenient. If your application needs to look up objects bound by CORBA applications, you may need to change your name syntax so that all CORBA CosNaming names can be represented.

JNDI clients can set the name syntax by setting a property. The property setting is applied by the initial context factory when you instantiate a new `java.naming.InitialContext` object. Names specified in JNDI operations on the initial context are parsed according to the specified name syntax.

You can set the property:

- From the command line by entering the actual string value. For example:

```
java -Dcom.ibm.websphere.naming.name.syntax=ins
```

- In a `jndi.properties` file by creating a file named `jndi.properties` as a text file with the desired properties settings. For example:

```
...
com.ibm.websphere.naming.name.syntax=ins
...
```

Include the file at the beginning of the classpath, so that the class loader loads your copy of `jndi.properties` before any other copies.

- Within a Java program by using the **PROPS.NAME_SYNTAX*** Java constants, defined in the ***com.ibm.websphere.naming.PROPS*** file. The constant definitions follow:

```

public static final String NAME_SYNTAX =
    "com.ibm.websphere.naming.name.syntax";
public static final String NAME_SYNTAX_JNDI = "jndi";
public static final String NAME_SYNTAX_INS = "ins";

```

To use the previous properties in a Java program, add the property setting to a hashtable and pass it to the `InitialContext` constructor as follows:

```

java.util.Hashtable env = new java.util.Hashtable();
...
env.put(PROPS.NAME_SYNTAX, PROPS.NAME_SYNTAX_INS); // Set name syntax to INS
...
javax.naming.Context initialContext = new javax.naming.InitialContext(env);

```

Example: Getting the default initial context

There are various ways for a program to get the default initial context.

The following example gets the default initial context. Note that no provider URL is passed to the `javax.naming.InitialContext` constructor.

```

...
import javax.naming.Context;
import javax.naming.InitialContext;
...
Context initialContext = new InitialContext();
...

```

The default initial context returned depends the runtime environment of the JNDI client. Following are the initial contexts returned in the various environments:

Thin client

The initial context is the server root context of the server running on the local host at port 2809.

Pure client

The initial context is the context specified by the `java.naming.provider.url` property passed to `launchClient` command with the `-CCD` command line parameter. The context usually is the server root context of the server at the address specified in the URL, although it is possible to construct a `corbaname` or `corbaloc` URL which resolves to some other context.

If no provider URL is specified, it is the server root context of the server running on the host and port specified by the `-CCproviderURL`, or `-CCbootstrapHost` and `-CCbootstrapPort` command line parameters. The default host is the local host, and the default port is 2809.

Server process

The initial context is the server root context for that process.

Even though no provider URL is explicitly specified in the above example, the `InitialContext` constructor might find a provider URL defined in other places that it searches for property settings.

Users of properties which affect ORB initialization should read the rest of this section for a deeper understanding of exactly how initial contexts are obtained.

Determining which server is used to obtain the initial context

WebSphere Application Server name servers are CORBA CosNaming name servers, and WebSphere Application Server provides a CosNaming JNDI plug-in implementation for JNDI clients to perform naming operations on WebSphere Application Server name spaces. The WebSphere Application Server CosNaming plug-in implementation is selected through a JNDI property that is passed to the `InitialContext` constructor. This property is `java.naming.factory.initial`, and it specifies the initial context factory implementation to use to obtain an initial context. The factory returns a `javax.naming.Context` instance, which is part of its implementation.

The WebSphere Application Server initial context factory, `com.ibm.websphere.naming.WsnInitialContextFactory`, is typically used by WebSphere Application Server applications to perform JNDI operations. The WebSphere Application Server runtime environment is set up to use this WebSphere Application Server initial context factory if one is not specified explicitly by the JNDI client. When the initial context factory is invoked, an *initial context* is obtained. The following paragraphs explain how the WebSphere Application Server initial context factory obtains the initial context in client and server environments.

- **Registration of initial references in server processes**

Every WebSphere Application Server has an ORB used to receive and dispatch invocations on objects running in that server. Services running in the server process can register initial references with the ORB. Each initial reference is registered under a key, which is a string value. An initial reference can be any CORBA object. WebSphere Application Server name servers register several initial contexts as initial references under predefined keys. Each name server initial reference is an instance of the interface `org.omg.CosNaming.NamingContext`.

- **Obtaining initial references in pure client processes**

Pure JNDI clients, that is, JNDI clients which are not running in a WebSphere Application Server process, also have an ORB instance. This client ORB instance can be passed to the `InitialContext` constructor, but typically the initial context factory creates and initializes the client ORB instance transparently. A client ORB can be initialized with initial references, but the initial references most likely resolve to objects running in some server. The initial context factory does not define any default initial references when it initializes an ORB. If the `resolve_initial_references` method is invoked on the client ORB when no initial references have been configured, the method invocation fails. This condition is typical for pure client processes. To obtain an initial `NamingContext` reference, the initial context factory must invoke `string_to_object` with an IIOP type CORBA object URL, such as `corbaloc:iiop:myhost:2809`. The URL specifies the address of the server from which to obtain the initial context. The host and port information is extracted from the provider URL passed to the `InitialContext` constructor.

If no provider URL is defined, the WebSphere Application Server initial context factory uses the default provider URL of `corbaloc:iiop:localhost:2809`. The `string_to_object` ORB method resolves the URL and communicates with the target server ORB to obtain the initial reference.

- **Obtaining initial references in server processes**

If the JNDI client is running in a WebSphere Application Server process, the initial context factory obtains a reference to the server ORB instance if the JNDI client does not provide an ORB instance. Typically, JNDI clients running in server processes use the server ORB instance; that is, they do not pass an ORB instance to the `InitialContext` constructor. The name server which is running in the server process sets a provider URL as a `java.lang.System` property to serve as the default provider URL for all JNDI clients in the process. This default provider URL is `corbaloc:rir:/NameServiceServerRoot`. This URL resolves to the server root context for that server. (The URL is equivalent to invoking `resolve_initial_references` on the ORB with a key of `NameServiceServerRoot`. The name server registers the server root context as an initial reference under that key.)

- **Understanding the legacy ORB protocol**

Releases previous to WebSphere Application Server Version 5 used a different ORB implementation, which used a legacy protocol in contrast with the Interoperable Name Service (INS) protocol now used. This change has affected the implementation of the WebSphere Application Server initial context factory. **Certain types of pure clients can experience different behavior when getting initial JNDI contexts as compared to previous releases of WebSphere Application Server.** This behavior is discussed in more detail below.

The following ORB properties are used with the legacy ORB protocol for ORB initialization and are now deprecated:

- `com.ibm.CORBA.BootstrapHost`
- `com.ibm.CORBA.BootstrapPort`

The new INS ORB is different in a major respect, in that it exhibits no default behavior if no initial references are defined.

In the legacy ORB, the bootstrap host and port values defaulted to localhost and 900.

All initial references were obtained from the server running on the bootstrap host and port. So, if the ORB user provided no bootstrap host and port, all initial references are resolved from the server running on the local host at port 900. The INS ORB has no concept of bootstrap host or bootstrap port. All initial references are defined independently. That is, different initial references could resolve to different servers. If `ORB.resolve_initial_references` is invoked with a key such that the ORB is not initialized with an initial reference having that key, the call fails.

In releases of WebSphere Application Server previous to Version 5, the initial context factory invoked `resolve_initial_references` on the ORB in the absence of any provider URL. This action succeeded if a name server at the default bootstrap host and port was running. In the current release, with the INS ORB, this would fail. (Actually, the ORB would fall back to the legacy protocol during the deprecation period, but when the legacy protocol is no longer supported, the operation would fail.)

The initial context factory now uses a default provider URL of `corbaloc:iiop:localhost:2809`, and invokes `string_to_object` with the provider URL.

This operation preserves the behavior that pure clients in previous releases experienced when they set no ORB bootstrap properties or provider URL. **However, this different initial context factory implementation changes the behavior experienced by certain legacy pure clients, which do not specify a provider URL:**

- Clients which set the ORB bootstrap properties listed above when getting an initial context.
- Clients which supply their own ORB instance to the `InitialContext` constructor.

There are two ways to circumvent this change of behavior:

- Always specify an IOP type provider URL. This approach does not depend on the bootstrap host and port properties and continues to work when support for the bootstrap host and port properties is removed. For example, you can express bootstrap host and port property values of `myHost` and `2809`, respectively, as `corbaloc:iiop:myHost:2809`.
- Use an IIR type provider URL:
 - Specify `corbaloc:iir:/NameServiceServerRoot` if the ORB is initialized to use a WebSphere Application Server 5 server as the bootstrap server.
 - Specify `corbaname:iir:/NameService#domain/LegacyRoot` if the ORB is initialized to use a WebSphere Application Server 4.0.x server as the bootstrap server.
 - Specify `corbaloc:iir:/NameService` if the ORB is initialized to use a server other than a WebSphere Application Server 5 or 4.0.x server as the bootstrap server.

URLs of this type are equivalent to invoking `resolve_initial_references` on the ORB with the specified key. If the bootstrap host and port properties are being used to initialize the ORB, this approach will not work when the bootstrap and host properties are no longer supported.

- **The `InitialContext` constructor search order for JNDI properties**

If the code snippet shown at the beginning of this section is executed by an application, the bootstrap server depends on the value of the property, `java.naming.provider.url`. If the property is not set (in server processes the default value is set as a system property), the default host of `localhost` and default port of `2809` are used as the address of the server from which to obtain the initial context. The JNDI specification describes where the `InitialContext` constructor looks for `java.naming.provider.url` property settings, but briefly, the property is picked up from the following places in the order shown:

InitialContext constructor

This does not apply to the above example because the example uses the empty `InitialContext` constructor.

System environment

You can add JNDI properties to the system environment as an option on the Java command invocation and by program code. The recommended way to set the provider URL in the system environment is as an option supplied to the Java command invocation. Setting the provider URL in this manner is not temporal, so that getting a default initial context will always yield the same result. It is generally recommended that program code not set the provider URL property in the

system environment because as a side-effect, this could adversely affect other, possibly unrelated, code running elsewhere in the same process.

jndi.properties file

There may be many `jndi.properties` files that are within the scope of the class loader in effect. All `jndi.properties` files are used for setting JNDI properties, but the provider URL setting is determined by the first `jndi.properties` file returned by the class loader.

Example: Getting an initial context by setting the provider URL property

In general, JNDI clients should assume the correct environment is already configured so there is no need to explicitly set property values and pass them to the `InitialContext` constructor. However, a JNDI client might need to access a name space other than the one identified in its environment. In this case, it is necessary to explicitly set the `java.naming.provider.url` (provider URL) property used by the `InitialContext` constructor. A provider URL contains bootstrap server information that the initial context factory can use to obtain an initial context. Any property values passed in directly to the `InitialContext` constructor take precedence over settings of those same properties found elsewhere in the environment.

You can use two different provider URL forms with WebSphere Application Server's initial context factory:

- A CORBA object URL (new for J2EE 1.3)
- An IIOP URL

CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. CORBA object URLs are part of the OMG CosNaming Interoperable Naming Specification. A corbaname URL, for example, can include initial context and lookup name information and can be used as a lookup name without the need to explicitly obtain another initial context. The IIOP URLs are the legacy JNDI format, but are still supported by the WebSphere Application Server initial context factory.

The following examples illustrate the use of these URLs.

- "Using a CORBA object URL"
- "Using a CORBA object URL with multiple name server addresses"
- "Using a CORBA object URL from a non-WebSphere Application Server JNDI implementation" on page 1866
- "Using an IIOP URL" on page 1866

Using a CORBA object URL

This example shows a CORBA object URL.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
...
```

Using a CORBA object URL with multiple name server addresses

CORBA object URLs can contain more than one bootstrap address. You can use this feature when attempting to obtain an initial context from a server cluster. You can specify the bootstrap addresses for all servers in the cluster in the URL. The operation succeeds if at least one of the servers is running, eliminating a single point of failure. There is no guarantee of any particular order in which the address list will be processed. For example, the second bootstrap address may be used to obtain the initial context even though the server at the first bootstrap address in the list is available.

Multiple-address provider URLs resolving to servers on non-z/OS systems cannot contain bootstrap addresses for node agent processes. The URLs should only contain the bootstrap addresses of members of the same cluster. Otherwise, incorrect behavior might occur. When resolving to servers running on the z/OS operating system, the URL can contain bootstrap addresses for node agent processes.

An example of a corbaloc URL with multiple addresses follows.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.ibm.websphere.naming.WsnInitialContextFactory");
// All of the servers in the provider URL below are members of
// the same cluster.
env.put(Context.PROVIDER_URL,
        "corbaloc::myhost1:9810,:myhost1:9811,:myhost2:9810");
Context initialContext = new InitialContext(env);
...
```

Using a CORBA object URL from a non-WebSphere Application Server JNDI implementation

Initial context factories for CosNaming JNDI plug-in implementations other than the WebSphere Application Server initial context factory most likely obtain an initial context using the object key, `NameService`. When you use such a context factory to obtain an initial context from a WebSphere Application Server name server, the initial context is the cell root context. Since system artifacts such as EJB homes associated with a server are bound under the server's server root context, names used in JNDI operations must be qualified. If you want to use relative names, ensure your initial context is the server root context under which the target object is bound. In order to make the server root context the initial context, specify a corbaloc provider URL with an object key of `NameServiceServerRoot`.

This example shows a CORBA object type URL from a non-WebSphere Application Server JNDI implementation. This example assumes full CORBA object URL support by the non-WebSphere Application Server JNDI implementation. The object key of `NameServiceServerRoot` is specified so that the initial context will be the specified server's server root context.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.somecompany.naming.TheirInitialContextFactory");
env.put(Context.PROVIDER_URL,
        "corbaname:iiop:myhost.mycompany.com:9810/NameServiceServerRoot");
Context initialContext = new InitialContext(env);
...
```

If qualified names are used, you can use the default key of `NameService`.

Using an IIOP URL

The IIOP type of URL is a legacy format which is not as flexible as CORBA object URLs. However, URLs of this type are still supported. The following example shows an IIOP type URL as the provider URL.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
```

```

    "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "iiop://myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
...

```

Example: Setting the provider URL property to select a different root context as the initial context

Each server contains its own server root context, and, when bootstrapping to a server, the server root is the default initial JNDI context. Most of the time, this default is the desired initial context, since system artifacts such as EJB homes are bound there. However, other root contexts exist, which can contain bindings of interest. It is possible to specify a provider URL to select other root contexts.

Examples for selecting other root contexts follow:

- Initial root contexts with a CORBA object URL
- Initial root contexts with the name space root property

Selecting the initial root context with a CORBA object URL

There are several object keys registered with the bootstrap server that you can use to select the root context for the initial context. To select a particular root context with a CORBA object URL object key, set the object key to the corresponding value. The default object key is NameService. Using JNDI yields the server root context. A table that lists the different root contexts and their corresponding object key follows:

Root Context	CORBA Object URL Object Key
Server Root	NameServiceServerRoot
Cell Persistent Root	NameServiceCellPersistentRoot
Cell Root	NameServiceCellRoot
Node Root	NameServiceNodeRoot

The following example shows the use of a corbaloc URL with the object key set to select the cell persistent root context as the initial context.

```

...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
    "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL,
    "corbaloc:iiop:myhost.mycompany.com:2809/NameServiceCellPersistentRoot");
Context initialContext = new InitialContext(env);
...

```

Selecting the initial root context with the name space root property

You can also select the initial root context by passing a name space root property setting to the InitialContext constructor. Generally, the object key setting described above is sufficient. Sometimes a property setting is preferable. For example, you can set the root context property on the Java invocation to make which server root is being used as the initial context transparent to the application. The default server root property setting is defaultroot, which yields the server root context.

Root Context	Name Space Root Property Value
Server Root	bootstrapserverroot
Cell Persistent Root	cellpersistentroot
Cell Root	cellroot

Root Context	Name Space Root Property Value
Node Root	bootstrapnoderoot

The initial context factory ignores the name space root property if the provider URL contains an object key other than NameService.

The following example shows use of the name space root property to select the cell persistent root context as the initial context. Note that available constants are used instead of hard-coding the property name and value.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
env.put(PROPS.NAME_SPACE_ROOT, PROPS.NAME_SPACE_ROOT_CELL_PERSISTENT);
Context initialContext = new InitialContext(env);
...
```

Example: Looking up an EJB home with JNDI

Most applications that use JNDI run in a container. Some do not. The name used to look up an object depends on whether or not the application is running in a container. Sometimes it is more convenient for an application to use a corbaname URL as the lookup name. Container-based JNDI clients and thin Java clients can use a corbaname URL.

The following examples show how to perform JNDI lookups from different types of applications.

- “JNDI lookup from an application running in a container”
- “JNDI lookup from an application that does not run in a container” on page 1869
- “JNDI lookup with a corbaname URL” on page 1870

JNDI lookup from an application running in a container

Applications that run in a container can use `java:` lookup names. Lookup names of this form provide a level of indirection such that the lookup name used to look up an object is not dependent on the object's name as it is bound in the name server's name space. The deployment descriptors for the application provide the mapping from the `java:` name and the name server lookup name. The container sets up the `java:` name space based on the deployment descriptor information so that the `java:` name is correctly mapped to the corresponding object.

The following example shows a lookup of an EJB home. The actual home lookup name is determined by the application's deployment descriptors. The enterprise bean (EJB) resides in an EJB container, which provides an interface between the bean and the application server on which it resides.

```
// Get the initial context as shown in a previous example
...
// Look up the home interface using the JNDI name
try {
    java.lang.Object ejbHome =
        initialContext.lookup(
            "java:comp/env/com/mycompany/accounting/AccountEJB");
    accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
        (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
```

```

}
  catch (NamingException e) { // Error getting the home interface
    ...
  }
}

```

JNDI lookup from an application that does not run in a container

Applications that do not run in a container cannot use `java:` lookup names because it is the container which sets the `java:` name space up for the application. Instead, an application of this type must look the object up directly from the name server. Each application server contains a name server. System artifacts such as EJB homes are bound relative to the server root context in that name server. The various name servers are federated by means of a system name space structure. The recommended way to look up objects on different servers is to qualify the name so that the name resolves from any initial context in the cell. If a relative name is used, the initial context must be the same server root context as the one under which the object is bound. The form of the qualified name depends on whether the qualified name is a topology-based name or a fixed name. A topology based name depends on whether the object resides in a single server or a server cluster. Examples of each form of qualified name follow.

- **Topology-based qualified names**

Topology-based qualified names traverse through the system name space to the server root context under which the target object is bound. A topology-based qualified name resolves from any initial context in the cell. The topology-based qualified name depends on whether the object resides on a single server or server cluster. Examples of each lookup follow.

Single server

The following example shows a lookup of an EJB home that is running in the single server, `MyServer`, configured in the node, `Node1`.

```

// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
  java.lang.Object ejbHome = initialContext.lookup(
    "cell/nodes/Node1/servers/MyServer/com/mycompany/accounting/AccountEJB");
  accountHome = (AccountHome)javadoc.rmi.PortableRemoteObject.narrow(
    (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
  ...
}

```

Server cluster

The example below shows a lookup of an EJB home which is running in the cluster, `MyCluster`. The name can be resolved if any of the cluster members is running.

```

// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
  java.lang.Object ejbHome = initialContext.lookup(
    "cell/clusters/MyCluster/com/mycompany/accounting/AccountEJB");
  accountHome = (AccountHome)javadoc.rmi.PortableRemoteObject.narrow(
    (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
  ...
}

```

- **Fixed qualified names**

If the target object has a cell-scoped fixed name defined for it, you can use its qualified form instead of the topology-based qualified name. Even though the topology-based name works, the fixed name does

not change with the specific cell topology or with the movement of the target object to a different server. An example lookup with a qualified fixed name is shown below.

```
// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
    java.lang.Object ejbHome = initialContext.lookup(
        "cell/persistent/com/mycompany/accounting/AccountEJB");
    accountHome = (AccountHome)jvax.rmi.PortableRemoteObject.narrow(
        (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
    ...
}
```

JNDI lookup with a corbaname URL

A corbaname can be useful at times as a lookup name. If, for example, the target object is not a member of the federated name space and cannot be located with a qualified name, a corbaname can be a convenient way to look up the object. A lookup with a corbaname URL follows.

```
// Get the initial context as shown in a previous example
...
// Look up the home interface using a corbaname URL
try {
    java.lang.Object ejbHome = initialContext.lookup(
        "corbaname:iiop:someHost:2809#com/mycompany/accounting/AccountEJB");
    accountHome = (AccountHome)jvax.rmi.PortableRemoteObject.narrow(
        (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
    ...
}
```

Example: Looking up a JavaMail session with JNDI

A program can conduct a JNDI lookup of a JavaMail resource. Deployment descriptors of the application determine the lookup name that you specify.

The following example shows a lookup of a JavaMail resource:

```
// Get the initial context as shown above
...
Session session =
    (Session) initialContext.lookup("java:comp/env/mail/MailSession");
```

JNDI interoperability considerations

You must take extra steps to enable your programs to interoperate with non-WebSphere Application Server JNDI clients and to bind resources from MQSeries to a name space.

EJB clients running in an environment other than WebSphere Application Server accessing EJB applications running on WebSphere Application Server V5 or V6 servers

When an EJB application running in WebSphere Application Server V5 or V6 is accessed by a non-WebSphere Application Server EJB client, the JNDI initial context factory is presumed to be a non-WebSphere Application Server implementation. In this case, the default initial context is the cell root. If the JNDI service provider being used supports CORBA object URLs, the corbaname format can be used to look up the EJB home. The construction of the stringified name depends on whether the object is installed on a single server or cluster.

Single server

Following is a URL that has the bootstrap host **myHost**, the port **2809**, and the enterprise bean installed in the server **server1** in node **node1** and bound in that server under the name **myEJB**:

```
initialContext.lookup(  
    "corbaname:iiop:myHost:2809#cell/nodes/node1/servers/server1/myEJB");
```

Server cluster

Following is a URL that has the bootstrap host **myHost**, the port **2809**, and the enterprise bean installed in a server cluster named **myCluster** and bound in that cluster under the name **myEJB**:

```
initialContext.lookup(  
    "corbaname:iiop:myHost:2809#cell/clusters/myCluster/myEJB");
```

The lookup works with any name server bootstrap host and port configured in the same cell.

The lookup also works if the bootstrap host and port belong to a member of the cluster itself. To avoid a single point of failure, the bootstrap server host and port for each cluster member can be listed in the URL as follows:

```
initialContext.lookup(  
    "corbaname:iiop:host1:9810, :host2:9810#cell/clusters/myCluster/myEJB");
```

The name prefix **cell/clusters/myCluster/** is not necessary if bootstrapping to the cluster itself, but it will work. The prefix is needed, however, when looking up enterprise beans in other clusters. Name bindings under the **clusters** context are implemented on the name server to resolve to the server root of a running cluster member during a lookup; thus avoiding a single point of failure.

Without CORBA object URL support

If the JNDI initial context factory being used does not support CORBA object URLs, the initial context can be obtained from the server, and the lookup can be performed on the initial context as follows:

```
Hashtable env = new Hashtable();  
env.put(CONTEXT.PROVIDER_URL, "iiop://myHost:2809");  
Context ic = new InitialContext(env);  
Object o = ic.lookup("cell/clusters/myCluster/myEJB");
```

Binding resources from MQSeries 5.2

In releases previous to WebSphere Application Server V5, the MQSeries jmsadmin tool could be used to bind resources to the name space. When used with a WebSphere Application Server V5 or V6 name space, the resource is bound within a transient partition in the name space and does not persist past the life of the server process. Instead of binding the MQSeries resources with the jmsadmin tool, bind them from the WebSphere Application Server administrative console, under **Resources** in the console navigation tree.

JNDI caching

To increase the performance of JNDI operations, the WebSphere Application Server JNDI implementation employs caching to reduce the number of remote calls to the name server for lookup operations. For most cases, use the default cache setting.

When an InitialContext object is instantiated, an association is established between the InitialContext instance and a cache. The initial context and any contexts returned directly or indirectly from a lookup on the initial context are all associated with that same cache instance. By default, the association is based on the provider URL, in particular, the host name and port. The caller can specify the cache name to override this default behavior. A cache instance of a given name is shared by all instances of InitialContext configured to use a cache of that name which were created with the same context class loader in effect. Two EJB applications running in the same server will use their own cache instances, if they are using different context class loaders, even if the cache names are the same.

After an association between an InitialContext instance and cache is established, the association does not change. A `javax.naming.Context` object returned from a lookup operation inherits the cache association of the Context object on which the lookup was performed. Changing cache property values with the `Context.addToEnvironment()` or `Context.removeFromEnvironment()` method does not affect cache behavior. You can change properties affecting a given cache instance with each InitialContext instantiation.

A cache is restricted to a process and does not persist past the life of that process. A cached object is returned from lookup operations until either the maximum cache life for the cache is reached, or the maximum entry life for the object's cache entry is reached. After this time, a lookup on the object causes the cache entry for the object to be refreshed. By default, caches and cache entries have unlimited lifetimes.

Usually, cached objects are relatively static entities, and objects becoming stale is not a problem. However, you can set timeout values on cache entries or on a cache so that cache contents are periodically refreshed.

If a bind or rebind operation is executed on an object, the change is not reflected in any caches other than the one associated with the context from which the bind or rebind was issued. This scenario is most likely to happen when multiple processes are involved, since different processes do not share the same cache, and context objects in all threads in a process typically share the same cache instance for a given name service provider.

JNDI cache settings

Various cache property settings follow. Ensure that all property values are string values.

com.ibm.websphere.naming.jndicache.cachename

The name of the cache to associate with an initial context instance can be specified with this property.

It is possible to create multiple InitialContext instances, each operating on the name space of a different name server. By default, objects from each bootstrap address are cached separately, since they each involve independent name spaces and name collisions could occur if they used the same cache. The provider URL specified when the initial context is created by default serves as the basis for the cache name. With this property, a JNDI client can specify a cache name. Valid options for cache names follow:

Valid options	Resulting cache behavior
providerURL (default)	Use the value for <code>java.naming.provider.url</code> property as the basis for the cache name. Cache names are based on the bootstrap host and port specified in the URL. The bootstrap host is normalized to a fully qualified name, if possible. For example, <code>"corbaname:iiop:server1:2809#some/starting/context"</code> and <code>"corbaloc:iiop://server1"</code> are normalized to the same cache name. If no provider URL is specified, a default cache name is used.
Any string	Use the specified string as the cache name. You can use any arbitrary string with a value other than <code>"providerURL"</code> as a cache name.

com.ibm.websphere.naming.jndicache.cacheobject

Turn caching on or off and clear an existing cache with this property.

By default, when an InitialContext is instantiated, it is associated with an existing cache or, if one does not exist, a new one is created. An existing cache is used with its existing contents. In some circumstances, this behavior is not desirable. For example, when objects that are looked up change frequently, they can become stale in the cache. Other options are available. The following table lists these other options along with the corresponding property value.

Valid values	Resulting cache behavior
--------------	--------------------------

populated (default)	Use a cache with the specified name. If the cache already exists, leave existing cache entries in the cache; otherwise, create a new cache.
cleared	Use a cache with the specified name. If the cache already exists, clear all cache entries from the cache; otherwise, create a new cache.
none	Do not cache. If this option is specified, the cache name is irrelevant. Therefore, this option will not disable a cache that is already associated with other InitialContext instances. The InitialContext that is instantiated is not associated with any cache.

com.ibm.websphere.naming.jndicache.maxcachelife

Impose a limit to the age of a cache with this property.

By default, cached objects remain in the cache for the life of the process or until cleared with the `com.ibm.websphere.naming.jndicache.cacheobject` property set to "cleared". This property enables a JNDI client to set the maximum life of a cache. This property differs from the `maxentrylife` property (below) in that the entire cache is cleared when the cache lifetime is reached. The table below lists the various `maxcachelife` values and their affect on cache behavior:

Valid options	Resulting cache behavior
0 (default)	Make the cache lifetime unlimited.
Positive integer	Set the maximum lifetime of the entire cache, in minutes, to the specified value. When the maximum lifetime for the cache is reached, the next attempt to read any entry from the cache causes the cache to be cleared

com.ibm.websphere.naming.jndicache.maxentrylife

Impose a limit to the age of individual cache entries with this property.

By default, cached objects remain in the cache for the life of the process or until cleared with the `com.ibm.websphere.naming.jndicache.cacheobject` property set to `cleared`. This property enables a JNDI client to set the maximum lifetime of individual cache entries. This property differs from the `maxcachelife` property in that individual entries are refreshed individually as their maximum lifetime reached. This might avoid any noticeable change in performance that might occur if the whole cache is cleared at once. The table below lists the various `maxentrylife` values and their effect on cache behavior:

Valid options	Resulting cache behavior
0 (default)	Lifetime of cache entries is unlimited.
Positive integer	Set the maximum lifetime of individual cache entries, in minutes, to the specified value. When the maximum lifetime for an entry is reached, the next attempt to read the entry from the cache causes the individual cache entry to refresh.

Example: Controlling JNDI cache behavior from a program

You can specify JNDI cache properties in a program to control the behavior of a JNDI cache.

Following are examples that illustrate how you can use JNDI cache properties to achieve the desired cache behavior. Cache properties take effect when an InitialContext object is constructed.

```
import java.util.Hashtable;
import javax.naming.InitialContext;
import javax.naming.Context;
import com.ibm.websphere.naming.PROPS;
```

```
/*****
```

```
Caching discussed in this section pertains to the WebSphere Application
Server initial context factory. Assume the property,
java.naming.factory.initial, is set to
```

```

"com.ibm.websphere.naming.WsnInitialContextFactory" as a
java.lang.System property.
*****/

Hashtable env;
Context ctx;

// To clear a cache:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_CLEARED);
ctx = new InitialContext(env);

// To set a cache's maximum cache lifetime to 60 minutes:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_MAX_LIFE, "60");
ctx = new InitialContext(env);

// To turn caching off:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE);
ctx = new InitialContext(env);

// To use caching and no caching:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_POPULATED);
ctx = new InitialContext(env);
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE);
Context noCacheCtx = new InitialContext(env);

Object o;

// Use caching to look up home, since the home should rarely change.
o = ctx.lookup("com/mycom/MyEJBHome");
// Narrow, etc. ...

// Do not use cache if data is volatile.
o = noCacheCtx.lookup("com/mycom/VolatileObject");
// ...

```

JNDI name syntax

JNDI name syntax is the default syntax and is suitable for typical JNDI clients.

This syntax includes the following special characters: forward slash (/) and backslash (\). Components in a name are delimited by a forward slash. The backslash is used as the escape character. A forward slash is interpreted literally if it is escaped, that is, preceded by a backslash. Similarly, a backslash is interpreted literally if it is escaped.

INS name syntax

INS syntax is designed for JNDI clients that need to interoperate with CORBA applications.

The INS syntax allows a JNDI client to make the proper mapping to and from a CORBA name. INS syntax is very similar to the JNDI syntax with the additional special character, dot (.). Dots are used to delimit the id and kind fields in a name component. A dot is interpreted literally when it is escaped. Only one unescaped dot is allowed in a name component. A name component with a non-empty id field and empty kind field is represented with only the id field value and must not end with an unescaped dot. An empty name component (empty id and empty kind field) is represented with a single unescaped dot. An empty string is not a valid name component representation.

JNDI to CORBA name mapping considerations

WebSphere Application Server name servers are an implementation of the CORBA CosNaming interface. WebSphere Application Server provides a JNDI implementation which you can use to access CosNaming name servers through the JNDI interface. Issues can exist when mapping JNDI name strings to and from CORBA names.

Each component in a CORBA name consists of an `id` and `kind` field, but a JNDI name component consists of no such fields. Each component in a JNDI name is atomic. Typical JNDI clients do not need to make a distinction between the `id` and `kind` fields of a name component, or know how JNDI name strings map to CORBA names. JNDI clients of this sort can use the JNDI syntax described below. When a name is parsed according to JNDI syntax, each name component is mapped to the `id` field of the corresponding CORBA name component. The `kind` field always has an empty value. This basic syntax is the least obtrusive to the JNDI client in that it has the fewest special characters. However, you cannot represent with this syntax a CORBA name with a non-empty `kind` field. This restriction can prevent EJB applications from interoperating with CORBA applications.

Some clients, however must interoperate with CORBA applications which use CORBA names with non-empty `kind` fields. These JNDI clients must make a distinction between `id` and `kind` so that JNDI names are correctly mapped to CORBA names, particularly when the CORBA names contain components with non-empty `kind` fields. Such JNDI clients can use the INS name syntax. With its additional special character, you can use INS to represent any CORBA name. Use of this syntax is not recommended unless it is necessary, because this syntax is more restrictive from the JNDI client's perspective in that the JNDI client must be aware that name components with multiple unescaped dots are syntactically invalid. INS name syntax is part of the OMG CosNaming Interoperable Naming Specification.

Example: Setting the syntax used to parse name strings

JNDI clients that must interoperate with CORBA applications might need to use INS name syntax to represent names in string format.

The name syntax property can be passed to the `InitialContext` constructor through its parameter, in the System properties, or in a `jndi.properties` file. The initial context and any contexts looked up from that initial context parse name strings based on the specified syntax.

The following example shows how to set the name syntax to make the initial context parse name strings according to INS syntax.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS; // WebSphere naming constants
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, ...);
env.put(PROPS.NAME_SYNTAX, PROPS.NAME_SYNTAX_INS);
Context initialContext = new InitialContext(env);
// The following name maps to a CORBA name component as follows:
//   id = "a.name", kind = "in.INS.format"
// The unescaped dot is used as the delimiter.
// Escaped dots are interpreted literally.
java.lang.Object o = initialContext.lookup("a\\.name.in\\.INS\\.format");
...
```

Chapter 18. Object Request Broker

Managing Object Request Brokers

Use this task to manage Object Request Brokers (ORB). An ORB manages the interaction between clients and servers using the Internet InterORB Protocol (IIOP).

Default property values are set when the product starts and the Java Object Request Broker (ORB) service is initialized. These properties control the run-time behavior of the ORB and can also affect the behavior of product components that are tightly integrated with the ORB, such as security. It might be necessary to modify some ORB settings under certain conditions.

Every request or response exchange consists of a client-side ORB and a server-side ORB. It is important to set the ORB properties for both sides as necessary.

After an ORB instance has been established in a process, changes to ORB properties do not affect the behavior of the running ORB instance. The process must be stopped and restarted for the modified properties to take effect.

A list of possible tasks for managing ORB follows. These steps can be performed in any order.

Adjust timeout settings to improve handling of network failures. See “Object Request Broker service settings” for more information.

Object Request Brokers

An Object Request Broker (ORB) manages the interaction between clients and servers, using the Internet InterORB Protocol (IIOP). It enables clients to make requests and receive responses from servers in a network-distributed environment.

The ORB provides a framework for clients to locate objects in the network and to call operations on those objects as if the remote objects are located in the same running process as the client, providing location transparency. The client calls an operation on a local object, known as a *stub*. The stub forwards the request to the remote object, where the operation runs and the results are returned to the client.

The client-side ORB is responsible for creating an IIOP request that contains the operation and required parameters, and for sending the request on the network. The server-side ORB receives the IIOP request, locates the target object, invokes the requested operation, and returns the results to the client. The client-side ORB demarshals the returned results and passes the result to the stub, which, in turn, returns to the client application, as if the operation had been run locally.

This product uses an ORB to manage communication between client applications and server applications as well as communication among product components. During product installation, default property values are set when the ORB is initialized. These properties control the run-time behavior of the ORB and can also affect the behavior of product components that are tightly integrated with the ORB, such as security. This product does not support the use of multiple ORB instances.

ORB service transport channels are used for ORB I/O operations within an application server environment. These transport chains are part of the channel framework function that provides a common networking service for all components.

Object Request Broker service settings

Use this page to configure the Java Object Request Broker (ORB) service.

To view this administrative console page, click **Servers > Application servers > *server_name* > Container services > ORB service** .

Several settings are available for controlling internal Object Request Broker (ORB) processing. You can use these settings to improve application performance in the case of applications that contain enterprise beans. You can make changes to these settings for the default server or any application server that is configured in the administrative domain.

Request timeout

Specifies the number of seconds to wait before timing out on a request message.

If you use command-line scripting, the full name of this system property is `com.ibm.CORBA.RequestTimeout`.

Data type	int
Units	Seconds
Default	180
Range	0 - largest integer recognized by Java

ORB tracing

Enables the tracing of ORB General Inter-ORB Protocol (GIOP) messages.

This setting affects two system properties: `com.ibm.CORBA.Debug` and `com.ibm.CORBA.CommTrace`. If you set these properties through command-line scripting, you must set both properties to `true` to enable the tracing of GIOP messages.

Data type	Boolean
Default	Not enabled (false)

Pass by reference

Specifies how the ORB passes parameters. If enabled, the ORB passes parameters by reference instead of by value, to avoid making an object copy. If you do not enable the pass by reference option, a copy of the parameter passes rather than the parameter object itself. This can be expensive because the ORB must first make a copy of each parameter object.

You can use this option only when the Enterprise JavaBeans (EJB) client and the EJB are on the same classloader. This requirement means that the EJB client and the EJB must be deployed in the same EAR file.

If the Enterprise JavaBeans (EJB) client and server are installed in the same WebSphere Application Server instance, and the client and server use remote interfaces, enabling the pass by reference option can improve performance up to 50%. The pass by reference option helps performance only where non-primitive object types are passed as parameters. Therefore, int and floats are always copied, regardless of the call model.

Important: Enable this property with caution because unexpected behavior can occur. If an object reference is modified by the callee, the caller's object is modified as well, since they are the same object.

If you use command-line scripting, the full name of this system property is `com.ibm.CORBA.iiop.noLocalCopies`.

Data type	Boolean
Default	Not enabled (false)

The use of this option for enterprise beans with remote interfaces violates Enterprise JavaBeans (EJB) Specification, Version 2.0 (see section 5.4). Object references passed to Enterprise JavaBeans (EJB) methods or to EJB home methods are not copied and can be subject to corruption.

Consider the following example:

```
Iterator iterator = collection.iterator();
MyPrimaryKey pk = new MyPrimaryKey();
while (iterator.hasNext()) {
    pk.id = (String) iterator.next();
    MyEJB myEJB = myEJBHome.findByPrimaryKey(pk);
}
```

In this example, a reference to the same `MyPrimaryKey` object passes into WebSphere Application Server with a different ID value each time. Running this code with pass by reference enabled causes a problem within the application server because multiple enterprise beans are referencing the same `MyPrimaryKey` object. To avoid this problem, set the `com.ibm.websphere.ejbcontainer.allowPrimaryKeyMutation` system property to `true` when the pass by reference option is enabled. Setting the pass by reference option to `true` causes the EJB container to make a local copy of the `PrimaryKey` object. As a result, however, a small portion of the performance advantage of setting the pass by reference option is lost.

As a general rule, any application code that passes an object reference as a parameter to an enterprise bean method or to an EJB home method must be scrutinized to determine if passing that object reference results in loss of data integrity or in other problems.

After examining your code, you can enable the pass by reference option by setting the `com.ibm.CORBA.iop.noLocalCopies` system property to `true`. You can also enable the pass by reference option in the administrative console. Click **Servers > Application servers > server_name > Container services > ORB Service** and select **Pass by reference**.

Object Request Broker custom properties

There are several ways to configure an ORB. For example, you can use ORB custom property settings, or system property settings to configure an ORB, or you can provide objects during ORB initialization.

If you use ORB custom properties to configure an ORB, you must understand that there are two types of default values for some of these properties: JDK default values and WebSphere Application Server default values. The JDK default is the value that the ORB uses for a property if the property is not specified in any way. The WebSphere Application Server default is the value that WebSphere Application Server sets for a property in one of the following files:

- The `orb.properties` file when an application server is installed.
- The `server.xml` when an application server is configured.

Because WebSphere Application Server explicitly sets its default value, if both a WebSphere Application Server and a JDK default value is defined for a property, the WebSphere Application Server default takes precedence over the JDK default.

For more information about the different ways to specify ORB properties and the precedence order, see the JDK Diagnostic Guide for the version of the JDK that you are using. These guides are available at <http://www-128.ibm.com/developerworks/java/jdk/diagnosis/>.

The WebSphere Application Server `orb.properties` file, that is located in the WebSphere Application Server `was_home/java/jre/lib` directory, contains WebSphere Application server ORB custom properties that are initially set to WebSphere Application Server default values during the WebSphere Application Server installation process.

You can specify new values for the ORB custom properties in the administrative console. Any value you specify takes precedence over any JDK or WebSphere Application Server default values for these

properties. The ORB custom properties settings that you specify in the administrative console are stored in the WebSphere Application Server server.xml system file and are passed to an ORB in a properties object whenever an ORB is initialized.

To use the administrative console to set ORB custom properties, in the administrative console, click **Servers >Application servers > server_name >Container services > ORB service >Custom properties**. You can then change the setting of one of the listed custom properties or click **New** to add a new property to the list. Then click **Apply** to save your change. When you finish making changes, click **OK** and then click **Save** to save your changes.

To use the java command on a command line, use the -D option. For example:

```
java -Dcom.ibm.CORBA.propname1=value1 -Dcom.ibm.CORBA.propname2=value2 ... application name
```

To use the launchclient command on a command line, prefix the property with -CC. For example:

```
launchclient yourapp.ear -CCDcom.ibm.CORBA.propname1=value1 -CCDcom.ibm.CORBA.propname2=value2  
... optional application arguments
```

The Custom properties page might already include Secure Sockets Layer (SSL) properties that were added during WebSphere Application Server installation. A list of additional properties associated with the Java ORB service follows. Unless otherwise indicated, the default values provided in the descriptions of these properties are the JDK default values.

com.ibm.CORBA.BootstrapHost

Specifies the domain name service (DNS) host name or IP address of the machine on which initial server contact for this client resides. This setting is deprecated and is scheduled for removal in a future release.

For a command-line or programmatic alternative, see “Client-side programming tips for the Java Object Request Broker service” on page 1886.

com.ibm.CORBA.BootstrapPort

Specifies the port to which the ORB connects for bootstrapping, the port of the machine on which the initial server contact for this client listens. This setting is deprecated and is scheduled for removal in a future release.

For a command-line or programmatic alternative, see “Client-side programming tips for the Java Object Request Broker service” on page 1886.

Default	2809
----------------	------

com.ibm.CORBA.ConnectTimeout

The com.ibm.CORBA.ConnectTimeout property specifies the maximum time in seconds that the client ORB waits before timing out when attempting to establish an IIOp connection with a remote server ORB. Generally, client applications use this property. The property is not used by the application server by default. However, if necessary, you can specify the property for each individual application server through the administrative console.

Client applications can specify the com.ibm.CORBA.ConnectTimeout property in one of two ways:

- By including it in the orb.properties file.
- By using the -CCD option to set the property with the launchclient script. This example specifies a maximum timeout value of ten seconds:

```
launchclient clientapp.ear -CCDcom.ibm.com.CORBA.ConnectTimeout=10...
```

Begin by setting your timeout value to 20-30 seconds, but consider factors such as network congestion and application server load and capacity. Lower values can provide better failover performance, but can result in exceptions if the remote server does not have enough time to complete the connection.

Valid Range	0-300 (seconds)
Default	0 (the client ORB waits indefinitely)

com.ibm.CORBA.ConnectionInterceptorName

Specifies the connection interceptor class that is used to determine the type of outbound IIOp connection to use for a request, and if secure, the quality of protection characteristics associated with the request.

WebSphere Application Server default	com.ibm.ISecurityLocalObjectBaseL13InpSecurityConnectionInterceptor
JDK default	None.

com.ibm.CORBA.enableLocateRequest

Specifies whether the ORB uses the locate request mechanism to find objects in a WebSphere Application Server cell. Use this property for performance tuning.

When this property is set to true, the ORB first sends a short message to the server to find the object that it needs to access. This first contact is called the *locate request*. If most of your initial method invocations are very small, setting this property to false might improve performance because this setting change can reduce the GIOP traffic by as much as half. If most of your initial method invocations are large, you should set this property to true so that the small locate request message is sent instead of the large message. The large message is then sent to the proper target after the desired object is found.

WebSphere Application Server default	true
JDK default	false

com.ibm.CORBA.FragmentSize

Specifies the size of General Inter-ORB Protocol (GIOP) fragments used by the ORB. If the total size of a request exceeds the set value, the ORB breaks up and sends multiple fragments until the entire request is sent. Set this property on the client side with a -D system property if you use a stand-alone Java application.

Adjust the `com.ibm.CORBA.FragmentSize` property if the amount of data that is sent over Internet Inter-ORB Protocol (IIOp) in most General Inter-ORB Protocol (GIOP) requests exceeds one kilobyte or if thread dumps show that most client-side threads seem to be waiting while sending or receiving data. Adjust this property so that most messages have few or no fragments.

If you want to instruct the ORB not to break up any of the requests or replies it sends, set this property to 0 (zero). However, setting the value to zero does not prevent the ORB from receiving GIOP fragments in requests or replies sent by another existing ORB.

Units	Bytes.
Default	1024
Range	From 64 to the largest value of a Java integer type that is divisible by 8

com.ibm.CORBA.ListenerPort

Specifies the port on which this server listens for incoming requests. The setting of this property is valid for client-side ORBs only.

Default	Next available system-assigned port number
Range	0 to 2147483647

com.ibm.CORBA.LocalHost

Specifies the host name or IP address of the system on which the server ORB is running. If you do not specify a value for this property, during ORB initialization WebSphere Application Server sets this property to the host name or IP address specified for the BOOTSTRAP_ADDRESS end point in serverindex.xml. For client applications, if no value is specified for this property, the ORB obtains a value at run time by calling `InetAddress.getLocalHost().getHostAddress()` method.

com.ibm.CORBA.numJNIReaders

Specifies the number of JNI reader threads to be allocated in the ORB's JNI reader thread pool. Each thread can handle up to 1024 connections.

Attention: Before setting this property, make sure that a JSSE provider has been selected as the provider for the SSL repertoire associated with the port on which the ORB service listens for incoming requests. IBMJSSE2 is the default provider setting for SSL repertoires and does not provide the file descriptor that JNIReader Threads require.

Valid Range	1-2147483647
Default	4

com.ibm.CORBA.ORBPluginClass.com.ibm.ws.orbimpl.transport.JNIReaderPoolImpl

Specifies that JNI reader threads will be used. The property name specifies the class name of the ORB component that manages the pool of JNI reader threads and interacts with the native OS library used to process multiple connections simultaneously.

Attention:

- Make sure the library is in the WebSphere Application Server bin directory.
For an Intel platform, the library is Selector.dll and for a UNIX platform, it is libSelector.a or libSelector.so.
For the UNIX platform, if the prefix "lib" is missing, the file should be renamed.
- When specifying this property using the administrative console, enter `com.ibm.CORBA.ORBPluginClass.com.ibm.ws.orbimpl.transport.JNIReaderPoolImpl` for the property name and an empty string ("") for the value.

When specifying this property on the java command, do not include a value:

```
-Dcom.ibm.CORBA.ORBPluginClass.com.ibm.ws.orbimpl.transport.JNIReaderPoolImpl
```

Valid Range	not applicable
Default	none

com.ibm.CORBA.RasManager

Specifies an alternative to the default RAS manager of the ORB. This property must be set to `com.ibm.websphere.ras.WsOrbRasManager` before the ORB can be integrated with the rest of WebSphere Application Server RAS processing.

WebSphere Application Server default	<code>com.ibm.websphere.ras.WsOrbRasManager</code>
JDK default	None.

com.ibm.CORBA.ServerSocketQueueDepth

Specifies the maximum number of connection requests that can remain unhandled by the WebSphere Application Server ORB before the Application Server starts to reject new incoming connection requests. This property corresponds to the `backlog` argument to a `ServerSocket` constructor and is handled directly by TCP/IP.

If you see a "connection refused" message in a trace log, usually either the port on the target machine isn't open, or the server is overloaded with queued-up connection requests. Increasing the value specified for this property can help alleviate this problem if there does not appear to be any other problem in the system.

Default	50
Range	From 50 to the largest value of the Java int type

com.ibm.CORBA.ShortExceptionDetails

Specifies that the exception detail message that is returned whenever the server ORB encounters a CORBA system exception contains a short description of the exception as returned by the toString method of java.lang.Throwable class. Otherwise, the message contains the complete stack trace as returned by the printStackTrace method of java.lang.Throwable class.

com.ibm.CORBA.WSSSLClientSocketFactoryName

Specifies the class that the ORB uses to create SSL sockets for secure outbound IOP connections.

WebSphere Application Server default	com.ibm.ws.security.orbssl.WSSSLClientSocketFactoryImpl
JDK default	None.

com.ibm.CORBA.WSSSLServerSocketFactoryName

Specifies the class that the ORB uses to create SSL sockets for inbound IOP connections.

WebSphere Application Server default	com.ibm.ws.security.orbssl.WSSSLServerSocketFactoryImpl
JDK default	None.

com.ibm.websphere.ObjectIDVersionCompatibility

This property applies when you have a mixed release cluster for which you are performing an incremental cell upgrade, and at least one of the releases is earlier than V5.1.1.

In an environment that includes mixed release cells, the migration program automatically sets this property to 1.

After you upgrade all of the cluster members to the same release, you can removing this property from the list of ORB custom properties or you can change the value that is specified for the property to 2. Either action improves performance.

When this property is set to 1, the ORB runs using version 1 object identities, which are required for mixed cells that contain application servers with releases prior to V5.1.1. If you do not specify a value for this property or if you set this property to 2, the ORB runs using version 2 object identities, which cannot be used with pre-V5.1.1 application servers.

See the *Migrating, coexisting, and interoperating* PDF for instructions on how to perform an incremental cell upgrade.

com.ibm.websphere.threadpool.strategy.implementation

Specifies the logical pool distribution (LPD) thread pool strategy the next time you start the application server, and is enabled if set to com.ibm.ws.threadpool.strategy.LogicalPoolDistribution.

Attention: This is a deprecated function and will be removed in a future version of the product. Do not configure logical pool distribution unless you have already configured it for a previous release of WebSphere Application Server.

Some requests have shorter start times than others. LPD is a mechanism for providing these shorter requests greater access to start threads. For more information, see the information center.

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.calcinterval

Specifies how often the logical pool distribution (LPD) mechanism readjusts the pool start target times. This property cannot be turned off after this support is installed.

Attention: Do not configure logical pool distribution unless you have already configured it with a previous release of WebSphere Application Server. This function is deprecated and will be removed in a future version of the product.

LPD must be enabled (see `com.ibm.websphere.threadpool.strategy.implementation`).

Data type	Integer
Units	Milliseconds
Default	30
Range	20,000 milliseconds minimum

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.lruinterval

Specifies how long the logical pool distribution internal data is kept for inactive requests. The mechanism tracks several statistics for each request type that is received. Consider removing requests that have been inactive for awhile.

Attention: Do not configure logical pool distribution unless you have already configured it with a previous release of WebSphere Application Server. This function is deprecated and will be removed in a future version of the product.

LPD must be enabled (see `com.ibm.websphere.threadpool.strategy.implementation`).

Data type	Integer
Units	Milliseconds
Default	300,000 (5 minutes)
Range	60,000 (1 minute) minimum

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.outqueues

Specifies how many pools are created and how many threads are allocated to each pool in the logical pool distribution mechanism.

Attention: Do not configure logical pool distribution unless you have already configured it with a previous release of WebSphere Application Server. This function is deprecated and will be removed in a future version of the product.

The ORB parameter for max threads controls the total number of threads. The outqueues parameter is specified as a comma separated list of percentages that add up to 100. For example, the list 25,25,25,25 sets up 4 pools, each allocated 25% of the available ORB thread pool. The pools are indexed left to right from 0 to n-1. Each outqueue is dynamically assigned a target start time by the calculation mechanism. Target start times are assigned to outqueues in increasing order so pool 0 gets the requests with the least start time and pool n-1 gets requests with the highest start times.

LPD must be enabled (see `com.ibm.websphere.threadpool.strategy.implementation`).

Data type	Integers in comma separated list
Default	25,25,25,25
Range	Percentages in list must total 100 percent

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.statsinterval

Specifies that statistics are dumped to stdout after this interval expires, but only if requests are processed. This process keeps the mechanism from filling the log files with redundant information. These statistics are beneficial for tuning the logical pool distribution mechanism.

Attention: Do not configure logical pool distribution unless you have already configured it with a previous release of WebSphere Application Server. This function is deprecated and will be removed in a future version of the product.

LPD must be enabled (see `com.ibm.websphere.threadpool.strategy.implementation`).

Data type	Integer
Units	Milliseconds
Default	0 (off)
Range	30,000 (30 seconds) minimum

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.workqueue

Specifies the size of a new queue where incoming requests wait for dispatch. Pertains to the logical pool distribution mechanism.

Attention: Do not configure logical pool distribution unless you have already configured it with a previous release of WebSphere Application Server. This function is deprecated and will be removed in a future version of the product.

LPD must be enabled (see `com.ibm.websphere.threadpool.strategy.implementation`).

Data type	Integer
Default	96
Range	10 minimum

com.ibm.ws.orb.services.redirector.MaxOpenSocketsPerEndpoint

Specifies the maximum number of connections that the IIOp Tunnel Servlet should maintain in its connection cache for each target host or port. If the number of concurrent client requests to a single host or port exceeds the setting for this property, the IIOp Tunnel Servlet opens a temporary connection to the target server for each extra client request, and then closes the connection after it receives the reply. Connections that are opened but not used within five minutes are removed from the cache for the IIOp Tunnel Servlet.

WebSphere Application Server default	3
JDK default	Not applicable
Range	0 - largest integer recognized by Java

com.ibm.ws.orb.services.redirector.RequestTimeout

Specifies the number of seconds that the IIOp Tunnel Servlet waits for a reply from the target server on behalf of a client before timing out. If a value is not specified for this property, or is improperly specified, the `com.ibm.CORBA.RequestTimeout` property setting for the application server on which the IIOp Tunnel Servlet is installed is used as the setting for the `com.ibm.ws.orb.services.redirector.RequestTimeout` property.

The value you specify for this property should be at least as high as the highest client setting for the `com.ibm.CORBA.RequestTimeout` property, otherwise the IIOp Tunnel Servlet might timeout more quickly than the client would normally timeout while waiting for a reply. If this property is set to zero, the IIOp Tunnel Servlet does not time out.

WebSphere Application Server default	com.ibm.CORBA.RequestTimeout property setting for the application server on which the IIOPTunnelServlet is installed.
JDK default	Not applicable
Range	0 - largest integer recognized by Java

com.ibm.ws.orb.transport.useMultiHome

Specifies whether the WebSphere Application Server ORB binds to all network interfaces in the system. If true is specified, the ORB binds to all network interfaces that are available to it. If false is specified, the ORB only binds to the network interface specified for the com.ibm.CORBA.LocalHost system property.

WebSphere Application Server default	true
JDK default	true

javax.rmi.CORBA.UtilClass

Specifies the name of the Java class that WebSphere Application Server uses to implement the javax.rmi.CORBA.UtilDelegate interface.

This property supports delegation for method implementations in the javax.rmi.CORBA.Util class. The javax.rmi.CORBA.Util class provides utility methods that can be used by stubs and ties to perform common operations. The delegate is a singleton instance of a class that implements this interface and provides a replacement implementation for all of the methods of javax.rmi.CORBA.Util. To enable a delegate, provide the class name of the delegate as the value of the javax.rmi.CORBA.UtilClass system property. The default value provides support for the com.ibm.CORBA.iioptunnel.nolocalcopies property.

WebSphere Application Server default	com.ibm.ws.orb.WSUtilDelegateImpl
JDK default	None.

Client-side programming tips for the Java Object Request Broker service

This topic includes programming tips for applications that communicate with the client-side Object Request Broker (ORB) that is part of the Java ORB service.

Resolution of initial references to services

Client applications can use the ORBInitRef and ORBDefaultInitRef properties to configure the network location that the Java ORB service uses to find a service such as naming. When set, these properties are included in the parameters that are used to initialize the ORB, as illustrated in the following example:

```
org.omg.CORBA.ORB.init(java.lang.String[] args,
                    java.util.Properties props)
```

You can set these properties in client code or by command-line argument. It is possible to specify more than one service location by using multiple ORBInitRef property settings (one for each service), but only a single ORBDefaultInitRef value can be specified.

For setting in client code, these properties are com.ibm.CORBA.ORBInitRef.*service_name* and com.ibm.CORBA.ORBDefaultInitRef, respectively. For example, to specify that the naming service (NameService) is located in sample.server.com at port 2809, set the com.ibm.CORBA.ORBInitRef.NameService property to corbaloc::sample.server.com:2809/NameService.

For setting by command-line argument, these properties are -ORBInitRef and -ORBDefaultInitRef, respectively. To locate the same naming service specified previously, use the following Java command:

After these properties are set for services that the ORB supports, Java 2 Platform, Enterprise Edition (J2EE) applications can call the `resolve_initial_references` function on the ORB, as defined in the CORBA/IIOP specification, to obtain the initial reference to a given service.

Preferred API for obtaining an ORB instance

For J2EE applications, you can use either of the following approaches. However, it is strongly recommended that you use the Java Naming and Directory Interface (JNDI) approach to ensure that the same ORB instance is used throughout the client application; you avoid the unintended inconsistencies that might occur when different ORB instances are used.

JNDI approach: For J2EE applications (including enterprise beans, J2EE clients and servlets), you can obtain an ORB instance by creating a JNDI InitialContext object and looking up the ORB under the `java:comp/ORB` name, as illustrated in the following example:

```
javax.naming.Context ctx = new javax.naming.InitialContext();
org.omg.CORBA.ORB orb =
    (org.omg.CORBA.ORB)javax.rmi.PortableRemoteObject.narrow(ctx.lookup("java:comp/ORB"),
                                                            org.omg.CORBA.ORB.class);
```

The ORB instance obtained using JNDI is a singleton object, shared by all the J2EE components that are running in the same Java virtual machine process.

CORBA approach: Because thin-client applications do not run in a J2EE container, they cannot use JNDI interfaces to look up the ORB. In this case, you can obtain an ORB instance by using CORBA programming interfaces, as follows:

```
java.util.Properties props = new java.util.Properties();
java.lang.String[] args = new java.lang.String[0];
org.omg.CORBA.ORB orb = org.omg.CORBA.ORB.init(args, props);
```

In contrast to the JNDI approach, the CORBA specification requires that a new ORB instance be created each time the `ORB.init` method is called. If necessary to change the ORB default settings, you can add ORB property settings to the Properties object that is passed in the `ORB.init` method call.

The use of the `com.ibm.ejs.oa.EJSORB.getORBInstance` method, supported in previous releases of this product is deprecated.

API restrictions with sharing an ORB instance among J2EE application components

For performance reasons, it often makes sense to share a single ORB instance among components in a J2EE application. As required by the J2EE Specification, Version 1.3, all Web and EJB containers provide an ORB instance in the JNDI namespace as `java:comp/ORB`. Each container can share this instance among application components but is not required to. For proper isolation between application components, application code must comply with the following restrictions:

- Do not call the ORB shutdown or destroy methods
- Do not call `org.omg.CORBA_2_3.ORB` methods `register_value_factory`, or `unregister_value_factory`

In addition, do not share an ORB instance among application components in different J2EE applications.

Required use of `rmic` and `idlj` that ship with the IBM Developer Kit

The Java Runtime Environment (JRE) used by this product includes the `rmic` and `idlj` tools. You use the tools to generate Java language bindings for the CORBA/IIOP protocol.

During product installation, the tools are installed in the *app_server_root/java/ibm_bin* directory. Versions of these tools included with Java development kits in the *\$JAVA_HOME/bin* directory other than the IBM Developer Kit installed with this product are incompatible with this product.

When you install this product, the *app_server_root/java/ibm_bin* directory is included in the *\$PATH* search order to enable use of the *rmic* and *idlj* scripts provided by IBM. Because the scripts are in the *app_server_root/java/ibm_bin* directory instead of the JRE standard *app_server_root/java/bin* directory, it is unlikely that you can overwrite them when applying maintenance to a JRE not provided by IBM.

In addition to the *rmic* and *idlj* tools, the JRE also includes Interface Definition Language (IDL) files. The files are based on those defined by the Object Management Group (OMG) and can be used by applications that need an IDL definition of selected ORB interfaces. The files are placed in the *app_server_root/java/ibm_lib* directory.

Before using either the *rmic* or *idlj* tool, ensure that the *app_server_root/java/ibm_bin* directory is included in the proper *PATH* variable search order in the environment. If your application uses IDL files in the *app_server_root/java/ibm_lib* directory, also ensure that the directory is included in the *PATH* variable.

Character code set conversion support for the Java Object Request Broker service

The CORBA/IIOP specification defines a framework for negotiation and conversion of character code sets used by the Java Object Request Broker (ORB) service.

This product supports the framework and provides the following system properties for modifying the default settings:

com.ibm.CORBA.ORBCharEncoding

Specifies the name of the native code set that the ORB uses for character data (referred to as *NCS-C* in the CORBA/IIOP specification). By default, the ORB uses UTF8. Valid code set values for this property are shown in the table that follows this list; values that are valid only for *ORBWCharDefault* are indicated.

com.ibm.CORBA.ORBWCharDefault

Specifies the default code set that the ORB uses for transmission of wide character data when no code set for wide character data is found in the tagged component in the Interoperable Object Reference (IOR) or in the GIOP service context. If no code set for wide character data is found and this property is not set, the ORB raises an exception, as specified in the CORBA specification. No default value is set for this property. The only valid code set values for this property are UCS2 or UTF16.

Note: If you are using a distributed application server with WebSphere Application Server for z/OS, you must set this property on the distributed client to UCS2 or you might experience an exception.

The CORBA code set negotiation and conversion framework specifies the use of code set registry IDs as defined in the Open Software Foundation (OSF) code set registry. The ORB translates the Java *file.encoding* names shown in the following table to the corresponding OSF registry IDs. These IDs are then used by the ORB in the IOR Code set tagged component and GIOP code set service context as specified in the CORBA and IIOP specification.

Java name	OSF registry ID	Comments
ASCII	0x00010020	
ISO8859_1	0x00010001	
ISO8859_2	0x00010002	
ISO8859_3	0x00010003	

Java name	OSF registry ID	Comments
ISO8859_4	0x00010004	
ISO8859_5	0x00010005	
ISO8859_6	0x00010006	
ISO8859_7	0x00010007	
ISO8859_8	0x00010008

ORB services advanced settings on the z/OS platform

Use this topic to support Object Request Broker (ORB) service advanced settings. This support includes ORB listener keep alive, ORB Secure Sockets Layer (SSL) listener keep alive, control threads, and workload profile.

To view this administrative console page, click **Servers > Application servers > server_name > Container services > ORB service > z/OS additional settings**.

ORB listener keep alive

Defines the value in seconds provided to TCP/IP on the SOCK_TCP_KEEPALIVE option for the Internet Inter-ORB Protocol (IIOP) listener.

This option verifies that idle sessions are still valid by polling the client TCP/IP stack. If the client goes away without notifying the server, the session is still active on the server side. Use this property to clean up these unnecessary sessions. If the client does not respond, the session closes. The default is 0 (zero). If the property is not set, the TCP/IP option is not set. Setting the SOCK_TCP_KEEPALIVE option generates network traffic on idle sessions, which can cause problems.

Data type	Integer
Range	0 - 2147460

ORB SSL listener keep alive

This property defines the value in seconds provided to TCP/IP on the SOCK_TCP_KEEPALIVE option for the SSL IIOp listener.

This option verifies if idle sessions are still valid by polling the client TCP/IP stack. If the client goes away without notifying the server, the session is still active on the server side. Use this option to clean up these unnecessary sessions. If the client does not respond, the session closes. The default is 0 (zero). If the property is not set, the TCP/IP option is not set. Setting the SOCK_TCP_KEEPALIVE option generates network traffic on idle sessions, which can be undesirable.

Data type	Integer
Range	0 - 2147460

Workload manager timeout

Specifies the maximum time in seconds that IIOp requests are queued and dispatched to a servant process.

Data type	Integer
Range	0 - 2147040
Default	300
Disable workload manager queue timeout	0

Object request broker component troubleshooting tips

The following topics might help you diagnose problems with the Object request broker (ORB) component.

Enabling tracing for the Object Request Broker component

The object request broker (ORB) service is one of the WebSphere Application Server run time services. Tracing messages that are sent and received by the ORB is a useful starting point for troubleshooting the ORB service. You can selectively enable or disable tracing of ORB messages for each server in a WebSphere Application Server installation, and for each application client.

For instructions on how to set trace controls so that tracing occurs for the ORB subcomponent, see [Setting trace controls for IBM service](#).

Log files and messages associated with Object Request Broker

For a summary of how messages get routed in WebSphere Application Server, see [Message routing](#).

Java packages containing the Object Request Broker service

The ORB service resides in the following Java packages:

- com.ibm.com.CORBA.*
- com.ibm.rmi.*
- com.ibm.ws.orb.*
- com.ibm.ws.orbimpl.*
- com.ibm.ws390.orb.*
- org.omg.CORBA.*
- javax.rmi.CORBA.*
- com.ibm.ws390.ziop.*
- com.ibm.ws390.channel.ziop.*

JAR files that contain the previously mentioned packages include:

- *java_app_server_root/jre/lib/ext/ibmorb.jar*
- *java_app_server_root/jre/lib/ext/iwsorbutil.jar*
- *app_server_root/lib/iwsorb.jar*
- *app_server_root/lib/runtimews390.jar*
- *app_server_root/lib/bootstrap.jar*

Tools used with Object Request Broker

The tools used to compile Java remote interfaces to generate language bindings used by the ORB at runtime reside in the following APIs:

- *com.ibm.tools.rmic.**
- *com.ibm.idl.**

The JAR file that contains these APIs is *app_server_root/java/lib/ibmtools.jar*.

Object Request Broker properties

The ORB service requires a number of ORB properties for correct operation. It is not necessary for most users to modify these properties, and only the system administrator should modify them when required. Consult IBM Support personnel for assistance. The properties reside in the *orb.properties* file, located at *app_server_root/java/jre/lib/orb.properties*.

If none of these steps fixes your problem, check to see if the problem has been identified and documented by looking at the available online support (hints and tips, technotes, and fixes).

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Chapter 19. Transactions

Using the transaction service

These topics provide information about using transactions with WebSphere applications

WebSphere applications can use transactions to coordinate multiple updates to resources as atomic units (as indivisible units of work) such that all or none of the updates are made permanent.

In WebSphere Application Server, transactions are handled by three main components:

- A transaction manager. The transaction manager supports the enlistment of recoverable XAResources and ensures that each such resource is driven to a consistent outcome either at the end of a transaction or after a failure and restart of the application server.

In addition, WebSphere Application Server for z/OS supports the coordination of resource managers through RRS (z/OS resource recovery services).

- A container in which the J2EE application runs. The container manages the enlistment of XAResources on behalf of the application when the application performs updates to transactional resource managers (for example, databases). Optionally, the container can control the demarcation of transactions for enterprise beans configured for container-managed transactions.
- An application programming interface (UserTransaction) that is available to bean-managed enterprise beans and servlets. This allows such application components to control the demarcation of their own transactions.

For more information about using transactions with WebSphere applications, see the following topics:

- Using the ActivitySession service

Transaction support in WebSphere Application Server

This topic provides conceptual information about the support for transactions provided by the Transaction Service of WebSphere Application Server.

A transaction is unit of activity within which multiple updates to resources can be made atomic (as an indivisible unit of work) such that all or none of the updates are made permanent. For example, multiple SQL statements to a relational database are committed atomically by the database during the processing of an SQL COMMIT statement. In this case, the transaction is contained entirely within the database manager and can be thought of as a *resource manager local transaction (RMLT)*. In some contexts, a transaction is referred to as a *logical unit of work (LUW)*. If a transaction involves multiple resource

managers, for example multiple database managers, then an external transaction manager is required to coordinate the individual resource managers. A transaction that spans multiple resource managers are referred to as a *global transaction*. WebSphere Application Server is a transaction manager that can coordinate global transactions, be a participant in a received global transaction and also provides an environment in which resource manager local transactions can run.

The way that applications use transactions depends on the type of application component, as follows:

- A session bean can either use container-managed transactions (where the bean delegates management of transactions to the container) or bean-managed transactions (component-managed transactions where the bean manages transactions itself).
- Entity beans use container-managed transactions.
- Web components (servlets) and application client components use component-managed transactions.

WebSphere Application Server is a transaction manager that supports the coordination of resource managers through their XAResource interface and participates in distributed global transactions with transaction managers that support the CORBA Object Transaction Service (OTS) protocol or Web Service Atomic Transaction (WS-AtomicTransaction) protocol. WebSphere Application Server also participates in transactions imported through J2EE Connector 1.5 resource adapters. You can also configure WebSphere applications to interact with databases, JMS queues, and JCA connectors through their *local transaction* support, when you do not require distributed transaction coordination.

In addition to supporting the coordination of XAResource-based resource managers, WebSphere Application Server for z/OS supports the coordination of resource managers through RRS (z/OS resource recovery services). RRS-compliant resource managers include DB2, WebSphere MQ, IMS, and CICS. IBM WebSphere Application Server for z/OS is capable of coordinating a mix of RRSTransactional resource managers and XA capable resource managers under the same global transaction.

Resource managers that offer transaction support can be categorized into those that support two-phase coordination (by offering an XAResource interface or by supporting RRS) and those that support only one-phase coordination (for example through a LocalTransaction interface). The WebSphere Application Server transaction support provides coordination, within a transaction, for any number of two-phase capable resource managers. It also enables a single one-phase capable resource manager to be used within a transaction in the absence of any other resource managers, although a WebSphere transaction is not necessary in this case.

Under normal circumstances you cannot mix one-phase commit capable resources and two-phase commit capable resources in the same global transaction, because one-phase commit resources cannot support the prepare phase of two-phase commit. There are some special circumstances where it is possible to include mixed-capability resources in the same global transaction:

- In scenarios where there is only a single one-phase commit resource provider that participates in the transaction and where all the two-phase commit resource-providers that participate in the transaction are used in a read-only fashion. In this case, the two-phase commit resources all vote read-only during the prepare phase of two-phase commit. Because the one-phase commit resource provider is the only provider to actually perform any updates, the one-phase commit resource does not need to be prepared.
- In scenarios where there is only a single one-phase commit resource provider that participates in the transaction with one or more two-phase commit resource providers and where *last participant support* is enabled. Last participant support enables the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction. For more information about last participant support, see Using one-phase and two-phase commit resources in the same transaction.

The ActivitySession service provides an alternative unit-of-work (UOW) scope to that provided by global transaction contexts. It is a distributed context that can be used to coordinate multiple one-phase resource managers. The WebSphere EJB container and deployment tooling support ActivitySessions as an

extension to the J2EE programming model. EJBs can be deployed with lifecycles that are influenced by ActivitySession context, as an alternative to transaction context. An application can then interact with a resource manager for the period of a client-scoped ActivitySession, rather than only the duration of an EJB method, and have the resource manager's local transaction outcome directed by the ActivitySession. For more information about ActivitySessions, see Using the ActivitySession service.

You can use transaction classes to classify client workload for workload management. The workload is different WebSphere transactions targeted to separate servant regions, each with goals defined by appropriate service classes. Each transaction is dispatched in its own WLM enclave in a servant region process, and is managed according to the goals of its service class. The server controller, which workload management views as a queue manager, uses the enclave associated with a client request to manage the priority of the work. If the work has a high priority, workload management can direct the work to a high-priority servant in the server. If the work has a low priority, workload management can direct the work to a low-priority servant. The effect is to partition the work according to priority within the same server.

Resource manager local transaction (RMLT)

A resource manager local transaction (RMLT) is a resource manager's view of a local transaction; that is, it represents a unit of recovery on a single connection that is managed by the resource manager.

Resource managers include:

- Enterprise Information Systems that are accessed through a resource adapter, as described in the J2EE Connector Architecture 1.0.
- Relational databases that are accessed through a JDBC datasource.
- JMS queue and topic destinations.

Resource managers offer specific interfaces to enable control of their RMLTs. J2EE connector resource adapters that include support for local transactions provide a LocalTransaction interface to enable applications to request that the resource adapter commit or rollback RMLTs. JDBC datasources provide a Connection interface for the same purpose.

The boundary at which all RMLTs must be complete is defined in WebSphere Application Server by a local transaction containment (LTC).

Global transactions

If an application uses two or more resources, then an external transaction manager is needed to coordinate the updates to both resource managers in a *global transaction*.

Global transaction support is available to web and enterprise bean J2EE components and, with some limitation, to application client components. Enterprise bean components can be subdivided into beans that exploit container-managed transactions (CMT) or bean-managed transactions (BMT).

BMT enterprise beans, application client components, and web components can use the Java Transaction API (JTA) UserTransaction interface to define the demarcation of a global transaction. The UserTransaction interface can be obtained by a JNDI lookup of `java:comp/UserTransaction` or from the SessionContext object using the `getUserTransaction` method..

The UserTransaction is not available to the following components:

- CMT enterprise beans. Any attempt by such beans to obtain the interface results in an exception in accordance with the EJB specification.

Ensure that programs that perform a JNDI lookup of the UserTransaction interface, use an InitialContext that resolves to a local implementation of the interface. Also ensure that such programs use a JNDI location appropriate for the EJB version.

Before the EJB 1.1 specification, the JNDI location of the UserTransaction interface was not specified. Each EJB container implementor defined it in an implementation-specific manner. Earlier versions of

WebSphere Application Server, up to and including Version 3.5.x (without EJB 1.1), bind the UserTransaction interface to a JNDI location of `jta/usertransaction`. WebSphere Application Server Version 4, and later releases, bind the UserTransaction interface at the location defined by EJB 1.1, which is `java:comp/UserTransaction`. WebSphere Application Server, from Version 5 no longer provides the `jta/usertransaction` binding within Web and EJB containers to applications at a J2EE level of 1.3 or later. For example, from EJB 2.0 applications can use only the `java:comp/UserTransaction` location.

A web component or enterprise bean (CMT or BMT) can get the ExtendedJTATransaction interface through a lookup of `java:comp/websphere/ExtendedJTATransaction`. This interface provides access to the transaction identity and a mechanism to receive notification of transaction completion.

Local transaction containment (LTC)

A *local transaction containment (LTC)* is used to define the application server behavior in an unspecified transaction context.

(Unspecified transaction context is defined in the Enterprise JavaBeans 2.0 (or later) specification; for example, at <http://java.sun.com/products/ejb/2.0.html>.)

A LTC is a bounded unit-of-work scope within which zero, one, or more resource manager local transactions (RMLTs) can be accessed. The LTC defines the boundary at which all RMLTs must be complete; any incomplete RMLTs are resolved, according to policy, by the container. An LTC is local to a bean instance; it is not shared across beans even if those beans are managed by the same container. LTCs are started by the container before dispatching a method on a J2EE component (such as an enterprise bean or servlet) whenever the dispatch occurs in the absence of a global transaction context. LTCs are completed by the container depending on the application-configured LTC boundary; for example at the end of the method dispatch. There is no programmatic interface to the LTC support; rather LTCs are managed exclusively by the container and configured by the application deployer through transaction attributes in the application deployment descriptor.

A local transaction containment cannot exist concurrently with a global transaction. If application component dispatch occurs in the absence of a global transaction, the container always establishes an LTC. The only exceptions to this behavior is when an application component dispatch occurs without container interposition; for example, for a stateless session bean `create`.

A local transaction containment can be scoped to an ActivitySession context that lives longer than the enterprise bean method in which it is started, as described in ActivitySessions and transaction contexts.

Local and global transaction considerations

Applications use resources, such as JDBC data sources or connection factories, that are configured through the Resources view of the WebSphere Application Server Administrative Console. How these resources participate in a global transaction depends on the underlying transaction support of the resource provider. For example, most JDBC providers can provide either XA or non-XA versions of a data source. A non-XA data source can support only resource manager local transactions (RMLTs), but an XA data source can support two-phase commit coordination, as well as local transactions.

Additionally, some JDBC Providers support the use of z/OS Resource Recovery Service (RRS) to coordinate transaction processing. This type of JDBC Provider is RRSTransactional. When RRS is used, both local and global transactions are supported.

If an application uses two or more resource providers that support only RMLTs, then atomicity cannot be assured because of the one-phase nature of these resources. To ensure atomic behavior, the application should use resources that support XA coordination or RRS coordination and should access them within a global transaction.

If an application uses only one RMLT, the atomic behavior can be guaranteed by the resource manager, which can be accessed under a local transaction containment context.

An application can also access a single resource manager under a global transaction context, even if that resource manager does not support the XA coordination. An application can do this, because WebSphere Application Server performs an “only resource optimization” and interacts with the resource manager under a RMLT. Within a global transaction context, any attempt to use more than one resource provider that supports only RMLTs causes the global transaction to be rolled back.

At any moment, an instance of an enterprise bean can have work outstanding in either a global transaction context or a local transaction containment context, but never both. An instance of an enterprise bean can change from running under one type of context to the other (in either direction), if all outstanding work in the original context is complete. Any violation of this principle causes an exception to be thrown when the enterprise bean tries to start the new context.

Client support for transactions

This topic describes the support of application clients for the use of transactions.

Application clients running in a J2EE client container can explicitly demarcate transaction boundaries as described in Using component-managed transactions. Application clients cannot perform, directly within the client container, transactional work in the context of any global transaction that they start, because the client container is not a recoverable process.

Application clients can make requests to remote objects, such as enterprise beans, within the context of a client-initiated transaction. Any transactional work performed in a remote, recoverable server process is coordinated as part of the client-initiated transaction. The transaction coordinator is created on the first server process to which the client-initiated transaction is propagated.

A client can begin a transaction then, for example, access a JDBC data source directly in the client process. In such cases, any work performed through the JDBC provider is not coordinated as part of the global transaction. Instead, the work runs under a resource manager local transaction. The client container process is non-recoverable and contains no transaction coordinator with which a resource manager can be enlisted.

A client can begin a transaction then call a remote application component, such as an enterprise bean. In such cases, the client-initiated transaction context is implicitly propagated to the remote application server where a transaction coordinator is created. Any resource managers accessed on the recoverable application server (or any other application server hosting application components invoked by the client) are enlisted in the global transaction.

Client application components need to be aware that locally-accessed resource managers are not coordinated by client-initiated transactions. Client applications acknowledge this through a deployment option that enables access to the UserTransaction interface in the client container. By default, access to the UserTransaction interface in the client container is not enabled. To enable UserTransaction demarcation for an application client component, set the **Allow JTA Demarcation** extension property in the client deployment descriptor. For information about editing the client deployment descriptor, refer to the Application Server Toolkit information, in the navigation pane of this infocenter.

Transactional high availability

The high availability of the transaction service enables any server in a cluster to recover the transactional work for any other server in the same cluster. This facility forms part of the overall WebSphere Application Server high availability (HA) strategy.

This feature is in addition to the support for Peer restart and recovery, which enables you to restart on a peer system in the sysplex.

As a vital part of providing recovery for transactions, the transaction service logs information about active transactional work in the *transaction recovery log*. The transaction recovery log stores the information in a persistent form, which means that any transactional work in progress at the time of a server failure can be

resolved when the server is restarted. This activity is known as *transaction recovery processing*. In addition to completing outstanding transactions, this processing also ensures that any locks held in the associated resource managers are released.

Peer recovery processing

The standard recovery process that is performed when an application server restarts is for the server to retrieve and process the logged transaction information, recover transactional work and complete in-doubt transactions. Completion of the transactional work (and hence the release of any database locks held by the transactions) takes place after the server successfully restarts and processes its transaction logs. If the server is slow to recover or requires manual intervention, the transactional work cannot be completed and access to associated databases is disrupted.

To minimize such disruption to transactional work and the associated databases, WebSphere Application Server provides a high availability strategy known as *transaction peer recovery*.

Peer recovery is provided within a server cluster. A peer server (another cluster member) can process the recovery logs of a failed server while the peer continues to manage its own transactional workload. You do not have to wait for the failed server to restart, or start a new application server specifically to recover the failed server.

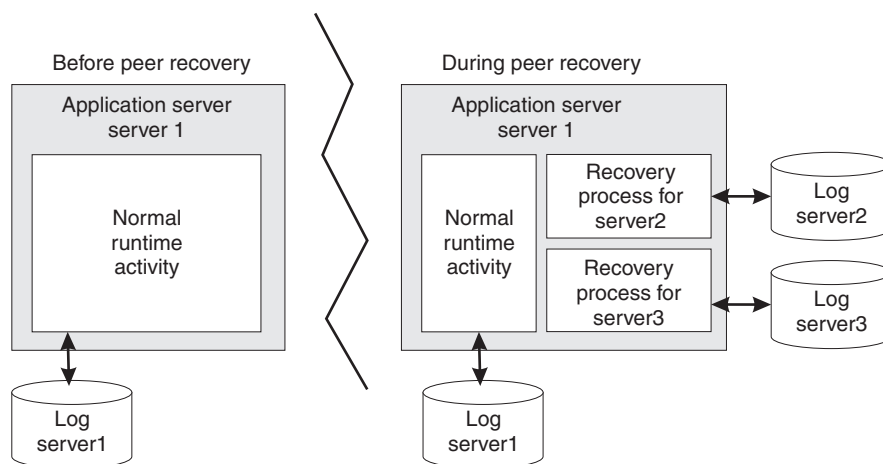

Figure 20. Peer recovery

The peer recovery process is the logical equivalent to restarting the failed server, but does not constitute a complete restart of the failed server within the peer server. The peer recovery process provides an opportunity to complete outstanding work; it cannot start new work beyond recovery processing. No forward processing is possible for the failed server.

Peer recovery moves the high availability requirements away from individual servers and onto the server cluster. After such failures, the management system of the cluster dispatches new work onto the remaining servers; the only difference is the potential drop in overall system throughput. If a server fails, all that is required is to complete work that was active on the failed server and redirect requests to an alternate server.

By default, peer recovery is disabled until you enable failover of transaction log recovery in the cluster configuration, and restart the cluster members. After you enable transaction log recovery, WebSphere Application Server supports two styles for the initiation of transaction peer recovery: automated and manual. You determine which style is more appropriate, based on your deployment considerations, and

specify that style by configuring the appropriate high availability policy. This high availability policy is referred to elsewhere in these topics as the *policy for the transaction service*.

Automated peer recovery

This style is the default for peer recovery initiation. If an application server fails, WebSphere Application Server automatically selects a server to perform peer recovery processing on its behalf, and passes recovery back to the failed server when it restarts. To use this model, all you have to do is enable transaction log recovery and configure the recovery log location for each cluster member.

Manual peer recovery

You must explicitly configure this style of peer recovery. If an application server fails, you use the administrative console to select a server to perform recovery processing on its behalf.

Peer recovery example

The following diagrams illustrate the peer recovery process that takes place if a single server fails. Figure 2 shows three stable servers running in a WebSphere Application Server cluster. The workload is balanced between these servers, which results in locks held by the back-end database on behalf of each server.

Figure 21. Server cluster up and running, just before server failure

Figure 3 shows the state of the system after server 1 fails without clearing locks from the database. Servers 2 and 3 can run their existing transactions to completion and release existing locks in the back-end database, but further access might be impaired because of the locks still held on behalf of server 1. In practice, some level of access by servers 2 and 3 is still possible, assuming appropriately configured lock granularity, but for this example assume that servers 2 and 3 attempt to access locked records and become blocked.

Figure 22. Server 1 fails. Servers 2 and 3 become blocked as a result.

Figure 4 shows a peer recovery process for server 1 running inside server 3. The transaction service portion of the recovery process retrieves the information that is persisted by server 1, and uses that information to complete any in-doubt transactions. In this figure, the peer recovery process is partially complete as some locks are still held by the database on behalf of server 1.

Figure 23. Peer recovery process started in server 3

Figure 5 shows the state of the server cluster when the peer recovery process is complete. The system is in a stable state with just two servers, between which the workload is balanced. Server 1 can be restarted, and will have no recovery processing of its own to perform.

Figure 24. Server cluster stable again with just two servers: server 2 and server 3.

Deployment considerations for transactional high availability:

Before you use the high availability (HA) function, you must consider deployment issues such as your file system type, or where you plan to store the transaction recovery logs. In particular, your file system type can have important consequences for your recovery configuration.

Common configuration

Transaction peer recovery requires a common configuration of the resource providers between the participating server members to perform peer recovery between servers. Therefore, peer recovery processing can only take place between members of the same server cluster. Although a cluster can contain servers that are at different versions of WebSphere Application Server, peer recovery can only be performed between servers in the cluster that are at Version 6 or later.

Physical storage

For application servers to perform transaction peer recovery for each other, they must be able to access the transaction recovery logs of all the other members in the cluster. Ensure that the log files are stored on a medium that is accessible by all members of the cluster. This medium, and access to it, for example through a local area network (LAN), must support the file-based force operation that is used by the recovery log service to force data to disk. After the force operation is complete, information must be persistently stored on physical disk media.

For example, you can use IBM Network attached storage (NAS) (<http://www.ibm.com/servers/storage/nas/index.html>) mounted on each node, and shared SCSI drives, but not simple network share. All nodes must have read and write access to the recovery logs.

Figure 25. Recovery logs on NAS storage are available to all servers

In addition, configure the mechanism by which the remote log files are accessed, to exploit any fault tolerance in the underlying file system. For example, by using the Network File System (NFS) and hard mounting the remote directory containing the log files using the `-o hard` option of the NFS mount command, the NFS client will retry a failed operation until the NFS server becomes available again.

Two types of potential server failure exist: software failure and hardware failure. Software failures generally do not affect other application servers directly. Even servers on the same physical hardware can perform peer recovery processing. If a hardware failure occurs, all the servers that are deployed on the failed hardware become unavailable. Servers on other hardware are required to handle peer recovery processing. Any HA configuration requires that servers are deployed across multiple and discrete hardware systems.

File system

The file system type is an important deployment consideration as it is the main factor in deciding whether to use automated or manual peer recovery. For more information, see “How to choose between automated and manual transaction peer recovery.”

How to choose between automated and manual transaction peer recovery:

Your type of file system is the dominant factor in deciding which kind of transaction peer recovery to use. Different file systems have different behaviors, and the file locking behavior in particular is important when choosing between automated and manual peer recovery.

WebSphere Application Server high availability (HA) support uses a heartbeat mechanism to determine whether servers are still running. Servers are considered failed if they stop responding to heartbeat requests. Some scenarios, such as system overloading and network partitioning (explained elsewhere in this topic), can cause servers to stop responding to heartbeats, even though the servers are still running. WebSphere Application Server uses file locking technology to prevent such events from causing concurrent access to transaction recovery logs, because access to a recovery log by more than one server can lead to loss of data integrity.

However, not all file systems provide the necessary file locking semantics, specifically that file locks are released when a server fails. For example, Network File System Version 4 (NFSv4) provides this release behavior, whereas Network File System Version 3 (NFSv3) does not.

NFSv4 releases locks held on behalf of a host in case that host fails. Peer recovery can occur automatically without the need to restart the failed hardware. Therefore, this version of NFS is better suited for use with automated peer recovery.

NFSv3 holds file locks on behalf of a failed host until that host can restart. In this context, the host is the physical machine running the application server that requested the lock and it is the restart of the host, not the application server, that eventually triggers the locks to release.

To illustrate file locking on NFSv3, consider the behavior when a cluster member fails:

1. Server H is running on host H and holds an exclusive file lock for its own recovery log files.
2. Server P is running on host P and holds an exclusive file lock for its own recovery log files.
3. Host H fails, taking server H with it. The NFS lock manager on the file server holds the locks that are granted to server H on its behalf.
4. A peer recovery event is triggered in server P for server H by WebSphere Application Server.
5. Server P attempts to gain an exclusive file lock for this peer recovery log, but is unable to do so as it is held on behalf of server H. The peer recovery process is blocked.
6. At an unspecified time, host H is restarted. The locks held on its behalf are released.
7. The peer recovery process in server P is unblocked and granted the exclusive file locks that are needed to perform peer recovery.
8. Peer recovery takes place in server P for server H.
9. Server H is restarted.
10. If peer recovery is still in progress in server P, the recovery is halted.
11. Server P releases the exclusive lock on the recovery logs and returns ownership of the recovery logs back to server H.
12. Server H obtains the exclusive lock and can now perform standard transaction logging.

Because of this behavior, on NFSv3 you must disable file locking to use automated peer recovery. Disabling file locking can lead to concurrent access to recovery logs so it is vital that you protect your system from system overloading and network partitioning first. Alternatively, you can configure manual peer recovery, where you prevent concurrent access by manually triggering peer recovery processing only for servers that have actually failed.

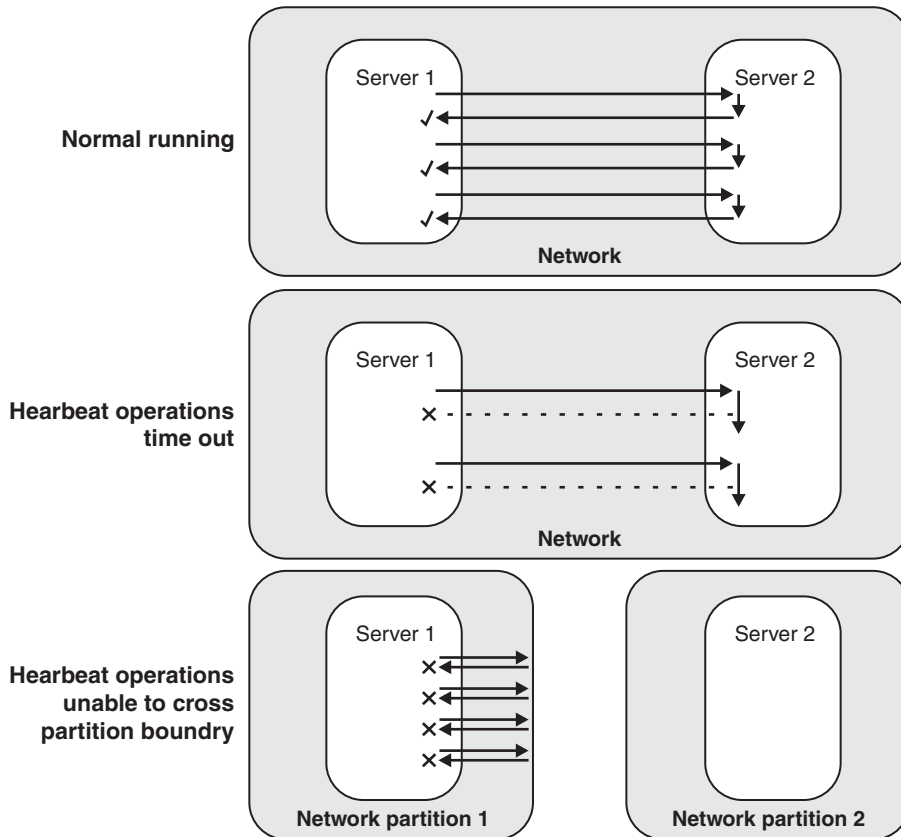

System overloading

System overloading occurs when a machine becomes very heavily loaded such that response times are extremely poor and requests begin to time out. Several potential causes exist for such overloading, including:

- The server is underpowered and cannot handle the workload.
- The server received a temporary surge of requests.
- Insufficient physical memory is available. As a result, the operating system is too busy paging to give the application server the required CPU time.

Network partitioning

Network partitioning occurs when a communications failure in a network results in two smaller networks that are independent and cannot contact each other.

During normal running, two servers on the network exchange heartbeats. During system overloading, heartbeat operations time out, giving the appearance of a server failure. After network partitioning, each server is in a separate network and heartbeats cannot pass between them, also giving the appearance of a server failure.

Figure 26. Heartbeats in a system running normally, compared to heartbeats after the apparent server failures of system overloading and network partitioning

High availability policies for the transaction service:

WebSphere Application Server provides integrated high availability (HA) support in which system subcomponents, such as the transaction service, are made highly available. An HA policy provides the logic that governs the manner in which each WebSphere Application Server HA component behaves within the overall HA framework. In the case of the transaction service, the transaction HA policy provides the logic to determine which servers own a recovery log at any time.

Typically, transaction policies assign ownership of a recovery log to the server that originally created it (the home server) and that server can then use the recovery log for both recovery and normal transactional activity. In the event that the home server is unavailable or fails, ownership can pass to a peer server to perform recovery processing.

Conceptually, a policy can be thought of as consisting of two key components, a policy type and a policy configuration.

Policy type

The policy type determines whether peer recovery initiation is manual or automated. The policy essentially provides the logic for determining updated recovery log ownership in the event of a server failure. The

following WebSphere Application Server policy types are used for transaction peer recovery (other HA policy types exist, but are not used by the transaction service):

Static Ownership of the recovery log is defined in the WebSphere Application Server configuration. At run time, the static policy assigns ownership accordingly. Any changes to ownership require a change to the static configuration and therefore this policy type is used for manually initiated peer recovery.

One-of-N

Ownership of the recovery log is determined dynamically by the WebSphere Application Server HA framework and assigned to exactly one of the N cluster members. This policy type is used for automated peer recovery.

Transaction compensation and business activity support

A *business activity* is a collection of tasks that are linked together so that they have an agreed outcome. Unlike atomic transactions, activities such as sending an e-mail can be difficult or impossible to roll back atomically, and therefore require a compensation process in the event of an error. The WebSphere Application Server business activity support provides this compensation ability through *business activity scopes*.

When to use business activity support

Use the business activity support when you have an application that requires compensation. An application requires compensation if its operations cannot be atomically rolled back. Typically, this scenario is due to one of the following reasons:

- The application uses multiple non-extended-architecture (XA) resources.
- The application uses more than one atomic transaction, for example, enterprise beans that have **Requires new** as the setting for the **Transaction** field in the container transaction deployment descriptor.
- The application does not run under a global transaction.

The following diagram shows a simple Web service application that uses the business activity support. The Retailer, Warehouse and Manufacturing services are running in non-WebSphere Application Server environments. The Retailer service calls the Supplier service, running on WebSphere Application Server, which delegates tasks to the Warehouse and Manufacturing services. The implementation of the Supplier service contains a stateless session bean, which calls other stateless session beans that are associated with the Warehouse and Manufacturing services, and that perform compensatable work. These other session beans each have a *compensation handler*, a piece of logic that is associated with an application component at run time, and performs compensation activity such as resending an e-mail.

Application design considerations

Business activity contexts are propagated with application messages, and can therefore be distributed between application components that are not co-located in the same server. Unlike atomic transaction contexts, business activity contexts are propagated on both synchronous (blocking) call-response messages and asynchronous one-way messages. An application component that runs under a business activity scope is responsible for ensuring that any asynchronous work it initiates is complete before the component's own processing is complete. An application that initiates asynchronous work using a fire-and-forget message pattern must not use business activity scopes, because such applications have no means of detecting whether this asynchronous processing has completed.

Only enterprise beans that have container-managed transactions can use the business activity functionality. Enterprise beans that exploit business activity scopes can offer Web service interfaces, but can also offer standard enterprise bean local or remote Java interfaces. Business activity context is propagated in Web service messages using a standard, interoperable Web Services Business Activity CoordinationContext element. WebSphere Application Server can also propagate business activity context on RMI calls to enterprise beans when Web services are not being used, but this form of the context is not interoperable with non-WebSphere Application Server environments. You might want to use this homogeneous scenario if you require compensation for an application that is internal to your business. If you want to use business activity compensation in a heterogeneous environment, expose your application components as Web services.

Business activity contexts can be propagated across firewalls and outside the WebSphere Application Server domain. The topology that you use to achieve this propagation can affect the high availability and affinity behavior of the business activity transaction.

Application development and deployment considerations

WebSphere Application Server provides a programming model for creating business activity scopes, and for associating compensation handlers with those business activity scopes. WebSphere Application Server also provides an application programming interface to specify compensation data, and check or alter the status of a business activity. To use the business activity support you must set certain application deployment descriptors appropriately, provide a compensation handler class if required, and enable business activity support on any servers that run the application.

Note: Applications can exploit the business activity support only if you deploy them to a WebSphere Application Server Version 6.1 server. Applications cannot use the business activity support if you deploy them to a cluster that includes WebSphere Application Server Version 6.0.x servers.

Business activity scopes

The scope of a business activity is that of a core WebSphere Application Server unit of work: a global transaction, an activity session, or local transaction containment (LTC). A business activity scope is not a new unit of work (UOW); it is an attribute of an existing core UOW. Therefore, a one-to-one relationship exists between a business activity scope and a UOW.

Any core UOW can have a business activity scope associated with it. If a component running under a UOW that is associated with a business activity scope calls another component, that request propagates the business activity scope; any work done by the new component is associated with the same business activity scope as the calling component. The called component can create a new UOW, for example if an enterprise bean has a **Transaction** setting of **Requires new**, or runs under the same UOW as the calling component. If a new UOW is started then a new business activity scope is created and associated with the new UOW. The newly created business activity scope is a child of the business activity scope associated with the calling UOW. In the following diagram, EJB1a running under UOW1 calls two components: EJB1b that also runs under UOW1, and EJB2 that creates a new UOW, UOW2. The enterprise bean EJB1b, calls another enterprise bean, EJB3, which creates another new UOW, UOW3. Because each new UOW is created by a calling component whose UOW already has an association with business activity scope BAScope1, the newly created UOWs are associated with new inner business activity scopes, BAScope2 and BAScope3.

Inner business activity scopes must complete before the outer business activity scope completes. Inner business activity scopes, for example BAScope2, have an association with the outer business activity scope, in this case BAScope1. Each business activity scope is directed to close if its associated UOW completes successfully, or to compensate if its associated UOW fails. If BAScope2 completes successfully, any active compensation handlers that are owned by BAScope2 are moved to BAScope1, and are directed in the same way as the completion direction of BAScope1: either compensate or close. If BAScope2 fails, the active compensation handlers are compensated automatically, and nothing is moved to the outer BAScope1. When an inner business activity scope fails, as a result of its associated UOW failing, an application server exception is thrown to the calling application component, running in the outer UOW.

For example, if the inner UOW fails it might throw a `TransactionRolledBackException` exception. If the calling application can handle the exception, for example by retrying the called component or by calling another component, then the calling UOW, and its associated business activity scope, can complete successfully even though the inner business activity scope failed. If the application design requires the calling UOW to fail, and for its associated business activity scope to be compensated, then the calling application component must cause its UOW to fail, for example by allowing any system exception from the UOW that failed to be handled by its container.

When the outer business activity scope completes, its success or failure determines the completion direction (close or compensate) of any active compensation handlers that are owned by the outer business activity scope, including those promoted by the successful completion of inner business activity scopes. If the outer business activity scope completes successfully, it drives all active compensation handlers to close. If the outer business activity scope fails, it drives all active compensation handlers to compensate.

This compensation behavior is summarized in the following table.

Table 55. Compensation behavior for a single business activity scope

Inner business activity scope	Outer business activity scope	Compensation behavior
Succeeds	Succeeds	Any compensation handlers that are owned by the inner business activity scope wait for the outer UOW to complete. When the outer UOW succeeds, the outer business activity scope drives all compensation handlers to close.
Fails	Succeeds	Any active compensation handlers that are owned by the inner business activity scope are compensated. An exception is thrown to the outer UOW; if this exception is caught, when the outer UOW succeeds, the outer business activity scope drives all remaining active compensation handlers to close.
Fails	Fails	Any active compensation handlers that are owned by the inner business activity scope are compensated. An exception is thrown to the outer UOW; if this exception is not caught, the outer business activity scope fails. When the outer business activity scope fails, either because of the unhandled exception or for some other reason, all remaining active compensation handlers are compensated.
Succeeds	Fails	Any compensation handlers that are owned by the inner business activity scope wait for the outer UOW to complete. When the outer UOW fails, the outer business activity scope drives all compensation handlers to compensate.

When a UOW with an associated business activity scope completes, the business activity scope always completes in the same direction as the UOW that it is associated with. The only way that you can influence the direction of the business activity scope is to influence the UOW that it is associated with, which you can do by using the `setCompensateOnly` method of the business activity API.

A compensation handler that is registered within a transactional UOW might be inactive initially, depending on the method invoked from the business activity API. Inactive handlers in this situation become active when the UOW in which that handler is declared completes successfully. A compensation handler that is registered outside a transactional UOW always becomes active immediately. For more information, see “The business activity API” on page 1918.

Each business activity scope in the diagram represents a business activity. For example, the outer business activity running under `BAScope1` can be a holiday booking scenario, with `BAScope2` being a flight booking activity and `BAScope3` a hotel booking. If either the flight or hotel bookings fail, the overall holiday booking by default also fails. Alternatively if, for example, the flight booking fails, you might want your application to try booking a flight using another component that represents a different airline. If the overall holiday booking fails, the application can use compensation handlers to cancel any flights or hotels that are already successfully booked.

Use of business activity scopes by application components

Application components do not use business activity scopes by default. You use the WebSphere Application Server assembly tools to specify the use of a business activity scope and to identify any compensation handler class for the component:

Default configuration

If a business activity context is present on a request received by a component with no business activity scope configuration, the context is stored by the container but never used during the method scope of the target component. A new business activity scope is not created. If the target component invokes another component, the stored business activity context is propagated and can be used by other compensating components.

Run enterprise bean methods under a business activity scope

Any business activity context present on the incoming request is received by the container and made available to the target component. If a new UOW is created for the target method, for example because the enterprise bean method has a **Transaction** setting of **Requires new**, the received business activity scope becomes an outer business activity scope to a newly created business activity. If the UOW is propagated from the calling component and used by the method, then the received business activity scope is used by the method. If a business activity scope does not exist on the invocation, a new business activity scope is created and used by the method.

To create a business activity scope when an enterprise bean is invoked, you must configure the enterprise bean to run enterprise bean methods under a business activity scope. You must also configure the deployment descriptors for the method being invoked, to specify the creation of a new UOW upon invocation. For instructions on how to perform these actions, see [Creating an application that exploits the business activity support](#).

The effect of application server shutdown on active transactions and later recovery

When an application server shuts down, any active transactions are rolled back. If all transactions are successfully completed in this way, message WTRN0105I is logged, and on the next server restart no recovery activity is needed. If message CWWTR0105I is not logged for an application server shutdown, this does not indicate that there has been a failure, only that recovery activity is required when the server restarts.

A clean shutdown of all application servers should be achieved before the product is uninstalled, to avoid data integrity problems.

Extended JTA support

Extended JTA support provides application programming interfaces additional to the UserTransaction interface that is defined in the JTA as part of the J2EE specification. Specifically, the API extensions provide the following functionality:

- Access to global and local transaction identifiers associated with the thread.

The global id is based on the tid in `CosTransactions::PropagationContext`: and the local id identifies the transaction uniquely within the local JVM.

- A transaction synchronization callback that enables any J2EE component to register an interest in transaction completion.

This can be used by advanced applications to flush updates before transaction completion and clear up state after transaction completion. J2EE (and related) specifications position this function generally as the domain of the J2EE containers.

An application uses a JNDI lookup of `java:comp/websphere/ExtendedJTATransaction` to get an `ExtendedJTATransaction` object, which it then uses as follows:

```
ExtendedJTATransaction exJTA = (ExtendedJTATransaction)ctx.lookup("
  java:comp/websphere/ExtendedJTATransaction");
SynchronizationCallback sync = new SynchronizationCallback();
exJTA.registerSynchronizationCallback(sync);
```

The `ExtendedJTATransaction` object supports the registration of one or more application-provided `SynchronizationCallbacks`. Depending on how the callback is registered, each registered callback is called at one of the following points:

- At the end of every transaction that runs on the application server (whether the transaction is started locally or imported).
- At the end of the transaction for which the callback was registered.

The following information provides an overview of the interfaces provided by the Extended JTA support. For more detailed information, see the Javadoc.

SynchronizationCallback interface

An object implementing this interface is enlisted once through the ExtendedJTATransaction interface, and receives notification of transaction completion.

Although an object implementing this interface can run in a J2EE server, there is no specific J2EE component active when this object is called. So, the object has limited direct access to any J2EE resources. Specifically, it has no access to the java: namespace or to any container-mediated resource. Such an object can cache a reference to a J2EE component (for example, a stateless session bean) that it delegates to. The object would then have all the normal access to J2EE resources and could be used, for example, to acquire a JDBC connection and flush updates to a database during beforeCompletion.

ExtendedJTATransaction interface

A WebSphere programming model extension to the J2EE JTA support. An object implementing this interface is bound, by WebSphere J2EE containers that support this interface, at java:comp/websphere/ExtendedJTATransaction. Access to this object, when called from an EJB container, is not restricted to component-managed transactions.

Support for Web Services protocols

WebSphere Application Server supports a number of Web Services protocols. These protocols provide standard ways of defining Web service applications, allowing the applications to operate independently of the product, platform or programming language used.

Web Services protocols are defined by the Oasis group. Refer to the Oasis Web site, <http://www.oasis-open.org>, for specifications and further information on each protocol. Use the sub-topics below to find out more information about the support for each protocol in WebSphere Application Server.

- “Web Services Atomic Transaction support in WebSphere Application Server”
- “Web Services Business Activity support in WebSphere Application Server” on page 1913
- “Web Services transactions, firewalls and intermediary nodes” on page 1913

Web Services Atomic Transaction support in WebSphere Application Server:

The Web Services Atomic Transaction support in WebSphere Application Server provides transactional quality of service to the Web services environment. This enables distributed Web service applications, and the resources they use, to take part in distributed global transactions.

The Web Services Atomic Transaction (WS-AT) support is an implementation of the following specifications on WebSphere Application Server. These specifications define a set of Web services that enable Web service applications to participate in global transactions distributed across the heterogeneous Web service environment.

- Web Services Atomic Transaction (WS-AT), at <http://www-106.ibm.com/developerworks/webservices/library/ws-atomtran/>
WS-AT is a specific coordination type that defines protocols for atomic transactions.
- Web Service Coordination (WS-COOR), at <http://www-106.ibm.com/developerworks/webservices/library/ws-coor/>
WS-COOR specifies a CoordinationContext and a Registration service with which Participant web services may enlist to take part in the protocols offered by specific coordination types.

The WS-AT support is an interoperability protocol that introduces no new programming interfaces for transactional support. Global transaction demarcation is provided by standard J2EE use of the JTA UserTransaction interface. If a Web service request is made by an application component running under a global transaction, then a WS-AT CoordinationContext is implicitly propagated to the target Web service, but only if the appropriate application deployment descriptors have been set as described in Configuring transactional deployment attributes.

If WebSphere Application Server is the system hosting the target endpoint for a Web service request that contains a WS-AT CoordinationContext, then WebSphere automatically establishes a subordinate JTA transaction in the target runtime environment that becomes the transactional context under which the target Web service application executes.

The following figure, Figure 27, shows a transaction context shared between two WebSphere application servers for a Web service request that contains a WS-AT CoordinationContext.

Figure 27. Transaction context shared between two WebSphere application servers.

WS-AT support restrictions

In this version of WebSphere Application Server, WS-AT contexts cannot be started from a non-recoverable client process.

Work requests for the same WS-AT transaction sent to a server cluster are not guaranteed to be assigned to the same cluster member every time. In such cases, the work for a transaction might be handled by multiple cluster members. If transactional work of multiple cluster members contends over the same transactional resource then a deadlock condition can result.

Application design considerations

WS-AT is a two-phase commit transaction protocol and is suitable for short duration transactions only.

Because the purpose of an atomic transaction is to coordinate resource managers that isolate transactional updates by holding transactional locks on resources, it is generally not recommended that WS-AT transactions be distributed across enterprise domains. Inter-enterprise transactions typically require a looser semantic than two-phase commit and, in such scenarios, it can be more appropriate to use a compensating business transaction, for example a Web Services Business Activity or as part of a BPEL process.

WS-AT is most appropriate for distributing transaction context across Web services deployed within a single enterprise. Only request-response message exchange patterns carry transaction context since the originator (application or container) of a transaction needs to be sure that all business tasks executed under that transaction have finished before requesting the completion of a transaction. Web services invoked by a one-way request never run under the transaction of the requesting client.

Application development considerations

There are no specific development tasks required for Web service applications to take advantage of WS-AT. There are some application deployment descriptors that need to be set appropriately, as described in Configuring transactional deployment attributes.

Application developers do not need to explicitly register WS-AT participants. The WebSphere Application Server runtime takes responsibility for the registration of WS-AT participants, in the same way as the registration of XAResources in the JTA transaction to which the WS-AT transaction is federated. At transaction completion time, all XAResources and WS-AT participants are atomically coordinated by the WebSphere Application Server transaction service.

If a JTA transaction is active on the thread when a Web service Application request is made, the transaction is propagated across on the Web service request and established in the target environment. This is analogous to the distribution of transaction context over IIOP as described in the EJB specification. Any transactional work performed in the target environment becomes part of the same global transaction.

Web Services Business Activity support in WebSphere Application Server:

With Web Services Business Activity (WS-BA) support in WebSphere Application Server, Web services on disparate systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll back atomically, and therefore require a compensation process in the event of an error.

The Web Services Business Activity (WS-BA) support is an implementation of the following specifications in WebSphere Application Server. These specifications define a set of protocols that enable Web service applications to participate in loosely coupled business processes that are distributed across the heterogeneous Web service environment, with the ability to compensate actions if an error occurs. For example, an application that sends an e-mail cannot unsend it following a failure. The application can, however, provide a business-level compensation handler that sends another e-mail advising of the new circumstances. A *business activity* is a group of general tasks that you want to link together so that the tasks have an agreed outcome.

- Web Services Business Activity (WS-BA), at <http://www-106.ibm.com/developerworks/library/specification/ws-tx/#ba>
WS-BA is a specific coordination type that defines protocols for business activities.
- Web Service Coordination (WS-COOR), at <http://www-106.ibm.com/developerworks/webservices/library/ws-coor/>
WS-COOR specifies a CoordinationContext and a registration service with which participant Web services can enlist to take part in the protocols that are offered by specific coordination types.

In addition to supporting the WS-BA interoperability protocol, WebSphere Application Server provides a programming interface for creating business activities and compensation handlers. With this programming interface, you can specify compensation data and check or alter the status of a business activity.

You can also use this compensation ability with applications that are not Web services, as long as these applications involve communication between WebSphere Application Servers only. See the related topics for more information.

Web Services transactions, firewalls and intermediary nodes:

You can configure your system to enable propagation of Web Services Atomic Transactions (WS-AT) message contexts and Web Service Business Activities (WS-BA) message contexts across firewalls or outside the WebSphere Application Server domain. With this configuration you can distribute Web service applications that use WS-AT or WS-BA across disparate systems. The topology that you use can have an effect on the high availability and affinity behavior of the transactions.

The topologies that are available to you are as follows:

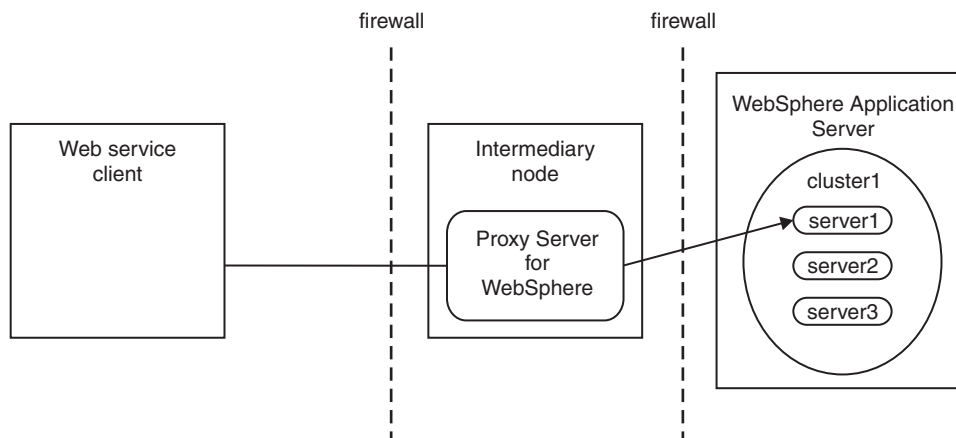

Direct connection

No intermediary node exists in this topology. The client communicates directly with a specific WebSphere Application Server. This topology supports high availability for transactions on requests made within a cluster, and affinity of transactions.

Proxy Server for IBM WebSphere Application Server

In this topology, the client communicates with a Proxy Server for IBM WebSphere Application Server, which dynamically routes the client requests to the appropriate server within a WebSphere Application Server cluster.

The proxy server supports high availability, workload management, and affinity of transactions. After you create the proxy server you do not have to perform any extra additional steps to enable these features.

HTTP server, such as IBM HTTP Server

In this topology, the client communicates with an HTTP server, which always routes the client requests to a specific server within a WebSphere Application Server cluster. You configure the HTTP server to specify the WebSphere Application Server to route requests to.

The HTTP server cannot provide either affinity or high availability for transactions. However, transactional integrity is assured because recovery processing occurs after the failed server restarts.

Note: You can still enable high availability on the WebSphere Application Server. Clients accessing this server through an HTTP server cannot have high availability of transactions, however other clients accessing the same server can.

If you have an existing HTTP server, but want the high availability and workload management capabilities of a Proxy Server for WebSphere, create a Proxy Server for IBM WebSphere Application Server and configure the HTTP server to route all requests to the proxy server, as in the following scenario.

HTTP server in conjunction with a Proxy Server for IBM WebSphere Application Server

The client communicates with an HTTP server, which you configure to forward the client's requests to a Proxy Server for IBM WebSphere Application Server. The proxy then dynamically routes the requests to the appropriate server within WebSphere Application Server.

The proxy server provides the client with the high availability and affinity behavior that the HTTP server cannot.

Use of local transactions

Local transaction containment (LTC) support, and its configuration through local transaction extended deployment descriptors, gives IBM WebSphere Application Server application programmers a number of advantages. This topic describes those advantages and how they relate to the settings of the local transaction extended deployment descriptors. This topic also describes points to consider to help you best configure transaction support for some example scenarios that use local transactions.

Develop an enterprise bean or servlet that accesses one or more databases that are independent and require no coordination.

If an enterprise bean does not need to use global transactions, it is often more efficient to deploy the bean with the Container Transaction deployment descriptor **Transaction** attribute set to Not supported instead of Required.

With the extended local transaction support of IBM WebSphere Application Server, applications can perform the same business logic in an unspecified transaction context as they can under a global transaction. An enterprise bean, for example, runs under an unspecified transaction context if it is deployed with a **Transaction** attribute of Not supported or Never.

The extended local transaction support provides a container-managed, implicit local transaction boundary within which application updates can be committed and their connections cleaned up by the container. Applications can then be designed with a greater degree of independence from deployment concerns. This makes using a **Transaction** attribute of Supports much simpler, for example, when the business logic may be called either with or without a global transaction context.

An application can follow a get-use-close pattern of connection usage regardless of whether or not the application runs under a transaction. The application can depend on the close behaving in the same way and not causing a rollback to occur on the connection if there is no global transaction.

There are many scenarios where ACID coordination of multiple resource managers is not needed. In such scenarios running business logic under a **Transaction** policy of Not supported performs better than if it had been run under a Required policy. This benefit is exploited through the **Local Transactions - Resolution-control** extended deployment setting of ContainerAtBoundary. With this setting, application interactions with resource providers (such as databases) are managed within implicit RMLTs that are both started and ended by the container. The RMLTs are committed by the container at the configured **Local Transactions - Boundary**; for example at the end of a method. If the application returns control to the container by an exception, the container rolls back any RMLTs that it has started.

This usage applies to both servlets and enterprise beans.

Use local transactions in a managed environment that guarantees clean-up.

Applications that want to control RMLTs, by starting and ending them explicitly, can use the default **Local Transactions - Resolution-control** extended deployment setting of Application. In this case, the container ensures connection cleanup at the boundary of the local transaction context.

J2EE specifications that describe application use of local transactions do so in the manner provided by the default setting of **Local Transactions - Resolution-control=Application** and **Local Transactions - Unresolved-action=Rollback**. By configuring the **Local Transactions - Unresolved-action** extended deployment setting to Commit, then any RMLTs started by the application but not completed when the local transaction containment ends (for example, when the method ends) are committed by the container. This usage applies to both servlets and enterprise beans.

Coordinate multiple one-phase resource managers.

For resource managers that do not support XA transaction coordination, a client can exploit ActivitySession-bounded local transaction contexts. Such contexts give a client the same ability to control the completion direction of the resource updates by the resource managers as the client has for transactional resource managers. A client can start an ActivitySession and call its entity beans under that context. Those beans can perform their RMLTs within the scope of that ActivitySession and return without completing the RMLTs. The client can later complete the ActivitySession in a commit or rollback direction and cause the container to drive the ActivitySession-bounded RMLTs in that coordinated direction.

To determine how best to configure the transaction support for an application, depending on what you want to do with transactions, consider the following points.

General points

- You want to start and end global transactions explicitly in the application (BMT session beans and servlets only).

For a session bean, set the **Transaction type** to Bean (to use bean-managed transactions) in the component's deployment descriptor. (You do not need to do this for servlets.)

- You want to access several XA resources atomically across one or more bean methods.

In the Container transaction deployment descriptor, set **Transaction** to Required, Requires new, or Mandatory.

- You want to access several non-XA resources in a method and want to manage them independently.

In the component's deployment descriptor, set **Local Transactions - Resolution-control** to Application and set **Local Transactions - Unresolved-action** to **Rollback**. In the Container transaction deployment descriptor, set **Transaction** to Not supported.

- You want to use a single non-XA resource and one or more XAResources.

Use the *Last Participant Support*.

Points specific to WebSphere Application Server for z/OS

- You want to use a non-XA resource along with multiple two-phase RRS resources.

A non-XA resource in a transaction along with RRS resources is supported any time a global transaction is active. A global transaction is active when the deployment descriptor has **Transaction** set to Supports, Required, Requires New, or Mandatory. Global transactions also are active for component-managed deployments.

Transaction service custom property

WebSphere Application Server for z/OS provides the `DISABLE_TRANSACTION_TIMEOUT_GRACE_PERIOD` and `RLS_LOGSTREAM_COMPRESS_INTERVAL` transaction service custom properties.

Transaction Service custom properties can be specified in the administrative console by clicking **Servers > Application Servers > server > Container Services > Transaction service > Custom Properties > New**.

DISABLE_TRANSACTION_TIMEOUT_GRACE_PERIOD

Specifies whether there is a delay between a transaction timeout and the abnormal ending of the servant region that was running the transaction.

If you set this value to false, a global transaction that times out is marked rollback-only. The transaction server gives the associated application an additional period of time, approximately four minutes, to complete. If the application completes in this time, the transaction is rolled back. If the application does not complete in this time, the application and associated servant region are ended abnormally, with an ABENDEC3 or ABENDSEC3 error.

Set this value to true to remove the delay, and abnormally end the application and servant region immediately.

Data Type	Boolean
Acceptable values	true, false
Default	false

RLS_LOGSTREAM_COMPRESS_INTERVAL

Specifies, in seconds, the interval at which the recovery log service attempts to compress any logstreams application components are using. The Transaction Service (XA partner log) and the Compensation Service components can be configured to use the recovery log service.

The logstream is checked for compression once per interval. This operation can cause unnecessary CPU usage if the logstream is not being used.

Recommendations:

- If you do not use a logstream for the compensation service, set this property to a value that is higher than the default value.
- If your recovery log service uses logstreams, do not set this property to too high a value. If the recovery log service logstreams become full before the compression interval expires, transactions might start to fail until the logstreams are compressed.

- If none of your components are configured to use a logstream, you set this property to 0 (zero) to disable this function.

Data Type	Integer
Acceptable values	0 - 2,147,483,647 (0 disables the function)
Default	30 seconds

The business activity API

Use the business activity API to create business activities and compensation handlers for an application component, and to log data that is required for compensating an activity in the event of a failure.

Overview

The business activity support provides a `UserBusinessActivity` API, a `CompensationHandler` interface and two exceptions: `RetryCompensationHandlerException` and `CompensationHandlerFailedException`. You can look up the `UserBusinessActivity` interface from the application server Java Naming and Directory Interface (JNDI) at `java:comp/websphere/UserBusinessActivity`. For example:

```
InitialContext ctx = new InitialContext();
UserBusinessActivity uba = (UserBusinessActivity) ctx.lookup("java:comp/websphere/UserBusinessActivity");
```

If an application component is running work that might require compensating upon failure, you must provide a compensation handler class that is assembled as part of the deployed application. This new Java class must implement the `com.ibm.websphere.wsba.CompensationHandler` interface, which supports the `close` and `compensate` methods, which take a parameter of a Service Data Object (SDO). During normal application processing, the application can make one or more invocations to the `setCompensationDataImmediate` or `setCompensationDataAtCommit` methods, passing in an SDO representing the current state of the work performed.

When the underlying unit of work (UOW) that the root business activity is associated with completes, all registered compensators are coordinated to complete. During completion, either the `compensate` or the `close` method is called on the compensation handler, passing in the most recent compensation data logged by the application component as a parameter. Your compensation handler implementation must be able to understand the data that is stored in the SDO `DataObject`; using this data, the compensation handler must be able to determine the nature of the work performed by the enterprise bean and `compensate` or `close` in an appropriate manner, for example by undoing changes made to database rows in the event of a failure. You associate the compensation handler with an application component by using the assembly tooling, such as Rational Application Developer.

Active and inactive compensation handlers

You implement the `CompensationHandler` interface for any application component that executes code that might need to be compensated within a business activity scope. `CompensationHandler` objects are registered implicitly with the business activity scope under which the application runs, whenever the application calls the `UserBusinessActivity` API to specify compensation data. Compensation handlers can be in one of two states, active or inactive, depending on any transactional UOW under which they are registered. A compensation handler registered within a transactional UOW might be initially inactive until the transaction commits, at which point it becomes active (see below). A compensation handler registered outside a transactional UOW always becomes active immediately.

When a business activity completes, it drives active compensation handlers only. Any inactive compensation handlers that are associated with the business activity are discarded and never driven.

Logging compensation data

The business activity API specifies two methods that allow the application to log compensation data. This data is made available to the compensation handlers during their processing upon completion of the business activity. The application calls one of these methods, depending on whether it expects transactions to be part of the business activity.

setCompensationDataAtCommit()

Call this method if the application expects a global transaction on the thread.

- If a global transaction is present on the thread, the `CompensationHandler` object is initially inactive. If the global transaction fails, it rolls back any transactional work done within its transaction context in an atomic manner, and drives the business activity to compensate other completed UOWs. The compensation handler does not need to be involved. If the global transaction commits successfully, the compensation handler becomes active because it is required to compensate the durable work that is completed by the global transaction, if the overall business activity fails. The `setCompensationDataAtCommit` method configures the `CompensationHandler` instance to perform this compensation function.
- If a global transaction is not present when this method is called, the compensation handler becomes active immediately.

For example, using the same business activity instance as in the previous example:

```
DataObject compensationData = doWorkWhichWouldNeedCompensating();
uba.setCompensationDataAtCommit(compensationData);
```

setCompensationDataImmediate()

Call this method if the application does not expect a global transaction on the thread.

The `setCompensationDataImmediate` method makes a `CompensationHandler` instance active immediately, regardless of the current UOW context at the time that the method is invoked. The compensation handler is always able to participate during completion of the business activity.

The role of the `setCompensationDataImmediate` method is to compensate any non-transactional work, in other words, work that can be performed either inside or outside a global transaction, but is not governed by the transaction. For example, sending an e-mail. The compensation handler must be active immediately so if a failure occurs within a business activity, this non-transactional work is always compensated.

Although these two compensation data logging methods, if called within the same enterprise bean, use the same `CompensationHandler` class, they create two separate instances of the `CompensationHandler` class at run time. Therefore, the actions of the methods are mutually exclusive; calling one of the methods does not overwrite any work carried out by the other method.

A `CompensationHandler` instance is not added to a business activity automatically when a business-activity-enabled enterprise bean is invoked. The association is done explicitly through the business activity API, using one of the compensation data logging methods described previously. If such a method is called passing in `null` as a parameter, the `CompensationHandler` instance is added to the current business activity, and `null` is passed later to either the `compensate` or the `close` method upon completion of the business activity scope. With this process, you can add the compensation handler to the business activity, and code default behavior within the compensation handler. It is your responsibility to handle the case of `null`s that pass back to your `CompensationHandler` instance. This scenario happens only if you call a compensation data logging method with `null` as a parameter.

As described previously, the business activity support adds a `CompensationHandler` instance to the business activity when a compensation data logging method is called for the first time by the enterprise bean using that business activity. At the same time, a snapshot of the J2EE context is taken and logged with the compensation data. Upon completion of the business activity, all the compensation handlers that were added to the business activity are driven to `compensate` or `close`. The code that you create within the

CompensationHandler class is guaranteed to run within the same J2EE context that was captured in the earlier snapshot.

For details about the methods available in the business activity API, see the WebSphere Application Server application programming interface reference information.

Transaction service exceptions

This topic lists the exceptions that can be thrown by the WebSphere Application Server transaction service. The exceptions are listed in the following groups:

- Standard exceptions
- Heuristic exceptions

If the EJB container catches a system exception from the business method of an enterprise bean, and the method is running within a container-managed transaction, the container rolls back the transaction before passing the exception on to the client. For more information about how the container handles the exceptions thrown by the business methods for beans with container-managed transaction demarcation, see the section *Exception handling* in the Enterprise JavaBeans 2.0 specification. That section specifies the container's action as a function of the condition under which the business method executes and the exception thrown by the business method. It also illustrates the exception that the client receives and how the client can recover from the exception.

Standard exceptions

The standard exceptions such as `TransactionRequiredException`, `TransactionRolledbackException`, and `InvalidTransactionException` are defined in the Java Transaction API (JTA) 1.0.1 Specification.

InvalidTransactionException

This exception indicates that the request carried an invalid transaction context.

TransactionRequiredException exception

This exception indicates that a request carried a null transaction context, but the target object requires an active transaction.

TransactionRolledbackException exception

This exception indicates that the transaction associated with processing of the request has been rolled back, or marked for roll back. Thus the requested operation either could not be performed or was not performed because further computation on behalf of the transaction would be fruitless.

Heuristic exceptions

A heuristic decision is a unilateral decision made by one or more participants in a transaction to commit or rollback updates without first obtaining the consensus outcome determined by the Transaction Service. Heuristic decisions are an issue only after the participant has been prepared and the second phase of commit processing is underway. Heuristic decisions are normally made only in unusual circumstances, such as repeated failures by the transaction manager to communicate with a resource manager during two-phase commit. If a heuristic decision is taken, there is a risk that the decision differs from the consensus outcome, resulting in a loss of data integrity.

The following list provides a summary of the heuristic exceptions. For more detail, see the Java Transaction API (JTA) 1.0.1 Specification.

HeuristicRollback exception

This exception is raised on the commit operation to report that a heuristic decision was made and that all relevant updates have been rolled back.

HeuristicMixed exception

This exception is raised on the commit operation to report that a heuristic decision was made and that some relevant updates have been committed and others have been rolled back.

UserTransaction interface - methods available

For details about the methods available with the UserTransaction interface, see the WebSphere Application Server application programming interface reference information (Javadoc) or the Java Transaction API (JTA) 1.0.1 Specification.

CICS tuning tips for z/OS

These recommendations only apply to WebSphere applications that access CICS.

The LGDFINT system initialization parameter specifies the log defer interval used by CICS log manager when determining how long to delay a forced journal write request before invoking the MVS system logger. The value is specified in milliseconds. Performance evaluations of typical CICS transaction workloads have shown that the default setting of 5 milliseconds gives the best balance between response time and central processor cost. Be aware that CICS performance can be adversely affected by a change to the log defer interval value. Too high a value will delay CICS transaction throughput due to the additional wait before invoking the MVS system logger. An example of a scenario where a reduction in the log defer interval might be beneficial to CICS transaction throughput would be where many forced log writes are being issued, and little concurrent task activity is occurring. Such tasks will spend considerable amounts of their elapsed time waiting for the log defer period to expire. In such a situation, there is limited advantage in delaying a call to the MVS system logger to write out a log buffer, since few other log records will be added to the buffer during the delay period.

- Set the LGDFINT system initialization parameter to 5.
While CICS is running, you can use the CEMT SET SYSTEM[LOGDEFER(*value*)] command to alter the LGDFINT setting dynamically.
- Set the CICS RECEIVECOUNT value high enough to handle all concurrent EXCI pipes on the system.
The default value is 4. You set this value in the EXCI sessions resource definition.

For more detailed information on CICS, refer to the *CICS Performance Guide*.

GRS tuning tips for z/OS

WebSphere for z/OS uses GRS to communicate information between servers in a sysplex. When there are multiple servers defined in a system or a sysplex, a request may end up on the wrong server. To determine where the transaction is running WebSphere uses GRS. Therefore, if you are using global transactions, WebSphere will issue an enqueue for that transaction at the start of the transaction and hold on to that enqueue until the transaction ends. WebSphere for z/OS uses GRS enqueues for the following:

- Two-phase commit transactions involving more than one server
- HTTP sessions in memory
- Stateful EJBs
- "Sticky" transactions to keep track of pseudo-conversational states.
- If you **are not** in a sysplex, you should configure GRS=NONE.
- If you **are** in a sysplex, we strongly recommend GRS=STAR.

This requires configuring GRS to use the coupling facility. All of the WebSphere enqueues are issued with RNL=NO, which prevents misconfiguring the GR SRNLxx with inappropriate values. See the GRS documentation for details on setting this up.

Configuring transaction properties for an application server

Use this task to change the transaction log properties, to move your transaction logs to a new location, or to update the parameters for the server's transaction logs.

You might want to move to your logs to a different storage device. Perform this task when you are ready to move your transaction logs or when you need to make a change to the parameters. You must restart the application server to make configuration changes take effect.

To configure the transaction properties for an application server, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, select **Servers-> Manage Application Servers-> your_app_server** This displays the properties of the application server, *your_app_server*, in the content pane.
3. Under Container Settings, expand Container Services, then click Transaction Service to display the properties page for the transaction service, as two notebook pages:

Configuration

The values of properties defined in the configuration file. If you change these properties, the new values are applied when the application server next starts.

Runtime

The runtime values of properties. If you change these properties, the new values are applied immediately, but are overwritten with the Configuration values when the application server next starts.

4. To review transaction-related configuration properties, ensure that the Configuration page is displayed.
5. **Optional:** Review or change the value of transaction timeout properties:

Total transaction lifetime timeout

Type the number of seconds a transaction can remain inactive before it is ended by the transaction service. A value of 0 (zero) indicates that there is no timeout limit.

Client inactivity timeout

Type the number of seconds after which a client is considered inactive and the transaction service ends any transactions associated with that client. A value of 0 (zero) indicates that there is no timeout limit.

6. **Optional:** Review or change heuristic-related properties:

Heuristic retry limit

The number of times that the application server retries a completion signal, such as commit or rollback, after a transient exception from a resource manager or remote partner.

Heuristic retry wait

The number of seconds that the application server waits before retrying a completion signal, such as commit or rollback, after a transient exception from a resource manager or remote partner.

Enable logging for heuristic reporting

Select this property to enable the application server to log "about to commit one-phase resource" events from transactions that involve a one-phase commit resource and two-phase commit resources.

Heuristic completion direction

Select the direction used to complete a transaction that has a heuristic outcome; either the application server commits or rolls back the transaction, or depends on manual completion by the administrator.

7. Review or change other configuration properties, to suit your requirements. For more information about the properties of the transaction service, see "Transaction service settings" on page 1923.
8. Click **OK** and save.
9. Stop then restart the application server.

If you change the transaction log directory configuration property to an incorrect directory name, the application server will restart but be unable to open the transaction logs. You should change the configuration property to a valid directory name, then restart the application server.

If you are running the application server as non-root, modify the permissions on the new transaction log location. If you want to use peer recovery of transactions on a shared device with non-root users, make sure that your non-root users and groups have matching identification numbers across machines

Transaction service settings

Use this page to specify settings for the transaction service. The transaction service is a server runtime component that can coordinate updates to multiple resource managers to ensure atomic updates of data. Transactions are started and ended by applications or the container in which the applications are deployed.

To view this administrative console page, click **Servers > Application Servers > *server_name* > Container Services > Transaction Service**.

Related concepts

“Web Services transactions, firewalls and intermediary nodes” on page 1913

You can configure your system to enable propagation of Web Services Atomic Transactions (WS-AT) message contexts and Web Service Business Activities (WS-BA) message contexts across firewalls or outside the WebSphere Application Server domain. With this configuration you can distribute Web service applications that use WS-AT or WS-BA across disparate systems. The topology that you use can have an effect on the high availability and affinity behavior of the transactions.

Transaction log directory

Specifies the location of the JTA Partner Log.

Set this property to change the log file directory for an application server only if the applications use distributed resources or XA transactions; for example, multiple databases and resources are accessed within a single transaction.

On z/OS, this log is used for recovery of XA resources. When the application that runs on the WebSphere product accesses XA resources, the WebSphere product stores information about the resource to enable XA transaction recovery.

Syntax

[location type URL tag] location specification

where

- *location type URL tag* specifies the optional location type for the JTA Partner Log:
 - *dir://* specifies that the JTA Partner Log location is in a fully qualified HFS directory specified by *location specification*. *dir://* is the default.
- *location specification* specifies the location name for the JTA Partner Log:
 - To specify a logstream, use the syntax `logstream://HLQ`
If your Application Server installation followed the convention of configuring logstreams to the coupling facility (CF), the logstream is named according to the syntax `HLQ.server.X`, where HLQ is a user-defined value between 1-8 characters specified in the installation dialog. Use this HLQ value to specify the JTA Partner Log location.
 - If the *location type URL tag* is *dir://*, use a fully qualified HFS directory for the *location specification*. The complete name of the directory must be unique within the WebSphere node.

Default

dir://app_server_root/tranlog/server name

If you migrate a WebSphere Application Server Version 5 node to Version 6, the stored location of this configuration property is moved from the server level to the node (server index) level. If you have specified a non-default log directory for a Version 5 application server, you are prompted to save the transaction service settings again, to confirm that you want the log directory saved to the node level.

Total transaction lifetime timeout

Specifies the default maximum time, in seconds, allowed for transactions started on this server to complete. Any such transactions that do not complete before this timeout occurs are rolled back.

Component-managed transactions that do not have a timeout explicitly set are also assigned this value.

If you set this value to 0, only the maximum transaction timeout configuration value applies.

Data type	Integer
Units	Seconds
Default	120
Range	0 to 2 147 040

Asynchronous response timeout

Specifies the amount of time, in seconds, that the server waits for responses to WS-AT protocol messages.

Data type	Integer
Units	Seconds
Default	30
Range	0 to 2 147 483 647

Client inactivity timeout

Specifies the maximum duration, in seconds, between transactional requests from a remote client. Any period of client inactivity that exceeds this timeout results in the transaction being rolled back in this application server.

If you set this value to 0, there is no timeout limit.

Data type	Integer
Units	Seconds
Default	60
Range	0 to 2 147 483 647

Maximum transaction timeout

Specifies the maximum time to complete, in seconds, for transactions that run in this server. This value should be greater than or equal to the total transaction timeout.

This limit constrains transaction timeout set programmatically by BMT beans and values imported with contexts received from foreign servers.

This value limits the upper bound of all other transaction related timeouts. For example, if a component attempts to set a transaction timeout of 360 seconds, and the Maximum Transaction Timeout setting is 300 seconds, the Maximum Transaction Timeout setting of 300 seconds is used.

If set to 0, there is no limit and therefore the timeout specified by the Total transaction lifetime timeout property or component timeout is used.

Data type	Integer
Units	Seconds
Default	300
Range	0 to 2 147 040

Heuristic retry limit

Specifies the number of times that the application server retries a completion signal, such as commit or rollback, after a transient exception from a resource manager or remote partner.

If the application server abandons the retries, then the resource manager or remote partner is responsible for ensuring that the resource or partner's branch of the transaction is completed appropriately. The application server raises (on behalf of the resource or partner) an exception that indicates a heuristic hazard. If a commit was requested, the transaction originator receives an exception on the commit operation; if the transaction is container-initiated, then the container returns a remote exception or EJB exception to the EJB client.

Data type	Integer
Default	0
Range	0 to 2 147 483 647

A value of 0 (the default) means retry forever.

Heuristic retry wait

Specifies the number of seconds that the application server waits before retrying a completion signal, such as commit or rollback, after a transient exception from a resource manager or remote partner.

Data type	Integer
Default	0
Range	0 to 2 147 483 647

If you leave this value at 0, the application server still makes subsequent attempts to complete the transaction. It incrementally lengthens the wait time before each attempt, to improve system throughput.

Heuristic completion direction

Specifies the direction that is used to complete a transaction that has a heuristic outcome; either the application server commits or rolls back the transaction, or depends on manual completion by the administrator.

Data type	Drop-down list
Default	ROLLBACK
Range	

COMMIT

The Application server heuristically commits the transaction.

ROLLBACK

The Application server heuristically rolls back the transaction.

MANUAL

The application server depends on an administrator to manually complete or roll back transactions with heuristic outcomes.

Enable file locking

Specifies whether the use of file locks is enabled when opening the transaction service recovery log.

If you enable this setting, a file lock will be obtained before accessing the transaction service recovery log files. File locking is used to ensure that, in a highly available WebSphere Application Server deployment,

only one application server can access a particular transaction service recovery log at any one time. This setting has no effect in a standard deployment where you have not configured high availability support.

Attention: This setting requires a compatible network file system, such as network file system version 4, to operate correctly.

Data type	Check box
Default	Selected

Enable protocol security

Specifies whether the secure exchange of transaction service protocol messages is enabled.

This setting has no effect unless you enable WebSphere Application Server security on the server.

Data type	Check box
Default	Selected

HTTP proxy prefix

Specifies the prefix used by WS-AtomicTransaction and WS-BusinessActivity requests that are sent through an intermediary node using the HTTP protocol.

Set this field if you are using an intermediary node, such as an HTTP server or Proxy Server for WebSphere, to send requests that comply with the Web Services Atomic Transaction or Web Services Business Activity protocols. The format for the prefix is as follows:

`http://host_name:port`

where

- *host_name* is the host name used by clients to contact the Web service
- *port* is the port for which the service is configured to accept client requests

If the intermediary node is not a Proxy Server, the prefix must be unique for each server. If you are using a Proxy Server, prefixes can be the same for each server in a cluster, because the Proxy Server determines dynamically which server to forward the request to.

The HTTPS prefix will be used if WebSphere Application Server security is enabled and protocol security is enabled for the transaction service, otherwise the HTTP prefix will be used.

Data type	String
Default	None

HTTPS proxy prefix

Specifies the prefix used by WS-AtomicTransaction and WS-BusinessActivity requests that are sent through an intermediary node using the HTTPS protocol.

Set this field if you are using an intermediary node, such as an HTTP server or Proxy Server for WebSphere, to send requests that comply with the Web Services Atomic Transaction or Web Services Business Activity protocols. The format for the prefix is as follows:

`https://host_name:port`

where

- *host_name* is the host name used by clients to contact the Web service
- *port* is the port for which the service is configured to accept client requests

If the intermediary node is not a Proxy Server, the prefix must be unique for each server. If you are using a Proxy Server, prefixes can be the same for each server in a cluster, because the Proxy Server determines dynamically which server to forward the request to.

The HTTPS prefix will be used if WebSphere Application Server security is enabled and protocol security is enabled for the transaction service, otherwise the HTTP prefix will be used.

Data type	String
Default	None

Manual transactions

Specifies the number of transactions that await manual completion by an administrator.

If there are transactions awaiting manual completion, you can click the **Review** link to display a list of those transactions on the Transactions needing manual completion panel.

Data type	Integer
Default	0

Retry transactions

Specifies the number of transactions with some resources being retried.

If there are transactions with resources being retried, you can click the **Review** link to display a list of those transactions on the Transactions retrying resources panel.

Data type	Integer
Default	0

Heuristic transactions

Specifies the number of transactions that have completed heuristically.

If there are transactions that have completed heuristically, you can click the **Review** link to display a list of those transactions on the Transactions with heuristic outcome panel.

Data type	Integer
Default	0

Imported prepared transactions

Specifies the number of transactions that are imported and prepared but not yet committed.

If there are transactions that have been imported and prepared but not yet committed, you can click the **Review** link to display a list of those transactions on the Transactions imported and prepared panel.

Data type	Integer
Default	0

Transactions needing manual completion

Use this page to review transactions that need manual completion.

It is unusual for transactions to require manual completion. A transaction needs manual completion in the following circumstances:

1. An application was exploiting the last participant support to coordinate a single one-phase capable resource and one or more two-phase capable resources.

2. A failure occurred during the commit of the one-phase capable resource.
3. The transaction service heuristic completion direction is set to **Manual**, in the transaction service settings.

An administrator reviewing transactions in this state can review the actual outcome of any one-phase resources, using facilities provided by the specific resource manager, then use this page to complete the transaction accordingly.

To view this administrative console page, click **Servers** → **Application Servers** → [Content pane] *server_name* → **[Container Settings] Container Services** → **Transaction Service** → **Runtime** → **Manual transactions - Review**.

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, click the check boxes next to the transactions that you want to act on, then use the buttons provided.

Local ID

The local identifier of the transaction.

Global ID

The global identifier of the transaction.

Buttons

Commit

Heuristically commit the selected transactions.

Rollback

Heuristically roll back the selected transactions.

Transactions retrying resources

Use this page to review transactions with resources being retried.

If the transaction manager has prepared resources, but has lost contact with the resource managers before committing them or aborting them, then the transaction manager retries the commit or rollback requests to the affected resource managers. The number of times and frequency that the transaction manager retries such commit or rollback requests is configured on the **Heuristic retry limit** and **Heuristic retry wait** properties of the transaction service settings.

An administrator can use this page to make the transaction service abandon the retries of one or more transactions. If a resource manager cannot be contacted, WebSphere Application Server relegates that resource manager to an in-doubt (prepared) state. The administrator then needs to use mechanisms specific to the resource manager to resolve the in-doubt status.

WebSphere Application Server for z/OS can relegate the resource manager to an in-doubt (prepared) state *only if* the RRS transaction context is available.

To view this administrative console page, click **Servers** → **Application Servers** > [Content pane] *server_name* > **[Container Settings] Container Services** → **Transaction Service** → **Runtime** → **Retry transactions - Review**.

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, click the check boxes next to the transactions that you want to act on, then use the buttons provided.

Local ID

The local identifier of the transaction.

Status

The status of the transaction, shown as an integer value. The values correspond to the following status:

- 0 - active
- 1 - marked for rollback
- 2 - prepared
- 3 - committed
- 4 - rolled back
- 5 - unknown
- 6 - none
- 7 - preparing
- 8 - committing
- 9 - rolling back

Global ID

The global identifier of the transaction.

Buttons

Finish Abandon retrying resources for the selected transactions.

Transactions with heuristic outcome

Use this page to review transactions that completed with a heuristic outcome.

The page is provided for information purposes only. After you have reviewed the information in this page, then the only action required is to remove the transactions from the list. If you do not remove a transaction from the list, it is kept in the list for three days or until the server is shut down, whichever occurs first.

To view this administrative console page, click **Servers** → **Application Servers** [Content pane] *server_name* [Container Settings] **Container Services** → **Transaction Service** → **Runtime** → **Heuristic transactions - Review**.

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, click the check boxes next to the transactions that you want to act on, then use the buttons provided.

Local ID

The local identifier of the transaction.

Heuristic outcome

The outcome of the transaction.

Global ID

The global identifier of the transaction.

Buttons

Clear Remove the selected transactions from the list.

Transactions imported and prepared

Use this page to review transactions that have been imported and prepared but not yet committed.

Under normal circumstances no administrative action is required for any of the transactions listed on this page. This page lists those transactions that are in a prepared state, but are being directed by an external transaction manager (for example, another WebSphere application server) from a transaction context that has been propagated.

Under aberrant circumstances, however, an administrator can configure WebSphere Application Server to resolve the transactions listed on this page independent of the external transaction manager. (This step might be necessary if, for example, the external transaction manager has become unavailable for an unacceptable period of time.)

WebSphere Application Server for z/OS can resolve the transactions according to the selections made on this page *only if* the RRS transaction context is available.

Note: If the completion direction (commit or rollback) chosen administratively differs from the eventual direction of the external transaction manager, then the overall outcome of the transaction is not atomic and data corruption can result.

To view this administrative console page, click **Servers** → **Application Servers** [Content pane] *server_name* → **[Container Settings] Container Services** → **Transaction Service** → **Runtime** → **Imported prepared transactions - Review**.

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, click the check boxes next to the transactions that you want to act on, then use the buttons provided.

Local ID

The local identifier of the transaction.

Global ID

The global identifier of the transaction.

Buttons

Commit

Heuristically commit the selected transactions.

Rollback

Heuristically roll back the selected transactions.

Transaction resources

Use this page to review resources used by a transaction.

To view this administrative console page, click **Servers** → **Application Servers** [Content pane] *server_name* → **[Container Settings] Container Services** → **Transaction Service** → **Runtime** → *transaction_type local_ID*.

Where:

- *transaction_type* is one of:
 - **Manual transactions - Review**
 - **Retry transactions - Review**
 - **Heuristic transactions - Review**
 - **Imported prepared transactions - Review**
- *local_ID* is the local ID of the transaction (as an active link in the list of transactions).

The details displayed depend on the resource provider.

Configuring transaction properties for peer recovery

Peer recovery for the transaction service enables servers in a cluster to complete outstanding work for a failed cluster member. Follow the steps in this topic to configure the transaction properties that are required for peer recovery of failed application servers in a cluster.

Transaction peer recovery requires a common configuration of the resource providers between the participating server members in order to be able to perform peer recovery between servers. This means that peer recovery processing can only take place between members of the same server cluster. Although a cluster can contain servers that are at different versions of WebSphere Application Server, you must enable and configure high availability only if all servers in the cluster are at Version 6 or later.

Peer recovery of transactions is in addition to the support for Peer restart and recovery, which enables you to restart on a peer system in the sysplex. For more information about configuring peer restart and recovery, see [Setting up peer restart and recovery](#).

Configuring the transaction properties that are required for peer recovery is part of the overall task for configuring a cluster to use high availability support.

1. Configure the transaction log directory setting for each server in the cluster. You can configure the location of the transaction log directory using either the administrative console or commands. The configuration is stored in the `serverindex.xml` node-level configuration file.

Each server in the cluster must be able to access the log directories of other servers in the same cluster. For this reason, do not leave this setting unset. If you do not set a directory, the application server assumes a default location within the appropriate profile directory, which might not be accessible to other servers in the cluster.

The storage mechanism that is used to host recovery log files (for example, you can use IBM Network attached storage (NAS) and shared SCSI drives, but not simple network share) and access to that mechanism (for example, through a local area network (LAN)), must support the file-based force operation that is used by the recovery log service to force data to disk.

In addition, configure the mechanism by which the remote log files are accessed, to exploit any fault tolerance in the underlying file system. For example, by using the Network File System (NFS) and hard mounting the remote directory containing the log files using the `-o hard` option of the NFS mount command, the NFS client will retry a failed operation until the NFS server becomes available again.

For more information about configuring transaction log directories, see [Configuring transaction properties for an application server](#).

Note: If you have migrated from a previous version of WebSphere Application Server, be aware that previous versions stored the recovery log configuration in the `server.xml` server-level configuration file. If you run existing scripting that configures the original recovery log settings, or migrate Version 5 application servers to a later version of WebSphere Application Server, the original transaction log directory configuration in the `server.xml` file is updated. The administrative console detects this condition and prompts you to save the configuration when you view the transaction service panel. This save operation saves the changed configuration to the `serverindex.xml` file, and resets the older fields to null. Change your existing scripting to target the `serverindex.xml` file at the earliest opportunity. New scripting should also target the `serverindex.xml` file.

2. Enable the high availability function for the cluster, by completing the following steps on the cluster configuration panel of the WebSphere Application Server administrative console:
 - a. In the administrative console, click **Servers** → **Clusters** → *cluster_name*.
 - b. Select the **Enable failover of transaction log recovery** option.
 - c. Click **OK**.

For more information about enabling the high availability function for a cluster, see [Server cluster settings](#).

3. Decide which kind of transaction peer recovery to use by referring to “How to choose between automated and manual transaction peer recovery” on page 1902.
4. Perform one of the following actions, depending on the configuration that you require.
 - If you want to use automated peer recovery, follow the steps in “Configuring automated peer recovery for the transaction service” on page 1933.

- If you want to use manual peer recovery, configure a policy for the transaction service, as described in “Configuring manual peer recovery for the transaction service.”

Configuring manual peer recovery for the transaction service

Manual peer recovery processing is not the default setting; you must enable it through configuration. Administrator intervention is then required to trigger any peer recovery processing.

Perform this task if you want to use manual peer recovery for the transaction service. A scenario where you might want to use manual peer recovery is when your file system does not provide the required level of file locking support, and no constraints are in place to ensure that overloading or network partitioning does not occur. For more information, see “How to choose between automated and manual transaction peer recovery” on page 1902.

After you configure manual peer recovery, your intervention is required only when a server fails and cannot be restarted; in this case, use the administrative console to specify which peer server performs recovery processing for the failed server.

Manual peer recovery configuration is provided by a group of policies known as *static policies*, where one policy definition is provided per application server. Individual definitions are required to define server-specific configuration within the policy which, in this case, is the identity of the server that initiates a peer recovery process.

1. Create the required static policy definitions.
 - a. In the administrative console click **Servers** → **Core groups** → **Core group settings**. All the members of a cluster reside in a single core group, which by default is the DefaultCoreGroup core group. Click the core group that contains your cluster. The Core groups configuration panel is displayed.
 - b. Under **Additional Properties**, click **Policies**. The current set of policies is displayed. You can identify the current policy that applies to transactional high availability (HA) by the match criteria type = WAS_TRANSACTIONS. The default policy has a policy type of **One of N policy**. If this policy exists, you do not have to remove it because it is overridden by the static policy that you are creating.
 - c. Click **New** to create a new policy.
 - d. Select **Static policy** and click **Next**.
 - e. Provide a name for the policy. This value is a free-form text string that is used only as a label in the administrative console. However, to assist readability in the administrative console, use a name that associates the policy with a particular server, for example, TM-SERVER1 policy.
 - f. Enter a description if required, and click **OK**.
 - g. Set values for the **Is alive timer** and the **Quorum** options, if required.
 - h. Under **Additional Properties**, click **Match criteria** to open an empty match criteria panel.
 - i. Click **New** to create a new match criterion. Match criteria are key-value pairs that are used to define the scope of a policy.
 - j. Enter type in the **Name** field and WAS_TRANSACTIONS in the **Value** field. Click **OK**. This match criterion is used to associate the policy with the transaction service.
 - k. Click **New** to create a second new match criterion.
 - l. Enter GN_PS in the **Name** field and *cell_name\node_name\server_name* in the **Value** field, where *cell_name*, *node_name* and *server_name* are the names of your cell, node and server. For example, dmgrCell1\appnode1\server1. Click **OK**. This match criterion is used to associate the policy with a particular server.
 - m. Return to the configuration page for the new policy, and under **Additional Properties**, click **Static group servers**. The Static group servers panel is displayed. This panel lists all the servers in the core group and classifies them as either core group servers or static group servers.

- n. From the **Core group servers** list, select the server that is associated with the policy and click **Add >>** to move it to the **Static group servers** list. The static group servers list is the set of servers that attempts to own the recovery logs at the same time. Adding an incorrect server to this list can compromise data integrity. For normal operation, follow these rules to guarantee data integrity:
 - Add only one server to the list of static group servers. Adding two servers causes recovery log contention, because both servers attempt to own the associated recovery logs. The exception to this rule is adding a second server as part of manual peer recovery initiation. For more information, see “Managing manual peer recovery of the transaction service” on page 1935.
 - Add only the server that is associated with the policy to the list. Adding a different server prevents the home server from owning its recovery logs, and stops the home server from starting correctly.
2. Repeat the procedure in step 1 for each server in the cluster.
3. Save your changes to the master configuration, ensuring that you select the **Synchronize changes with Nodes** check box.
4. Stop and restart the cluster members for the changes to take effect.

Manual transaction peer recovery is configured for all the servers in the cluster. Automatic transaction peer recovery can no longer occur.

If a server fails, follow the instructions in “Managing manual peer recovery of the transaction service” on page 1935, to trigger recovery processing.

Configuring automated peer recovery for the transaction service

Configure automated peer recovery to enable cluster members to automatically complete outstanding work for a failed cluster member. After you have configured automated peer recovery, recovery processing occurs without any intervention on your part.

Make sure that you understand the infrastructure requirements for automatic peer recovery. For more information, see “How to choose between automated and manual transaction peer recovery” on page 1902 and “Disabling file locking” on page 1934.

Automated peer recovery processing is the default setting when high availability is enabled. Follow the steps in this topic to ensure that your system is configured correctly. If you configured manual peer recovery and want to return to automated peer recovery, you must reconfigure the system back to the default settings.

1. Verify that high availability is enabled, and that the location of the transaction recovery log is specified, as described in “Configuring transaction properties for peer recovery” on page 1930.
2. Remove any high availability (HA) policies with a policy type of `Static`. Such policies might exist if you previously configured the system for manual peer recovery.
 - a. In the administrative console click **Servers** → **Core groups** → **Core group settings**. All the members of a cluster reside in a single core group, which by default is the `DefaultCoreGroup` core group. Click the core group that contains your cluster. The Core groups configuration panel is displayed.
 - b. Under **Additional Properties**, click **Policies**. The current set of policies is displayed.
 - c. Select any policies with a **Policy type** of `Static`, and a **Match criteria** that includes `type = WAS_TRANSACTIONS`. Click **Delete**.
3. Check to see if the required One-of-N transaction HA policy already exists. This policy has a **Policy type** of `One-of-N`, and a **Match criteria** that includes `type = WAS_TRANSACTIONS`. If this policy already exists, you do not need to take any further action. If the policy does not already exist, create it according to the following substeps.
 - a. Click **New** to create a new policy.

- b. Select **One of N policy** and click **Next**.
- c. Provide a name for the policy. This value is a free-form text string that is used only as a label in the administrative console, however to assist readability in the administrative console, use a name that associates the policy with the required behavior, for example, Clustered TM policy.
- d. Enter a description, if required.
- e. Select the **Fail back** check box to ensure that a failed server reclaims its recovery log when it restarts, and click **OK**.
- f. Set values for the **Is alive timer**, **Quorum**, and **Preferred servers only** options, if required. See the contextual help for more information.
- g. Under **Additional Properties**, click **Match criteria** to open an empty Match criteria panel.
- h. Click **New** to create a new match criterion.
- i. Enter type in the **Name** field and WAS_TRANSACTION in the **Value** field. Click **OK**.
- j. Save your changes to the master configuration, ensuring that you select the **Synchronize changes with Nodes** check box.
- k. Stop and restart the cluster members for the changes to take effect.

Automated transaction peer recovery is configured for all the servers in the cluster. If a server fails, another server in the cluster will complete any outstanding work for the failed server.

Disabling file locking

If you use Network File System Version 3 (NFSv3) for storing transaction recovery logs, and you want to use automated peer recovery, you must first disable file locking.

If you choose to perform this task you must configure your system to prevent system overloading and network partitioning, as described in “How to choose between automated and manual transaction peer recovery” on page 1902. These situations can lead to the initiation of a peer recovery process for an active server.

Attention: If you do not take this precautionary step, data corruption can occur.

The following list contains some actions that you can take to prevent system overloading and network partitioning:

- Modify the core group heartbeat settings to change the amount of time after which WebSphere Application Server considers a server failed. For more information, see High availability manager.
- Ensure that your network is safe from network partitioning by, for example, installing backup network adapters.
- Modify the workload management throttling so that the server cannot be overloaded.

WebSphere Application Server obtains an exclusive lock on the physical recovery log files whenever it is instructed to perform recovery processing, and releases this lock when it is instructed to pass ownership of the logs to another server. Access to a recovery log is performed only when the exclusive lock is held.

NFSv3 supports exclusive file locks, but holds them on behalf of a failed host until that host can restart. In this context, the host is the physical machine running the application server that requests the lock and it is the restart of the host, not the application server, that eventually triggers the locks to release. See “How to choose between automated and manual transaction peer recovery” on page 1902 for more information.

To provide a more appropriate failover behavior, you can either use manual failover, and configure the system as described in “Configuring manual peer recovery for the transaction service” on page 1932, or you can disable the use of exclusive file locking.

1. In the administrative console, click **Servers** → **Application Servers** → *server_name* > [**Container Settings**] **Container Services** → **Transaction Service**.
2. Clear the **Enable file locking** check box.

3. Click **Apply** or **OK**.
4. Save your change to the master configuration.
5. Repeat the previous steps for every server in the cluster.
6. Restart the servers in the cluster for the changes to take effect.

Exclusive file locking is disabled for all the servers in the cluster.

Having taken steps to mitigate the risk to recovery log integrity when locking is disabled, you can tune the heartbeating parameters of the WebSphere Application Server high availability (HA) framework to change the conditions under which a server is considered failed. By considering the characteristics of applications, network, and peak workloads, determine an acceptable period of time after which the likelihood of an incorrectly diagnosed server failure is acceptably small.

A trade-off exists between reducing the risk of an incorrect diagnosis of server failure and increasing the time for automated failover and peer recovery to occur. By default, a server is considered failed after 20 heartbeats, with a 10-second frequency, are missed. These defaults are custom properties of the core group that you can modify.

Managing manual peer recovery of the transaction service

After you configure manual peer recovery, you trigger a recovery process by using the administrative console; peer recovery can no longer take place automatically. This requirement applies to transaction peer recovery processing only; standard recovery processing of server recovery logs, driven when the server starts, still occurs automatically.

Before you initiate the peer recovery process, verify that the problem server actually failed and cannot restart. To ensure data integrity, you must initiate a manual peer recovery process only for servers that are not running.

You usually direct a peer recovery process if an application server becomes unavailable for some reason, for example, a machine failure. The choice of peer server, within the cluster, is arbitrary.

1. In the administrative console click **Servers** → **Core groups** → **Core group settings**.
2. Click the core group that contains the failed server. The Core groups configuration panel is displayed.
3. Under **Additional Properties**, click **Policies**.
4. Click the static policy that is associated with the failed server. The Configuration settings for this policy are displayed.
5. Under **Additional Properties**, click **Static group servers**. The General Properties panel is displayed.
6. During normal running, the static group servers list must contain only the server that is associated with the policy. However, if you determine that the server failed, you can add a second server to perform the peer recovery processing. From the Core group servers list, select the server on which you want to initiate the peer recovery process. Ensure that you select an application server, rather than a system server such as the node agent or domain manager. Click **Add >>** to add the server to the static group servers list. Do not add more than one server.
7. Save your changes to the master configuration, ensuring that you select the **Synchronize changes with Nodes** check box. This step causes a recovery process for the failed server to begin on the peer server.
8. When recovery processing is complete, you must reverse the configuration changes that you made before restarting the failed server. Return to the Static group servers list, select the peer server that you added previously and click **Remove <<**. Click **OK**.
9. Save your changes to the master configuration, ensuring that you select the **Synchronize changes with Nodes** check box.

The server that you selected performed transaction peer recovery, completing any outstanding work for the failed server.

Verify that you have reversed the configuration changes that you made, then restart the failed server if required.

Managing active and prepared transactions

Use this task to manage active and prepared transactions that might need administrator action.

Under normal circumstances, every effort is made to finish a transaction. However, due to RRS and native contexts finishing, finishing the transaction may not be possible. In this case, the transaction is marked `rollback_only` so that it rolls back at the next available window. In other situations, you may need to finish a transaction manually. For example, you may want to finish a transaction that has become stuck polling a resource manager that you know will not become available again within the desired timeframe.

Note: If you choose to complete a transaction on an application server, it is recorded as having completed in the transaction service logs for that server, so will not be eligible for recovery during server start up. If you complete a transaction, you are responsible for cleaning up any in-doubt transactions on the resource managers affected.

You can use the administrative console to display a snapshot of all the transactions in an application server that are in the following states:

Manual transactions

Transactions awaiting administrative completion. For each transaction, the local id or global id is displayed. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to commit or rollback transactions in this state.

Retry transactions

Transactions with some resources being retried. For each transaction, the local id or global id is displayed, and whether the transaction is committing or rolling back. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to finish (abandon retrying) transactions in this state.

Heuristic transactions

Transactions that have completed heuristically. For each transaction, the local id or global id and the heuristic outcome is displayed. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to clear the transaction from the list.

Imported prepared transactions

Transactions that have been imported and prepared but not yet committed. For each transaction, the local id or global id is displayed. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to commit or rollback transactions in this state.

To manage the active and prepared transactions for an application server, use the administrative console to complete the following steps:

1. Display the Transaction Service runtime page for application server:
 - a. In the navigation pane, click **Servers-> Application Servers**
 - b. In the content pane, click the name of the application server
 - c. In the content pane, click the **Runtime** tab.
 - d. Under Additional Properties, click **Transaction Service**

This displays values for the runtime properties of the transaction service, including the number of transactions in the active and prepared states.

2. To display a snapshot of the transactions in a specific state, click **Review** in the field label.
3. **Optional:** If you want to display information about the resources associated with a transaction, click the name of the transaction.
4. **Optional:** If you want to act on a transaction, select the check box provided on the entry for the transaction, then click one of the buttons provided. Alternatively, to act on all transactions, select the check box in the header of the transactions table, then click a button.

Interoperating transactionally between application servers

This topic describes some considerations and actions that you can take to interoperate transactionally between different types of application servers.

WebSphere Application Server is a transaction manager that supports transactional interoperation with other transaction managers through either the CORBA Object Transaction Service (OTS) protocol or, for JSR-109 compliant requests, Web Service Atomic Transaction (WS-AtomicTransaction) protocol. This is in addition to its ability to coordinate XA resource managers and to be coordinated by J2EE Connector 1.5 resource adapters.

If you have enabled WebSphere Application Server security, you need to disable protocol security on servers at version 6.0.2 or later to be able to interoperate transactionally with servers at earlier versions.

To disable protocol security on a server, complete the following steps:

1. In the administrative console, click **Servers** → **Application Servers** → *server_name*[**Container Settings**] **Container Services** → **Transaction Service**
2. Clear the **Enable protocol security** check box.
3. Click **Apply** or **OK**.
4. Save your changes to the master configuration.
5. Restart the server.

Configuring an intermediary node for Web services transactions

Intermediary nodes allow the exchange of Web Services Atomic Transaction and Web Services Business Activity protocol messages across firewalls and outside the WebSphere Application Server domain. You configure an intermediary node to specify which WebSphere Application servers the node routes requests to.

1. Decide what type of intermediary node to configure: a Proxy Server for IBM WebSphere Application Server, an HTTP server, or both.
2. Perform one of the following steps, according to the choice you made in the previous step.
 - If you are creating an intermediary node that is a Proxy Server for IBM WebSphere Application Server, follow the instructions in *Setting up the proxy server and follow-on topics*, ensuring that you enable Web services support on the proxy server.
 - If you are creating an intermediary node that is an HTTP server, configure the node to communicate with the appropriate WebSphere Application Servers, as follows.
 - a. Allocate a set of unique virtual hosts to the HTTP server; one virtual host for each WebSphere Application Server that you want the HTTP server to communicate with.
 - b. In the HTTP server, map each virtual host to a WebSphere Application Server. For example, you might allocate a virtual host name of vhost1 to the HTTP server, then within the HTTP server, map vhost1 to a WebSphere Application Server called server1.
 - If you are using both a Proxy Server for IBM WebSphere Application Server and an HTTP server, perform the following steps.

- a. Follow the instructions in Setting up the proxy server and follow-on topics, ensuring that you enable Web services support on the proxy server.
- b. Configure the HTTP server to route all requests to the proxy server, as described in Routing requests from a plug-in to a proxy server.

You configured the intermediary node ready for use by WebSphere Application Server.

Configure WebSphere Application Server to use the intermediary node by specifying, for each server, the appropriate virtual host of the intermediary node. See “Enabling WebSphere Application Server to use an intermediary node for Web services transactions.”

Enabling WebSphere Application Server to use an intermediary node for Web services transactions

You can use intermediary nodes with Web Services Atomic Transactions or Web Services Business Activities to support the exchange of associated requests across firewalls and outside the WebSphere Application Server domain. You configure WebSphere Application Server to use an intermediary node by specifying the HTTP or HTTPS protocol prefix for the node, in each server that is accessed through the intermediary.

Configure the intermediary node that you want to use, and ensure that you know the address or addresses of the intermediary node that you want to map to servers in your WebSphere Application Server configuration.

1. In the administrative console, click **Servers** → **Application Servers** > *server_name* > **[Container Services] Transaction Service**.
2. Type the prefix for the intermediary node in the **HTTP proxy prefix** or **HTTPS proxy prefix** field. This prefix is the intermediary node address that maps to this server. The HTTPS prefix is used if WebSphere Application Server security is enabled and protocol security is enabled for the transaction service; otherwise the HTTP prefix is used.
If you are using an HTTP server to route messages through a Proxy Server for WebSphere Application Server, the prefix applies to the HTTP server.
3. Save your changes to the master configuration.
4. Repeat the previous steps for each server that is accessed through the intermediary node.
5. Restart the servers.

You configured your system to use an intermediary node. Test your configuration to ensure that messages are routed as you expect.

Configuring a server to use business activity support

Business activity support provides compensation for activities such as sending an e-mail, which can be difficult or impossible to roll back atomically. With this compensation, applications on disparate systems can coordinate activities that are more loosely coupled than atomic transactions. To use the business activity support you must first enable it on each server that you plan to use.

If you have an application component that uses the business activity support, you must enable the support on each server that runs the application.

1. In the administrative console, click **Servers** → **Application servers** > *server_name* > **[Container Settings] Container Services** → **Compensation Service**.
2. Select the **Enable service at server startup** check box.

3. If required, modify the compensation handler retry interval and limit. These values control the frequency with which the CompensationHandler handler compensate and close methods are retried, when either throw a RetryCompensationHandlerException exception, and the number of times that these methods are retried.
4. Save your changes to the master configuration.
5. Repeat the previous steps for each server that you plan to use.
6. Restart all the servers for the changes to take effect.

The business activity support is enabled for the application server. Verify a successful enablement by checking for the message, CWSCP0005I: The Compensation service started successfully. in the SystemOut.log file for the relevant server.

Deploy the business-activity-enabled application to the server.

Note: Applications can exploit the business activity support only if you deploy them to a WebSphere Application Server Version 6.1 server. Applications cannot use the business activity support if you deploy them to a cluster that includes WebSphere Application Server Version 6.0.x servers.

Compensation service settings

Use this page to manage the compensation service. The compensation service supports server-level configuration for compensation enablement and logging.

To view this administrative console page, click **Servers** → **Application servers** → *server_name* → **[Container Settings] Container services** → **Compensation service**.

Enable service at server startup

Specifies whether the application server attempts to start the compensation service when the server next starts up.

Default	Selected
Range	Selected When the application server starts, it attempts to start the compensation service automatically.
	Cleared The server does not try to start the compensation service. If compensation is used in applications that run on this server, the system administrator must start the service manually or select this property and then restart the server.

Recovery log directory

Specifies a directory path that, if set, overrides the location where the compensation service stores log files for recovery of this server.

A blank value in the server configuration is expanded by the compensation service at startup as the directory *profile_root/recoveryLogs/cell_name/node_name/server_name/compensation*. The variable *profile_root* is the home directory for the WebSphere Application Server profile used for the server.

When compensation is used, the WebSphere product stores information that is needed to perform compensation after a system failure on a physical storage device. In a higher application load, this persistence slows down performance of the application server due to its dependency on the operating system and the underlying storage systems.

To achieve better performance, move the compensation log files to a storage device with more physical disk drives, or preferably RAID disk drives. When the log files are moved to the file systems on the RAIDed

disks, the task of writing data to the physical media is shared across the multiple disk drives. This sharing provides more concurrent access to persist compensation information and faster access to that data from the logs. Depending upon the design of the application and storage subsystem, performance gains can range from 10% to 100%, or even more in some cases.

This change is applicable only to the configuration where the application has compensation configured. Consider setting this property when the application server shows one or more of following signs:

- CPU utilization remains low despite an increase in compensatable requests
- Transactions fail with several timeouts
- The server stops and needs to be restarted
- The disk on which the server is running shows higher use

Data type	String
Default	<i>profile_root/recoveryLogs/cell_name/node_name/ server_name/compensation</i>
Recommended	Where <i>profile_root</i> is the home directory for the WebSphere Application Server profile used for the server. Create a file system with at least 3 to 4 disk drives RAIDed together in a RAID-0 configuration. Create the compensation log on this file system with the default size. When the server is running under load, check the disk input and output. If the disk input and output time is more than 5%, consider adding more physical disks to lower the value. If the disk input and output is low, but the server load is still high, consider increasing the size of the log files.

Recovery Log File Size

Specifies the maximum megabyte size of the recovery log file that the compensation service uses for recovery data. The default value is 5 megabytes.

The amount of data logged by the compensation service is influenced by the number of concurrently-active applications that use compensation, and the size of the application data that is provided as input to the compensation logic.

The compensation service reserves space on a physical storage device at server start for compensation recovery data. If this size is not sufficient for active compensation data, then the log files grow dynamically until they reach the maximum size specified by this value.

Data type	Integer
Units	Megabytes
Default	5
Range	1 through 2147483647 megabytes

Although the allowed range for Recovery Log File Size is 1 through 2147483647, the maximum size that is actually possible depends on the maximum size allowed by the operating system for a mapped file.

Compensation handler retry limit

Specifies the maximum number of times that the compensation service retries a compensation handler.

This value specifies the number of times that the compensation service calls the `CompensationHandler` methods `compensate()` and `close()`.

Set this value to -1 to retry the `compensate()` and `close()` methods indefinitely. Set the value to 0 to never retry either method.

Data type	Integer
Default	-1
Range	-1 or above

Compensation handler retry interval

Specifies the time interval, in seconds, that the compensation service waits before retrying a compensation handler.

The compensation service retries a compensation handler by recalling the `CompensationHandler` methods `compensate()` and `close()` if either throws a `RetryCompensationHandlerException`.

Data type	Integer
Units	Seconds
Default	30
Range	0 or above

Chapter 20. Learn about WebSphere programming extensions

Use this section as a starting point to investigate the WebSphere programming model extensions for enhancing your application development and deployment.

See *Learn about WebSphere applications: Overview and new features* for a brief description of each WebSphere extension.

See the *Developing and deploying applications* PDF book for a brief description of each WebSphere extension.

In addition, now your applications can use the Eclipse extension framework. Your applications are extensible as soon as you define an extension point and provide the extension processing code for the extensible area of the application. You can also plug an application into another extensible application by defining an extension that adheres to the target extension point requirements. The extension point can find the newly added extension dynamically and the new function is seamlessly integrated in the existing application. It works on a cross Java 2 Platform, Enterprise Edition (J2EE) module basis.

The application extension registry uses the Eclipse plug-in descriptor format and application programming interfaces (APIs) as the standard extensibility mechanism for WebSphere applications. Developers that build WebSphere application modules can use WebSphere Application Server extensions to implement Eclipse tools and to provide plug-in modules to contribute functionality such as actions, tasks, menu items, and links at predefined extension points in the WebSphere application. Read the information about Application extension registry in the *Developing and deploying applications* PDF book.

ActivitySessions

Configuring the default ActivitySession timeout for an application server

Use this task to configure the default ActivitySession timeout for an application server, after which any started ActivitySessions are completed automatically by the ActivitySession service.

The ActivitySession timeout is used to reset any ActivitySession whose remote client has failed to complete the ActivitySession in a timely fashion. The initial default timeout can be configured separately for each application server, and can be overridden programmatically by the `setSessionTimeout` method of the `UserActivitySession` interface. If an ActivitySession that contains a transaction reaches the timeout, the transaction's timeout is accelerated so that it is timed out (and rolled back) immediately before the ActivitySession is reset.

To configure the default ActivitySession timeout for an application server, use the WebSphere Administrative console to complete the following steps:

1. Start the WebSphere Administrative console.
2. In the navigation pane, click **Servers** → **Application Servers** This displays a list of the application servers in the content pane.
3. In the Content pane, click the name of the application server that you want to configure. This displays the properties for the application server in the content pane.
4. Under Container Settings, click **Business Process Services** → **ActivitySession Service** This displays the ActivitySession service properties in the content pane.
5. Ensure that the **Enable service at server startup** check box is selected. You must enable the service for the timeout to have an effect.
6. Set the **ActivitySession timeout** property to the default timeout as an integer number of seconds.
 - -1 indicates that ActivitySessions never timeout

- 0 indicates that the default timeout, 300 seconds, applies
 - Other values are an integer number of seconds
7. Click **OK**.
 8. Save your changes to the master configuration.
 9. To have the changed configuration take effect, stop then restart the application server.

Related concepts

The ActivitySession service

The ActivitySession service provides an alternative unit-of-work (UOW) scope to that provided by global transaction contexts. An ActivitySession context can be longer-lived than a global transaction context and can encapsulate global transactions.

ActivitySession service settings

Use this page to configure the properties of the ActivitySession service. The ActivitySession service is a unit-of-work service to coordinate one-phase resources or to extend the activation and passivation of an enterprise bean.

To view this administrative console page, click **Servers** → **Application servers** → *server_name* → **[Container Settings] Business Process Services** → **ActivitySession service**.

Enable service at server startup:

Specifies whether the application server attempts to start the ActivitySession service when the server next starts up.

Default	Cleared
Range	<p>Cleared</p> <p>The server does not try to start the ActivitySession service. If ActivitySessions are to be used in applications that run on this server, the system administrator must select this property then restart the server.</p> <p>Selected</p> <p>When the application server starts, it attempts to start the ActivitySession service automatically.</p>

Default timeout:

Specifies the default timeout for an activity session. A server automatically completes an activity session if a remote client has failed to complete the activity session within this time period.

The initial default timeout can be configured separately for each application server, and can be overridden programmatically by the UserActivitySession interface (setSessionTimeout).

Data type	Integer
Units	Seconds
Default	300 (5 minutes)
Range	<p>-1 through 1000000000 seconds</p> <ul style="list-style-type: none"> • -1 indicates that ActivitySessions never timeout • 0 indicates that the default timeout applies • Other values are an integer number of seconds

Disabling or enabling the ActivitySession service

Use this task to disable or enable the ActivitySession service for an application server.

You can use the ActivitySession **Startup** property to specify whether or not the ActivitySession service is started automatically for an application server.

To disable or enable the ActivitySession service for an application server, use the Administrative console to configure the ActivitySession **Startup** property:

1. Start the Administrative console.
2. In the navigation pane, click **Servers** → **Application Servers** This displays a list of the application servers in the content pane.
3. In the Content pane, click the name of the application server that you want to configure. This displays the properties for the application server in the content pane.
4. Under Container Settings, click **Business Process Services** → **ActivitySession Service** This displays the ActivitySession service properties in the content pane.
5. Select or clear the **Startup** property as needed:

Selected

The ActivitySession service is started when the application server is started. This enables applications that specify use of ActivitySessions in their deployment descriptors to run on such an application server.

Cleared

[Default] The ActivitySession service is not started when the application server is started. Applications that specify use of ActivitySessions in their deployment descriptors cannot start on such an application server.

Any attempt to start an application that uses ActivitySessions is rejected and a message issued:

```
WACS0043E: Error found starting an application. application_name specified an ActivitySession attribute that is not allowed when the ActivitySession service is not enabled
```

If this happens during server startup, the server continues to start without the application.

6. Click **OK**.
7. Save your changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Application profiling

Task overview: Application profiling

You can use application profiling to configure multiple access intent policies on the same entity bean.

Application profiling reflects the fact that different units of work have different use patterns for enlisted entities and can require different kinds of support from the server runtime environment. For more information, see Application Profiling.

1. Assembling applications for application profiles. This topic describes how to configure tasks, create application profiles, and configure tasks on profiles.

2. Managing application profiles. This topic describes how to add and remove tasks from application profiles using the administrative console.
3. Using the TaskNameManager API. This topic describes how to programmatically set the current task name, but you should use this technique sparingly. Wherever possible, use the declarative method instead, which results in more portable function.

Application profiling

You can use application profiling to identify particular units of work to the WebSphere Application Server runtime environment. The run time can tailor its support to the exact requirements of that unit of work.

Access intent is currently the only runtime component that makes use of the application profiling functionality. For example, you can configure one transaction to load an entity bean with strong update locks and configure another transaction to load the same entity bean without locks.

Application profiling introduces two new concepts in order to achieve this function: *tasks* and *profiles*.

Tasks A task is a configurable name for a unit of work. *Unit of work* in this case means either a transaction or an ActivitySession. The task name is typically assigned declaratively on a J2EE component that can initiate a unit of work. Most commonly, the task is configured on a method of an Enterprise JavaBeans file that is declared either for container-managed transactions or bean-managed transactions. Any unit of work that begins in the scope of a configured task is associated with that task name. A unit of work can only be named when it is initiated, and the name cannot change for the lifetime of that unit of work. A unit of work ignores any subsequent task name configurations at any point after it has begun. The task is used for the duration of its unit of work to identify configured policies specific to that unit of work.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.x client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the *launchClient* command.

Profiles

A profile is simply a mapping of a task to a set of access intent policies that are configured on entity beans. When an invocation on a bean (whether by a finder method, a CMR getter, or a dynamic query) requires data to be retrieved from the back end system, the current task associated with the request is used to determine the exact requirement of the transaction. The same bean loads and behaves differently in the context of the task-to-profile mapping. Each profile provides the developer an opportunity to reconfigure the application's access intent. If a request is operating in the absence of a task, the runtime environment uses either a method-level access intent (if any) or a bean-level default access intent.

Note: The application profile configuration is application scope configuration data. If any Enterprise JavaBean (EJB) module contains an application profile configuration, all other EJB modules are implicitly regulated by the Application Profiling service even if they do not contain application profile configuration data.

For example, an application has two EJB modules: EJBModule1 and EJBModule2.

The EJBModule1 has an application profile named AppProfile1. This AppProfile1 is registered by a task named task1. This task1 becomes a *known-to-application task* and is

honored when associated with a unit of work within this application. With the presence of any known-to-application task, method level access intent configurations are ignored and only bean level access intent configurations are applied.

The EJBModule2 contains no application profile configuration data. All entity beans are **not** configured with bean level access intent explicitly, but some methods have method level access intent configurations. If an entity bean in the EJBModule2 is loaded in a unit of work that is associated with task1, the bean-level access intent configuration is applied and method level access intent configuration is ignored. Because the bean level access intent is not set explicitly, the default bean level access intent, which is wsPessimisticUpdate-WeakestLockAtLoad, is applied.

Tasks and units of work considerations:

The application profiling function works under the unit of work (UOW) concept. UOW in this case means either a transaction or an ActivitySession.

The task name on a method is used only when a UOW is begun, because of that method being invoked. This gives it a more predictable data access pattern based on the active unit of work. To be more specific, this approach ensures that a bean type with only one configured access intent is loaded within a UOW, because a bean is configured with only one access intent within an application profile. This configured access intent for a bean type is determined at assembly time and is enforced by the Application Profile service.

A task name is always associated with a unit of work, and that task name does not change for the duration of that UOW. When a UOW associated with a method is begun because of that method being invoked, if a task name is associated with the method then that task name is used to name the UOW. A task assigned to a unit of work is considered a named UOW.

If a task name is not associated with the method that began the UOW, then a default access intent is used and the UOW is unnamed. A unit of work can only be named when the UOW is begun and that task name remains for the life of the UOW. Furthermore, the task assigned to a UOW can never be changed for the life of that UOW. Any task names associated with a method are ignored if that method does not begin a UOW (either container managed or component managed).

It is not possible to change the task name assigned to a unit of work. However, it is possible that in a call sequence consisting of many different application calls a different task name might need to be used for different calls. In this case it is important for the deployer to begin a new UOW and associate with the UOW the necessary task name. For example, assume you have the following beans: sb1 is a session bean, eb2 and eb3 are container managed persistence (CMP) entity beans. When sb1 is called, a transaction is begun and task 't1' is associated with it. Further assume that sb1 then calls eb2 and eb3. If neither eb2 or eb3 create a unit of work, then these beans execute within the UOW context from sb1 and as such its task name (t1). If eb2 or eb3 need to execute within a task name other than t1, then these beans must define a unit of work and associate with it the appropriate task name.

Note that if an application deployer does not specifically configure a transaction on a method, WebSphere Application Server creates a global transaction by default. This is important because if a task is defined on a method, but a UOW is not specifically configured on that method, the EJB container automatically creates a global transaction on behalf of that method. As such, this task name is associated with the UOW and any application profiles mapped to this task are used.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on

requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

Application profiles:

An application profile is the set of access intent policies that should be selectively applied for a particular unit of work (a transaction or *ActivitySession*).

Application profiling enables applications to run under different sets of policies depending on the active task under which the application is operating.

The active task depends upon the current unit of work mechanism. If the current unit of work is a global transaction, then the task is the name associated with that transaction. If the global transaction was not named when it was initiated, then there is no active task anywhere in the scope of that transaction.

If the current unit of work is a local transaction associated with an *ActivitySession*, then the task is the name associated with that *ActivitySession*. If the *ActivitySession* was not named when it was initiated, then there is no active task for any local transaction bound to that *ActivitySession*. If the current unit of work is a local transaction that is not associated with an *ActivitySession*, then the task is the name associated with that local transaction. If the local transaction was not associated with a task when the local transaction was initiated, then there is no active task for the duration of that local transaction. In other words, the active task is the task associated with the unit of work on the thread that is coordinating database resources. If the controlling unit of work was not associated with a task when that unit of work was initiated, then there is no active task in the scope of that unit of work.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.x client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the *launchClient* command.

Consider an application that centralizes the student records for a school district. These records are frequently accessed by the school district's central office in order to generate reports. The report generation process would be optimized if it held no locks with the back end system, and if the records could be read into memory with as few back end operations as possible. Occasionally, however, the records are updated by the students' instructors. Without the ability to distinguish between transactions, the developer is forced to assume a worst-case scenario and, wishing to use pessimistic concurrency, lock the records for all transactions.

Using the application profiling service, the developer can configure in as many ways as necessary the access intent under which the students' records are loaded. Under one profile, the records can be configured with an exclusive pessimistic update intent, not only locking-out competing transactions but ensuring that the student is not removed from the system before the transaction completes. Under another profile, the records can be configured with an optimistic intent as part of an object graph that is read from the back end system in a single database operation. The task represented by the pessimistic profile receives the strong-locking semantics required for certain transactions, while the task represented by the optimistic profile receives the performance benefits appropriate for other transactions.

Application profiling performance considerations:

Application profiling enables assembly configuration techniques that improve your application run time, performance and scalability. You can configure tasks that identify incoming requests, identify access intents determining concurrency and other data access characteristics, and profiles that map the tasks to the access intents.

The capability to configure the application server can improve performance, efficiency and scalability, while reducing development and maintenance costs. The application profiling service has no tuning parameters, other than a checkbox for disabling the service if the service is not necessary. However, the overhead for the application profile service is small and should not be disabled, or unpredictable results can occur.

Access intents enable you to specify data access characteristics. The WebSphere runtime environment uses these hints to optimize the access to the data, by setting the appropriate isolation level and concurrency. Various access intent hints can be grouped together in an access intent policy.

In WebSphere Application Server, it is recommended that you configure bean level access intent for loading a given bean. Application profiling enables you to configure multiple access intent policies on the entity bean, if desired. Some callers can load a bean with the intent to read data, while others can load the bean for update. The capability to configure the application server can improve performance, efficiency, and scalability, while reducing development and maintenance costs.

Access intents enable the EJB container to be configured providing optimal performance based on the specific type of enterprise bean used. Various access intent hints can be specified declaratively at deployment time to indicate to WebSphere resources, such as the container and persistence manager, to provide the appropriate access intent services for every EJB request.

The application profiling service improves overall entity bean performance and throughput by fine tuning the run time behavior. The application profiling service enables EJB optimizations to be customized for multiple user access patterns without resorting to "worst case" choices, such as pessimistic update on a bean accessed with the `findByPrimaryKey` method, regardless of whether the client needs it for read or for an update.

Application profiling provides the capability to define the following hierarchy: **Container-Managed Tasks > Application Profiles > Access Intent Policies > Access Intent Overrides**. Container-managed tasks identify units of work (UOW) and are associated with a method or a set of methods. When a method associated with the task is invoked, the task name is propagated with the request. For example, a UOW refers to a unique path within the application that can correspond to a transaction or `ActivitySession`. The name of the task is assigned declaratively to a J2EE client or servlet, or to the method of an enterprise bean. The task name identifies the starting point of a call graph or subgraph; the task name flows from the starting point of the graph downstream on all subsequent IOP requests, identifying each subsequent invocation along the graph as belonging to the configured task. As a best practice, wherever a UOW starts, for example, a transaction or an `ActivitySession`, assign a task to that starting point.

The application profile service associates the propagated tasks with access intent policies. When a bean is loaded and data is retrieved, the characteristics used for the retrieval of the data are dictated by the application profile. The application profile configures the access intent policy and the overrides that should be used to access data for a specific task.

Access intent policies determine how beans are loaded for specific tasks and how data is accessed during the transaction. The access intent policy is a named group of access intent hints. The hints can be used, depending on the characteristics of the database and resource manager. Various access intent hints applied to the data access operation govern data integrity. The general rule is, the more data integrity, the more overhead. More overhead causes lower throughput and the opportunity for simultaneous data access from multiple clients.

If specified, access intent overrides provide further configuration for the access intent policy.

Best practices

Application profiling is effective in a variety of different scenarios. The following are example situations where application profiling is useful

- **The same bean is loaded with different data access patterns**

The same bean or set of beans can be reused across applications, but each of those applications has differing requirements for the bean or for beans within the invocation graph. One application can require that beans be loaded for update, while another application requires beans be loaded for read only. Application profiling enables deploy time configuration for beans to distinguish between EJB loading requirements.

- **Different clients have different data access requirements**

The same bean or set of beans can be used for different types of client requests. When those clients have different requirements for the bean, or for beans within the invocation graph, application profiling can be used to tailor the bean loading characteristics to the requirements of the client. One client can require beans be loaded for update, while another client requires beans be loaded for read only. Application profiling enables deploy time configuration for beans to distinguish between EJB loading requirements.

Monitoring tools

You can use the Tivoli Performance Viewer, database and logs as monitoring tools.

You can use the Tivoli Performance Viewer to monitor various metrics associated with beans in an application profiling configuration. The following sections describe at a high level the Tivoli Performance Viewer metrics that reflect changes when access intents and application profiling are used:

- **Collection scope**

The enterprise beans group contains EJB life cycle information, either a cumulative value for a group of beans, or for specific beans. You can monitor this information to determine the difference between using the ActivitySession scope versus the transaction scope. For the transaction scope, depending on how the container transactions are defined, activates and passivates can be associated with method invocations. The application could use the ActivitySession scope to reduce the frequency of activates and passivates. For more information, see "Using the ActivitySession service."

- **Collection increment**

The enterprise beans group contains EJB life cycle information, either a cumulative value for a group of beans, or for specific beans. You can monitor *Num Activates* to watch the number of enterprise beans activated for a particular findByPrimaryKey operation. For example, if the collection increment is set to 10, rather than the default 25, the *Num Activates* value shows 25 for the initial findByPrimaryKey, before any result set iterator runs. If the number of activates rarely exceeds the collection increment, consider reducing the collection increment setting.

- **Resource manager prefetch increment**

The resource manager prefetch increment is a hint acted upon by the database engine to depend upon the database. The Tivoli Performance Viewer does not have a metric available to show the effect of the resource manager prefetch increment setting.

- **Read ahead hint**

The enterprise beans group contains EJB life cycle information, either a cumulative value for a group of beans, or for specific beans. You can monitor *Num Activates* to watch the number of enterprise beans activated for a particular request. If a read ahead association is not in use, the *Num Activates* value shows a lower initial number. If a read ahead association is in use, the *Num Activates* value represents the number of activates for the entire call graph.

Database tools are helpful in monitoring the different bean loading characteristics that introduce contention and concurrency issues. These issues can be solved by application profiling, or can be made worse by the misapplication of access intent policies.

Database tools are useful for monitoring locking and contention characteristics, such as locks, deadlocks and connections open. For example, for locks the DB2 Snapshot Monitor can show statistics for lock waits, lock time-outs and lock escalations. If excessive lock waits and time-outs are occurring, application profiling can define specific client tasks that require a more string level of locking, and other client tasks that do not require locking. Or, a different access intent policy with less restrictive locking could be applied. After applying this configuration change, the snapshot monitor shows less locking behavior. Refer to information about the database you are using on how to monitor for locking and contention.

The **application server logs** can be monitored for information about rollbacks, deadlocks, and other data access or transaction characteristics that can degrade performance or cause the application to fail.

Application profiling tasks

Tasks are named units of work. They are the mechanism by which the runtime environment determines which access intent policies to apply when an entity bean's data is loaded from the back end system.

Application profiles enable developers to configure an entity bean with multiple access intent policies; if there are n instances of profiles in a given application, each bean can be configured with as many as n access intent policies.

A task is associated with a transaction or an ActivitySession at the initiation of the unit of work. The task, which cannot change for the lifetime of the unit of work, is always available anywhere within the scope of that unit of work to apply the access intent policy configured for that particular unit of work.

If an enterprise application is configured to use application profiling in any part of the application, then application profiling is active and method-level access intent configurations are ignored when units of works are associated with known-to-application tasks.

If an entity bean is loaded in a unit of work that is not associated with a task, or is associated with a task that is unassociated with an application profile, the default bean-level access intent or the method-level access intent configuration is applied. If a unit of work is associated with a task that is configured with an application profile, the bean-level access intent configuration within the appropriate application profile is applied.

Note: The application profile configuration is application scope configuration data. If any enterprise Javabeen (EJB) module contains an application profile configuration, all other EJB modules are implicitly regulated by the Application Profiling service even if they do not contain application profile configuration data.

For example, an application has two EJB modules: EJBModule1 and EJBModule2.

The EJBModule1 has an application profile named AppProfile1. This AppProfile1 is registered by a task named task1. This task1 becomes a *known-to-application task* and is honored when associated with a unit of work within this application. With the presence of any known-to-application task, method level access intent configurations are ignored and only bean level access intent configurations are applied.

The EJBModule2 contains no application profile configuration data. All entity beans are **not** configured with bean level access intent explicitly, but some methods have method level access intent configurations. If an entity bean in the EJBModule2 is loaded in a unit of work that is associated with task1, the bean-level access intent configuration is applied and method level access intent configuration is ignored. Because the bean level access intent is not set explicitly, the default bean level access intent, which is wsPessimisticUpdate-WeakestLockAtLoad, is applied.

The active task depends upon the current unit of work mechanism. If the current unit of work is a global transaction, then the task is the name associated with that transaction. If the global transaction was not named when it was initiated, then there is no active task anywhere in the scope of that transaction.

If the current unit of work is a local transaction associated with an `ActivitySession`, then the task is the name associated with that `ActivitySession`. If the `ActivitySession` was not named when it was initiated, then there is no active task for any local transaction bound to that `ActivitySession`. If the current unit of work is a local transaction that is not associated with an `ActivitySession`, then the task is the name associated with that local transaction. If the local transaction was not associated with a task when the local transaction was initiated, then there is no active task for the duration of that local transaction. In other words, the active task is the task associated with the unit of work on the thread that is coordinating database resources. If the controlling unit of work was not associated with a task when that unit of work was initiated, then there is no active task in the scope of that unit of work.

For example, consider a school district application that calls through a session bean in order to interact with student records. One method on the session bean allows administrators to modify the students' records; another method supports student requests to view their own records. Without application profiling, the two tasks would operate anonymously and the runtime environment would be unable to distinguish work operating on behalf of one task or the other. To optimize the application, a developer can configure one of the methods on the session bean with the task "updateRecords" and the other method on the session bean with the task "readRecords". When registered with an application profile that has the student bean configured with the appropriate locking access intent, the "updateRecords" task is assured that it is not unnecessarily blocking transactions that need to only read the records. For more information about the relationships between tasks and units of work, see "Tasks and units of work considerations" on page 1947.

Tasks can be configured to be managed by the container or to be programmatically established by the application. Container managed tasks can be configured on servlets, JavaServer Pages (JSP) files, application clients, and the methods of Enterprise JavaBeans (EJB). Configured container-managed tasks are only associated with units of work that the container initiates after the task name is set. Application managed tasks can be configured on all J2EE components. In the case of enterprise beans they must be bean managed transactions."

best-practices: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.x client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the `appprofileCompatibility` system property to `true` in the client process. You can do this by specifying the `-CCDappprofileCompatibility=true` option when invoking the `launchClient` command.

Application profiling interoperability

Using application profiling with 5.x compatibility mode or in a clustered environment with mixed WebSphere Application Server product versions and mixed platforms can affect its behavior in different ways.

The effect of 5.x Compatibility Mode

Application profiling supports *forward* compatibility. Application profiles created in previous versions of WebSphere Application Server (Enterprise Edition 5.0 or WebSphere Business Integration Server Foundation 5.1) can only run in WebSphere Application Server Version 6 or later if the Application Profiling 5.x Compatibility Mode attribute is turned on. If the 5.x Compatibility Mode attribute is off, Version 5 application profiles might display unexpected behavior.

Similarly, application profiles that you create using the latest version of WebSphere Application Server are not compatible with Version 5 or earlier versions. Even applications configured with application profiles run

on Version 6.x servers with the Application Profiling 5.x Compatibility Mode attribute turned on cannot interact with applications configured with profiles run on Version 5 servers.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.x client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to **true** in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the *launchClient* command.

Considerations for a clustered environment

In a clustered environment with mixed WebSphere Application Server product versions and mixed platforms, applications configured with application profiles might exhibit unexpected behavior because previous versions of server members cannot support the application profiling of Version 6.x.

If a clustered environment contains both Version 5.x and 6.x server members, and if any applications are configured with application profiles, the Application Profiling 5.x Compatibility Mode attribute must be turned on in Version 6 server members. Still, this cluster can only support Version 5 application profiling behavior. To support applications configured with Version 6 application profiles in a cluster environment, all server members in the cluster must be at the Version 6.x level.

WebSphere Application Server Enterprise Edition Version 5.0.2

If you use WebSphere Application Server Enterprise Edition 5.0.2, you must apply WebSphere Application Server Version 5 service pack 7 or later service pack to enable Application Profiling interoperability.

Managing application profiles

Using the administrative console, you can add tasks to or remove tasks from application profiles.

1. Start the administrative console.
2. Select **Applications > Enterprise Applications > application_name > Application Profiles > profile_name > Tasks**.
3. On the Tasks collection page, you can add new tasks to the profile, delete tasks, edit current task settings, and so on.

Note that, within the scope of an application, no task can be configured on more than one application profile. In such a situation, your application cannot be restarted until you correct the configuration.

4. Save your configuration.
5. Restart the application in order for your changes to take effect.

Using the TaskNameManager interface

Using the TaskNameManager interface, you can programmatically set the current task name. It enables both overriding of the current task associated with the thread of execution and resetting of the current task with the original task.

Except for J2EE 1.3 applications that are running on a server where the 5.x Compatibility Mode attribute is selected, this interface cannot be used within Enterprise JavaBeans that are configured for container-managed transactions or container-managed ActivitySessions because units of work can only be associated with a task at the exact time that the unit of work is initiated. The call to set the task name must therefore be invoked before the unit of work is begun. Units of work cannot be named after they are begun. Calls on this interface during the execution of a container-managed unit of work are simply ignored.

Application profiling does not support queries of the task that is in operation at run time. Instead, applications interact with logical task names that are declaratively configured as application managed tasks. Logical references enable the actual task name to be changed without having to recompile applications.

Wherever possible, avoid setting tasks programmatically. The declarative method results in more portable function that can be easily adjusted without requiring redevelopment and recompilation.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the *launchClient* command.

1. Configure application-managed tasks. Application profiling requires that a task name reference be declared for any task that is to be set programmatically. Task name references introduce a level of indirection so that the actual task set at run time can be adjusted by reassembly without requiring recoding or recompilation. Any attempt to set a task name that is undeclared as a task reference results in the raising of an exception. If a unit of work has already begun when a task name is set, then that existing unit of work is not associated with the task name. Only units of work that are begun after the task name is set are associated with the task.

Configure application-managed tasks as described in the following topics:

- Configuring application managed tasks for web components.
- Configuring application managed tasks for application clients.
- Configuring application managed tasks for Enterprise JavaBeans.

2. Perform a Java Naming and Directory Interface (JNDI) lookup on the *TaskNameManager* interface:

```
InitialContext ic = new InitialContext();
TaskNameManager tnManager = ic.lookup
("java:comp/websphere/AppProfile/TaskNameManager");
```

The *TaskNameManager* interface is not bound into the namespace if the application profiling service is disabled.

3. Set the task name:

```
try {
tnManager.setTaskName("updateAccount");
}
catch (IllegalTaskNameException e) {
// task name reference not configured. Handle error.
}
// . . .
//
```

The name passed to the *setTaskName()* method ("updateAccount" in this example) is actually a task name reference that you configured in step one.

4. Begin a *UserTransaction*

Note: If you are using a J2EE 1.3 application with the 5.x Compatibility mode set, the task name set in step 3 is now the active task name and you can disregard this step.

If you are using a J2EE application and the compatibility mode is not set, or if you are using a J2EE 1.4 application, you must begin a transaction for the task name to become active. A task name can

only be associated with a transaction. Furthermore, it is associated with a transaction when that transaction is begun, and that task name is associated with the transaction for the life of the transaction. Therefore, the task name set above is not active at this point. You must begin a `UserTransaction` as the following code snippet illustrates:

```
try{
    InitialContext initCtx = new InitialContext();
    userTran = (UserTransaction) initCtx.lookup("java:comp/UserTransaction");
    userTran.begin();
}
catch(Exception e){
}
// . . .
//
```

Notice the `resetTaskName()` method on the `TaskNameManager` interface. Resetting the task name has no effect unless called by a J2EE 1.3 application running on a server for which the 5.x Compatibility Mode attribute is selected on the Application Profile Service's console page. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. A call to `resetTask()` should only be used by J2EE 1.3 applications when the 5.x Compatibility mode is set to undo the effects of any `setTaskName()` method operations and reestablish whatever task name was current when the component began execution. If the `setTaskName()` method has not been called, the `resetTaskName()` method has no effect.

TaskNameManager interface:

The `TaskNameManager` is the programmatic interface to the application profiling function. Because on rare occasions it may be necessary to programmatically set the current task name, the `TaskNameManager` interface enables both overriding of the current task associated with the thread of execution and resetting of the current task with the original task.

Application profiling enables you to identify particular units of work to the WebSphere Application Server runtime environment. The run time can tailor its support to the exact requirements of that unit of work. Access intent is currently the only runtime component that makes use of the application profiling functionality. For example, you can configure one transaction to load an entity bean with strong update locks and configure another transaction to load the same entity bean without locks.

Application profiling introduces two concepts in order to achieve this function: tasks and profiles.

A *task* is a configurable name for a unit of work. *Unit of work* in this case means either a transaction or an `ActivitySession`.

A *profile* is simply a mapping of a task to a set of access intent policies that are configured on entity beans. When an invocation on a bean (whether by a finder method, a container managed relationship (CMR) getter, or a dynamic query) requires data to be retrieved from the back end system, the task of the active unit of work associated with the request is used to determine the exact requirement of the transaction. The same bean loads and behaves differently in the context of the task-to-profile mapping. Each profile provides the developer an opportunity to reconfigure the application's access intent.

Except for J2EE 1.3 applications that are executing on a server where the *5.x Compatibility Mode* attribute is selected, this interface cannot be used within Enterprise JavaBeans that are configured for container-managed transactions or container-managed `ActivitySessions` because units of work can only be associated with a task at the exact time that the unit of work is initiated. The call to set the task name must therefore be started before the unit of work is begun. Units of work cannot be named after they are begun. Calls on this interface during the execution of a container-managed unit of work are simply ignored.

The `TaskNameManager` interface is available to all J2EE components using the following Java Naming and Directory Interface (JNDI) lookup:

```

java:comp/websphere/AppProfile/TaskNameManager
package com.ibm.websphere.appprofile;

/**
 * The TaskNameManager is the programmatic interface
 * to the application profiling function. Using this interface,
 * programmers can set the current task name on the
 * thread of execution. The task name must have been
 * configured in the deployment descriptors as a task
 * reference associated with a task. The set task
 * name's scope is the duration of the method
 * invocation in the EJB and Web components and for
 * the duration of the client process, or until the
 * resetTaskName() method is invoked.
 */
public interface TaskNameManager {

/**
 * Set the thread's current task name to the specified
 * parameter. The task name must have been configured as
 * a task reference with a corresponding task or the
 * IllegalArgumentException exception is thrown.
 */
public void setTaskName(String taskName) throws IllegalArgumentException;

/**
 * Sets the thread's task name to the value that was set
 * at, or imported into, the beginning of the method
 * invocation (for EJB and Web components) or process
 * (for J2EE clients).
 */
public void resetTaskName();

}

```

Application profiling exceptions

The following exceptions are thrown in response to various illegal actions related to application profiling.

com.ibm.ws.exception.RuntimeWarning

This exception is thrown when the application is started, if the application is configured incorrectly.

The startup is consequently terminated. Some examples of bad configurations include:

- A task configured on two different application profiles.
- A method configured with two different task run-as policies .

com.ibm.websphere.appprofile.IllegalTaskNameException

This exception is raised if an application attempts to programmatically set a task when that task has not been configured as a task name reference.

Application profiling service settings

Use this page to enable or disable the application profiling service.

Applications that are configured to use the application profiling service do not start successfully unless the application profiling service is enabled.

To view this administrative console page, click **Servers > Application Servers > server_name > Container Services > Application Profiling Service**.

Enable service at server startup:

Specifies whether the server attempts to start the application profiling service.

Default

Selected

Range**Selected**

When the application server starts, it attempts to start the application profiling service automatically.

Cleared

The application profiling service is not enabled when an application server starts. Applications configured with application profiling cannot be started on servers that do not enable the application profiling service.

5.x Compatibility Mode:

When selected, J2EE 1.3 applications that use application profiling execute exactly as they did in the 5.x releases of WebSphere Application Server.

For a Version 6.x client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the *launchClient* command.

Operation in this mode can lead to unexpected deadlocks during database access. Also, tasks do not propagate on remote invocations between J2EE 1.3 and J2EE 1.4 applications, possibly resulting in the use of unexpected access intent policies. This mode also results in performance degradation if applications configured with application profiling are installed on the server.

Support for J2EE 1.3 applications operating with 5.x Compatibility Mode = true is deprecated as of WebSphere Application Server Version 6.x. When cleared, J2EE 1.3 applications that use application profiling execute with the same constraints as J2EE 1.4 applications. In this mode, tasks are established only when a new unit of work begins. This means the complete unit of work executes under at most one task.

Default Range**Selected****Selected**

J2EE 1.3 applications that are dependent on the behavior of application profiling service for Version 5.x can run with the same behavior in Version 6.0.

Cleared

Tasks are established only when a new global unit of work begins.

Application profile collection

Use this page to view application profiles and manage tasks associated with application profiles.

An application profile is a set of policies that are to be applied during the execution of an enterprise bean and a set of tasks that are associated with that profile. Mapping tasks to application profiles will control which access intent policies are applied at run time for the units of work that correspond to a particular task.

You can use an assembly tool such as Application Server Toolkit (AST) or Rational Application Developer to add or delete application profiles. The AST is shipped with WebSphere Application Server version 6.x.

To view this administrative console page, click **Applications > Enterprise Applications > application_name > Application Profiles**.

Name:

The name of the application profile.

The name must be unique; multiple profiles cannot share the same name.

Data type String

Description:

A description of the application profile.

Data type String

Application profile settings:

Use this page to modify application profile settings.

To view this administrative console page, click **Applications > Enterprise Applications > application_name > Application Profiles > application_profile_name**.

Name:

The name of the application profile.

The name must be unique; multiple profiles cannot share the same name.

Data type String

Description:

A description of the application profile.

Data type String

Task collection:

Use this page to manage tasks.

Requests associated with any of the configured tasks operate under the access-intent policies that are configured with the profile. A task can be configured on only *one* application profile.

To view this administrative console page, click **Applications > Enterprise Applications > application_name > Application Profiles > application_profile_name > Tasks**.

Name:

The name of the task.

The task name must be unique among the set of application profiles.

Data type String

Description:

A description of the task.

Data type String

Task settings:

Use this page to modify task settings.

To view this administrative console page, click **Applications > Enterprise Applications > application_name > Application Profiles > application_profile_name > Tasks > task_name**.

Name:

The name of the task.

The task name must be unique among the set of application profiles.

Data type String

Description:

A description of the task.

Asynchronous beans

Using asynchronous beans

The asynchronous beans feature adds a new set of APIs that enable Java 2 Platform Enterprise Edition J2EE applications to run asynchronously inside an Integration Server.

This topic provides a brief overview of the tasks involved in using asynchronous beans. For a more detailed description of the asynchronous beans model, review the conceptual topic *Asynchronous beans*. For detailed information on the programming model for supported asynchronous beans interfaces, see the topic *Work managers*.

1. Configure work managers.
2. Configure timer managers.
3. Assemble applications that use asynchronous beans work managers.
4. Develop work objects to run code in parallel.
5. Develop event listeners.
6. Develop asynchronous scopes.

Asynchronous beans

An asynchronous bean is a Java object or enterprise bean that can run asynchronously by a Java 2 Platform Enterprise Edition (J2EE) application, using the J2EE context of the asynchronous bean creator.

Asynchronous beans can improve performance by enabling a J2EE program to decompose operations into parallel tasks. Asynchronous beans support the construction of stateful, active J2EE applications. These applications address a segment of the application space that J2EE has not previously addressed (that is, advanced applications that require application threading, active agents within a server application, or distributed monitoring capabilities).

Asynchronous beans can run using the J2EE security context of the creator J2EE component. These beans also can run with copies of other J2EE contexts, such as:

- Internationalization context
- Application profiles, which are not supported for J2EE 1.4 applications and deprecated for J2EE 1.3 applications
- Work areas

Asynchronous bean interfaces

Four types of asynchronous beans exist:

Work object

There are two work interfaces that essentially accomplish the same goal. The legacy Asynchronous Beans work interface is `com.ibm.websphere.asynchbeans.Work`, and the CommonJ work interface is `commonj.work.Work`. A work object runs parallel to its caller using the work manager `startWork` or `schedule` method (`startWork` for legacy Asynchronous Beans and `schedule` for CommonJ). Applications implement work objects to run code blocks asynchronously. For more information on the Work interface, see the API documentation.

Timer listener

This interface is an object that implements the `commonj.timers.TimerListener` interface. Timer listeners are called when a high-speed transient timer expires. For more information on the TimerListener interface, see the API documentation.

Alarm listener

An alarm listener is an object that implements the `com.ibm.websphere.asynchbeans.AlarmListener` interface. Alarm listeners are called when a high-speed transient alarm expires. For more information on the AlarmListener interface, see the API documentation.

Event listener

An event listener can implement any interface. An event listener is a lightweight, asynchronous notification mechanism for asynchronous events within a single Java virtual machine (JVM). An event listener typically enables J2EE components within a single application to notify each other about various asynchronous events.

Supporting interfaces

Work manager

Work managers are thread pools that administrators create for J2EE applications. The administrator specifies the properties of the thread pool and a policy that determines which J2EE contexts the asynchronous bean inherits.

CommonJ Work manager

The CommonJ work manager is similar to the work manager. The difference between the two is that the CommonJ work manager contains a subset of the asynchronous beans work manager methods. Although CommonJ work manager functions in a J2EE 1.4 environment, each JNDI lookup of a work manager does not return a new instance of the `WorkManager`. All the JNDI lookup of work managers within a scope have the same instance.

Timer manager

Timer managers implement the `commonj.timers.TimerManager` interface, which enables J2EE applications, including servlets, EJB applications, and JCA Resource Adapters, to schedule future timer notifications and receive timer notifications. The timer manager for Application Servers specification provides an application-server supported alternative to using the J2SE `java.util.Timer` class, which is inappropriate for managed environments.

Event source

An event source implements the `com.ibm.websphere.asynchbeans.EventSource` interface. An event source is a system-provided object that supports a generic, type-safe asynchronous notification server within a single JVM. The event source enables event listener objects, which implement any interface to be registered. For more information on the EventSource interface, see the API documentation.

Event source events

Every event source can generate its own events, such as listener count changed. An application

can register an event listener object that implements the class `com.ibm.websphere.asynchbeans.EventSourceEvents`. This action enables the application to catch events such as listeners being added or removed, or a listener throwing an unexpected exception. For more information on the `EventSourceEvents` class, see the API documentation.

Additional interfaces, including alarms and subsystem monitors, are introduced in the topic *Developing Asynchronous scopes*, which discusses some of the advanced applications of asynchronous beans.

Transactions

Every asynchronous bean method is called using its own transaction, much like container-managed transactions in typical enterprise beans. It is very similar to the situation when an Enterprise Java Beans (EJB) method is called with `TX_NOT_SUPPORTED`. The runtime starts a local transaction before invoking the method. The asynchronous bean method is free to start its own global transaction if this transaction is possible for the calling J2EE component. For example, if an enterprise bean creates the component, the method that creates the asynchronous bean must be `TX_BEAN_MANAGED`.

When you call an entity bean from within an asynchronous bean, for example, you must have a global transactional context available on the current thread. Because asynchronous bean objects start local transactional contexts, you can encapsulate all entity bean logic in a session bean that has a method marked as `TX_REQUIRES` or equivalent. This process establishes a global transactional context from which you can access one or more entity bean methods.

If the asynchronous bean method throws an exception, any local transactions are rolled back. If the method returns normally, any incomplete local transactions are completed according to the unresolved action policy configured for the bean. EJB methods can configure this policy using their deployment descriptor. If the asynchronous bean method starts its own global transaction and does not commit this global transaction, the transaction is rolled back when the method returns.

Access to J2EE component metadata

If an asynchronous bean is a J2EE component, such as a session bean, its own metadata is active when a method is called. If an asynchronous bean is a simple Java object, the J2EE component metadata of the creating component is available to the bean. Like its creator, the asynchronous bean can look up the `java:comp` namespace. This look up enables the bean to access connection factories and enterprise beans, just as it would if it were any other J2EE component. The environment properties of the creating component also are available to the asynchronous bean.

The `java:comp` namespace is identical to the one available for the creating component; the same restrictions apply. For example, if the enterprise bean or servlet has an EJB reference of `java:comp/env/ejb/MyEJB`, this EJB reference is available to the asynchronous bean. In addition, all of the connection factories use the same resource-sharing scope as the creating component.

Connection management

An asynchronous bean method can use the connections that its creating J2EE component obtained using `java:comp` resource references. (For more information on resource references, see *References*). However, the bean method must access those connections using a `get`, `use` or `close` pattern. There is no connection caching between method calls on an asynchronous bean. The connection factories or datasources can be cached, but the connections must be retrieved on every method call, used, and then closed. While the asynchronous bean method can look up connection factories using a global Java Naming and Directory Interface (JNDI) name, this is not recommended for the following reasons:

- The JNDI name is hard coded in the application (for example, as a property or string literal).
- The connection factories are not shared because there is no way to specify a sharing scope.

For code examples that demonstrate both the correct and the incorrect ways to access connections from asynchronous bean methods, see the topic [Example: Asynchronous bean connection management](#).

Deferred start of Asynchronous Beans

Asynchronous beans support deferred start by allowing serialization of J2EE service context information. The `WorkWithExecutionContext` `createWorkWithExecutionContext(Work r)` method on the `WorkManager` interface will create a snapshot of the J2EE service contexts enabled on the `WorkManager`. The resulting `WorkWithExecutionContext` object can then be serialized and stored in a database or file. This is useful when it is necessary to store J2EE service contexts such as the current security identity or `Locale` and later inflate them and run some work within this context. The `WorkWithExecutionContext` object can run using the `startWork()` and `doWork()` methods on the `WorkManager` interface.

All `WorkWithExecutionContext` objects must be deserialized by the same application that serialized it. All EJBs and classes must be present in order for Java to successfully inflate the objects contained within.

Deferred start and security

The asynchronous beans security service context might require Common Secure Interoperability Version 2 (CSIv2) identity assertion to be enabled. Identity assertion is required when a `WorkWithExecutionContext` object is deserialized and run to Java Authentication and Authorization Service (JAAS) subject identity credential assignment. Review the following topics to better understand if you need to enable identity assertion, when using a `WorkWithExecutionContext` object:

- [Configuring Common Secure Interoperability Version 2 and Security Authentication Service authentication protocol](#)
- [Identity Assertion](#)

There are also issues with interoperating with `WorkWithExecutionContext` objects from different versions of the product. See [Interoperating with asynchronous beans](#) .

Work managers:

A work manager is a thread pool created for J2EE applications that use asynchronous beans.

Using the administrative console, an administrator can configure any number of work managers. The administrator specifies the properties of the work manager, including the J2EE context inheritance policy for any asynchronous beans that use the work manager. The administrator binds each work manager to a unique place in Java Naming and Directory Interface (JNDI). You can use work manager objects in any one of the following interfaces:

- [Asynchronous beans](#)
- [CommonJ work manager](#) (For details, see the [CommonJ work manager](#) section in this article.)

The selected type of interface is resolved during the JNDI lookup time. The interface type is the value that you specify in the `ResourceRef`, rather than the interface type specified in the configuration object. For example, you can have one `ResourceRef` for each interface per configuration object, and each `ResourceRef` lookup returns that appropriate type of instance.

The work managers provide a programming model for the J2EE 1.4 applications. For more information, see the [Programming model](#) section in this article.

When writing a Web or EJB component that uses asynchronous beans, the developer should include a resource reference in each component that needs access to a work manager. For more information on resource references, see the article [References](#). The component looks up a work manager using a logical name in the component, `java:comp` namespace, just as it looks up a data source, enterprise bean or connection factory.

The deployer binds physical work managers to logical work managers when the application is deployed.

For example, if a developer needs three thread pools to partition work between bronze, silver, and gold levels, the developer writes the component to pick a logical pool based on an attribute in the client application profile. The deployer has the flexibility to decide how to map this request for three thread pools. The deployer might decide to use a single thread pool on a small machine. In this case, the deployer binds all three resource references to the same work manager instance (that is, the same JNDI name). A larger machine might support three thread pools, so the deployer binds each resource reference to a different work manager. Work managers can be shared between multiple J2EE applications installed on the same server.

An application developer can use as many logical work managers as necessary. The deployer chooses whether to map one physical work manager or several to the logical work manager defined in the application.

All J2EE components that need to share asynchronous scope objects must use the same work manager. These scope objects have an affinity with a single work manager. An application that uses asynchronous scopes should verify that all of the components using scope objects use the same work manager.

When multiple work managers are defined, the underlying thread pools are created in a Java virtual machine (JVM) only if an application within that JVM looks up the work manager. For example, there might be ten thread pools (work managers) defined, but none are actually created until an application looks these pools up.

Note: Asynchronous beans do not support submitting work to remote JVMs.

CommonJ Work Manager

The CommonJ work manager is similar to the work manager. The difference between the two is that the CommonJ work manager contains a subset of the asynchronous beans work manager methods. Although CommonJ work manager functions in a J2EE 1.4 environment, the interface does not return a new instance for each JNDI naming lookup, since this specification is not included in the J2EE specification.

Remote start of work. The CommonJ Work specification optional feature for work running remotely is not supported. Even if a unit of work implements the `java.io.Serializable` interface, the unit of work does not run remotely.

How to look up a work manager

An application can look up a work manager as follows. Here, the component contains a resource reference named `wm/myWorkManager`, which was bound to a physical work manager when the component was deployed:

```
InitialContext ic = new InitialContext();
WorkManager wm = (WorkManager) ic.lookup("java:comp/env/wm/myWorkManager");
```

Inheritance J2EE contexts

Asynchronous beans can inherit the following J2EE contexts.

Internationalization context

When this option is selected and the internationalization service is enabled, and the internationalization context that exists on the scheduling thread is available on the target thread.

Work area

When this option is selected, the work area context for every work area partition that exists on the scheduling thread is available on the target thread.

Application profile (deprecated)

Application profile context is not supported and not available for J2EE 1.4 applications. For J2EE

1.3 applications, when this option is selected, the application profile service is enabled, and the application profile service property, **5.x compatibility mode**, is selected. The application profile task that is associated with the scheduling thread is available on the target thread for J2EE 1.3 applications. For J2EE 1.4 applications, the application profile task is a property of its associated unit of work, rather than a thread. This option has no effect on the behavior of the task in J2EE 1.4 applications. The scheduled work that runs in a J2EE 1.4 application does not receive the application profiling task of the scheduling thread.

Security

The asynchronous bean can be run as anonymous or as the client authenticated on the thread that created it. This behavior is useful because the asynchronous bean can do only what the caller can do. This action is more useful than a RUN_AS mechanism, for example, which prevents this kind of behavior. When you select the **Security** option, the JAAS subject that exists on the scheduling thread is available on the target thread. If not selected, the thread runs anonymously.

Component metadata

Component metadata is relevant only when the asynchronous bean is a simple Java object. If the bean is a J2EE component, such as an enterprise bean, the component metadata is active.

The contexts that can be inherited depend on the work manager used by the application that creates the asynchronous bean. Using the administrative console, the administrator defines the sticky context policy of a work manager by selecting the services on which the work manager is to be made available.

Programming model

Work managers support the following programming models.

- **CommonJ Specification.** The Application Server Version 6.0 CommonJ programming model uses the WorkManager and TimerManager to manage threads and timers asynchronously in the J2EE 1.4 environment.
- **Asynchronous beans and CommonJ specification extensions.** The current asynchronous beans Event Source, asynchronous scopes, subsystem monitors and J2EEContext interfaces are a part of the CommonJ extension.

The following table describes the method mapping between the CommonJ and Asynchronous beans APIs. You can change the current asynchronous beans interfaces to use the CommonJ interface, while maintaining the same functions.

CommonJ package	API	Asynchronous beans package	API
Work manager		Work manager	
Asynchronous beans	Field - IMMEDIATE (long)		Field - IMMEDIATE (int)
	Field - INDEFINITE		Field - INDEFINITE
	schedule(Work) throws WorkException, IllegalArgumentException		startWork(Work) throws WorkException, IllegalArgumentException
	schedule(Work, WorkListener) throws WorkException, IllegalArgumentException Note: Configure the work manager work timeout property to the value you previously specified as timeout_ms on startWork. The default timeout value is INDEFINITE.		startWork(Work, timeout_ms, WorkListener) throws WorkException, IllegalArgumentException

	waitForAll(workItems, timeout_ms)		join(workItems, JOIN_AND, timeout_ms)
	waitForAny(workItems, timeout_ms)		join(workItems, JOIN_OR, timeout_ms)
WorkItem		WorkItem	
	getResult		getResult
	getStatus		getStatus
WorkListener		WorkListener	
	workAccepted(WorkEvent)		workAccepted(WorkEvent)
	workCompleted(WorkEvent)		workCompleted(WorkEvent)
	workRejected(WorkEvent)		workRejected(WorkEvent)
	workStarted(WorkEvent)		workStarted(WorkEvent)
WorkEvent		WorkEvent	
	Field - WORK_ACCEPTED		Field - WORK_ACCEPTED
	Field - WORK_COMPLETED		Field - WORK_COMPLETED
	Field - WORK_REJECTED		Field - WORK_REJECTED
	Field - WORK_STARTED		Field - WORK_STARTED
	getException		getException
	getType		getType
	getWorkItem().getResult() Note: This API is valid only after the work is complete.		getWork
Work	(extends Runnable)	Work	(Extends Runnable)
	isDaemon		*
	release		release
RemoteWorkItem	Not in this release. Use Distributed WorkManager in Extended Deployment or future release	NA

Table 57. Create your work using MyWork

Asynchronous beans	CommonJ
<pre>public class MyWork implements com.ibm.websphere.asynchbeans.Work { public void release() { } public void run() { System.out.println("Running....."); } }</pre>	<pre>public class MyWork implements commonj.work.Work{ public boolean isDaemon() { return false; } public void release () { } public void run () { System.out.println("Running....."); } }</pre>

Table 58. Submit the work

Asynchronous beans	CommonJ
--------------------	---------

Table 58. Submit the work (continued)

<pre> MyWork work1 = new MyWork(new URI = "http://www.example./com/1"); MyWork work2 = new MyWork(new URI = "http://www.example./com/2"); WorkItem item1; WorkItem item2; Item1=wm.startWork(work1); Item2=wm.startWork(work2); // case 1: block until all items are done ArrayList col1 = new ArrayList(); Col1.add(item1); Col1.add(item2); wm.join(col1, WorkManager.JOIN_AND, (long)WorkManager.IMMEDIATE); // when the works are done System.out.println("work1 data="+work1.getData()); System.out.println("work2 data="+work2.getData()); // case 2: wait for any of the items to complete. Boolean ret = wm.join(col1, WorkManager.JOIN_OR, 1000); </pre>	<pre> MyWork work1 = new MyWork(new URI = "http://www.example./com/1"); MyWork work2 = new MyWork(new URI = "http://www.example./com/2"); WorkItem item1; WorkItem item2; Item1=wm.schedule(work1); Item2=wm.schedule(work2); // case 1: block until all items are done Collection col1 = new ArrayList(); col1.add(item1); col1.add(item2); wm.waitForAll(col1, WorkManager.IMMEDIATE); // when the works are done System.out.println("work1 data="+work1.getData()); System.out.println("work2 data="+work2.getData()); // case 2: wait for any of the items to complete. Collection finished = wm.waitForAny(col1, // check the workItems status if (finished != null) { Iterator I = finished.iterator(); if (i.hasNext()) { WorkItem wi = (WorkItem) i.next(); if (wi.equals(item1)) { System.out.println("work1 = "+ work1.getData()); } else if (wi.equals(item2)) { System.out.println("work1 = "+ work1.getData()); } } } } </pre>
--	---

Table 59. Create a timer manager

Asynchronous beans	CommonJ
<pre> InitialContext ctx = new InitialContext(); com.ibm.websphere.asynchbeans.WorkManager wm = (com.ibm.websphere.asynchbeans.WorkManager) ctx.lookup("java:comp/env/wm/MyWorkMgr"); AsynchScope ascope; Try { Ascope = wm.createAsynchScope("ABScope"); } Catch (DuplicateKeyException ex) { Ascope = wm.findAsynchScope("ABScope"); ex.printStackTrace(); } // get an AlarmManager AlarmManager aMgr= ascope.getAlarmManager(); </pre>	<pre> InitialContext ctx = new InitialContext(); Commonj.timers.TimerManager tm = (commonj.timers.TimerManager) ctx.lookup("java:comp/env/tm/MyTimerManager"); </pre>

Table 60. Fire the timer

Asynchronous beans	CommonJ

Table 60. Fire the timer (continued)

<pre>// create alarm ABAlarmListener listener = new ABAlarmListener(); Alarm am = aMgr.create(listener, "SomeContext", 1000*60);</pre>	<pre>// create Timer TimerListener listener = new StockQuoteTimerListener("qqq", "johndoe@example.com"); Timer timer = tm.schedule(listener, 1000*60); // Fixed-delay: schedule timer to expire in // 60 seconds from now and repeat every // hour thereafter. Timer timer = tm.schedule(listener, 1000*60, 1000*30); // Fixed-rate: schedule timer to expire in // 60 seconds from now and repeat every // hour thereafter Timer timer = tm.scheduleAtFixedRate(listener, 1000*60, 1000*30);</pre>
--	---

Timer managers:

The timer manager combines the functions of the asynchronous beans alarm manager and asynchronous scope. So, when a timer manager is created, it internally uses an asynchronous scope to provide the timer manager life cycle functions.

You can look up the timer manager in the JNDI name space. This capability is different from the alarm manager that is retrieved through the asynchronous beans scope. Each lookup of the timer manager returns a new logical timer manager that can be destroyed independently of all other timer managers.

A timer manager can be configured with a number of thread pools through the administrative console. For deployment you can bind this timer manager to a resource reference at assembly time, so the resource reference can be used by the application to look up the timer manager.

The Java code to look up the timer manager is:

```
InitialContext ic = new InitialContext();
TimerManager tm = (TimerManager)ic.lookup("java:comp/env/tm/TimerManager");
```

The programming model for setting up the alarm listener and the timer listener is different. The following code example shows that difference.

Table 61. Set up the timer listener

Asynchronous beans	CommonJ
---------------------------	----------------

Table 61. Set up the timer listener (continued)

<pre> public class ABAlarmListener implements AlarmListener { public void fired(Alarm alarm) { System.out.println("Alarm fired. Context =" + alarm.getContext()); } </pre>	<pre> public class StockQuoteTimerListener implements TimerListener { String context; String url; public StockQuoteTimerListener(String context, String url){ this.context = context; This.url = url; } public void timerExpired(Timer timer) { System.out.println("Timer fired. Context =" + ((StockQuoteTimerListener)timer.getTimerListener()) .getContext()); } public String getContext() { return context; } } </pre>
--	---

Example: Using connections with asynchronous beans:

An asynchronous bean method can use the connections that its creating Java 2 Platform Enterprise Edition (J2EE) component obtained using java:comp resource references.

For more information on resource references, see the topic References. The following is an example of an asynchronous bean that uses connections correctly:

```

class GoodAsynchBean
{
    DataSource ds;
    public GoodAsynchBean()
    throws NamingException
    {
        // ok to cache a connection factory or datasource
        // as class instance data.
        InitialContext ic = new InitialContext();
        // it is assumed that the created J2EE component has this
        // resource reference defined in its deployment descriptor.
        ds = (DataSource)ic.lookup("java:comp/env/jdbc/myDataSource");
    }
    // When the asynchronous bean method is called, get a connection,
    // use it, then close it.
    void anEventListener()
    {
        Connection c = null;
        try
        {
            c = ds.getConnection();
            // use the connection now...
        }
        finally
        {
            if(c != null) c.close();
        }
    }
}

```

The following example of an asynchronous bean that uses connections incorrectly:

```

class BadAsynchBean
{
    DataSource ds;
    // Do not do this. You cannot cache connections across asynch method calls.

```

```

Connection c;

public BadAsynchBean()
    throws NamingException
{
    // ok to cache a connection factory or datasource as
    // class instance data.
    InitialContext ic = new InitialContext();
    ds = (DataSource)ic.lookup("java:comp/env/jdbc/myDataSource");
    // here, you broke the rules...
    c = ds.getConnection();
}
// Now when the asynch method is called, illegally use the cached connection
// and you likely see J2C related exceptions at run time.
// close it.
void someAsynchMethod()
{
    // use the connection now...
}
}

```

Work manager service settings

Use this page to enable or disable the work manager service that manages work manager resources used by the server.

To view this administrative console page, click **Servers > Application Servers > *server_name* > Work Manager Service** .

Startup:

Specifies whether the server attempts to start the work manager service.

Default
Range

Selected
Selected

When the application server starts, it attempts to start the work manager service automatically.

Cleared

The server does not try to start the work manager service. If work manager resources are to be used on this server, the system administrator must start the work manager service manually or select this property then restart the server.

Configuring timer managers

A timer manager acts as a thread pool for application components that use asynchronous beans. Use the administrative console to configure timer managers. The timer manager service is enabled by default.

If you are not familiar with timer managers, review the conceptual section, [Timer managers](#), in the [Asynchronous beans](#) topic.

You can define multiple timer managers for each cell. Each timer manager is bound to a unique place in Java Naming and Directory Interface (JNDI).

Note: The timer manager service is only supported from within the Enterprise Java Beans (EJB) container or Web container. Looking up and using a configured timer manager from a J2EE application client container is not supported.

1. Start the administrative console.
2. Select **Resources > Asynchronous beans > Timer managers**.

3. Specify a **Scope** value and click **New**.
4. Specify the following required properties:
 - Scope** The scope of the configured resource. This value indicates the location for the configuration file.
 - Name** The display name for the timer manager.
 - JNDI Name**
 - The Java Naming and Directory Interface (JNDI) name for the timer manager. This name is used by asynchronous beans that need to look up the timer manager. Each timer manager must have a unique JNDI name within the cell.
 - Number of Timer Threads**
 - The maximum number of threads that are used for timers.
5. [Optional] Specify a **Description** and a **Category** for the timer manager.
6. [Optional] Select the **Service Names** (J2EE contexts) on which you want this timer manager to be made available. Any asynchronous beans that use this timer manager then inherit the selected J2EE contexts from the component that creates the bean. The list of selected services also is known as the "sticky" context policy for the timer manager. Selecting more services than are actually required might impede performance.
7. Save your configuration.

The timer manager is now configured and ready for access by application components that need to manage the start of asynchronous code.

Timer manager collection

Use this page to view the configuration properties of timer managers, which enable applications to schedule future timer notifications and to receive timer notification callbacks to application-specified listeners within a Java 2 Platform, Enterprise Edition (J2EE) environment. The timer manager binds to the Java Naming and Directory Interface (JNDI) name space.

A timer manager contains a pool of threads bound into JNDI.

To view this administrative console page, click **Resources > Asynchronous beans < Timer managers**.

Name:

Specifies the name by which the timer manager is known for administrative purposes.

Data type String

JNDI Name:

Specifies the JNDI name used to look up the timer manager in the name space.

Data type String

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Description:

Specifies a description of this timer manager for administrative purposes.

Data type String

Category:

Specifies a string that can be used to classify or group this timer manager.

Data type String

Timer manager settings:

Use this page to modify timer manager settings. Timer managers enable applications to schedule future timer notifications and to receive timer notification callbacks to application-specified listeners within a Java 2 Platform, Enterprise Edition (J2EE) environment. The timer manager binds to the Java Naming and Directory Interface (JNDI) name space.

A timer manager contains a pool of threads bound into JNDI.

To view this administrative console page, click **Resources > Asynchronous beans > Timer managers** *timermanager_name*.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

Specifies the name by which the timer manager is known for administrative purposes.

Data type String

JNDI Name:

Specifies the JNDI name used to look up the timer manager in the namespace.

Data type String

Description:

Specifies a description of this timer manager for administrative purposes.

Data type String

Category:

Specifies a string that can be used to classify or group this timer manager.

Data type String

Default Transaction Class:

Specifies the transaction class that is used for WLM workload classification of non-daemon work that is not already associated with a service class.

Data type String

Range 0-8 characters

Service Names:

Specifies a list of services to make available to this timer manager.

Asynchronous beans can inherit J2EE context information by enabling one or more J2EE service contexts on the timer manager resource in the WebSphere administrative console or by setting the `serviceNames` attribute of the `TimerManagerInfo` configuration object. When specifying the `serviceNames` attribute each enabled service should be separated by a semicolon. For example:

`security;UserWorkArea;com.ibm.ws.i18n`. When a J2EE service context is enabled, it propagates the context from the scheduling thread to the target thread. If not enabled, the target thread does not inherit the context of the scheduling thread and a default context is applied. Any related J2EE context that is already present on the thread is suspended before any new J2EE context is applied.

The context information of each selected service is propagated to each timer that is created using this timer manager. Selecting services that are not needed can negatively impact performance.

Work area

Use the administrative console or the `UserWorkArea` service name to enable work area partitions. When enabled, the work area context for every work area partition that exists on the scheduling thread is available on the target thread. This feature is optional.

Security

Use the administrative console or the `security` service name to enable the Java Authentication and Authorization Service (JAAS) subject. When this feature and administrative security are enabled, the JAAS subject that is present on the scheduling thread is applied to the target thread. If not enabled, the target thread is run anonymously without a JAAS subject on the thread. This feature is optional.

Internationalization

Use the administrative console or the `com.ibm.ws.i18n` service name to enable the internationalization context information. When the internationalization context and the Internationalization service is enabled, the internationalization context that exists on the scheduling thread is available on the target thread. This feature is optional.

Number of Timer Threads:

Specifies the maximum number of threads that are used for timers.

Data type

Integer

Configuring work managers

A work manager acts as a thread pool for application components that use asynchronous beans. Use the administrative console to configure work managers.

If you are not familiar with work managers, review the conceptual topic, [Work managers](#).

The work manager service is always enabled. In previous versions of the product, the work manager service could be disabled using the administration console or configuration service. The work manager service configuration objects are still present in the configuration service, but the `enabled` attribute is ignored.

You can define multiple work managers for each cell. Each work manager is bound to a unique place in Java Naming and Directory Interface (JNDI).

Note: The work manager service is only supported from within the Enterprise Java Beans (EJB) Container or Web Container. Looking up and using a configured work manager from a J2EE application client container is not supported.

1. Start the administrative console.
2. Select **Resources > Asynchronous beans > Work managers**.
3. Specify a **Scope** value and click **New**.
4. Specify the required properties for work manager settings.

Scope The scope of the configured resource. This value indicates the location for the configuration file.

Name The display name for the work manager.

JNDI Name

The Java Naming and Directory Interface (JNDI) name for the work manager. This name is used by asynchronous beans that need to look up the work manager. Each work manager must have a unique JNDI name within the cell.

Number of Alarm Threads

The maximum number of threads to use for processing alarms. A single thread is used to monitor pending alarms and dispatch them. An additional pool of threads is used for dispatching the threads. All alarm managers on the asynchronous beans associated with this work manager share this set of threads. A single alarm thread pool exists for each work manager, and all of the asynchronous beans associated with the work manager share this pool of threads.

Minimum Number Of Threads

The initial number of threads to be created in the thread pool.

Maximum Number Of Threads

The maximum number of threads to be created in the thread pool. The maximum number of threads can be exceeded temporarily if the **Growable** check box is selected. These additional threads are discarded when the work on the thread completes.

Thread Priority

The priority to assign to all threads in the thread pool.

Every thread has a priority. Threads with higher priority are run before threads with lower priority. For more information about how thread priorities are used, see the javadoc for the setPriority method of the java.lang.Thread class in the Java Standard Edition specification.

5. [Optional] Specify a **Description** and a **Category** for the work manager.
6. [Optional] Select the **Service Names** (J2EE contexts) on which you want this work manager to be made available. Any asynchronous beans that use this work manager then inherit the selected J2EE contexts from the component that creates the bean. The list of selected services also is known as the "sticky" context policy for the work manager. Selecting more services than are actually required might impede performance.

Other optional fields include:

Work timeout

Specifies the number of milliseconds to wait before a scheduled work object is released. If a value is not specified, then the timeout is disabled.

Work request queue size

Specifies the size of the work request queue. The work request queue is a buffer that holds scheduled work objects and may be any value 1 or greater. The thread pool pulls work from this queue. If you do not specify a value or the value is 0, the queue size is managed automatically. Large values can consume significant system resources.

Work request queue full action

Specifies the action taken when the thread pool is exhausted, and the work request queue is full. This action starts when you submit non-daemon work to the work manager. If set to FAIL, the work manager API methods creates an exception instead of blocking.

7. Save your configuration.

The work manager is now configured and ready for access by application components that need to manage the start of asynchronous code.

Work manager collection

Use this page to view the collection properties of work managers, which contain a pool of threads bound into the Java Naming and Directory Interface.

To view this administrative console page, click **Resources > Asynchronous beans > Work managers**.

Name:

Specifies the name by which the work manager is known for administrative purposes.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name used to look up the work manager in the namespace.

Data type String

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Description:

Specifies the description of this work manager for administrative purposes.

Category:

Specifies a category name that is used to classify or group this work manager.

Work manager settings:

Use this page to modify work manager settings. Work managers contain a pool of threads bound into Java Naming and Directory Interface.

To view this administrative console page, click **Resources > Asynchronous beans > Work managers > workmanager_name**.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

Specifies the name by which the work manager is known for administrative purposes.

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name used to look up the work manager in the namespace.

Description:

Specifies the description of this work manager for administrative purposes.

Category:

Specifies a string that you can use to classify or group this work manager.

Work timeout:

Specifies the number of milliseconds to wait before a scheduled work object is released. If not specified, the timeout is disabled.

Default 0

Work request queue size:

Specifies the size of the work request queue. The work request queue is a buffer that holds scheduled work objects and may be any value 1 or greater. The thread pool pulls work from this queue. If you do not specify a value or the value is 0, the queue size is managed automatically. Large values can consume significant system resources.

Default 0

Work request queue full action:

Specifies the action taken when the thread pool is exhausted, and the work request queue is full. This action starts when you submit non-daemon work to the work manager.

If set to FAIL, the work manager API methods creates an exception instead of blocking.

Default BLOCK
Range FAIL

Service names:

Specifies a list of services to make available to this work manager.

Asynchronous beans can inherit J2EE context information by enabling one or more J2EE service contexts on the work manager resource in the WebSphere administrative console or by setting the serviceNames attribute of the WorkManagerInfo configuration object. When specifying the serviceNames attribute each enabled service should be separated by a semicolon. For example:

security;UserWorkArea;com.ibm.ws.i18n. When a J2EE service context is enabled, it propagates the context from the scheduling thread to the target thread. If not enabled, the target thread does not inherit the context of the scheduling thread and a default context is applied. Any related J2EE context that is already present on the thread is suspended before any new J2EE context is applied.

The context information of each selected service is propagated to each work or alarm that is created using this work manager. Selecting services that are not needed can negatively impact performance.

Application profile (deprecated)

Use the administrative console or the AppProfileService service name to enable the application profile tasks. Application profile context is not supported and not available for J2EE 1.4 applications. For J2EE 1.3 applications, the application profile context is deprecated and is only available when **Application Profile Service 5.x Compatibility Mode** is enabled and both the scheduling thread and target thread are J2EE 1.3 applications. When enabled, all application profile tasks that are available on the scheduling thread are available on the target thread. The scheduled work that runs in a J2EE 1.4 application does not get the application profiling task of the scheduling thread. This feature is optional.

Work area

Use the administrative console or the UserWorkArea service name to enable work area partitions. When enabled, the work area context for every work area partition that exists on the scheduling thread is available on the target thread. This feature is optional.

Security

Use the administrative console or the security service name to enable the Java Authentication and Authorization Service (JAAS) subject. When this feature and administrative security are enabled, the JAAS subject that is present on the scheduling thread is applied to the target thread. If not enabled, the target thread is run anonymously without a JAAS subject on the thread. This feature is optional.

Internationalization

Use the administrative console or the com.ibm.ws.i18n service name to enable the internationalization context information. When the internationalization context and the Internationalization service is enabled, the internationalization context that exists on the scheduling thread is available on the target thread. This feature is optional.

Thread pool properties:

Specifies the priority of the threads available in this work manager.

Number of alarm threads

Specifies the desired maximum number of threads used for alarms. The default value is 2.

Minimum number of threads

Specifies the minimum number of threads available in this work manager.

Maximum number of threads

Specifies the maximum number of threads available in this work manager.

Thread priority

Specifies the priority of the threads available in this work manager.

Growable

Specifies whether the number of threads in this work manager can be increased.

Default transaction class:

Specifies the transaction class name used to classify work run by this work manager instance when the z/OS Work Load Manager Service class information is not contained in the work context information.

Data type

String

Range

0-8 characters

Daemon transaction class:

Specifies the transaction class that is used for the Work Load Manager Service workload classification of daemon work.

Data type	String
Range	0-8 characters

Dynamic cache

Task overview: Using the dynamic cache service to improve performance

Use the dynamic cache service to improve application performance by caching the output of servlets, commands, and JavaServer Pages (JSP) files.

The dynamic cache service works within an application server Java virtual machine (JVM), intercepting calls to cacheable objects. For example, it intercepts calls through a servlet service method or a command execute method, and either stores the output of the object to the cache or serves the content of the object from the dynamic cache.

1. Enable the dynamic cache service globally. To use the features associated with dynamic caching, you must enable the service in the administrative console. See “Enabling the dynamic cache service” on page 1993 for more information.
2. Configure the type of caching that you are using:
 - “Configuring servlet caching” on page 1998.
 - “Configuring portlet fragment caching” on page 1998.
 - “Configuring Edge Side Include caching” on page 2005.
 - “Configuring command caching” on page 2028.
 - “Example: Caching Web services” on page 1980.
 - “Configuring the Web services client cache” on page 2030.
3. Monitor the results of your configuration using the dynamic cache monitor. For more information, see “Displaying cache information” on page 2046.
4. If you have any problems with your configuration, see the *Troubleshooting and support* PDF.

To use the `DistributedMap` and `DistributedObjectCache` interfaces for the dynamic cache, see “Using the `DistributedMap` and `DistributedObjectCache` interfaces for the dynamic cache” on page 2036.

Dynamic cache

Caching the output of servlets, commands, and JavaServer Pages (JSP) improves application performance. WebSphere Application Server consolidates several caching activities including servlets, Web services, and WebSphere commands into one service called the *dynamic cache*. These caching activities work together to improve application performance, and share many configuration parameters that are set in the dynamic cache service of an application server.

You can use the dynamic cache to improve the performance of servlet and JSP files by serving requests from an in-memory cache. Cache entries contain servlet output, the results of a servlet after it runs, and metadata.

Eviction policies using the disk cache garbage collector

The disk cache garbage collector is responsible for evicting objects out of the disk cache, based on a specified eviction policy.

The garbage collector keeps a certain amount of space on disk available, which is governed by the configuration attribute that limits the amount of disk space that is used for caching objects. To enable the eviction policy, enable the Limit disk cache size in GB and/or Limit disk cache size in entries options in the administrative console.

The garbage collector is triggered when the disk space reaches a specified high threshold (a percentage of the Limit disk cache size in entries or in GB) and evicts objects, based on the eviction policy, from the disk in the background until the disk cache size reaches a specified low threshold (a percentage of the Limit disk cache size in entries or in GB). Eviction triggers when one or both of the high thresholds is reached for Limit disk cache size in GB and Limit disk cache size in entries. The supported policies are:

- None: This is the default policy. Objects are evicted only when they expire, or if they are invalidated.
- Random: The expired objects are removed first. If the disk size still has not reached the low threshold limit, objects are picked from the disk cache in random order and removed until the disk size reaches a low threshold limit.
- Size: The expired objects are removed first. If the disk size still has not reached the low threshold limit, then largest-sized objects are removed until the disk size reaches a low threshold limit.

Limit disk cache size in GB and High Threshold determines when to trigger eviction and when the disk cache is considered near full. It is computed as a function of the user-specified limit. If the specified limit is 10 GB (3 GB is the minimum), the cache subsystem initially creates three files that can grow to 1 GB in size for cache data, dependency ID information, and template information. Each time more space is needed to contain cache data, dependency ID information, or template information, a new file is created. Each of these files grow in 1 GB increments until the total number of files that are created is equal to disk cache in size in GB (in this case ten). Although the initial size of the new file may be much smaller than 1 GB, the dynamic cache service always rounds up to the next GB.

Eviction triggers when the cache data size reaches the high threshold and continues until the cache data size reaches the low threshold. Calculation of cache data size is dynamic. The following formula describes how to calculate the actual cache data size limit:

cache data size limit = disk cache size (in GB) - number of dependency files per GB - number of template files

When the cache data size limit is defined, the trigger point is calculated as follows:

eviction trigger point = cache data size limit * high threshold
size of evicted entries = cache data size * (high threshold - low threshold)

Consider the following scenarios:

- **Scenario 1**

- Disk cache size in GB = 10 GB
- High threshold = 90%
- Low Threshold = 80%

Initially, there is one file for dependency ID and template ID.

cache data size limit = $10 - (1+1) = 8$ GB
eviction trigger point = $8 * 90\% = 7.2$ GB
size of evicted entries = $8 * (90\% - 80\%) = 0.8$ GB

In the above scenario, eviction starts when the data cache size reaches 7.2 GB and continues until the cache size is 6.4 GB (7.2 - 0.8).

- **Scenario 2**

In scenario 1, if the dependency files grow to more than 1 GB, an additional dependency file generates. The eviction trigger point launches dynamically as follows:

cache data size limit = $10 - (2+1) = 7$ GB
eviction trigger point = $7 * 90\% = 6.3$ GB
size of evicted entries = $7 * (90\% - 80\%) = 0.7$ GB

In the above scenario, eviction starts when the data cache size reaches 6.3 GB, and continues until the cache size is 5.6 GB (6.3 - 0.7).

Disk cache eviction for limit disk cache size in entries. Consider the following scenario:

- Disk cache size in entries = 100000
- High threshold = 90%
- Low threshold = 80%

eviction trigger point = 100000 * 90% = 90000
number of entries evicted = 100000 * (90% - 80%) = 10000

In this scenario, eviction starts when the number of cache entries reaches 90000 and 10000 entries are evicted from the cache.

Example: Caching Web services

This topic includes examples of building a set of cache policies and SOAP messages for a Web services application.

The following is an example of building a set of cache policies for a simple Web services application. The application in this example stores stock quotes and has operations to read, update the price of, and buy a given stock symbol.

Following are two SOAP message examples that the application can receive, with accompanying HTTP Request headers.

The first message sample contains a SOAP message for a GetQuote operation, requesting a quote for IBM. This is a read-only operation that gets its data from the back end, and is a good candidate for caching. In this example the SOAP message is cached and a timeout is placed on its entries to guarantee the quotes it returns are current.

Message example 1

```
POST /soap/servlet/soaprouter
HTTP/1.1
Host: www.myhost.com
Content-Type: text/xml; charset="utf-8"
SOAPAction: urn:stockquote-lookup
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<SOAP-ENV:Body>
<m:getQuote xmlns:m="urn:stockquote">
<symbol>IBM</symbol>
</m:getQuote>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

The SOAPAction HTTP header in the request is defined in the SOAP specification and is used by HTTP proxy servers to dispatch requests to particular HTTP servers. WebSphere Application Server dynamic cache can use this header in its cache policies to build IDs without having to parse the SOAP message.

Message example 2 illustrates a SOAP message for a BuyQuote operation. While message 1 is cacheable, this message is not, because it updates the back end database.

Message example 2

```
POST /soap/servlet/soaprouter
HTTP/1.1
Host: www.myhost.com
Content-Type: text/xml; charset="utf-8"
SOAPAction: urn:stockquote-update
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
```

```

SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<SOAP-ENV:Body>
<m:buyStock xmlns:m="urn:stockquote">
<symbol>IBM</symbol>
</m:buyStock>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

The following graphic illustrates how to invoke methods with the SOAP messages. In Web services terms, especially Web Service Definition Language (WSDL), a service is a collection of operations such as getQuote and buyStock. A body element namespace (urn:stockquote in the example) defines a service, and the name of the first body element indicates the operation.

The following is an example of WSDL for the getQuote operation:

```

<?xml version="1.0"?>
<definitions name="StockQuoteService-interface"
targetNamespace="http://www.getquote.com/StockQuoteService-interface"
xmlns:tns="http://www.getquote.com/StockQuoteService-interface"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
xmlns="http://schemas.xmlsoap.org/wsdl/"
<message name="SymbolRequest">
<part name="return" type="xsd:string"/>
</message>
<portType name="StockQuoteService">
<operation name="getQuote">
<input message="tns:SymbolRequest"/>
<output message="tns:QuoteResponse"/>
</operation>
</portType>
<binding name="StockQuoteServiceBinding"
type="tns:StockQuoteService">
<soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
<operation name="getQuote">
<soap:operation soapAction="urn:stockquote-lookup"/>
<input>
<soap:body use="encoded" namespace="urn:stockquote"
encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
</input>
<output>
<soap:body use="encoded" namespace="urn:stockquotes"
encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
</output>
</operation>
</binding>
</definition>

```

To build a set of cache policies for a Web services application, configure WebSphere Application Server dynamic cache to recognize cacheable service operation of the operation.

WebSphere Application Server inspects the HTTP request to determine whether or not an incoming message can be cached based on the cache policies defined for an application. In this example, buyStock and stock-update are not cached, but stockquote-lookup is cached. In the cachespec.xml file for this Web application, the cache policies need defining for these services so that the dynamic cache can handle both SOAPAction and service operation.

WebSphere Application Server uses the operation and the message body in Web services cache IDs, each of which has a component associated with them. Therefore, each Web services <cache-id> rule contains only two components. The first is for the operation. Because you can perform the stockquote-lookup operation by either using a SOAPAction header or a service operation in the body, you must define two different <cache-id> elements, one for each method. The second component is of type "body", and defines how WebSphere Application Server should incorporate the message body into the cache ID. You can use a hash of the body, although it is legal to use the literal incoming message in the ID.

The incoming HTTP request is analyzed by WebSphere Application Server to determine which of the <cache-id> rules match. Then, the rules are applied to form cache or invalidation IDs.

The following is sample code of a cachespec.xml file defining SOAPAction and servicesOperation rules:

```
<cache>
<cache-entry>
  <class>webservice</class>
  <name>/soap/servlet/soaprouter</name>
  <sharing-policy>not-shared</sharing-policy>
  <cache-id>
    <component id="" type="SOAPAction">
      <value>urn:stockquote-lookup</value>
    </component>
    <component id="Hash" type="SOAPEnvelope"/>
      <timeout>3600</timeout>
      <priority>1</priority>
    </component>
  </cache-id>
  <cache-id>
    <component id="" type="serviceOperation">
      <value>urn:stockquote:getQuote</value>
    </component>
    <component id="Hash" type="SOAPEnvelope"/>
      <timeout>3600</timeout>
      <priority>1</priority>
    </component>
  </cache-id>
</cache-entry>
</cache>
```

Dynamic cache MBean statistics

The dynamic cache service provides an MBean interface to access cache statistics.

Access cache statistics with the MBean interface, using JACL

- Obtain the MBean identifier with the **queryNames** command, for example:
\$AdminControl queryNames type=DynaCache,* // Returns a list of the available dynamic cache MBeans
Select your dynamic cache MBean and run the following command:
set mbean <dynamic_cache_mbean>
- Retrieve the names of the available cache statistics:
\$AdminControl invoke \$mbean getCacheStatisticNames
- Retrieve the names of the available cache instances:
\$AdminControl invoke \$mbean getCacheInstanceNames
- Retrieve all of the available cache statistics for the base cache instance:

```
$AdminControl invoke $mbean getAllCacheStatistics
```

- Retrieve all of the available cache statistics for the named cache instance:

```
$AdminControl invoke $mbean getAllCacheStatistics "services/cache/servletInstance_4"
```

- Retrieve cache statistics that are specified by the names array for the base cache instance:

```
$AdminControl invoke $mbean getCacheStatistics  
{ "DiskCacheSizeInMB ObjectsReadFromDisk4000K RemoteObjectMisses" }
```

Note: This command should all be entered on one line. It is broken here for printing purposes.

- Retrieve cache statistics that are specified by the names array for the named cache instance:

```
$AdminControl invoke $mbean getCacheStatistics  
{ services/cache/servletInstance_4 "ExplicitInvalidationsLocal CacheHits" }
```

Note: This command should all be entered on one line. It is broken here for printing purposes.

Example: Configuring the dynamic cache

This example puts all the steps together for configuring the dynamic cache with the `cachespec.xml` file, showing the use of the cache ID generation rules, dependency IDs, and invalidation rules.

Suppose that a servlet is used to manage a simple news site. This servlet uses the query parameter "action" to determine if the request is being used to "view" news or "update" news (used by the administrator). Another query parameter "category" is used to select the news category. Suppose that this site supports an optional customized layout that is stored in the user's session using the attribute name "layout". Here are example URL requests to this servlet:

`http://yourhost/yourwebapp/newscontroller?action=view&category=sports` (Returns a news page for the sports category)

`http://yourhost/yourwebapp/newscontroller?action=view&category=money` (Returns a news page for the money category)

`http://yourhost/yourwebapp/newscontroller?action=update&category=fashion` (Allows the administrator to update news in the fashion category)

Here are the steps for configuring dynamic cache for this example with the `cachespec.xml` file:

1. Define the `<cache-entry>` elements necessary to identify the servlet. In this case, the servlet's URI is "newscontroller" so this is the cache-entry's `<name>` element. Because this example caches a servlet or JavaServer Pages (JSP) file, the cache entry class is "servlet".

```
<cache-entry>  
<name> /newscontroller </name>  
<class>servlet </class>  
</cache-entry>
```

2. Define cache ID generation rules. This servlet is cached only when `action=view`, so one component of the cache ID is the parameter "action" when the value equals "view". The news category is also an essential part of the cache ID. Finally, the optional session attribute for the user's layout is included in the cache ID. The cache entry now is :

```
<cache-entry>  
<name> /newscontroller </name>  
<class>servlet </class>  
<cache-id>  
<component id="action" type="parameter">  
<value>view</value>  
<required>true</required>  
</component>  
<component id="category" type="parameter">  
<required>true</required>  
</component>  
<component id="layout" type="session">
```

```

    <required>false</required>
  </component>
</cache-id>
</cache-entry>

```

3. Define dependency ID rules. For this servlet, a dependency ID is added for the category. Later, when the category is invalidated due to an update event, all views of that news category are invalidated. Following is an example of the cache entry after adding the dependency-id:

```

<cache-entry>
  <name>newscontroller </name>
  <class>servlet </class>
  <cache-id>
    <component id="action" type="parameter">
      <value>view</value>
      <required>true</required>
    </component>
    <component id="category" type="parameter">
      <required>true</required>
    </component>
    <component id="layout" type="session">
      <required>false</required>
    </component>
  </cache-id>
  <dependency-id>category
    <component id="category" type="parameter">
      <required>true</required>
    </component>
  </dependency-id>
</cache-entry>

```

4. Define invalidation rules. Since a category dependency ID is already defined, define an invalidation rule to invalidate the category when action=update. To incorporate the conditional logic, we will add "ignore-value" components into the invalidation rule. These components do not add to the output of the invalidation ID, but only determine whether or not the invalidation ID is created and run. The final cache-entry now looks like this:

```

<cache-entry>
  <name>newscontroller </name>
  <class>servlet </class>
  <cache-id>
    <component id="action" type="parameter">
      <value>view</value>
      <required>true</required>
    </component>
    <component id="category" type="parameter">
      <required>true</required>
    </component>
    <component id="layout" type="session">
      <required>false</required>
    </component>
  </cache-id>
  <dependency-id>category
    <component id="category" type="parameter">
      <required>true</required>
    </component>
  </dependency-id>
  <invalidation>category
    <component id="action" type="parameter" ignore-value="true">
      <value>update</value>
      <required>true</required>
    </component>
    <component id="category" type="parameter">
      <required>true</required>
    </component>
  </invalidation>
</cache-entry>

```

Accessing dynamic cache PMI counters

The dynamic cache statistics interface is defined as `WSDynamicCacheStats` under the `com.ibm.websphere.pmi.stat` package.

Dynamic cache statistics are structured as follows in the Performance Monitoring Infrastructure (PMI) tree:

```

_Dynamic Caching+
├── <Servlet: instance_1>
│   ├── Templates+
│   │   ├── <template_1>
│   │   └── <template_2>
│   │       ├── Disk+
│   │       └── <Disk Offload Enabled>
│   └── <Object: instance_2>
│       ├── Object Cache+
│       └── <Counters>
+ indicates logical group
    
```

`StatDescriptor` locates and accesses particular statistics in the PMI tree. For example:

1. `StatDescriptor` to represent statistics for cache servlet: instance_1 templates group template_1: `new StatDescriptor (new String[] {WSDynamicCacheStats.NAME, "Servlet: instance1", WSDynamicCacheStats.TEMPLATE_GROUP, "template_1"});`
2. `StatDescriptor` to represent statistics for cache servlet: instance_1 disk group Disk Offload Enabled: `new StatDescriptor (new String[] {WSDynamicCacheStats.NAME, "Servlet: instance_1", WSDynamicCacheStats.DISK_GROUP, WSDynamicCacheStats.DISK_OFFLOAD_ENABLED});`
3. `StatDescriptor` to represent statistics for cache object: instance2 object cache group Counters: `new StatDescriptor (new String[] {WSDynamicCacheStats.NAME, "Object: instance_2", WSDynamicCacheStats.OBJECT_GROUP, WSDynamicCacheStats.OBJECT_COUNTERS});`

Important: Cache instance names are prepended with cache type ("Servlet: " or "Object: ").

Counter definitions for Servlet Cache

Name of PMI statistics	Path	Description	Version
<code>WSDynamicCacheStats.MaxInMemoryCacheEntryCount</code>	<code>WSDynamicCacheStats.NAME</code> - "Servlet: instance_1"	The maximum number of in-memory cache entries.	5.0 and later
<code>WSDynamicCacheStats.InMemoryCacheEntryCount</code>	<code>WSDynamicCacheStats.NAME</code> - "Servlet: instance_1"	The current number of in-memory cache entries	5.0 and later
<code>WSDynamicCacheStats.HitsInMemoryCount</code>	<code>WSDynamicCacheStats.NAME</code> - "Servlet: cache_instance_1" - <code>WSDynamicCacheStats.TEMPLATE_GROUP</code> - "Template_1"	The number of requests for cacheable objects that are served from memory.	5.0 and later
<code>WSDynamicCacheStats.HitsOnDiskCount</code>	<code>WSDynamicCacheStats.NAME</code> - "Servlet: cache_instance_1" - <code>WSDynamicCacheStats.TEMPLATE_GROUP</code> - "Template_1"	The number of requests for cacheable objects that are served from disk.	5.0 and later

Name of PMI statistics	Path	Description	Version
WSDynamicCacheStats. ExplicitInvalidationCount	WSDynamicCacheStats.NAME - "Servlet: cache_instance_1" - WSDynamicCacheStats. TEMPLATE_GROUP -"Template_1"	The number of explicit invalidations.	5.0 and later
WSDynamicCacheStats. LruInvalidationCount	WSDynamicCacheStats.NAME - "Servlet: cache_instance_1" - WSDynamicCacheStats. TEMPLATE_GROUP -"Template_1"	The number of cache entries that are removed from memory by a Least Recently Used (LRU) algorithm. instance.	5.0 and later
WSDynamicCacheStats. TimeoutInvalidationCount	WSDynamicCacheStats.NAME - "Servlet: cache_instance_1" - WSDynamicCacheStats. TEMPLATE_GROUP -"Template_1"	The number of cache entries that are removed from memory and disk because their timeout has expired.	5.0 and later
WSDynamicCacheStats. InMemoryAndDisk CacheEntryCount	WSDynamicCacheStats.NAME - "Servlet: cache_instance_1" - WSDynamicCacheStats. TEMPLATE_GROUP -"Template_1"	The current number of used cache entries in memory and disk.	5.0 and later
WSDynamicCacheStats. RemoteHitCount	WSDynamicCacheStats.NAME - "Servlet: cache_instance_1" - WSDynamicCacheStats. TEMPLATE_GROUP -"Template_1"	The number of requests for cacheable objects that are served from other Java virtual machines within the replication domain.	5.0 and later
WSDynamicCacheStats. MissCount	WSDynamicCacheStats.NAME - "Servlet: cache_instance_1" - WSDynamicCacheStats. TEMPLATE_GROUP -"Template_1"	The number of requests for cacheable objects that were not found in the cache.	5.0 and later

DISK_OFFLOAD_ENABLED	The number of invalidations resulting in the removal of entries from disk due to exceeding the disk cache size or disk cache size in GB limit.	6.1

Enabling the dynamic cache service

Enable the dynamic cache service to improve application performance by caching the output of servlets, Web services, and WebSphere Application Server commands into memory.

Develop a cache policy for your application. The cache policy defines rules for what responses to cache and the amount of time the responses should be held in the cache. See “Configuring cacheable objects with the cachespec.xml file” on page 2014 for more information.

The dynamic cache service is enabled by default. However, you can enable or disable the service through the administrative console.

1. Open the administrative console.
2. In the administrative console, click **Servers > Application servers > *server_name* > Container services > Dynamic cache service.**
3. Select **Enable service at server startup** .
4. Click **Apply** or **OK**.
5. Restart WebSphere Application Server. You might want to enable servlet caching before restarting WebSphere Application Server. See “Configuring servlet caching” on page 1998 for more information.

The dynamic cache service caches content for requests that have cache policies configured.

You might want to enable dynamic cache disk offload. This option moves cache entries that are expired from memory to disk for potential future access. See “Configuring dynamic cache disk offload” on page 2002 for more information.

Dynamic cache service settings

Use this page to configure and manage the dynamic cache service settings.

To view this administrative console page, click **Servers > Application servers > server_name > Container services > Dynamic cache service**.

Enable service at server startup:

Specifies whether the dynamic cache is enabled when the server starts.

Cache size:

Specifies a positive integer as the value for the maximum number of entries the cache holds.

Enter the cache size value in this field between the range of 100 through 200,000.

Default priority:

Specifies the default priority for cache entries, determining how long an entry stays in a full cache.

Default	1
Range	1 to 255

Enable disk offload:

Specifies whether disk offload is enabled.

By default, the dynamic cache maintains the number of entries configured in memory. If new entries are created while the cache is full, the priorities that are configured for each cache entry and a least recently used algorithm are used to remove entries from the cache. In addition to having a cache entry removed from memory when the cache is full, you can enable disk offload to have a cache entry copied to the file system (the location is configurable). Later, if that cache entry is needed, it is moved back to memory from the file system.

Before you enable disk offload, consider the following:

- You cannot specify the number of cache entries that are offloaded to disk.
- You cannot specify the amount of disk space to use.

Offload location:

Specifies the location on the disk to save cache entries when disk offload is enabled.

If disk offload location is not specified, the default location, `${WAS_TEMP_DIR}/node/server name/_dynacache/cache JNDI name` will be used. If disk offload location is specified, the node, server name, and cache instance name are appended. For example, `${USER_INSTALL_ROOT}/diskoffload` generates the location as `${USER_INSTALL_ROOT}/diskoffload/node/server name/cache JNDI name`. This value is ignored if disk offload is not enabled.

The default value of the `${WAS_TEMP_DIR}` property is `${USER_INSTALL_ROOT}/temp`. If you change the value of the `${WAS_TEMP_DIR}` property after starting WebSphere Application Server, but do not move the disk cache contents to the new location:

- The application server creates a new disk cache file at the new disk offload location.
- If the Flush to disk setting is enabled, all the disk cache content at the old location is lost when you restart the Application Server

When you are specifying a directory, consider the following:

- If you expect to cache a large number of objects or large objects that will be around for some time, consider using a separate disk drive if you are using Windows operating systems, or a separate file system if you are using UNIX platforms.
- If you use the default directory and the disk fills up, WebSphere Application Server could possibly stall if it needs to write messages to log files, and there is no more space.
- If you specify a directory such as /tmp on UNIX platforms and that directory fills up, you may have trouble logging onto the system.
- Depending on the operating system, you may see disk full messages on the console.

Flush to disk:

Specifies if in-memory cached objects are saved to disk when the server is stopped. This value is ignored if **Enable disk offload** is not selected.

Default	false
---------	-------

Limit disk cache size in GB:

Specifies a value for the maximum disk cache size in GB. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	3 and above.
-------	--------------

Limit disk cache size in entries:

Specifies a value for the maximum disk cache size in number of entries. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.
-------	---

Limit disk cache entry size:

Specifies a value for the maximum size of an individual cache entry in MB. Any cache entry larger than this, when evicted from memory, will not be offloaded to disk. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.
-------	---

Disk cache performance settings:

Specifies the level of performance that is required by the disk cache. This setting applies only if **enableDiskOffload** is specified for the cache. Performance levels determine how memory resources should be used on background activity such as cache cleanup, expiration, garbage collection, and so on. This setting applies only if enable disk offload is specified for the cache.

High performance and high memory usage	Indicates that all metadata will be kept in memory.
--	---

Balanced performance and balanced memory usage	Indicates some metadata will be kept in memory. This is the default performance setting and will provide an optimal balance of performance and memory usage for most users.
Low performance and low memory usage	Indicates that limited metadata will be kept in memory.
Custom performance	Indicates that the administrator will explicitly configure the memory settings that will be used to support the above background activity. The administrator sets these values using the DiskCacheCustomPerformanceSettings object.

Disk cache cleanup frequency:

Specifies a value for the disk cache cleanup frequency, in minutes. If this value is set to 0, the cleanup runs only at midnight. This setting applies only when the Disk Offload Performance Level is low, balanced, or custom. The high performance level does not require disk cleanup, and this value is ignored.

Value	0 to 1440
-------	-----------

Maximum buffer for cache identifiers per metaentry:

Specifies a value for the maximum number of cache identifiers that are stored for an individual dependency ID or template in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk offload performance level is CUSTOM.

Value	100 to MAXINT
-------	---------------

Maximum buffer for dependency identifiers:

Specifies a value for the maximum number of dependency identifier buckets in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.

Value	100 to MAXINT
-------	---------------

Maximum buffer for templates:

Specifies a value for the maximum number of template buckets that are in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.

Value	10 to MAXINT
-------	--------------

Disk cache eviction algorithm:

Specifies the eviction algorithm that the disk cache will use to evict entries once the high threshold is reached. This setting applies only if enable disk offload is specified for the cache. This setting does not apply when the disk cache eviction policy is set to none.

None	No eviction policy, so the disk cache can grow until it reaches its limit at which time the dynamic cache service stops writing to disk
------	---

Random	When the disk size reaches a high threshold limit, the disk cache garbage collector wakes up and randomly picks entries on the disk and evicts them until the size reaches a low threshold limit.
Size	When the disk size reaches a high threshold limit, the disk cache garbage collector wakes up and picks the largest entries on the disk and evicts them until the disk size reaches a low threshold limit.

High threshold:

Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The lower value is used when limit disk cache size in GB and limit disk cache size in entries are specified. This setting does not apply when the disk cache eviction policy is set to none.

Values	1 to 100
--------	----------

Low threshold:

Specifies when the eviction policy will end. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The lower value is used limit disk cache size in GB and limit disk cache size in entries are specified. This setting does not apply when the disk cache eviction policy is set to none.

Values	1 to 100
--------	----------

Enable cache replication:

Use cache replication to have cache entries copied to multiple application servers that are configured in the same replication domain.

Full group replication domain:

Specifies a replication domain from which your data is replicated.

Choose from any replication domains that have been defined. If there are no replication domains listed, you must create one during cluster creation or manually in the administrative console by clicking **Environment > Internal replication domains > New**. The replication domain you choose to use with the dynamic cache service must be using a Full group replica. Do not share replication domains between replication consumers. Dynamic cache should use a different replication domain from session manager or stateful session beans.

Replication type:

Specifies the global sharing policy for this application server.

The following settings are available:

- **Both push and pull** sends the cache ID of newly updated content to other servers in the replication domain. Then, if one of the other servers requests the content, and that server has the ID of the cache entry for the previously updated content, it will retrieve the content from the publishing server. On the other hand, if a request is made for an ID which has not been previously published, the server assumes it does not exist in the cluster and creates a new entry.
- **Push only** sends the cache ID and cache content of new content to all other servers in the replication domain.

- The sharing policy of **Not Shared** results in the cache ID and cache content not being shared with other servers in the replication domain.

The default is **Not Shared**.

Push frequency:

Specifies the time, in seconds, to wait before pushing new or modified cache entries to other servers.

A value of 0 (zero) sends the cache entries immediately. Setting this property to a value greater than 0 (zero) results in a "batch" push of all cache entries that are created or modified during the time period. The default is 1 (one).

Configuring servlet caching

Configure servlet caching to save the output of servlets and JavaServer Pages (JSP) files to the dynamic cache.

To enable servlet caching, you must complete "Enabling the dynamic cache service" on page 1993.

1. In the administrative console, click **Servers > Application servers > server_name > Web container settings > Web container** in the console navigation tree.
2. Select **Enable servlet caching** under the Configuration tab.
3. Click **Apply** or **OK**.
4. Restart WebSphere Application Server. See Managing application servers for more information.

Define the cache policy for your servlets by "Configuring cacheable objects with the cachespec.xml file" on page 2014.

Servlet caching:

After a servlet is invoked and completes generating the output to cache, a cache entry is created containing the output and the side effects of the servlet. These side effects can include calls to other servlets or JavaServer Pages (JSP) files or metadata about the entry, including timeout and entry priority information.

Unique entries are distinguished by an ID string that is generated from the HttpServletRequest object each time the servlet runs. You can then base servlet caching on:

- Request parameters and attributes of the Universal Resource Identifier (URI) that was used to invoke the servlet
- Session information
- Other options, including cookies

Because JavaServer Pages files are compiled into servlets, the dynamic cache function treats JavaServer Pages files the same as servlets, except in specifically documented situations.

To enable servlet caching see "Configuring servlet caching." To configure cache policies for your servlets, see "Configuring cacheable objects with the cachespec.xml file" on page 2014.

Configuring portlet fragment caching

Configure portlet fragment caching with the WebSphere Application Server administrative console to save the output of portlets to the dynamic cache.

To enable portlet fragment caching, you must complete "Enabling the dynamic cache service" on page 1993.

1. In the administrative console, click **Servers > Application servers > server_name > Portlet container settings > Portlet container** in the administrative console navigation tree.
2. Select **Enable portlet fragment cache** under the Configuration tab.

3. Click **Apply** or **OK**.
4. Restart WebSphere Application Server.
See the *Setting up the application serving environment* PDF for more information.

Define the cache policy for your portlets by “Configuring cacheable objects with the cachespec.xml file” on page 2014.

Portlet fragment caching:

After a portlet is invoked and completes generating the output to cache, a cache entry is created, containing the output and the side effects of the portlet. These side effects can include calls to other portlets or metadata about the entry, including timeout and entry priority information.

Unique entries are distinguished by an ID string that generated from the PortletRequest object each time the portlet runs. You can then base portlet fragment caching on:

- Request parameters and attributes
- Session information
- Portlet-specific information, portlet session, portlet window ID, portlet mode, and portlet window state

To enable portlet fragment caching see “Configuring portlet fragment caching” on page 1998. To configure cache policies for your portlets, see “Configuring cacheable objects with the cachespec.xml file” on page 2014.

Configuring portlet fragment caching with the wsadmin tool

You can configure portlet fragment caching with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the *Using the administrative clients* PDF for more information.

Important: If you use the wsadmin tool to enable portlet fragment caching, you must make sure that servlet caching is also enabled. Similarly if you use the wsadmin tool to disable portlet fragment caching, you must make sure that servlet caching is also disabled. The settings for these two caching functions must stay synchronized. If you enable or disable portlet fragment caching using the administrative console, synchronization is automatically taken care of for you.

1. Locate the server object. The following example selects the first server found:

Using Jacl:

```
set s1 [$AdminConfig getid /Server:server1/]
```

Using Jython:

```
s1 = AdminConfig.getid('/Server:server1/')
```

2. List the Web containers and assign them to the wc variable, for example:

Using Jacl:

```
set wc [$AdminConfig list PortletContainer $s1]
```

Using Jython:

```
wc = AdminConfig.list('PortletContainer', s1)
```

3. Set the enablePortletCaching attribute to true and assign it to the serEnable variable, for example:

Using Jacl:

```
set serEnable "{enablePortletCaching true}"
```

Using Jython:

```
serEnable = [['enablePortletCaching', 'true']]
```

4. Enable caching, for example:

Using Jacl:

```
$AdminConfig modify $wc $serEnable
```

Using Jython:

```
AdminConfig.modify(wc, serEnable)
```

Configuring caching for Struts and Tiles applications

Use this task to cache Struts and Tiles applications.

Before you configure Struts and Tiles caching, you should have a developed application. For more information about developing Struts and Tiles applications, see *The Apache Struts Web Application Framework* on the Apache Web site at <http://struts.apache.org/>.

Use this task when you want to cache data in Struts and Tiles applications.

Struts is an open source framework for building Web applications using the Model-View-Controller (MVC) architecture. The Struts framework has a controller component and integrates with other technologies to provide the model and the view. Struts provide a control layer for the Web application, which reduces construction time and maintenance costs.

The Tiles framework builds on the `jsp:include` feature and is bundled with the Struts Web application framework. The Tiles framework reduces the duplication between JavaServer Pages (JSP) files and makes Web site layouts flexible and easy to maintain by assembling presentation pages from component parts.

Struts and Tiles caching is an extension of servlet and JSP caching, so the actions performed for each type of caching are very similar. See “Servlet caching” on page 1998 for more information.

1. Enable servlet and JSP caching. Enabling servlet caching automatically enables Struts and Tiles caching. See “Configuring servlet caching” on page 1998 for more information.
2. Develop the cache policy. A cache policy is required to cache a struts or tiles response.

To develop a Struts cache policy:

The Struts framework provides the controller component in the MVC-style application. The controller is a servlet called `org.apache.struts.action.ActionServlet.class`. In the `web.xml` file of the application, a servlet mapping of `*.do` is added for this Struts ActionServlet servlet so that every request for a Web address that ends with `.do` is processed. The ActionServlet servlet uses the information in the `struts-config.xml` file to decide which Struts action class runs the request for the specified resource.

Cache policy using a previous version of WebSphere Application Server

In the previous version of WebSphere Application Server, only one cache policy per servlet was supported. However, when you are using Struts, every request that ends in `.do` maps to the same ActionServlet servlet. To cache Struts responses, write a cache policy for the ActionServlet servlet based on its servlet path.

For example, consider two Struts actions: `/HelloParam.do` and `/HelloAttr.do`. To cache the responses based on the id request parameter and the arg request attribute respectively, use the following cache policy:

```
<cache-entry>
  <class>servlet</class>
  <name>org.apache.struts.action.ActionServlet.class</name>
  <cache-id>
    <component id="" type="servletpath">
      <value>/HelloParm.do</value>
    </component>
  </cache-id>
  <cache-id>
    <component id="" type="servletpath">
      <value>/HelloAttr.do</value>
    </component>
    <component id="arg" type="attribute">
```

```

    <required>true</required>
  </component>
</cache-id>
</cache-entry>

```

Cache policy using WebSphere Application Server, Version 6.0 or later

With the current version of WebSphere Application Server, you can map multiple cache policies for a single servlet. You can rewrite the previous cache policy as in the following example:

```

<cache-entry>
  <class>servlet<
  <name>/HelloParam.do</name>
  <cache-id>
    <component id="id" type="parameter">
      <required>true</required>
    </component>
  </cache-entry>
<cache-entry>
  <class>servlet</class>
  <name>/HelloAttr.do</name>
  <cache-id>
    <component id="arg" type="attribute">
      <required>true</required>
    </component>
  </cache-id>
</cache-entry>

```

To develop a Tiles cache policy:

The Tiles framework is built on the `jsp:include` tag, so everything that applies to JSP caching also applies to Tiles. You must set the `flush` attribute to `true` in any fragments that are included using the `tiles:insert` tag for the fragments to be cached correctly. The extra feature in tiles caching over JSP caching is based on the `tiles` attribute. For example, you might develop the following `layout.jsp` template:

```

<html>
  <%String categoryId = request.getParameter("categoryId")+"test"; %>
  <tiles:insert attribute="header">
    <tiles:put name="categoryId" value="<%= categoryId %>" />
  </tile:insert>
  <table>
    <tr>
      <td width="70%" valign="top"><tiles:insert attribute="body" /> </td>
    </tr>
    <tr>
      <td colspan="2"><tiles:insert attribute="footer" /></td>
    </tr>
  </table>
</body>
</html>

```

The nested `tiles:put` tag specifies the attribute of the inserted tile. In the `layout.jsp` template, the `categoryId` attribute is defined and passed on to the tile that is inserted into the placeholder for the header. In the following example, the `layout.jsp` file is inserted into another JSP file:

```

<html>
<body>
  <tiles:insert page="layout.jsp?categoryId=1002" flush="true">
    <tiles:put name="header" value="/header.jsp" />
    <tiles:put name="body" value="/body.jsp" />
    <tiles:put name="footer" value="/footer.jsp" />
  </tiles:insert>
</body>
</html>

```

The `categoryId` tile attribute is passed on to the `header.jsp` file. The `header.jsp` file can use the `<tiles:useAttribute>` tag to retrieve the value of `categoryId`. To cache the `header.jsp` file based on the value of the `categoryId` attribute, you can use the following cache policy:

```
<cache-entry>
  <class>servlet</class>
  <name>/header.jsp</name>
  <cache-id>
    <component id="categoryId" type="tiles_attribute">
      <required>true</required>
    </component>
  </cache-id>
</cache-entry>
```

3. Ensure your cache policy is working correctly. You can modify the policies within the `cachespec.xml` file while your application is running. See “Configuring cacheable objects with the `cachespec.xml` file” on page 2014 for more information about cache policies.

See “Task overview: Using the dynamic cache service to improve performance” on page 1978 for more information about the dynamic cache.

Configuring dynamic cache disk offload

Use this task to configure dynamic cache disk offload, which saves cache entries that are deleted from the memory cache to disk.

By default, when the number of cache entries reaches the configured limit for a given application server, cache entries are removed from the memory cache, allowing newer entries to be stored in the cache. Use disk offload to copy the cache entries that are being removed from the memory cache to disk for potential future access.

You can use disk offload if you have one servant in your application server. If there are multiple servants enabled in your configuration, do not enable disk offload. If you enable disk offload for an application server that has multiple servants, each servant attempts to save data to the same location on the disk. For more information about enabling and disabling multiple servants, see the *Setting up the application serving environment* PDF.

1. In the administrative console, click **Servers > Application servers > *server_name* > Container services > Dynamic cache service**.
2. Select **Enable disk offload**.
3. After you enable the disk offload, you can set the **Disk offload location**. The disk offload location specifies where to save the cache entries on the disk. The disk offload location must be unique for any application servers that are defined on the same node. If you have multiple servers defined on the same node, make sure the disk offload location is different for each server.
4. Enable **Flush to disk** if you want cache objects that are in memory to be saved to disk when the server is stopped. Disk offload must be enabled if you choose this option. If you do not enable flush to disk, all the cache objects are deleted when the server stops.
5. Click **Apply** or **OK**.
6. Restart WebSphere Application Server.

You enabled disk offload. Memory cache entries are moved to disk for potential future access.

When you have two or more application servers with servlet caching enabled and the application servers specify the same disk offload location for their caches through the dynamic cache service, the following exceptions might occur:

```
java.lang.NullPointerException
  at com.ibm.ws.cache.CacheOnDisk.readTemplate(CacheOnDisk.java:686)
  at com.ibm.ws.cache.Cache.internalInvalidateByTemplate(Cache.java:828)
```

or:

```
java.lang.NullPointerException
    at com.ibm.ws.cache.CacheOnDisk.readCacheEntry(CacheOnDisk.java:600)
    at com.ibm.ws.cache.Cache.getCacheEntry(Cache.java:341)
```

If one server is run as root and the other servers are run as non-root, this problem could occur. For example, if server1 runs as root and server2 runs as wasuser or wasgroup, the cache files in the disk offload location might be created with root permissions. This situation causes the applications running on the non-root servers to crash when they try to read or write to the cache.

Managing cache entries stored on a disk:

Use this page to set Java virtual machine (JVM) custom properties to maintain cache entries that are saved to disk.

Steps for this task

You can set the custom properties globally to affect all cache instances, or you can set the custom property on a single cache instance. In most cases, set the properties on the individual cache instances. To set the custom properties on the default cache instance, use the global option. If you set the same property both globally and on a cache instance, the value that is set on the cache instance overrides the global value.

To configure the custom properties on a single object cache instance or servlet cache instance, perform the following steps:

1. In the administrative console, click one of the following paths:
 - To configure a servlet cache instance, click **Resources > Cache instances > Servlet cache instances > *servlet_cache_instance_name* > Custom properties > New.**
 - To configure an object cache instance, click **Resources > Cache instances > Object cache instances > *object_cache_instance_name* > Custom properties > New.**
2. Type the name of the custom property. When configuring these custom properties on a single cache instance, you do not use the full property path. For example, type `explicitBufferLimitOnStop` to configure the `com.ibm.ws.cache.CacheConfig.explicitBufferLimitOnStop` custom property.
3. Type a valid value for the property in the **Value** field.
4. Save the property and restart WebSphere Application Server.

To configure the custom property globally across all configured cache instances, perform the following steps:

1. In the administrative console, click **Servers > Application servers > *server_name* > Java and process management > Process definition > Java virtual machine > Custom properties > New.**
2. Type the name of the custom property (for example, `com.ibm.ws.cache.CacheConfig.explicitBufferLimitOnStop`) in the **Name** field.
3. Type a valid value for the property in the **Value** field.
4. Save the property and restart WebSphere Application Server.

com.ibm.ws.cache.CacheConfig.htodCleanupFrequency

Use this property to change the amount of time between disk cache cleanup.

Important: Setting this custom property manually is deprecated for V6.1. Therefore, you should use the administrative console to set this property. To set this property in the administrative console, click one of the following paths:

- To configure a servlet cache instance, click **Resources > Cache instances > Servlet cache instances > *servlet_cache_instance_name*.**

- To configure an object cache instance, click **Resources > Cache instances > Object cache instances > *object_cache_instance_name***.

Then:

1. Under Disk Cache setting, select the Enable disk offload field if it is not already selected.
2. Under Performance Settings, select Balanced performance and balanced memory usage or Custom.
3. In the Disk cache cleanup frequency field, specify an appropriate length of time, in minutes.

By default, the disk cache cleanup is scheduled to run at midnight to remove expired cache entries and cache entries that have not been accessed in the past 24 hours. However, if you have thousands of cache entries that might expire within one or two hours, the files that are in the disk cache can grow large and become unmanageable. Use the `com.ibm.ws.cache.CacheConfig.htodCleanupFrequency` custom property to change the time interval between disk cache cleanup.

Units	minutes For example, a value of 60 means 60 minutes between each disk cache cleanup.
Default	0 The disk cache cleanup occurs at midnight every 24 hours.

com.ibm.ws.cache.CacheConfig.htodDelayOffloadEntriesLimit

Use this property to specify the number of different cache IDs that can be saved in memory for the dependency ID and template buffers. Consider increasing this value if you have a lot of memory in your server and you want to increase the performance of your disk cache.

Important: Setting this custom property manually is deprecated for V6.1. Therefore, you should use the administrative console to set this property. To set this property in the administrative console, click one of the following paths:

- To configure a servlet cache instance, click **Resources > Cache instances > Servlet cache instances > *servlet_cache_instance_name***.
- To configure an object cache instance, click **Resources > Cache instances > Object cache instances > *object_cache_instance_name***.

Then:

1. Under Disk Cache setting, select the Enable disk offload field, if it is not already selected.
2. Under Disk Cache settings, select Limit disk cache size in entries, if it is not already selected.
3. In the Disk cache size field, specify the number of cache IDs that can be saved in memory for the dependency ID and template buffers.

Units	number of cache IDs For example, a value of 1000 means that each dependency ID or template ID can have up to 1000 different cache IDs in memory.
Default	1000
Minimum	100

Tune the delay offload function

Use these properties to tune the delay offload function for the disk cache.

Important: Setting these custom properties manually is deprecated for V6.1. You should use the administrative console to set these properties. The individual property descriptions include information on how to use the administrative console to set these properties.

The delay offload function uses extra memory buffers for dependency IDs and templates to delay the disk offload and minimize the input and output operations. However, if most of your cache IDs are longer than 100 bytes, the delay offload function might use too much memory. Use any combination of the following properties to tune your configuration:

- To increase or decrease the in-memory limit of cache IDs for dependency ID and template buffers, use the `com.ibm.ws.cache.CacheConfig.htodDelayOffloadEntriesLimit` custom property.
- To disable the disk cache delay offload function, use the `com.ibm.ws.cache.CacheConfig.htodDelayOffload` custom property. Disabling this property saves all cache entries to disk immediately after removing them from the memory cache.

com.ibm.ws.cache.CacheConfig.explicitBufferLimitOnStop

Use this custom property when the flush-to-disk-on-stop feature is enabled. When the server is stopping, offloads are limited to the value specified for this property, pending removal of entries in the explicit invalidation buffer. If this property is set to 0, there is no limit to the number of offloads that can occur. Only positive integers are accepted as values for this property. If the number of entries in the explicit invalidation buffer is greater than the specified limit, all of the disk files for this specified cache instance are deleted after the server stops.

Important: You cannot use the administrative console to set this property.

Configuring Edge Side Include caching

The Web server plug-in contains a built-in ESI processor. The ESI processor can cache whole pages, as well as fragments, providing a higher cache hit ratio. The cache implemented by the ESI processor is an in-memory cache, not a disk cache, therefore, the cache entries are not saved when the Web server is restarted.

Edge Side Include (ESI) is configured through the `plugin-cfg.xml` file.

When a request is received by the Web server plug-in, it is sent to the ESI processor, unless the ESI processor is disabled. It is enabled by default. If a cache miss occurs, a `Surrogate-Capabilities` header is added to the request and the request is forwarded to the WebSphere Application Server. If servlet caching is enabled in the application server, and the response is edge cacheable, the application server returns a `Surrogate-Control` header in response to the WebSphere Application Server plug-in.

The value of the `Surrogate-Control` response header contains the list of rules that are used by the ESI processor to generate the cache ID. The response is then stored in the ESI cache, using the cache ID as the key. For each ESI include tag in the body of the response, a new request is processed so that each nested include results in either a cache hit or another request that forwards to the application server. When all nested includes have been processed, the page is assembled and returned to the client.

The ESI processor is configurable through the WebSphere Web server plug-in configuration file `plugin-cfg.xml`. The following is an example of the beginning of this file, which illustrates the ESI configuration options.

```
<?xml version="1.0"?>
<Config>
  <Property Name="esiEnable" Value="true"/>
  <Property Name="esiMaxCacheSize" Value="1024"/>
  <Property Name="esiInvalidationMonitor" Value="false"/>
```

- The first option, esiEnable, can be used to disable the ESI processor by setting the value to false. ESI is enabled by default. If ESI is disabled, then the other ESI options are ignored.
- The second option, esiMaxCacheSize, is the maximum size of the cache in 1K byte units. The default maximum size of the cache is 1 megabyte. If the cache is full, the first entry to be evicted from the cache is the entry that is closest to expiration.
- The third option, esiInvalidationMonitor, specifies if the ESI processor should receive invalidations from the application server. ESI works well when the Web servers following a threading model are used, and only one process is started. When multiple processes are started, each process caches the responses independently and the cache is not shared. This could lead to a situation where, the system's memory is fully used up by ESI processor. There are three methods by which entries are removed from the ESI cache: first, an entry expiration timeout occurs; second, an entry is purged to make room for newer entries; or third, the application server sends an explicit invalidation for a group of entries. For the third mechanism to be enabled, the esiInvalidationMonitor property must be set to true and the DynaCacheEsi application must be installed on the application server. The DynaCacheEsi application is located in the installableApps directory and is named DynaCacheEsi.ear. If the ESIInvalidationMonitor property is set to true but the DynaCacheEsi application is not installed, then errors occur in the Web server plug-in and the request fails.
- On distributed platforms, the cache for the ESI processor is monitored through the CacheMonitor application. In order for ESI processor cache to be visible in the CacheMonitor, the DynaCacheEsi application must be installed as described above, and the ESIInvalidationMonitor property must be set to true in the plugin-cfg.xml file.
- When WebSphere Application Server is used to serve static data, such as images and HTML on the application server, the URLs are also cached in the ESI processor. This data has a default timeout of 300 seconds. You can change the timeout value by adding the property com.ibm.servlet.file.esi.timeOut to the Java virtual machine (JVM) command line parameters. The following example shows how to set a one minute timeout on static data cached in the plug-in:

```
-Dcom.ibm.servlet.file.esi.timeOut=60
```

For information about configuring alternate URL, see the *Tuning guide* PDF.

Configuring alternate URL:

Alternate URL is a method for edge caching JavaServer Pages (JSP) files and servlet responses that you can not request externally. Dynamic cache provides support to recognize the presence of an Edge Side Include (ESI) processor and to generate ESI include tags and appropriate cache policies for edge fragments that can be cached. However, you must be able to externally request an edge fragment from the application server before it can be cached. In other words, if a user types the URL in their browser with the appropriate parameters and cookies for the fragment, WebSphere Application Server must be able to return the content for that fragment.

One of the standard Java 2 Platform, Enterprise Edition (J2EE) programming architectures is the model-view-controller (MVC) architecture, where a call to a controller servlet might include one or more child JSP files to construct the view. When using the MVC programming model, the child JSP files are edge cached only if you can request these JSP files externally, which is not usually the case. For example, if a child JSP file uses one or more request attributes that are determined and set by the controller servlet, you cannot cache that JSP file on the edge. You can use alternate URL support to overcome this limitation by providing an alternate controller servlet URL used to invoke the JSP file.

The alternate URL for a JSP file or a servlet is set in the cachespec.xml file as a property with the name alternate_url. You can set the alternate URL either on a per cache-entry basis or on a per cache-id

basis. It is valid only if the `EdgeCacheable` property is also set for that entry. If the `EdgeCacheable` property is not set, the `alternate_url` property is ignored. The following is a sample cache policy using the `alternate_url` property:

```
<cache-entry>
  <class>servlet</class>
  <name>/AltUrlTest2.jsp</name>
  <property name="EdgeCacheable">true</property>
  <property name="alternate_url">/alturlcontroller2</property>
    <cache-id>
      <timeout>600</timeout>
      <priority>2</priority>
    </cache-id>
</cache-entry>
```

For more information on the `cachespec.xml` file, see “Cachespec.xml file” on page 2015.

Configuring external cache groups

The dynamic cache can control caches outside of the application server, such as the Edge server, an IBM HTTP Server, or an HTTP Server ESI Fragment Processor plug-in.

When external cache groups are defined, the dynamic cache matches externally cacheable cache entries with those groups, and pushes cache entries and invalidations out to those groups. This allows WebSphere Application Server to manage dynamic content beyond the application server. The content can then be served from the external cache, instead of the application server, improving savings in performance.

1. Open the administrative console.
2. Enable the dynamic cache.
 - a. In the administrative console, click **Servers > Application servers > server_name > Container services > Dynamic cache service**.
 - b. Select **Enable service at server startup** to enable the dynamic cache each time the application server starts.
3. Define the external cache group that WebSphere Application Server should control.
 - a. In the administrative console, click **Servers > Application servers > server_name > Container services > Dynamic cache service > External cache groups**.
 - b. Click **New** or choose an external cache group from the list.
4. Configure cache group members.
 - a. Click **External cache groups** from the dynamic cache administrative console page. Then click **New** or choose an external cache group from the list.
 - b. Click **External cache group members > New** or choose an external cache group member from the list.
 - c. Type the configuration string in the **Address** field.
 - d. Type the adapter bean name in the **Adapter Bean Name** field.
 - e. **Save** the configuration.
 - f. Click **Apply** or **OK**.

External cache group collection:

Use this page to define sets of external caches controlled by WebSphere Application Server on Web servers such as IBM Edge Server and IBM HTTP Server.

To view this administrative console page, click **Servers > Application servers > server_name > Container services > Dynamic cache service > External cache groups**.

Name:

Specifies the external cache group name.

The external cache group name needs to match the **ExternalCache** property as defined in the servlet or JavaServer Pages file `cachespec.xml` file.

When external caching is enabled, the cache matches pages with its Universal Resource Identifiers (URI) and pushes matching pages to the external cache. The entries can then be served from the external cache, instead of from the application server.

Type:

Specifies the external cache group type.

External cache group settings:

Use this page to configure sets of external caches controlled by WebSphere Application Server on Web servers, such as IBM Edge Server and IBM HTTP Server.

To view this administrative console page, click **Servers > Application servers > *server_name* > Container services > Dynamic cache service > External cache groups > *external_cache_group***.

Name:

Specifies the external cache group name.

The external cache group name must match the **ExternalCache** property as defined in the servlet or JavaServer Pages (JSPs) `cachespec.xml` file.

When external caching is enabled, the cache matches pages with its Universal Resource Identifiers (URIs) and pushes matching pages to the external cache. The entries can then be served from the external cache, instead of the application server. This ability creates a significant savings in performance.

External cache group member collection:

Use this page to define specific caches that are members of a cache group.

To view this administrative console page, click **Servers > Application servers > *server_name* > Container services > Dynamic cache service > External cache groups > *external_cache_group* > External cache group members**.

Address:

Specifies a configuration string used by external cache adapter bean to connect to the external cache.

AdapterBeanName:

Specifies the adapter bean name.

Example adapter bean names supported in WebSphere Application Server are:

AFPA
AdapterBeanName: com.ibm.ws.cache.servlet.Afpa
Address: Port on which afpa listens

ESI
AdapterBeanName: com.ibm.websphere.servlet.cache.ESIInvalidatorServlet
Address: On the z/OS platform, the port on which ESI listens, otherwise local host.
IBM Web Traffic Express (WTE) (IBM Edge Server)
AdapterBeanName: com.ibm.websphere.edge.dynacache.WteAdapter
Address: hostname:port (host name and port on which WTE is listening)

External cache group member settings:

Use this page to configure specific caches that are members of a cache group.

To view this administrative console page, click **Servers > Application servers > server_name > Container services > Dynamic cache service > External cache groups > external_cache_group > External cache group members > external_cache_group_member**.

Address:

Specifies a configuration string used by external cache adapter bean to connect to the external cache.

Adapter bean name:

Specifies the adapter bean name.

Example adapter bean names supported in WebSphere Application Server are:

AFPA
AdapterBeanName: com.ibm.ws.cache.servlet.Afpa
Address: Port on which afpa listens
ESI
AdapterBeanName: com.ibm.websphere.servlet.cache.ESIInvalidatorServlet
Address: On the z/OS platform, the port on which ESI listens, otherwise, local host.
IBM Web Traffic Express (WTE) (IBM Edge Server)
AdapterBeanName: com.ibm.websphere.edge.dynacache.WteAdapter
Address: hostname:port (host name and port on which WTE is listening)

Configuring high-speed external caching through the Web server:

IBM HTTP Server for Windows NT and Windows 2000 operating systems contains a high-speed cache referred to as the *Fast Response Cache Accelerator*, or *cache accelerator*. The Fast Response Cache Accelerator is available on Windows NT and Windows 2000 operating systems and AIX platforms. However, support to cache dynamic content is only available on Windows NT and Windows 2000 operating systems. You can enable cache accelerator to cache static and dynamic content.

To enable cache accelerator for caching static content, add the following directives to the http.conf configuration file, in the IBM HTTP Server conf directory:

- AfpEnable
- AfpCache on
- AfpLogFile "*app_server_root\IBMHttpServer\logs\afplog*" V-ECLF

To enable cache accelerator for caching dynamic content, such as servlets and JavaServer Pages (JSP) files, configure the WebSphere Application Server and the IBM HTTP Server for distributed platforms:

1. Configure WebSphere Application Server to enable Fast Response Cache Accelerator. It is important to follow all the steps for every application server in the cluster.
 - a. Configure an external cache group on the application server:
 - 1) Click **Servers > Application servers > *server_name* > Container services > Dynamic cache service > External cache groups.**
 - 2) Click **New** on the External cache group administrative console page to define an external cache group named `afpa` for each application server that uses the cache accelerator.
 - 3) In the **External cache group** field, type `afpa` and apply the changes.
 - b. Add a member to the group with an adapter bean name of `com.ibm.ws.cache.servlet.Afpa`.
 - 1) Click **Afpa > External cache group members.**
 - 2) Click **New** on the External cache group members administrative console page.
 - 3) In the **AdapterBean name** field, type `com.ibm.ws.cache.servlet.Afpa`.
 - 4) In the **Address** field, enter an unused port number.
 - c. Add a cache policy in the `cachespec.xml` file for the servlet or JSP file you want to cache. Add the following property to the cache policy:

```
<property name="ExternalCache">afpa</property>
```

2. Enable cache accelerator on the IBM HTTP Server for distributed platforms:

- a. Add the following directives to the end of the `httpd.conf` file:
 - `AfpaEnable`
 - `AfpaCache on`
 - `AfpaLogFile "app_server_root\IBMHttpServer\logs\afpalog" V-ECLF`
 - `LoadModule afpaplugin_module app_server_root/bin/afpaplugin.dll`
 - `AfpaPluginHost WAS_Hostname:port`, where `WAS_Hostname` is the host name of the application server and `port` is the port you specified in the Address field while configuring the external cache group member

The `LoadModule` directive loads the IBM HTTP Server plug-in that connects the Fast Response Cache Accelerator to the WebSphere Application Server fragment cache. If multiple IBM HTTP Servers are routing requests to a single application server, add the directives above to the `http.conf` file of each of these IBM HTTP Servers for distributed platforms. If one IBM HTTP Server is routing requests to a cluster of application servers, add the `AfpaPluginHost WAS_Hostname:port` directive to the `http.conf` file for each application server in the cluster. For example, if there are three application servers in the cluster, add the following directives to the `http.conf` file:

- `LoadModule afpaplugin_module app_server_root/bin/afpaplugin.dll`
- `AfpaPluginHost WAS1_Hostname:port1`
- `AfpaPluginHost WAS2_Hostname:port2`
- `AfpaPluginHost WAS3_Hostname:port3`

Configuring fast response cache accelerator cache size through a distributed platforms Web server:

In the default IBM HTTP Server for distributed platforms configuration, the maximum fast cache accelerator dynamic cache size is calculated as 1/8 of physical pin-able memory.

On a machine with 384 megabytes of RAM, it allows a maximum of approximately 50 megabytes for the Fast Cache Accelerator dynamic cache. When this limit is reached, the cache accelerator deletes older entries to cache new entries.

Using the IBM HTTP Server for distributed platforms `AfpaDynaCacheMax` directive, tune the maximum allowed cache size:

1. Place the directive in the global server configuration scope, along with the other default Fast Cache Accelerator directives.

2. Enable fast cache accelerator. To enable the fast cache accelerator, update the following directives in this IBM HTTP Server's `http.conf` file:

```
AfpaEnable
AfpaCache on
AfpaLogFile "c:/Program Files/IBM HTTP Server/logs/afpalog" V-ECLF
AfpaDynaCacheMax 10
```

These settings limit the dynamic cache size to 10 megabytes. If you use these directives to increase cache size, do not make the cache so large that all the physical memory is consumed. Determine how much memory is available when all applications are running, by using the Windows Task Manager.

Assign no more than 50% of available physical memory to the dynamic cache. Specifying too large a cache not only decreases the performance of other applications, but also puts you at a risk for completely running out of memory.

The default configuration does not include the `AfpaDynaCacheMax` directive where the cache size is automatically calculated as 1/8 of physical memory.

Configuring cache replication

Use this task to improve performance by configuring the data replication service (DRS) to replicate data from the dynamic cache service across the consumers in a replication domain.

See “Cache replication” on page 2013 for more information about replicating data for the dynamic cache service.

You should have a replication domain created for the dynamic cache service. Configure a different replication domain for each type of consumer of the replication domain. For example, configure two different replication domains for dynamic cache and session manager. There are two ways to configure replication domains:

- To create replication domains manually, click **Environment > Replication domains** in the administrative console.
- To create a new replication domain automatically when you create a cluster, click **Servers > Clusters > New** in the administrative console.

For more details about configuring replication domains, see *Replicating data across application servers in a cluster*.

Do not use the default value of a single replica for the **Number of replicas** for dynamic cache replication domains. Instead, use a full group replica for any replication domains that you configure for dynamic cache.

Note: If you configured cache replication with a previous version of WebSphere Application Server, review *Migrating servers from multi-broker replication domains to data replication domains* to learn about the new type of replication domains that you should use with the current version of WebSphere Application Server.

Use this task to improve performance in a clustered environment by enabling the data replication service (DRS) to replicate cached data across the servers in a cluster. Invalidations of cache entries are sent across the cluster to keep the cached data consistent and valid.

1. In the administrative console, click **Servers > Application servers > *server_name* > Container services > Dynamic cache service**.
2. To enable replication, select **Enable cache replication**.
3. Choose a replication domain. Use different replication domains for each type of consumer. For example, dynamic cache should use a different replication domain than session manager. The only replication domains that you can select in this panel include replication domains that are configured to use full-group replication. In a full-group configuration, every cache entry is replicated to every other cache that is configured in the servers that are in the replication domain. If none of the replication

domains in your configuration meet these requirements, the list is empty. In this case, create a replication domain or alter an existing replication domain so that you have a replication domain that can perform full-group replication. See *Replicating data across application servers in a cluster* for more information.

4. Define the dynamic cache replication settings. Click **Enable cache replication**. On this page, you can define when and how often data is replicated across the dynamic cache replication domain. For more information about these settings, see “Dynamic cache service settings” on page 1994.
5. To enable cache replication on a base server that has multiple servants configured, you must define the following JVM custom properties.
 - a. In the administrative console, click **Servers > Application servers > server_name > Java and process management > Process definition > Servant > Java Virtual Machine > Custom properties > New**.
 - b. Add the new property name as `DynacacheEnableUnmanagedServerReplication` and set the value to `true`.
 - c. Add another JVM property to specify the global sharing policy for the base z/OS server. Click **New** and add a new JVM custom property that is called `DynacacheUnmanagedServerReplicationType`. Use one of the following values:

Value	Description
NOT_SHARED	Cache entries for this object are not shared among different application servers. These entries can contain non-serializable data. For example, a cached servlet can place non-serializable objects into the request attributes, if the class type supports it.
PUSH	Cache entries for this object are automatically distributed to the dynamic caches in other application servers or cooperating Java Virtual Machines (JVMs). Each cache has a copy of the entry at the time it is created. These entries cannot store non-serializable data.
PULL	Cache entries for this object are shared between application servers on demand. If an application server gets a cache miss for this object, it queries the cooperating application servers to see if they have the object. If no application server has a cached copy of the object, the original application server runs the request and generates the object. These entries cannot store non-serializable data. This mode of sharing is not recommended.
PUSH_PULL	Cache entries for this object are shared between application servers on demand. When an application server generates a cache entry, it broadcasts the cache ID of the created entry to all cooperating application servers. Each server then knows whether an entry exists for any given cache ID. On a given request for that entry, the application server knows whether to generate the entry or pull it from somewhere else. These entries cannot store non-serializable data.

If you do not define one of these values, the default is `NOT_SHARED`.

6. Define sharing policies in the `cachespec.xml` file.
 To use cache replication among multiple servants on a base server, you must create a `cachespec.xml` file to define the cacheable objects that you want to create. You can override the global sharing policy by specifying a specific sharing policy in the cache policy. For example, if your global policy is to use Push only, you can change the sharing policy of a specific cache entry by making this change to your cache policy:

```

<cache-entry>
  <sharing-policy>not-shared</sharing-policy>
  <class>servlet</class>
  <name>/app</name>
  <cache-id>
    <component id="action" type="parameter">
      <value>portfolio</value>
      <required>true</required>
    </component>
    <component id="JSESSIONID" type="cookie">
      <required>true</required>
    </component>
    <property name="EdgeCacheable">true</property>
  </cache-id>
</cache-entry>

```

For more information about the sharing policies that can be defined in the `cachespec.xml` file, see “Cachespec.xml file” on page 2015.

Cache entries copy to the other application servers in the configured replication domain.

Use the cache monitor to view the contents of the cache. See “Displaying cache information” on page 2046 for more information.

Cache replication

With replication, data is generated one time and copied or replicated to other servers in the cluster, saving time and resources. Caching in a cluster has additional concerns. In particular, the same data can be required and generated in multiple places. Also, the permission the resources need to generate the cached data can be restricted, preventing access to the data.

Cache replication deals with these concerns by generating the data one time and copying it to the other servers in the cluster. It also aids in cache consistency. Cache entries that are not needed are removed or replaced.

The data replication configuration can exist as part of the Web container dynamic cache configuration accessible through the administrative console, or on a per cache entry basis through the `cachespec.xml` file. With the `cachespec.xml` file, you can configure cache replication at the Web container level, but disable it for a specific cache entry.

You can configure cache replication on a base server that has multiple servants enabled or on servers that are in a clustered environment. If you enable cache replication in a clustered environment, the replication occurs among all of the servants even if only a single server in the cluster is active.

Cache replication can take on three forms:

- **PUSH** - Send out new entries, both ID and data, and updates to those entries.
- **PULL** - Requests data from other servers in the cluster when that data is not locally present. This mode of replication is not recommended.
- **PUSH/PULL** - Sends out IDs for new entries, then, only requests from other servers in the cluster entries for IDs previously broadcast. The dynamic cache always sends out cache entry invalidations.

You can also perform a batch update. Specifically, for PUSH or PUSH/PULL, the dynamic cache broadcasts the update asynchronously, based on a timed interval rather than sending them immediately when they are created. Invalidations are sent immediately. Distribution of invalidations prevents stale data from residing in a cluster. For more information about configuring cache replication, see “Configuring cache replication” on page 2011 and “Dynamic cache service settings” on page 1994.

Configuring cacheable objects with the cachespec.xml file

Use this task to define cacheable objects inside the `cachespec.xml`, found inside the Web module `WEB-INF` or enterprise bean `META-INF` directory.

Enable the dynamic cache. See “Enabling the dynamic cache service” on page 1993 for more information.

You can save a global `cachespec.xml` in the application server properties directory, but the recommended method is to place the cache configuration file with the deployment module. The root element of the `cachespec.xml` file is `<cache>`, which contains `<cache-entry>` elements.

The `<cache-entry>` element can be nested within the `<cache>` element or a `<cache-instance>` element. The `<cache-entry>` elements that are nested within the `<cache>` element are cached in the default cache instance. Any `<cache-entry>` elements that are in the `<cache-instance>` element are cached in the instance that is specified in the **name** attribute on the `<cache-instance>` element.

Within a `<cache-entry>` element are parameters that allow you to complete the following tasks to enable the dynamic cache with the `cachespec.xml` file:

1. Develop a `cachespec.xml` file.
 - a. Create a caching configuration file.

In the `<app_server_root>/properties` directory, locate the `cachespec.sample.xml` file.
 - b. Copy the `cachespec.sample.xml` file to `cachespec.xml` in Web module `WEB-INF` or enterprise bean `META-INF` directory.

2. Define the cache-entry elements necessary to identify the cacheable objects. See the topic “Cachespec.xml file” on page 2015 for a list of elements.

3. Develop cache ID rules.

To cache an object, WebSphere Application Server must know how to generate unique IDs for different invocations of that object. The `<cache-id>` element performs that task. Each cache entry can have multiple cache-ID rules that run in order until either a rule returns cache-ID that is not empty or no more rules remain to run. If no cache-ID generation rules produce a valid cache ID, then the object is not cached. Develop the cache IDs in one of two ways:

- Use the `<component>` element defined in the cache policy of a cache entry (recommended). See “Cachespec.xml file” on page 2015 for more information about the `<component>` element.
- Write custom Java code to build the ID from input variables and system state. To configure the cache entry to use the ID generator, specify your `IdGenerator` in the XML file by using the `<idgenerator>` tag, for example:

```
<cache-entry>
  <class>Servlet</class>
  <name>/Servlet/CommandProcessor</name>
  <cache-id>
    <idgenerator>com.mycompany.SampleIdGeneratorImpl</idgenerator>
    <timeout>60</timeout>
  </cache-id>
</cache-entry>
```

4. Specify dependency ID rules. Use dependency ID elements to specify additional cache group identifiers that associate multiple cache entries to the same group identifier.

The dependency ID is generated by concatenating the dependency ID base string with the values returned by its component elements. If a required component returns a null value, then the entire dependency ID does not generate and is not used. You can validate the dependency IDs explicitly through the dynamic cache API, or use another cache-entry `<invalidation>` element. Multiple dependency ID rules can exist per cache entry. All dependency ID rules run separately. See “Cachespec.xml file” on page 2015 for a list of `<component>` elements.

5. Invalidate other cache entries as a side effect of this object start, if relevant. You can define invalidation rules in exactly the same manner as dependency IDs. However, the IDs that are generated by invalidation rules are used to invalidate cache entries that have those same dependency IDs. The invalidation ID is generated by concatenating the invalidation ID base string with the values returned by its component element. If a required component returns a null value, then the entire invalidation ID is not generated and no invalidation occurs. Multiple invalidation rules can exist per cache-entry. All invalidation rules run separately.
6. Ensure your cache policy is working correctly. You can modify the policies within the `cachespec.xml` file while your application is running. The dynamic cache reloads the updated file automatically. If you are caching static content and you are adding the cache policy to an application for the first time, you must restart the application. You do not need to restart the application server to activate the new cache policy. See “Verifying the cacheable page” for more information.

Typically you declare several `<cache-entry>` elements inside a `cachespec.xml` file.

When new versions of the `cachespec.xml` are detected, the old policies are replaced. Objects that cached through the old policy file are not automatically invalidated from the cache; they are either reused with the new policy or eliminated from the cache through its replacement algorithm.

For each of the three IDs (cache, dependency, invalidation) generated by cache entries, a `<cache-entry>` can contain multiple elements. The dynamic cache runs the `<cache-id>` rules in order, and the first one that successfully generates an ID is used to cache that output. If the object is to be cached, each one of the `<dependency-id>` elements is run to build a set of dependency IDs for that cache entry. Finally, each of the `<invalidation>` elements are run, building a list of IDs that the dynamic cache invalidates, whether or not this object is cached.

Verifying the cacheable page

Use this task to verify that the dynamic cache service has its cache policies configured correctly and is serving cached content.

The dynamic cache service should be enabled. You should have a cache policy developed for your application. See “Configuring cacheable objects with the `cachespec.xml` file” on page 2014 for more information. You must have servlet caching enabled in the web container. See “Configuring servlet caching” on page 1998 for more information.

You can verify the cacheable page by invoking the snoop servlet in the default application. If the dynamic cache is working correctly, refreshing the servlet repeatedly results in viewing cached content.

1. View the Snoop servlet in the default application by accessing the URI: `/snoop` The Snoop servlet is a part of the default application. See “Default Application” on page 115 for more information.
2. Invoke and reload the URI several times using a different Web browser or using different parameters. This action returns the same output for the snoop servlet. The snoop servlet is now operating incorrectly, because it displays the request information from its first invocation rather than from the current request.
3. Inspect the entry in the cache with the dynamic cache monitor. See “Displaying cache information” on page 2046 for more information.

Cachespec.xml file

The cache parses the `cachespec.xml` file when the server starts, and extracts a set of configuration parameters from each `cache-entry` element. Every time a new servlet or other cacheable object initializes, the cache attempts to match each of the `cache-entry` elements to find the configuration information for that object.

The `cache-entry` elements can be inside the root cache element or inside a `cache-instance` element. Cache entries that are in the root element are cached with the default cache instance. Cache entries that

are in the <cache-instance> element are cached in that particular cache instance. Different cacheable objects have different class elements. You can define the specific object that a cache policy refers to using the name element.

Location

Place the cachespec.xml file with the deployment module. Use an assembly tool to define the cacheable objects. See *Assembling applications* for more information about assembling applications. You can also place a global cachespec.xml file in the application server properties directory.

The cachespec.dtd file is available in the application server properties directory. The cachespec.dtd file defines the legal structure and the elements that can be in your cachespec.xml file.

Usage notes

Cachespec.xml elements

The root element of the cachespec.xml file is cache and contains cache-instance and cache-entry elements. The cache-entry elements can also be placed inside of cache-instance elements to make that cache entry part of a cache instance that is different from the default.

cache-instance

```
<cache-instance name="cache_instance_name"></cache-instance>
```

The name attribute is the Java Naming and Directory Interface (JNDI) name of the cache instance that is set in the administrative console.

Each cache-instance element must contain at least one cache-entry element. A cache entry that is matched within a cache-instance element is cached in the servlet cache instance that is specified by the name attribute. If identical cache-entry elements exist across cache-instance elements, the first cache-entry element that is matched is used.

cache-entry

Each cache entry must specify certain basic information that the dynamic cache uses to process that entry. This section explains the function of each cache entry element of the cachespec.xml file including:

- class
- name
- sharing-policy
- skip-cache
- property
- cache-id

With the current version of WebSphere Application Server, you can define multiple cache policies for a single servlet. For example, if you define multiple mappings for a servlet in the web.xml file, you can create a cache entry for each one of the mappings.

class

```
<class>command | servlet | webservice | JAXRPCClient | static | portlet </class>
```

This element is required and specifies how the application server interprets the remaining cache policy definition. The value `servlet` refers to servlets and JavaServer Pages (JSP) files that are deployed in the WebSphere Application Server servlet engine. The `webservice` class extends the servlet with special component types for Web services requests. The `JAXRPCClient` is used to define a cache entry for the

Web services client cache. The value, `command`, refers to classes using the WebSphere Application Server command programming model. The value, `static`, refers to files that contain static content. The following examples illustrate the class element:

```
<class>command</class>
<class>servlet</class>
<class>webservice</class>
<class>JAXRPCClient</class>
<class>static</class>
<class>portlet</class>
```

name

```
<name>name</name>
```

Use the following guidelines for the name element to specify a cacheable object:

- For commands, this required element must include the package name, if any, and class name, including a trailing `.class`, of the configured object.
- For servlets and JSP files, if the `cachespec.xml` file is in the WebSphere Application Server properties directory, this required element must include the full URI of the JSP file or servlet to cache. For servlets and JSP files, if the `cachespec.xml` file is in the Web application, this required element can be relative to the specific Web application context root.
- For Web services, include the Universal Resource Identifier (URI) of the Simple Object Access Protocol (SOAP) router that is associated with the Web service that you want to cache.
- For Web services client cache, the name is the target end point of the cacheable Web service or the URI of the SOAP router that is associated with the cacheable Web service. You can use the SOAP address location in the Web Services Description Language (WSDL) file to define the name for the Web services client cache.
- For static files, if the `cachespec.xml` file is in the WebSphere Application Server properties directory, this required element must include the full URI of the file to cache. If the `cachespec.xml` file is in the Web application, this required element can be relative to the specific Web application context root. For a Web application with a context root, the cache policy for files using the static class must be specified in the Web application, and not in the properties directory.
- For portlets, if the `cachespec.xml` file is in the WebSphere Application Server properties directory, this required element must include the full context path and name of the portlet to cache. If the `cachespec.xml` file is in the Web application, this required element is the portlet name that is relative to the specific Web application context root.

Tip: The preferred location of the `cachespec.xml` file is in the Web application, not the properties directory.

You can specify multiple name elements within a cache-entry if you have different mappings that refer to the same servlet.

The following examples illustrate the name element:

```
<name>com.mycompany.MyCommand.class</name>
<name>default_host:/servlet/snoop</name>
<name>com.mycompany.beans.MyJavaBean</name>
<name>mywebapp/myjsp.jsp</name>
<name>/soap/servlet/soaprouter</name>
<name>http://remotecompany.com:9080/service/getquote</name>
<name>mywebapp/myLogo.gif</name>
```

sharing-policy

```
<sharing-policy> not-shared | shared-push | shared-pull | shared-push-pull</sharing-policy>
```

When working within a cluster with a distributed cache, these values determine the sharing characteristics of entries that are created from this object. If this element is not present, a `not-shared` value is assumed.

On the z/OS platform, you can enable replication between servants in a base application server by using the `DynacacheEnableUnmanagedServerReplication` and `DynacacheUnmanagedServerReplicationType` Java virtual machine (JVM) custom properties. When enabling a replication, the default value is `not-shared`. This property does not affect distribution to Edge Side Include processors through the Edge fragment caching property. See “Configuring cache replication” on page 2011 for more information.

Value	Description
<code>not-shared</code>	Cache entries for this object are not shared among different application servers. These entries can contain non-serializable data. For example, a cached servlet can place non-serializable objects into the request attributes, if the <code><class></code> type supports it.
<code>shared-push</code>	Cache entries for this object are automatically distributed to the dynamic caches in other application servers or cooperating Java virtual machines (JVMs). Each cache has a copy of the entry at the time it is created. These entries cannot store non-serializable data.
<code>shared-pull</code>	Cache entries for this object are shared between application servers on demand. If an application server gets a cache miss for this object, it queries the cooperating application servers to see if they have the object. If no application server has a cached copy of the object, the original application server runs the request and generates the object. These entries cannot store non-serializable data. This mode of sharing is not recommended.
<code>shared-push-pull</code>	Cache entries for this object are shared between application servers on demand. When an application server generates a cache entry, it broadcasts the cache ID of the created entry to all cooperating application servers. Each server then knows whether an entry exists for any given cache ID. On a given request for that entry, the application server knows whether to generate the entry or pull it from somewhere else. These entries cannot store non-serializable data.

The following example shows a sharing policy:

```
<sharing-policy>not-shared</sharing-policy>
```

skip-cache

Takes the name of a request attribute, which if present in the request context, dictates that the response cannot be retrieved from the cache instance that is specified. This property is useful for previewing content in production systems and verifying that the application is working and performing as expected.

```
<cache>
  <skip-cache-attribute>att1</skip-cache-attribute> <!--Applies only to the base cache- -->
  ...
  <cache-instance name="instance1">
    <skip-cache-attribute>att2</skip-cache-attribute> <!--Applies only to this instance- -->
    ...
  </cache-instance>
</cache>
```

property

```
<property name="key">value</property>
```

where *key* is the name of the property for this cache entry element, and *value* is the corresponding value.

You can set optional properties on a cacheable object, such as a description of the configured servlet. The class determines valid properties of the cache entry. At this time, the following properties are defined:

Property	Valid classes	Value
ApplicationName	All	Overrides the J2EEName application ID so that multiple applications can share a common cache ID namespace.
EdgeCacheable	Servlet	True or false. The default is false. If the property is true, then the given servlet or JSP file is externally requested from an Edge Side Include processor. Whether or not the servlet or JSP file is cacheable depends on the rest of the cache specification.
ExternalCache	Servlet and portlet	Specifies the external cache name. The external cache name needs to match the external cache group name.
consume-subfragments	Servlet, Web service, or portlet	<p>True or false. The default is false. When a servlet is cached, only the content of that servlet is stored, and includes placeholders for any other fragments to which it includes or forwards. Consume-subfragments (CSF) tells the cache not to stop saving content when it includes a child servlet. The parent entry, the one marked CSF, includes all the content from all fragments in its cache entry, resulting in one big cache entry that has no includes or forwards, but the content from the whole tree of entries. Consume-subfragments can save a significant amount of application server processing, but is typically only useful when the external HTTP request contains all the information needed to determine the entire tree of included fragments.</p> <p>Use the <exclude> element to tell the cache to stop consuming for the excluded fragment and instead, create a placeholder for the include or forward. For example, exclude A.jsp from the consume-subfragment, as follows:</p> <pre><property name="consume-sbufragments">true <exclude>/A.jsp<exclude> </property></pre>

do-not-consume	Servlet, Web service, or portlet	True or false. The default is false. When a fragment parent has the consume-subfragment property set to true the child fragment content is saved in the cache entry of the parent. Do-not-consume (DNC) tells the cache to stop saving the content for this fragment in the parent cache-entry and create a placeholder instead for the include or forward.
alternate_url	Servlet	Specifies the alternate URL that is used to invoke the servlet or JSP file. The property is valid only if the EdgeCacheable property also is set for the cache entry.
persist-to-disk	All	True or false. The default is true. When this property is set to false, the cache entry is not written to the disk when overflow or server stopping occurs.
save-attributes	Servlet and portlet	<p>True or false. The default is true. When this property is set to false, the request attributes are not saved with the cache entry.</p> <p>Use the <exclude> element to specify the request attributes that do not apply to the save-attributes property. For example, to save only the attr1 attribute with the cache entry:</p> <pre><property name="save-attributes">false <exclude>attr1</exclude> </property></pre> <p>To save all attributes except the attr1 attribute in the cache entry, set the property to true in the preceding sample. If you do not use the <exclude> element, either all or no request attributes are saved with the cache entry.</p>
delay-invalidations	Command	True or false. When this property is set to true, the commands that are invalidating cached objects based on the invalidation rules in this cache entry invalidate the cache entries after running. By default, the invalidation occurs before the command runs.

store-cookies	Servlet and portlet	<p>Takes one or more cookie name as its argument which is saved along with the cache object and restored by the servlet cache in the response with a set-cookie header.</p> <p>Save all cookies except cookie1 as part of the cache-entry as follows:</p> <pre><property name="store-cookies">true <exclude>cookie</exclude> </property></pre> <p>Save only cookie1 as part of the cache-entry, as follows:</p> <pre><property name="store-cookies">false <exclude><cookie1</exclude> </property></pre>
ignore-get-post	Servlet and portlet	<p>True or false. The default is false. When the property is set to true the request type is not appended to the cache-id for GET and POST requests unless the requestType component requestType component subelement is defined. By default the request type is automatically appended to the cache-id for GET and POST requests.</p>
do-not-cache	Servlet and portlet	<p>Defines a fragment that is neither cached nor consumed by its parent.</p> <pre><cache-entry> ... <property name="do-not-cache"> true</property></pre> <p>or</p> <pre><cache-id> <property name="do-not-cache"> true</property> </cache-id> </cache-entry></pre>

cache-id

To cache an object, the application server must know how to generate a unique ID for different invocations of that object. These IDs are built either from user-written custom Java code or from rules that are defined in the cache policy of each cache entry. Each cache entry can have multiple cache ID rules that run in order until either:

- A rule returns a non-empty cache ID, or
- No more rules are left to run.

If none of the cache ID generation rules produce a valid cache ID, the object is not cached.

Each cache-id element defines a rule for caching an object and is composed of the sub-elements component, timeout, inactivity, priority, property, idgenerator, and metadatagenerator. The following example illustrates a cache-id element:

```
<cache-id>
  component* | timeout? | inactivity? | priority? | property* | idgenerator? | metadatagenerator?
</cache-id>
```

component subelement

Use the component subelement to generate a portion of the cache ID. The component subelement consists of the attributes id, type, and ignore-value, and the elements index, method, field, required, value, and not-value.

- Use the id attribute to identify the component.
- Use the type attribute to identify the type of component. The following table lists the values for the type.

Type	Valid classes	Meaning
method	Command	Calls the indicated method on the command or object
field	Command	Retrieves the named field in the command or object
parameter	Servlet and portlet	Retrieves the named parameter value from the request object
parameter-list	Servlet and portlet	Retrieves a list of values for the named parameter
session	Servlet and portlet	Retrieves the named value from the HTTP session
cookie	Servlet	Retrieves the named cookie value
attribute	Servlet	Retrieves the named request attribute
header	Servlet, Web service, and portlet	Retrieves the named request header
pathInfo	Servlet	Retrieves the pathInfo element from the request
servletpath	Servlet	Retrieves the servlet path
locale	Servlet and portlet	Retrieves the request locale
requestType	Servlet and portlet	Retrieves the HTTP request method from the request.
tiles_attribute	Servlet and portlet	Retrieves the value of an attribute from a tile.
SOAPEnvelope	Web service and Web services client cache	Retrieves the SOAPEnvelope element from a Web services request. An ID attribute of Hash uses a Hash of the SOAPEnvelope element, while Literal uses the SOAPEnvelope element as received.
SOAPAction	Web service	Retrieves the SOAPAction header, if available, for a Web services request.
serviceOperation	Web service	Retrieves the service operation for a Web services request
serviceOperationParameter	Web service	Retrieves the specified parameter from a Web services request

Type	Valid classes	Meaning
operation	Web services client cache	Indicates an operation type in the Web Services Description Language (WSDL) file. The id attribute is ignored and the value is the operation or method name. If the namespace of the operation is specified, format the value as namespaceOfOperation:nameOfOperation
part	Web services client cache	Indicates an input message part in the WSDL file or a request parameter. Its id attribute is the part or parameter name, and the value is the part or parameter value.
SOAPHeaderEntry	Web services client cache	Retrieves special information in the Simple Object Access Protocol (SOAP) header of the Web services request. The id attribute specifies the name of the entry. In addition, the entry of the SOAP header in the SOAP request must have the actor attribute, which contains com.ibm.websphere.cache. For example: <pre><soapenv:Header> <getQuote soapenv:actor= "com.ibm.websphere.cache">IBM </getQuote> </soapenv:Header></pre>
portletSession	Portlet	Retrieves the named value from the portlet session
portletWindowId	Portlet	Retrieves the portlet window ID from the portlet request object
portletMode	Portlet	Retrieves the portlet mode from the portlet request object
portletWindowsState	Portlet	Retrieves the portlet window state from the portlet request object
sessionID	Servlet and portlet	Retrieves the HTTP session ID

- Use the ignore-value attribute to specify whether or not to use the value that is returned by this component in cache ID formation. This attribute is optional with a default value of false. If the value is true, only the ID of the component is used when creating a cache ID, or no output is used when creating a dependency or invalidation ID.
- Use the method element to call a void method on a returned object. You can infinitely nest method and field objects in any combination. The method must be public and is not valid for edge-cacheable components. For example:

```
<component id="getUser" type="method"><method>getUserInfo
<method>getName</method></method></component>
```

This method is equivalent to getUser().getUserInfo().getName()

For component types attribute, method, or field that can return an object, when the object returned is a collection or array, the ID is created with a comma separated list of the elements in the collection or array. For example, if the request attribute users returns an array [a, b] and the cache entry is defined like the following example:

```

<cache-entry>
  <class>servlet</class>
  <name>xxx.jsp</name>
  <cache-id>
    .
    .
    <component id="users" type="attribute">
      <required>>true</required>
    </component>
    .
  </cache-id>
  <dependency-id>dep
    <component id="users" type="attribute">
      <required>>true</required>
    </component>
  </dependency-id>
</cache-entry>

```

The cache id contains the string users: a,b. The dependency id is dep: a,b.

Use the multipleIDs attribute with the component types to specify and generate multiple dependency IDs (or invalidation IDs), based on the items in the collection or array. For example:

```

<cache-entry>
  <class>servlet</class>
  <name>xxx.jsp</name>
  <cache-id>
    .
    .
    <component id="users" type="attribute">
      <required>>true</required>
    </component>
    .
  </cache-id>
  <dependency-id>dep
    <component id="users" type="attribute" multipleIDs="true">
      <required>>true</required>
    </component>
  </dependency-id>
</cache-entry>

```

The cache policy will generate the following dependency IDs:

- dep:a,b
- dep:a
- dep:b

Use the index element with the previous component type to add only the value of the element at the specified index position in the collection or array, to the ID that is being created.

```

<cache-entry>
  <class>servlet</class>
  <name>xxx.jsp</name>
  <cache-id>
    .
    .
    <component id="users" type="attribute">
      <required>>true</required>
      <index>1</index>
    </component>
    .
  </cache-id>
  <dependency-id>dep
    <component id="users" type="attribute" multipleIDs="true">

```

```

    <required>true</required>
  </component>
</dependency-id>
</cache-entry>

```

The previous cache policy generates the following component to use in the cache ID: users: b. Use the `<method>` element to call a void method on a returned object.

- Use the field element to access a field in a returned object. You can infinitely nest method and field objects in any combination. The field must be public. This field is not valid for edge-cacheable components. For example:

```

<component id="getUser" type="method"><method>getUserInfo
<field>name</field></method></component>

```

This method is equivalent to the `getUser().getUserInfo().name` method.

- Use the required element to specify whether or not this component must return a non-null value for this cache ID to represent a valid cache. If set to `true`, this component must return a non-null value for this cache ID to represent a valid cache ID. If set to `false`, the default, a non-null value is used in the formation of the cache ID and a null value means that this component is not used at all in the ID formation. For example:

```

<required>true</required>

```

- Use the value element to specify values that must match to use this component in cache ID formation. For example:

```

<component id="getUser" type="method"><value>blue</value>
<value>red</value> </component>

```

- Use the not-value element to specify values that must not match to use this component in cache ID formation. This method is similar to value element, but instead prescribes the defined values from caching. You can use multiple not-value elements when more than one value that is not valid exists. For example:

```

<component id="getUser" type="method">
<required>true</required>
<not-value>blue</not-value>
<not-value>red</not-value></component>

```

The component subelement can have either a method and a field element, a value element, or a not-value element. The method and field elements apply to commands only. The following example illustrates the attributes of a component sub-element:

```

<component id="isValid" type="method" ignore-value="true"><component>

```

timeout subelement

The timeout subelement is used to specify an absolute time-to-live (TTL) value for the cache entry. For example,

```

<timeout>value</timeout>

```

where *value* is the amount of time, in seconds, to keep the cache entry. Cache entries that are in memory are kept indefinitely, as long as the entries remain in memory. Cache entries that are stored on disk are evicted if they are not accessed for 24 hours.

inactivity subelement

The inactivity subelement is used to specify a time-to-live (TTL) value for the cache entry based on the last time that the cache entry was accessed. It is a subelement of the cache-id element.

```

<inactivity>value</inactivity>

```

where *value* is the amount of time, in seconds, to keep the cache entry in the cache after the last cache hit.

priority subelement

Use the priority subelement to specify the priority of a cache entry in a cache. The priority weighting is used by the least recently used (LRU) algorithm of the cache to decide which entries to remove from the cache if the cache runs out of storage space. For example,

```
<priority>value</priority>
```

where *value* is a positive integer between 1 and 255 inclusive.

Samples

The following sample keeps the cache entry in the cache for a minimum of 35 seconds and a maximum of 180 seconds. If the cache entry is accessed within each 35 second inactivity period, the inactivity period is extended for another 35 seconds. However, because the timeout element is also configured, the cache entry is always invalidated after 180 seconds. If the cache entry is not accessed within the 35 second period, the entry is removed from the cache.

```
<cache-id>
  <component id="timeout" type="parameter">
    <required>true</required>
  </component>
  <timeout>180</timeout>
  <inactivity>35</inactivity>
  <priority>1</priority>
</cache-id>
```

The following sample keeps the cache entry in the cache for a minimum of 600 seconds. If the cache entry is accessed within each 600 second period, the inactivity period is extended for another 600 seconds. If the cache entry is not accessed within the 600 second period, the cache entry is removed from the cache.

```
<cache-id>
  <component id="timeout" type="parameter">
    <required>true</required>
  </component>
  <inactivity>600</inactivity>
  <priority>1</priority>
</cache-id>
```

In the following sample, the value for inactivity has no meaning because the timeout period is less than the inactivity period. The cache entry is always invalidated after 180 seconds, no matter how often the cache entry is accessed.

```
<cache-id>
  <component id="timeout" type="parameter">
    <required>true</required>
  </component>
  <timeout>180</timeout>
  <inactivity>600</inactivity>
  <priority>1</priority>
</cache-id>
```

property subelement

Use the property subelement to specify generic properties for the cache entry. For example,

```
<property name="key">value</property>
```

where *key* is the name of the property to define, and *value* is the corresponding value.

For example:

```
<property name="description">The Snoop Servlet</property>
```

Property	Valid classes	Meaning
sharing-policy/timeout/priority	All	Overrides the settings for the containing cache entry when the request matches this cache ID.
EdgeCacheable	Servlet	Overrides the settings for the containing cache entry when the request matches this cache ID.

idgenerator and metadatagenerator sub-elements

Use the `idgenerator` element to specify the class name that is loaded for the generation of the cache ID. The `IdGenerator` element must implement the `com.ibm.websphere.servlet.cache.IdGenerator` interface for a servlet or the `com.ibm.websphere.webservices.IdGenerator` interface for the Web services client cache. An example of the `idgenerator` element follows:

```
<idgenerator> class name </idgenerator>
```

Where `class name` is the fully-qualified name of the class to use. Define this generator class in a shared library.

Use the `metadatagenerator` element inside the `cache-id` element to specify the class name loaded for the metadata generation. The `MetadataGenerator` class must implement the `com.ibm.websphere.servlet.cache.MetadataGenerator` interface for a servlet or the `com.ibm.websphere.cache.webservices.MetadataGenerator` interface for Web services client cache. The `MetadataGenerator` class defines properties like `timeout`, `inactivity`, external caching properties or dependencies. An example of the `metadatagenerator` element follows:

```
<metadatagenerator> classname </metadatagenerator>
```

In this example, `class name` is the fully-qualified name of the class to use. Define this generator class in a shared library.

dependency-id element

Use the `dependency-id` element to specify additional cache identifiers that associate multiple cache entries to the same group identifier.

The value of the `dependency-id` element is generated by concatenating the dependency ID base string with the values that are returned by its component elements. If a required component returns a null value, the entire dependency does not generate and is not used. Validate the dependency IDs explicitly through the dynamic cache API, or use the `invalidation` element. Multiple dependency ID rules can exist in one `cache-entry` element. All dependency rules run separately.

invalidation element

To invalidate cached objects, the application server must generate unique invalidation IDs. Build invalidation IDs by writing custom Java code or through rules that are defined in the cache policy of each cache entry. The following example illustrates an invalidation in the cache policy:

```
<invalidation>component* | invalidationgenerator? </invalidation>
```

invalidationgenerator subelement

The `invalidationgenerator` element is used with the Web Services client cache only. Use the `invalidationgenerator` element to specify the class name to load for generating invalidation IDs. The

InvalidationGenerator class must implement the com.ibm.websphere.cache.webservices.InvalidationGenerator interface. An example of the invalidationgenerator element follows:

```
<invalidationgenerator>class name</invalidationgenerator>
```

In this example, classname is the fully qualified name of the class that implements the com.ibm.websphere.cache.webservices.InvalidationGenerator interface. Define this generator class in a shared library.

Configuring command caching

Cacheable commands are stored in the cache for reuse with a similar mechanism for servlets and JavaServer Pages (JSP) files.

In this case, however, the unique cache IDs are generated based on methods and fields present in the command as input parameters. For example, a **GetStockQuote** command can have a symbol as its input parameter.

A unique cache ID can generate from the name of the command, plus the value of the symbol.

To use command caching you must:

Create a command.

1. Define an interface. The Command interface specifies the most basic aspects of a command. You must define the interface that extends one or more of the interfaces in the command package. The command package consists of three interfaces:
 - TargetableCommand
 - CompensableCommand
 - CacheableCommand

In practice, most commands implement the TargetableCommand interface, which allows the command to run remotely. The code structure of a command interface for a targetable command follows:

```
...
import com.ibm.websphere.command.*;
public interface MyCommand extends TargetableCommand {
    // Declare application methods here
}
```

2. Provide an implementation class for the interface. Write an interface that extends the CacheableCommandImpl class and implements your command interface. This class contains the code for the methods in your interface, the methods inherited from extended interfaces like the CacheableCommand interface, and the required or abstract methods in the CacheableCommandImpl class. You can also override the default implementations of other methods provided in the CacheableCommandImpl class.

Command class

Extend one or more of the three interfaces included in the command package to write a command interface. The base interface for all commands is the Command interface.

The Command interface provides only the client-side interface for generic commands and declares three basic methods:

- **isReadyToCallExecute**. This method is called on the client side before the command runs on server.
- **execute**. This method passes the command to the target and returns any data.
- **reset**. This method reverts any output properties to the values they had before the execute method was called so that you can reuse the object.

The implementation class for your interface must contain implementations for the `isReadyToCallExecute` and `reset` methods.

CacheableCommandImpl class

Commands are implemented by extending the class `CacheableCommandImpl`, which implements the `CacheableCommand` interface.

The `CacheableCommandImpl` class is an abstract class that provides implementations for some of the methods in the `CacheableCommand` interface, for example, setting return values. This class declares additional methods that the application must implement, for example, how to run the command.

The code structure of an implementation class for the `CacheableCommand` interface follows:

```
...
import com.ibm.websphere.command.*;
public class MyCommandImpl extends CacheableCommandImpl
implements MyCommand {
// Set instance variables here      ...
// Implement methods in the MyCommand interface      ...
// Implement abstract methods in the CacheableCommandImpl class
...
}
```

Example: Caching a command object

Cacheable commands are stored in the cache for reuse with a similar mechanism for servlets and JavaServer Pages (JSP) files.

This example of command caching is a simple stock quote command.

The following is a stock quote command bean. It accepts a ticker as an input parameter and produces a price as its output parameter.

```
public class QuoteCommand extends CacheableCommandImpl
{
    private String ticker;
    private double price;
    // called to validate that command input parameters have been set
    public boolean isReadyToCallExecute() {
        return (ticker!=null);
    }
    // called by a cache-hit to copy output properties to this object
    public void setOutputProperties(TargetableCommand fromCommand) {
        QuoteCommand f = (QuoteCommand)fromCommand;
        this.price = f.price;
    }

    // business logic method called when the stock price must be retrieved
    public void performExecute()throws Exception {...}

    //input parameters for the command
    public void setTicker(String ticker) { this.ticker=ticker;}
    public String getTicker() { return ticker;}

    //output parameters for the command
    public double getPrice() { return price;};
}
```

To cache the above command object using the stock ticker as the cache key and using a 60 second time-to-live, use the following cache policy:

```
<cache>
<cache-entry>
<class>command</class>
<sharing-policy>not-shared</sharing-policy>
```

```

<name>QuoteCommand</name>
<cache-id>
  <component type="method" id="getTicker">
    <required>true</required>
  </component>
  <priority>3</priority>
  <timeout>60</timeout>
</cache-id>
</cache-entry>
</cache>

```

Configuring the Web services client cache

Configuring the Web services client cache can improve the performance of your application server by caching the responses from remote Web services for a specified amount of time.

You should have the dynamic cache service enabled. To enable the dynamic cache service, see “Task overview: Using the dynamic cache service to improve performance” on page 1978. Before attempting to configure the Web services client cache, you should understand how to create basic cache policies. See “Configuring cacheable objects with the cachespec.xml file” on page 2014 for more information.

Enabling the Web services client cache is an option to improve the performance of your system by using the dynamic cache service to save responses from remote Web services for a specified amount of time. For more information about the Web Services client cache, see “Web services client cache” on page 2035.

1. Locate the Web Services Description Language (WSDL) file for the remote service. Portions of the WSDL file contain information that you will use in writing your cache policy. For more information about WSDL files, see “WSDL” on page 459. Following is an example of portions of a WSDL file that contains values that are used for the purpose of demonstration.

```

<definitions targetNamespace="http://TradeSample.com/"
  xmlns:tns="http://TradeSample.com/"
  xmlns="http://schemas.xmlsoap.org/wsdl/"
  xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <message name="getQuoteRequest">
    <part name="symbol" type="xsd:string"/>
  </message>
  .....
  .....
  <binding name="SoapBinding" type="tns:GetQuote">
    <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
    <operation name="getQuote">
      <soap:operation soapAction=""/>
      <input name="getQuoteRequest">
        <soap:body namespace="http://TradeSample.com/"
          use="encoded"
          encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
      </input>
      .....
    </operation>
  </binding>
  <service name="GetQuoteService">
    <port binding="tns:SoapBinding" name="SoapPort">
      <soap:address location="http://TradeSample.com:9080/service/getquote"/>
    </port>
  </service>
</definitions>

```

The highlighted text indicates values that are used in writing your cache policy.

2. Choose how you plan to generate the cache id for your Web services client caching. You can build your cache id rules by using one of four options:
 - By calculating a hash of the SOAPEnvelope

- By using SOAPHeader entries
- By using operation and part parameters
- By using custom Java code to build the cache id from input SOAP message content

Using SOAPHeader entries is the best option if you can include information for building cache keys as part of the SOAP header. This method creates easy to read cache keys and can be built without parsing the SOAP body. Use custom Java code to generate a specific cache id based on the SOAP message. If you cannot include the header information, you can calculate the hash of the SOAPEnvelope for performance or parse the SOAP Body for user-friendly cache keys.

3. Develop your cache policy.

All Web services client cache policies must have the **class** *JAXRPCClient*. The **name** element in each cache entry is the target endpoint location that is defined in the WSDL file. You can find this address in the WSDL file by finding the `<soap:address location="."/ >` tag located in the **port** element. In the WSDL file for this sample, the address is `http://TradeSample.com:9080/service/getquote`. Develop the rest of your cache policy by using one of the following options:

- **Calculate a hash of the SOAPEnvelope to identify the request**

```
<cache>
  <cache-entry>
    <class>JAXRPCClient</class>
    <name>http://TradeSample.com:9080/service/getquote</name>
    <cache-id>
      <component id="hash" type="SOAPEnvelope"/>
      <timeout>60</timeout>
    </cache-id>
  </cache-entry>
</cache>
```

Note the **component** attributes to create a cache id based on a hash calculation of the SOAPEnvelope. The cache id for this sample is generated as `http://TradeSample.com:9080/service/getquote:Hash=xxxHashSoapEnvelope`.

- **Use the SoapHeader to identify the request**

```
<cache>
  <cache-entry>
    <class>JAXRPCClient</class>
    <name>http://TradeSample.com:9080/service/getquote</name>
    <cache-id>
      <component id="urn:stock:getQuote" type="SOAPHeaderEntry"/>
    </cache-id>
  </cache-entry>
</cache>
```

This cache id is built by using special information in the SOAP header to identify requests for entries in the cache. Specify the **type** as `SOAPHeaderEntry` and the **id** as the operation name located in the **binding** element in the WSDL file. The cache id for this sample is generated as `http://TradeSample.com:9080/service/getquote:urn:stock:getQuote=IBM`.

An example of a SOAP request generated by the client using SOAP Header:

Note that the **soapenv:actor** attribute must contain `com.ibm.websphere.cache`.

```
POST /wsgwsoap1/soaprpcrouther HTTP/1.1
SOAPAction: ""
Context-Type: text/xml; charset=utf-8
User-Agent: Java/1.4.1
Host: localhost
Accept: text/html, image/gif, image/jpeg, *; q=.2, */*; q=.2
Connection: keep-alive
Content-Length: 645
```

```
<?xml version="1.0" encoding="UTF-8"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
```

```

xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Header>
  <getQuote soapenv:actor="com.ibm.websphere.cache" xmlns="urn:stock">IBM</getQuote>
</soapenv:Header>
<soapenv:Body>
  soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding">
  <getQuote xmlns="urn:ibmwsgw#GetQuoteSample">
    <symbol xsi:type="xsd:string">IBM</symbol>
  </getQuote>
</soapenv:Body>
</soapenv:Envelope>

```

- **Use operation and part to identify the request**

```

<cache>
  <cache-entry>
    <class>JAXRPCClient</class>
    <name>http://TradeSample.com:9080/service/getquote</name>
    <cache-id>
      <component id="" type="operation">
        <value>http://TradeSample.com/:getQuote</value>
      </component>
      <component id="symbol" type="part"/>
    </cache-id>
  </cache-entry>
</cache>

```

This example uses operation and request parameters. The operation can be a method name in the WSDL file located in the **binding** element or a method name in the Document/Literal Invocation (DII). If the namespace of the operation is defined, the value should be formatted as namespaceOfOperation:nameOfOperation. The part type can be defined in the **message** element of the WSDL file, as a request parameter, or as a request parameter of the DII invocation. Its id attribute is the part or parameter name, and the value is the part or parameter value. The cache id generated from using operation and request parameters is http://TradeSample.com:9080/service/getquote:operation=http://TradeSample.com/:getQuote/symbol=IBM.

An example of the SOAP request generated by the client using operation and part:

```

POST /wsgwsoap1/soaprpcrouter HTTP/1.1
SOAPAction: ""
Content-Type: text/xml;charset=utf-8
User-Agent: Java/1.4.1
Host: localhost
Accept: text/html, image/gif, image/jpeg, *; q=.2, */*; q=.2
Connection: keep-alive
Current-Length: 645

```

```

<?xml version="1.0" encoding="UTF-8"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body
  soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
  <getQuote xmlns="urn:ibmwsgw#GetQuoteSample">
    <symbol xsi:type="xsd:string">IBM</symbol>
  </getQuote>
</soapenv:Body>
</soapenv:Envelope>

```

- **Use custom Java code to build the cache id from input SOAP message content**

If you use custom Java code to build the cache id, create an ID generator Java class that implements the IdGenerator interface defined in the com.ibm.websphere.cache.webservices.IdGenerator package and add a reference to the class you create in the cachespec.xml file by using the **idgenerator** tag.

You can also implement the `com.ibm.websphere.cache.webservices.MetadataGenerator` package to assign cache metadata such as timeout, priority, and dependency ids to cache entries using the **metadatagenerator** tag.

Implement the `com.ibm.websphere.cache.webservices.InvalidationGenerator` interface and use the **invalidationgenerator** tag in the `cachespec.xml` file to generate cache ids and to invalidate entries in the cache. The id generated by the invalidation generator can be a cache id or a dependency id. For example, if you develop an ID generator class named `SampleIdGeneratorImpl`, a metadata generator class named `SampleMetaDataGeneratorImpl`, and an invalidation generator class named `SampleInvalidationGeneratorImpl`, your `cachespec.xml` file might contain the following:

```
<cache-entry>
  <class>JAXRPCClient</class>
  <name>http://TradeSample.com:9080/service/getquote</name>
  <cache-id>
    <idgenerator>com.mycompany.SampleIdGeneratorImpl</idgenerator>
    <metadatagenerator>
      com.mycompany.SampleMetaDataAndInvalidationGeneratorImpl
    </metadatagenerator>
    <timeout>60</timeout>
  </cache-id>
  <invalidation>http://TradeSample.com:9080/service/GetQuote
    <invalidationgenerator>
      com.mycompany.SampleMetaDataAndInvalidationGeneratorImpl
    </invalidationgenerator>
  </invalidation>
</cache-entry>
```

The `SampleIdGeneratorImpl` class is a custom Java class that implements the `com.websphere.cache.webservices.IdGenerator` interface. The `SampleIdGeneratorImpl` class contains the `getId` method:

```
String getId(javax.xml.rpc.handler.soap.SOAPMessageContext messageContext)
```

The following is an example of the `SampleIdGeneratorImpl.java` class.

```
public class SampleIdGeneratorImpl implements IdGenerator {
//The SampleIdGenerator class builds cache keys using SOAP header entries
  public String getId(javax.xml.rpc.handler.soap.SOAPMessageContext
    messageContext) {
    ....
    // retrieve SOAP header entries from SOAPMessage
    SOAPHeader sh = soapEnvelope.getHeader();
    if (sh != null) {
      Iterator it = sh.examineHeaderElements("com.mycompany.actor");
      while (it.hasNext()) {
        SOAPHeaderElement element =
          (SOAPHeaderElement)it.next();
        Name name = element.getElementName();
        String headerEntryName = name.getLocalName();
        if (headerEntryName.equals("getQuote")){
          String sNamespace = element.getNamespaceURI("");
          if (sNamespace != null && !sNamespace.equals("")) {
            headerEntryName = sNamespace + ":" + headerEntryName;
            String quotes = element.getValue();
          }
        }
        ...
        ...
        // create a method "parseAndSort" to parse and sort quotes
        // By parsing and sorting quotes, you avoid duplicate cache
        // entries.
        // quotes e.g. IBM,CSCO,MSFT,INTC
        // to return a cache key "urn:stock:getQuote=CSCO,IBM,INTC,MSFT"
        String sortQuotes = parseAndSort(quotes);
        cacheKey = headerEntryName + "=" + sortQuotes;
      }
    }
  }
}
```

```

    }
    return cacheKey;
}
}

```

The cache id for this sample is generated as `http://TradeSample.com:9080/service/getquote:urn:stock:symbol=CSCO,IBM,INTC,MSFT`.

The `SampleMetaDataAndInvalidationGeneratorImpl` class is a custom Java class that implements the `com.websphere.cache.webservices.MetaDataGenerator` interface and the `com.websphere.cache.webservices.InvalidatorGenerator` interface. The `SampleMetaDataAndInvalidationGeneratorImpl` class contains the `setMetaData` method and the `getInvalidationIds` method. You can also set up two smaller classes instead of this one large class. For example, create one class for the metadata generator and a different class for the invalidation generator. The following are method prototypes for the `setMetaData` method and the `getInvalidationIds` method:

```

void setMetaData (javax.xml.rpc.handler.soap.SOAPMessageContext messageContext,
    com.ibm.websphere.cache.webservices.JAXRPCEntryInfo entryInfo)
String[] getInvalidationIds (javax.xml.rpc.handler.soap.SOAPMessageContext messageContext)

```

An example of the `SampleMetaDataAndInvalidationGeneratorImpl.java` class follows:

```

public class SampleMetaDataAndInvalidationGeneratorImpl implements
    MetaDataGenerator, InvalidationGenerator {
    //assigns time limit, and priority metadata
    public void setMetadadata(javax.xml.rpc.handler.soap.SOAPMessageContext messageContext,
        com.ibm.websphere.cache.webservices.JAXRPCEntryInfo entryInfo) {
        ....

// retrieve SOAP header entries from SOAPMessage
SOAPHeader sh = soapEnvelope.getHeader();
    if (sh != null) {
        Iterator it = sh.examineHeaderElements("com.mycompany.actor");
        while (it.hasNext()) {
            SOAPHeaderElement element =
                (SOAPHeaderElement)it.next();
            Name name = element.getElementName();
            String headerEntryName = name.getLocalName();
                if (headerEntryName.equals("metadata")) {
// retrieve each metadata element and set metadata
                    entryInfo.setTimeLimit(timeLimit);
                    entryInfo.setPriority(priority);
                }
            }
        }

//builds invalidation ids using SOAP header.
public String[] getInvalidationIds(javax.xml.rpc.handler.soap.SOAPMessageContext
    messageContext) { ....
// retrieve SOAP header entries from SOAPMessage
    String[] invalidationIds = new String[1];
SOAPHeader sh = soapEnvelope.getHeader();
    if (sh != null) {
        Iterator it = sh.examineHeaderElements("com.mycompany.actor");
        while (it.hasNext()) {
            SOAPHeaderElement element =
                (SOAPHeaderElement)it.next();
            Name name = element.getElementName();
            String headerEntryName = name.getLocalName();
                if (headerEntryName.equals("invalidation")) {
String sNamespace = element.getNamespaceURI("");
            if (sNamespace != null && !sNamespace.equals("")) {
                headerEntryName = sNamespace + ":symbol";
                String quotes = element.getValue();
            }
            ...
            ...

```

```

        // create a method "parseAndSort" to parse and sort quotes
        // By parsing and sorting quotes, you avoid duplicate cache
        // entries.
        // quotes e.g. SUNW,NT
        // to return a cache key "urn:stock:symbol=NT,SUNW"
        String sortQuotes = parseAndSort(quotes);
        invalidationIds[0] = headerEntryName + "=" + sortQuotes;
    }
}
return invalidationIds;
}
}

```

The invalidation id for this sample is generated as:

`http://TradeSample.com:9080/service/getquote:urn:stock:symbol=NT,SUNW`

An example of the SOAP request generated by the client when using custom Java code follows:

```

POST /wsgwsoap1/soaprpcrouter HTTP/1.1
SOAPAction: ""
Context-type: text/xml, charset=utf-8
User-Agent: Java/1.4.1
Host: localhost
Accept: text/html, image/gif, image/jpeg, *, q=.2, */*; q=.2
Connection: keep-alive
Content-Length:645

<?xml version="1.0" encoding="UTF-8"?>
<soapenv:Envelope
  xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
  xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <soapenv:Header>
    <getQuote soapenv:actor="com.mycompany.actor"
      xmlns="urn:stock">IBM,CSCO,MSFT,INTC</getQuote>
    <metaData soapenv:actor="com.mycompany.actor" xmlns="urn:stock">
      <priority>10</priority>
      <timeLimit>30000</timeLimit>
    </metaData>
    <invalidation soapenv:actor="com.mycompany.actor"
      xmlns="urn:stock">SUNW, NT</invalidation>
  </soapenv:Header>
  <soapenv:Body
    soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding">
    <getQuote xmlns="urn:ibmwsgw#GetQuoteSample">
      <symbol xsi:type="xsd:string">IBM,CSCO,MSFT,INTC</symbol>
    </getQuote>
  </soapenv:Body>
</soapenv:Envelope>

```

4. Save the cache policy to the appropriate directory.

- If you are using the Web Services Gateway on SOAP channel 1, the directory is:
`<app_server_root>\installedApps\wsgwsoap1.servername.nodename.ear/wsgwsoap.war/WEB-INF`
- If you are using a simple JAX-RPC client in your application to invoke remote Web services, save your cache policy in the Web module WEB-INF of your JAX-RPC application.

You can monitor the results of your Web services client cache policy by using the dynamic cache monitor. See “Displaying cache information” on page 2046 for more information.

Web services client cache

The Web services client cache is a part of the dynamic cache service that is used to increase the performance of Web services clients by caching responses from remote Web services.

After a response is returned from a remote Web service, the response is saved in the client cache on the application server. Any identical requests that are made to the same remote Web service are then

responded to from the cache for a specified period of time. The Web services client cache relies primarily on time-based invalidations because the target web service can be outside of your enterprise network and unaware of your client caching. Therefore, you can specify the amount of time in the cache and the rules to build cache entry IDs in the cache in your client application.

The Web services client cache is provided as a JAX-RPC handler on your application server. This JAX-RPC cache handler intercepts the SOAP requests that flow through it from application clients. It then identifies a cache policy based on the target Web service. After a policy is found, all the cache ID rules are evaluated one by one until a valid rule is detected.

You can build cache id rules for Web services in three ways:

- By calculating a hash of the SOAPEnvelope
- By using SOAP header entries
- By using operation and part parameters
- By using custom Java code to build the cache id from an input SOAP message

Building the cache id rules using the SOAP header is faster because it does not have to parse the entire body of the SOAP document. For more information about building the cache policies for the Web services client cache, see “Configuring the Web services client cache” on page 2030.

Using the DistributedMap and DistributedObjectCache interfaces for the dynamic cache

By using the DistributedMap or DistributedObjectCache interfaces, Java 2 platform, Enterprise Edition (J2EE) applications and system components can cache and share Java objects by storing a reference to the object in the cache.

Enable the dynamic cache service. See “Enabling the dynamic cache service” on page 1993 for more information.

The DistributedMap and DistributedObjectCache interfaces are simple interfaces for the dynamic cache. Using these interfaces, J2EE applications and system components can cache and share Java objects by storing a reference to the object in the cache. The default dynamic cache instance is created if the dynamic cache service is enabled in the administrative console. This default instance is bound to the global Java Naming and Directory Interface (JNDI) namespace using the name `services/cache/distributedmap`.

Multiple instances of the DistributedMap and DistributedObjectCache interfaces on the same Java virtual machine (JVM) enable applications to separately configure cache instances as needed. Each instance of the DistributedMap interface has its own properties that can be set using “Object cache instance settings” on page 2039.

Tip: For more information about the DistributedMap and DistributedObjectCache interfaces, see the API documentation for the `com.ibm.websphere.cache` package. See Reference: Generated API documentation for more information.

Important: If you are using custom object keys, you must place your classes in a shared library. You can define the shared library at cell, node, or server level. Then, in each server create a class loader and associate it with the shared library that you defined. See the *Setting up the application serving environment* PDF for more information.

There are three methods for configuring and using cache instances.

- **Method 1 - Administrative console** You can create additional cache instances using the administrative console.

1. In the administrative console, select **Resources > Object cache instances** and create a new object cache instance.

If you defined two object cache instances in the administrative console with JNDI names of **services/cache/instance_one** and **services/cache/instance_two**, you can use the following code to look up the cache instances:

```
InitialContext ic = new InitialContext();
DistributedMap dm1 = (DistributedMap)ic.lookup("services/cache/instance_one");

DistributedMap dm2 = (DistributedMap)ic.lookup("services/cache/instance_two");
```

// or

```
InitialContext ic = new InitialContext();
DistributedObjectCache dm1 = (DistributedObjectCache)ic.lookup("services/cache/instance_one");

DistributedObjectCache dm2 = (DistributedObjectCache)ic.lookup("services/cache/instance_two");
```

- **Method 2 - Properties file** You can create cache instances using the `cacheinstances.properties` file and package the file in your Enterprise Archive (EAR) file.

Following is an example of how you can create additional cache instances using the `cacheinstances.properties` file:

```
cache.instance.0=/services/cache/instance_one
cache.instance.0.cacheSize=1000
cache.instance.0.enableDiskOffload=true
cache.instance.0.diskOffloadLocation=${app_server_root}/diskOffload
cache.instance.0.flushToDiskOnStop=true
cache.instance.0.useListenerContext=true
cache.instance.0.enableCacheReplication=false
cache.instance.0.disableDependencyId=false
cache.instance.0.htodCleanupFrequency=60
cache.instance.1=/services/cache/instance_two
cache.instance.1.cacheSize=1500
cache.instance.1.enableDiskOffload=false
cache.instance.1.flushToDiskOnStop=false
cache.instance.1.useListenerContext=false
cache.instance.1.enableCacheReplication=true
cache.instance.1.replicationDomain=DynaCacheCluster
cache.instance.1.disableDependencyId=true
```

The preceding example creates two cache instances named `instance_one` and `instance_two`. `instance_one` has a cache entry size of 1,000 and `instance_two` has a cache entry size of 1,500. Disk offload is enabled in `instance_one` and disabled in `instance_two`. Use listener context is enabled in `instance_one` and disabled in `instance_two`. Flush to disk on stop is enabled in `instance_one` and disabled in `instance_two`. Cache replication is enabled in `instance_two` and disabled in `instance_one`. The name of the data replication domain for `instance_two` is `DynaCacheCluster`. Dependency ID support is disabled in `instance_two`.

You must place the cacheinstances.properties file in either your application server or application class path. For example, you can use your application WAR file, WEB-INF\classes directory, or was_root\classes directory. The first entry in the properties file (cache.instance.0) specifies the JNDI name for the cache instance in the global namespace. You can use the following code to look up the cache instance:

```
InitialContext ic = new InitialContext();
DistributedMap dm1 = (DistributedMap)ic.lookup("services/cache/instance_one");
DistributedMap dm2 = (DistributedMap)ic.lookup("services/cache/instance_two");
```

For more information about the DistributedMap and DistributedObjectCache interfaces, see the API documentation for the com.ibm.websphere.cache package.

- **Method 3 - Resource references**

Note: Method three is an extension to method one or method two, listed above. First use either method one or method two.

Define a resource-ref in your module deployment descriptor (web.xml and ibm-web-bnd.xml files) and look up the cache using the java:comp namespace.

Resource-ref example:

File: web.xml

```
<resource-ref id="ResourceRef_1">
  <res-ref-name>dmap/LayoutCache</res-ref-name>
  <res-type>com.ibm.websphere.cache.DistributedMap</res-type>
  <res-auth>Container</res-auth>
  <res-sharing-scope>Shareable</res-sharing-scope>
</resource-ref>
<resource-ref id="ResourceRef_2">
  <res-ref-name>dmap/UserCache</res-ref-name>
  <res-type>com.ibm.websphere.cache.DistributedMap</res-type>
  <res-auth>Container</res-auth>
  <res-sharing-scope>Shareable</res-sharing-scope>
</resource-ref>
```

File: ibm-web-bnd.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<webappbnd:WebAppBinding xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI"
xmlns:webappbnd="webappbnd.xmi"
xmlns:webapplication="webapplication.xmi" xmlns:commonbnd="commonbnd.xmi"
xmlns:common="common.xmi"
xmi:id="WebApp_ID_Bnd" virtualHostName="default_host">
  <webapp href="WEB-INF/web.xml#WebApp_ID"/>
  <resRefBindings xmi:id="ResourceRefBinding_1" jndiName="services/cache/instance_one">
    <bindingResourceRef href="WEB-INF/web.xml#ResourceRef_1"/>
  </resRefBindings>
  <resRefBindings xmi:id="ResourceRefBinding_2" jndiName="services/cache/instance_two">
    <bindingResourceRef href="WEB-INF/web.xml#ResourceRef_2"/>
  </resRefBindings>
</webappbnd:WebAppBinding>
```

The following example shows how to look up the resource-ref:

```
InitialContext ic = new InitialContext();
DistributedMap dm1a = (DistributedMap)ic.lookup("java:comp/env/dmap/LayoutCache");
DistributedMap dm2a = (DistributedMap)ic.lookup("java:comp/env/dmap/UserCache");
// or
DistributedObjectCache dm1a = (DistributedObjectCache)ic.lookup("java:comp/env/dmap/LayoutCache");
DistributedObjectCache dm2a = (DistributedObjectCache)ic.lookup("java:comp/env/dmap/UserCache");
```

The previous resource-ref example maps java:comp/env/dmap/LayoutCache to /services/cache/instance_one and java:comp/env/dmap/UserCache to /services/cache/instance_two. In the examples, DistributedMap dm1 and dm1a are the same object. DistributedMap dm2 and dm2a are the same object.

Restriction: DistributedMap and DistributedObjectCache do not have authorization or access control associated with the cache entries.

To learn how to share cached objects in a clustered environment, see “Shared cached objects in a clustered environment.”

Shared cached objects in a clustered environment

This section discusses what you should do when sharing cached objects in a clustered environment.

In a clustered environment, the content you place in cache might be shared with other servers in the cluster. The content might also be offloaded to disk. If you intend to have the cached objects shared or offloaded to disk, you must make these particular objects serializable. If the objects you place in cache are non-serializable, you must specify that the sharing policy for these objects is not shared. The DistributedMap interface DistributedMap interface contains information about how to specify the sharing policy for a cached object. Specifying a sharing policy other than not shared for non-serializable objects can result in poor system performance.

Object cache instance settings

An object cache instance is a location, in addition to the default shared dynamic cache, where any Java 2 Platform, Enterprise Edition (J2EE) application can store, distribute, and share data. This gives applications greater flexibility and better tuning of the cache resources. Use the DistributedMap programming interface to access this cache instance. See the API documentation for more information.

To view this administrative console page, click **Resources > Cache instances > Object cache instances > cache_instance_name**.

Name:

Specifies the required display name for the resource.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource. Use this name when looking up a reference to this cache instance. The results return a DistributedMap object.

Description:

Specifies a description for the resource. This field is optional.

Category:

Specifies a category string to classify or group the resource. This field is optional.

Cache size:

Specifies a positive integer for the maximum number of entries the cache holds. The cache size is usually in the thousands.

Default	2000
Range	100 - 200,000

Default priority:

Specifies the default priority for servlets that can be cached. This value determines how long an entry stays in a full cache.

The recommended value is one. The range is one through 255.

Enable disk offload:

Specifies if disk offloading is enabled.

If you have disk offload disabled, when a new entry is created while the cache is full, the priorities are configured for each entry and the least recently used algorithm are used to remove the entry from the cache in memory. If you enable disk offload, the entry that would be removed from the cache is copied to the local file system. The location of the file is specified by the disk offload location.

Default	false
---------	-------

Offload location:

Specifies the directory that is used for disk offload.

If disk offload location is not specified, the default location, `${WAS_TEMP_DIR}/node/server name/_dynacache/cache JNDI name` will be used. If disk offload location is specified, the node, server name, and cache instance name are appended. For example, `${USER_INSTALL_ROOT}/diskoffload` generates the location as `${USER_INSTALL_ROOT}/diskoffload/node/server name/cache JNDI name`. This value is ignored if disk offload is not enabled.

The default value of the `${WAS_TEMP_DIR}` property is `${USER_INSTALL_ROOT}/temp`. If you change the value of the `${WAS_TEMP_DIR}` property after starting WebSphere Application Server, but do not move the disk cache contents to the new location:

- The Application Server creates a new disk cache file at the new disk offload location.
- If the Flush to disk setting is enabled, all the disk cache content at the old location is lost when you restart the Application Server

Flush to disk:

Specifies if in-memory cached objects are saved to disk when the server is stopped. This value is ignored if Enable Disk Offload is not selected.

Default	false
---------	-------

Limit disk cache size in GB:

Specifies a value for the maximum disk cache size in GB. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.
-------	---

Limit disk cache size in entries:

Specifies a value for the maximum disk cache size in number of entries. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.
-------	---

Limit disk cache entry size:

Specifies a value for the maximum size of an individual cache entry in MB. Any cache entry larger than this, when evicted from memory, will not be offloaded to disk. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.
-------	---

Performance settings:

Specifies the level of performance that is required by the disk cache. This setting applies only if **enableDiskOffload** is specified for the cache. Performance levels determine how memory resources should be used on background activity such as cache cleanup, expiration, garbage collection, and so on. This setting applies only if enable disk offload is specified for the cache.

High performance and high memory usage	Indicates that all metadata will be kept in memory.
Balanced performance and balanced memory usage	Indicates some metadata will be kept in memory. This is the default performance setting and will provide an optimal balance of performance and memory usage for most users.
Low performance and low memory usage	Indicates that limited metadata will be kept in memory.
Custom performance	Indicates that the administrator will explicitly configure the memory settings that will be used to support the above background activity. The administrator sets these values using the DiskCacheCustomPerformanceSettings object.

Disk cache cleanup frequency:

Specifies a value for the disk cache cleanup frequency, in minutes. If this value is set to 0, the cleanup runs only at midnight. This setting applies only when the Disk Offload Performance Level is low, balanced, or custom. The high performance level does not require disk cleanup, and this value is ignored.

Value	0 to 1440
-------	-----------

Maximum buffer for cache identifiers per metaentry:

Specifies a value for the maximum number of cache identifiers that are stored for an individual dependency ID or template in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk offload performance level is custom.

Value	100 to MAXINT
-------	---------------

Maximum buffer for dependency identifiers:

Specifies a value for the maximum number of dependency identifier buckets in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.

Value	100 to MAXINT
-------	---------------

Maximum buffer for templates:

Specifies a value for the maximum number of template buckets that are in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.

Value	10 to MAXINT
-------	--------------

Eviction policy algorithm:

Specifies the eviction algorithm that the disk cache will use to evict entries once the high threshold is reached. This setting applies only if enable disk offload is specified for the cache.

None	No eviction policy, so the disk cache can grow until it reaches its limit at which time the dynamic cache service stops writing to disk
Random	When the disk size reaches a high threshold limit, the disk cache garbage collector wakes up and randomly picks entries on the disk and evicts them until the size reaches a low threshold limit.
Size	When the disk size reaches a high threshold limit, the disk cache garbage collector wakes up and picks the largest entries on the disk and evicts them until the disk size reaches a low threshold limit.

High threshold:

Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The disk cache garbage collector is awakened when the disk size exceeds high threshold limit. The lower value limits disk cache size in GB and disk cache size in entries. This setting does not apply when the disk cache eviction policy is set to none.

Values	1 to 100
--------	----------

Low threshold:

Specifies when the eviction policy ends. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The lower value limits disk cache size in GB and disk cache size in entries. The disk cache garbage collector, when awakened, evicts entries until the disk size reaches the low threshold limit. This setting does not apply when the disk cache eviction policy is set to none.

Values	1 to 100
--------	----------

Use listener context:

Set this value to true to have invalidation events sent to registered invalidation listeners using the Java 2 Platform, Enterprise Edition (J2EE) context of the listener. If you want to use listener J2EE context for callback, set this value to **true**. If you want to use the caller thread context for callback, set this to **false**.

Dependency ID support:

Specifies that the dynamic cache service, supports cache entry dependency IDs. Disable this option if you do not need to use dependency IDs. Dependency IDs specify additional cache group identifiers that associate multiple cache entries to the same group identifier in your cache policy.

This option might not be available for cache instances that were created with a previous version of WebSphere Application Server.

Default	true
---------	------

Enable cache replication:

Use cache replication to enable sharing of cache IDs, cache entries, and cache invalidations with other servers in the same replication domain.

This option might be unavailable for cache instances created with a previous version of WebSphere Application Server.

Full group replication domain:

Specifies a replication domain from which your data is replicated.

Specifies a replication domain from which your data is replicated. Choose from any replication domains that have been defined. If there are no replication domains listed, you must create one during cluster creation or manually in the administrative console by clicking **Environment > Internal replication domains > New**. The replication domain you choose to use with the dynamic cache service must be using a Full group replica. Do not share replication domains between replication consumers. Dynamic cache should use a different replication domain from session manager or stateful session beans.

Replication type:

Specifies the global sharing policy for this cache instance.

The following settings are available:

- **Both push and pull** sends the cache ID of newly updated content to other servers in the replication domain. Then, if one of the other servers requests the content, and that server has the ID of the cache entry for the previously updated content, it will retrieve the content from the publishing server. If a request is made for an ID which has not been previously published, the server assumes it does not exist in the cluster and creates a new entry.
- **Pull only** shares cache entries for this object between application servers on demand. If an application server gets a cache miss for this object, it queries the cooperating application servers to see if they have the object. If no application server has a cached copy of the object, the original application server runs the request and generates the object. These entries cannot store non-serializable data. This mode of sharing is not recommended.
- **Push only** sends the cache ID and cache content of new content to all other servers in the replication domain.
- The sharing policy of **Not Shared** results in the cache ID and cache content not being shared with other servers in the replication domain.

The default setting for a an environment without clustering is **Not Shared**. When enabling replication, the default value is **Not Shared**.

Push frequency:

Specifies the time, in seconds, to wait before pushing new or modified cache entries to other servers.

A value of 0 (zero) sends the cache entries immediately. Setting this property to a value greater than 0 (zero) results in a "batch" push of all cache entries that are created or modified during the time period. The default is 1 (one).

Object cache instance collection

Use this page to configure and manage object cache instances, which in addition to the default shared dynamic cache, can store, distribute, and share data for Java 2 Platform, Enterprise Edition (J2EE) applications. Use cache instances to give applications better flexibility and tuning of the cache resources.

To view this administrative console page, click **Resources > Cache instances > Object cache instances**.

Use the DistributedObjectCache programming interface to access the cache instances. For more information about the DistributedObjectCache application programming interface, see the API documentation.

Scope:

Specify CELL SCOPE to view and configure cache instances that are available to all servers within the cell. Specify NODE SCOPE to view and configure cache instances that are available to all servers with the particular node. Specify SERVER SCOPE to view and configure cache instances that are available only on the specific server.

Name:

Specifies the required display name for the resource.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource. Use this name when looking up a reference to this cache instance. The results return a DistributedMap object.

Cache size:

Specifies a positive integer for the maximum number of entries the cache holds. The cache size is usually in the thousands. The default is 2000.

The minimum value is 100, with no set maximum value.

Invalidation listeners

Invalidation listener mechanism uses Java events for alerting applications when contents are removed from the cache.

Applications implement the InvalidationListener interface (defined in the `com.ibm.websphere.cache` package) and register it to the cache using the DistributedMap interface. Listeners receive InvalidationEvents (defined in the `com.ibm.websphere.cache` package) when entries from the cache are removed, due to an explicit user invalidation, timeout, least recently used (LRU) eviction, cache clear, or disk timeout. Applications can immediately recalculate the invalidated data and prime the cache before the next user request.

Enable listener support in DistributedMap before registering listeners. DistributedMap can also be configured to use the invalidation listener Java 2 Platform, Enterprise Edition (J2EE) context from registration time during callbacks. Setting the value of the custom property `useListenerContext` to true enables the invalidation listener J2EE context for callbacks. See Cache instance settings for more information.

The following example shows how to set up an invalidation listener:

```
dmap.enableListener(true); // Enable cache invalidation listener.  
InvalidationListener listener = new MyListenerImpl(); //Create invalidation listener object.  
dmap.addInvalidationListener(listener); //Add invalidation listener.  
:
```

```

:
:
dmap.removeInvalidationListener(listener); //Remove the invalidation listener.
//This increases performance.
dmap.enableListener(false); // Disable cache invalidation listener.
//This increases performance.

```

For more information about invalidation listeners, see Reference: Generated API documentation for the `com.ibm.websphere.cache` package.

Disabling template-based invalidations during JSP reloads

By setting the Java virtual machine (JVM) `com.ibm.ws.cache.CacheConfig.disableTemplateInvalidation` custom property to **true**, the template-based invalidations are disabled during JSP reloads.

To set any of these JVM custom properties, complete the following steps:

1. In the administrative console, click **Servers > Application servers > *server_name* > Process definition > Java virtual machine > Custom properties > New**.
2. Enter `com.ibm.ws.cache.CacheConfig.disableTemplateInvalidation` in the **Name** field.
3. Enter `true` in the **Value** field.
4. Save the property and restart WebSphere Application Server.

Using object cache instances

Perform this task so that your application can access dynamic cache object cache instances with the `DistributedMap` or `DistributedObjectCache` interfaces.

Before you begin, enable the dynamic cache service. See “Enabling the dynamic cache service” on page 1993 for more information.

Using object cache instances can improve the performance of your application because you can programmatically store and share frequently used objects. By using object cache instances, you also have the necessary control over the dynamic cache when you are running multiple applications in an application server. See “Cache instances” on page 574 for more information.

1. Configure one or more cache instances.
 - a. In the administrative console, click **Resources > Cache instances > Object cache instances**.
 - b. Specify the scope for the cache instance.
Cell scope makes the cache instance available to all servers within the cell. Node scope makes the cache instance available to all servers on the particular node. Cluster scope makes the cache instance available to all members in a specified cluster. Server scope makes the cache instance available to only the selected server. You can mix scopes if necessary.
 - c. Click **Apply** after changing the scope.
 - d. Click **New**.
 - e. Enter the Java Naming and Directory Interface (JNDI) name for this cache instance.
This is name that you pass to the `InitialContext.lookup()` method from within your application. For example, `services/cache/instance_one`.
 - f. Enter or modify other properties as needed.
2. Update your application. To store and retrieve objects in an object cache instance, you need a `DistributedMap` or `DistributedObjectCache` reference for the named object cache instance. See “Using the `DistributedMap` and `DistributedObjectCache` interfaces for the dynamic cache” on page 2036 for more information.

You configured object cache instances that you can access programmatically with the `DistributedMap` and `DistributedObjectCache` interfaces.

Displaying cache information

Use this task to monitor the activity of the dynamic cache service.

The dynamic cache monitor is an installable Web application that displays simple cache statistics, cache entries, and cache policy information for servlet cache instances.

The cache monitor provides information on the cache in the servant to which your browser connects to interact with the monitor. In an environment with multiple servants, the cache monitor provides a partial view of caching activity.

1. Use the administrative console to install the cache monitor application from the *app_server_root/installableApps* directory. The name of the application is *CacheMonitor.ear*. For more information about installing applications, see “Installing application files with the console” on page 40. Install the cache monitor onto the application server you are want to monitor.

The cache monitor application must be installed on the *default_host* (908x).

2. Configure the Web container transport chain and host alias for the server with cache monitor installed.
 - a. If you installed the cache monitor on the *admin_host* (port 906x), check if a Web container transport chain has been created. Click **Application servers** > *server_name* > **Web container settings** > **Web container transport chains**. If a Web container transport chain (port 906x) does not exist you must create a Web container transport chain in the *admin_host* for this server. If you are using *server1*, a Web container transport chain is installed by default for admin port 9060.
 - b. Add a host alias for the port your server is using. Click **Environment** > **Virtual hosts** > *host_type* > **Host aliases** and create a new **Host name** and **Port** to add to the list.
 - c. You can then access the cache monitor using `http://your_host_name:your_port_number/cachemonitor`.

Tip: You can find the port number in the *SystemOut.log* file. Look for message `TCPC0001I` or `SRVE0171I`.

3. Access the cache monitor using a Web browser and the URL `http://your_host_name:your_port_number/cachemonitor`, where *your port number* is the port associated with the host on which you installed the cache monitor application.
4. Verify the list of cache instances that are shown. For each cache instance, you can perform the following actions:

Tip: You must select the servlet cache instance that you want to monitor. If you do not use servlet cache instances by using `<cache-instance>` tags in your *cachespec.xml* file, all the content is in the **baseCache** instance.

- View the Statistics page and verify the cache configuration and cache data. Click **Reset Statistics** to reset the counters.
- View the Cache Policies page to see which cache policies are currently loaded in the dynamic cache. Click on a template to view the cache ID rules for the template.
- View the Cache Contents page to examine the contents that are currently cached in memory.
- View the Edge Statistics page to view data about the current ESI processors configured for caching. Click **Refresh Statistics** to see the latest statistics or content from the ESI processors. Click **Reset Statistics** to reset the counters.
- View the Disk Offload page to view the disk configuration, statistics, and the content that is currently off-loaded from memory to disk.

When you are viewing contents on memory or disk, click on a template to view all entries for that template, click on a dependency ID to view all entries for the ID, or click on the cache ID to view all the data that is cached for that entry.

5. Use the cache monitor to perform basic operations on data in a cache instance.

Remove an entry from cache

Click **Invalidate** when viewing a cache entry.

Remove all entries for a certain dependency ID

Click **Invalidate** when viewing entries for a dependency ID.

Remove all entries for a certain template

Click **Invalidate** when viewing entries for a template.

Move an entry to the front of the Least Recently Used queue to avoid eviction

Click **Refresh** when viewing a cache entry.

Move an entry from disk to cache

Click **Send to Memory** when viewing a cache entry on disk.

Clear the entire contents of the cache

Click **Clear Cache** while viewing statistics or contents.

Clear the contents on the ESI processors

Click **Clear Cache** while viewing ESI statistics or contents.

Clear the contents of the disk cache

Click **Clear Disk** while viewing disk contents.

Cache monitor

Cache monitor is an installable Web application that provides a real-time view of the current state of dynamic cache. You use it to help verify that dynamic cache is operating as expected. The only way to manipulate the data in the cache is by using the cache monitor. It provides a GUI interface to manually change data.

Cache monitor provides information on the cache in the servant to which your browser connects to interact with the monitor. In an environment that has multiple servants, cache monitor provides a partial view of caching activity.

Cache monitor provides a way to:

- **Verify the configuration of dynamic cache**

After you create multiple servlet cache instances in the administrative console, you can configure properties, including the maximum size of the cache and disk offload location on each cache instance, as well as advanced features such as controlling external caches. You can verify the configuration of the dynamic cache by viewing of the configured features and properties in the cache monitor.

- **Verify the cache policies**

To cache an object, unique IDs must be generated for different invocations of that object. To create unique IDs for each object, provide rules for each cacheable object in the `cachespec.xml` file, found inside the Web module `WEB-INF` or enterprise bean `META-INF` directory. See “Cachespec.xml file” on page 2015 for more information. Each cacheable object can have multiple cache ID rules that run in sequence until either a rule returns a cache ID or no more rules remain. If none of the cache ID generation rules produce a valid cache ID, then the object is not cached. There can be multiple `cachespec.xml` files with multiple cache ID rules. With cache monitor, you can verify the policies of each object. You can also view all of the cache policies for each cache instance that is currently loaded in dynamic cache. This view is also convenient to verify that the `cachespec.xml` file was read by the dynamic cache without errors.

- **Monitor cache statistics**

You can view the essential cache data, such as number of cache hits, cache misses, and number of entries in each cache instance. With this data, you can tune the cache configuration to improve the dynamic cache performance. For example, if the number of used entries is often high, and entries are being removed and recreated, consider increasing the maximum size of the cache or enabling disk offload.

- **Monitor the data flowing through the cache**

Once a cacheable object is invoked, dynamic cache creates a cache entry for it that contains the output of the actions that are performed and metadata, such as time to live, sharing policy, and so on. Entries are distinguished by a unique ID string that is based on the rules specified in the `cachespec.xml` file for the particular object name. Objects with the same name might generate multiple cache IDs for different

invocations, based on request parameters and attributes for each invocation. You can view of all the cache entries that are in the cache instance, based on the unique ID. You can also view the group of cache entries that share a common name (also known as template). Cache entries can also be grouped together by a dependency ID, which is used to invalidate the entire group of entries dependent on a common entity. Therefore, cache monitor also provides a view of the group of cache entries that share a common dependency ID.

For each entry, cache monitor also displays metadata, such as time to live, priority and sharing-policy, and provides a view of the output that has been cached. This helps the customer to verify which pages have been cached, that the pages have been cached in the correct cache instance with the right attributes such as time to live, priority, and that the pages have the right content.

- **Monitor the data in the edge cache**

Dynamic cache provides support to recognize the presence of an Edge Side Include (ESI) processor and to generate ESI include tags and appropriate cache policies for edge cacheable fragments. With the ESI processor, you can cache whole pages, as well as fragments, providing a higher cache hit ratio. There can be multiple ESI processors running on multiple hosts configured for caching.

You can view a list of all ESI processes and their hosts that are enabled for caching. Select a host or a processor, and view its edge cache statistics and the current cache entries.

- **View the data offloaded to the disk**

By default, when the number of cache entries reaches the configured limit for a given server, cache entries are removed, enabling new entries to enter the cache service. With disk offload, the removed cache entries are copied to disk for future access. You can view the content that is copied to disk that corresponds to the view of the contents cached in memory for each cache instance.

- **Manage the data in the cache**

You can perform the following basic operations on the data in the cache:

- Remove an entry from a cache instance
- Remove all entries for a certain dependency ID
- Remove all entries for a certain name (template)
- Move an entry to the front of the least recently used queue to avoid removal of the cache entry
- Move an entry from the disk to the memory within a cache instance
- Clear the entire contents of the cache instance
- Clear the contents of the disk for the cache instance

With these operations, you can manually change the state of the cache without having to restart the server.

Edge cache statistics:

Cache monitor provides a view of the edge cache statistics.

The following statistics are available:

- **ESI Processors.** The number of processes that are configured as edge caches.
- **Number of Edge Cached Entries.** The number of entries that are currently cached on all edge servers and processes.
- **Cache Hits.** The number of requests that match entries on edge servers.
- **Cache Misses By URL.** A cache policy does not exist on the edge server for the requested template.

Note:

- The initial ESI request for a template that has a cache policy on WebSphere Application Server results in a miss.
- Every request for a template that does not have a cache policy on WebSphere Application Server results in a miss by URL on the edge server.
- **Cache Misses By Cache ID.** The policy for the requested template exists on the edge server, and a cache ID is created, based on the ID rules and the request attributes, but the cache entry for this ID does not exist.

Note: If the policy exists on the edge server for the requested template, but a cache ID match is not found, based on the ID rules and the request attributes, it is not treated as a cache miss.

- **Cache Timeouts.** The number of entries that are removed from the edge cache based on the timeout value.
- **Evictions.** The number of entries that are removed from the edge cache due to invalidations received from WebSphere Application Server.

Tuning dynamic cache with the cache monitor

Use this task to interpret cache monitor statistics to improve the performance of the dynamic cache service.

Verify that dynamic cache is enabled and that the cache monitor application is installed on your application server.

See the Displaying cache information topic in the *Administering applications and their environment* PDF to configure the cache monitor application.

Use the cache monitor to watch cache hits versus misses. By comparing these two values, you can determine how much dynamic cache is helping your application, and if you can take any additional steps to further improve performance and decrease the cost of processing for your application server.

1. Start cache monitor and click on **Cache Statistics**. You can view the following cache statistics:

Cache statistic	Description
Cache Size	The maximum number of entries that the cache can hold.
Used Entries	The number of cache entries used.
Cache Hits	The number of request responses that are served from the cache.
Cache Misses	The number of request responses that are cacheable but cannot be served from the cache.
LRU Evictions	The number of cache entries removed to make room for new cache entries.
Explicit Removals	The number of cache entries removed or invalidated from the cache based on cache policies or were deleted from the cache through the cache monitor.

2. You can also view the following cache configuration values:

Cache configuration value	Description
Default priority	Specifies the default priority for all cache entries. Lower priority entries are moved from the cache before higher priority entries when the cache is full. You can specify the priority for individual cache entries in the cache policy.
Servlet Caching Enabled	If servlet caching is enabled, results from servlets and JavaServer Pages (JSP) files are cached. See the <i>Administering applications and their environment</i> PDF for more information.
Disk Offload Enabled	Specifies if entries that are being removed from the cache are saved to disk. See the <i>Administering applications and their environment</i> PDF for more information.

3. Wait for the application server to add data to the cache. You want the number of used cache entries in the cache monitor to be as high as it can go. When the number of used entries is at its highest, the cache can serve responses to as many requests as possible.

4. When the cache has a high number of used entries, reset the statistics. Watch the number of cache hits versus cache misses. If the number of hits is far greater than the number of misses, your cache configuration is optimal. You do not need to take any further actions. If you find a higher number of misses with a lower number of hits, the application server is working hard to generate responses instead of serving the request using a cached value. The application server might be making database queries, or running logic to respond to the requests.
5. If you have a large number of cache misses, increase the number of cache hits by improving the probability that a request can be served from the cache.

To improve the number of cache hits, you can increase the cache size or configure additional cache policies. See the *Administering applications and their environment* PDF for more information to increase the cache size and to configure cache policies.

By using the cache monitor application, you optimized the performance of the dynamic cache service.

See the *Administering applications and their environment* PDF for more information about the dynamic cache.

Using servlet cache instances

Use this task to configure servlet cache instances.

Before you begin, enable the dynamic cache service. See “Enabling the dynamic cache service” on page 1993 for more information.

Perform this task so that your application can access dynamic cache servlet cache instances. Using servlet cache instances can improve the performance of your application because you can store the output and the side effects of an invoked servlet. Servlet cache instances also give you the necessary control over the cache for multiple applications that are running in an application server. See “Cache instances” on page 574 for more information.

1. Enable servlet caching. See “Configuring servlet caching” on page 1998 for more information.
2. Configure one or more cache instances.
 - a. In the administrative console, click **Resources > Cache instances > Servlet cache instances**.
 - b. Specify the scope of the cache instance. Specify a scope of cell to make the cache instance available to all the servers that are in the cell. Node scope makes the cache instance available to all servers in a node. Server scope makes the cache instance available to the selected server only. If necessary, you can mix the scopes.
 - c. Click **Apply** to save the scope.
 - d. Specify the settings for the cache instance. The **Name** and **Java Naming and Directory interface (JNDI)** name fields are required. The **JNDI name** is the name attribute that is specified in the <cache-instance> element in the cachespec.xml file. An example of a JNDI name that is specified in the cachespec.xml file follows:

```
<cache-instance name="services/cache/instance_one">
```

In this example, specify `services/cache/instance_one` as the **JNDI name**.

3. Update your application. To use a servlet cache instance, you must specify a <cache-instance> element that has a name that is equal to the JNDI Name for this cache instance.

Servlet cache instance collection

A servlet cache instance is a location, in addition to the default shared dynamic cache, where dynamic cache can store, distribute, and share data. By using servlet cache instances, your applications have greater flexibility and better tuning of the cache resources. The Java Naming and Directory Interface (JNDI) name specified for the cache instance is mapped to the name attribute in the <cache-instance> tag in the cachespec.xml configuration file.

To view this administrative console page, click **Resources > Cache instances > Servlet cache instances**.

Scope:

Specify CELL SCOPE to view and configure cache instances that are available to all servers within the cell. Specify NODE SCOPE to view and configure cache instances that are available to all servers with the particular node. Specify SERVER SCOPE to view and configure cache instances that are available only on the specific server.

Name:

Specifies the required display name for the resource.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource. Specify this name in the name attribute field in the <cache-instance> tag in the cachespec.xml configuration file. This tag is used to find the particular cache instance in which to store cache entries.

Cache size:

Specifies a positive integer for the maximum number of entries the cache holds. The cache size is usually in the thousands. The default is 2000.

The minimum value is 100, with no set maximum value.

Servlet cache instance settings

A servlet cache instance is a location, in addition to the default shared dynamic cache, where dynamic cache can store, distribute, and share data. By using servlet cache instances, your applications have greater flexibility and better tuning of the cache resources. The Java Naming and Directory Interface (JNDI) name specified for the cache instance is mapped to the name attribute in the <cache-instance> tag in the cachespec.xml configuration file.

To view this administrative console page, click **Resources > Cache instances > Servlet cache instances > cache_instance_name**.

Name:

Specifies the required display name for the resource.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource. Specify this name in the name attribute field in the <cache-instance> tag in the cachespec.xml configuration file. This tag is used to find the particular cache instance in which to store cache entries.

Description:

Specifies a description for the resource. This field is optional.

Category:

Specifies a category string to classify or group the resource. This field is optional.

Cache size:

Specifies a positive integer for the maximum number of entries the cache holds. The cache size is usually in the thousands.

Default	2000
Range	100 - no set maximum value

Default priority:

Specifies the default priority for servlets that can be cached. This value determines how long an entry stays in a full cache.

The recommended value is one.

Enable disk offload:

Specifies if disk offloading is enabled.

If you have disk offload disabled, when a new entry is created while the cache is full, the priorities are configured for each entry and the least recently used algorithm are used to remove the entry from the cache in memory. If you enable disk offload, the entry that would be removed from the cache is copied to the local file system. The location of the file is specified by the disk offload location.

Default	false
---------	-------

Offload location:

Specifies the directory used for disk offload.

If disk offload location is not specified, the default location, `${WAS_TEMP_DIR}/node/server name/_dynacache/cache JNDI name` will be used. If disk offload location is specified, the node, server name, and cache instance name are appended. For example, `${USER_INSTALL_ROOT}/diskoffload` generates the location as `${USER_INSTALL_ROOT}/diskoffload/node/server name/cache JNDI name`. This value is ignored if disk offload is not enabled.

The default value of the `${WAS_TEMP_DIR}` property is `${USER_INSTALL_ROOT}/temp`. If you change the value of the `${WAS_TEMP_DIR}` property after starting WebSphere Application Server, but do not move the disk cache contents to the new location:

- The Application Server creates a new disk cache file at the new disk offload location.
- If the Flush to disk setting is enabled, all the disk cache content at the old location is lost when you restart the Application Server

Flush to disk:

Specifies if in-memory cached objects are saved to disk when the server is stopped. This value is ignored if Enable Disk Offload is not selected.

Default	false
---------	-------

Limit disk cache size in GB:

Specifies a value for the maximum disk cache size in GB. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.
-------	---

Limit disk cache size in entries:

Specifies a value for the maximum disk cache size in number of entries. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.
-------	---

Limit disk cache entry size:

Specifies a value for the maximum size of an individual cache entry in MB. Any cache entry larger than this, when evicted from memory, will not be offloaded to disk. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.
-------	---

Performance settings:

Specifies the level of performance that is required by the disk cache. This setting applies only if **enableDiskOffload** is specified for the cache. Performance levels determine how memory resources should be used on background activity such as cache cleanup, expiration, garbage collection, and so on. This setting applies only if enable disk offload is specified for the cache.

High performance and high memory usage	Indicates that all metadata will be kept in memory.
Balanced performance and balanced memory usage	Indicates some metadata will be kept in memory. This is the default performance setting and will provide an optimal balance of performance and memory usage for most users.
Low performance and low memory usage	Indicates that limited metadata will be kept in memory.
Custom	Indicates that the administrator will explicitly configure the memory settings that will be used to support the above background activity. The administrator sets these values using the DiskCacheCustomPerformanceSettings object.

Disk cache cleanup frequency:

Specifies a value for the disk cache cleanup frequency, in minutes. If this value is set to 0, the cleanup runs only at midnight. This setting applies only when the Disk Offload Performance Level is low, balanced, or custom. The high performance level does not require disk cleanup, and this value is ignored.

Value	0 to 1440
-------	-----------

Maximum buffer for cache identifiers per metaentry:

Specifies a value for the maximum number of cache identifiers that are stored for an individual dependency ID or template in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk offload performance level is CUSTOM.

Value	100 to MAXINT
-------	---------------

Maximum buffer for dependency identifiers:

Specifies a value for the maximum number of dependency identifier buckets in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.

Value	100 to MAXINT
-------	---------------

Maximum buffer for templates:

Specifies a value for the maximum number of template buckets that are in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.

Value	10 to MAXINT
-------	--------------

Eviction policy algorithm:

Specifies the eviction algorithm that the disk cache will use to evict entries once the high threshold is reached. This setting applies only if enable disk offload is specified for the cache.

None	No eviction policy, so the disk cache can grow until it reaches its limit at which time the dynamic cache service stops writing to disk
Random	When the disk size reaches a high threshold limit, the disk cache garbage collector wakes up and randomly picks entries on the disk and evicts them until the size reaches a low threshold limit.
Size	When the disk size reaches a high threshold limit, the disk cache garbage collector wakes up and picks the largest entries on the disk and evicts them until the disk size reaches a low threshold limit.

High threshold:

Specifies when the eviction policy starts. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The disk cache garbage collector is awakened when the disk size exceeds high threshold limit. The lower value limits disk cache size in GB and disk cache size in entries. This setting does not apply when the disk cache eviction policy is set to none.

Values	1 to 100
--------	----------

Low threshold:

Specifies when the eviction policy ends. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The lower value limits disk cache size in GB and disk cache size in entries. The disk cache garbage collector, when awakened, evicts entries until the disk size reaches the low threshold limit. This setting does not apply when the disk cache eviction policy is set to none.

Values	1 to 100
--------	----------

Enable cache replication:

Use cache replication to enable sharing of cache IDs, cache entries, and cache invalidations with other servers in the same replication domain.

This option might be unavailable for cache instances created with a previous version of WebSphere Application Server.

Full group replication domain:

Specifies a replication domain from which your data is replicated.

Specifies a replication domain from which your data is replicated. Choose from any replication domains that have been defined. If there are no replication domains listed, you must create one during cluster creation or manually in the administrative console by clicking **Environment > Internal replication domains > New**. The replication domain you choose to use with the dynamic cache service must be using a Full group replica. Do not share replication domains between replication consumers. Dynamic cache should use a different replication domain from session manager or stateful session beans.

Replication type:

Specifies the global sharing policy for this cache instance.

The following settings are available:

- **Both push and pull** sends the cache ID of newly updated content to other servers in the replication domain. Then, if one of the other servers requests the content, and that server has the ID of the cache entry for the previously updated content, it will retrieve the content from the publishing server. If a request is made for an ID which has not been previously published, the server assumes it does not exist in the cluster and creates a new entry.
- **Pull only** shares cache entries for this object between application servers on demand. If an application server gets a cache miss for this object, it queries the cooperating application servers to see if they have the object. If no application server has a cached copy of the object, the original application server runs the request and generates the object. These entries cannot store non-serializable data. This mode of sharing is not recommended.
- **Push only** sends the cache ID and cache content of new content to all other servers in the replication domain.
- The sharing policy of **Not Shared** results in the cache ID and cache content not being shared with other servers in the replication domain.

The default setting for a an environment without clustering is **Not Shared**. When enabling replication, the default value is **Not Shared**.

Push frequency:

Specifies the time, in seconds, to wait before pushing new or modified cache entries to other servers.

A value of 0 (zero) sends the cache entries immediately. Setting this property to a value greater than 0 (zero) results in a "batch" push of all cache entries that are created or modified during the time period. The default is 1 (one).

Using the DynamicContentProvider interface for dynamic cache

Use this task to configure the DynamicContentProvider interface for cached servlets and JavaServer Pages (JSP) files.

The dynamic cache service should be enabled and you should be using servlet caching. See “Enabling the dynamic cache service” on page 1993 and “Configuring servlet caching” on page 1998 for more information.

A cacheable servlet or JavaServer Pages (JSP) file might contain a state in the response that does not belong to the fragment for that servlet or JSP. When the state changes, the cached servlet or JSP is not valid for caching. Use the `com.ibm.websphere.servlet.cache.DynamicContentProvider` interface to make the fragment cacheable.

Servlets or JSP files that implement the `DynamicContentProvider` interface can add user exits in fragments that are cacheable by calling the `addDynamicContentProvider(DCP)` method on the wrapper response object. When the dynamic cache renders the page, it identifies the user exit and calls the dynamic content provider to add the dynamic content to the rendered page.

1. Provide an implementation class of the `com.ibm.websphere.servlet.cache.DynamicContentProvider` interface. An example of an implementation follows:

```
class DynamicContentProviderImpl implements com.ibm.websphere.servlet.cache.  
    DynamicContentProvider {  
    DynamicContentProviderImpl() {}  
  
    public void provideDynamicContent(HttpServletRequest request, OutputStream streamWriter)  
        throws IOException {  
        String dynamicContent = System.currentTimeMillis();  
        streamWriter.write(dynamicContent.getBytes());  
    }  
    public void provideDynamicContent(HttpServletRequest request, Writer streamWriter)  
        throws IOException {  
        String dynamicContent = System.currentTimeMillis();  
        streamWriter.write(dynamicContent.toCharArray());  
    }  
}
```

2. Add user exits to your servlet or JSP file by calling the `addDynamicContentProvider(DCP)` method on the wrapper response object. An example follows:

```
public class DCPServlet extends CacheTestCase {  
    public void performTest(HttpServletRequest request, HttpServletResponse response)  
        throws IOException, ServletException {  
        out.println("Testing the DCP feature begin "+System.currentTimeMillis());  
        DynamicContentProvider dcp = new DynamicContentProviderImpl();  
        ServletCacheResponse scr = (ServletCacheResponse)(response);  
        scr.addDynamicContentProvider(dcp);  
        out.println("Testing the DCP feature end"+System.currentTimeMillis());  
    }  
}
```

See “Task overview: Using the dynamic cache service to improve performance” on page 1978 for more information about the other tasks that you can perform with the dynamic cache.

Dynamic query

Using EJB query

The EJB query language is used to specify a query over container-managed entity beans. The language is similar to SQL. An EJB query is independent of the bean’s mapping to a persistent store.

An EJB query can be used in three situations:

- To define a finder method of an EJB entity bean.
- To define a select method of an EJB entity bean.
- To dynamically specify a query using the `executeQuery()` dynamic API.

Finder and select queries are specified in the bean's deployment descriptor using the <ejb-q1> tag; they are compiled into SQL during deployment. Dynamic queries are included within the application code itself.

WebSphere's EJB query language is compliant with the EJB QL defined in Sun's EJB 2.1 specification and has additional capabilities as listed in the topic Comparison of EJB 2.x specification and WebSphere Query Language.

- Before using EJB query, familiarize yourself with query language concepts, starting with the topic, EJB Query Language.
- Define an EJB query in one of the following ways:
 - **Application Server Toolkit.** When defining an EJB 2.1 entity bean in an EJB deployment descriptor editor, on the **Beans** page click **Add** under **Queries** and, in the Add Finder Descriptor wizard, define a `find` or `ejbSelect` method. See the online **Application Server Toolkit information** for documentation on wizard options.
 - **Rational Application Developer.** When defining an entity bean, specify the <ejb-q1> tag for the finder or select method.
 - **Dynamic query service.** Add the `executeQuery()` method to your application.

See the topic Example: EJB queries.

EJB query language

An EJB query is a string that contains the following elements:

- a SELECT clause that specifies the enterprise beans or values to return;
- a FROM clause that names the bean collections;
- an optional WHERE clause that contains search predicates over the collections;
- an optional GROUP BY and HAVING clause (see Aggregation functions);
- an optional ORDER BY clause that specifies the ordering of the result collection.

Collections of entity beans are identified in EJB queries through the use of their abstract schema name in the query FROM clause.

The elements of EJB query language are discussed in more detail in the following related topics.

Example: EJB queries:

Here is an example EJB schema, followed by a set of example queries:

Table 62. DeptBean schema

Entity bean name (EJB name)	DeptEJB (not used in query)
Abstract schema name	DeptBean
Implementation class	com.acme.hr.deptBean (not used in query)
Persistent attributes (cmp fields)	<ul style="list-style-type: none"> • deptno - Integer (key) • name - String • budget - BigDecimal
Relationships	<ul style="list-style-type: none"> • emps - 1:Many with EmpEJB • mgr - Many:1 with EmpEJB

Table 63. EmpBean schema

Entity bean name (EJB name)	EmpEJB (not used in query)
Abstract schema name	EmpBean
Implementation class	com.acme.hr.empBean (not used in query)

Table 63. EmpBean schema (continued)

Persistent attributes (cmp fields)	<ul style="list-style-type: none"> • empid - Integer (key) • name - String • salary - BigDecimal • bonus - BigDecimal • hireDate - java.sql.Date • birthDate - java.util.Calendar • address - com.acme.hr.Address
Relationships	<ul style="list-style-type: none"> • dept - Many:1 with DeptEJB • manages - 1:Many with DeptEJB

Address is a serializable object used as cmp field in EmpBean. The definition of address is as follows:

```
public class com.acme.hr.Address extends Object implements Serializable {
public String street;
public String state;
public String city;
public Integer zip;
    public double distance (String start_location) { ... } ;
    public String format ( ) { ... } ;
}
```

The following query returns all departments:

```
SELECT OBJECT(d) FROM DeptBean d
```

The following query returns departments whose name begins with the letters "Web". Sort the result by name:

```
SELECT OBJECT(d) FROM DeptBean d WHERE d.name LIKE 'Web%' ORDER BY d.name
```

The keywords SELECT and FROM are shown in uppercase in the examples but are case insensitive. If a name used in a query is a reserved word, the name must be enclosed in double quotes to be used in the query. You can find a list of reserved words in "EJB query: Reserved words" on page 2078. Identifiers enclosed in double quotes are case sensitive. This example shows how to use a cmp field that is a reserved word:

```
SELECT OBJECT(d) FROM DeptBean d WHERE d."select" > 5
```

The following query returns all employees who are managed by Bob. This example shows how to navigate relationships using a path expression:

```
SELECT OBJECT (e) FROM EmpBean e WHERE e.dept.mgr.name='Bob'
```

A query can contain a parameter which refers to the corresponding value of the finder or select method. Query parameters are numbered starting with 1:

```
SELECT OBJECT (e) FROM EmpBean e WHERE e.dept.mgr.name= ?1
```

This query shows navigation of a multivalued relationship and returns all departments that have an employee that earns at least 50000 but not more than 90000:

```
SELECT OBJECT(d) FROM DeptBean d, IN (d.emps) AS e
WHERE e.salary BETWEEN 50000 and 90000
```

There is a join operation implied in this query between each department object and its related collection of employees. If a department has no employees, the department does not appear in the result. If a department has more than one employee that earns more than 50000, that department appears multiple times in the result.

The following query eliminates the duplicate departments:

```
SELECT DISTINCT OBJECT(d) from DeptBean d, IN (d.emps) AS e WHERE e.salary > 50000
```

Find employees whose bonus is more than 40% of their salary:

```
SELECT OBJECT(e) FROM EmpBean e where e.bonus > 0.40 * e.salary
```

Find departments where the sum of salary and bonus of employees in the department exceeds the department budget:

```
SELECT OBJECT(d) FROM DeptBean d where d.budget <
( SELECT SUM(e.salary+e.bonus) FROM IN(d.emps) AS e )
```

A query can contain DB2 style date-time arithmetic expressions if you use java.sql.* datatypes as CMP fields and your datastore is DB2. Find all employees who have worked at least 20 years as of January 1st, 2000:

```
SELECT OBJECT(e) FROM EmpBean e where year( '2000-01-01' - e.hireDate ) >= 20
```

If the datastore is not DB2 or if you prefer to use java.util.Calendar as the CMP field, then you can use the java millisecond value in queries. The following query finds all employees born before Jan 1, 1990:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.birthDate < 631180800232
```

Find departments with no employees:

```
SELECT OBJECT(d) from DeptBean d where d.emps IS EMPTY
```

Find all employees whose earn more than Bob:

```
SELECT OBJECT(e) FROM EmpBean e, EmpBean b
WHERE b.name = 'Bob' AND e.salary + e.bonus > b.salary + b.bonus
```

Find the employee with the largest bonus:

```
SELECT OBJECT(e) from EmpBean e WHERE e.bonus =
(SELECT MAX(e1.bonus) from EmpBean e1)
```

The above queries all return EJB objects. A finder method query must always return an EJB Object for the home. A select method query can in addition return CMP fields or other EJB Objects not belonging to the home.

The following would be valid select method queries for EmpBean. Return the manager for each department:

```
SELECT d.mgr FROM DeptBean d
```

Return department 42 manager's name:

```
SELECT d.mgr.name FROM DeptBean d WHERE d.deptno = 42
```

Return the names of employees in department 42:

```
SELECT e.name FROM EmpBean e WHERE e.dept.deptno=42
```

Another way to write the same query is:

```
SELECT e.name from DeptBean d, IN (d.emps) AS e WHERE d.deptno=42
```

Finder and select queries allow only a single CMP field or EJBOject in the SELECT clause. A select query can return aggregate values in Enterprise JavaBeans 2.1 using SUM, MIN, MAX, AVG and COUNT.

```
SELECT max(e.salary) FROM EmpBean e WHERE e.dept.deptno=42
```

The dynamic query API allows multiple expressions in the SELECT clause. The following query would be a valid dynamic query, but not a valid select or finder query:

```
SELECT e.name, e.salary+e.bonus as total_pay , object(e), e.dept.mgr
FROM EmpBean e
ORDER BY 2
```

The following dynamic query returns the number of employees in each department:

```
SELECT e.dept.deptno as department_number , count(*) as employee_count
FROM EmpBean e
GROUP BY by e.dept.deptno
ORDER BY 1
```

The dynamic query API allows queries that contain bean or value object methods:

```
SELECT object(e), e.address.format( )
FROM EmpBean e EmpBean e
```

FROM clause: The FROM clause specifies the collections of objects to which the query is to be applied. Each collection is specified either by an abstract schema name (ASN) or by a path expression identifying a relationship. An identification variable is defined for each collection.

Conceptually, the semantics of the query is to form a temporary collection of tuples, **R**, with elements consisting of all possible combinations of objects from the collections. This collection is subject to the constraints imposed by any path relationships and by the JOIN operation. The JOIN can be either an *inner* or *outer* join.

The identification variables are bound to elements of the tuple. After forming the temporary collection, the search conditions of the WHERE clause are applied to R, and yield a new temporary collection, **R1**. The ORDER BY, GROUP BY, HAVING, and SELECT clauses are applied to R1 to yield the final result.

```
from_clause::=FROM identification_variable_declaration [, {identification_variable_declaration |
collection_member_declaration } ]*

identification_variable_declaration::= range_variable_declaration [join]*

join := [ { LEFT [OUTER] | INNER } ] JOIN {collection_valued_path_expression | single_valued_path_expression}
[AS] identifier
```

Examples: Joining collections

DeptBean contains records 10, 20, and 30. EmpBean contains records 1, 2, and 3 that are related to department 10, and records 4 and 5 that are related to department 20. Department 30 has no employees.

```
SELECT d FROM DeptBean AS d, EmpBean AS e
WHERE d.name = e.name
```

The comma syntax performs an inner join resulting in all possible combinations. In this example, R would consist of 15 tuples (3 departments x 5 employees). If any collection is empty, then R is also empty. The keyword *AS* is optional.

This example shows that a collection can be joined with itself.

```
SELECT d FROM DeptBean AS d, DeptBean AS d1
```

R would consist of 9 tuples (3 departments x 3 departments).

Examples: Relationship joins

A collection can be a relationship based on a previously declared identifier as in

```
SELECT e FROM DeptBean AS d , IN (d.emps) AS e
```

R would contain 5 tuples. Department 30 would not appear in R because it contains no employees. Department 10 would appear in 3 tuples and department 20 would appear in 2 tuples. IN can only refer to multi-valued relationships. The following is not valid

```
SELECT m FROM EmpBean e, IN( e.dept.mgr) as m INVALID
```

When joining with a relationship the alternate syntax INNER JOIN (keyword INNER is optional) can also be used, as shown here.

```
SELECT e FROM DeptBean AS d INNER JOIN d.emps AS e
```

An ASN declaration (**d** in the above query) can be followed by one or more join clauses. The relationship following the JOIN keyword must be related (directly or indirectly) to the ASN declaration. Unlike the case with the IN clause, relationships used in a join clause can be single- or multi-valued. This query has the same semantics as the query

```
SELECT e FROM DeptBean AS d , IN (d.emps) AS e
```

You can use multiple joins together.

```
SELECT m FROM EmpBean e JOIN e.dept d JOIN d.mgr m
```

This is equivalent to

```
SELECT m FROM EmpBean e JOIN e.dept.mgr m
```

Examples: OUTER JOIN

An OUTER JOIN results in a temporary collection that contains combinations of the *left* and *right* operands, subject to the relationship constraints and such that the left operand always appears in R. In the example an outer join results in a temporary collection R that contains department 30, even though the collection **d.emps** is empty. The tuple contains Department 30 along with a NULL value. References to **e** in the query yields a null value.

```
SELECT e FROM DeptBean AS d LEFT OUTER JOIN d.emps AS e
```

The keyword OUTER is optional, as shown here..

```
SELECT e FROM DeptBean AS d LEFT JOIN d.emps AS e
```

You can also use combinations of INNER and OUTER JOIN.

```
SELECT m FROM EmpBean e JOIN e.dept d LEFT JOIN d.mgr m
```

Inheritance in EJB query: If an EJB inheritance hierarchy has been defined for an abstract schema, using the abstract schema name in a query statement implies the collection of objects for that abstract schema as well as all subtypes.

Example: Inheritance

Suppose that bean ManagerBean is defined as a subtype of EmpBean and ExecutiveBean is a subtype of ManagerBean in an EJB inheritance hierarchy. The following query returns employees as well as managers and executives:

```
SELECT OBJECT(e) FROM EmpBean e
```

Path expressions: An identification variable followed by the navigation operator (.) and a cmp or relationship name is a path expression.

A path expression that leads to a cmr field can be further navigated if the cmr field is single-valued. If the path expression leads to a multi-valued relationship, then the path expression is terminal and cannot be further navigated. If the path expression leads to a cmp field whose type is a value object, it is possible to navigate to attributes of the value object.

Example: Value object

Assume that address is a cmp field for EmpBean, which is a value object.

```
SELECT object(e) FROM EmpBean e
WHERE e.address.distance('San Jose') < 10 and e.address.zip = 95037
```

It is best to use the composer pattern to map value object attributes to relational columns if you intend to search on value attributes. If you store value objects in serialized format, then each value object must be retrieved from the database and deserialized. Value object methods can only be done in dynamic queries.

A path expression can also navigate to a bean method. The method must be defined on either the remote or local bean interface. Methods can only be used in dynamic queries. You cannot mix both remote and local methods in a single query statement.

If the query contains remote methods, the dynamic query must be executed using the query remote interface. Using the query remote interface causes the query service to activate beans and create instances of the remote bean interface

Likewise, a query statement with local bean methods must be executed with the query local interface. This causes the query service to activate beans and local interface instances.

Do not use get methods to access cmp and cmr fields of a bean.

If a method has overloaded definitions, the overloaded methods must have different number of parameters.

Methods must have non-void return types and method arguments and return types must be either primitive types byte, short, int, long, float, double, boolean, char or wrapper types from the following list:

Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.sql.Date, java.sql.Time, java.sql.Timestamp, java.util.Date

If any input argument to a method is NULL, it is assumed the method returns a NULL value and the method is not invoked.

A collection valued path expression can be used in the FROM clause as a collection member declaration, and with the IS EMPTY, MEMBER OF, and EXISTS predicates in the WHERE clause.

FROM EmpBean e WHERE e.dept.mgr.name='Bob'	OK
FROM EmpBean e WHERE e.dept.emps.name='BOB'	INVALID -- cannot navigate through emps because it is multivalued
FROM EmpBean e, IN (e.dept.emps) e1 WHERE e1.name='BOB'	OK
FROM EmpBean e WHERE e.dept.emps IS EMPTY	OK

WHERE clause: The WHERE clause contains search conditions composed of the following:

- literal values
- input parameters
- expressions
- basic predicates
- quantified predicates
- BETWEEN predicate
- IN predicate
- LIKE predicate
- NULL predicate
- EMPTY collection predicate
- MEMBER OF predicate
- EXISTS predicate
- IS OF TYPE predicate

If the search condition evaluates to TRUE, the tuple is added to the result set.

Literals: A string literal is enclosed in single quotes. A single quote that occurs within a string literal is represented by two single quotes; For example: 'Tom''s'. A string literal cannot exceed the maximum length that is supported by the underlying persistent datastore.

A numeric literal can be any of the following:

- an exact value such as 57, -957, +66
- any value supported by Java long
- a decimal literal such as 57.5, -47.02
- an approximate numeric value such as 7E3, -57.4E-2

A decimal or approximate numeric value must be in the range supported by the underlying persistent datastore.

A boolean literal can be the keyword TRUE or FALSE and is case insensitive.

Input parameters: Input parameters are designated by the question mark followed by a number; For example: ?2

Input parameters are numbered starting at 1 and correspond to the arguments of the finder or select method; therefore, a query must not contain an input parameter that exceeds the number of input arguments.

An input parameter can be a primitive type of byte, short, int, long, float, double, boolean, char or wrapper types of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Char, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp, an EJBObject, or a binary data string in the form of Java byte[].

An input parameter must not have a NULL value. To search for the occurrence of a NULL value the NULL predicate should be used.

Expressions: Conditional expressions can consist of comparison operators and logical operators (AND, OR, NOT).

Arithmetic expressions can be used in comparison expressions and can be composed of arithmetic operations and functions, path expressions that evaluate to a numeric value and numeric literals and numeric input parameters.

String expressions can be used in comparison expressions and can be composed of string functions, path expressions that evaluate to a string value and string literals and string input parameters. A cmp field of type char is handled as if it were a string of length 1.

Binary expressions can be used in comparison expressions and can be composed of path expressions that evaluate to the Java byte[] type as well as input parameters of type byte[].

Boolean expressions can be used with = and <> comparison and can be composed of path expressions that evaluate to a boolean value and TRUE and FALSE keywords and boolean input parameters.

Reference expressions can be used with = and <> comparison and can be composed of path expressions that evaluate to a cmr field, an identification variable and an input parameter whose type is an EJB reference

Four different expression types are supported for working with date-time types. For portability the java.util.Calendar type should be used. DB2 style date, time and timestamp expressions are supported if the datastore is DB2 and the CMP field is of type java.util.Date, java.sql.Date, java.sql.Time or java.sql.Timestamp. If you use DB2 UDB, you might obtain a syntax error when using the java.sql.Timestamp.ojbect. You must use the syntax `TIMESTAMP 'yyyy-mm-dd hh:mm:ss.nnnn'`.

A Calendar type can be compared to another Calendar type, an exact numeric literal or input parameter of type long whose value is the standard Java long millisecond value.

The following query finds all employees born before Jan 1, 1990:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.birthDate < 631180800232
```

Date expressions can be used in comparison expressions and can be composed of operators + - , date duration expressions and date functions, path expressions that evaluate to a date value, string representation of a date and date input parameters.

Time expressions can be used in comparison expressions and can be composed of operators + - , time duration expressions and time functions, path expressions that evaluate to a time value, string representation of time and time input parameters.

Timestamp expressions can be used in comparison expressions and can be composed of operators + - , timestamp duration expressions and timestamp functions, path expressions that evaluate to a timestamp value, string representation of a timestamp and timestamp input parameters.

Standard bracketing () for ordering expression evaluation is supported.

The operators and their precedence order from highest to lowest are:

- Navigation operator (.)
- Arithmetic operators in precedence order:
 - + - unary
 - * / multiply, divide
 - + - add, subtract
- Comparison operators: =, >, <, >=, <=, <>(not equal)
- Logical operator NOT
- Logical operator AND
- Logical operator OR

Null value semantics: The following describe the semantics of NULL values:

- Comparison or arithmetic operations with an unknown (NULL) value yield an unknown value
- In a Java 2 platform, Enterprise Edition (J2EE) version 1.3 application, a path expression uses an outer-join semantic where a NULL field or cmr value evaluates to NULL. In J2EE version 1.4, the path expression uses an inner-join semantic.
- The IS NULL and IS NOT NULL operators can be applied to path expressions and return TRUE or FALSE. Boolean operators AND, OR and NOT use three valued logic.

AND	True	False	Unknown
True	True	False	Unknown
False	False	False	False
Unknown	Unknown	False	Unknown

OR	True	False	Unknown
True	True	True	True
False	True	False	Unknown
Unknown	True	Unknown	Unknown

	NOT
True	False
False	True

	NOT
Unknown	Unknown

Example: Null value semantics

```
select object(e) from EmpBean where e.salary > 10 and e.dept.budget > 100
```

If salary is NULL the evaluation of `e.salary > 10` returns unknown and the employee object is not returned. If the cmr field dept or budget is NULL evaluation of `e.dept.budget > 100` returns unknown and the employee object is not returned.

```
select object(e) from EmpBean where e.dept.budget is null
```

In J2EE 1.3 if dept or budget is NULL evaluation of `e.dept.budget is null` returns TRUE and the employee object is returned. In J2EE 1.4 the employee object is returned only if budget is NULL.

```
select object(e) from EmpBean e , in (e.dept.emps) e1 where e1.salary > 10
```

If dept is NULL, then the multivalued path expression `e.dept.emps` results in an empty collection (not a collection that contains a NULL value). An employee with a null dept value will not be returned.

```
select object(e) from EmpBean e where e.dept.emps is empty
```

If dept is NULL the evaluation of the predicate in unknown and the employee object is not returned.

```
select object(e) from EmpBean e , EmpBean e1 where e member of e1.dept.emps
```

If dept is NULL evaluation of the member of predicate returns unknown and the employee is not returned.

Date time arithmetic and comparisons: DATE, TIME and TIMESTAMP values may be compared with another value of the same type. Comparisons are chronological. Date time values can also be incremented, decremented, and subtracted.

If the datastore is DB2, then DB2 string representation of DATE, TIME and TIMESTAMP types can also be used. A string representation of a date or time can use ISO, USA, EUR or JIS format. A string representation of a timestamp uses ISO format.

Format	Date format	Date examples	Time format	Time examples
ISO	yyyy-mm-dd	1987-02-24 1987-2-24	hh.mm.ss	13.50.00 13.50
USA	mm/dd/yyyy	2/24/1987	hh:mm AM or PM	1:50 pm 02:10 AM
EUR	dd.mm.yyyy	24.02.1987 24.2.1987	hh.mm.ss	13.50.00 13.55
JIS	yyyy-mm-dd	1987-02-24	hh:mm:ss	13:50 13:50:05

Example 1: Date time arithmetic comparisons

```
e.hiredate > '1990-02-24'
```

The timestamp of February 24th, 1990 1:50 pm can be represented as follows:

```
'1990-02-24-13.50.00.000000' or  
'1990-02-24-13.50.00'
```

If the datastore is DB2, DB2 decimal durations can be used in expressions and comparisons. A date duration is a decimal(8,0) number that represents the difference between two dates in the format YYYYMMDD. A time duration is a decimal(6,0) number that represents the difference between two time values as HHMMSS. A timestamp duration is a decimal(20,6) number representing the differences between two timestamp values as YYYYMMDDHHMMSS.ZZZZZZ (ZZZZZZ is the number of microseconds and is to the right of the decimal point) .

Two date values (or time values or timestamp values) can be subtracted to yield a duration. If the second operand is greater than the first the duration is a negative decimal number. A duration can be added or subtracted from a datetime value to yield a new datetime value.

Example 2: Date time arithmetic comparisons

`DATE('3/15/2000') - '12/31/1999'` results in a decimal number 215 which is a duration of 0 years, 2 months and 15 days.

Durations are really decimal numbers and can be used in arithmetic expressions and comparisons.

`(DATE('3/15/2000') - '12/31/1999') + 14 > 215` evaluates to TRUE.

`DATE('12/31/1999') + DECIMAL(215,8,0)` results in a date value 3/15/2000.

`TIME('11:02:26') - '00:32:56'` results in a decimal number 102930 which is a time duration of 10 hours, 29 minutes and 30 seconds.

`TIME('00:32:56') + DECIMAL(102930,6,0)` results in a time value of 11:02:26.

`TIME('00:00:59') + DECIMAL(240000,6,0)` results in a time value of 00:00:59.

`e.hiredate + DECIMAL(500,8,0) > '2000-10-01'` means compare the hiredate plus 5 months to the date 10/01/2000.

Basic predicates: Basic predicates can be of two forms

expression-1 comparison-operator expression-2
expression-3 comparison-operator (subselect)

The subselect must not return more than one value and the subselect can not return a type of an EJB reference. Boolean types and reference types only support = and <> comparisons.

Example: Basic predicates

```
d.name='Java Development'  
e.salary > 20000  
e.salary > ( select avg(e.salary) from EmpBean e)
```

Quantified predicates: A quantified predicate compares a value with a set of values produced by a subselect.

expression comparison-operator SOME | ANY | ALL (subselect)

The expression must not evaluate to a reference type.

When SOME or ANY is specified the result of the predicate is as follows:

- TRUE if the comparison is true for at least one value returned by the subselect.
- FALSE if the subselect is empty or if the comparison is false for every value returned by the subselect.
- UNKNOWN if the comparison is not true for all of the values returned by the subselect and at least one of the comparisons is unknown because of a null value.

When ALL is specified the result of the predicate is as follows:

- TRUE if the subselect returns empty or if the comparison is true to every value returned by the subselect.
- FALSE if the comparison is false for at least one value returned by the subselect.
- UNKNOWN if the comparison is not false for all values returned by the subselect and at least one comparison is unknown because of a null value.

BETWEEN predicate: The BETWEEN predicate determines whether a given value lies between two other given values.

```
expression [NOT] BETWEEN expression-2 AND expression-3
```

The expression must not evaluate to a boolean or reference type.

Example: BETWEEN predicate

```
e.salary BETWEEN 50000 AND 60000
```

is equivalent to:

```
e.salary >= 50000 AND e.salary <= 60000
```

```
e.name NOT BETWEEN 'A' AND 'B'
```

is equivalent to:

```
e.name < 'A' OR e.name > 'B'
```

IN predicate: The IN predicate compares a value to a set of values and can have one of two forms:

```
expression [NOT] IN ( subselect )
```

```
expression [NOT] IN ( value1, value2, .... )
```

ValueN can either be a literal value or an input parameter. The expression can not evaluate to a reference type.

Example: IN predicate

```
e.salary IN ( 10000, 15000 )
```

is equivalent to

```
( e.salary = 10000 OR e.salary = 15000 )
```

```
e.salary IN ( select e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

is equivalent to

```
e.salary = ANY ( select e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

```
e.salary NOT IN ( select e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

is equivalent to

```
e.salary <> ALL ( select e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

LIKE predicate: The LIKE predicate searches a string value for a certain pattern.

```
string-expression [NOT] LIKE pattern [ ESCAPE escape-character ]
```

The pattern value is a string literal or parameter marker of type string in which the underscore (`_`) stands for any single character and percent (`%`) stands for any sequence of characters (including empty sequence). Any other character stands for itself. The escape character can be used to search for character `_` and `%`. The escape character can be specified as a string literal or an input parameter.

If the string-expression is null, then the result is unknown.

If both string-expression and pattern are empty, then the result is true.

Example: LIKE predicate

- `'' LIKE ''` is true
- `'' LIKE '%'` is true
- `e.name LIKE '12%3'` is true for `'123'` `'12993'` and false for `'1234'`
- `e.name LIKE 's_me'` is true for `'some'` and `'same'`, false for `'soome'`

- e.name LIKE '/_foo' escape '/' is true for '_foo', false for 'afoo'
- e.name LIKE '//_foo' escape '/' is true for 'afoo' and for 'bfoo'
- e.name LIKE '///_foo' escape '/' is true for '/_foo' but false for 'afoo'

NULL predicate: The NULL predicate tests for null values.

```
single-valued-path-expression IS [NOT] NULL
```

Example: NULL predicate

```
e.name IS NULL
e.dept.name IS NOT NULL
e.dept IS NOT NULL
```

EMPTY collection predicate: To test if a multivalued relationship is empty, use the following syntax:

```
collection-valued-path-expression IS [NOT] EMPTY
```

Example: Empty collection predicate

To find all departments with no employees:

```
SELECT OBJECT(d) FROM DeptBean d WHERE d.emps IS EMPTY
```

MEMBER OF predicate: This expression tests whether the object reference specified by the single valued path expression or input parameter is a member of the designated collection. If the collection valued path expression designates an empty collection the value of the MEMBER OF expression is FALSE.

```
{ single-valued-path-expression | input_parameter } [ NOT ] MEMBER [ OF ] collection-valued-path-expression
```

Example: MEMBER OF predicate

Find employees that are not members of a given department number:

```
SELECT OBJECT(e) FROM EmpBean e , DeptBean d
WHERE e NOT MEMBER OF d.emps AND d.deptno = ?1
```

Find employees whose manager is a member of a given department number:

```
SELECT OBJECT(e) FROM EmpBean e, DeptBean d
WHERE e.dept.mgr MEMBER OF d.emps and d.deptno=?1
```

EXISTS predicate: The exists predicate tests for the presence or absence of a condition specified by a subselect.

```
EXISTS ( subselect )
EXISTS collection-valued-path-expression
```

The result of EXISTS is true if the subselect returns at least one value or the path expression evaluates to a nonempty collection, otherwise the result is false.

To negate an EXISTS predicate, precede it with the logical operator NOT.

Example: EXISTS predicate

Return departments that have at least one employee earning more than 1000000:

```
SELECT OBJECT(d) FROM DeptBean d
WHERE EXISTS ( SELECT 1 FROM IN (d.emps) e WHERE e.salary > 1000000 )
```

Return departments that have no employees:

```
SELECT OBJECT(d) FROM DeptBean d
WHERE NOT EXISTS ( SELECT 1 FROM IN (d.emps) e)
```

The above query can also be written as follows:

```
SELECT OBJECT(d) FROM DeptBean d WHERE NOT EXISTS d.emps
```

IS OF TYPE predicate: The IS OF TYPE predicate is used to test the type of an EJB reference. It is similar in function to the Java instance of operator. IS OF TYPE is used when several abstract beans have been grouped into an EJB inheritance hierarchy. The type names specified in the predicate are the bean abstract names. The ONLY option can be used to specify that the reference must be exactly this type and not a subtype.

```
identification-variable IS OF TYPE ( [ONLY] type-1, [ONLY] type-2, ..... )
```

Example: IS OF TYPE predicate

Suppose that bean ManagerBean is defined as a subtype of EmpBean and ExecutiveBean is a subtype of ManagerBean in an EJB inheritance hierarchy.

The following query returns employees as well as managers and executives:

```
SELECT OBJECT(e) FROM EmpBean e
```

If you are interested in objects which are employees and not managers and not executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE( ONLY EmpBean )
```

If you are interested in object which are managers or executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE( ManagerBean)
```

The above query is equivalent to the following query:

```
SELECT OBJECT(e) FROM ManagerBean e
```

If you are interested in managers only and not executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE( ONLY ManagerBean)
```

or:

```
SELECT OBJECT(e) FROM ManagerBean e  
WHERE e IS OF TYPE (ONLY ManagerBean)
```

Scalar functions: EJB query contains scalar functions for doing type conversions, string manipulation, and for manipulating date-time values. The list of scalar functions is documented in the topic EJB query: Scalar functions.

Example: Scalar functions

Find employees hired in 1999:

```
SELECT OBJECT(e) FROM EmpBean e where YEAR(e.hireDate) = 1999
```

The only scalar functions that are guaranteed to be portable across backend datastore vendors are the following:

- ABS
- MOD
- SQRT
- CONCAT
- LENGTH
- LOCATE
- SUBSTRING
- UCASE
- LCASE

The other scalar functions should be used only when DB2 is the backend datastore.

EJB query: Scalar functions: EJB query contains scalar built-in functions, as listed below, for doing type conversions, string manipulation, and for manipulating date-time values.

Numeric functions

```
ABS ( < any numeric datatype > ) -> < any numeric datatype >
MOD ( <int>, <int> ) -> int
SQRT ( < any numeric datatype > ) -> Double
```

Type conversion functions

```
CHAR ( < any numeric datatype > ) -> string
CHAR ( < string > ) -> string
CHAR ( < any datetime datatype > [, Keyword k ] ) -> string
```

Datetime datatype is converted to its string representation in a format specified by the keyword k. The valid keywords values are ISO, USA, EUR or JIS. If k is not specified the default is ISO.

```
BIGINT ( < any numeric datatype > ) -> Long
BIGINT ( < string > ) -> Long
```

The function in the second line of the following code converts the argument to an integer n by truncation, and returns the date that is n-1 days after January 1, 0001:

```
DATE ( < date string > ) -> Date
DATE ( < any numeric datatype> ) -> Date
```

The following function returns date portion of a timestamp:

```
DATE( timestamp ) -> Date
DATE ( < timestamp-string > ) -> Date
```

The following function converts number to decimal with optional precision p and scale s.

```
DECIMAL ( < any numeric datatype > [, p [, s ] ] ) -> Decimal
```

The following function converts string to decimal with optional precision p and scale s.

```
DECIMAL ( < string > [, p [, s ] ] ) -> Decimal
DOUBLE ( < any numeric datatype > ) -> Double
DOUBLE ( < string > ) -> Double
FLOAT ( < any numeric datatype > ) -> Double
FLOAT ( < string > ) -> Double
```

Float is a synonym for DOUBLE.

```
INTEGER ( < any numeric datatype > ) -> Integer
INTEGER ( < string > ) -> Integer
REAL ( < any numeric datatype > ) -> Float
SMALLINT ( < any numeric datatype > ) -> Short
SMALLINT ( < string > ) -> Short
TIME ( < time > ) -> Time
TIME ( < time-string > ) -> Time
TIME ( < timestamp > ) -> Time
TIME ( < timestamp-string > ) -> Time
TIMESTAMP ( < timestamp > ) -> Timestamp
TIMESTAMP ( < timestamp-string > ) -> Timestamp
```

String functions

```
CONCAT ( <string>, <string> ) -> String
```

The following function returns a character string representing absolute value of the argument not including its sign or decimal point. For example, `digits(-42.35)` is "4235".

```
DIGITS ( Decimal d ) -> String
```

The following function returns the length of the argument in bytes. If the argument is a numeric or datetime type, it returns the length of internal representation.

```
LENGTH ( < string > ) -> Integer
```

The following function returns a copy of the argument string where all upper case characters have been converted to lower case.

```
LCASE ( < string > ) -> String
```

The following function returns the starting position of the first occurrence of argument 1 inside argument 2 with optional start position. If not found, it returns 0.

```
LOCATE ( String s1 , String s2 [ , Integer start ] ) -> Integer
```

The following function returns a substring of `s` beginning at character `m` and containing `n` characters. If `n` is omitted, the substring contains the remainder of string `s`. The result string is padded with blanks if needed to make a string of length `n`.

```
SUBSTRING ( String s , Integer m [ , Integer n ] ) -> String
```

The following function returns a copy of the argument string where all lower case characters have been converted to upper case.

```
UCASE ( < string > ) -> String
```

Date - time functions

The following function returns the day portion of its argument. For a duration, the return value can be -99 to 99.

```
DAY ( Date ) -> Integer  
DAY ( < date-string > ) -> Integer  
DAY ( < date-duration > ) -> Integer  
DAY ( Timestamp ) -> Integer  
DAY ( < timestamp-string > ) -> Integer  
DAY ( < timestamp-duration > ) -> Integer
```

The following function returns one more than number of days from January 1, 0001 to its argument.

```
DAYS ( Date ) -> Integer  
DAYS ( < Date-string > ) -> Integer  
DAYS ( Timestamp ) -> Integer  
DAYS ( < timestamp-string > ) -> Integer
```

The following function returns the hour part of its argument. For a duration, the return value can be -99 to 99.

```
HOUR ( Time ) -> Integer  
HOUR ( < time-string > ) -> Integer  
HOUR ( < time-duration > ) -> Integer  
HOUR ( Timestamp ) -> Integer  
HOUR ( < timestamp-string > ) -> Integer  
HOUR ( < timestamp-duration > ) -> Integer
```

The following function returns the microsecond part of its argument.

```
MICROSECOND ( Timestamp ) -> Integer  
MICROSECOND ( < timestamp-string > ) -> Integer  
MICROSECOND ( < timestamp-duration > ) -> Integer
```

The following function returns the minute part of its argument. For a duration, the return value can be -99 to 99.

```
MINUTE ( Time ) -> Integer
MINUTE ( < time-string > ) -> Integer
MINUTE ( < time-duration > ) -> Integer
MINUTE ( Timestamp ) -> Integer
MINUTE ( < timestamp-string > ) -> Integer
MINUTE ( < timestamp-duration > ) -> Integer
```

The following function returns the month portion of its argument. For a duration, the return value can be -99 to 99.

```
MONTH ( Date ) -> Integer
MONTH ( < date-string > ) -> Integer
MONTH ( < date-duration > ) -> Integer
MONTH ( Timestamp ) -> Integer
MONTH ( < timestamp-string > ) -> Integer
MONTH ( < timestamp-duration > ) -> Integer
```

The following function returns the second part of its argument. For a duration, the return value can be -99 to 99.

```
SECOND ( Time ) -> Integer
SECOND ( < time-string > ) -> Integer
SECOND ( < time-duration > ) -> Integer
SECOND ( Timestamp ) -> Integer
SECOND ( < timestamp-string > ) -> Integer
SECOND ( < timestamp-duration > ) -> Integer
```

The following function returns the year portion of its argument. For a duration, the return value can be -9999 to 9999.

```
YEAR ( Date ) -> Integer
YEAR ( < date-string > ) -> Integer
YEAR ( < date-duration > ) -> Integer
YEAR ( Timestamp ) -> Integer
YEAR ( < timestamp-string > ) -> Integer
YEAR ( < timestamp-duration > ) -> Integer
```

Aggregation functions: Aggregation functions operate on a set of values to return a single scalar value. You can use these functions in the select and subselect methods. The following example illustrates an aggregation:

```
SELECT SUM (e.salary) FROM EmpBean e WHERE e.dept.deptno =20
```

This aggregation computes the total salary for department 20.

The aggregation functions are AVG, COUNT, MAX, MIN, and SUM. The syntax of an aggregation function is illustrated in the following example:

```
aggregation-function ( [ ALL | DISTINCT ] expression )
```

or:

```
COUNT( [ ALL | DISTINCT ] identification-variable )
```

or:

```
COUNT( * )
```

The DISTINCT option eliminates duplicate values before applying the function. ALL is the default option and does not eliminate duplicates. Null values are ignored in computing the aggregate function except in the cases of COUNT(*) and COUNT(identification-variable), which return a count of all the elements in the set.

If your datastore is Informix, you must limit the expression argument to a single valued path expression when using the COUNT function or the DISTINCT forms of the functions SUM, AVG, MIN, and MAX.

Defining return type

For a select method using an aggregation function, you can define the return type as a primitive type or a wrapper type. The return type must be compatible with the return type from the datastore. The MAX and MIN functions can apply to any numeric, string or datetime datatype and return the corresponding datatype. The SUM and AVG functions take a numeric type as input, and return the same numeric type that is used in the datastore. The COUNT function can take any datatype, and returns an integer.

When applied to an empty set, the SUM, AVG, MAX, and MIN functions can return a null value. The COUNT function returns zero (0) when it is applied to an empty set. Use wrapper types if the return value might be NULL; otherwise, the container displays an ObjectNotFound exception.

Using GROUP BY and HAVING

The set of values that is used for the aggregate function is determined by the collection that results from the FROM and WHERE clause of the query. You can divide the set into groups and apply the aggregation function to each group. To perform this action, use a GROUP BY clause in the query. The GROUP BY clause defines grouping members, which comprise a list of path expressions. Each path expression specifies a field that is a primitive type of byte, short, int, long, float, double, boolean, char, or a wrapper type of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time or java.sql.Timestamp.

The following example illustrates the use of the GROUP BY clause in a query that computes the average salary for each department:

```
SELECT e.dept.deptno, AVG ( e.salary) FROM EmpBean e GROUP BY e.dept.deptno
```

In division of a set into groups, a NULL value is considered equal to another NULL value.

Just as the WHERE clause filters tuples (that is, records of the return collection values) from the FROM clause, the groups can be filtered using a HAVING clause that tests group properties involving aggregate functions or grouping members:

```
SELECT e.dept.deptno, AVG ( e.salary) FROM EmpBean e
GROUP BY e.dept.deptno
HAVING COUNT(*) > 3 AND e.dept.deptno > 5
```

This query returns the average salary for departments that have more than three employees and the department number is greater than five.

It is possible to use a HAVING clause without a GROUP BY clause, in which case the entire set is treated as a single group, to which the HAVING clause is applied.

SELECT clause: For finder and select queries, the syntax of the SELECT clause is illustrated in the following example:

```
SELECT [ ALL | DISTINCT ]
{ single-valued-path-expression | aggregation expression | OBJECT ( identification-variable ) }
```

The SELECT clause consists of either a single identification variable that is defined in the FROM clause, or a single valued path expression that evaluates to a object reference or CMP value. You can use the DISTINCT keyword to eliminate duplicate references.

For a query that defines a finder method, the query must return an object type consistent with the home that is associated with the finder method. For example, a finder method for a department home can not return employee objects.

Example: SELECT clause

Find all employees that earn more than John:

```
SELECT OBJECT(e) FROM EmpBean ej, EmpBean e
WHERE ej.name = 'John' and e.salary > ej.salary
```

Find all departments that have one or more employees who earn less than 20000:

```
SELECT DISTINCT e.dept FROM EmpBean e where e.salary < 20000
```

A select method query can have a path expression that evaluates to an arbitrary value:

```
SELECT e.dept.name FROM EmpBean e where e.salary < 2000
```

The previous query returns a collection of name values for those departments having employees earning less than 20000.

A select method query can return an aggregate value:

```
SELECT avg(e.salary) FROM EmpBean e
```

Example: Valid dynamic queries

For dynamic queries the syntax is as follows:

```
SELECT { ALL | DISTINCT } [ selection , ]* selection
selection ::= { expression | scalar-subselect [[AS] id ] }
```

A scalar-subselect is a subselect that returns a single value.

The following are examples of dynamic queries:

```
SELECT e.name, e.salary+e.bonus as total_pay from EmpBean e
SELECT SUM( e.salary+e.bonus) from EmpBean e where e.dept.deptno = ?1
```

ORDER BY clause: The ORDER BY clause specifies an ordering of the objects in the result collection:

```
ORDER BY [ order_element ,]* order_element
order_element ::= { path-expression | integer } [ ASC | DESC ]
```

The path expression must specify a single valued field that is a primitive type of byte, short, int, long, float, double, char or a wrapper type of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Character, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp.

ASC specifies ascending order and is the default. DESC specifies descending order.

Integer refers to a selection expression in the SELECT clause.

Example: ORDER BY clause

Return department objects in decreasing deptno order:

```
SELECT OBJECT(d) FROM DeptBean d ORDER BY d.deptno DESC
```

Return employee objects sorted by department number and name:

```
SELECT OBJECT(e) FROM EmpBean e ORDER BY e.dept.deptno ASC, e.name DESC
```

UNION operation: The UNION clause specifies a combination of the output of two subqueries. The two queries must return the same number of elements and compatible types. For the purposes of UNION, all EJB types in the same inheritance hierarchy are considered compatible. UNION requires that equality be defined for the element types.

```
query_expression := query_term [UNION [ALL] query_term]*
```

```
query_term := {select_clause_dynamic from_clause [where_clause]
 [group_by_clause] [having_clause] } | (query_expression) }
```

You cannot use dependent value objects with UNION.

UNION ALL combines all results together in a single collection.

UNION combines results but eliminates duplicates.

If ORDER BY is used together with UNION, the ORDER BY must refer to selection expression using integer numbers.

Examples: UNION operation

This example returns a collection of all employee objects of type EmpBean and all manager objects of type ManagerBean where ManagerBean is a subtype of EmpBean.

```
select e from EmpBean e union all select m from DeptBean d, in(d.mgr) m
```

This example shows a query that is not valid, because EmpBean and DeptBean are not compatible.

```
select e from EmpBean e union all select d from DeptBean d
```

Subqueries: A subquery can be used in quantified predicates, EXISTS predicate or IN predicate. A subquery should only specify a single element in the SELECT clause. When a path expression appears in a subquery, the identification variable of the path expression must be defined either in the subquery, in one of the containing subqueries, or in the outer query. A scalar subquery is a subquery that returns one value. A scalar subquery can be used in a basic predicate and in the SELECT clause of a dynamic query.

Example: Subqueries

```
SELECT OBJECT(e) FROM EmpBean e
WHERE e.salary > ( SELECT AVG(e1.salary) FROM EmpBean e1)
```

The above query returns employees who earn more than average salary of all employees.

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.salary >
( SELECT AVG(e1.salary) FROM IN (e.dept.emps) e1 )
```

The above query returns employees who earn more than average salary of their department.

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.salary =
( SELECT MAX(e1.salary) FROM IN (e.dept.emps) e1 )
```

The above query returns employees who earn the most in their department.

```
SELECT OBJECT(e) FROM EmpBean e
WHERE e.salary > ( SELECT AVG(e.salary) FROM EmpBean e1
WHERE YEAR(e1.hireDate) = YEAR(e.hireDate) )
```

The above query returns employees who earn more than the average of employees hired in same year.

EJB query language limitations and restrictions: This topic outlines current known limitations and restrictions.

- EJB query language (QL) queries involving enterprise beans with keys made up of relationships to other enterprise beans appear as not valid and cause errors at deployment time. This is a known problem.
- The IBM EJB QL support extends the EJB 2.0 specification in various ways, including relaxing some restrictions, adding support for more DB2 functions, and so on. If portability across various vendor databases or EJB deployment tools is a concern, then care should be taken to write all EJB QL queries strictly according to Chapter 11 in the EJB 2.0 specification.

- Pre-loading across m:n relationships results in the generation of inaccurate structured query language (SQL). This is a known limitation that may be addressed in the future.
- Pre-loading across self referencing relationships causes inaccurate SQL to be generated.
- Avoid relationships between parent and children enterprise beans within the same inheritance hierarchy that are not well-defined.
- EJB Query Language validation for EJB 2.0 JAR files currently runs as a part of the EJB-RDB Mapping validation. If a mapping document (Map.mapxmi file) does not exist in the project, the EJB queries are not validated.

EJB query compatibility issues with SQL: Because an Enterprise JavaBeans query is compiled into SQL, you must be aware of compatibility issues between the Java language and SQL. The two languages differ along the following points that can be critical to correct EJB query formulation:

- The comparison semantics of SQL strings do not exactly match those of the Java language. For example: 'A' (the letter A) and 'A ' (the letter A plus a blank space) are considered equal in SQL, but not in the Java language.
- Comparisons and collating order depend on the underlying database. For example, if you are using DB2 with an EBCDIC code page, the collating order is not the same as doing the sort in a Java program. Some databases sort the NULL value low while others sort the NULL value high.
- An arithmetic overflow causes an exception in SQL, but not in the Java language.
- SQL databases have differing minimum and maximum ranges for floating point values, which can differ from floating point value ranges in the Java language. Values near the range limits of Java Double may fail to translate into SQL.
- Java methods do not translate into SQL; therefore standard EJB queries cannot include Java methods.

Note: Only with the dynamic EJB query service can you use functions that do not translate into SQL. Such functions include Java methods and converters or composers that are used in mapping enterprise beans to relational databases (RDBs). A standard finder or select query that uses any of these functions fails at deployment time with the message "Cannot push down query". (You can resolve this problem by changing either the query or the mapping.) The dynamic query run time, however, processes the query by performing the operation involving the function in the application server.

Database restrictions for EJB query: General database restriction

All of the enterprise beans involved in a given query must map to the same data source. The EJB query does not support cross-data source join operations.

Specific database restrictions

Different database products place different restrictions on elements that can be included in EJB query statements. Following is a list of those restrictions; check with your database administrator to see if any apply in your environment:

- Certain functions are used in queries that run against DB2 only, because these functions are not supported by other databases. These functions include date and time arithmetic expressions, certain scalar functions (those *not* listed as portable across vendors), and implied scalar functions when used for mapping certain CMP fields. For example, consider mapping an int numeric type to a decimal (5,2) type field. When deployed against a database other than DB2, a finder or select query that contains a CMP field with this particular mapping fails, producing a Cannot push down query error message.
- A CMP of type String, when mapped to a character large object (CLOB) in the database, cannot be used in comparison operations because the database does not support CLOB comparisons.

- Databases can impose limits on the length of string values that are used either as literals or input parameters with comparison operators. These limits can hinder query performance. For example: For DB2 on the z/OS platform, the search "name = ?1" can fail if the value of ?1 at run time is greater than 255 in length.
- Mapping a numeric CMP type to a column that contains a dissimilar type can cause unexpected results. For example, consider the case of mapping the int numeric type to a column of type decimal (5,2). This scenario does not preserve an exact decimal value (for example, the value 12.25) over the course of transfer from the database to the enterprise bean CMP field, and back again to the database. This mapping causes replacement of the initial value with a whole number (in this case, 12). Consequently, you want to avoid using the CMP field in comparison operations when the CMP field uses a mapping of this nature.
- Some databases do not support a datatype that corresponds to the semantics of java.sql.Time. For example: If a CMP field of type java.sql.Time is mapped to an Oracle DATE column, comparisons on time might not produce the expected result because the year-month-day portion of the column value is truncated in the mapping.
- Some databases treat a zero length string value (" ") as a null value; this approach can affect the query results. For the sake of portability, avoid the use of zero length string values.
- Some databases perform division between two integer values using integer arithmetic rules, while others use non-integer rules. This discrepancy might not be desirable in environments that use both kinds of databases. For the sake of portability, avoid the division of integer values in an EJB query.
- Current releases of UDB DB2 for i5/OS only support a TIMESTAMP value of the format 'yyyy-mm-dd-hh.mm.ss.nnnnnn'. This is not compatible with the standard format supported by the java.sql.Timestamp class, which is 'yyyy-mm-dd-hh mm.ss.nnnnnn'. The TIMESTAMP scalar function should be used to convert a string representation of a java.sql.Timestamp object to a value that can be recognized by DB2 UDB for i5/OS.

Rules for data type manipulation in EJB query: Rules on CMP field type

You can use a CMP field of any type in a SELECT clause. You must, however, use fields of only the following types in search conditions and in grouping or ordering operations:

- Primitive types: byte, short, int, long, float, double, boolean, char
- Object types: Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.util.Date
- JDBC types: java.sql.Date, java.sql.Time, java.sql.Timestamp
- Binary string: byte[]

Converters and basic types

If ALL of the following conditions occur:

- a CMP field of one of the basic types listed previously is mapped to an SQL column using a converter
- the CMP field appears in the left hand side of a basic predicate
- the right hand side of the predicate is a literal or input parameter

then the toData() method of the converter is used to compute the SQL search value.

For example, given a converter that maps the integer value 10 to the string value "Ten," the following EJB query:

```
e.cmp = 10
```

is translated into the following SQL query:

```
column = 'Ten'
```

If you include a more complicated predicate, such as in the following example:

```
e.cmp * 10 > e.salary
```

in a finder or select query, you receive the Cannot push down query error message. Use the dynamic EJB query service for such multi-function queries; the dynamic query run time processes the predicate in the application server.

Overall, converters preserve equality, collating sequence, and NULL values. If a converter does not meet these requirements, avoid using it for CMP field comparison operations.

User types, converters, and composers

A user type cannot be used in a comparison operation or expression. You can, however, use subfields of the user type in a path expression. For example, consider the CMP `addr` field with the type `com.exam.Address`, and `street`, `city`, and `state` subfields. The following syntax for a query on this CMP field is not valid:

```
e.addr = ?1
```

However, a query that designates one of the subfields is valid:

```
e.addr.street = ?1
```

A CMP field can be mapped to an SQL column using Java serialization. Using the CMP field in predicates or expressions for deployment queries usually results in the Cannot push down query error message. The dynamic query run time processes the expression by reading and deserializing all instances of the user type in the application server.

However, this expensive process sacrifices performance. You can maintain performance by using a composer in a deployment EJB query. In the previous example, if you want to map the `addr` field to a binary type, you use a composer to map each subfield to a binary column in the database.

EJB query: Reserved words:

The following words are reserved in WebSphere EJB query:

all, as, distinct, empty, false, from, group, having, in, is, like, select, true, union, where

Avoid using identifiers that start with underscore (for example, `_integer`) as these are also reserved.

EJB query: BNF syntax:

```
EJB QL ::= [select_clause] from_clause [where_clause] [order_by_clause]
```

```
DYNAMIC EJB QL := query_expression [order_by_clause]
```

```
query_expression := query_term [UNION [ALL] query_term]*
```

```
query_term := {select_clause_dynamic from_clause [where_clause]  
[group_by_clause] [having_clause] } | (query_expression) } [order_by_clause]
```

```
from_clause ::= FROM identification_variable_declaration  
[, {identification_variable_declaration | collection_member_declaration } ]*
```

```
identification_variable_declaration ::= collection_member_declaration |  
range_variable_declaration [join]*
```

```
join := [ { LEFT [OUTER] | INNER } ] JOIN {collection_valued_path_expression | single_valued_path_expression}  
[AS] identifier
```

```
collection_member_declaration ::= IN ( collection_valued_path_expression ) [AS] identifier
```

```
range_variable_declaration ::= abstract_schema_name [AS] identifier
```

```

single_valued_path_expression ::=
    {single_valued_navigation | identification_variable}. ( cmp_field |
    method | cmp_field.value_object_attribute | cmp_field.value_object_method )
    | single_valued_navigation

single_valued_navigation ::=

    YEAR( expression )

xrel ::= XREL identification_variable . { single_valued_cmr_field | collection_valued_cmr_field }
        [, identification_variable . { single_valued_cmr_field | collection_valued_cmr_field } ]*

```

Comparison of EJB 2.1 specification and WebSphere query language: WebSphere Application Server Version supports the following extensions to the Enterprise JavaBeans Query Language.

Item	
Delimited identifiers	
Dependent Value object attributes used in path expressions	
EJB Inheritance	
EXISTS predicate	
Java methods: EJB bean methods or value object methods	dynamic query only
Multiple element select clauses	dynamic query only
SQL Date/time expressions	
Subqueries, group by, and having clauses	

Using the dynamic query service

Following are common reasons for using the dynamic query service rather than the regular EJB query service (which can be referred to as *deployment query*):

- You need to programmatically define a query at application run time, rather than at deployment.
- You need to return multiple CMP or CMR fields from a query. (Deployment queries allow only a single element to be specified in the SELECT clause.) For more information, see the Example: EJB queries article.
- You want to return a computed expression in the query.
- You want to use value object methods or bean methods in the query statement. For more information, see Path expressions.
- You want to interactively test an EJB query during development, but do not want to repeatedly deploy your application each time you update a finder or select query.

The dynamic query API is a stateless session bean; using it is similar to using any other J2EE EJB application bean. You can consult the API specifications in Reference: Generated API documentation (the section for package `com.ibm.websphere.ejbquery`).

The dynamic query bean has both a remote and a local interface. If you want to return remote EJB references from the query, or if the query statement contains remote methods, you must use the query remote interface:

```
remote interface = com.ibm.websphere.ejbquery.Query
remote home interface = com.ibm.websphere.ejbquery.QueryHome
```

If you want to return local EJB references from the query, or if the query statement contains local methods, you must use the query local interface:

```
local interface = com.ibm.websphere.ejbquery.QueryLocal
local home interface = com.ibm.websphere.ejbquery.QueryLocalHome
```

Because it uses less application server memory, the local interface ensures better overall EJB performance than the remote.

1. Verify that the `query.ear` application file is installed on the application server on which your application is to run, if that server is different from the default application server created during installation of the product.

The query.ear file is located in the *app_server_root* directory, where <WAS_HOME> is the location of the WebSphere Application Server. The product installation program installs the query.ear file on the default application server using a JNDI name of
com/ibm/websphere/ejbquery/Query

(You or the system administrator can change this name.)

2. Set up authorization for the methods `executeQuery()`, `prepareQuery()`, and `executePlan()` in the remote and local dynamic query interfaces to control access to sensitive data. (This step is necessary only if your application requires security.)

Because you cannot control which ASN names, CMP fields, or CMR fields can be used in a dynamic EJB query, you or your system administrator must place restrictions on use of the methods. If, for example, a user is permitted to run the `executeQuery` method, he or she can run any valid dynamic query. In a production environment, you certainly want to restrict access to the remote query interface methods.

3. Write the dynamic query as part of your application client code. You can consult the following examples as query models; they illustrate which import statements to use, and so on:
 - Remote interface dynamic query example
 - Local interface dynamic query example
4. If the CMP you want to query is on a different module, you should:
 - a. do a remote lookup on query.ear
 - b. map the query.ear file to the server that the queried CMP bean is installed on.
5. Compile and run your client program with the file **qryclient.jar** in the classpath.

Example: Dynamic query remote interface

When you run a dynamic EJB query using the remote interface, you are calling the `executeQuery` method on the Query interface. The `executeQuery` method has a transaction attribute of `REQUIRED` for this interface; therefore you do not need to explicitly establish a transaction context for the query to run.

Begin with the following import statements:

```
import com.ibm.websphere.ejbquery.QueryHome;
import com.ibm.websphere.ejbquery.Query;
import com.ibm.websphere.ejbquery.QueryIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;
```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```
String query =
"select e.name as name , object(e) as emp from EmpBean e where e.salary < 50000";
```

Create a Query object by obtaining a reference from the QueryHome class. (This class defines the `executeQuery` method.) Note that for the sake of simplicity, the following example uses the dynamic query JNDI name for the Query object:

```
InitialContext ic = new InitialContext();

Object obj = ic.lookup("com/ibm/websphere/ejbquery/Query");

QueryHome qh =
( QueryHome) javax.rmi.PortableRemoteObject.narrow( obj, QueryHome.class );
Query qb = qh.create();
```

You then must specify a maximum size for the query result set, which is defined in the `QueryIterator` object. (See *Class QueryIterator* in Reference: Generated API documentation for more details.) This example sets the maximum size of the result set to 99:

```
QueryIterator it = qb.executeQuery(query, null, null ,0, 99 );
```

The iterator contains a collection of `IQueryTuple` objects, which are records of the return collection values. (See *Class IQueryTuple* in Reference: Generated API documentation for more details.) Corresponding to the criteria of our example query statement, each tuple in this scenario contains one value of *name* and one value of *object(e)*. To display the contents of this query result, use the following code:

```
while (it.hasNext() ) {
    IQueryTuple tuple = (IQueryTuple) it.next();
    System.out.print( it.getFieldName(1) );
    String s = (String) tuple.getObject(1);
    System.out.println( s);
    System.out.println( it.getFieldName(2) );
    Emp e = ( Emp) javax.rmi.PortableRemoteObject.narrow( tuple.getObject(2), Emp.class );
    System.out.println( e.getPrimaryKey().toString());
}
```

The output from the program might look something like the following:

```
name Bob
emp 1001
name Dave
emp 298003
...
```

Finally, catch and process any exceptions. An exception might occur because of a syntax error in the query statement or a run-time processing error. The following example catches and processes these exceptions:

```
} catch (QueryException qe) {
    System.out.println("Query Exception "+ qe.getMessage() );
}
```

Handling large result collections for the remote interface query

If you intend your query to return a large collection, you have the option of programming it to return results in multiple smaller, more manageable quantities. Use the `skipRow` and `maxRow` parameters on the remote `executeQuery` method to retrieve the answer in chunks. For example:

```
int skipRow=0;
int maxRow=100;
QueryIterator it = null;
do {
    it = qb.executeQuery(query, null, null ,skipRow, maxRow );
    while (it.hasNext() ) {
        // display result
        skipRow = skipRow + maxRow;
    }
} while ( ! it.isComplete() );
```

Example: Dynamic query local interface

When you run a dynamic EJB query using the local interface, you are calling the `executeQuery` method on the `QueryLocal` interface. This interface does not initiate a transaction for the method; therefore you must explicitly establish a transaction context for the query to run.

Note: To establish a transaction context, the following example calls the `begin()` and `commit()` methods. An alternative to using these methods is simply embedding your query code within an EJB method that runs within a transaction context.

Begin your query code with the following import statements:

```

import com.ibm.websphere.ejbquery.QueryLocalHome;
import com.ibm.websphere.ejbquery.QueryLocal;
import com.ibm.websphere.ejbquery.QueryLocalIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;

```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```

String query =
"select e.name, object(e) from EmpBean e where e.salary < 50000 ";

```

Create a QueryLocal object by obtaining a reference from the QueryLocalHome class. (This class defines the executeQuery method.) Note that in the following example, ejb/query is used as a local EJB reference pointing to the dynamic query JNDI name (com/ibm/websphere/ejbquery/Query):

```

InitialContext ic = new InitialContext();
QueryLocalHome qh = ( LocalQueryHome) ic.lookup( "java:comp/env/ejb/query" );
QueryLocal qb = qh.create();

```

The last portion of code initiates a transaction, calls the executeQuery method, and displays the query results. The QueryLocalIterator class is instantiated because it defines the query result set. (See *Class QueryIterator* in Reference: Generated API documentation for more details.) Keep in mind that the iterator loses validity at the end of the transaction; you must use the iterator in the same transaction scope as the executeQuery call.

```

userTransaction.begin();
QueryLocalIterator it = qb.executeQuery(query, null, null);
while (it.hasNext() ) {
    IQueryTuple tuple = (IQueryTuple) it.next();
    System.out.print( it.getFieldName(1) );
    String s = (String) tuple.getObject(1);
    System.out.println( s);
    System.out.println( it.getFieldName(2) );
    EmpLocal e = ( EmpLocal ) tuple.getObject(2);
    System.out.println( e.getPrimaryKey().toString());
}
userTransaction.commit();

```

In most situations, the QueryLocalIterator object is *demand-driven*. That is, it causes data to be returned incrementally: for each record retrieval from the database, the next() method must be called on the iterator. (Situations can exist in which the iterator is not demand-driven. For more information, consult the "Local query interfaces" subsection of the Dynamic query performance considerations topic.)

Because the full query result set materializes incrementally in the application server memory, you can easily control its size. During a test run, for example, you may decide that return of only a few tuples of the query result is necessary. In that case you should use a call of the close() method on the QueryLocalIterator object to close the query loop. Doing so frees SQL resources that the iterator uses. Otherwise, these resources are not freed until the full result set accumulates in memory, or the transaction ends.

Dynamic query performance considerations

General performance considerations

Use of the following elements in your dynamic query can diminish application performance somewhat:

- Datatype converters and Java methods

Why: In general, query operations and predicates are translated into SQL so that the database server can perform them. If your query includes datatype converters (for EJB to RDB mapping, for example) or Java methods, however, the associated predicates and operations of your query must be performed in the memory of the application server.

- EJB methods and criteria that call for the return of EJB references

Why: Queries that incorporate these elements trigger full activation of EJBs in the memory of the application server. (Returning a list of CMP fields from a query does not cause an EJB to be activated.)

When assessing application performance, you should also be aware that dynamic queries share connections with the persistence manager. Consequently, an application that includes a mixture of finder methods, CMR navigation, and dynamic queries relies on a single shared connection between the persistence manager and the dynamic query service to perform these tasks.

Limiting the return collection size

- **Remote interface queries:** The QueryIterator class of the remote interface mandates that all of your query results materialize in application server memory over the course of one method call. The SQL cursor(s) used to run the EJB query are closed upon completion of that call. Because this requirement poses a high risk for creating bottlenecks within the database server, you need to limit the size of any potentially large result collections.
- **Local interface queries:** In most situations, the QueryLocalIterator object behaves as a wrapper around an SQL cursor. It is *demand-driven*; it causes data to be returned incrementally. For each record retrieval from the database, the next() method must be called on the iterator.

Use of certain operations in local interface queries, however, overrides the demand-driven behavior. In these cases, the query results fully materialize in memory just as do the result collections of remote interface queries. An example of such a case is:

```
select e.myBusinessMethod( ) from EmpBean e
where e.salary < 50000 order by 1 desc
```

This query requires performance of an EJB method to produce the final result collection. Consequently, the full dataset from the database must be returned in one collection to application server memory, where the EJB method can be run on the dataset in its entirety. For that reason, local interface query operations that invoke EJB methods are generally not demand-driven. You cannot control the return collection size for such queries.

Because they *are* demand-driven, all other local interface queries allow you to control the size of return collections. You can use a call of the close() method on the QueryLocalIterator object to close the query loop after the desired number of return values has been fetched from the datastore. Otherwise, the SQL cursor(s) used to run the EJB query are not closed until the full result set accumulates in memory, or the transaction ends.

Access intent implications for dynamic query

WebSphere Application Server gives you the option to set access intent policies for your entity enterprise beans as a way of managing their transfer of data with the underlying datastore. An access intent policy controls the isolation level used on the data source connection, as well as the database locks used during data retrieval. By manipulating these elements, you can maximize the efficiency of your application's data flow. To learn more, begin with the topics "Access intent policies" on page 233 and "Concurrency control" on page 233.

When formulating dynamic queries, keep in mind the following considerations concerning their interaction with access intent policies:

- A dynamic query uses the first ASN name in the FROM clause to determine access intent.
- The collection increment attribute of an access intent policy is not used in processing a dynamic query.
- When performed on entity beans that have a pessimistic-Update access intent policy, your dynamic queries must return updateable collections. Therefore you need to formulate your query statements to return only collections of entity beans, *not* collections of CMP fields. For example, the statement `select object(c) from Customer` is valid for a dynamic query performed under the constraint of a pessimistic-Update policy. The statement `select c.name from Customer c`, however, is not a valid dynamic query under this constraint.
- Using pessimistic-Update policy places restrictions on the types of query expressions. The restrictions depend on the back end database type and release. Refer to the topic Access intent -- isolation levels and update locks for details.

Dynamic query API: prepareQuery() and executePlan() methods

Use these methods to more efficiently allocate the overhead associated with dynamic query. They are equivalent in function to the prepareStatement() and executeQuery() methods of the JDBC API.

To perform a dynamic EJB query, the application server must parse the query string into SQL at run time. You can, of course, eliminate run-time overhead by choosing to perform a standard EJB query instead of a dynamic query. Sometimes referred to as *deployment queries*, standard queries are parsed and built at deployment, then performed by a finder or select method.

Another option is to write code that redistributes dynamic query overhead for better application performance. Begin by calling the prepareQuery() method in place of the executeQuery() method. The prepareQuery() method parses and translates your query, and returns a string called a *query plan*. The plan contains the SQL statement produced by parsing and translation, as well as other information needed by the dynamic query API. Save this string in your application and call the executePlan() method with the string to run your query. (You also might want to use the prepareQuery() method simply to see the SQL translation product; just call the method and display the return value.)

Pass the parameters of your query as an array of type Object on the prepareQuery() and the executePlan() method calls. Ensure that you pass appropriate data types, because the application server validates your query according to parameter type (rather than actual values) when it processes the prepareQuery() method call.

Example code

Note: In the example code that follows, the first executePlan() method call substitutes parms[0] for ?1. Hence the first query performed is functionally equivalent to the following query statement:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 50000
```

The second call runs a query that is functionally equivalent to this statement:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 60000
```

The example:

```
String query =  
"select e.name as name , object(e) as emp from EmpBean e where e.salary < ?1";  
QueryIterator it = null;  
Integer[] parms = new Integer[1];  
parms[0] = new Integer(0);
```

In the call to prepareQuery(), pass any Integer value. Doing so defines ?1 as an Integer type, as in the following:

```
String queryPlan= qb.prepareQuery(query, parms, null );  
  
parms[0] = new Integer(50000);
```

Next you run the query with a real value of Integer(50000) for ?1:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 50000 it =  
qb.executePlan( queryPlan, parms, 0, 99);  
  
parms[0] = new Integer(60000);
```

Run the query again with a different value of Integer(60000) for ?1:

```
it = qb.executePlan( queryPlan, parms, 0, 99);
```

Comparison of the dynamic and deployment EJB query services

You can use the dynamic query service to build and execute queries against entity beans constructed dynamically at run time, rather than defining them at deployment time. By using dynamic query you gain

the flexibility of queries defined at run time and utilize the power of EJB-Query Language (QL). Apart from supporting all of the capabilities of an EJB-QL query, dynamic query adds functionality not available to standard static query. Two examples are the ability to select multiple data fields directly from the bean itself (static queries currently only allow one) and executing business methods directly in the query.

You can effectively create more efficient and less resource intensive applications with dynamic query. For example, two data fields are required from the results of a query. Because a standard EJB-QL query can only select one data field, it is necessary to select the entire EJB object and extract the needed data from the returned results through data access methods, possibly traversing Container Managed Relationships (CMR) boundaries in the process. However, when using dynamic query, you can get both pieces of data directly from the query without additional CMR traversal or accessor methods. This principle is the key to evaluating whether or not dynamic query can be used for performance gain. You should review the amount of data that must be retrieved, in addition to the amount of business logic needed to retrieve it, for example, CMR traversal or accessor methods.

Using parameters in the query rather than literal values is another performance consideration. Under most circumstances, it is better to define conditional values as parameters in the query and then pass those parameters through the appropriate mechanisms. By using this method, you have a greater chance of matching a cached query plan, and you eliminate the need to parse and build the plan from scratch. For example, "SELECT Object(o) FROM schemaname AS o WHERE o.fieldname LIKE foo", is more appropriately expressed as "SELECT Object(o) FROM schemaname AS o WHERE o.fieldname LIKE ?1" with the value *foo* passed as a parameter to the executeQuery method. The result is that any subsequent execution of a dynamic query structure that is the same, except for different string literal conditions, is registered as a plan cache hit (which delivers better "observed" performance).

When used as a direct replacement for an equivalent static query, dynamic query is approximately 25% slower than the static variation. This slowdown is due to the need for parsing and building a plan for the query, in addition to executing it. In the static variation, these costs are paid at deploy time. Despite this, the added functionality gained through the use of dynamic query, specifically the ability to select multiple data fields in a single query even across CMRs, creates opportunities to utilize dynamic query for the sake of performance improvement.

Internationalization

Task overview: Globalizing applications

An application that can present information to users according to regional cultural conventions is said to be *globalized*: The application can be configured to interact with users from different localities in culturally appropriate ways. In a globalized application, a user in one region sees error messages, output, and interface elements in the requested language. Date and time formats, as well as currencies, are presented appropriately for users in the specified region. A user in another region sees output in the conventional language or format for that region. Globalization consists of two phases: *internationalization* (enabling an application component to use regional conventions) and *localization* (implementing a specific regional convention). This product supports globalization through the use of its localizable-text API and internationalization service.

- Make sure the server runtime environment is properly configured.

For more information about supported locales and character encodings, see "Working with locales and character encodings" on page 2093.

- Implement message catalogs in your application by using the localizable-text API.

This product supports the maintenance and deployment of centralized message catalogs for the output of properly formatted, language-specific (*localized*) interface strings.

For more information about the localizable-text API, see "Task overview: Internationalizing interface strings (localizable-text API)" on page 2090.

- Implement more extensive locale support by using the internationalization service.

With the internationalization service, you can manage the distribution of the internationalization information, or *internationalization context*, that is necessary to perform localizations within Java 2 Platform, Enterprise Edition (J2EE) application components. Supported application components also include Web service client environments and Web service-enabled enterprise beans.

For more information about the internationalization service, see “Task overview: Internationalizing application components (internationalization service)” on page 2091.

Globalization

An application that can present information to users according to regional cultural conventions is said to be *globalized*: The application can be configured to interact with users from different localities in culturally appropriate ways. In a globalized application, a user in one region sees error messages, output, and interface elements in the requested language. Date and time formats, as well as currencies, are presented appropriately for users in the specified region. A user in another region sees output in the conventional language or format for that region. Globalization consists of two phases: *internationalization* (enabling an application component to use regional conventions) and *localization* (implementing a specific regional convention).

Historically, the creation of globalized applications has been restricted to large corporations writing complex systems. However, given the rise in distributed computing and in the use of the World Wide Web, application developers are pressured to globalize a much wider variety of applications. This trend requires making globalization techniques much more accessible to application developers.

Internationalization of an application is driven by two variables, the time zone and the locale. The *time zone* indicates how to compute the local time as an offset from a standard time like Greenwich Mean Time. The *locale* is a collection of information about language, currency, and the conventions for presenting information like dates. A time zone can cover many locales, and a single locale can span time zones. With both time zone and locale, the date, time, currency, and language for users in a specific region can be determined.

A first step: Localization of interface strings

In an application that is not globalized, the user interface is unalterably written into the application code. Internationalizing a user interface adds a layer of abstraction into the design of an application. The additional layer of abstraction enables you to localize the application for each locale that must be supported by the application.

In a localized application, the locale determines the message catalog from which the application retrieves message strings. Instead of printing an error message, the application represents the error message with some language-neutral information; in the simplest case, each error condition corresponds to a key. To print a usable error message, the application looks up the key in a *message catalog*. Each message catalog is a list of keys with associated strings. Different message catalogs provide strings for the different languages that are supported. The application looks up the key in the appropriate catalog, retrieves the corresponding error message in the requested language, and prints the string for the user.

Localization of text can be used for far more than translating error messages. For example, by using keys to represent each element in a graphical user interface (GUI) and by providing the appropriate message catalogs, the GUI (buttons, menus, and so on) can support multiple languages. Extending support to additional languages requires that you provide message catalogs for those languages; in many cases, the application needs no further modification.

The localizable-text package is a set of Java classes and interfaces that can be used to localize the strings in distributed applications easily. Language-specific string catalogs can be stored centrally so that they can be maintained efficiently.

Globalization challenges in distributed applications

With the advent of Internet-based business computational models, applications increasingly consist of clients and servers that operate in different geographical regions. These differences introduce the following challenges to the task of designing a solid client-server infrastructure:

Clients and servers can run on computers that have different endian architectures or code sets

Clients and servers can reside in computers that have different endian architectures: A client can reside in a little-endian CPU, while the server code runs in a big-endian one. A client might want to call a business method on a server running in a code set different from that of the client.

A client-server infrastructure must define precise endian and code-set tracking and conversion rules. The Java platform has nearly eliminated these problems in a unique way by relying on its Java virtual machine (JVM), which encodes all of the string data in UCS-2 format and externalizes everything in big-endian format. The JVM uses a set of platform-specific programs for interfacing with the native platform. These programs perform any necessary code set conversions between UCS-2 and the native code set of a platform.

Clients and servers can run on computers with different locale settings

Client and server processes can use different locale settings. For example, a Spanish client might call a business method upon an object that resides on an American English server. Some business methods are locale-sensitive in nature; for example, given a business method that returns a sorted list of strings, the Spanish client expects that list to be sorted according to the Spanish collating sequence, not in the English collating sequence of the server. Because data retrieval and sorting procedures run on the server, the locale of the client must be available to perform a legitimate sort.

A similar consideration applies in instances where the server has to return strings containing date, time, currency, exception messages, and so on, that are formatted according to the cultural expectations of the client.

Clients and servers can reside in different time zones

Client and server processes can run in different time zones. To date, all internationalization literature and resources concentrate mainly on code set and locale-related issues. They have generally ignored the time zone issue, even though business methods can be sensitive to time zone as well as to locale.

For example, suppose that a vendor makes the claim that orders received before 2:00 PM are processed by 5:00 PM the same day. The times given, of course, are in the time zone of the server that is processing the order. It is important to know the time zone of the client to give customers in other time zones the correct times for same-day processing.

Other time zone-sensitive operations include time stamping messages logged to a server, and accessing file or database resources. The concept of Daylight Savings Time further complicates the time zone issue.

Java 2 Platform, Enterprise Edition (J2EE) provides support for application components that run on computers with differing endian architecture and code sets. It does not provide dedicated support for application components that run on computers with different locales or time zones.

The conventional method for solving locale and time zone mismatches across remote application components is to pass one or more extra parameters on all business methods needed to convey the client-side locale or time zone to the server. Although simple, this technique has the following limitations when used in Enterprise JavaBeans (EJB) applications:

- It is intrusive because it requires that one or more parameters be added to all bean methods in the call chain to locale-sensitive or time zone-sensitive methods.
- It is inherently error-prone.
- It is impracticable within applications that do not support modification, such as legacy applications.

The internationalization service addresses the challenges posed by locale and time zone mismatch without incurring the limitations of conventional techniques. The service systematically manages the distribution of internationalization contexts across the various components of EJB applications, including client applications, enterprise beans, and servlets. For more information, see “Task overview: Internationalizing application components (internationalization service)” on page 2091.

Language versions offered by this product

This product is offered in several languages, as enabled by the operating platform on which the product is installed.

For the z/OS platform, the following language versions are available:

- English
- Japanese

Globalization: Resources for learning

Task overview: Internationalizing interface strings (localizable-text API)

This topic summarizes the steps involved in implementing message catalogs through the localizable-text API.

This product supports the maintenance and deployment of centralized message catalogs for the output of properly formatted, language-specific (*localized*) interface strings.

1. Identify localizable text in your application.
2. Create the message catalogs that are necessary for the locales to be supported by your application.
3. In your application code, compose the language-specific strings for output.
4. Using an assembly tool, assemble your application code as one or more application components.
5. Prepare the localizable-text package for deployment with your localized application. In this step, you create a deployment Java archive (JAR) file.
6. Assemble the application modules and the deployment JAR file into a Java 2 Platform, Enterprise Edition (J2EE) application.
7. Deploy and manage the application.

Your application is deployed with localized text.

Task overview: Internationalizing application components (internationalization service)

This topic summarizes the steps involved in using the internationalization service.

With the internationalization service, you can manage the distribution of the internationalization information, or *internationalization context*, that is necessary to perform localizations within Java 2 Platform, Enterprise Edition (J2EE) application components. Supported application components also include Web service client environments and Web service-enabled enterprise beans.

1. Use the internationalization context API within application components to obtain or manage internationalization context.

Servlet and enterprise bean business methods can use internationalization context to perform locale- and time zone-sensitive localizations. Enterprise JavaBeans (EJB) client applications, and server components that are configured to manage internationalization context must use the internationalization context API to set the context elements scoped to their invocations.

You use the internationalization context API within Web service-enabled J2EE client programs and stateless session beans in the same manner that you would use conventional J2EE components, with one exception. Internationalization context propagated over Web service requests contains a time zone ID, whereas conventional Remote Method Invocation/ Internet Inter-ORB Protocol (RMI/IIOP) requests propagate complete time zone information, including the raw offset, Daylight Savings Time information, and so on.

2. Assemble internationalized applications.

The internationalization type specifies the internationalization policy that applies to a servlet or an enterprise bean and, in particular, indicates whether the application component or its hosting J2EE container manages internationalization context. Container internationalization attributes can be specified for container-managed servlet and enterprise bean business methods. These attributes tailor a policy by indicating which context the container scopes to an invocation. Configuring internationalization policies declaratively prescribes, by means of the application deployment descriptor, the distribution and management of context throughout an application.

As you edit the deployment descriptor for assembly, you can also set the internationalization type and configure any container internationalization attributes for the servlets and enterprise beans in your application.

You configure internationalization type and container internationalization attributes for Web service-enabled stateless session beans in the same manner as you do for conventional beans.

3. Manage the internationalization service.

Use the administrative console to enable the service on all application servers.

By default, the service is enabled within J2EE client environments but is disabled on application servers. You must enable the service on all application servers hosting your servlets and enterprise beans to use internationalization context.

4. Troubleshoot the internationalization service as needed.

Use the administrative console to enable the trace service to log internationalization service messages when debugging your applications.

The trace strings for the internationalization service follow; use both:

```
com.ibm.ws.i18n.context.*=all=enabled:com.ibm.websphere.i18n.context.*=all=enabled
```

Internationalization service

In a distributed client-server environment, application processes can run on different machines, configured for different locales, corresponding to different cultural conventions; they can also be located across geographical boundaries. The internationalization service can help manage your application in a globally distributed environment.

For an understanding of how differences in locale impact application development, read “Globalization” on page 2088.

Java 2 Platform, Enterprise Edition (J2EE) provides support for application components that run on computers with differing endian architecture and code sets. It does not provide dedicated support for application components that run on computers with different locales or time zones.

The internationalization service addresses the challenges posed by locale and time zone mismatch without incurring the limitations of conventional techniques. The service systematically manages the distribution of internationalization contexts across the various components of EJB applications, including client applications, enterprise beans, and servlets.

The service works by associating an internationalization context with every service request within an application. When a client-side component calls a business method, the internationalization service interposes by obtaining the internationalization context associated with the current client-side process and by attaching that context to the outgoing request. On the server side, the internationalization service again interposes by detaching the context from the incoming request and associating it with the server-side process on which the business method will run, effectively scoping the context to the business method. For HTTP requests, the caller context is constructed from the HTTP attributes and default values. The service propagates internationalization context on subsequent business method invocations in the same manner, which distributes the context of the originating request over the entire chain of business method invocations.

This basic operation of scoping and propagation is defined precisely by *internationalization context management policies*. Internationalization policies specify whether an application component or its hosting J2EE container are to manage internationalization context. For container-managed components, the policy indicates which internationalization context the container scopes to invocations on that component. Server components configured to manage internationalization context, as well as EJB clients, must use the internationalization context API to manage the internationalization context elements scoped to their invocations.

Every application component has a default policy, which can be overridden and tailored for servlets and enterprise beans at assembly time.

At run time, application components can use the internationalization context API to get any element of the internationalization contexts scoped to an invocation. To programmatically access context elements, application components first resolve an internationalization context API reference, then call the appropriate API method to access the various context elements, such as the caller locale or the invocation time zone. These elements can be used in calls to Java 2 SDK internationalization API methods; for example, to perform localizations such as formatting messages, configuring dates, or comparing strings.

Working with locales and character encodings

Internationalization support for this product relies on that provided by the Java 2 Platform, Standard Edition (J2SE). Support varies by platform.

- Verify that the operating system on which the application server is installed supports the locales and encodings that you plan to use.

Java internationalization support might use underlying services of the operating system. For example, if user IDs for your server are expected to contain non-English characters, make sure that the operating system is configured to process those characters.

- Plan for encoding changes as necessary.

Consider differences in encoding support among operating system subcomponents. Although this product and the Java platform are based on Unicode encoding, it is not always possible to run applications in a purely Unicode environment.

- Set the `console.encoding` property as necessary.

If your application produces an `UnsupportedEncodingException` exception, check your operating system documentation to determine if the target operating system supports the required encoding and adjust the runtime environment as needed.

Administering the internationalization service

To use internationalization context in an Enterprise JavaBeans (EJB) application, the internationalization service must be enabled in the runtime environments for all server-side components (servlets and enterprise beans, including session beans enabled for Web service usage) as well as all client-side components (EJB client applications and Web service clients).

If you do not require the internationalization service, do not enable it. Leaving the service disabled prevents any possible performance degradation incurred by the implicit distribution of internationalization resources.

The internationalization service cannot be enabled for HTTP clients, because support for internationalization in that case is provided by the browser, not by the application server.

- Enable or disable the internationalization service for servlets and enterprise beans. By default, the service is disabled for server-side components within the application server. You enable the service by using either the administrative console or the `wsadmin` tool.
- Enable or disable the internationalization service for EJB clients. By default, the service is disabled within the client container. You enable the service by using the `launchClient` tool.

Enabling the internationalization service for servlets and enterprise beans

Perform this task to enable the internationalization service in the application server runtime environment.

Any servlet or enterprise bean can use internationalization context if the internationalization service is enabled within the hosting WebSphere Application Server instance.

1. Start the administrative console.
2. Click **Servers > Application servers > *server_name* > Container services > Internationalization service**.
3. Enable the internationalization service.
 - a. If not already selected, select the **Enable service at server startup** check box.
 - b. Click **OK**.

When you select the **Enable service at server startup** setting, the application server automatically initializes and starts the internationalization service whenever the server starts. If you change this setting, be sure to restart the application server for the new setting to take effect.

To disable the service, clear the **Enable service at server startup** check box. In this case, the internationalization service is initialized but not started when the application server starts.

Administration through scripting

Alternatively, the internationalization service can be enabled from the command line by using the wsadmin tool. Start the wsadmin tool and enter the following commands:

```
set x [$AdminConfig list I18NService]
$AdminConfig modify $x { { enable true } }
$AdminConfig save
exit
```

If you enable or disable the internationalization service, be sure to stop and then restart the application server for the new setting to take effect.

Enabling the internationalization service for EJB clients

By default, the internationalization service is disabled for use within Enterprise JavaBeans (EJB) and Web-service enabled client applications. You must enable the service for client applications as well as for all server instances in the runtime environment.

Enable the service.

When calling the launchClient tool, include the argument `-CCDI18NService.enable=true` or `-CCDI18NService.enable=yes`.

Internationalization service settings

Use this page to enable or disable the internationalization service. The internationalization service manages the implicit propagation and scoping of locale and time zone information, called *internationalization context*, within application components. When the service is enabled, application components can use the internationalization context API to programmatically manage locale and time zone information. In turn, components can use that locale and time zone information with the Java 2 Platform, Standard Edition (J2SE) Internationalization API to perform localizations. If internationalization support is not required on the server, disabling the service can improve performance.

To view this administrative console page, click **Servers > Application servers > *server_name* > Container services > Internationalization service**.

Enable service at server startup:

Specifies whether the server attempts to start the internationalization service.

Default	Cleared
Range	Valid values are Selected or Cleared

More information about valid values follows:

Selected

When the application server starts, it attempts to start the internationalization service automatically.

Cleared

The server does not try to start the internationalization service.

To enable the internationalization service for applications on this server, the system administrator must select this property and then restart the server.

Internationalization service errors

Certain conditions might cause the internationalization service not to start, to issue `java.lang.IllegalStateException` exceptions while an application is running, or to exercise default behaviors.

The `java.lang.IllegalStateException` exception indicates one of the following things:

- An application component attempted an operation that is not supported by the internationalization programming model.

The `IllegalStateException` exception is issued whenever a server application component whose internationalization type is set to container-managed internationalization (CMI) attempts to set invocation context. This behavior is a violation of the CMI policy, under which servlets and enterprise beans cannot modify their invocation internationalization context.

- An anomaly occurred that disabled the service.

For instance, if the internationalization service is not properly initialized, the Java Naming and Directory Interface (JNDI) lookup on the `UserInternationalization` URL attribute issues a `javax.naming.NameNotFoundException` exception that contains an `IllegalStateException` instance.

The following conditions can occur while your internationalized application is running. These conditions might cause the internationalization service not to start, to issue `IllegalStateException` exceptions, or to exercise default behaviors:

- “The service is disabled ”
- “The service is not started”
- “Invalid context element” on page 2096
- “Missing context element” on page 2096
- “Invalid policy” on page 2097
- “Missing policy” on page 2097

If you encounter unexpected or exceptional behavior, the problem is likely related to one of these conditions. You need to examine the trace log to investigate these conditions, which requires that you configure the diagnostic trace service to generate messages about internationalization service function. To get started with logging and tracing, see [Tracing and logging configuration](#).

The trace strings for the internationalization service follow; use both:

```
com.ibm.ws.i18n.context.*=all=enabled:com.ibm.websphere.i18n.context.*=all=enabled
```

The service is disabled

The internationalization service is not initialized when the startup setting is cleared. The service generates a message that indicates whether it is enabled or disabled. Applications cannot access the internationalization API when the service is disabled. If an application attempts a JNDI lookup to obtain the `UserInternationalization` reference, the lookup fails with a `NamingException` exception, indicating that the reference cannot be found. In addition, the service does not scope (propagate) internationalization context on incoming (outgoing) business method calls.

The service is not started

The internationalization service is operational whenever it is in the `STARTED` state. For example, if an application attempts to access internationalization context and the service is not started, the API issues an `IllegalStateException` exception. In addition, the service does not provide runtime support for servlets and enterprise beans.

As an application server progresses through its life cycle, it initializes, starts, stops, and terminates (destroys) the internationalization service. If an anomaly occurs during initialization, the service does not start. After the service is started, its state can change to `BLOCKED` in the event that a serious error occurs. The service generates a message for every state change.

If a trace message indicates that the service is not `STARTED`, examine previous messages to determine the problem. For instance, the internationalization service does not start if the activity service is unavailable and a message is displayed to that effect during initialization of the internationalization service.

During startup, the following messages indicate potential configuration or runtime problems:

No ORB support

The service cannot obtain an instance of the object request broker (ORB). This condition is a fatal error. Examine the SystemErr.log and SystemOut.log files for information.

No TCM support

The service cannot obtain an instance of its thread context manager (TCM). This condition is a fatal error. Examine the SystemErr.log and SystemOut.log files for information.

No IIOB (activity service) support

The service cannot register with the activity service. This condition is a fatal error. The internationalization service cannot propagate or receive context on Internet Inter-ORB Protocol (IIOB) requests without activity service support. Examine the SystemErr.log and SystemOut.log files for information.

No AsynchBeans support

The service cannot register into the asynchronous beans environment. This warning indicates that the asynchronous beans environment cannot support internationalization context.

No EJB container support

The service cannot register with the Enterprise JavaBeans (EJB) container. This warning indicates that the internationalization service cannot support enterprise beans. Without EJB container support, internationalization contexts do not scope properly to EJB business methods. Review the trace log for any EJB container-related error conditions.

No Web container support

The service cannot register with the Web container. This warning indicates that the internationalization service cannot support servlets and JavaServer Page (JSP) files. Without Web container support, internationalization contexts do not scope properly to servlet service methods. Review the trace log for any Web container-related error conditions.

No Metadata support

The service cannot register with the metadata service. This warning indicates that the internationalization service cannot process the internationalization policies within application deployment descriptors. Without metadata support, the service associates the default internationalization context management policy, [CMI, RunAsCaller], to every servlet lifecycle method and enterprise bean business method invocation. Review the trace log for any metadata service-related error conditions.

No JNDI (Naming service) support

The service cannot bind the UserInternationalization object into the namespace. This condition is a fatal error. Application components are unable to access internationalization context API references, and are therefore unable to access internationalization context elements. Review the trace log for any Naming (JNDI) service-related error conditions.

No API support

The service cannot obtain an instance of an internationalization context API object. This condition is a fatal error. Application components are unable to access internationalization context API references, and are therefore unable to access internationalization context elements.

Invalid context element

The service detected an invalid internationalization context element. For example, the internationalization service does not support TimeZone instances of a type other than java.util.SimpleTimeZone. If the service encounters an unusable element, it logs a message and substitutes the corresponding default element of the JVM.

Missing context element

The service detected a missing internationalization context element. Incoming requests (for example, from application servers that do not support the internationalization service) lack internationalization context. When the service attempts to access a caller internationalization context element (which does not exist in this case), the service logs a message and substitutes the corresponding default element of the Java virtual machine (JVM).

Whenever possible, enable the internationalization service within all clients and hosting application servers that comprise an internationalized enterprise application. Read more information about Administering the internationalization service in the *Administering applications and their environment* PDF book.

Invalid policy

The internationalization service detected a malformed internationalization policy in the application deployment descriptor. The service replaces the malformed attribute with the appropriate default. For instance, if the internationalization type for an entity bean is set to `Application` during the run of a servlet or EJB business method call, the service logs the inconsistency and enforces the `Container` setting instead.

Also, AMI application components do have an implicit container internationalization attribute. By default they run as server. The service silently enforces the implicit policy, `[AMI, RunAsServer]`, and logs messages to this effect.

Invalid container internationalization attributes are likely to occur when specifying the `Locales` and `Time zone ID` fields. When encountering invalid locales and time zone IDs within attributes, the service replaces each value with the corresponding default element of the JVM. Be sure to follow the guidelines provided in the *Developing and deploying applications* PDF book.

Missing policy

The service detected a missing internationalization policy. The service replaces the missing policy with the appropriate default. For instance, if the internationalization type is missing for a servlet or enterprise bean, the service sets the attribute to `Container`.

Container internationalization attributes are not mandatory for CMI application components. In the event that a CMI servlet or EJB business method lacks a container internationalization attribute, the service silently enforces the implicit policy `[CMI, RunAsCaller]`.

When an application lacks internationalization policies in its deployment descriptor, or metadata support is unavailable, the service logs a message and applies the policy `[CMI, RunAsCaller]` on every servlet service method and EJB business method invocation.

Read the information in the *Developing and deploying applications* PDF book:

- Assembling internationalized applications
- Container internationalization attributes
- Internationalization type

Object pools

Using object pools

An object pool helps an application avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused.

Object pools are not meant to be used for pooling JDBC connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To use an object pool, the product administrator must define an *object pool manager* using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Note: The Object pool manager service is only supported from within the EJB container or Web container. Looking up and using a configured object pool manager from a Java 2 Platform Enterprise Edition (J2EE) application client container is not supported.

1. Start the administrative console.
2. Click **Resources > Object pool managers**.
3. Specify a **Scope** value and click **New**.
4. Specify the required properties for work manager settings.
 - Scope** The scope of the configured resource. This value indicates the location for the configuration file.
 - Name** The name of the object pool manager. This name can be up to 30 ASCII characters long.
 - JNDI Name**
 - The Java Naming and Directory Interface (JNDI) name for the pool manager.
5. [Optional] Specify a **Description** and a **Category** for the object pool manager.

After you have completed these steps, applications can find the object pool manager by doing a JNDI lookup using the specified JNDI name.

The following code illustrates how an application can find an object pool manager object:

```
InitialContext ic = new InitialContext();
ObjectPoolManager opm = (ObjectPoolManager)ic.lookup("java:comp/env/pool");
```

When the application has an ObjectPoolManager, it can cache an object pool for classes of the types it wants to use. The following is an example:

```
ObjectPool arrayListPool = null;
ObjectPool vectorPool = null;
try
{
    arrayListPool = opm.getPool(ArrayList.class);
    vectorPool = opm.getPool(Vector.class);
}
catch(InstantiationException e)
{
    // problem creating pool
}
catch(IllegalAccessException e)
{
    // problem creating pool
}
```

When the application has the pools, the application can use them as in the following example:

```
ArrayList list = null;
try
{
    list = (ArrayList)arrayListPool.getObject();
    list.clear(); // just in case
    for(int i = 0; i < 10; ++i)
    {
        list.add("" + i);
    }
    // do what ever we need with the ArrayList
}
finally
{
    if(list != null) arrayListPool.returnObject(list);
}
```

This example presents the basic pattern for using object pooling. If the application does not return the object, then the only adverse effect is that the object cannot be reused.

Object pool managers

Object pool managers control the reuse of application objects and Developer Kit objects, such as Vectors and HashMaps.

Multiple object pool managers can be created in an Application Server cell. Each object pool manager has a unique cell-wide Java Naming and Directory Interface (JNDI) name. Applications can find a specific object pool manager by doing a JNDI lookup using the specific JNDI name.

The object pool manager and its associated objects implement the following interfaces:

```
public interface ObjectPoolManager
{
    ObjectPool getPool(Class aClass)
        throws InstantiationException, IllegalAccessException;
    ObjectPool createFastPool(Class aClass)
        throws InstantiationException, IllegalAccessException;
}

public interface ObjectPool
{
    Object getObject();
    void returnObject(Object o);
}
```

Each object pool manager can be used to pool any Java object with the following characteristics:

- The object must be a public class with a public default constructor.
- If the object implements the `java.util.Collection` interface, it must support the optional `clear()` method.

Each pooled object class must have its own object pool. In addition, an application gets an object pool for a specific object using either the `ObjectPoolManager.getPool()` method or the `ObjectPoolManager.createFastPool()` method. The difference between these methods is that the `getPool()` method returns a pool that can be shared across multiple threads. The `createFastPool()` method returns a pool that can only be used by a single thread.

If in a Java virtual machine (JVM), the `getPool()` method is called multiple times for a single class, the same pool is returned. A new pool is returned for each call when the `createFastPool()` method is called. Basically, the `getPool()` method returns a pool that is thread-synchronized.

The pool for use by multiple threads is slightly slower than a fast pool because of the need to handle thread synchronization. However, extreme care must be taken when using a fast pool. Consider the following interface:

```
public interface PoolableObject
{
    void init();
    void returned();
}
```

If the objects placed in the pool implement this interface and the `ObjectPool.getObject()` method is called, the object that the pool distributes has the `init()` method called on it. When the `ObjectPool.returnObject()` method is called, the `PoolableObject.returned()` method is called on the object before it is returned to the object pool. Using this method objects can be pre-initialized or cleaned up.

It is not always possible for an object to implement `PoolableObject`. For example, an application might want to pool `ArrayList` objects. The `ArrayList` object needs clearing each time the application reuses it. The application might extend the `ArrayList` object and have the `ArrayList` object implement a poolable object. For example, consider the following:

```

public class PooledArrayList extends ArrayList implements PoolableObject
{
    public PooledArrayList()
    {
    }

    public void init() {
    }

    public void returned()
    {
        clear();
    }
}

```

If the application uses this object, in place of a true ArrayList object, the ArrayList object is cleared automatically when it is returned to the pool.

Clearing an ArrayList object simply marks it as empty and the array backing the ArrayList object is not freed. Therefore, as the application reuses the ArrayList, the backing array expands until it is big enough for all of the application requirements. When this point is reached, the application stops allocating and copying new backing arrays and achieves the best performance.

It might not be possible or desirable to use the previous procedure. An alternative is to implement a custom object pool and register this pool with the object pool manager as the pool to use for classes of that type. The class is registered by the WebSphere administrator when the object pool manager is defined in the cell. Take care that these classes are packaged in Java Archive (JAR) files available on all of the nodes in the cell where they might be used.

Object pool managers collection

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers**.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Name:

Specifies the name by which the object pool manager is known for administrative purposes.

Data type	String
Range	1 through 30 ASCII characters

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the object pool manager.

Data type	String
------------------	--------

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Description:

Specifies the description of the object pool manager.

Data type String

Category:

Specifies the category name used to classify or group this object pool manager.

Data type String

Object pool managers settings:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers > *objectpoolmanager_name***

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

The name by which the object pool manager is known for administrative purposes.

Data type String
Range 1 through 30 ASCII characters

JNDI Name:

The Java Naming and Directory Interface (JNDI) name for the object pool manager.

Data type String

Description:

A description of the object pool manager.

Data type String

Category:

A category name used to classify or to group this object pool manager.

Data type String

Custom object pool collection:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers > *objectpoolmanager_name* > Custom object pools**.

Use custom object pools to insert additional logic around the following mechanisms:

- Constructing an object pool (A list of properties can be set)
- Flushing the object pool
- Getting objects from the pool
- Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool the product administrator must define an object pool manager using the administrative console. You can create multiple object pool managers in an Application Server cell.

Pool class name:

Specifies the fully qualified class name of the objects that are stored in the custom object pool.

Data type String

Pool implementation class name:

Specifies the fully qualified class name of the implementation class for the custom object pool.

Data type String

Custom object pool settings:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers > *objectpoolmanager_name* > Custom object pools > *objectpool_name***.

Use custom object pools to insert additional logic around the following mechanisms:

- Constructing an object pool (A list of properties can be set)
- Flushing the object pool
- Getting objects from the pool
- Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Pool Class Name:

The fully qualified class name of the objects that are stored in the object pool.

Data type String

Pool Impl Class Name:

The fully qualified class name of the CustomObjectPool implementation class for this object pool.

Data type String

Object pool service settings

Use this page to enable or disable the object pool service, which manages object pool resources used by the server.

To view this administrative console page, click **Servers > Application Servers > server_name > Container services > Object Pool Service**.

Enable service at server startup:

Specifies whether the server attempts to start the object pool service.

Default	Cleared
Range	<p>Selected</p> <p>When the application server starts, it attempts to start the object pool service automatically.</p> <p>Cleared</p> <p>The server does not try to start the object pool service. If object pool resources are used on this server, then the system administrator must start the object pool service manually or select this property, and then restart the server.</p>

Object pools: Resources for learning

This topic provides links to find relevant supplemental information about object pools.

Use the following links to find relevant supplemental information about object pools. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links

are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Furthermore, these links provide guidance on using object pools. Since object pooling is a general topic and the WebSphere Application Server product implementation is only one way to use it, you must understand when object pooling is necessary. These articles help you make that decision.

Programming model and decisions

- Build your own ObjectPool in Java to boost application speed
- Improve the robustness and performance of your ObjectPool
- Recycle broken objects in resource pools

MBeans for object pool managers and object pools

Legacy MBean names for object pool managers and object pools are deprecated. The legacy names are based on the object pool manager name (which is not required to be unique) rather than the object pool manager JNDI name. For object pools, the legacy name is also lacking any identifier of the version of the pooled class. Additionally, object pool Performance Monitoring Instrumentation (PMI) statistics are aggregated for object pools with the same legacy object pool MBean name.

For example, if the object pool manager and pooled class are as follows:

```
object pool manager name:      My ObjectPool
object pool manager JNDI name: op/MyObjectPool
pooled class name:           java.util.ArrayList
hash code of java.util.ArrayList.class: 1111eb3f (hexadecimal)
```

the legacy object pool manager MBean name will be:

```
ObjectPoolManager_My ObjectPool
```

and the legacy object pool MBean name will be:

```
ObjectPool_My ObjectPool_java.util.ArrayList
```

Instead of using the deprecated legacy MBean names, use the MBean names that are based on the JNDI name of the object pool manager.

For the example above, the JNDI name-based object pool manager MBean name is:

```
ObjectPoolManager_op/MyObjectPool
```

and the JNDI name-based object pool MBean name is:

```
ObjectPool_op/MyObjectPool_java.util.ArrayList.class@1111eb3f
```

Formats for MBean names

Type	Name format
Deprecated legacy object pool manager MBean name:	ObjectPoolManager_[object pool manager name]
JNDI name-based object pool manager MBean name:	ObjectPoolManager_[object pool manager JNDI name]
Deprecated legacy object pool MBean name:	ObjectPool_[object pool manager name]_[pooled class name]
JNDI name-based object pool MBean name:	ObjectPool_[object pool manager JNDI name]_[pooled class name].class@[hexadecimal representation of the hash code of the pooled class' java.lang.Class reference]

In all of the above formats, characters that are not valid for MBean names are replaced with the '.' character.

Scheduler

Using schedulers

Schedulers enable J2EE application tasks to run at a requested time. Schedulers also enable application developers to create their own stateless session EJB components to receive event notifications during a task life cycle, allowing the plugging-in of custom logging utilities or workflow applications.

You can schedule the following types of tasks:

- Invoke a session bean method
- Send a Java Message Service (JMS) message to a queue or topic

Stateless session EJB components are also used to provide generic calendaring. Developers can either use the supplied calendar bean or create their own for their existing business calendars. For example, one of your business processes might involve invoicing for services. With the scheduler's use of stateless EJB components, you can schedule when periodic email distributions are to be sent to your customers who have received invoices. The scheduler service performs these tasks, repeating as necessary, according to the metadata for that task.

A scheduler is the mechanism by which the timer service for Enterprise Java Beans 2.1 runs. You can configure the EJB timer service to use many of the features that schedulers provide. See the timer service for Enterprise Java Beans 2.1 documentation for more details.

Use the following table to determine which persistent timer service is best for you:

Schedulers	EJB timers
Run stateless session EJB components and sends JMS messages	Run all EJB types except for stateful session beans
Persistent, transactional and highly available.	Persistent, transactional and highly available.
Tasks guaranteed to run only once	Timers guaranteed to run only once, if the timer EJB uses a container-managed global transaction
Run repeating tasks using any calculation rules	Run repeating tasks using a repeating interval defined in milliseconds
Uses a modified fixed-delay time calculation to determine repeating intervals (next run time based on the start-time of the previous task)	Uses a fixed-rate time calculation to determine repeating intervals (time of the next task is based on the original scheduled time).
Programmatic task monitoring capability with the use of the NotificationSink stateless session EJB	No programmatic timer monitoring
Abort late or time-sensitive tasks from running	Abort late or time-sensitive tasks from running (achieved through manual detection within the <code>javax.ejb.TimerObject</code> implementation).
Manage any task lifecycle (find, suspend, resume, cancel and purge tasks programmatically and through Java Management Extensions (JMX)).	Find and cancel its timers programmatically. Administrators find and cancel timers using a command-line utility.
Store a limited amount of text with the data, like a Name (arbitrary data stored externally.)	Store arbitrary data with a timer

This task demonstrates how to manage, develop and interoperate with schedulers and subsequent tasks.

1. Manage the scheduler service. This article includes instructions for creating and configuring schedulers, creating and configuring a database for schedulers and administering schedulers.
2. Develop and schedule tasks. This article includes instructions for developing various types of tasks, receiving notifications from a task, submitting tasks to a scheduler, and managing tasks.

Note: Creating and manipulating scheduled tasks through the Scheduler API interface is only supported from within the Enterprise Java Beans (EJB) container or Web container (JavaServer Pages or servlets). Looking up and using a configured scheduler from a Java 2 Platform Enterprise Edition (J2EE) application client container is not supported.

3. Interoperate with schedulers. This article explains how to manage scheduler in a clustered environment with mixed WebSphere Application Server product versions and mixed platforms.

Scheduler daemon

A scheduler daemon is a background thread that searches for tasks to run in the database.

A scheduler daemon is started for each scheduler defined on each server. If Scheduler 1 is configured on server1, then only one scheduler daemon runs on server1 unless it is cloned. If Scheduler 1 is defined at the node scope level, then the scheduler will run on each server within that node.

The poll interval determines the frequency at which the persistent store is queried. By default, this value is set to 30 seconds. When a task is found that is scheduled to run within the current poll interval, an asynchronous beans alarm is set. The task then runs as close to this time as possible using an alarm thread from the scheduler's associated work manager. Thus, the number of alarm threads configured on the work manager determines how many concurrent tasks are executed. No tasks are lost. If we reach this limit, then new tasks are simply queued to be executed when an alarm thread becomes available. The actual firing time is dictated by server load and availability of free threads in the alarm thread pool of the associated work manager.

Scheduler daemons in a cluster

When multiple schedulers are configured to use the same tables (as is the case in a clustered environment), any of the daemons can find a task and set the alarm in its Java virtual machine (JVM). The task is executed in the virtual machine where the scheduler daemon first runs, until the daemon is stopped and another daemon starts. If an application on server1 schedules a task to run and server2 was started before server1, then the task runs on server2.

Example: Stopping and starting scheduler daemons using Java Management Extensions API:

Use the wsadmin scripting tool to invoke a Jac1 script and stop and start a scheduler daemon.

This example JACL script can be invoked using the wsadmin scripting tool. It will attempt to stop and start a scheduler daemon.

```
# Example JACL Script to restart a Scheduler Daemon

set schedJNDIName sched/MyScheduler

# Find the WASScheduler MBean
regsub -all {/} $schedJNDIName "." schedJNDIName
set mbeanName Scheduler_${schedJNDIName}
puts "Looking up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]

# Invoke the stopDaemon operation.
puts "Stopping the daemon..."
$AdminControl invoke $sched stopDaemon
puts "The daemon has stopped."

# Invoke the startDaemon operation.
puts "Starting the daemon..."
$AdminControl invoke $sched startDaemon 0
puts "The daemon has started."
```

Example: Dynamically changing scheduler daemon poll intervals using Java Management Extensions API:

Use the wsadmin scripting tool to invoke a JACL script and dynamically change scheduler daemon poll intervals.

To dynamically change scheduler daemon poll intervals, use the wsadmin scripting tool to invoke this example JACL script. Invoking this example sets the poll interval of the scheduler daemon to 60 seconds.

```
# Example JACL Script to set the Scheduler daemon's poll interval

set schedJNDIName sched/MyScheduler

# Find the WASScheduler MBean
regsub -all {/} $schedJNDIName "." schedJNDIName
set mbeanName Scheduler_$schedJNDIName
puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]

# Set the poll interval to 60 seconds (60000 ms)
$AdminControl setAttribute $sched pollInterval 60000
puts "Poll interval set."
```

Interoperating with schedulers

Schedulers support forward compatibility. Tasks created in previous versions of WebSphere Application Server Enterprise Edition 5.0 or WebSphere Business Integration Server Foundation 5.1 continue to run in WebSphere Application Server, Version 6.x schedulers. Tasks that you create using Version 6.x are not compatible with product schedulers from Version 5.x. Version 5.x schedulers do not run any Version 6.x tasks.

Schedulers and versions

All schedulers that are configured to use the same database and tables are considered a clustered scheduler. To guarantee that your tasks run correctly, all servers in a scheduler cluster must be at the same version. If the servers are at different versions, tasks created with a Version 6.x scheduler might not run. If a mixed-Version environment is required for a short period of time, then all scheduler poll daemons should be stopped on all Version 5.x servers to allow a Version 6.x server to run all tasks. This action allows the Version 6.x schedulers to obtain leases and run tasks that have been created with a Version 6.x scheduler.

Running tasks created with schedulers prior to Version 5.0.2 is not supported. See the topic, "Interoperating with the Scheduler service," in the WebSphere Application Server Enterprise Edition Version 5.0.2 information center for details on how to migrate these tasks to a more recent version. See the Information Center Library to access the Version 5.0.2 information center.

Scheduler calendars

The scheduler provides stateless session bean interfaces which allow creating common calendars which can be used by the scheduler and any J2EE application.

The SchedulerCalendars.ear application is available and provides a default UserCalendar EJB implementation which allows using the SIMPLE and CRON calendars. Although this application is not required when using the scheduler, it is available to use from any J2EE application.

For details on how the SIMPLE and CRON calendars behave, see the API documentation for the com.ibm.websphere.scheduler.UserCalendar interface.

Specifying a UserCalendar with the scheduler

A UserCalendar is specified using the setUserCalendar() method of the TaskInfo interface of the scheduler. This interface allows you to select the JNDI name of the home interface of a UserCalendar bean. Because some UserCalendar bean implementations might handle multiple types of calendars, the interface also

allows you to optionally select which type of calendar to use. A list of valid calendar types can be retrieved by invoking the `getCalendarNames()` method of the `UserCalendar` interface.

If the `setUserCalendar()` method is not invoked, or if a value of null or empty-string is specified for the home JNDI name parameter, then the default `UserCalendar` is used internally by the scheduler. When the default `UserCalendar` is accessed internally, it is not necessary that the `SchedulerCalendar.ear` system application be installed.

You might want to use the default `UserCalendar` directly in your other J2EE applications, apart from the scheduler. In this case, you may use the `UserCalendarHome.DEFAULT_CALENDAR_JNDI_NAME` value to look up the default `UserCalendar` from your applications. You may also supply this value to the `setUserCalendar()` method of the `TaskInfo` interface. You will need to ensure the `SchedulerCalendar.ear` system application was either automatically installed or that you have installed it manually.

Scheduler service settings

Use this page to enable or disable the scheduler service. The scheduler service manages scheduler resources used by the server. The administrative console page used to configure the scheduler service is not available for version 6 (and above) servers. It is only available for version 5.x servers.

To view this administrative console page, click **Servers > Application Servers > *server_name* > Scheduler Service**.

Startup:

Specifies whether the server attempts to start the scheduler service.

Default	Selected
Range	Selected When the application server starts, it attempts to start the scheduler service automatically.
	Cleared The server does not try to start the scheduler service. If scheduler resources are to be used on this server, the system administrator must start the scheduler service manually or select this property, then restart the server.

Managing schedulers

Schedulers are configured using the administrative console, configuration service or scripting and are available to all servers on which a scheduler is visible.

You can create multiple schedulers within a single server, cluster, node or cell. Each configured scheduler is an independent task scheduling engine that has a unique Java Naming and Directory Interface (JNDI) name, persistent storage device and daemon.

1. Configure schedulers.
2. Create the database for schedulers.

Configuring schedulers

Before your application can make use of the scheduler service, you must configure a scheduler using the administrative console, configuration service or scripting. Conceptually, a scheduler is similar to a data source in that you must specify various configuration attributes, including a JNDI name where the instance is bound. Once defined, an application using the Scheduler API or `WASScheduler` MBean can look up the scheduler object and call various methods to manage tasks.

The scheduler service is always enabled. In previous versions of the product, the scheduler service could be disabled using the administrative console or configuration service. Scheduler service configuration objects are present in the configuration service, but the enabled attribute is ignored.

To achieve high availability, you can configure a duplicate scheduler on each server in a cluster, or create a scheduler at the cluster scope. For example, each server that contains a scheduler with the JNDI name `sched/MyScheduler`, with the same database configuration parameters (data source and table prefix) behaves as a single clustered scheduler. Each server in the scheduler cluster has a running scheduler instance, which increases the number of poll daemons and allows automatic failover. For more information on creating clusters for high availability, see the article, "WebSphere Enterprise Scheduler planning and administration guide."

Typically, create schedulers at the server or cluster scope. Scheduler poll daemons run in each server within the configured scope, which means that if you create a scheduler at the node or cell scope, the scheduler poll daemon can attempt to run tasks on any of the servers in the node or cell. If applications are not mapped uniformly over each server in that scope, the scheduler might not run tasks correctly. Since applications are mapped to servers and clusters, there is less chance for error and less competition between daemons to run tasks.

Depending on your preferred method of configuration, select one of the following steps to configure schedulers.

1. Configuring schedulers using the administrative console.
2. Configuring schedulers using Java Management Extensions API (JMX).

A scheduler is configured and ready to use.

Configuring scheduler default transaction isolation:

The scheduler uses read-committed transaction isolation, by default, when reading tasks using the `get` or `find` APIs on the `com.ibm.websphere.scheduler.Scheduler` interface and `WASScheduler` MBean. The default behavior for a scheduler can be changed to read-uncommitted, which allows the `get` and `find` methods to return the current or next state of the task in the database. This topic describes how to change the default behavior for the `get` and `find` methods.

See the scheduler API documentation to view the `com.ibm.websphere.scheduler.TaskInfo.setTaskExecutionOptions()` method, which details how to return the next state of the task or the current state of the task.

Note: If the scheduler database does not support uncommitted reads, such as Oracle, this parameter has no effect.

To change the default behavior for the `get` and `find` methods, complete the following steps:

1. From the administrative console, click **Resources** > **Schedulers** > `scheduler_name`.
2. Click **Custom Properties**.
3. Click **New**.
4. Add the following properties:

Name	<code>defaultReadTransactionIso</code>
Type	<code>java.lang.Integer</code>
Value	1 (for read-uncommitted transaction isolation) 2 (for read-committed transaction isolation)

5. Click **Apply**.
6. Click **OK**.

7. Save the changes, and verify that you initiate a file synchronization before restarting the servers.
8. Restart the Application Server for the changes to take effect.

Configuring schedulers using the administrative console:

Schedulers can be created or configured using the administrative console.

1. Start the administrative console.
2. Select **Resources > Schedulers**.
3. Click **New**.
4. Specify configuration settings. Fields marked with an asterisk (*) are required. The settings are described in detail in the topic "Scheduler settings."
5. Click OK or Apply to save the changes.
6. Save the changes to the configuration repository.

A scheduler is now configured and ready to use for newly installed applications. If the scheduler JNDI name is not yet visible to your application, restarting the application or restarting application server will allow the scheduler to be seen.

When schedulers are created for the first time, the poll daemon will not automatically start and must be started manually and will only start automatically the next time the server is started. To start the poll daemon manually, see the scheduler daemons topic.

Note: Changes to existing scheduler configurations will not take affect until after the application server is restarted.

Schedulers collection:

Use this page to manage scheduler configurations. Schedulers are persistent and transactional timer services that can run business logic. Each scheduler runs tasks independently and has a programming interface accessible from J2EE applications using the Java Naming and Directory Interface (JNDI). You can also manage schedulers using a Java Management Extensions (JMX) MBean. See the scheduler documentation in the Information Center for details on how to configure and use schedulers.

To view this administrative console page, click **Resources > Schedulers**.

Name:

Specifies the name of the data source where persistent tasks are stored.

Data type String

JNDI name:

Specifies the JNDI name of the work manager, which is used to manage the number of tasks that can run concurrently with the scheduler. The work manager also can limit the amount of J2EE context applied to the task.

The JNDI name specifies where this scheduler instance is bound in the name space. Clients can look this name up directly, although the use of resource references is recommended.

Data type String

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Data source JNDI name:

Specifies the alias for the user name and password that are used to access the data source.

Any data source available in the name space can be used with a scheduler. Multiple schedulers can share a single data source while using different tables by specifying a table prefix.

Data type String

Table prefix:

Specifies the string prefix to affix to the scheduler tables.

Multiple independent schedulers can share the same database if each instance specifies a different prefix string.

Data type String

Poll interval:

Specifies the interval, in seconds, that a scheduler polls the database. The default value is appropriate for most applications.

Each poll operation can be consuming. If the interval is extremely small and there are many scheduled tasks, polling can consume a large portion of system resources.

Data type	Integer
Units	Seconds
Default	30
Range	Any positive long integer

Work manager JNDI name:

Specifies the JNDI name of the work manager, which is used to manage the number of tasks that can run concurrently with the scheduler. The work manager also can limit the amount of J2EE context applied to the task.

The work manager is a server object that serves as a logical thread pool for the scheduler. Each repeating task that is created using this scheduler uses the **Number of alarm threads** specified in the work manager, which affects the number of tasks that can run concurrently. Use the work manager **Service Names** property to limit the amount of context information that is propagated to the task when it runs.

When a task runs, the task is run in the work manager associated with the scheduler instance. You can control the number of actively running tasks at a given time by configuring schedulers with a specific work manager. The number of tasks that can run concurrently is governed by the **Number of alarm threads** parameter on the work manager.

Note: When you configure a scheduler resource on a Version 5.x node or server, the scheduler must reference a work manager in the same scope. For example, a scheduler instance configured at the server1 scope must use a work manager also configured at the server1 scope.

Verify tables:

Specifies to validate that scheduler data sources, table prefixes, security authentication information and tables are configured correctly.

You can use this verification method in production and development environments without altering database properties.

Create tables:

Specifies to create the necessary tables and indices required for a scheduler to operate.

This method of creating scheduler tables is designed for simple topologies and development environments. Use the supplied scheduler data definition language files for advanced or production environments and for databases that do not support this feature. .

Drop tables:

Specifies the removal of tables and indices required for schedulers to operate.

This method of removing scheduler tables and indices is recommended for development environments and does not delete previously scheduled tasks.

Schedulers settings:

Use this page to modify scheduler settings.

To view this administrative console page, click **Resources > Schedulers > scheduler_name**.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

Specifies the name by which this scheduler is known for administrative purposes.

Data type String

JNDI name:

Specifies the name of the data source where persistent tasks are stored.

The JNDI name specifies where this scheduler instance is bound in the namespace. Clients can look this name up directly, although the use of resource references is recommended.

Data type String

Description:

Specifies the description of this scheduler for administrative purposes.

Data type String

Category:

Specifies a string that can be used to classify or group this scheduler.

Data type String

Data source JNDI name:

Specifies the name of the data source where persistent tasks are stored.

Any data source available in the name space can be used with a scheduler. Multiple schedulers can share a single data source while using different tables by specifying a table prefix.

Data type String

Data source alias:

Specifies the alias for the user name and password that are used to access the data source.

Data type String

Table prefix:

Specifies the string prefix to affix to the scheduler tables. Multiple independent schedulers can share the same database if each scheduler specifies a different prefix string.

Multiple independent schedulers can share the same database if each instance specifies a different prefix string.

Note: Use a table prefix with all capital characters. If lowercase characters are used for the table prefix, they are automatically capitalized at run time.

Data type String

Poll interval:

Specifies the interval, in seconds, that a scheduler polls the database. The default value is appropriate for most applications.

Each poll operation can be consuming. If the interval is extremely small and there are many scheduled tasks, polling can consume a large portion of system resources.

Data type	Integer
Units	Seconds
Default	30
Range	Any positive long integer

Work manager JNDI name:

Specifies the JNDI name of the work manager, which is used to manage the number of tasks that can run concurrently with the scheduler. The work manager also can limit the amount of J2EE context applied to the task.

The work manager is a server object that serves as a logical thread pool for the scheduler. Each repeating task that is created using this scheduler uses the **Number of alarm threads** specified in the work manager, which affects the number of tasks that can run concurrently. Use the work manager **Service Names** property to limit the amount of context information that is propagated to the task when it runs.

When a task runs, the task is run in the work manager associated with the scheduler instance. You can control the number of actively running tasks at a given time by configuring schedulers with a specific work manager. The number of tasks that can run concurrently is governed by the **Number of alarm threads** parameter on the work manager.

Note: When you configure a scheduler resource on a Version 5.x node or server, the scheduler must reference a work manager in the same scope. For example, a scheduler instance configured at the server1 scope must use a work manager also configured at the server1 scope.

Use administration roles:

Specifies that when this option and administrative security are both enabled, the user administration roles are enforced when the scheduler JMX commands or APIs are used to create and modify tasks. If this option is not enabled, all the users can create and modify tasks.

Schedulers require several user roles to plan for, develop, administer and operate the scheduler service: administrator, developer and operator.

Data type	check box
Default	unchecked
Range	<ul style="list-style-type: none">• Operator, Administrator --Calls any of the scheduler MBean or API methods and runs any of the scheduler administrative console functions.• Monitor, Configurator --Calls the scheduler MBean or API methods, but cannot create tasks or modify the state of any tasks. Only read-only methods and properties are accepted.

Configuring schedulers using Java Management Extensions:

Schedulers can be created or configured using the Java Management Extensions (JMX) API using one of several scripting languages or Java.

To run with Java, two JAR files need to be present in the program class path: `wsexception.jar` and `wasjmx.jar`.

Complete these steps when using Java programs that utilize JMX.

1. Look up the host and get an administration client handle.
2. Get a configuration service handle.
3. Update the `resource-pme.xml` file using the configuration service, as needed.
 - a. Find the SchedulerProvider for a given scope.
 - b. Create a SchedulerConfiguration and specify all required parameters identifying the SchedulerProvider as the parent object.
4. Reload the `resource-pme.xml` file to bind the newly created scheduler into the JNDI namespace. Perform this step if you want to use the newly created scheduler immediately, without restarting the application server.
 - a. Locate the DataSourceConfigHelper MBean using the name.
 - b. Invoke the reload() operation.

A scheduler is now configured and ready to use for newly installed applications. If the scheduler JNDI name is not yet visible to your application, reinstalling the application or restarting the application server will allow the scheduler to be seen.

When schedulers are created for the first time, the poll daemon does not automatically start, and you must start it manually. When you restart the server, the poll daemon starts automatically. To start the poll daemon manually, see scheduler daemons.

Note: Changes to existing scheduler configurations will not take effect until after the application server is restarted.

Example: Using scripting to create and configure schedulers:

Use the wsadmin scripting tool to invoke a Jac1 script and create a SchedulerConfiguration resource.

The following Jac1 example script can be invoked using the wsadmin scripting tool, which creates a SchedulerConfiguration resource using the DefaultWorkManager at the server scope.

```
# Example JACL Script to create a SchedulerConfiguration
# at the server scope

# Change the cell, node and server to match your environment
set cellName MyCell
set nodeName MyNode
set serverName server1

# We can just grab the first provider, since there is only one at the
# server scope level.

set schedProv [$AdminConfig getid /Cell:$cellName/Node:$nodeName/Server:$serverName/
SchedulerProvider:SchedulerProvider]
if {$schedProv == ""} {
    puts "Unable to find SchedulerProvider for server: $serverName. Aborting."
    exit
}
puts "Found a SchedulerProvider"

# Create a WorkManager for our scheduler at the server scope.
# We could use any of the other scopes as long as it is at the same
# or higher than the Scheduler's scope.

set wrkMgrProv [$AdminConfig getid /Cell:$cellName/Node:$nodeName/Server:$serverName/
WorkManagerProvider:WorkManagerProvider/]
if {$wrkMgrProv == ""} {
    puts "Unable to find the WorkManagerProvider for server: $serverName. Aborting."
    exit
}
puts "Found a WorkManagerProvider"

set wmName "MyScheduler WorkManager"
set wmJNDIName "wm/MySchedWorkManager"
set wmIsGrowable false
set wmMaxThreads 1
set wmMinThreads 0
set wmNumAlarmThreads 10
set wmServiceNames "com.ibm.ws.i18n;security;UserWorkArea;zos.wlm"
set wmThreadPriority 5

# Setup our DefaultWorkManager attributes
set createAttrs [subst { \
    {isGrowable $wmIsGrowable} \
    {jndiName $wmJNDIName} \
    {maxThreads $wmMaxThreads} \
    {minThreads $wmMinThreads} \
    {name "$wmName"} \
    {numAlarmThreads $wmNumAlarmThreads} \
    {serviceNames "$wmServiceNames"} \
    {threadPriority $wmThreadPriority} ]}]
```

```

puts "Creating a WorkManager"
$AdminConfig create WorkManagerInfo $wrkMgrProv $createAttrs
puts "WorkManager Created"

# Setup our SchedulerConfiguration attributes
set schedulerName          MyScheduler
set schedulerJNDIName      sched/MyScheduler
set datasourceJNDIName     jdbc/MySchedulerDatasource
set datasourceAlias        MySchedulerAlias
set pollInterval           30
set tablePrefix            MSCD
set useAdminRoles          true

set createAttrs [subst { \
  {name $schedulerName} \
  {datasourceJNDIName $datasourceJNDIName} \
  {datasourceAlias $datasourceAlias} \
  {jndiName $schedulerJNDIName} \
  {pollInterval $pollInterval} \
  {tablePrefix $tablePrefix} \
  {useAdminRoles true} \
  {workManagerInfoJNDIName $wmJNDIName}}]

puts "Creating a Scheduler"
$AdminConfig create SchedulerConfiguration $schedProv $createAttrs
puts "Scheduler created"

# Save the configuration
$AdminConfig save

```

“Configuring schedulers using Java Management Extensions” on page 2114

Schedulers can be created or configured using the Java Management Extensions (JMX) API using one of several scripting languages or Java.

Using scripting (wsadmin)

The WebSphere administrative (wsadmin) scripting program is a powerful, non-graphical command interpreter environment enabling you to run administrative operations in a scripting language.

Creating a scheduler resource reference:

When you define schedulers in the server configuration, the object instance is bound into the global name space under the configured Java Naming Directory Interface (JNDI) name. You can use a resource reference to avoid manually coding this JNDI name into your application. Using a resource reference allows administrators to map applications to the appropriate schedulers.

You can alternatively create a scheduler resource reference by editing the XML directly. A Scheduler resource reference is a Java 2 Platform Enterprise Edition (J2EE) compliant resource that uses the class `com.ibm.websphere.scheduler.Scheduler` as the object type. For information regarding the XML file format, see the J2EE Specification.

1. Start an assembly tool, such as Application Server Toolkit or Rational Application Developer.
2. Open the J2EE perspective.
3. Open your EJB or Web module with the Deployment Descriptor Editor.
4. Click the **Reference** tab at the bottom of the window.
5. Click **Add**.
6. Select the **Resource reference** option.
7. Click **Next**.
8. Complete the Reference fields as shown in the following properties:

Name The reference name, for example, *sched/MyScheduler*. According to this example, the name you choose has a local reference name of **java:comp/env/sched/MyScheduler**.

Type Select **com.ibm.websphere.scheduler.Scheduler**, and click **OK**.

Authentication

Select container.

Description

Any relevant description.

9. Click finish.
10. **(Optional)** Enter a global JNDI name of a configured scheduler in the JNDI name field in the **Bindings** section of the **Reference** window. You can specify or override this value when you install the application.
11. Save your changes to the deployment descriptor.

A scheduler resource reference is now available to use within your application

Creating the database for schedulers

Each scheduler requires a database in which to store its persistent information. Schedulers use this database for storing tasks and then running them. The choice of database and location should be determined by the application developer and server administrator.

Scheduler performance is ultimately limited by database performance. If you need more tasks per second, you can run the scheduler daemons on larger systems, use clusters for the session beans used by the tasks or partition the tasks by using multiple schedulers. Eventually, however, the scheduler database becomes saturated, and a larger or better-tuned database system is needed. For detailed information on scheduler topologies see the technical paper, "WebSphere Enterprise Scheduler planning and administration guide".

Multiple schedulers can share a database when you specify unique table prefix values in each scheduler configuration. This sharing can lower the cost of administering scheduler databases.

Complete the following steps to create scheduler databases.

1. Create a database. To create the database for a scheduler or to determine if an existing database is adequate for a scheduler, review the topic, "Create scheduler databases".
2. Create the scheduler tables. There are three methods for creating the tables for a scheduler:
 - a. Create tables for schedulers using the administrative console. Use the administrative console to add, delete and verify database tables through your Web browser. This method is ideal for developers and simple scheduler topologies.
 - b. Create tables for schedulers using JMX or scripting.
Use JMX to add, delete and verify database tables programmatically with Java or scripting. This method is ideal for automating scheduler configurations for simple scheduler topologies.
 - c. Create tables for schedulers using DDL files. Manually edit the DDL files through your favorite text editor, and verify that mapping between the table names and the scheduler resources and data sources is correct.

Creating scheduler databases:

The scheduler uses the scheduler database for storing and running tasks. To create a scheduler database, your database system must be installed and available.

The performance of schedulers is ultimately limited by the performance of the database. If you need more tasks per second, you can run the scheduler daemons on larger systems or you can use clusters for the session beans used by the tasks. Eventually, however, the task database becomes saturated and you then need a larger or better-tuned database system.

Multiple applications can share a scheduler database. This sharing can lower the cost of administering scheduler databases.

The scheduler requires a database, a JDBC provider, and a data source.

1. Create the database according to the description for your database system:
 - Creating a Cloudscape database for schedulers.
 - Creating a DB2 database for schedulers.
 - Creating a DB2 database for z/OS for schedulers.
 - Creating a DB2 for iSeries database for schedulers.
 - Creating an Informix database for schedulers.
 - Creating a Microsoft SQL Server database for schedulers.
 - Creating an Oracle database for schedulers.
 - Creating a Sybase database for schedulers.
2. If the database is not on the same machine as your IBM WebSphere Application Server, verify that you can access the database from your application server machine.
3. Configure your JDBC provider and data source. For details, see the topic *Creating and configuring a JDBC provider and data source*. The JDBC driver can be either one-phase or two-phase commit depending on whether other transactions take place using other data sources, for example, while using the scheduler. The data source can represent multiple versions of the product.

The database is created and ready for you to create scheduler tables.

Creating Cloudscape databases for schedulers:

This topic describes how to create Cloudscape databases for schedulers using data definition language (DDL) or structured query language (SQL) files.

To create Cloudscape databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Open a command-line window.
2. Verify that you have administrator rights for the database system.
3. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in Java code, which results in code page conversion problems when a client uses an incompatible code page.
4. Use the `ij` utility supplied with the Cloudscape system to create the database. To use `ij` to create a database called `scheddb` which is located in `/opt`, for example, you would do the following:

```
ij.sh
ij>connect '/opt/scheddb;create=true';
ij>quit;
```

The embedded version of Cloudscape supports only one local connection. If the Application Server product is running and accessing a Cloudscape database, then any attempts to open a second connection to the database from the command line are rejected.

Note: Add a semi-colon (;) at the end of each command. Otherwise, `ij` does not execute the command.

5. Exit the `ij` utility by issuing the quit command: `quit;`

The Cloudscape database for the scheduler service exists.

Creating DB2 databases for schedulers:

This topic describes how to create DB2 databases for scheduler, using data definition language (DDL) or structured query language (SQL) files.

To create DB2 databases for scheduler, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Open a DB2 command-line window.
2. Make sure that you have administrator rights for the database system.
3. Verify that the database supports Unicode (UTF-8). Otherwise, it cannot store all the characters that can be handled in Java code, which might result in code page conversion problems, when a client uses an incompatible code page.

To avoid deadlocks, be sure that the DB2 isolation level is set to "read stability". If necessary, enter the command

```
db2set DB2_RR_TO_RS=YES
```

then restart the DB2 instance to activate the change.

4. In the DB2 command line processor, enter this command to create the database with an example name, scheddb:

```
db2 CREATE DATABASE scheddb USING CODESET UTF-8 TERRITORY en-us
```

A DB2 database named scheddb has been created.

The DB2 database for the scheduler exists.

Creating DB2 for z/OS databases for schedulers:

This topic describes how to create DB2 for z/OS databases for schedulers using data definition language (DDL) or structured query language (SQL) files.

To create DB2 for z/OS databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. You must have a DB2 subsystem installed in the z/OS platform on a UNIX or Windows machine.
2. On the z/OS machine that hosts the database:
 - a. Log on to the native z/OS environment.
 - b. If multiple DB2 systems are installed, then decide which subsystem you want to use.
 - c. Create a storage group and note the name.
 - d. Decide which user ID is used to connect to the database from the remote machine running the product. Normally, for security reasons, this user ID is not the one you used to create the database.
 - e. Grant the user ID the rights to access the database and storage group. The user ID must also have permission to create new tables for the database.
3. On the server machine:
 - a. Change to the *Scheduler* subdirectory in the application server installation root directory.
 - b. Edit the createTablespaceDB2ZOS.dd1 script. Replace @STG@ with the storage group name. Replace @DBNAME@ with the database name (not the subsystem name), and replace @SCHED_TABLESPACE@ with the name of a valid tablespace.
 - c. Run your customized version of createTablespaceDB2ZOS.dd1, as described in the header of the script.
 - d. To avoid deadlocks, verify that the DB2_RR_TO_RS DB2 flag is set to **YES**. If necessary, restart the DB2 instance to activate the change.

The DB2 for z/OS database for the scheduler service is created.

Creating DB2 for iSeries databases for schedulers:

This topic describes how to create DB2 for iSeries databases for scheduler, using data definition language (DDL) or structured query language (SQL) files.

To create DB2 for iSeries databases for scheduler, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Run the following command to start an interactive SQL session:

```
STRSQL
```

2. In interactive SQL, enter this command to create the collection with an example name, scheddb:

```
CREATE COLLECTION scheddb
```

3. Exit the interactive SQL session.

4. Change the owner for the new collection to QEJBSVR by executing the following command:

```
CHGOBJOWN OBJ(scheddb) OBJTYPE(*LIB) NEWOWN(QEJBSVR)
```

where scheddb is the name of the collection you created in the previous step.

The DB2 for iSeries database for the scheduler exists.

Creating Informix databases for schedulers:

This topic describes how to create Informix databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

To create Informix databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Open a command-line window.
2. Verify that you have administrator rights for the database system.
3. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible code page.
4. If you want to create a new database named scheddb, for example, enter the command:

```
dbaccess CREATE DATABASE scheddb with log
```

The Informix database for scheduler exists.

Creating Microsoft SQL Server databases for schedulers:

This topic describes how to create Microsoft SQL Server databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

To create Microsoft SQL Server databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Make sure that you are using a user ID that has administrator rights for the database system.
2. In the **Enterprise Manager**, expand a server group, then expand a server. A Microsoft SQL Server database named scheddb is created.
3. Right-click **Databases**, then click **New Database**.
4. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible codepage.
5. Type the name scheddb.

6. Modify any default values, and save your changes. The Microsoft SQL Server database, scheddb, is created.

The Microsoft SQL Server database for scheduler exists.

Creating Oracle databases for schedulers:

This topic describes how to create Oracle databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

To create Oracle databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible code page.
4. Use the Database Configuration Assistant to create the database, scheddb, for example. Verify that you select the **JServer** option for the database. Use a Unicode code page when creating the database. The text data you pass to the APIs must be compatible with the selected code page.

The Oracle database for scheduler exists.

Creating Sybase databases for schedulers:

This topic describes how to create Sybase databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

This topic describes how to create Sybase databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Make sure that you have the DTM option for Sybase ASE installed.
4. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible code page.
5. Use the Sybase isql utility to create the database, scheddb, for example. See your Sybase product documentation for details.

The Sybase database for the scheduler exists.

Scheduler table management functions:

The administration console and the WASSchedulerConfiguration MBeans provide simplified methods for creating scheduler tables and schema, verifying that the scheduler tables and schema are setup properly and are accessible and removing scheduler tables and schema.

When connecting to a deployment manager or node agent, the operation attempts to verify, create, or drop the tables based on the most granular scope where the scheduler and associated data source is located. If a scheduler is configured at the server scope, the data source at the node scope, and the verify tables operation is being run from a deployment manager for example, the deployment manager attempts to connect to server1 and run the operation there. If the server is unavailable, then it attempts to verify at the node agent level and then at the deployment manager level.

Note: There are limitations when running the table management functions relating to data source access. See the Verifying a connection topic for details on these limitations. If a connection cannot be verified successfully, the scheduler table management functions will fail.

Verify tables

Validates that scheduler data sources, table prefixes, security authentication information and tables are configured correctly. You can use this verification method in production and development environments without altering database properties.

Create tables

Creates the necessary tables and indices required for schedulers to operate. This method of creating scheduler tables is designed for simple topologies and development environments. Use the supplied scheduler data definition language files for advanced or production environments and for databases that do not support this feature. For details, see the topic Creating scheduler tables using the administrative console.

Drop tables

Specifies the removal of tables and indices required for schedulers to operate. This method of removing scheduler tables and indices is recommended for development environments. When you drop tables, the action removes all previously scheduled tasks, and the scheduler no longer operates successfully, until the tables are recreated.

Scheduler table definition:

Schedulers require database tables and indices with a table prefix. This page provides reference information about the tables.

Each scheduler requires several database tables and indices to operate. Each table name and index described in this topic requires a table prefix. For example, if the scheduler is configured with a table prefix value, **SCHED_**, the table with the name, **TASK**, would be named **SCHED_TASK**. See Scheduler settings for details on the table prefix.

To create the tables, see Creating the database for schedulers. To see the exact schema definition such as field sizes and types, see Creating scheduler tables using DDL files. This section references the location where the DDL or SQL statements are stored. These statements create the table schema.

Note: The information in this topic is provided for problem determination. Do not alter the scheduler table names, field names or index names. The data content format might change without notice. Be aware of this factor when accessing the tables directly. Modifying data in the tables without using the Scheduler API might cause failures.

TASK

The TASK table contains the tasks that have been scheduled, but not yet purged. The primary key for this table is the TASKID which equates to the getTaskID() method on the com.ibm.websphere.scheduler.TaskStatus interface.

Since there is one row in this table for each task, it is important that the database and table support row-locking. Using page, or table locks, inhibits the scheduler from running tasks concurrently.

Field name	Purpose and notes
------------	-------------------

TASKID	Contains all of the tasks that have been scheduled, but not yet purged. The primary key for this table is TASKID which equates to the <code>getTaskID()</code> method on the <code>com.ibm.websphere.scheduler.TaskStatus</code> interface. Since there is one row in this table for each task, it is important that the database and table support row-locking. Using page, or table locks, will inhibit the scheduler from running tasks concurrently.
VERSION	Internal version ID of this row format.
ROW_VERSION	The version of this row. Used for optimistic locking.
TASKTYPE	The type of task: 1 =BeanTaskInfo, 2 =MessageTaskInfo
TASKSUSPENDED	This value indicates if the task is suspended or if it is running. The task is suspended if the value BITWISE AND 1 equals 1 . The task is running if the value BITWISE AND 2 equals 2 .
CANCELLED	The value, 1 , if the task is cancelled.
NEXTFIRETIME	The date in milliseconds using <code>java.util.Date.getTime()</code> when the task is scheduled to run next.
STARTBYINTERVAL	The start-by-interval of the task.
STARTBYTIME	Reserved.
VALIDFROMTIME	The task start time.
VALIDTOTIME	Reserved.
REPEATINTERVAL	The task repeat interval.
MAXREPEATS	The number of times to run the task.
REPEATSLEFT	The number of times the task has yet to run.
TASKINFO	Internal binary data.
NAME	The task name.
AUTOPURGE	The value, 1 , if the task is to automatically purge upon completion.
FAILUREACTION	Reserved.
MAXATTEMPTS	Reserved.
QOS	Reserved.
PARTITIONID	Reserved.
OWNERTOKEN	The task owner.
CREATETIME	The time in milliseconds using <code>java.util.Date.getTime()</code> when the task was created.

The TASK table also has the following indices that are required to allow the scheduler to run and access tasks concurrently:

- TASK_IDX1 – Used to access individual tasks using the Scheduler API.
- TASK_IDX2 – Used by the poll daemon to load expiring tasks.

TREG

The TREG table is used to store scheduler information that is shared between redundant schedulers. This table is not highly used.

Field name	Purpose and notes
REGKEY	The registry key. This is the primary key of the table.
REGVALUE	The registry value.

LMGR

The LMGR table is used to track the leases that redundant schedulers use. This table is not highly used.

Field name	Purpose and notes
LEASENAME	The name of the lease. This is the scheduler JNDI name and is the primary key.
LEASEOWNER	The owner of the lease. The format is Cell/Node/Server.
LEASE_EXPIRE_TIME	The time in milliseconds using java.util.Date.getTime() when the lease for the scheduler expires.
DISABLED	Reserved.

LMPR

The LMPR table is used to store arbitrary properties for the lease. This table is not highly utilized.

Field name	Purpose and notes
LEASENAME	The name of the lease. See the LMGR table.
NAME	The name of the property.
VALUE	The value of the property.

The LMPR table also has the following index:

- LMPR_IDX1 – Used to retrieve properties for a given lease.

Creating scheduler tables using the administrative console:

To create scheduler tables using the administrative console, the scheduler requires a database, a Java DataBase Connectivity (JDBC) provider and a data source.

Note: Limitations for Oracle XA databases

Oracle XA prohibits required schema operations in a global transaction environment. Local transactions are not supported. If you have schedulers that use an Oracle XA data source, either temporarily change the scheduler configuration to use a non-XA Oracle data source, or create the tables manually using the supplied DDL files. If you use the administrative console to create or drop scheduler tables for a scheduler configured to use an Oracle XA data source, then you receive a SchedulerDataStoreException error message, and the operation fails.

Note: Limitations for DB2 z/OS databases

Creating and dropping tables using the administrative console is not supported for DB2 z/OS databases. A database administrator is typically involved with defining and managing databases on DB2 z/OS systems. The administration interface is targeted for the non-database administrator or developer who does not want to know the specifics of setting up the scheduler database. The scheduler has DDL files available for the database administrator to create the required tables.

1. Verify that the database to be used for this scheduler is available and accessible by the application server. Review the Creating scheduler databases and tables topic for instructions on creating a database. The remaining steps describe how to create scheduler tables in an existing database.
2. Start the administrative console.
3. Create a JDBC data source that refers to the scheduler database.
4. Test the data source connection.
5. Create a scheduler. This configuration object contains the desired table prefix and the JNDI name of the JDBC data source. Verify that you save the new Scheduler to the configuration repository before you proceed to the next step.
6. Click **Resources > Schedulers** to view all defined schedulers.
7. Select one or more schedulers.
8. Click **Create Tables** to create the tables for the selected schedulers in their associated database. The tables and indices you created reflect the table prefixes and data sources specified in each scheduler configuration.
9. Restart the server or start the poll daemon to run scheduler tasks.

Scheduler tables and schema are created.

Creating scheduler tables using scripting and Java Management Extensions:

Creating scheduler tables using scripting and Java Management Extensions requires a database, a JDBC provider, and a data source.

Note: Limitations for Oracle XA databases

Oracle XA prohibits required schema operations in a global transaction environment. Local transactions are not supported. If you have schedulers that use an Oracle XA data source, either temporarily change the scheduler configuration to use a non-XA Oracle data source, or create the tables manually using the supplied DDL files. If you use the administrative console to create or drop scheduler tables for a scheduler configured to use an Oracle XA data source, then you receive a SchedulerDataStoreException error message, and the operation fails.

Note: Limitations for DB2 z/OS databases

Creating and dropping tables using the administrative console is not supported for DB2 z/OS databases. A database administrator is typically involved with defining and managing databases on DB2 z/OS systems. The administration interface is targeted for the non-database administrator or developer who does not want to know the specifics of setting up the scheduler database. The scheduler has DDL files available for the database administrator to create the required tables.

1. Verify that the database to be used for this Scheduler is available and accessible by the application server. Review the Creating scheduler databases and tables topic for instructions on creating a database. The remainder of these steps describe how to create scheduler tables in an existing database.
2. Launch the wsadmin tool and connect to a deployment manager or application server. This process requires an active server to be available and fails, if you are disconnected from the server.
3. Create a JDBC data source that refers to the scheduler database.
4. Test the data source connection.
5. Create a scheduler. This configuration object contains the desired table prefix and the JNDI name of the JDBC data source. Verify that you save the new Scheduler to the configuration before you proceed to the next step.
6. Run the **createTables** MBean operation.
 - a. Look up the SchedulerConfiguration object or use the object you created in a previous step.

- b. Locate the **WASSchedulerConfiguration** MBean.
 - c. Run one of the **createTables** MBean operation on the **WASSchedulerConfiguration** object to create the tables for the specified **SchedulerConfiguration** object in its associated database. The tables and indices that you created reflect the table prefix and data source specified in the scheduler configuration.
7. Restart the server or start the poll daemon to run scheduler tasks.

Scheduler tables and schema are created.

Example: Using scripting to verify scheduler tables:

Use the wsadmin scripting tool to invoke a Jac1 script and verify tables and indices for a scheduler.

The following Jac1 example script can be invoked using the wsadmin scripting tool, which verifies that the tables and indices are created correctly for a scheduler. See the “Configuring Schedulers” topic for details on how a scheduler is created.

```
# Example JACL Script to verify the scheduler tables

# The name of the scheduler to verify
set schedName "My Scheduler"

puts ""
puts "Looking-up Scheduler Configuration Helper MBean"
puts ""
set schedHelper [$AdminControl queryNames WebSphere:*,type=WASSchedulerCfgHelper]

#Access the configuration object.
set myScheduler [$AdminConfig getid /SchedulerConfiguration:$schedName/]

if {$myScheduler == ""} {
    puts ""
    puts "Error: Scheduler $schedName could not be found."
    puts ""
    exit
}

# Invoke the verifyTables method on the helper MBean.

puts ""
puts "Verifying tables for:"
puts "$myScheduler"
puts ""

if { [catch {$AdminControl invoke $schedHelper verifyTables $myScheduler} errorInfo] } {
    puts ""
    puts "Error verifying tables: $errorInfo"
    puts ""
} else {
    puts ""
    puts "Tables verified successfully."
    puts ""
}
}
```

Example: Using scripting to create scheduler tables:

Use the wsadmin scripting tool to invoke a JACL script and create scheduler tables.

The following JACL example script can be invoked using the wsadmin scripting tool, which creates the scheduler tables for a configured scheduler. See the “Configuring Schedulers” topic for details on how to create a scheduler.

```
# Example JACL Script to create the scheduler tables

# The name of the scheduler to create tables for
set schedName "My Scheduler"

puts ""
puts "Looking-up Scheduler Configuration Helper MBean"
puts ""
set schedHelper [$AdminControl queryNames WebSphere:*,type=WASSchedulerCfgHelper]

#Access the configuration object.
set myScheduler [$AdminConfig getid /SchedulerConfiguration:$schedName/]

if {$myScheduler == ""} {
    puts ""
    puts "Error: Scheduler with name: $schedName could not be found."
    puts ""
    exit
}

# Invoke the createTables method on the helper MBean.

puts ""
puts "Creating tables for:"
puts "$myScheduler"
puts ""

if {[catch {
    set result [$AdminControl invoke $schedHelper createTables $myScheduler]
    if {$result} {
        puts ""
        puts "Successfully created the tables."
        puts ""
    } else {
        puts ""
        puts "The tables were already created."
        puts ""
    }
} errorInfo ]} {
    puts ""
    puts $errorInfo
    puts ""

The administration console and the WASSchedulerConfiguration MBeans provide simplified methods for creating scheduler tables and schema, verifying that the scheduler tables and schema are setup properly and are accessible and removing scheduler tables and schema.

Creating scheduler tables using DDL files:

This topic provides the steps for creating scheduler tables using DDL files.

Your database system must be installed and available.

The scheduler requires a database, a JDBC provider, and a data source.

Complete the following steps to create scheduler tables using DDL files.

1. Verify that your database is created. See the topic “Creating scheduler databases.”
2. Create the database tables according to the instructions for your database system.
 - Creating Cloudscape tables for schedulers.
 - Creating DB2 tables for schedulers.
 - Creating DB2 tables for z/OS for schedulers.
 - Creating Informix tables for schedulers.
 - Creating Microsoft SQL Server tables for schedulers.
 - Creating Oracle tables for schedulers.
 - Creating Sybase tables for schedulers.

Creating Cloudscape tables for schedulers:

This topic describes how to create tables for schedulers on Cloudscape databases, using data definition language (DDL) or structured query language (SQL) files.

This task requires you to configure a database and make it available. See the “Creating Cloudscape databases for schedulers” topic, for more information.

To create tables for schedulers on Cloudscape databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Open a command-line window.
2. Create the schema.
 - a. Using a text editor, edit the script, `%app_server_root%\Scheduler\createSchemaCloudscape.ddl`, according to the instructions at the top of the file.

Note: When setting the table prefix, capitalize all characters.

- b. Enter one of the following commands.

Note: Cloudscape provides both an embedded and network server version. This example is for the embedded version of Cloudscape. See the Cloudscape product documentation for more details on running DDL scripts.

On Windows systems (using the example name, scheddb):

```
%app_server_root%\cloudscape\bin\embedded\ij.bat %app_server_root%\Scheduler\createSchemaCloudscape.ddl
```

On UNIX systems (using the example name, scheddb):

```
%app_server_root%/cloudscape/bin/embedded/ij.sh %app_server_root%/Scheduler/createSchemaCloudscape.ddl
```

The Cloudscape tables and schema for the scheduler exist.

Creating DB2 tables for schedulers:

This topic describes how to create tables for scheduler on DB2 databases, using data definition language (DDL) or structured query language (SQL) files.

This task requires you to configure a database and make it available. See the "Creating DB2 databases for schedulers" topic for more information.

To create tables for scheduler on DB2 databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Open a DB2 command-line window.
2. Verify that you have administrator rights for the database system.
3. Create the table space and schema.
 - a. Analyze the results of your experiences during development and system testing. The size of your database depends on many factors. If possible, distribute table space containers across different logical disks, and implement an appropriate security policy. Consider the performance implications of your choices for buffer pools and log file settings.
 - b. Using a text editor, edit the following scripts according to the instruction at the top of each file.

Note: When setting the table prefix, capitalize all characters.

```
%WAS_HOME%\Scheduler\createTablespaceDB2.ddl, %WAS_HOME%\Scheduler\createSchemaDB2.ddl,  
%WAS_HOME%\Scheduler\dropSchemaDB2.ddl, and %WAS_HOME%\Scheduler\dropTablespaceDB2.ddl.
```

- c. Verify that you are attached to the correct instance. Check the environment variable `DB2INSTANCE`.
- d. To connect to the database, scheddb, for example, and enter the command:
`db2 connect to scheddb`
- e. Create the table space. Enter the following command:
`db2 -tf createTablespaceDB2.ddl`

Verify that the script output contains no errors. If there were any errors, you can drop the table space using the following script:

```
dropTablespaceDB2.dd1
```

- f. To create the schema (tables and indices), in the DB2 command line processor, enter the command `db2 -tf createSchemaDB2.dd1`. Verify that the script output contains no errors. If there were any errors, you can use the following file to drop the schema:

```
dropSchemaDB2.dd1
```

- g. Verify that the `DB2_RR_TO_RS` DB2 flag is set to **YES** to avoid deadlocks. Restart the DB2 instance to activate the change, if needed.

The DB2 tables and schema for the scheduler exist.

Creating DB2 for z/OS tables for schedulers:

This topic describes how to create tables for a scheduler on a DB2 for z/OS database using data definition language (DDL) or structured query language (SQL) files.

This task requires that you configure a database and make it available. See the "Creating DB2 for z/OS databases for schedulers" topic for more information.

In addition, you must have the following two machines:

1. The z/OS machine that is hosting the database
2. The WebSphere Application Server machine that is running the scheduler

To create tables for a scheduler on a DB2 for z/OS database, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Work with the z/OS machine that hosts the database to:
 - a. Log on to the native z/OS environment.
 - b. Decide which subsystem you want to use, if multiple DB2 systems are installed.
 - c. Note of the Internet Protocol (IP) port to which the DB2 subsystem is listening.
 - d. Use the DB2 administration menu to create a new database named, for example, `SCHEDDB`. Note the database name.
 - e. Create a storage group and note the name.
 - f. Decide which user ID is used to connect to the database from the remote machine running the product. Normally, for security reasons, this user ID is not the one you used to create the database.
 - g. Grant the user ID the rights to access the database and storage group. The user ID must also have permission to create new tables for the database.
2. Work with the Application Server machine to:
 - a. Verify that you have DB2 Connect Gateway (Version 8.1 fix pack 3 or higher) installed. This component is part of the DB2 UDB ESE package; however, you can also install it separately.
 - b. Catalog the remote database using the following commands, either in a script or in a DB2 command line window:

```
catalog tcpip node zosnode remote hostname server IP_port ostype mvs;  
catalog database subsystem as subsystem at node zosnode authentication dcs;  
catalog dcs database subsystem as subsystem parms ',,INTERRUPT_ENABLED'
```

An important difference exists between DB2 UDB and DB2 for z/OS. DB2 UDB does not have the concept of a subsystem, but DB2 for z/OS does have subsystems. To avoid confusion between Database name and Subsystem name, remember that because DB2 for z/OS runs in a subsystem, the `catalog node` and `catalog database` commands must identify the appropriate subsystem. On DB2 UDB, the subsystem name is not a known concept, and the database name to which it connects is actually the name of the DB2 for z/OS subsystem.

- c. Verify that you can establish a connection to the remote subsystem by entering the following command:

db2 connect to **subsystem** user **userid** using **password**

- d. Change to the scheduler subdirectory in the application server installation root directory.
- e. Edit the createTablespaceDB2ZOS.dd1 script. Replace @STG@ with the storage group name. Replace @DBNAME@ with the database name (not the subsystem name), and replace @SCHED_TABLESPACE@ with the name of a valid table space. After you replace the database name, place it into an existing JCL and run the job.
- f. Run your customized version of createTablespaceDB2ZOS.dd1, as described in the header of the script. If this script does not work, or if you want to remove the table space, edit and run the dropTablespaceDB2ZOS.dd1 script.
- g. Edit the createSchemaDB2ZOS.dd1 script. Replace @STG@ with the storage group name. Replace @DBNAME@ with the database name (not the subsystem name). Replace @TABLE_PREFIX@ with the Table Prefix in the configured scheduler resource, and replace @SCHED_TABLESPACE@ with a valid table space that was created by the createTablespaceDB2ZOS.dd1 script.

Note: When setting the table prefix, capitalize all characters.

- h. Run your customized version of the createSchemaDB2ZOS.dd1 script, as described in the header of the script. If this script does not work, or if you want to remove the tables and views, use dropSchemaDB2ZOS.dd1 to drop the schema.
- i. To avoid deadlocks, verify that the DB2_RR_TO_RS DB2 flag is set to **YES**. If necessary, restart the DB2 instance to activate the change. In addition, verify that the table space was created with the LOCKSIZE ROW statement.

The DB2 for z/OS tables and schema for the scheduler exist.

Creating Informix tables for schedulers:

This topic describes how to create tables for schedulers on Informix databases, using data definition language (DDL) or structured query language (SQL) files.

This task requires that you configure a database and make it available. See the "Creating Informix databases for schedulers" topic for more information.

To create tables for schedulers on Informix databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Open a command-line window.
2. Verify that you have administrator rights for the database system.
3. Create the schema.
 - a. Using a text editor, edit the script %WAS_HOME%\Scheduler\createSchemaInformix.sql according to the instruction at the top of the file.

Note: When setting the table prefix, capitalize all characters.

- b. Enter the following command, using the database, scheddb, for example:

```
dbaccess scheddb createSchemaInformix.sql
```

The Informix tables and schema for the scheduler exist.

Creating Microsoft SQL Server tables for schedulers:

This topic describes how to create tables for schedulers on Microsoft SQL Server databases, using data definition language (DDL) or structured query language (SQL) files.

This task requires you to configure a database and make it available. See the "Creating Microsoft SQL Server databases for schedulers" topic for more information.

To create tables for schedulers on Microsoft SQL Server databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Open a command-line window.
2. Change to the directory where the configuration scripts for scheduler are located. This is the Scheduler subdirectory of the IBM WebSphere Application Server installation directory.

On Windows systems, enter:

```
cd %app_server_root%\Scheduler
```

On UNIX systems, enter:

```
cd $app_server_root/Scheduler
```

3. Use a text editor to edit the schema creation script, createSchemaMSSQL.sql, according to the instructions at the beginning of the file.

Note: When setting the table prefix, capitalize all characters.

4. Create the schema:
 - a. Verify that you have administrator rights for the database system. The user ID you use to create the schema must be the one that you configure WebSphere Application Server to use when accessing the database.
 - b. Run the following script to create the schema (tables and views) :

```
isql -S <servername> -U<userid> -P<password> -D<databaseName> -i<script name>
```

The Microsoft SQL Server tables and schema for scheduler exist.

Creating Oracle tables for schedulers:

This topic describes how to create tables for schedulers on Oracle databases, using data definition language (DDL) or structured query language (SQL) files.

This task requires you to configure a database and make it available. See the "Creating Oracle databases for schedulers" topic for more information.

To create tables for schedulers on Oracle databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Create the table space and schema.
 - a. Using a text editor, edit the following scripts according to the instructions at the top of the files.

Note: When setting the table prefix, capitalize all characters.

```
%app_server_root%\Scheduler\createTablespaceOracle.ddl and %app_server_root%\Scheduler\createSchemaOracle.ddl
```

- b. Set the environment variable ORACLE_SID, if you do not want the schema to be created in the default instance.
- c. Run the script, createTablespaceOracle.ddl, to create the table space.

For test purposes, use the same location for all table spaces and pass the path as a command line argument to the script. For example, on Windows systems, the user ID is scheduser, password is schedpwd, database name is scheddb, and table space path is d:\mydb\ts. Enter the command: sqlplus scheduser/schedpwd@scheddb @createTablespaceOracle.ddl d:\mydb\ts If you get any errors creating the table space, you can use dropTablespaceOracle.ddl to drop the table space.
- d. Run the script, createSchemaOracle.ddl, to create the schema. For example, on Windows systems, enter the following script:

```
sqlplus scheduser/schedpwd@scheddb @createSchemaOracle.ddl
```

If you see any errors creating the schema (tables and views), you can drop the schema by running script:

```
dropSchemaOracle.ddl
```

The Oracle tables and schema for scheduler exist.

Creating Sybase tables for schedulers:

This topic describes how to create tables for schedulers on Sybase databases, using data definition language (DDL) or structured query language (SQL) files.

This task requires you to configure a database and make it available. See the "Creating Sybase databases for schedulers" topic for more information.

To create tables for schedulers on Sybase databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Make sure that you have the Distributed Transaction Management (DTM) option for Sybase ASE installed.
 - a. Set enable DTM to **1** in the Sybase server configuration.
 - b. Set enable xact coordination to **1** in the Sybase server configuration.
 - c. Add the **dtm_tm_role** role to the Sybase administration user ID. For example, enter the user ID sa.
 - d. Restart the Sybase server.
4. Use the Sybase isql utility to create a database. For example, enter the database name scheddb. See your Sybase product documentation for details.
5. Create the schema:
 - a. Using a text editor, edit the following script according to the instructions located at the top of the file.

Note: When setting the table prefix, capitalize all characters.

```
<app_server_root>\Scheduler\createSchemaSybase12.ddl
```

- b. Enter the following command:

```
isql -S <servername> -U <userid> -P <password> -D scheddb -i createSchemaSybase12.ddl
```

The Sybase tables and schema for scheduler exist.

Startup beans

Using startup beans

There are two types of startup beans: application startup beans and Module startup beans.

A module startup bean is a session bean that is loaded when an EJB Jar file starts. Module startup beans enable Java 2 Platform Enterprise Edition (J2EE) applications to run business logic automatically, whenever an EJB module starts or stops normally. An application startup bean is a session bean that is loaded when an application starts. Application startup beans enable Java 2 Platform Enterprise Edition (J2EE) applications to run business logic automatically, whenever an application starts or stops normally.

Startup beans are especially useful when used with asynchronous bean features. For example, a startup bean might create an alarm object that uses the Java Message Service (JMS) to periodically publish heartbeat messages on a well-known topic. This enables clients or other server applications to determine whether the application is available.

1. For Application startup beans, use the home interface, `com.ibm.websphere.startupservice.AppStartUpHome`, to designate a bean as an Application startup bean. For Module startup beans, use the home interface, `com.ibm.websphere.startupservice.ModStartUpHome`, to designate a bean as a Module startup bean.
2. For Application startup beans, use the remote interface, `com.ibm.websphere.startupservice.AppStartUp`, to define `start()` and `stop()` methods on the bean. For Module startup beans, use the remote interface, `com.ibm.websphere.startupservice.ModStartUp`, to define `start()` and `stop()` methods on the bean.

The startup bean `start()` method is called when the module or application starts and contains business logic to be run at module or application start time.

The `start()` method returns a boolean value. **True** indicates that the business logic within the `start()` method ran successfully. Conversely, **False** indicates that the business logic within the `start()` method failed to run completely. A return value of `False` also indicates to the Application server that application startup is aborted.

The startup bean `stop()` methods are called when the module or application stops and contains business logic to be run at module or application stop time. Any exception thrown by a `stop()` method is logged only. No other action is taken.

The `start()` and `stop()` methods must never use the `TX_MANDATORY` transaction attribute. A global transaction does not exist on the thread when the `start()` or `stop()` methods are invoked. Any other `TX_*` attribute can be used. If `TX_MANDATORY` is used, an exception is logged, and the application start is aborted.

The `start()` and `stop()` methods on the remote interface use **Run-As** mode. **Run-As** mode specifies the credential information to be used by the security service to determine the permissions that a principal has on various resources. If security is on, the **Run-As** mode needs to be defined on all of the methods called. The identity of the bean without this setting is undefined.

There are no restrictions on what code the `start()` and `stop()` methods can run, since the full Application Server programming model is available to these methods.

3. Use an *optional* environment property integer, `wasStartupPriority`, to specify the start order of multiple startup beans in the same Java Archive (JAR) file. If the environment property is found and is the wrong type, application startup is aborted. If no priority value is specified, a default priority of 0 is used. It is recommended that you specify the priority property. Beans that have specified a priority are sorted using this property. Beans with numerically lower priorities are run first. Beans that have the same priority are run in an undefined order. All priorities must be positive integers. Beans are stopped in the opposite order to their start priority. The priority values for module startup beans and application startup beans are mutually exclusive. All modules will be started prior to the application being declared as "started" and therefore the `start()` methods for module startup beans within an application will be invoked prior to the `start()` methods for any application startup beans. Likewise, all application startup bean `stop()` methods for a specific Java Archive (JAR) file will be invoked prior to any module startup bean `stop()` methods for that JAR.
4. For module startup beans, the order in which EJB modules are started can be adjusted via the "Starting weight" value associated with each module
5. To control who can invoke startup bean methods via WebSphere Security do the following:
 - a. Define the method permissions for the `Start()` and `Stop()` methods as you would for any EJB. (See "Defining method permissions for EJB modules.")
 - b. Ensure that the User that is mapped to the Security Role defined for the startup bean methods is the same user that is defined as the "Server user ID" within the User Registry.

View the startup beans service settings.

Startup beans service settings

Use this page to enable startup beans that control whether application-defined startup beans function on this server. Startup beans are session beans that run business logic through the invocation of `start` and `stop` methods when applications start and stop. If the startup beans service is disabled, then the automatic

invocation of the start and stop methods does not occur for deployed startup beans when the parent application starts or stops. This service is disabled by default. Enable this service only when you want to use startup beans. Startup beans are especially useful when used with asynchronous beans.

To view this administrative console page, click **Servers > Application servers > *server_name* > Container services > Startup beans service**.

Enable service at server startup:

Specifies whether the server attempts to initiate the startup beans service.

Default
Range

Cleared

Selected

When the application server starts, it attempts to initiate the startup bean service automatically.

Cleared

The server does not try to initiate the startup beans service. All startup beans do not start or stop with the application. If you use startup beans on this server, then the system administrator must start the startup beans service manually or select this property, and then restart the server.

Enabling startup beans in the administrative console

Enabling startup beans in the administrative console enables Java 2 Platform Enterprise Edition (J2EE) applications to run business logic automatically, whenever an application starts or stops normally.

Use the following steps to enable startup beans in the administrative console.

1. Start the administrative console.
2. Select **Servers > Application Servers > *server_name* > Container Services > Startup beans service**.
3. Select the **Enable service at server startup** check box.
4. Click **Apply** to save the configuration.

View the startup beans service settings.

Work area

Task overview: Implementing shared work areas

The work area service enables application developers to implicitly propagate information beyond the information passed in remote calls. Applications can create a work area, insert information into it, and make remote invocations. The work area is propagated with each remote method invocation, eliminating the need to explicitly include an appropriate argument in the definition of each method. The methods on the server side can use or ignore the information in the work area as appropriate.

Before proceeding with the steps to implement work areas, as described below, review the topic Work area service: Overview.

1. Developing applications that use work areas. Applications interact with the work area service by implementing the UserWorkArea interface.
2. Managing work areas. The work area service is managed using the administrative console.

Overview of work area service

One of the foundations of distributed computing is the ability to pass information, typically in the form of arguments to remote methods, from one process to another. When application-level software is written over middleware services, many of the services rely on information beyond that passed in the application's remote calls. Such services often make use of the implicit propagation of private information in addition to the arguments passed in remote requests; two typical users of such a feature are security and transaction services. Security certificates or transaction contexts are passed without the knowledge or intervention of the user or application developer. The implicit propagation of such information means that application developers do not have to manually pass the information in method invocations, which makes development less error-prone, and the services requiring the information do not have to expose it to application developers. Information such as security credentials can remain secret.

The work area service gives application developers a similar facility. Applications can create a work area, insert information into it, and make remote invocations. The work area is propagated with each remote method invocation, eliminating the need to explicitly include an appropriate argument in the definition of every method. The methods on the server side can use or ignore the information in the work area as appropriate. If methods in a server receive a work area from a client and subsequently invoke other remote methods, the work area is transparently propagated with the remote requests. When the creating application is done with the work area, it terminates it.

There are two prime considerations in deciding whether to pass information explicitly as an argument or implicitly by using a work area. These considerations are:

- Pervasiveness: Is the information used in a majority of the methods in an application?
- Size: Is it reasonable to send the information even when it is not used?

When information is sufficiently pervasive that it is easiest and most efficient to make it available everywhere, application programmers can use the work area service to simplify programming and maintenance of code. The argument does not need to go onto every argument list. It is much easier to put the value into a work area and propagate it automatically. This is especially true for methods that simply pass the value on but do nothing with it. Methods that make no use of the propagated information simply ignore it.

Work areas can hold any kind of information, and they can hold an arbitrary number of individual pieces of data, each stored as a property.

Work area property modes: The information in a work area consists of a set of properties; a property consists of a key-value-mode triple. The key-value pair represents the information contained in the property; the key is a name by which the associated value is retrieved. The mode determines whether the property can be removed or modified.

Property modes

There are four possible mode values for properties, as shown in the following code example:

Code example: The PropertyModeType definition

```
public final class PropertyModeType {
    public static final PropertyModeType normal;
    public static final PropertyModeType read_only;
    public static final PropertyModeType fixed_normal;
    public static final PropertyModeType fixed_readonly;
};
```

A property's mode determines three things:

- Whether the value associated with the key can be modified
- Whether the property can be deleted
- Whether the mode associated with the key-value pair can be modified

The two read-only modes forbid changes to the information in the property; the two fixed modes forbid deletion of the property.

The work area service does not provide methods specifically for the purpose of modifying the value of a key or the mode associated with a property. To change information in a property, applications simply rewrite the information in the property; this has the same effect as updating the information in the property. The mode of a property governs the changes that can be made. Modifying key-value pairs describes the restrictions each mode places on modifying the value and deleting the property. Changing modes describes the restrictions on changing the mode.

Changing modes

The mode associated with a property can be changed only according to the restrictions of the original mode. The read-only and fixed read-only properties do not permit modification of the value or the mode. The fixed normal and fixed read-only modes do not allow the property to be deleted. This set of restrictions leads to the following permissible ways to change the mode of a property within the lifetime of a work area:

- If the current mode is normal, it can be changed to any of the other three modes: fixed normal, read-only, fixed read-only.
- If the current mode is fixed normal, it can be changed only to fixed read-only.
- If the current mode is read-only, it can be changed only by deleting the property and re-creating it with the desired mode.
- If the current mode is fixed read-only, it cannot be changed.
- If the current mode is not normal, it cannot be changed to normal. If a property is set as fixed normal and then reset as normal, the value is updated but the mode remains fixed normal. If a property is set as fixed normal and then reset as either read-only or fixed read-only, the value is updated and the mode is changed to fixed read-only.

Note: The key, value, and mode of any property can be effectively changed by terminating (completing) the work area in which the property was created and creating a new work area. Applications can then insert new properties into the work area. This is not precisely the same as changing the value in the original work area, but some applications can use it as an equivalent mechanism.

Nested work areas: Applications can nest work areas. When an application creates a work area, a work area context is associated with the creating thread. If the application thread creates another work area, the new work area is nested within the existing work area and becomes the current work area. Nested work areas allow applications to define and scope properties for specific tasks without having to make them available to all parts of the application. All properties defined in the original, enclosing work area are visible to the nested work area. The application can set additional properties within the nested work area that are not part of the enclosing work area.

An application working with a nested work area does not actually see the nesting of enclosing work areas. The current work area appears as a flat set of properties that includes those from enclosing work areas. In the figure below, the enclosing work area holds several properties and the nested work area holds additional properties. From the outermost work area, the properties set in the nested work area are not visible. From the nested work area, the properties in both work areas are visible.

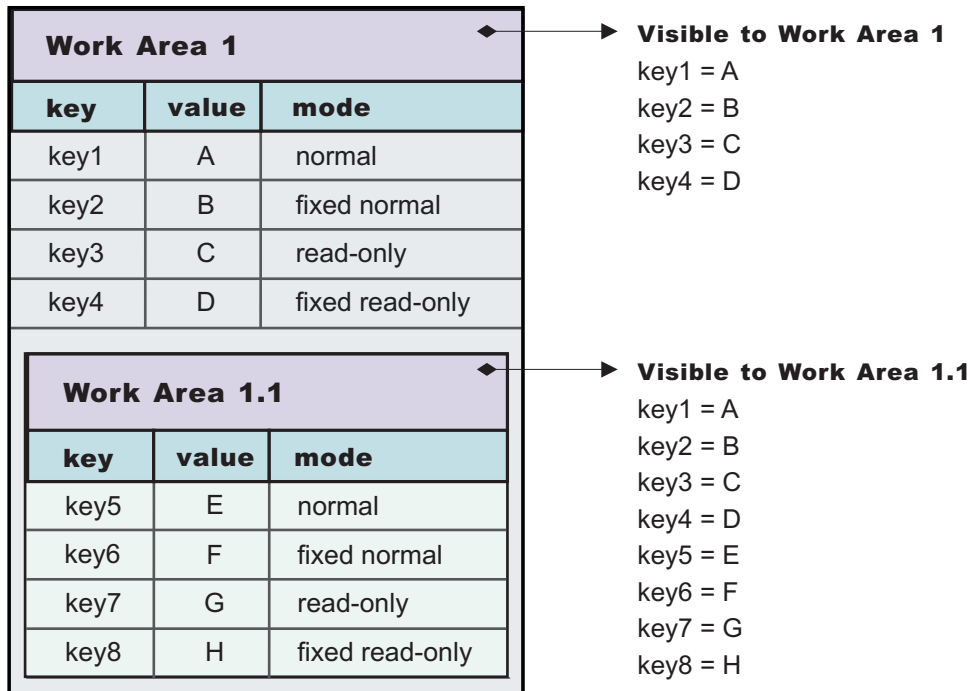

Figure 28. Defining new properties in nested work areas

Nesting can also affect the apparent settings of the properties. Properties can be deleted from or directly modified only within the work areas in which they were set, but nested work areas can also be used to temporarily override information in the property without having to modify the property. Depending on the modes associated with the properties in the enclosing work area, the modes and the values of keys in the enclosing work area can be overridden within the nested work area.

The mode associated with a property when it is created determines whether nested work areas can override the property. From the perspective of a nested work area, the property modes used in enclosing work areas can be grouped as follows:

- Modes that permit a nested work area to override the mode or the value of a key locally. The modes that permit overriding are:
 - Normal
 - Fixed normal
- Modes that do not permit a nested work area to override the mode or the value of a key locally. The modes that do not permit overriding are:
 - Read-only
 - Fixed read-only

If an enclosing work area defines a property with one of the modes that can be overridden, a nested work area can specify a new value for the key or a new mode for the property. The new value or mode becomes the value or mode seen by subsequently nested work areas. Changes to the mode are governed by the restrictions described in Changing modes. If an enclosing work area defines a property with one of the modes that cannot be overridden, no nested work area can specify a new value for the key.

A nested work area can delete properties from enclosing work areas, but the changes persist only for the duration of the nested work area. When the nested work area is completed, any properties that were added in the nested area vanish and any properties that were deleted from the nested area are restored.

The following figure illustrates the overriding of properties from an enclosing work area. The nested work area redefines two of the properties set in the enclosing work area. The other two cannot be overridden. The nested work area also defines two new properties. From the outermost work area, the properties set

or redefined in the nested work are not visible. From the nested work area, the properties in both work areas are visible, but the values seen for the redefined properties are those set in the nested work area.

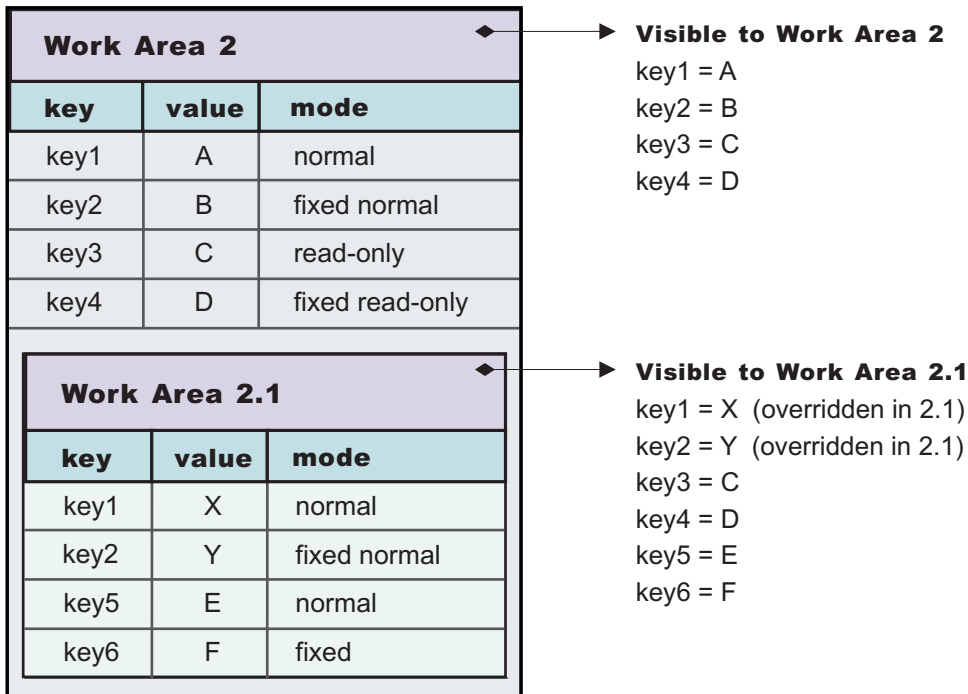

Figure 29. Redefining existing properties in nested work areas

Distributed work areas: The propagation of work area context operates differently depending on whether a work area partition is defined as bidirectional or not. In either case all work area context propagates to a target object on a remote invocation. However, whether the context propagates from a target object back to the originator depends on whether a partition is defined as bidirectional.

Non-bidirectional work area partitions (UserWorkArea partition)

If a remote invocation is issued from a thread associated with a work area, a copy of the work area is automatically propagated to the target object, which can use or ignore the information in the work area as necessary. If the calling application has a nested work area associated with it, a copy of the nested work area and all its ancestors is propagated to the target. The target application can locally modify the information, as allowed by the property modes, by creating additional nested work areas; this information is propagated to any remote objects it invokes. However, no changes made to a nested work area on a target object are propagated back to the calling object. The caller's work area is unaffected by changes made in the remote method.

Bidirectional work area partitions

If a remote invocation is issued from a thread associated with a work area, a copy of the work area is automatically propagated to the target object, which can use or ignore the information in the work area as necessary. If the calling application has a nested work area associated with it, a copy of the nested work area and all its ancestors is propagated to the target. The target application can locally modify the information, as allowed by the property modes, this information is propagated to any remote objects it invokes. In a partition that is not defined as bidirectional, a target application must begin a nested work area before making changes to the imported work area. However, if a partition is defined as bidirectional, a target application need not begin a nested work area before operating on an imported work area. By not beginning a nested work area, any new context set into the work area, or any context changes made by the target application, is not only propagated on future remote invocations but is also propagated back to

the originating application (that is, the one who initiated the remote invocation) thus allowing bidirectional propagation of work area context. If the target application does not want new or changed context to propagate back to the originating application, then the target application must begin a nested work area to scope the context to its process. However, the new or changed context in the nested work area propagates on any future remote invocation the target application may make.

WorkArea service: Special considerations: Developers who use work areas should consider the following issues that could potentially cause problems: interoperability between the EJB and CORBA programming models; and the use of work areas with Java's Abstract Windowing Toolkit.

EJB and CORBA interoperability

Although the work area service can be used across the EJB and CORBA programming models, many composed data types cannot be successfully used across those boundaries. For example, if a SimpleSampleCompany instance is passed from the WebSphere environment into a CORBA environment, the CORBA application can retrieve the SimpleSampleCompany object encapsulated within a CORBA Any object from the work area, but it cannot extract the value from it. Likewise, an IDL-defined struct defined within a CORBA application and set into a work area is not readable by an application using the UserWorkArea class.

best-practices: Applications can avoid this incompatibility by directly setting only primitive types, like integers and strings, as values in work areas, or by implementing complex values with structures designed to be compatible, like CORBA valuetypes.

Also, CORBA Anys that contains either the tk_null or tk_void typecode can be set into the work area by using the CORBA interface. However, the work area specification cannot allow the Java 2 Platform, Enterprise Edition (J2EE) implementation to return null on a lookup that retrieves these CORBA-set properties without incorrectly implying that there is no value set for the corresponding key. For example, when a user attempts to retrieve a nonexistent key from a work area, the work area service returns null to indicate that the specified key does not contain a value, implying that the key itself is not in use or does not exist. In the case where CORBA Anys contains either tk_null or tk_void, when a user requests the key associated with one of these values, the work area service returns null as expected. In this case, the key may actually exist and the work area service was simply returning the key's value of null. Therefore, when working with CORBA Anys, a user must not make any implications when a null is returned from a work area because it could mean that either there isn't a property associated with the given key, or that there is a property associated with the given key and it contains a tk_null or tk_void, for example, a null in the J2EE environment. If a J2EE application tries to retrieve CORBA-set properties that are non-serializable, or contain CORBA nulls or void references, the com.ibm.websphere.workarea.IncompatibleValue exception is raised.

Using work areas with Java's Abstract Windowing Toolkit (AWT)

Work areas must be used cautiously in applications that use Java's Abstract Windowing Toolkit (AWT). The AWT implementation is multithreaded, and work areas begun on one thread are not available on another. For example, if a program begins a work area in response to an AWT event, such as pressing a button, the work area might not be available to any other part of the application after the execution of the event completes.

Work area service performance considerations: The work area service is designed to address complex data passing patterns that can quickly grow beyond convenient maintenance. A *work area* is a note pad that is accessible to any client that is capable of looking up Java Naming Directory Interface (JNDI). After a work area is established, data can be placed there for future use in any subsequent method calls to both remote and local resources.

You can utilize a work area when a large number of methods require common information or if information is only needed by a method that is significantly further down the call graph. The former avoids the need for

complex parameter passing models where the number of arguments passed becomes excessive and hard to maintain. You can improve application function by placing the information in a work area and subsequently accessing it independently in each method, eliminating the need to pass these parameters from method to method. The latter case also avoids unnecessary parameter passing and helps to improve performance by reducing the cost of marshalling and de-marshalling these parameters over the Object Request Broker (ORB) when they are only needed occasionally throughout the call graph.

When attempting to maximize performance by using a work area, cache the UserWorkArea partition that is retrieved from JNDI wherever it is accessed. You can reduce the time spent looking up information in JNDI by retrieving it once and keeping a reference for the future. JNDI lookup takes time and can be costly.

Additional caching mechanisms available to a user-defined partition are defined by the configuration property, "Deferred Attribute Serialization". This mechanism attempts to minimize the number of serialization and deserialization calls. See "Work area partition service" on page 2145 for further explanation of this configuration attribute.

The maxSendSize and maxReceiveSize configuration parameters can affect the performance of the work area. Setting these two values to 0 (zero) effectively turns off the policing of the size of context that can be sent in a work area. This action can enhance performance, depending on the number of nested work areas an application uses. In applications that use only one work area, the performance enhancement might be negligible. In applications that have a large number of nested work areas, there might be a performance enhancement. However, a user must note that by turning off this policing it is possible that an extremely large amount of data might be sent to a server.

Performance is degraded if you use a work area as a direct replacement to passing a single parameter over a single method call. The reason is that you incur more overhead than just passing that parameter between method calls. Although the degradation is usually within acceptable tolerances and scales similarly to passing parameters with regard to object size, consider degradation a potential problem before utilizing the service. As with most functional services, intelligent use of the work areas yields the best results.

The work area service is a tool to simplify the job of passing information from resource to resource, and in some cases can improve performance by reducing the overhead that is associated with a parameter passing when the information is only sparsely accessed within the call graph. Caching the instance retrieved from JNDI is important to effectively maximize performance during runtime.

Managing the work area service - the UserWorkArea partition

The work area service is managed using the administrative console. There are two administrative tasks associated with work areas:

- Enabling the work area service. The work area service is disabled by default on servers but enabled by default on the client
- Managing the size of work areas. Applications can set maximum sizes on each work area to be sent and to be accepted.

Enabling the work area service - the UserWorkArea partition

For an application to take advantage of work areas, the work area service must be enabled for both clients and servers. On a server the service is disabled by default. On the client, the service is enabled by default.

For an application to take advantage of the default partition, UserWorkArea partition, this partition must be enabled by enabling the work area service for both clients and servers. The work area service on a server is disabled by default and the work area service on a client is enabled by default. Note that rather than using this default work area partition, a user can create their own work area partition using the "Work area

partition service” on page 2145. For a description of the differences between these two services please see Understand the difference between the work area service and the work area partition service.

1. Enable (or disable) the use of the UserWorkArea partition on a server:
 - a. Start the administrative console.
 - b. Select **Servers > Application servers > *server_name* > Business Process Services > Work area service**.
 - c. Select or clear the **Startup** check box. This specifies whether or not the server should automatically start the work area service when the server starts.
 - d. Save the new configuration and restart the server to apply the new configuration.
2. Enable (or disable) the UserWorkArea partition on a client: Set the `com.ibm.websphere.workarea.enabled` property to TRUE or FALSE before starting the client. For example, to disable the work area service, when invoking the `launchClient` script found in the `install_root/bin` directory, add the following system property to the `launchClient` invocation:
`-CCDcom.ibm.websphere.workarea.enabled=false`

Alternatively, this property can be set in a property file that is used by the `launchClient` script. See “Running application clients” on page 278 for additional information.

After enabling the UserWorkArea partition, manage the size of the work areas that this server can send and the number of work areas that this server can accept. See the article, “Managing the size of work areas” on page 2144.

Work area service settings:

Use this page to manage the work area service.

The work area service manages the scope and implicit propagation of application context. The work area service panel in the administrative console configures the UserWorkArea partition only and has no effect on the work area partition service panel.

To view this administrative console page, click **Servers > Application servers > *server_name* > Business Process Services > Work area service** .

For additional information about work area, see the `com.ibm.websphere.workarea` package in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference > Developer > API documentation > Application programming interfaces**.

Enable service at server startup:

Specifies whether the server attempts to start the work area service.

Selected

When the application server starts, it attempts to start the work area service automatically.

Cleared

The server does not try to start the work area service. If work areas are used on this application server, the system administrator must start the service manually or select this property and then restart the server.

Maximum send size:

Specifies the maximum size of data that can be sent within a single work area.

Data type	Integer
Units	Bytes

Default 10000
Range -1, 0 (no limit) and 1 to 2147483647

The following values are also used to define the maximum send size.

-1	Default.
0	No limit.

Maximum receive size:

Specifies the maximum size of data that a single work area can receive.

Data type Integer
Units Bytes
Default 10000
Range -1, 0 (no limit) and 1 to 2147483647

The following values are also used to define the maximum receive size.

-1	Default.
0	No limit.

Enable Web service propagation:

Specifies whether the work area is propagated on Web service requests. This option is disabled by default.

Managing the size of work areas

Applications can set maximum sizes on each work area that is sent or received. By default, the maximum size of a work area that is sent by a client and received, then possibly resent, by a server is 32,768 bytes. The maximum size that you can specify is determined by the maximum value expressible in the Java Integer data type, 2,147,483,647. The smallest maximum size that you can specify is 1. Using a maximum size of 1 byte effectively means that no requests associated with the work area can leave the system or enter another system. A value of 0 means that no limit is imposed. A value of -1 means that the default value is to be honored. The default value is also used if an invalid value or a malformed property is specified. You can change this size as described in this topic.

1. Change the size of the work area that can be sent or received by a server:
 - a. Start the administrative console.
 - b. Select **Servers > Application servers > server_name > Business Process Services** .
 - To change the send size or receive size on the work area service (namely the "UserWorkArea" partition):
 - Select **Work area service**.
 - To change the send size or receive size on a user defined partition:
 - Select **Work area partition service**.
 - Select a partition.
 - c. Enter a new value in the **Maximum send size** field to modify the size of the work area that this server can send, or enter a new value in the **Maximum receive size** field to modify the size of the work area that this server can accept.
 - d. Save the new configuration and restart the server to apply the new configuration.

2. Change the size of the work area that can be sent by a client. This step only applies to the UserWorkArea partition on the client. To set the maximum send or receive size on a user defined partition, you must set these values when creating the partition on the client. For more information on creating a partition on a client, see the client section in “Configuring work area partitions.” To change the size of the work area that can be sent by a client, set the `com.ibm.websphere.workarea.maxSendSize` property to the desired number of bytes before starting the client. You can set the maximum send size as follows:
 - Set the maximum send size when invoking the `launchClient` invocation script found in the `$WAS_HOME/bin` directory. For example, to set the maximum size to 10,000 bytes, add the following system properties to the `launchClient` invocation as needed:
`-CCDcom.ibm.websphere.workarea.maxSendSize=10000`
 - Set the maximum send size property, `com.ibm.websphere.workarea.maxSendSize`, in a property file that is used by the `launchClient` script. See “Running application clients” on page 278 for additional information.

Since the UserWorkArea partition is defined as unidirectional, for example, context only propagates on outbound calls and not on the return of those calls, setting the maximum receive size is ignored.

Configuring work area partitions

The work area partition service extends the work area service by allowing the creation of multiple work areas with more configuration options than what is available to the UserWorkArea partition. Follow these steps to create and configure a work area partition:

1. Create a user defined partition on the server.
 - a. Start the administrative console.
 - b. Click **Servers > Application servers > server_name > Business process services > Work area partition service**.
 - c. Click **New**.
 - d. On the settings page for work area partitions, specify values such as the partition name, `maxSendSize` and `maxReceiveSize`, then click OK.
 - e. Save the new configuration.
 - f. Restart the server to apply the new configuration.
2. Create a user defined partition on the client. Use the `createWorkAreaPartition` method described in the “The Work area partition manager interface” on page 2147 article to programmatically create a partition. See “Example: Work area partition manager” on page 2150 for an example of using this method.

You have created a work area partition.

Retrieve the partition through the work area partition manager interface and use it as defined by the work area service and the UserWorkArea interface. See the topic “Example: Work area partition manager” on page 2150 for an example.

Work area partition service

The work area partition service is an extension of the work area service that allows the creation of multiple custom work areas. The work area partition service is an optional service to users. Any user that currently uses the work area service and the UserWorkArea partition can continue using it in the same manner. The UserWorkArea partition is created automatically (if it has not been disabled) by the work area partition service. By allowing a user the option to create their own work area partition through the work area partition service, they can have more control over configuration and access to their partition.

Unlike the UserWorkArea partition, which is publicly known, work areas created by the work area partition service are accessible to, and known only by the creator. However, the work area partition service does not strictly enforce that a partition is accessed and/or operated on exclusively by the partition creator. There are no limitations should the creator want to publish their work area partition and make it publicly

available by binding their partition reference in java naming or by other means. However, the work area partition service does try to hide a partition as much as possible should a user not want others to know about a certain partition. The work area partition service does not allow a person to determine, or query the names of all the partitions that have been created; however, it does not restrict the partitions from being accessed by users other than the creator of that partition. The context of a partition, such as the UserWorkArea partition or a user defined partition, is scoped to a single thread and is not accessible by multiple threads.

The work area partition reference that is returned to a user implements `javax.naming.Referenceable`, as well as `com.ibm.websphere.UserWorkArea`, therefore a user can bind their partition into a name to make their partition publicly available. An alternative to using Java naming to bind and access the partition is to use the work area partition manager interface. Anyone can access the work area partition manager interface; therefore, if a user wants to make their partition publicly available, they simply need to publish their partition name. Other users can then call the `getWorkAreaPartition` method on the work area partition manager interface with the published name.

The `WorkAreaPartitionManager.createWorkAreaPartition` method can only be used from a Java 2 Platform, Enterprise Edition (J2EE) client. To create a work area partition on the server side, one must use the administrative console. On the server side a work area partition must be created during server startup because each partition needs to be register with the appropriate Web and Enterprise JavaBeans (EJB) collaborators before the server has started. Custom work area partitions are created by the work area partition service and defined by the `UserWorkArea` interface.

The work area partition service also allows a user to configure partitions with additional properties that are not available on the `UserWorkArea` partition, such as bidirectional propagation of work area partition context and deferred attribute serialization. These properties are available as configuration properties when creating a partition. For a complete list of the configuration properties available when creating a partition, please see the section "Configurable Work Area Partition Properties" in "The Work area partition manager interface" on page 2147. The properties are defined as follows:

Bidirectional propagation of work area context

If a remote invocation is issued from a thread associated with a work area, a copy of the work area is automatically propagated to the target object, which can use or ignore the information in the work area as necessary. If the calling application has a nested work area associated with it, a copy of the nested work area and all its ancestors are propagated to the target application. The target application can locally modify the information, as allowed by the property modes, by creating additional nested work areas; this information is propagated to any remote objects that it invokes.

Whether context changes propagate back to a calling application from a remote application depends on the configuration of the work area partition. If a user creates a partition to be bidirectional (selects the Bidirectional property during creation), changes made by a remote application propagates back to the calling application, meaning that changes made to the work area context by a downstream process will propagate back up stream. The `UserWorkArea` partition is not configured (and can never be configured) to be bidirectional; therefore context changes only flow to downstream processes and do not propagate back upstream. See "Bidirectional propagation" on page 2153 for further explanation.

Deferred attribute serialization of work area context

By default, on each set operation the attribute set into a work area is automatically serialized by the work area service. On each subsequent get operation on that same attribute it is deserialized and returned to the requester. This gives the work area service complete control of the attribute such that any changes to a mutable object are not reflected in the work area's copy of the attribute unless a user specifically resets the attribute into the work area. However, this can potentially lead to excessive serialization and deserialization.

Excessive serialization and deserialization can result in observable performance degradation under heavy load. The deferred attribute serialization configuration property is a caching feature that reduces serialization and deserialization operations. When deferred attribute serialization is enabled in a client or server process, by selecting the Deferred Attribute Serialization field during the creation of the work area, attributes set into the work area service are not automatically serialized during the set operation. Rather, a reference to the attribute is stored in the work area. If the attribute is mutable, then changes to the object are reflected in the work area's reference to that attribute. When a get operation is performed on that attribute, the reference to that object is returned and no deserialization is performed.

Attributes are not actually serialized until the thread with which the attribute is associated makes a remote IIOOP invocation. At that point the attribute is serialized and the serialized form of the attribute is cached. If the attribute is not reset into the work area, changes to the original attribute are still reflected within the attribute contained within the work area because the work area still holds a cached reference to the original object. However, if the work area has not been told that the attribute has changed by resetting the attribute into the work area, subsequent remote requests continues to use the cached serialized version of the attribute and direct changes to the mutable attribute are not propagated. This is an important distinction between enabling and not enabling the deferred attribute serialization configuration property and a user must pay close attention to this difference and how mutable objects are handled when enabling deferred attribute serialization. The work area service releases cached references and cached serialized versions of attributes when any of the following occur:

- An attribute is reset or removed.
- The work area is explicitly completed by the application.
- Server component ends execution of the request during which the work area was begun.
- Client process which began the work area terminates.

Partition context propagation across process boundaries

Work area context automatically propagates from client to server when a client makes a remote call to a server. If a client is configured with, for example, three different work area partitions when it makes a remote call to a server, server1; the context associated with each partition on the client thread propagates to server1. If the same three partitions reside (have been created) on server1, the context is demarshalled to the appropriate partition. However, if none or only a few of the three partitions have been created on server1, only the context associated with a partition that is resident on both the client and server is demarshalled. The context associated with a partition that is not resident on server1 is still resident on server1 but will not be accessible. The context associated with partitions that are not resident on server1 must remain resident on server1 in case another remote call is made to a different server. Going one step further, if server1 makes a call to yet another server, server2 and assume server2 has created all the same partitions that the client has, server2 receives the context for the partitions that were not resident on server1. Any partitions that reside on server1 that did not reside on the client, now have its context propagated to server2.

For additional information about work area, see the `com.ibm.websphere.workarea` package in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference > Developer > API documentation > Application programming interfaces**.

The Work area partition manager interface

Applications interact with the work area partition service by using the work area partition manager interface. A user can retrieve an instance of the work area partition manager interface out of naming and use the methods that are defined in the following section.

An implementation of the work area partition manager interface is bound in Java naming at `java:comp/websphere/WorkAreaPartitionManager`. This interface is responsible for creating, retrieving, and manipulating work area partitions:

```

package com.ibm.websphere.workarea;

import com.ibm.websphere.workarea.UserWorkArea;
import com.ibm.websphere.workarea.PartitionAlreadyExistsException;
import com.ibm.websphere.workarea.NoSuchPartitionException;
import java.util.Properties;

public interface WorkAreaPartitionManager {

    //Returns an instance of a work area partition for the given name, or throws an exception if the
    //partition name doesn't exists.
    public UserWorkArea getWorkAreaPartition(String partitionName) throws NoSuchPartitionException;

    //Returns a new instance of a work area partition (an implementation of the UserWorkArea interface)
    //or throws an exception if the partition name already exists. The createWorkAreaPartition should
    //only be used within a Java 2 platform, Enterprise Edition (J2EE) client and NOT on the
    //server. To create a work area partition on the server, use the WebSphere administrative
    //console.
    public UserWorkArea createWorkAreaPartition(String partitionName, Properties props) throws
        PartitionAlreadyExistsException, java.lang.IllegalAccessException;
}

```

EJB applications can use the work area partition manager interface only within the implementation of methods in either the remote or local interface, or both; likewise, servlets can use the interface only within the service method of the HTTPServlet class. Use of work areas within any life cycle method of a servlet or enterprise bean is considered a deviation from the work area programming model and is not supported.

Programmatically creating a work area partition through the createWorkAreaPartition method is only available on the Java 2 platform, Enterprise Edition (J2EE) client. To create a work area partition on the server, use the WebSphere administrative console as described in "Configuring work area partitions" on page 2145. All partitions in a server process must be created before server startup is complete so that the work area service can register with the appropriate container collaborators. Therefore, calling the createWorkAreaPartition method in a server process after the server starts results in a java.lang.IllegalAccessException exception. The createWorkAreaPartition method can be called in a J2EE application client at any time.

Configurable Work Area Partition Properties

This section applies to the use of the createWorkAreaPartition method on the WorkAreaPartitionManager interface. As is described above, this method should only be used on a Java 2 platform, Enterprise Edition (J2EE) client. To create a partition on the server, please see Configuring work area partitions.

The "createWorkAreaPartition" method on the WorkAreaPartitionManager interface takes a java.util.Properties objects. This Properties object, and the properties it contains, is used to define the work area partition. Below is an example of creating a Properties object and setting a property:

Note: A more detailed example of the usage of the WorkAreaPartitionManager can be found at "Example: Work area partition manager" on page 2150.

```

java.util.Properties props = new java.util.Properties();
props.put("maxSendSize","12345");

```

Acceptable key/values pairs (properties) for defining a partition are as follows:

- *maxSendSize* - Indicates the maximum size (bytes) of a work area that can be sent on a remote call. Acceptable values are:
 - "-1" = Uses the default size of 32767.
 - "0" = Unlimited size, this value will not be policed which might help performance a bit depending on the number of work area an application has.
 - "1" = Integer.MAX_VALUE

- *maxReceiveSize* - Indicates the maximum size (bytes) of a work area that can be received. Acceptable values are:
 - "-1" = Uses the default size of 32767.
 - "0" = Unlimited size, this value will not be policed which might help performance a bit depending on the number of work area an application has.
 - "1" = Integer.MAX_VALUE
- *Bidirectional* - Indicates if work area context that is changed by a downstream process should be propagated back upstream to the originator of that context. For a more complete description of this property, please see the section "Bidirectional propagation of work area context" at "Work area partition service" on page 2145. Acceptable values are:
 - "true" = Context changes will be returned from a remote call.
 - "false" = Context changes will not be returned from a remote call.

Note: The default setting is "false."

- *DeferredAttributeSerialization* - Indicates if the serialization of attribute should be optimized to occur exactly once per process. For a more complete description of this property, please see the section "Deferred attribute serialization of work area context" at "Work area partition service" on page 2145. Acceptable values are:
 - "true"
 - When an attribute is set into the work area, it will not be serialized until a remote request is made.
 - If the value is unchanged by response, the serialized form will be used for subsequent requests; the live object will be retrieved via getters.
 - When requests are made during a remote request, a value will be deserialized on demand exactly once. The serialized form will be used for subsequent requests from this remote process on this distributed thread; subsequent requests in process for the same attribute will return the already deserialized value. There are risks with concurrency with *DeferredAttributeSerialization*. After serialization in a client process, updates to the attribute will no longer be reflected in the work area's copy until the value is explicitly reset through the *UserWorkArea* interface. Changes made to a retrieved reference in a downstream process will not be propagated to subsequent downstream requests (or returned on the reply as a changed value) unless explicitly reset through the *UserWorkArea* interface.
 - "false"
 - When an attribute is set into the work area, it will be immediately serialized and the bytes will be stored.
 - When an attribute is retrieved from the work area, it will always be deserialized from stored bytes.

Note: The default value is "false."

- *EnableWebServicePropagation* - Indicates if work area context should propagate on a *WebService* call. Acceptable values are:
 - "true" = Context will propagate on a *WebService* call.
 - "false" = Context will not propagate on a *WebService* call.

Note: The default value is "false."

Exceptions

The work area partition service defines the following exceptions for use with the work area partition manager interface:

PartitionAlreadyExistsException

This exception is raised by the *createWorkAreaPartition* method on the *WorkAreaPartitionManager* implementation if a user tries to create a work area partition with a partition name that already exists. Partition names must be unique.

NoSuchPartitionException

This exception is raised by the `getWorkAreaPartition` method on the `WorkAreaPartitionManager` implementation if a user requests a work area partition with a partition name that does not exist.

java.lang.IllegalAccessException

This exception is raised by the `createWorkAreaPartition` method on the `WorkAreaPartitionManager` implementation if a user tries to create a work area partition during run time on a server process. This method can only be used on a J2EE client process. In the server process, a partition must be created using the administrative console.

For additional information about work area, see the `com.ibm.websphere.workarea` package in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference > Developer > API documentation > Application programming interfaces**.

Example: Work area partition manager

The example below demonstrates the use of the work area partition manager interface. The sample illustrates how to create and retrieve a work area partition programmatically. Please note that programmatically creating a work area partition is only available on the Java 2 platform, Enterprise Edition (J2EE) client. To create a work area partition on the server one must use the administrative console. See "Work area partition service" on page 2145 for configuration parameters available to configure a partition.

```
import com.ibm.websphere.workarea.WorkAreaPartitionManager;
import com.ibm.websphere.workarea.UserWorkArea;
import com.ibm.websphere.workarea.PartitionAlreadyExistsException;
import com.ibm.websphere.workarea.NoSuchPartitionException;
import java.lang.IllegalAccessException;
import java.util.Properties;
import javax.naming.InitialContext;

//This sample demonstrates how to retrieve an instance of the
//WorkAreaPartitionManager implementation and how to use that
//instance to create a WorkArea partition and retrieve a partition.
//NOTE: Creating a partition in the way listed below is only available
//on a J2EE client. To create a partition on the server use the
//WebSphere administrative console. Retrieving a WorkArea
//partition is performed in the same way on both client and server.

public class Example {

    //The name of the partition to create/retrieve
    String partitionName = "myPartitionName";
    //The name in java naming the WorkAreaPartitionManager instance is bound to
    String jndiName = "java:comp/websphere/WorkAreaPartitionManager";

    //On a J2EE client a user would create a partition as follows:
    public UserWorkArea myCreate(){
        //Variable to hold our WorkAreaPartitionManager reference
        WorkAreaPartitionManager partitionManager = null;
        //Get an instance of the WorkAreaPartitionManager implementation
        try {
            InitialContext initialContext = new InitialContext();
            partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
        } catch (Exception e) { }

        //Set the properties to configure our WorkArea partition
        Properties props = new Properties();
        props.put("maxSendSize","12345");
        props.put("maxReceiveSize","54321");
        props.put("Bidirectional","true");
        props.put("DeferredAttributeSerialization","true");

        //Variable used to hold the newly created WorkArea Partition
        UserWorkArea myPartition = null;
    }
}
```

```

try{
    //This is the way to create a partition on the J2EE client. Use the
    //WebSphere Administrative Console to create a WorkArea Partition
    //on the server.
    myPartition = partitionManager.createWorkAreaPartition(partitionName,props);
}
catch (PartitionAlreadyExistsException e){ }
catch (IllegalAccessException e){ }

return myPartition;
}

//. . . .

//In order to retrieve a WorkArea partition at some time later or
//from some other class, do the following (from client or server):
public UserWorkArea myGet(){
    //Variable to hold our WorkAreaPartitionManager reference
    WorkAreaPartitionManager partitionManager = null;
    //Get an instance of the WorkAreaPartitionManager implementation
    try {
        InitialContext initialContext = new InitialContext();
        partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
    } catch (Exception e) { }

    //Variable used to hold the retrieved WorkArea partition
    UserWorkArea myPartition = null;
    try{
        myPartition = partitionManager.getWorkAreaPartition(partitionName);
    }catch(NoSuchPartitionException e){ }

    return myPartition;
}
}

```

Work area partition collection

Use this page to manage the work area service.

The work area partition service supports the definition of custom work area partitions.

To view this administrative console page, click **Servers > Application servers > *server_name* > Business Process Services > Work area partition service**.

Name:

Specifies the name of the work area partition that is used to retrieve the partition. This name must be unique.

Description:

Specifies the description of the work area partition.

Enable service at server startup:

Specifies whether the server attempts to start the specified service when the server starts.

Bidirectional:

Permits applications to modify the context of a work area that is imported by a J2EE request; modified properties are propagated back to the requestor environment. This option is disabled by default.

Maximum send size:

Specifies the maximum size of data that can be sent within a single work area. (0 = no limit; -1 = default)

A value of 0 means there is no limit to the data sent. The default value of -1 represents 32768 bytes of data sent.

Maximum receive size:

Specifies the maximum size of data that can be received within a single work area. (0 = no limit; -1 = default)

A value of 0 means there is no limit to the data received. The default value of -1 represents 32768 bytes of data received.

Deferred attribute serialization:

Specifies whether attribute serialization is deferred until the work area is propagated on a remote invocation.

Enable Web service propagation:

Specifies whether the work area partition is propagated on Web service requests. This option is disabled by default.

Work area partition settings:

Use this page to modify the work area partition settings.

The work area partition service supports the definition of custom work area partitions.

To view this administrative console page, click **Servers > Application servers > server_name > Business Process Services > Work area partition service > work_area_partition_name**.

Name:

Specifies the name of the work area partition that is used to retrieve the partition. This name must be unique.

Description:

Specifies the description of the work area partition.

Enable service at server startup:

Specifies whether the server attempts to start the specified service when the server starts.

Bidirectional:

Permits applications to modify the context of a work area that is imported by a J2EE request; modified properties are propagated back to the requestor environment. This option is disabled by default.

Maximum send size:

Specifies the maximum size of data that can be sent within a single work area. (0 = no limit; -1 = default)

Data type	Integer
Units	Bytes
Default	32768

Range -1, 0 (no limit) and 1 to 2147483647

Maximum receive size:

Specifies the maximum size of data that can be received within a single work area. (0 = no limit; -1 = default)

Data type	Integer
Units	Bytes
Default	32768
Range	-1, 0 (no limit) and 1 to 2147483647

Deferred attribute serialization:

Specifies whether attribute serialization is deferred until the work area is propagated on a remote invocation. This option is disabled by default.

Enable Web service propagation:

Specifies whether the work area partition is propagated on Web service requests. This option is disabled by default.

Bidirectional propagation

Example: Bidirectional propagation of work area context

Whether context changes propagate back to a calling application from a remote application depends on the configuration of the work area partition. If a user creates a bidirectional partition, changes made by a remote application propagate back to the calling application. In other words, changes made to the work area context by a downstream process propagate back up stream. Figure 1 illustrates distribution of work area context on a remote call when the partition containing the given work area is configured for bidirectional propagation of its work area context. For this illustration, the client and server must have created a partition with the same name.

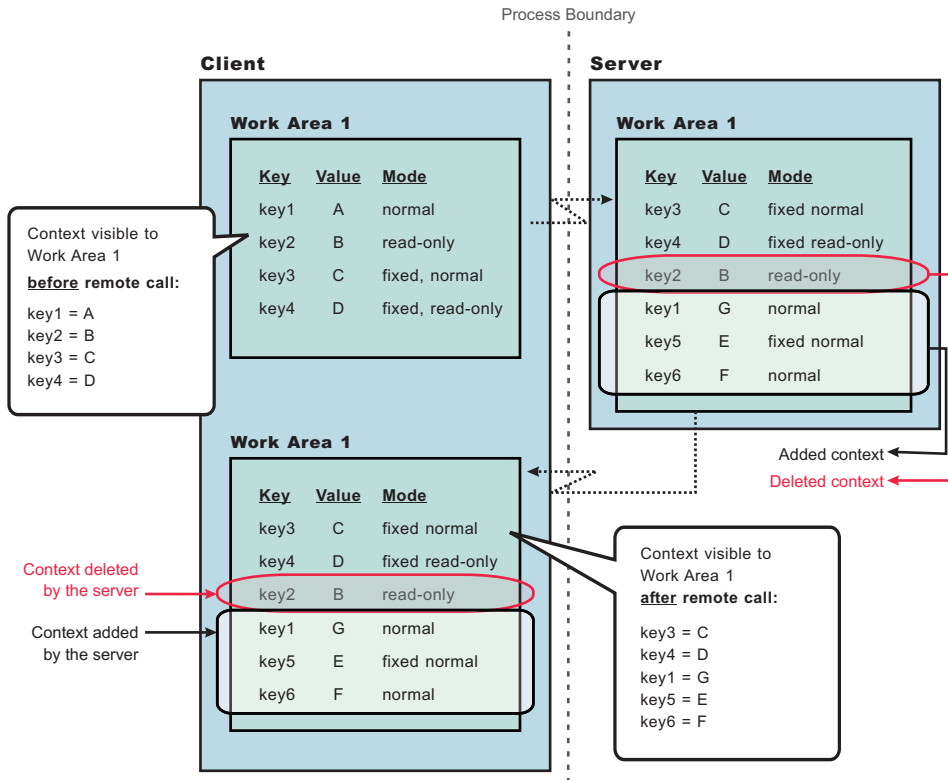

Figure 30. Figure 1

As Figure 1 shows, when the client makes a remote call to the server, the server receives the context set by the client process. The server then can make changes to this context or add to it. In this illustration, the server overwrites the value at **key1**, removes the property at **key2**, and adds two new properties at **key5** and **key6**. When the server application returns to the client, the work area context is propagated back to the client and demarshalled. The current work area is then updated with the new context. Note, that if the partition is not configured as bidirectional, and the server tries to change or remove context in work area, "Work Area 1", it will receive a `com.ibm.websphere.workarea.NotOriginator` exception since the client was the originator of the work area. The server can retrieve the context in "Work Area 1". This is the main distinction between bidirectional propagation of context and non-bidirectional propagation.

Bidirectional propagation of nested work area context

If a remote application needs to add context to a work area that is only used by itself or any other remote objects, the remote application should begin another work area. By beginning a new work area, the new context added is scoped to that application and does not flow back to the calling application. The major benefit of nesting work areas is that nesting work areas allows an application to scope work area context to a given application. Taking the above illustration one step further, if the server has begun a work area before overwriting the value at **key1**, removing the property at **key2**, or adding new properties at **key5** and **key6**; those changes would not have propagated back to the client. This is shown in Figure 2. You can also see from this figure that the client does not receive the context from the nested work area started by the server.

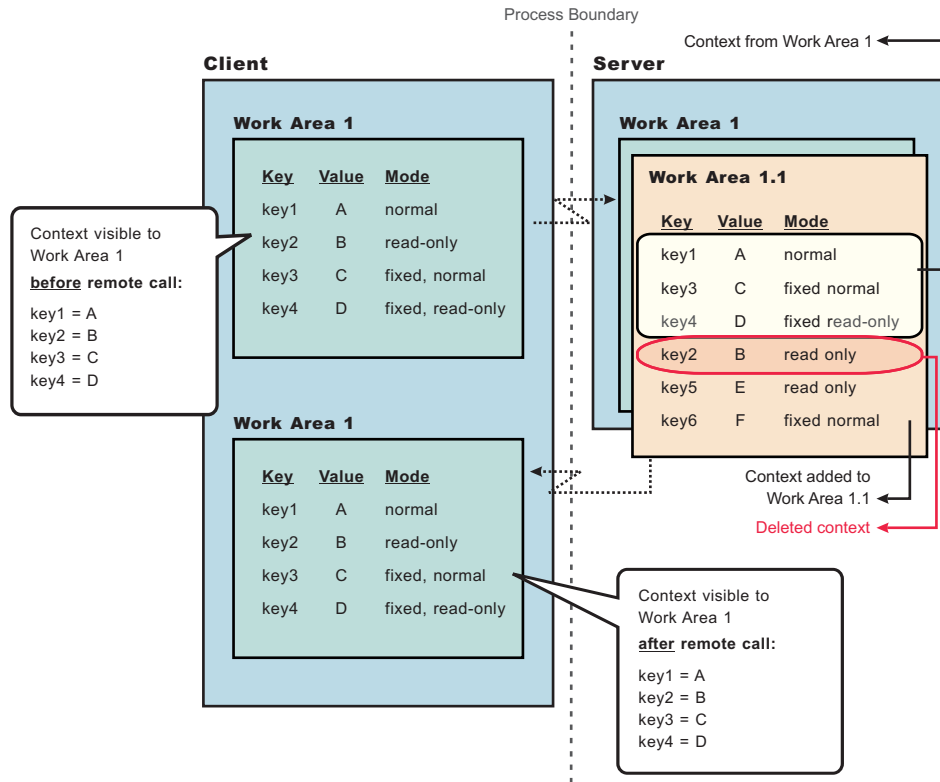

Figure 31. Figure 2

Accessing a user defined work area partition

The work area partition service provides a Java Naming and Directory Interface (JNDI) binding to an implementation of the work area partition manager interface under the name `java:comp/websphere/WorkAreaPartitionManager`. Applications that need to access their partition can perform a lookup on that JNDI name and then use the `getWorkAreaPartition` method on the work area partition manager, as shown in the following code example:

```
import com.ibm.websphere.workarea.*;
import javax.naming.*;

public class SimpleSampleServlet {
    ...

    //Variable to hold our WorkAreaPartitionManager implementation
    WorkAreaPartitionManager partitionManager = null;
    try {
        InitialContext initialContext = new InitialContext();
        partitionManager = (WorkAreaPartitionManager)
            initialContext.lookup("java:comp/websphere/WorkAreaPartitionManager");
    } catch (Exception e) {...}

    //Variable used to hold the retrieved WorkArea Partition
    UserWorkArea myPartition = null;
    try{
        myPartition = partitionManager.getWorkAreaPartition(partitionName);
    }catch(NoSuchPartitionException e){...}
}
```

The next step is to use the begin method to create a new work area and associate it with the calling thread, as described in the topic Beginning a new work area.

Propagating work area context over Web services

WebSphere Application Server Version 6.1 introduces the option to propagate work area context on a Web service call. Prior to WebSphere Application Server Version 6.1, work area context was only propagated over RMI/IIOP calls. The work area application programming interfaces (APIs) have not changed to implement this propagation. You can use the work area APIs as they have in the past and as outlined in the work area documentation. However, by default, work area context is not propagated on a Web service call, you must enable this option.

1. Enable a server to propagate work area context on a Web service call.
 - a. Start the administrative console.
 - b. Select **Servers > Application servers > *server_name* > Business Process Services**.
 - To enable the work area service, (the UserWorkArea partition) to propagate its context on a Web service call:
 - Select **Work area service**.
 - To enable an individual partition to propagate its context on a Web service call:
 - Select **Work area partition service**.
 - Select a partition.
 - c. Check the EnableWebServicePropagation field to enable Web service propagation.
 - d. Save the new configuration and restart the server to apply the new configuration.
2. Enable a client to propagate work area context on a Web service call:

Note: The steps below are for the work area service (the UserWorkArea partition). For user defined partitions the EnableWebServicePropagation property must be set when creating a partition on the client, see “The Work area partition manager interface” on page 2147.

- a. Set the property com.ibm.websphere.workarea.EnableWebServicePropagation to true when invoking the launchClient script found in the \$WAS_HOME/bin directory. For example, to set this property to true, add the following system properties to the launchClient invocation as needed:
-CCDcom.ibm.websphere.workarea.EnableWebServicePropagation=true
- b. Set the property com.ibm.websphere.workarea.EnableWebServicePropagation in a property file that is used by the launchClient script. See “Running application clients” on page 278 for additional information.

Chapter 21. Overview and new features for monitoring

Use the links provided in this topic to learn about monitoring capabilities.

New for administrators: Improved monitoring and performance tuning

A section of this topic describes what is new in the area of performance tuning.

Performance: Resources for learning

Use the following links to find relevant supplemental information about performance. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas. The following sections are covered in this reference:

Chapter 23. Monitoring end user response time

To analyze Web site response from a client viewpoint, use Tivoli Monitoring for Transaction Performance.

Monitoring system response time provides an external perspective of how the overall Web site responds and performs from an client viewpoint. It is important to understand the load and response time on your site. You have some options when monitoring at this level.

- Use Tivoli Monitoring for Transaction Performance to support you to inject and monitor synthetic transactions, helping you identify when your Web site experiences a problem.
- You may also use other performance monitoring tools.

Chapter 24. Monitoring overall system health

Monitoring overall system health is fundamentally important to understanding the health of every system involved with your system. This includes Web servers, application servers, databases, back-end systems, and any other systems critical to running your Web site.

If any system has a problem, it might cause the `servlet is slow` message to appear. IBM and several other business partners leverage the WebSphere APIs to capture performance data and to incorporate it into an overall 24-by-7 monitoring solution. WebSphere Application Server provides Performance Monitoring Infrastructure (PMI) data to help monitor the overall health of the WebSphere Application Server environment. PMI provides average statistics on WebSphere Application Server resources, application resources, and system metrics. Many statistics are available in WebSphere Application Server, and you might want to understand the ones that most directly measure your site's resources to detect problems.

To monitor overall system health, monitor the following statistics at a minimum:

Metric	Meaning
Average response time	Include statistics, for example, servlet or enterprise beans response time. Response time statistics indicate how much time is spent in various parts of WebSphere Application Server and might quickly indicate where the problem is (for example, the servlet or the enterprise beans).
Number of requests (transactions)	Enables you to look at how much traffic is processed by WebSphere Application Server, helping you to determine the capacity that you have to manage. As the number of transactions increase, the response time of your system might be increasing, showing the need for more system resources or the need to retune your system to handle increased traffic.
Number of live HTTP sessions	The number of live HTTP sessions reflects the concurrent usage of your site. The more concurrent live sessions, the more memory is required. As the number of live sessions increase, you might adjust the session time-out values or the Java virtual machine (JVM) heap available.
Database and connection pool size	
Java virtual memory (JVM)	Use the JVM metric to understand the JVM heap dynamics, including the frequency of garbage collection. This data can assist in setting the optimal heap size. In addition, use the metric to identify potential memory leaks.
CPU	You must observe these system resources to ensure that you have enough system resources, for example, CPU, I/O, and paging, to handle the workload capacity.
I/O	
System paging	

To monitor several of these statistics, WebSphere Application Server provides the Performance Monitoring Infrastructure to obtain the data, and provides the Tivoli Performance Viewer (TPV) in the administrative console to view this data.

1. Enable PMI through the administrative console to begin data collection.
2. Use TPV or third-party performance monitoring and management solutions to monitor performance.
3. Extend monitoring capabilities by developing your own monitoring applications or extending PMI.

Performance Monitoring Infrastructure (PMI)

Use this page to learn about Performance Monitoring Infrastructure and other tools to help monitor the overall health of the application server.

A typical Web system consists of a Web server, application server, and a database. Monitoring and tuning the application server is critical to the overall performance of the Web system. Performance Monitoring Infrastructure (PMI) is the core monitoring infrastructure for WebSphere Application Server and WebSphere family products like, Portal, Commerce, and so on. The performance data provided by WebSphere PMI helps to monitor and tune the application server performance.

When tuning the WebSphere Application Server for optimal performance, or fixing a poorly performing Java 2 Platform, Enterprise Edition (J2EE) application, it is important to understand how the various run time and application resources are behaving from a performance perspective. PMI provides a comprehensive set of data that explains the runtime and application resource behavior. For example, PMI provides database connection pool size, servlet response time, Enterprise JavaBeans (EJB) method response time, Java virtual machine (JVM) garbage collection time, CPU usage, and so on. This data can be used to understand the runtime resource utilization patterns of the thread pool, connection pool, and so on, and the performance characteristics of the application components like servlets, JavaServer Pages (JSP), and enterprise beans.

Using PMI data, the performance bottlenecks in the application server can be identified and fixed. For instance, one of the PMI statistics in the Java DataBase Connectivity (JDBC) connection pool is the *number of statements discarded from prepared statement cache*. This statistic can be used to adjust the prepared statement cache size in order to minimize the discards and to improve the database query performance. PMI data can be monitored and analyzed by Tivoli Performance Viewer (TPV), other Tivoli tools, your own applications, or third party tools. TPV is a graphical viewer for PMI data that ships with WebSphere Application Server. Performance advisors use PMI data to analyze the run-time state of the application server, and provide tuning advice to optimize the application server resource utilization.

PMI data can also be used to monitor the health of the application server. Some of the health indicators are CPU usage, Servlet response time, and JDBC query time. Performance management tools like Tivoli Monitoring for Web Infrastructure and other third party tools can monitor the PMI data and generate alerts based on some predefined thresholds.

PMI architecture

The Performance Monitoring Infrastructure (PMI) uses a client-server architecture.

The server collects performance data from various WebSphere Application Server components. A client retrieves performance data from one or more servers and processes the data. WebSphere Application Server, Version 6 supports the Java™ 2 Platform, Enterprise Edition (J2EE) Management Reference Implementation (JSR-77).

In WebSphere Application Server, Version 6 and later, PMI counters are enabled, based on a monitoring or instrumentation level. The levels are None, Basic, Extended, All, and Custom. These levels are specified in the PMI module XML file. Enabling the module at a given level includes all the counters at the given level plus counters from levels below the given level. So, enabling the module at the extended level enables all the counters at that level plus all the basic level counters as well.

JSR-077 defines a set of statistics for J2EE components as part of the `StatisticProvider` interface. The PMI monitoring level of Basic includes all of the JSR-077 specified statistics. PMI is set to monitor at a *Basic* level by default.

PMI and J2EE 1.4 Performance Data Framework

Java 2 Platform, Enterprise Edition (J2EE) 1.4 includes a Performance Data Framework that is defined as part of JSR-077 (Java 2 Platform, Enterprise Edition Management Specification).

This framework specifies the performance data that must be available for various J2EE components. WebSphere PMI complies with J2EE 1.4 standards by implementing the J2EE 1.4 Performance Data Framework.

In addition to providing statistics that are defined in J2EE 1.4, PMI provides additional statistics about the J2EE components, for example, servlets and enterprise beans, and WebSphere Application Server-specific components, for example, thread pools and workload management.

PMI data classification

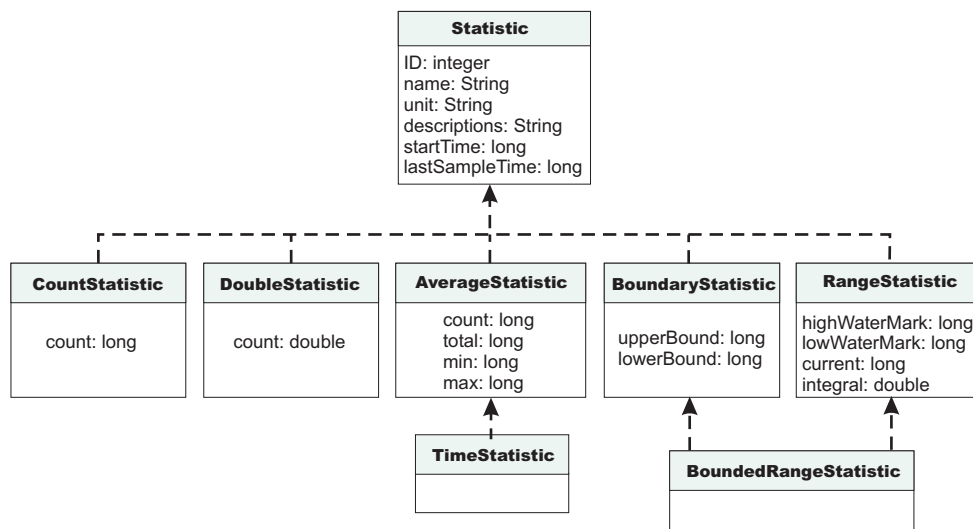

This topic describes the Performance Monitoring Infrastructure (PMI) data classification.

The static component consists of a name, ID and other descriptive attributes to identify the data. The dynamic component contains information that changes over time, such as the current value of a counter and the time stamp associated with that value.

The PMI data can be one of the following statistic types (these statistic types follow the J2EE 1.4 Performance Data Framework):

Statistic type	Description	Example
CountStatistic	Represents a running count of a given value.	Number of Servlet requests
AverageStatistic	Represents a simple average. Keeps track of total, count, min, and max. The average can be derived by total and count. (This type is WebSphere extension to J2EE Performance Data Framework)	Average HttpSession size in bytes.
TimeStatistic	Same as AverageStatistic, except that the unit of measure is milliseconds or seconds.	Average Servlet response time.
RangeStatistic	Represents a time-weighted average. Keeps track of current, low water mark, high water mark, time-weight total, and integral.	Number of concurrent Servlet requests.
BoundedRangeStatistic	Same as RangeStatistic, with lower bound and upper bound.	JDBC connection pool size.

The following diagram shows the statistic class hierarchy:

Statistic

- ID** A unique ID that identifies the Statistic within the given Stats (WebSphere PMI extension)
- name** Statistic name
- unit** Unit of measurement for the statistic

description

Textual description of the statistic

startTime

Time the first measurement was taken

lastSampleTime

Time the most recent measurement was taken

CountStatistic

count Count since the measurement started

DoubleStatistic

count Value since the measurement started

AverageStatistic

(WebSphere PMI extension. This is the same as the TimeStatistic defined in J2EE 1.4, except that it is used to track non-time-related measurements like byte size, etc.)

count Number of measurements

total Sum of the values of all the measurements

min Minimum value

max Maximum value

BoundaryStatistic**upperBound**

Upper limit of this attribute

lowerBound

Lower limit of this attribute

RangeStatistic**current**

Current value of this attribute

lowWaterMark

Lowest value of this attribute

upperWaterMark

Highest value of this attribute

integral

Time-weighted sum of this attribute [time-weighted average = integral / (lastSampleTime - startTime)] (WebSphere PMI extension)

In WebSphere Application Server, Version 4, PMI data was classified with the following types:

- **Numeric:** Maps to CountStatistic in the J2EE 1.4 specification. Holds a single numeric value that can either be a long or a double. This data type is used to keep track of simple numeric data, such as counts.
- **Stat:** Holds statistical data on a sample space, including the number of elements in the sample set, their sum, and sum of squares. You can obtain the mean, variance, and standard deviation of the mean from this data.
- **Load:** Maps to the RangeStatistic or BoundedRangeStatistic, based on J2EE 1.4 specification. This data type keeps track of a level as a function of time, including the current level, the time that level was reached, and the integral of that level over time. From this data, you can obtain the time-weighted average of that level. For example, this data type is used in the number of active threads and the number of waiters in a queue.

These PMI data types continue to be supported through the PMI client API. Statistical data types are supported through both the PMI API and Java Management Extension (JMX) API.

In WebSphere Application Server, Version 4 and Version 5, CountStatistic data require a *low* monitoring level, and TimeStatistic data require a *medium* monitoring level. RangeStatistic and BoundedRangeStatistic require a *high* monitoring level. There are a few counters that are exceptions to this rule. The average method response time, the total method calls, and active methods counters require a *high* monitoring level. The Java virtual machine counters, SerializableSessObjSize, and data tracked for each individual method (method level data) require a *maximum* monitoring level. Also, the level *maximum* enables synchronized update to all the statistic types.

WebSphere Application Server Versions 6.0 and above deprecate the monitoring levels (*Low*, *Medium*, *High*, and *Max*) and introduces fine-grained control to enable/disable statistics individually. The fine-grained control is available under the custom option. Refer to “Enabling PMI using the administrative console” on page 2275 for more details.

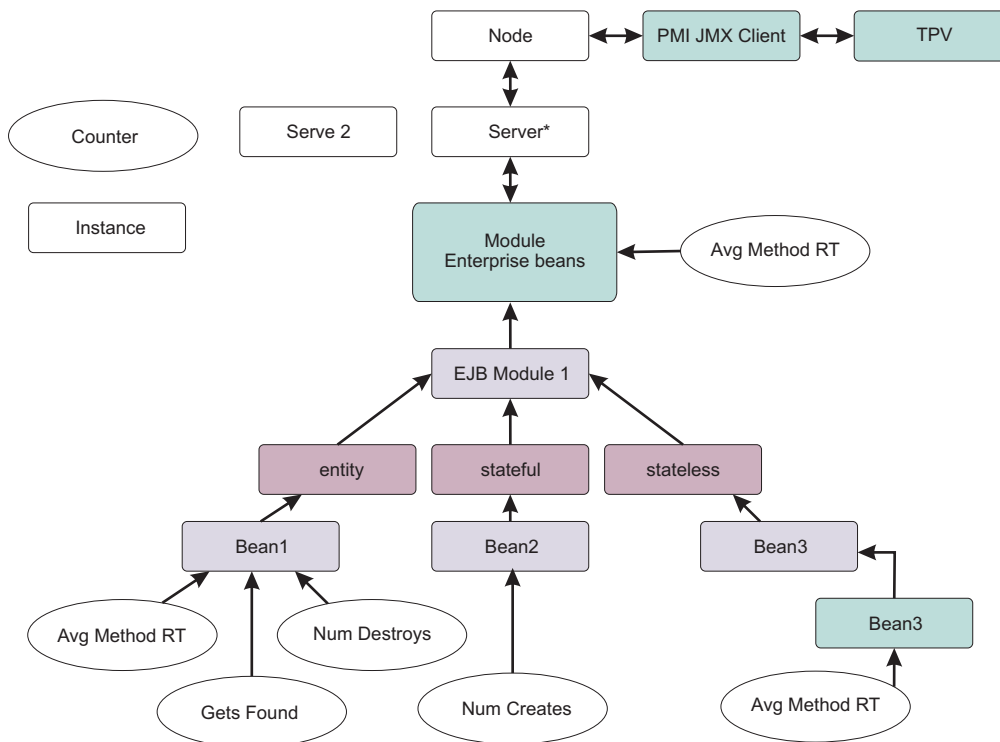

In order to reduce the monitoring overhead, updates to CountStatistic, DoubleStatistic, AverageStatistic, and TimeStatistic are not synchronized. Since this data tracks the total and average, the extra accuracy is generally not worth the performance cost. RangeStatistic and BoundedRangeStatistic are very sensitive; therefore, they are always synchronized. To enable synchronized updates for all the statistic types enable the 'Use sequential update' option. Refer to “Enabling PMI using the administrative console” on page 2275 for details.

PMI data organization

Use this page as a general overview of monitoring, data collection, and counters using Performance Monitoring Infrastructure (PMI) and Tivoli Performance Viewer (TPV).

Performance Monitoring Infrastructure (PMI) provides server-side monitoring and a client-side API to retrieve performance data. PMI maintains statistical data within the entire WebSphere Application Server domain, including multiple nodes and servers. Each node can contain one or more WebSphere Application Server. Each server organizes PMI data into modules and submodules.

Hierarchy of data collections used for performance reporting to Tivoli Performance Viewer (TPV)

Tivoli Performance Viewer, formerly Resource Analyzer, organizes performance data in a centralized hierarchy of the following objects:

- **Node.** A node represents a physical machine in the WebSphere Application Server administrative domain.
- **Server.** A server is a functional unit that provides services to clients over a network. No performance data is collected for the server itself.
- **Module.**

A module represents one of the resource categories for which collected data is reported to the performance viewer. Each module has a configuration file in XML format. This file determines organization and lists a unique identifier for each performance data in the module. Modules include enterprise beans, JDBC connection pools, J2C connection pool, Java virtual machine (JVM) run time (including Java Virtual Machine Tool Interface (JVMTI)), servlet session manager, transaction manager, Web applications, Object Request Broker (ORB), Workload Management (WLM), and dynamic cache.

- **Submodule.** A submodule represents a fine granularity of a resource category under the module. For example, ORB thread pool is a submodule of the thread pool category. Submodules can contain other submodules.
- **Counter.** A counter is a data type used to hold performance information for analysis. Each resource category (module) has an associated set of counters. The data points within a module are queried and distinguished by the MBean ObjectNames or PerfDescriptors. Examples of counters include the number of active enterprise beans, the time spent responding to a servlet request and the number of kilobytes of available memory.

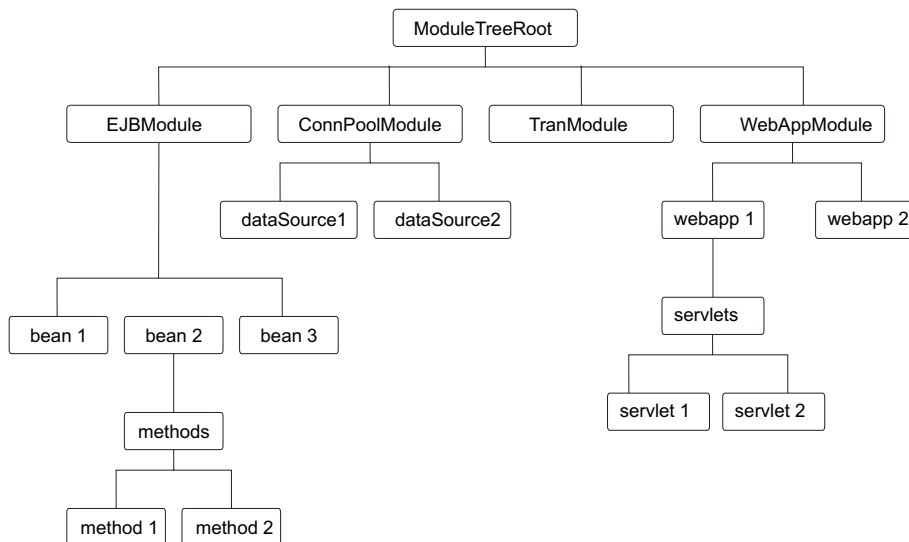

Tivoli Performance Viewer is a thin client integrated into the WebSphere Application Server administrative console. It provides a simple viewer for the performance data provided by Performance Monitoring Infrastructure (PMI), and allows users to view and manipulate the data for counters. A particular counter type can appear in several modules. For example, both the servlet and enterprise bean modules have a response time counter. In addition, a counter type can have multiple instances within a module. In the figure above, both the Enterprise beans module and Bean1 have an Avg Method RT counter.

Counters are enabled at the module level and can be enabled or disabled for elements within the module. For example, in the figure, if the enterprise beans module is enabled, its Avg Method RT counter is enabled by default. However, you can then disable the Avg Method RT counter even when the rest of the module counters are enabled. You can also, if desired, disable the Avg Method RT counter for Bean1, but the aggregate response time reported for the whole module no longer includes Bean1 data.

As part of a fine-grained control feature, WebSphere Application Server provides statistic sets which are pre-defined, fixed server-side sets, based on the PMI statistic usage scenarios. The PMI specification levels include: *none*, *basic*, *extended*, *all*, or *custom*. If you choose *none*, all PMI modules are disabled. Choosing *basic* provides the J2EE and the essential set of statistics to give you a basic level of monitoring. Selecting *extended* gives you the basic level of monitoring plus Work Load Monitor, Performance Advisor, and Tivoli resource models for a more robust monitoring set. Choosing *all* enables all statistics. Choosing *custom* gives you fine-grained control to enable or disable statistics individually.

There are only two states for a statistic: enabled or disabled. To provide an option to enable synchronized updates, WebSphere Application Server, provides a configuration parameter, `synchronizedUpdate`, at the PMI service level. When this attribute is true, all the statistic updates are synchronized. By default, the `synchronizedUpdate` parameter is set to false. The `synchronizedUpdate` parameter is the equivalent to the Max level in V5.0.x and V5.1.x.

Data collection can affect performance of the application server. The impact depends on the number of counters enabled, the type of counters enabled and the monitoring level set for the counters.

The following PMI modules are available to provide statistical data:

Enterprise bean module, enterprise bean, methods in a bean

Data counters for this category report load values, response times, and life cycle activities for enterprise beans. Examples include the average number of active beans and the number of times bean data is loaded or written to the database. Information is provided for enterprise bean methods and the remote interfaces used by an enterprise bean. Examples include the number of times a method is called and the average response time for the method. In addition, the Tivoli Performance Viewer reports information on the size and use of a bean objects cache or enterprise bean object pool. Examples include the number of calls attempting to retrieve an object from a pool and the number of times an object is found available in the pool.

JDBC connection pools

Data counters for this category contain usage information about the JDBC connection pools for a

database. Examples include the number of managed connections or physical connections and the total number of connections or connection handles.

Java 2 Connector (J2C) connection pool

Data counters for this category contain usage information about the Java 2 Platform, Enterprise Edition (J2EE) Connector architecture that enables enterprise beans to connect and interact with procedural back-end systems, such as Customer Information Control System (CICS), and Information Management System (IMS). Examples include the number of managed connections or physical connections and the total number of connections or connection handles.

Java virtual machine API (JVM)

Data counters for this category contain memory used by a process as reported by JVM run time. Examples are the total memory available and the amount of free memory for the JVM. JVM run time also includes data from the JVMTI. This data provides detailed information about the JVM running the application server.

Servlet session manager

Data counters for this category contain usage information for HTTP sessions. Examples include the total number of accessed sessions, the average amount of time it takes for a session to perform a request, and the average number of concurrently active HTTP sessions.

Thread pool

Data counters for this category contain information about the thread pools for Object Request Broker (ORB) threads and the Web container pools used to process HTTP requests. Examples include the number of threads created and destroyed, the maximum number of pooled threads allowed, and the average number of active threads in the pool.

Java Transaction API (JTA)

Data counters for this category contain performance information for the transaction manager. Examples include the average number of active transactions, the average duration of transactions, and the average number of methods per transaction.

Web applications, servlet

Data counters for this category contain information for the selected server. Examples include the number of loaded servlets, the average response time for completed requests, and the number of requests for the servlet.

Object Request Broker (ORB)

Data counters for this category contain information for the ORB. Examples include the object reference lookup time, the total number of requests, and the processing time for each interceptor.

Web services gateway (WSGW)

Data counters for this category contain information for WSGW. Examples include the number of synchronous and asynchronous requests and responses.

System data

Data counters for this category contain information for a machine (node). Examples include the CPU utilization and memory usage. Note that this category is available at node level, which means it is only available at node agent in the multiple servers version.

Workload Management (WLM)

Data counters for this category contain information for workload management. Examples include the number of requests, the number of updates and average response time.

Dynamic cache

Data counters for this category contain information for the dynamic cache service. Examples include in-memory cache size, the number of invalidations, and the number of hits and misses.

Web services

Data counters for this category contain information for the Web services. Examples include the number of loaded Web services, the number of requests delivered and processed, the request response time, and the average size of requests.

Alarm manager

Data counters for this category contain information for the Alarm Manager.

Object pool

Data counters for this category contain information for Object Pools.

Scheduler

Data counters for this category contain information for the Scheduler service.

You can access PMI data through the `getStatsObject` and the `getStatsArray` method in the `PerfMBean`. You need to pass the MBean `ObjectName(s)` to the `PerfMBean`.

Use the following MBean types to get PMI data in the related categories:

- `DynaCache`: dynamic cache PMI data
- `EJBModule*`: Enterprise Java Bean (EJB) module PMI data (`BeanModule`)
- `EntityBean*`: specific EJB PMI data (`BeanModule`)
- `JDBCProvider*`: JDBC connection pool PMI data
- `J2CResourceAdapter*`: Java 2 Connectivity (J2C) connection pool PMI data
- `JVM`: Java virtual machine PMI data
- `MessageDrivenBean*`: specific EJB PMI data (`BeanModule`)
- `ORB`: Object Request Broker PMI data
- `Server`: PMI data in the whole server, you must pass `recursive=true` to `PerfMBean`
- `SessionManager*`: HTTP Sessions PMI data
- `StatefulSessionBean*`: specific EJB PMI data (`BeanModule`)
- `StatelessSessionBean*`: specific EJB PMI data (`BeanModule`)
- `SystemMetrics`: system level PMI data
- `ThreadPool*`: thread pool PMI data
- `TransactionService`: JTA Transaction PMI data
- `WebModule*`: Web application PMI data
- `Servlet*`: servlet PMI data
- `WLMApServer`: Workload Management PMI data
- `WebServicesService`: Web services PMI data
- `WSGW*`: Web services gateway PMI data

To use the `AdminClient` API to query the MBean `ObjectName` for each MBean type. You can either query all the MBeans and then match the MBean type or use the query String for the type only: `String query = "WebSphere:type=mytype,node=mynode,server=myserver,*";`

Set the `mytype`, `mynode`, and `myserver` values accordingly. You get a `Set` value when you call the `AdminClient` class to query MBean `ObjectNames`. This response means that you can get multiple `ObjectNames`.

In the previous example, the MBean types with a star (*) mean that there can be multiple `ObjectNames` in a server for the same MBean type. In this case, the `ObjectNames` can be identified by both type and name (but `mbeanIdentifier` is the real UID for MBeans). However, the MBean names are not predefined. They are decided at run time based on the applications and resources. When you get multiple `ObjectNames`, you can construct an array of `ObjectNames` that you are interested in. Then you can pass the `ObjectNames` to `PerfMBean` to get PMI data. You have the recursive and non-recursive options. The recursive option returns `Stats` and sub-stats objects in a tree structure while the non-recursive option returns a `Stats` object for that MBean only. More programming information can be found in "Developing your own monitoring applications" on page 2285.

Enterprise bean counters

Use this page as a reference for properties of enterprise bean counters.

Counters for this category report load values, response times, and life cycle activities for enterprise beans.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
CreateCount	beanModule.create	The number of times that beans were created	3.5.5 and later	Per home	CountStatistic	Basic	Low
RemoveCount	beanModule.remove	The number of times that beans were removed	3.5.5 and later	Per home	CountStatistic	Basic	Low
PassivateCount	beanModule.passivates	The number of times that beans were passivated (entity and stateful)	3.5.5 and later	Per home	CountStatistic	Basic	Low
ActivateCount	beanModule.activates	The number of times that beans were activated (entity and stateful)	3.5.5 and later	Per home	CountStatistic	All	Low
LoadCount	beanModule.loads	The number of times that bean data was loaded from persistent storage (entity)	3.5.5 and later	Per home	CountStatistic	All	Low
StoreCount	beanModule.stores	The number of times that bean data was stored in persistent storage (entity)	3.5.5 and later	Per home	CountStatistic	All	Low
InstantiateCount	beanModule.instantiate	The number of times that bean objects were instantiated	3.5.5 and later	Per home	CountStatistic	All	Low
FreedCount	beanModule.destroys	The number of times that bean objects were freed	3.5.5 and later	Per home	CountStatistic	All	Low
Ready Count	beanModule.readyCount	The number of concurrently ready beans (entity and session). This counter was called concurrent active in Versions 3.5.5+ and 4.0.	3.5.5 and later	Per home	RangeStatistic	Basic	High
LiveCount	beanModule.concurrentLives	The number of concurrently live beans	3.5.5 and later	Per home	RangeStatistic	Extended	High

MethodResponseTime	beanModule.avgMethodRt	The average response time in milliseconds on the bean methods (home, remote, local)	3.5.5 and later	Per home	TimeStatistic	Basic	High
CreateTime	beanModule.avgCreateTime	The average time in milliseconds that a bean create call takes including the time for the load if any	5.0	Per home	TimeStatistic	All	Max
LoadTime	beanModule.loadTime	The average time in milliseconds for loading the bean data from persistent storage (entity)	5.0	Per home	TimeStatistic	All	Medium
StoreTime	beanModule.storeTime	The average time in milliseconds for storing the bean data to persistent storage (entity)	5.0	Per home	TimeStatistic	All	Medium
RemoveTime	beanModule.avgRemoveTime	The average time in milliseconds that a bean entries call takes including the time at the database, if any	5.0	Per home	TimeStatistic	All	Max
MethodCallCount	beanModule.totalMethodCalls	The total number of method calls	3.5.5 and later	Per home	CountStatistic	Basic	High
ActivationTime	beanModule.activationTime	The average time in milliseconds that a beanActivate call takes including the time at the database, if any	5.0	Per home	TimeStatistic	All	Medium
PassivationTime	beanModule.passivationTime	The average time in milliseconds that a beanPassivate call takes including the time at the database, if any	5.0	Per home	TimeStatistic	All	Medium

ActiveMethodCount	beanModule.activeMethods	The number of concurrently active methods - the number of methods called at the same time.	3.5.5 and later	Per home	TimeStatistic	All	High
RetrieveFromPoolCount	beanModule.getsFromPool	The number of calls retrieving an object from the pool (entity and stateless)	3.5.5 and later	Per home and per object pool	CountStatistic	All	Low
RetrieveFromPoolSuccessCount	beanModule.getsFound	The number of times that a retrieve found an object available in the pool (entity and stateless)	3.5.5 and later	Per home and per object pool	CountStatistic	All	Low
ReturnsToPoolCount	beanModule.returnsToPool	The number of calls returning an object to the pool (entity and stateless)	3.5.5 and later	Per home and per object pool	CountStatistic	Extended	Low
ReturnsDiscardCount	beanModule.returnsDiscarded	The number of times that the returning object was discarded because the pool was full (entity and stateless)	3.5.5 and later	Per home and per object pool	CountStatistic	Extended	Low
DrainsFromPoolCount	beanModule.drainsFromPool	The number of times that the daemon found the pool was idle and attempted to clean it (entity and stateless)	3.5.5 and later	Per home and per object pool	CountStatistic	All	Low
DrainSize	beanModule.avgDrainSize	The average number of objects discarded in each drain (entity and stateless)	3.5.5 and later	Per home and per object pool	TimeStatistic	All	Medium
PooledCount	beanModule.poolSize	The number of objects in the pool (entity and stateless)	3.5.5 and later	Per home and per object pool	RangeStatistic	Basic	High
MessageCount	beanModule.messageCount	The number of messages delivered to the bean onMessage method (message driven beans)	5.0	Per type	CountStatistic	Basic	Low

MessageBackoutCount	beanModule.messageBackoutCount	The number of messages that failed to be delivered to the bean onMessage method (message driven beans)	5.0	Per type	CountStatistic	All	Low
WaitTime	beanModule.avgSrvSessionWaitTime	The average time to obtain a ServerSession from the pool (message-driven bean)	5.0	Per type	TimeStatistic	All	Medium
ServerSessionPoolUsage	beanModule.serverSessionUsage	The percentage of the server session pool in use (message driven)	5.0	Per type	RangeStatistic	All	High

JDBC connection pool counters

Performance Monitoring Infrastructure (PMI) collects performance data for 4.0 and 5.0 Java Database Connectivity (JDBC) data sources. For a 4.0 data source, the data source name is used. For a 5.0 data source, the Java Naming and Directory Interface (JNDI) name is used.

The JDBC connection pool counters are used to monitor the performance of JDBC data sources. You can find the data by using the Tivoli performance viewer and looking under each application server by click ***application_server*** > **JDBC connection pool**.

Note: With the instrumentation level set to anything other than MAX, the values may be less accurate for TimeStatistics and CountStatistics (and in the case of CountStatistics, such as numConnectionHandles, can even be negative). This is due to counters not being synchronized. Synchronizing counters is very expensive in terms of resources, so it is only done when the instrumentation level is set to MAX.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
Num creates	connectionPoolModule.numCreates	The total number of connections created	3.5.5 and later	Per connection pool	CountStatistic	All	Low
Pool size	connectionPoolModule.poolSize	The size of the connection pool	3.5.5 and later	Per connection pool	BoundedRangeStatistic	All	High
Free pool size	connectionPoolModule.freePoolSize	The number of free connections in the pool (apply to 5.0 DataSource only)	5.0	Per connection pool	BoundedRangeStatistic	Basic	High
Num allocates	connectionPoolModule.numAllocates	The total number of connections allocated	3.5.5 and later	Per connection pool	CountStatistic	All	Low
Num returns	connectionPoolModule.numReturns	The total number of connections returned	4.0 and later	Per connection pool	CountStatistic	All	Low
Concurrent waiters	connectionPoolModule.concurrentWaiters	The number of threads that are currently waiting for a connection	3.5.5 and later	Per connection pool	RangeStatistic	All	High
Faults	connectionPoolModule.faults	The total number of faults, such as timeouts, in the connection pool	3.5.5 and later	Per connection pool	CountStatistic	All	Low
Num closes	connectionPoolModule.numDestroys	The total number of connections closed.	3.5.5 and later	Per connection pool	CountStatistic	All	Low
Avg wait time (ms)	connectionPoolModule.avgWaitTime	The average waiting time in milliseconds until a connection is granted	5.0	Per connection pool	TimeStatistic	All	Medium
Avg use time (ms)	connectionPoolModule.avgUseTime	The average time a connection is used (apply to 5.0 DataSource only). Difference between the time at which the connection is allocated and returned. This value includes the JDBC operation time.	5.0	Per connection pool	TimeStatistic	All	Medium
Percent used	connectionPoolModule.percentUsed	The average percent of the pool that is in use	3.5.5 and later	Per connection pool	RangeStatistic	Basic	High
Percent maxed	connectionPoolModule.percentMaxed	The average percent of the time that all connections are in use	3.5.5 and later	Per connection pool	RangeStatistic	All	High
Prepared stmt cache discards	connectionPoolModule.prepStmtCacheDiscards	The total number of statements discarded by the least recently used (LRU) algorithm of the statement cache	4.0 and later	Per connection pool	CountStatistic	All	Low
Num managed connections	connectionPoolModule.numManagedConnections	The number of ManagedConnection objects in use for a particular connection pool (applies to V5.0 DataSource objects only)	5.0	Per connection factory	CountStatistic	All	Low
Num connection handles	connectionPoolModule.numConnectionHandles	The number of Connection objects in use for a particular connection pool (apply to 5.0 DataSource only)	5.0	Per connection factory	CountStatistic	All	Low

JDBC time	connectionPoolModule.jdbcOperationTimer	The amount of time in milliseconds spent running in the JDBC driver, which includes time spent in the JDBC driver, network, and database (apply to 5.0 DataSource only)	5.0	Per data source	TimeStatistic	All	Medium
-----------	---	---	-----	-----------------	---------------	-----	--------

J2C connection pool counters

Use this page as a reference for properties of J2C connection pool counters.

The Java 2 Connector (J2C) connection pool counters are used to monitor J2C connection pool performance. You can find the data using the Tivoli performance viewer and clicking ***application_server*** > **J2C connection pool**.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
ManagedConnectionCount	j2cModule.numManagedConnections	The number of ManagedConnection objects in use	5.0	Per connection factory	CountStatistic	All	Low
ConnectionHandleCount	j2cModule.numConnectionHandles	The number of connections that are associated with ManagedConnections (physical connections) objects in this pool	5.0	Per connection factory	CountStatistic	All	Low
CreateCount	j2cModule.numManagedConnectionsCreated	The total number of managed connections created	5.0	Per connection factory	CountStatistic	Basic	Low
CloseCount	j2cModule.numManagedConnectionsDestroyed	The total number of managed connections destroyed	5.0	Per connection factory	CountStatistic	Basic	Low
AllocateCount	j2cModule.numManagedConnectionsAllocated	The total number of times that a managed connection is allocated to a client (the total is maintained across the pool, not per connection).	5.0	Per connection factory	CountStatistic	All	Low
FreedCount	j2cModule.numManagedConnectionsReleased	The total number of times that a managed connection is released back to the pool (the total is maintained across the pool, not per connection).	5.0	Per connection factory	CountStatistic	All	Low
FaultCount	j2cModule.faults	The number of faults, such as timeouts, in the connection pool	5.0	Per connection factory	CountStatistic	All	Low
FreePoolSize	j2cModule.freePoolSize	The number of free connections in the pool	5.0	Per connection factory	BoundedRangeStatistic	Basic	High
PoolSize	j2cModule.poolSize	Average number of managed connections in the pool.	5.0	Per connection factory	BoundedRangeStatistic	Basic	High
WaitingThreadCount	j2cModule.concurrentWaiters	Average number of threads concurrently waiting for a connection	5.0	Per connection factory	RangeStatistic	Basic	High
PercentUsed	j2cModule.percentUsed	Average percent of the pool that is in use. The value is determined by the total number of configured connections in the ConnectionPool, not the current number of connections.	5.0	Per connection factory	RangeStatistic	All	High
PercentMaxed	j2cModule.percentMaxed	Average percent of the time that all connections are in use	5.0	Per connection factory	RangeStatistic	All	High

WaitTime	j2cModule.avgWait	Average waiting time in milliseconds until a connection is granted	5.0	Per connection factory	TimeStatistic	Basic	Medium
UseTime	j2cModule.useTime	Average time in milliseconds that connections are in use	5.0	Per connection factory	TimeStatistic	Basic	Medium

Java virtual machine counters

The Java virtual machine (JVM) counters are used to monitor JVM performance. The total, used, and free heap size counters are available without any additional configuration settings. The remaining counters are available only when a Java virtual machine profiler is enabled. See [Enabling the Java virtual machine profiler data](#) for more information on this task.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
CpuUsage	jvmRuntimeModule.cpuUsage	The average percent of central processing unit (CPU) usage since the last query	6.1 and later	Per JVM	CountStatistic	Basic	Low
FreeMemory	jvmRuntimeModule.freeMemory	The free memory in the JVM run time	3.5.5 and later	Per JVM	CountStatistic	Extended	Low
UsedMemory	jvmRuntimeModule.usedMemory	The used memory in the JVM run time	3.5.5 and later	Per JVM	CountStatistic	Basic	Low
HeapSize	jvmRuntimeModule.totalMemory	The total memory in the JVM run time	3.5.5 and later	Per JVM	BoundedRangeStatistic. The upperBound and lowerBound are not implemented for the Total memory counter.	Basic	High
Up Time	jvmRuntimeModule.upTime	The amount of time that the JVM is running	5.0	Per JVM	CountStatistic	Basic	Low
GCCount	jvmRuntimeModule.numGcCalls	The number of garbage collection calls. This counter is not available unless the JVM profiler is enabled. See Enabling the JVM profiler data.	4.0 and later	Per JVM	CountStatistic	All	Max
GCIntervalTime	jvmRuntimeModule.avgTimeBetweenGcCalls	The average garbage collection value in seconds between two garbage collections. This counter is not available unless the JVM profiler is enabled. See Enabling the JVM profiler data.	4.0 and later	Per JVM	TimeStatistic	All	Max
GC Time	jvmRuntimeModule.avgGcDuration	The average duration of a garbage collection. This counter is not available unless the JVM profiler is enabled. See Enabling the JVM profiler data.	4.0 and later	Per JVM	TimeStatistic	All	Max
WaitsForLockCount	jvmRuntimeModule.numWaitsForLock	The number of times that a thread waits for a lock. This counter is not available unless the JVM profiler is enabled. See Enabling the JVM profiler data.	4.0 and later	Per JVM	CountStatistic	All	Max
WaitForLockTime	jvmRuntimeModule.avgTimeWaitForLock	The average time that a thread waits for a lock. This counter is not available unless the JVM profiler is enabled. See Enabling the JVM profiler data.	4.0 and later	Per JVM	TimeStatistic	All	Max

ThreadStartedCount	jvmRuntimeModule.numThreadsStarted	The number of threads started. This counter is not available unless the JVM profiler is enabled. See Enabling the JVM profiler data.	4.0 and later	Per JVM	CountStatistic	All	Max
ThreadEndedCount	jvmRuntimeModule.numThreadsDead	The number of failed threads. This counter is not available unless the JVM profiler is enabled. See Enabling the JVM profiler data.	4.0 and later	Per JVM	CountStatistic	All	Max
ObjectAllocateCount	jvmRuntimeModule.numObjectsAllocated	The number of objects that are allocated in the heap. This counter is not available unless the -XrunpmjvmpiProfiler option is set when starting the JVM.	From 4.0 to 6.0.x. It is deprecated in 6.1.	Per JVM	CountStatistic	All	Max
ObjectMovedCount	jvmRuntimeModule.numObjectsMoved	The number of objects in the heap. This counter is not available unless the -XrunpmjvmpiProfiler option is set when starting the JVM.	From 4.0 to 6.0.x. It is deprecated in 6.1.	Per JVM	CountStatistic	All	Max
ObjectFreedCount	jvmRuntimeModule.numObjectsFreed	The number of objects freed in the heap. This counter is not available unless the -XrunpmjvmpiProfiler option is set when starting the JVM.	From 4.0 to 6.0.x. It is deprecated in 6.1.	Per JVM	CountStatistic	All	Max

Important: The statistics that are gathered through the JVM Tool Interface (JVMTI) is different between the JVM provided by IBM and the Sun HotSpot-based JVM, including Sun HotSpot JVM on Solaris and HP's JVM for HP-UX.

Object Request Broker counters

Use this page as a reference for properties of Object Request Broker counters.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
LookupTime	orbPerfModule.referenceLookupTime	The time (in milliseconds) to look up an object reference before method dispatch can be carried out. An excessively long time can indicate an EJB container lookup problem.	5.0	Object Request Broker (ORB)	TimeStatistic	All	Medium
RequestCount	orbPerfModule.totalRequests	The total number of requests sent to the ORB	5.0	ORB	CountStatistic	All	Low
ConcurrentRequestCount	orbPerfModule.concurrentRequests	The number of requests that are concurrently processed by the ORB	5.0	ORB	RangeStatistic	All	High
ProcessingTime	orbPerfModule.interceptors.processingTime	The time (in milliseconds) it takes a registered portable interceptor to run	5.0	Per interceptor	TimeStatistic	All	Medium

Servlet session counters

Use this page as a reference for properties of servlet session counters.

Data counters for this category contain usage information for HTTP sessions.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
CreateCount	ServletSessionsModule.createdSessions	The number of sessions that were created	3.5.5 and later	Per Web application	CountStatistic	All	Low
InvalidateCount	ServletSessionsModule.invalidatedSessions	The number of sessions that were invalidated	3.5.5 and later	Per Web application	CountStatistic	All	Low
LifeTime	ServletSessionsModule.sessionLifeTime	The average session life time in milliseconds (time invalidated - time created)	3.5.5 and later	Per Web application	TimeStatistic	Extended	Medium
ActiveCount	ServletSessionsModule.activeSessions	The number of concurrently active sessions. A session is active if the WebSphere Application Server is currently processing a request that uses that session.	3.5.5 and later	Per Web application	RangeStatistic	All	High
LiveCount	ServletSessionsModule.liveSessions	The number of sessions that are currently cached in memory	5.0 and later	Per Web application	RangeStatistic	Basic	High
NoRoomForNewSessionCount	ServletSessionsModule.noRoomForNewSession	Applies only to session in memory with AllowOverflow=false. The number of times that a request for a new session cannot be handled because it exceeds the maximum session count.	5.0	Per Web application	CountStatistic	Extended	Low
CacheDiscardCount	ServletSessionsModule.cacheDiscards	The number of session objects that have been forced out of the cache. A least recently used (LRU) algorithm removes old entries to make room for new sessions and cache misses. Applicable only for persistent sessions.	5.0	Per Web application	CountStatistic	All	Low
ExternalReadTime	ServletSessionsModule.externalReadTime	The time (milliseconds) taken in reading the session data from the persistent store. For multirow sessions, the metrics are for the attribute; for single row sessions, the metrics are for the entire session. Applicable only for persistent sessions. When using a JMS persistent store, you can choose to serialize the replicated data. If you choose not to serialize the data, the counter is not available.	5.0	Per Web application	TimeStatistic	Extended	Medium

ExternalReadSize	javax.servlet.SessionModule.externalReadSize	Size of the session data read from persistent store. Applicable only for (serialized) persistent sessions; similar to external Read Time.	5.0	Per Web application	TimeStatistic	Extended	Medium
ExternalWriteTime	javax.servlet.SessionModule.externalWriteTime	The time (milliseconds) taken to write the session data from the persistent store. Applicable only for (serialized) persistent sessions. Similar to external Read Time.	5.0	Per Web application	TimeStatistic	Extended	Medium
ExternalWriteSize	javax.servlet.SessionModule.externalWriteSize	The size of the session data written to persistent store. Applicable only for (serialized) persistent sessions. Similar to external Read Time.	5.0	Per Web application	TimeStatistic	Extended	Medium
AffinityBreakCount	javax.servlet.SessionModule.affinityBreaks	The number of requests that are received for sessions that were last accessed from another Web application. This value can indicate failover processing or a corrupt plug-in configuration.	5.0	Per Web application	CountStatistic	All	Low
SessionObjectSize	javax.servlet.SessionModule.serializeableSessObjSize	The size in bytes of (the serializable attributes of) in-memory sessions. Only session objects that contain at least one serializable attribute object is counted. A session can contain some attributes that are serializable and some that are not. The size in bytes is at a session level.	5.0	Per Web application	TimeStatistic	All	Max
TimeSinceLastActivated	javax.servlet.SessionModule.timeSinceLastActivated	The time difference in milliseconds between previous and current access time stamps. Does not include session time out.	5.0	Per Web application	TimeStatistic	All	Medium
TimeoutInvalidationCount	javax.servlet.SessionModule.invalidatedViaTimeout	The number of sessions that are invalidated by timeout.	5.0	Per Web application	CountStatistic	All	Low
ActivateNonExistSessionCount	javax.servlet.SessionModule.activateNonExistSessions	The number of requests for a session that no longer exists, presumably because the session timed out. Use this counter to help determine if the timeout is too short.	5.0	Per Web application	CountStatistic	All	Low

Transaction counters

Use this page as a reference for properties of transaction counters.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
GlobalBegunCount	transactionModule.globalTransBegun	The total number of global transactions started on the server	4.0 and later	Per transaction manager or server	CountStatistic	Extended	Low
GlobalInvolvedCount	transactionModule.globalTransInvolved	The total number of global transactions involved on the server (for example, begun and imported)	4.0 and later	Per transaction manager or server	CountStatistic	All	Low
LocalBegunCount	transactionModule.localTransBegun	The total number of local transactions started on the server	4.0 and later	Per transaction manager or server	CountStatistic	Extended	Low
ActiveCount	transactionModule.activeGlobalTrans	The number of concurrently active global transactions	3.5.5 and later	Per transaction manager or server	CountStatistic	Basic	Low
LocalActiveCount	transactionModule.activeLocalTrans	The number of concurrently active local transactions	4.0 and later	Per transaction manager or server	CountStatistic	All	Low
GlobalTranTime	transactionModule.globalTranDuration	The average duration of global transactions	3.5.5 and later	Per transaction manager or server	TimeStatistic	Extended	Medium
LocalTranTime	transactionModule.localTranDuration	The average duration of local transactions	4.0 and later	Per transaction manager or server	TimeStatistic	Extended	Medium
GlobalBeforeCompletionTime	transactionModule.globalBeforeCompletionDuration	The average duration of before_completion for global transactions	4.0 and later	Per transaction manager or server	TimeStatistic	All	Medium
GlobalCommitTime	transactionModule.globalCommitDuration	The average duration of commit for global transactions	4.0 and later	Per transaction manager or server	TimeStatistic	All	Medium
GlobalPrepareTime	transactionModule.globalPrepareDuration	The average duration of prepare for global transactions	4.0 and later	Per transaction manager or server	TimeStatistic	All	Medium
LocalBeforeCompletionTime	transactionModule.localBeforeCompletionDuration	The average duration of before_completion for local transactions	4.0 and later	Per transaction manager or server	TimeStatistic	All	Medium
LocalCommitTime	transactionModule.localCommitDuration	The average duration of commit for local transactions	4.0 and later	Per transaction manager or server	TimeStatistic	All	Medium
CommittedCount	transactionModule.globalTransCommitted	The total number of global transactions committed	3.5.5 and later	Per transaction manager or server	CountStatistic	Basic	Low
RolledbackCount	transactionModule.globalTransRolledBack	The total number of global transactions rolled back	3.5.5 and later	Per transaction manager or server	CountStatistic	Basic	Low
OptimizationCount	transactionModule.numOptimization	The number of global transactions converted to single phase for optimization	4.0 and later	Per transaction manager or server	CountStatistic	All	Low
LocalCommittedCount	transactionModule.localTransCommitted	The number of local transactions committed	4.0 and later	Per transaction manager or server	CountStatistic	All	Low

LocalRolledbackCount	transactionModule.localTransRolledBack	The number of local transactions rolled back	4.0 and later	Per transaction manager or server	CountStatistic	All	Low
GlobalTimeoutCount	transactionModule.globalTransTimeout	The number of global transactions timed out	4.0 and later	Per transaction manager or server	CountStatistic	Extended	Low
LocalTimeoutCount	transactionModule.localTransTimeout	The number of local transactions timed out	4.0 and later	Per transaction manager or server	CountStatistic	Extended	Low

Thread pool counters

Use this page as a reference for properties of thread pool counters.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
CreateCount	threadPoolModule.threadCreates	The total number of threads created	3.5.5 and later	Per thread pool	CountStatistic	All	Low
DestroyCount	threadPoolModule.threadDestroys	The total number of threads destroyed	3.5.5 and later	Per thread pool	CountStatistic	All	Low
ActiveCount	threadPoolModule.activeThreads	The number of concurrently active threads	3.5.5 and later	Per thread pool	RangeStatistic	Extended	High
PoolSize	threadPoolModule.poolSize	The average number of threads in pool	3.5.5 and later	Per thread pool	BoundedRangeStatistic	Basic	High
PercentMaxed	threadPoolModule.percentMaxed	The average percent of the time that all threads are in use	3.5.5 and later	Per thread pool	RangeStatistic	All	High
DeclaredThreadHangCount	threadPoolModule.declaredThreadHang	The number of threads declared hung	5.1.1 and later	Per thread pool	CountStatistic	All	Max
ClearedThreadHangCount	threadPoolModule.declaredThreadHangCleared	The number of thread hangs cleared	5.1.1 and later	Per thread pool	CountStatistic	All	Max
ConcurrentHungThreadCount	threadPoolModule.concurrentlyHungThreads	The number of concurrently hung threads	5.1.1 and later	Per thread pool	RangeStatistic	All	Max
ActiveTime	threadPoolModule.activeTime	The average time in milliseconds the threads are in active state	5.1.1 and later	Per thread pool	TimeStatistic	All	Max

Web application counters

Data counters for this category contain information for the selected server.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
LoadedServletCount	webAppModule.numLoadedServlets	The number of loaded servlets	3.5.5 and later	Per Web application	CountStatistic	All	Low
ReloadCount	webAppModule.numReloads	The number of reloaded servlets	3.5.5 and later	Per Web application	CountStatistic	All	Low
RequestCount	webAppModule.servlets.totalRequests	Total number of requests that a servlet processed	3.5.5 and later	Per servlet	CountStatistic	Basic	Low
ConcurrentRequests	webAppModule.servlets.concurrentRequests	The number of requests that are concurrently processed	3.5.5 and later	Per servlet	RangeStatistic	Extended	High
Service Time	webAppModule.servlets.responseTime	The response time, in milliseconds, of a servlet request	3.5.5 and later	Per servlet	TimeStatistic	Basic	Medium
ErrorCount	webAppModule.servlets.numErrors	Total number of errors in a servlet or JavaServer Page (JSP)	3.5.5 and later	Per servlet	CountStatistic	Extended	Low

Workload Management counters

Use this page as a reference for properties of workload management counters.

Data counters for this category contain information for workload management.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
Num I/O requests	wlmModule.server.numIncomingRequests	The total number of incoming I/O requests to an application server	5.0	Per server	Count/Statistic	Extended	Low
Num strong affinity I/O requests	wlmModule.server.numIncomingStrongAffinityRequests	The number of incoming I/O requests to an application server that are based on a strong affinity. A strong affinity request is defined as a request that must be serviced by this application server because of a dependency that resides on the server. This request could not successfully be serviced on another member in the server cluster. In Version 5.0 ND edition, transactional affinity is the only example of a strong affinity.	5.0	Per server	Count/Statistic	All	Low
Num no affinity I/O requests	wlmModule.server.numIncomingNonAffinityRequests	The number of incoming I/O requests to an application server based on no affinity. This request was sent to this server based on workload management selection policies that were decided in the Workload Management (WLM) run time of the client.	5.0	Per server	Count/Statistic	All	Low
Num non-WLM enabled I/O requests	wlmModule.server.numIncomingNonWLMObjectRequests	The number of incoming I/O requests to an application server that came from a client that does not have the WLM run time present or where the object reference on the client was flagged not to participate in workload management.	5.0	Per server	Count/Statistic	All	Low
Num server cluster updates	wlmModule.server.numServerClusterUpdates	The number of times initial or updated server cluster data is sent to a server member from the deployment manager. This metric determines how often cluster information is being propagated.	5.0	Per server	Count/Statistic	All	Low
Num of WLM clients serviced	wlmModule.server.numOfWLMClientsServiced	The number of WLM enabled clients that have been serviced by this application server.	5.0	Per server	Count/Statistic	All	Low
Num concurrent requests	wlmModule.server.numOfConcurrentRequests	The number of remote I/O requests currently being processed by this server	5.0	Per server	Range/Statistic	Extended	High

Server response time	wlmModule.server.serverResponseTime		5.0	Per server	TimeStatistic	Extended	Medium
Num outgoing I/O requests	wlmModule.client.numOfOutgoingRequests	The response time (in milliseconds) of I/O requests being serviced by an application server. The response time is calculated based on the time the request is received to the time when the reply is sent back out.	5.0	Per WLM	CountStatistic	All	Low
Num server cluster updates	wlmModule.client.numClientClusterUpdates	The total number of outgoing I/O requests being sent from a client to an application server	5.0	Per WLM	CountStatistic	All	Low
Client response time	wlmModule.client.clientResponseTime	The number of times initial or updated server cluster data is sent to a WLM enabled client from server cluster member. Use this metric to determine how often cluster information is being propagated.	5.0	Per WLM	TimeStatistic	All	Medium

System counters

Use this page as a reference for properties of system counters.

Counters for this category contain information for a machine (node).

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
CPUUsageSinceLastMeasurement	systemModule.cpuUtilization	The average system CPU utilization taken over the time interval since the last reading. Because the first call is required to perform initialization, a value such as 0, which is not valid, will be returned. All subsequent calls return the expected value. On SMP machines, the value returned is the utilization averaged over all CPUs.	5.0	Per node	CountStatistic	Basic	Low
FreeMemory	systemModule.freeMemory	The amount of real free memory available on the system. Real memory that is not allocated is only a lower bound on available real memory, since many operating systems take some of the otherwise unallocated memory and use it for additional I/O buffering. The exact amount of buffer memory which can be freed up is dependent on both the platform and the application(s) running on it.	5.0	Per node	CountStatistic	All	Low
CPUUsageSinceServerStarted	systemModule.avgCpuUtilization	The average percent CPU Usage that is busy after the server is started.	5.0	Per node	TimeStatistic	Extended	Medium

Dynamic cache counters

Use this page as a reference for properties of dynamic cache counters.

You can use the Performance Monitoring Infrastructure (PMI) data for Dynamic Cache to monitor the behavior and performance of the dynamic cache service. For information on the functions and usages of dynamic cache, refer to “Task overview: Using the dynamic cache service to improve performance” on page 1978.

Use the DynaCache MBean to access the related data and display it under Dynamic Cache in TPV.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
MaxInMemoryCacheEntryCount	cacheModule..maxInMemoryCacheEntryCount	The maximum number of in-memory cache entries. It is located under servlet instance or object instance.	5.0 and later	Per Server	CountStatistic	All	Low
InMemoryCacheEntryCount	cacheModule.inMemoryCacheEntryCount	The current number of in-memory cache entries. It is located under servlet instance and object instance.	5.0 and later	Per Server	CountStatistic	All	Low
HitsInMemoryCount	cacheModule.hitsInMemoryCount	The number of requests for cacheable objects that are served from memory. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
HitsOnDiskCount	cacheModule.hitsOnDiskCount	The number of requests for cacheable objects that are served from disk. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
ExplicitInvalidationCount	cacheModule.explicitInvalidationCount	The number of explicit invalidations. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
LruInvalidationCount	cacheModule.lruInvalidationCount	The number of cache entries that are removed from memory by a Least Recently Used (LRU) algorithm. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low

TimeoutInvalidationCount	cacheModule.timeoutInvalidationCount	The number of cache entries that are removed from memory and disk because their timeout has expired. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
InMemoryAndDiskCacheEntryCount	cacheModule.inMemoryAndDiskCacheEntryCount	The current number of used cache entries in memory and disk. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
RemoteHitCount	cacheModule.remoteHitCount	The number of requests for cacheable objects that are served from other Java virtual machines within the replication domain. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
MissCount	cacheModule.missCount	The number of requests for cacheable objects that were not found in the cache. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
ClientRequestCount	cacheModule.clientRequestCount	The number of requests for cacheable objects that are generated by applications running on this application server. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low

DistributedRequestCount	cacheModule.distributedRequestCount	The number of requests for cacheable objects that are generated by cooperating caches in this replication domain. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
ExplicitMemoryInvalidationCount	cacheModule.explicitMemoryInvalidationCount	The number of explicit invalidations resulting in the removal of an entry from memory. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
ExplicitDiskInvalidationCount	cacheModule.explicitDiskInvalidationCount	The number of explicit invalidations resulting in the removal of an entry from disk. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
LocalExplicitInvalidationCount	cacheModule.localExplicitInvalidationCount	The number of explicit invalidations generated locally, either programmatically or by a cache policy. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
RemoteExplicitInvalidationCount	cacheModule.remoteExplicitInvalidationCount	The number of explicit invalidations received from a cooperating Java virtual machine in this replication domain. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low

RemoteCreationCount	cacheModule.remoteCreationCount	The number of cache entries that are received from cooperating dynamic caches. For servlet instance, it is located under template group. For object instance, it is located under object group.	5.0 and later	Per Server	CountStatistic	All	Low
ObjectsOnDisk	cacheModule.objectsOnDisk	The current number of cache entries on disk. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
HitsOnDisk	cacheModule.hitsOnDisk	The number of requests for cacheable objects that are served from disk. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
ExplicitInvalidationsFromDisk	cacheModule.explicitInvalidationFromDisk	The number of explicit invalidations resulting in the removal of entries from disk. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
TimeoutInvalidationsFromDisk	cacheModule.timeoutInvalidationsFromDisk	The number of disk timeouts. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
PendingRemovalFromDisk	cacheModule.pendingRemovalFromDisk	The current number of pending entries that are to be removed from disk. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
DependencyIDsOnDisk	cacheModule.dependencyIdsOnDisk	The current number of dependency ID that are on disk. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
DependencyIDsBufferedForDisk	cacheModule.dependencyIdsBufferedForDisk	The current number of dependency IDs that are buffered for the disk. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
DependencyIDsOffloadedToDisk	cacheModule.dependencyIdsOffloadedToDisk	The number of dependency IDs that are offloaded to disk. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low

Dependency/IDBasedInvalidationsFromDisk	cacheModule.dependency/IdBasedInvalidationsFromDisk	The number of dependency ID-based invalidations. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
TemplatesOnDisk	cacheModule.templatesOnDisk	The current number of templates that are on disk. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
TemplatesBufferedForDisk	cacheModule.templatesBufferedForDisk	The current number of templates that are buffered for the disk. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
TemplatesOffloadedToDisk	cacheModule.templatesOffloadedToDisk	The number of templates that are offloaded to disk. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
TemplateBasedInvalidationsFromDisk	cacheModule.templateBasedInvalidationsFromDisk	The number of template-based invalidations. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
GarbageCollectorInvalidationsFromDisk	cacheModule.garbageCollectorInvalidationsFromDisk	The number of garbage collector invalidations resulting in the removal of entries from disk cache due to high cache threshold has been reached. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low
OverflowInvalidationsFromDisk	cacheModule.overflowInvalidationsFromDisk	The number of invalidations resulting in the removal of entries from disk due to exceeding the disk cache size or disk cache size in GB limit. It is located under disk group.	6.1 and later	Per Server	CountStatistic	All	Low

Web services gateway counters

Use this page as a reference for properties of Web services gateway counters.

Counters for this category contain information for Web services gateways (WSGW). Examples include the number of synchronous and asynchronous requests and responses.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
SynchronousRequestCount	wsgwModule.synchronousRequests	The number of synchronous requests made.	5.0	Per Web service	CountStatistic	All	Low
SynchronousResponseCount	wsgwModule.synchronousResponses	The number of synchronous responses made.	5.0	Per Web service	CountStatistic	All	Low
AsynchronousRequestCount	wsgwModule.asynchronousRequests	The number of asynchronous requests made.	5.0	Per Web service	CountStatistic	All	Low
AsynchronousResponseCount	wsgwModule.asynchronousResponses	The number of asynchronous responses made.	5.0	Per Web service	CountStatistic	All	Low

Web services counters

Use this page as a reference for properties of Web services counters.

Counters for this category contain information for the Web services.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
LoadedWebServiceCount	webServicesModule.numLoadedServices	The number of loaded Web services	5.02 and above	Per service	CountStatistic	All	Low
ReceivedRequestCount	webServicesModule.services.numberReceived	The number of requests the service received	5.02 and above	Per Web service	CountStatistic	All	Low
DispatchedRequestCount	webServicesModule.services.numberDispatched	The number of requests the service dispatched or delivered	5.02 and above	Per Web service	CountStatistic	All	Low
ProcessedRequestCount	webServicesModule.services.numberSuccessful	The number of requests the service successfully processed	5.02 and above	Per Web service	TimeStatistic	All	Low
Response Time	webServicesModule.services.responseTime	The average response time, in milliseconds, for a successful request	5.02 and above	Per Web service	TimeStatistic	All	High
RequestResponseTime	webServicesModule.services.requestResponseTime	The average response time, in milliseconds, to prepare a request for dispatch	5.02 and above	Per Web service	TimeStatistic	All	Medium
DispatchResponseTime	webServicesModule.services.dispatchResponseTime	The average response time, in milliseconds, to dispatch a request	5.02 and above	Per Web service	TimeStatistic	All	Medium
ReplyResponseTime	webServicesModule.services.replyResponseTime	The average response time, in milliseconds, to prepare a reply after dispatch	5.02 and above	Per Web service	TimeStatistic	All	Medium
PayloadSize	webServicesModule.services.size	The average payload size in bytes of a received request or reply	5.02 and above	Per Web service	TimeStatistic	All	Medium
RequestPayloadSize	webServicesModule.services.requestSize	The average payload size in bytes of a request	5.02 and above	Per Web service	TimeStatistic	All	Medium
ReplyPayloadSize	webServicesModule.services.replySize	The average payload size in bytes of a reply	5.02 and above	Per Web service	TimeStatistic	All	Medium

Alarm Manager counters

Use this page as a reference for properties of alarm manager counters.

Counters for this category contain information for the Alarm Manager.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
AlarmsCreatedCount	alarmManagerModule.numCreates.name	The total number of alarms created by all asynchronous scopes for this WorkManager	5.0 and later	Per WorkManager	CountStatistic	All	High
AlarmsCancelledCount	alarmManagerModule.numCancelled.name	The number of alarms cancelled by the application	5.0 and later	Per WorkManager	CountStatistic	All	High
AlarmsFiredCount	alarmManagerModule.numFired.name	The number of alarms fired	5.0 and later	Per WorkManager	CountStatistic	All	High
AlarmLatencyDuration	alarmManagerModule.latency.name	The latency of alarms fired in milliseconds	5.0 and later	Per WorkManager	RangeStatistic	All	High
AlarmsPendingSize	alarmManagerModule.alarmsPending.name	The number of alarms waiting to fire	5.0 and later	Per WorkManager	RangeStatistic	All	High
AlarmRate	alarmManagerModule.alarmsPerSecond.name	The number of alarms firing per second	5.0 and later	Per WorkManager	RangeStatistic	All	High

Object Pool counters

Use this page as a reference for properties of Object Pool counters.

Counters for this category contain information for Object Pools.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
ObjectsCreatedCount	objectPoolModule.numCreates.name	The total number of objects created	5.0 and later	Per ObjectPool	CountStatistic	All	High
ObjectsAllocatedCount	objectPoolModule.numAllocates.name	The number of objects requested from the pool	5.0 and later	Per ObjectPool	CountStatistic	All	High
ObjectsReturnedCount	objectPoolModule.numReturns.name	The number of objects returned to the pool	5.0 and later	Per ObjectPool	CountStatistic	All	High
IdleObjectsSize	objectPoolModule.poolSize.name	The average number of idle object instances in the pool	5.0 and later	Per ObjectPool	RangeStatistic	All	High

Scheduler counters

Use this page as a reference for properties of Scheduler counters.

Counters for this category contain information for the Scheduler service.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
TaskFailureCount	schedulerModule.failedTasks.name	The number of tasks that failed to run	5.0 and later	Per Scheduler	CountStatistic	All	High
TaskFinishCount	schedulerModule.executedTasks.name	The number of tasks ran successfully	5.0 and later	Per Scheduler	CountStatistic	All	High
PollCount	schedulerModule.totalPolls.name	The number of poll cycles completed for all daemon threads	5.0 and later	Per Scheduler	CountStatistic	All	High
TaskFinishRate	schedulerModule.tasksPerSec.name	The number of tasks run per second	5.0 and later	Per Scheduler	RangeStatistic	All	High
TaskCollisionRate	schedulerModule.collisionsPerSec.name	The number of collisions encountered per second between competing poll daemons	5.0 and later	Per Scheduler	RangeStatistic	All	High
PollQueryDuration	schedulerModule.queryTime.name	The start time in milliseconds for each poll daemon thread's database poll query	5.0 and later	Per Scheduler	RangeStatistic	All	High
RunDuration	schedulerModule.execTime.name	The time in milliseconds taken to run a task.	5.0 and later	Per Scheduler	RangeStatistic	All	High
TaskExpirationRate	schedulerModule.taskLoadPerPoll.name	The number of tasks in a poll query	5.0 and later	Per Scheduler	RangeStatistic	All	High
TaskDelayDuration	schedulerModule.execLatency.name	The period of time in seconds that the task is delayed	5.0 and later	Per Scheduler	RangeStatistic	All	High
PollDuration	schedulerModule.pollTime.name	The number of seconds between poll cycles	5.0 and later	Per Scheduler	RangeStatistic	All	High
TaskRunRate	schedulerModule.taskExecPerPoll.name	The number of tasks run by each poll daemon thread. (Multiply this by the number of poll daemon threads to get the tasks run per effective poll cycle.)	5.0 and later	Per Scheduler	RangeStatistic	All	High

High availability manager counters

PMI maintains statistical data within the entire WebSphere Application Server domain, including multiple nodes and servers.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
Number of local groups	hamanagermodule.numLocalGroups	The total number of local groups.	6.0 and above	Per server	RangeStatistic	All	High
Group state rebuild time	hamanagermodule.rebuildTime	Time taken in milliseconds to rebuild the global group state. During the rebuild time, no fail-over can happen. If this time is too high and is unacceptable for the desired availability, you may want to increase the number of coordinators. For proper operation of this counter, you must host the active coordinator in an application server other than the deployment manager.	6.0 and above	Per server	TimeStatistic	All	High
Number of bulletin-board subjects	hamanagermodule.bbMgrNumSubjects	The total number of subjects managed.	6.0 and above	Per server	RangeStatistic	All	High
Number of bulletin-board subscriptions	hamanagermodule.bbMgrNumSubscriptions	The total number of bulletin-board subscriptions.	6.0 and above	Per server	RangeStatistic	All	High
Bulletin-board rebuild time	hamanagermodule.bbMgrRebuildTime	Time taken in milliseconds to rebuild the global state of the bulletin-board. During this time no messages will be received by the subscribers. If this time is too high, and is unacceptable, you may want to increase the number of coordinators. For proper operation of this counter, you must host the active coordinator in an application server other than the deployment manager.	6.0 and above	Per server	TimeStatistic	All	High
Number of local bulletin-board subjects	hamanagermodule.bbLocalNumSubjects	The total number of subjects being posted to locally. The number includes the proxy postings (if any) done by the core group bridge service on behalf of servers belonging to different WebSphere cells.	6.0 and above	Per server	RangeStatistic	All	High
Number of local bulletin-board subscriptions	hamanagermodule.bbLocalNumSubscriptions	The total number of local subject subscriptions. The number includes the proxy subscriptions (if any) done by the core group bridge service on behalf of servers belonging to different WebSphere cells.	6.0 and above	Per server	TimeStatistic	All	High

DCS stack counters

PMI maintains statistical data within the entire WebSphere Application Server domain, including multiple nodes and servers.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
Number of message buffer reallocations	DCSSStats.numOfReallocs	Number of message buffer reallocations due to inadequate buffer size. If this number is larger than 20 percent of the number of sent messages, you may want to contact IBM Support	6.0 and above	Per DCS stack	CountStatistic	All	Medium
Outgoing message size	DCSSStats.outgoingMessageSize	Minimal, maximal, and average size (in bytes) of the messages that were sent through the DCS stack	6.0 and above	Per DCS stack	AverageStatistic	All	High
Number of sent messages	DCSSStats.outgoingMessageCounter	Number of messages sent through the DCS stack	6.0 and above	Per DCS stack	CountStatistic	All	High
Incoming message size	DCSSStats.incomingMessageSize	Minimal, maximal and average size (in bytes) of the messages that were received by the DCS stack	6.0 and above	Per DCS stack	AverageStatistic	All	High
Number of received messages	DCSSStats.incomingMessageCounter	Number of messages received by the DCS stack	6.0 and above	Per DCS stack	CountStatistic	All	High
Amount of time needed for the synchronization procedure to complete	DCSSStats.vsCompleteCurrentTime	Amount of time needed to guarantee that all view members are synchronized.	6.0 and above	Per DCS stack	TimeStatistic	All	High
Number of messages retransmitted by local member during the view change	DCSSStats.numOfVSCompletionMessages	Number of messages that were retransmitted during the view change to ensure synchronization with other members.	6.0 and above	Per DCS stack	AverageStatistic	All	High
Number of times that the synchronization procedure timed out	DCSSStats.vsTimeoutExpiredCounter	Number of times that the synchronization procedure timed out.	6.0 and above	Per DCS stack	CountStatistic	All	Medium
Number of times that a high severity congestion event for outgoing messages was raised	DCSSStats.transmitterCongestedCounter	Number of times that a high severity congestion event for outgoing messages was raised.	6.0 and above	Per DCS stack	CountStatistic	All	Medium
Coalesce Time	DCSSStats.coalesceTime	Measures the amount of time it actually takes to coalesce a view.	6.0 and above	Per DCS stack	TimeStatistic	All	Medium
Join View Change Time	DCSSStats.mergeTime	Measures the time to do a merge view change. The DCS stack is blocked during this time.	6.0 and above	Per DCS stack	TimeStatistic	All	High
Remove View Change Time	DCSSStats.splitTime	Measures the time to do a split view change. The DCS stack is blocked during this time.	6.0 and above	Per DCS stack	TimeStatistic	All	High
Number of suspicions	DCSSStats.suspectCounter	Measures the number of times that the local member suspected other members.	6.0 and above	Per DCS stack	CountStatistic	All	High
Number of view changes	DCSSStats.viewCounter	Number of times that this member underwent view changes.	6.0 and above	Per DCS stack	CountStatistic	All	Medium
View group size	DCSSStats.groupSize	Measures the size of the group the local member belongs to.	6.0 and above	Per DCS stack	AverageStatistic	All	Medium

PortletContainer PMI counters

Use this page as a reference for properties of PortletContainer PMI counters.

Counter definitions

These counters are the PMI measurement points for a portlet and a portlet application.

Name	Key	Description	Version	Unit	Type	Level	Overhead
totalRequests	portletModule.totalRequests	The number of requests made to the portlet module.	6.1	unit.none	CountStatistic	All	Low
numErrors	portletModule.numErrors	The number of errors reported from the portlet module.	6.1	unit.none	CountStatistic	All	Low
concurrentRequests	portletModule.concurrentRequests	The number of concurrent requests.	6.1	unit.none	CountStatistic	All	High
renderResponseTime	portletModule.renderResponseTime	The render response time.	6.1	unit.ms	CountStatistic	All	Medium
actionResponseTime	portletModule.actionResponseTime	The action response time.	6.1	unit.ms	CountStatistic	All	Medium
numLoadedPortlets	portletAppModule.numLoadedPortlets	The number of portlets loaded.	6.1	unit.none	CountStatistic	All	Low

Related tasks

“Task overview: Managing portlets” on page 205
You can use this task to manage deployed portlet applications.

Use this page as a general overview of monitoring, data collection, and counters using Performance Monitoring Infrastructure (PMI) and Tivoli Performance Viewer (TPV).

Proxy counters

Use this page as a reference for properties of proxy counters.

You can use the Performance Monitoring Infrastructure (PMI) data to monitor the behavior and performance of the proxy service.

Counter definitions:

Name	Key	Description	Version	Granularity	Type	Level	Overhead
OutboundConnectionCount	OutboundConnectionCount	The total number of outbound connections since server start.	6.1	Per proxy server	CountStatistic	Basic	Low
ActiveOutboundConnectionCount	ActiveOutboundConnectionCount	The total concurrent outbound connection count at a specific time	6.1	Per proxy server	CountStatistic	Basic	Low
RequestCount	RequestCount	The total number of requests processed by the proxy server since server start.	6.1	Per proxy server	CountStatistic	Basic	Low
FailedRequestCount	FailedRequestCount	The number of failed requests due to an internal error.	6.1	Per proxy server	CountStatistic	Extended	Low
ProxiedRequestCount	ProxiedRequestCount	The number of requests forwarded to back-end application servers or Web servers.	6.1	Per proxy server	CountStatistic	Extended	Low
LocalRequestCount	LocalRequestCount	The number of requests served locally from the proxy. Includes cache hits and failed requests due to internal error.	6.1	Per proxy server	CountStatistic	Extended	Low
ResponseTime(TTLB)	ResponseTime(TTLB)	Proxy Server response time. The number of milliseconds that have passed before the last byte of the response was sent back to client.	6.1	Per request	TimeStatistic	Extended	Medium
ServerResponseTime	ServerResponseTime	Target server response time. The number of milliseconds that have passed before proxy received the first byte from target servers.	6.1	Per request	CountStatistic	Extended	Medium
CacheHitCountValidated	CacheHitCountValidated	The total cache hit count revalidated with target servers.	6.1	Per proxy server	CountStatistic	Basic	Low
CacheHitCountUnvalidated	CacheHitCountUnvalidated	The total cache hit count processed locally.	6.1	Per proxy server	CountStatistic	Basic	Low
CacheMissCount	CacheMissCount	The total cache miss count.	6.1	Per proxy server	CountStatistic	Basic	Low
CacheEsiInvalidateCount	CacheEsiInvalidateCount	The total ESI cache invalidate count.	6.1	Per proxy server	CountStatistic	Basic	Low
CacheEsiEdgeCacheableCount	CacheEsiEdgeCacheableCount	The number of responses that are ESI edge cacheable.	6.1	Per proxy server	CountStatistic	Extended	Low
CacheEsiEdgeCachedCount	CacheEsiEdgeCachedCount	The number of ESI edge cacheable responses that are really cached in the proxy server	6.1	Per proxy server	CountStatistic	Extended	Low

ActiveServiceContextCount	ActiveServiceContextCount	The number of active service contexts in the proxy at a given time.	6.1	Per proxy server	CountStatistic	Extended	High
SuspendedServiceContextCount	SuspendedServiceContextCount	The number of suspended service context in the proxy at a given time.	6.1	Per proxy server	CountStatistic	Extended	High

Related tasks

Chapter 24, “Monitoring overall system health,” on page 2163

Monitoring overall system health is fundamentally important to understanding the health of every system involved with your system. This includes Web servers, application servers, databases, back-end systems, and any other systems critical to running your Web site.

Monitoring the proxy server with PMI

You can monitor the traffic of a proxy server using the Performance Monitoring Infrastructure (PMI) function.

Service Integration Bus (SIB) and Messaging counters

These counters are part of Performance Monitoring Infrastructure (PMI), which provides server-side monitoring and a client-side API to retrieve performance data.

For information on SIB counters, see the following articles:

- “MessageStore Statistics”
- “Mediation Framework Statistics” on page 2238
- “Message Processor Statistics” on page 2241
- “Communications statistics” on page 2251

MessageStore Statistics:

Consult this information for properties of MessageStore statistics.

Counter definitions:

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Storage Management > Cache

Name	Key	Description	Version	Granularity	Type	Level
CacheAddStoredCount	MessageStoreStats.CacheAddStoredCount	The number of items that have been added to the message store during the current session that are either persistent or potentially persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheAddNotStoredCount	MessageStoreStats.CacheAddNotStoredCount	The number of items that have been added to the message store during the current session that are not persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheUpdateStoredCount	MessageStoreStats.CacheUpdateStoredCount	The number of items that have been updated in the message store during the current session that are either persistent or potentially persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheUpdateNotStoredCount	MessageStoreStats.CacheUpdateNotStoredCount	The number of items that have been updated in the message store during the current session that are not persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheRemoveStoredCount	MessageStoreStats.CacheRemoveStoredCount	The number of items that have been removed from the message store during the current session that are either persistent or potentially persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheRemoveNotStoredCount	MessageStoreStats.CacheRemoveNotStoredCount	The number of items that have been removed from the message store during the current session that are not persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheRestoreCount	MessageStoreStats.CacheRestoreCount	The number of items restored to memory from persistence during the current session	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheCurrentStoredCount	MessageStoreStats.CacheCurrentStoredCount	The number of items currently in the dynamic memory cache which are either persistent or potentially persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheCurrentNotStoredCount	MessageStoreStats.CacheCurrentNotStoredCount	The number of items currently in the dynamic memory cache which are never persisted	6.0 and later	Per Messaging Engine	CountStatistic	High

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Storage Management > Cache

CacheCurrentStoredByteCount	MessageStoreStats.CacheCurrentStoredByteCount	The total of the declared sizes of all items currently in the dynamic memory cache which are either persistent or potentially persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheCurrentNotStoredByteCount	MessageStoreStats.CacheCurrentNotStoredByteCount	The current total of the declared sizes of all items in the dynamic memory cache which are never persisted	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheTotalStoredCount	MessageStoreStats.CacheTotalStoredCount	The total number of items which have been added to the dynamic memory cache during the current session which are either persistent or potentially persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheTotalNotStoredCount	MessageStoreStats.CacheTotalNotStoredCount	The total number of items which have been added to the dynamic memory cache during the current session which are never persisted in cache	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheTotalStoredByteCount	MessageStoreStats.CacheTotalStoredByteCount	The total of the declared sizes of all items which have been added to the dynamic memory cache during the current session which are either persistent or potentially persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheTotalNotStoredByteCount	MessageStoreStats.CacheTotalNotStoredByteCount	The total of the declared sizes of all items which have been added to the dynamic memory cache during the current session which are never persisted in cache	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheStoredDiscardCount	MessageStoreStats.CacheStoredDiscardCount	The total number of items which have been discarded from the dynamic memory cache during the current session which are either persistent or potentially persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheNotStoredDiscardCount	MessageStoreStats.CacheNotStoredDiscardCount	The total number of items which have been discarded from the dynamic memory cache during the current session which are never persisted	6.0 and later	Per Messaging Engine	CountStatistic	High

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Storage Management > Cache

CacheStoredDiscardByteCount	MessageStoreStats.CacheStoredDiscardByteCount	The total of the declared sizes of all items which have been added to the dynamic memory cache during the current session which are either persistent or potentially persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheNotStoredDiscardByteCount	MessageStoreStats.CacheNotStoredDiscardByteCount	The total of the declared sizes of all items which have been added to the dynamic memory cache during the current session which are never persisted	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheStoredRefusalCount	MessageStoreStats.CacheStoredRefusalCount	The total number of items which have been refused entry to the dynamic memory cache during the current session which are either persistent or potentially persistent	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheNotStoredRefusalCount	MessageStoreStats.CacheNotStoredRefusalCount	The total number of items which have been refused entry to the dynamic memory cache during the current session which are never persisted	6.0 and later	Per Messaging Engine	CountStatistic	High
CacheStreamSpillingCount	MessageStoreStats.CacheStreamSpillingCount	Number of streams currently spilling potentially persistent items	6.0 and later	Per Messaging Engine	CountStatistic	High

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Storage Management > Cache

Name	Key	Description	Version	Granularity	Type	Level
SpillDispatcherRequestSize	MessageStoreStats.SpillDispatcherRequestSize	Measures the number of operations on nonpersistent data dispatched for spilling to the data store.	6.0 and later	Per Messaging Engine	AverageStatistic	High
SpillDispatcherBatchSize	MessageStoreStats.SpillDispatcherBatchSize	Measures the batching of operations on nonpersistent data dispatched for spilling to the data store.	6.0 and later	Per Messaging Engine	AverageStatistic	High
SpillDispatcherAvoidanceCount	MessageStoreStats.SpillDispatcherAvoidanceCount	Measures the number of operations on nonpersistent data dispatched for spilling to the data store but whose spilling was subsequently unnecessary.	6.0 and later	Per Messaging Engine	AverageStatistic	High
SpillDispatcherAvoidanceSize	MessageStoreStats.SpillDispatcherAvoidanceSize	Measures the number of bytes associated with operations on nonpersistent data dispatched for spilling to the data store but whose spilling was subsequently unnecessary.	6.0 and later	Per Messaging Engine	AverageStatistic	High
PersistentDispatcherRequestSize	MessageStoreStats.PersistentDispatcherRequestSize	Measures the number of operations on reliable persistent data dispatched for writing to the data store.	6.0 and later	Per Messaging Engine	AverageStatistic	High
PersistentDispatcherBatchSize	MessageStoreStats.PersistentDispatcherBatchSize	Measures the batching of operations on reliable persistent data dispatched for writing to the data store.	6.0 and later	Per Messaging Engine	AverageStatistic	High
PersistentDispatcherCancellationCount	MessageStoreStats.PersistentDispatcherCancellationCount	Counts the number of global transaction completion phases whose operations cancelled out before being written to the data store.	6.0 and later	Per Messaging Engine	AverageStatistic	High
PersistentDispatcherAvoidanceCount	MessageStoreStats.PersistentDispatcherAvoidanceCount	Measures the number of operations on reliable persistent data dispatched for writing to the data store but whose writing was subsequently unnecessary.	6.0 and later	Per Messaging Engine	AverageStatistic	High

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Storage Management > Cache

PersistentDispatcherAvoidanceSize	MessageStoreStats.PersistentDispatcherAvoidanceSize	Measures the number of bytes associated with operations on reliable persistent data which were dispatched for writing to the data store but whose writing was subsequently unnecessary.	6.0 and later	Per Messaging Engine	AverageStatistic	High
JDBCOpenCount	MessageStoreStats.JDBCOpenCount	JDBC connections open	6.0 and later	Per Messaging Engine	CountStatistic	High
JDBCTransactionCompleteCount	MessageStoreStats.JDBCTransactionCompleteCount	JDBC local transactions completed	6.0 and later	Per Messaging Engine	CountStatistic	High
JDBCTransactionCompleteCount	MessageStoreStats.JDBCTransactionCompleteCount	JDBC local transactions completed	6.0 and later	Per Messaging Engine	CountStatistic	High
JDBCTransactionAbortCount	MessageStoreStats.JDBCTransactionAbortCount	JDBC local transactions aborted	6.0 and later	Per Messaging Engine	CountStatistic	High
JDBCTransactionTime	MessageStoreStats.JDBCTransactionTime	Total execution time of internal batches	6.0 and later	Per Messaging Engine	TimeStatistic	High
JDBCItemInsertCount	MessageStoreStats.JDBCItemInsertCount	JDBC Item table inserts	6.0 and later	Per Messaging Engine	CountStatistic	High
JDBCItemDeleteCount	MessageStoreStats.JDBCItemDeleteCount	JDBC Item table deletes	6.0 and later	Per Messaging Engine	CountStatistic	High
JDBCItemUpdateCount	MessageStoreStats.JDBCItemUpdateCount	JDBC Item table updates	6.0 and later	Per Messaging Engine	CountStatistic	High
ItemInsertBatchCount	MessageStoreStats.ItemInsertBatchCount	Item table insert batches	6.0 and later	Per Messaging Engine	CountStatistic	High
ItemDeleteBatchCount	MessageStoreStats.ItemDeleteBatchCount	Item table delete batches	6.0 and later	Per Messaging Engine	CountStatistic	High
ItemUpdateBatchCount	MessageStoreStats.ItemUpdateBatchCount	Item table update batches	6.0 and later	Per Messaging Engine	CountStatistic	High
JDBCTransactionInsertCount	MessageStoreStats.JDBCTransactionInsertCount	JDBC transaction table inserts	6.0 and later	Per Messaging Engine	CountStatistic	High
JDBCTransactionDeleteCount	MessageStoreStats.JDBCTransactionDeleteCount	JDBC transaction table deletes	6.0 and later	Per Messaging Engine	CountStatistic	High
JDBCTransactionUpdateCount	MessageStoreStats.JDBCTransactionUpdateCount	JDBC transaction table updates	6.0 and later	Per Messaging Engine	CountStatistic	High
TransactionInsertBatchCount	MessageStoreStats.TransactionInsertBatchCount	Transaction table insert batches	6.0 and later	Per Messaging Engine	CountStatistic	High
TransactionDeleteBatchCount	MessageStoreStats.TransactionDeleteBatchCount	Transaction table delete batches	6.0 and later	Per Messaging Engine	CountStatistic	High
TransactionUpdateBatchCount	MessageStoreStats.TransactionUpdateBatchCount	Transaction table update batches	6.0 and later	Per Messaging Engine	CountStatistic	High

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Storage Management > Expiry

Name	Key	Description	Version	Granularity	Type	Level
ExpiryIndexItemCount	MessageStoreStats.ExpiryIndexItemCount	Current number of items in the expiry index. These are items created with an expiry time in the future and which have not yet been consumed.	6.0 and later	Per Messaging Engine	CountStatistic	High

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Storage Management > Transactions

Name	Key	Description	Version	Granularity	Type	Level
LocalTransactionStartCount	MessageStoreStats.LocalTransactionStartCount	Local transactions started	6.0 and later	Per Messaging Engine	CountStatistic	High
LocalTransactionAbortCount	MessageStoreStats.LocalTransactionAbortCount	Local transactions aborted	6.0 and later	Per Messaging Engine	CountStatistic	High
LocalTransactionCommitCount	MessageStoreStats.LocalTransactionCommitCount	Local transactions committed	6.0 and later	Per Messaging Engine	CountStatistic	High
GlobalTransactionStartCount	MessageStoreStats.GlobalTransactionStartCount	Global transactions started	6.0 and later	Per Messaging Engine	CountStatistic	High
GlobalTransactionInDoubtCount	MessageStoreStats.GlobalTransactionInDoubtCount	Global transactions in doubt	6.0 and later	Per Messaging Engine	CountStatistic	High
GlobalTransactionAbortCount	MessageStoreStats.GlobalTransactionAbortCount	Global transactions cancelled	6.0 and later	Per Messaging Engine	CountStatistic	High
GlobalTransactionCommitCount	MessageStoreStats.GlobalTransactionCommitCount	Global transactions committed	6.0 and later	Per Messaging Engine	CountStatistic	High

Mediation Framework Statistics:

Consult this information for properties of mediation framework statistics.

Counter definitions:

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Mediations > Mediation

Name	Key	Description	Version	Granularity	Type	Level
ThreadCount	Mediation.ThreadCount	The number of messages being mediated concurrently at a mediation.	6.0 and later	per mediation	RangeStatistic	High

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Mediations > Mediation > Destination

Name	Key	Description	Version	Granularity	Type	Level
MediationTime	Mediation.MediationTime	The amount of time in milliseconds taken to mediate a message at a mediated destination.	6.0 and later	per mediated destination	TimeStatistic	Low
MediatedMessagesCount	Mediation.MediatedMessageCount	The number of messages that have been mediated at a mediated destination.	6.0 and later	per mediated destination	CountStatistic	Low

Message Processor Statistics:

Consult this information for properties of message processor statistics.

Counter definitions:

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Destinations > Queues

Name	Key	Description	Version	Granularity	Type	Level
AvailableMessageCount	QueueStats.AvailableMessageCount	The number of messages available for a queue for consumption. If this number is close to the destination high messages value then review the high messages value.	6.0 and later and later	Per destination	CountStatistic	Low
UnavailableMessageCount	QueueStats.UnavailableMessageCount	The number of messages locked or uncommitted, this means messages that have been added or removed but the transaction has not been committed yet. If this number is high then check which messages are locked and why.	6.0 and later and later	Per destination	CountStatistic	Low
LocalProducerAttaches	QueueStats.LocalProducerAttachesCount	The number of times an attachment has been made to this queue by local producers. The lifetime of this value is the lifetime of the messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
LocalProducerCount	QueueStats.LocalProducerCount	The number of currently attached local producers.	6.0 and later and later	Per destination	CountStatistic	Low
LocalConsumerAttaches	QueueStats.LocalConsumerAttachesCount	The number of times an attachment has been made to this queue by local consumers. The lifetime of this value is the lifetime of the messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
LocalConsumerCount	QueueStats.LocalConsumerCount	The number of currently attached local consumers.	6.0 and later and later	Per destination	CountStatistic	Low
TotalMessagesProduced	QueueStats.TotalMessagesProducedCount	The total number of messages produced to this queue, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Destinations > Queues

BestEffortNon-persistentMessagesProduced	QueueStats.BestEffortNonPersistentMessagesProducedCount	The number of Best Effort Non-persistent messages produced, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
ExpressNon-persistentMessagesProduced	QueueStats.ExpressNonPersistentMessagesProducedCount	The number of Express Non-persistent messages produced, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
ReliableNon-persistentMessagesProduced	QueueStats.ReliableNonPersistentMessagesProducedCount	The number of Reliable Non-persistent messages produced, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
ReliablePersistentMessagesProduced	QueueStats.ReliablePersistentMessagesProducedCount	The number of Reliable Persistent messages produced, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
AssuredPersistentMessagesProduced	QueueStats.AssuredPersistentMessagesProducedCount	The number of Assured Persistent messages produced, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
TotalMessagesConsumed	QueueStats.TotalMessagesConsumedCount	The total number of messages consumed from this queue, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
BestEffortNon-persistentMessagesConsumed	QueueStats.BestEffortNonPersistentMessagesConsumedCount	The number of Best Effort Non-persistent messages consumed, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
ExpressNon-persistentMessagesConsumed	QueueStats.ExpressNonPersistentMessagesConsumedCount	The number of Express Non-persistent messages consumed, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Destinations > Queues

ReliableNon-persistentMessagesConsumed	QueueStats.ReliableNonPersistentMessagesConsumedCount	The number of Reliable Non-persistent messages consumed, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
ReliablePersistentMessagesConsumed	QueueStats.ReliablePersistentMessagesConsumedCount	The number of Reliable Persistent messages consumed, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
AssuredPersistentMessagesConsumed	QueueStats.AssuredPersistentMessagesConsumedCount	The number of Assured Persistent messages consumed, for the lifetime of this messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
ReportEnabledMessagesExpired.	QueueStats.ReportEnabledMessagesExpiredCount	The number of report enabled messages that expired while on this queue.	6.0 and later and later	Per destination	CountStatistic	Low
AggregateMessageWaitTime	QueueStats.AggregateMessageWaitTime	The time spent by messages in the bus at consumption. If this time is not what was expected then view the message via the admin console to decide what action needs to be taken.	6.0 and later and later	Per destination	CountStatistic	Low
LocalMessageWaitTime	QueueStats.LocalMessageWaitTime	The time spent by messages on this queue at consumption. If this time is not what was expected then view the message via the admin console to decide what action needs to be taken.	6.0 and later and later	Per destination	CountStatistic	Low

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Destinations > Queues

LocalOldestMessageAge	QueueStats.LocalOldestMessageAge	The longest time any message has spent on this queue. If this time is not what was expected then view the message via the admin console to decide what action needs to be taken.	6.0 and later and later	Per destination	CountStatistic	Low

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Destinations > Topicspaces

Name	Key	Description	Version	Granularity	Type	Level
IncompletePublicationCount	TopicspaceStats.IncompletePublicationCount	The number of publications not yet received by all current subscribers. If this number is unexpected then view the publication via the admin console to take any actions.	6.0 and later and later	Per destination	CountStatistic	Low
LocalPublisherAttaches	TopicspaceStats.LocalPublisherAttachesCount	The number of times an attachment has been made to this topicspace by local producers. The lifetime of this value is the lifetime of the messaging engine.	6.0 and later and later	Per destination	CountStatistic	Low
LocalPublisherCount	TopicspaceStats.LocalPublisherCount	The number of local publishers to topics in this topicspace.	6.0 and later and later	Per destination	CountStatistic	Low
TotalLocalSubscriptionCount	TopicspaceStats.TotalLocalSubscriptionCount	The number of local subscriptions to topics in this topicspace. Each subscription is counted once, even if the topic includes wildcards.	6.0 and later and later	Per destination	CountStatistic	Low
Non-DurableLocalSubscriptionCount	TopicspaceStats.NonDurableLocalSubscriptionCount	The number of non-durable subscriptions.	6.0 and later and later	Per destination	CountStatistic	Low
DurableLocalSubscriptionCount	TopicspaceStats.DurableLocalSubscriptionCount	The number of durable subscriptions.	6.0 and later and later	Per destination	CountStatistic	Low
TotalMessagesPublished	TopicspaceStats.TotalMessagesPublishedCount	The total number of publications to this topicspace.	6.0 and later and later	Per destination	CountStatistic	Low
BestEffortNon-persistentMessagesPublished	TopicspaceStats.BestEffortNonPersistentMessagesPublishedCount	The number of Best Effort Non-persistent messages published	6.0 and later and later	Per destination	CountStatistic	Low
ExpressNon-persistentMessagesPublished	TopicspaceStats.ExpressNonPersistentMessagesPublishedCount	The number of Express Non-persistent messages published	6.0 and later and later	Per destination	CountStatistic	Low

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Destinations > Topicspaces

ReliableNon-persistentMessagesPublished	TopicspaceStats.ReliableNonPersistentMessagesPublishedCount	The number of Reliable Non-persistent messages published	6.0 and later and later	Per destination	CountStatistic	Low
ReliablePersistentMessagesPublished	TopicspaceStats.ReliablePersistentMessagesPublishedCount	The number of Reliable Persistent messages published	6.0 and later and later	Per destination	CountStatistic	Low
AssuredPersistentMessagesPublished	TopicspaceStats.AssuredPersistentMessagesPublishedCount	The number of Assured Persistent messages published	6.0 and later and later	Per destination	CountStatistic	Low
TotalLocalSubscriptionHits	TopicspaceStats.TotalLocalSubscriptionHitCount	The cumulative total of subscriptions which have matched topicspace publications.	6.0 and later and later	Per destination	CountStatistic	Low
BestEffortNon-persistentLocalSubscriptionHits	TopicspaceStats.BestEffortNonPersistentLocalSubscriptionHitCount	The cumulative total of subscriptions which have matched Best Effort Non-persistent publications.	6.0 and later and later	Per destination	CountStatistic	Low
ExpressNon-persistentLocal SubscriptionHits	TopicspaceStats.ExpressNonPersistentLocalSubscriptionHitCount	The cumulative total of subscriptions which have matched Express Non-persistent publications.	6.0 and later and later	Per destination	CountStatistic	Low
ReliableNon-persistentLocalSubscriptionHits	TopicspaceStats.ReliableNonPersistentLocalSubscriptionHitCount	The cumulative total of subscriptions which have matched Reliable Non-persistent publications.	6.0 and later and later	Per destination	CountStatistic	Low
AssuredPersistentLocalSubscriptionHits	TopicspaceStats.AssuredPersistentLocalSubscriptionHitCount	The cumulative total of subscriptions which have matched Assured Persistent publications.	6.0 and later and later	Per destination	CountStatistic	Low
ReportEnabledPublicationExpired	TopicspaceStats.ReportEnabledPublicationsExpiredCount	The number of report enabled incomplete publications that expired while on this topicspace.	6.0 and later and later	Per destination	CountStatistic	Low

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Destinations > Topicspaces

LocalOldestPublication	TopicspaceStats.LocalOldestPublicationAge	The longest time any publication has spent on this topicspace. If this time is not what was expected then view the message via the admin console to decide what action needs to be taken.	6.0 and later	Per destination	TimeStatistic	max

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Destinations > Topicspaces > Topic > DurableSubscriptions

Name	Key	Description	Version	Granularity	Type	Level
AvailableMessageCount	DurableSubscriptionStats.AvailableMessageCount	The number of messages waiting to be consumed.	6.0 and later	per mediated destination	CountStatistic	Low
TotalMessagesConsumed	DurableSubscriptionStats.TotalMessagesConsumedCount	The total number of messages consumed from this durable subscription.	6.0 and later	per mediated destination	CountStatistic	Low
BestEffortNon-persistentMessagesConsumed	DurableSubscriptionStats.BestEffortNonPersistentMessagesConsumedCount	The number of Best Effort Non-persistent messages consumed, for the lifetime of this messaging engine.	6.0 and later	per mediated destination	CountStatistic	Low
ExpressNon-persistentMessagesConsumed	DurableSubscriptionStats.ExpressNonPersistentMessagesConsumedCount	The number of Express Non-persistent messages consumed, for the lifetime of this messaging engine.	6.0 and later	per mediated destination	CountStatistic	Low
ReliableNon-persistentMessagesConsumed	DurableSubscriptionStats.ReliableNonPersistentMessagesConsumedCount	The number of Reliable Non-persistent messages consumed, for the lifetime of this messaging engine.	6.0 and later	per mediated destination	CountStatistic	Low
ReliablePersistentMessages Consumed	DurableSubscriptionStats.ReliablePersistentMessagesConsumedCount	The number of Reliable Persistent messages consumed, for the lifetime of this messaging engine.	6.0 and later	per mediated destination	CountStatistic	Low
AssuredPersistentMessages Consumed	DurableSubscriptionStats.AssuredPersistentMessagesConsumedCount	The number of Assured Persistent messages consumed, for the lifetime of this messaging engine.	6.0 and later	per mediated destination	CountStatistic	Low
AggregateMessageWaitTime	DurableSubscriptionStats.AggregateMessageWaitTime	The time spent by messages in the bus at consumption. If this time is not what was expected then view the message via the admin console to decide what action needs to be taken.	6.0 and later	per mediated destination	TimeStatistic	High

Performance Modules > SIB Service > SIB Messaging Engines > Messaging Engine > Destinations > Topicspaces > Topic > DurableSubscriptions

LocalMessageWaitTime	DurableSubscriptionStats.LocalMessageWaitTime	The time spent by messages on this durable subscription at consumption. If this time is not what was expected then view the message via the admin console to decide what action needs to be taken.	6.0 and later	per mediated destination	TimeStatistic	High
LocalOldestPublication	DurableSubscriptionStats.LocalOldestPublicationAge	The longest time any message has spent on this subscription. If this time is not what was expected then view the message via the admin console to decide what action needs to be taken.	6.0 and later	per mediated destination	TimeStatistic	Max

Communications statistics:

Communications statistics is a type of data that PMI maintains within the entire WebSphere Application Server domain.

Counter definitions:

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

Name	Key	Description	Version	Granularity	Type	Level
BytesSentAtHighestPriorityCount	ClientDetailedStats.BytesSentAtHighestPriority	Number of bytes of data transmitted at the highest possible priority for transmission. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesSentAtVeryHighPriorityCount	ClientDetailedStats.BytesSentAtVeryHighPriority	Number of bytes of data transmitted at a very high priority. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesSentAtHighPriorityCount	ClientDetailedStats.BytesSentAtHighPriority	Number of bytes of data transmitted at a high priority. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesSentAtJMS9PriorityCount	ClientDetailedStats.BytesSentAtJMS9Priority	Number of bytes of data transmitted at the priority used by JMS priority 9 messages. Typically this is an accurate measure of the number of bytes of message data transmitted at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

BytesSentAtJMS8PriorityCount	ClientDetailedStats.BytesSentAtJMS8Priority	Number of bytes of data transmitted at the priority used by JMS priority 8 messages. Typically this is an accurate measure of the number of bytes of message data transmitted at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesSentAtJMS7PriorityCount	ClientDetailedStats.BytesSentAtJMS7Priority	Number of bytes of data transmitted at the priority used by JMS priority 7 messages. Typically this is an accurate measure of the number of bytes of message data transmitted at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesSentAtJMS6PriorityCount	ClientDetailedStats.BytesSentAtJMS6Priority	Number of bytes of data transmitted at the priority used by JMS priority 6 messages. Typically this is an accurate measure of the number of bytes of message data transmitted at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

BytesSentAtJMS5PriorityCount	ClientDetailedStats.BytesSentAtJMS5Priority	Number of bytes of data transmitted at the priority used by JMS priority 5 messages. Typically this is an accurate measure of the number of bytes of message data transmitted at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesSentAtJMS4PriorityCount	ClientDetailedStats.BytesSentAtJMS4Priority	Number of bytes of data transmitted at the priority used by JMS priority 4 messages. Typically this is an accurate measure of the number of bytes of message data transmitted at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesSentAtJMS3PriorityCount	ClientDetailedStats.BytesSentAtJMS3Priority	Number of bytes of data transmitted at the priority used by JMS priority 3 messages. Typically this is an accurate measure of the number of bytes of message data transmitted at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

BytesSentAtJMS2PriorityCount	ClientDetailedStats.BytesSentAtJMS2Priority	Number of bytes of data transmitted at the priority used by JMS priority 2 messages. Typically this is an accurate measure of the number of bytes of message data transmitted at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesSentAtJMS1PriorityCount	ClientDetailedStats.BytesSentAtJMS1Priority	Number of bytes of data transmitted at the priority used by JMS priority 1 messages. Typically this is an accurate measure of the number of bytes of message data transmitted at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesSentAtJMS0PriorityCount	ClientDetailedStats.BytesSentAtJMS0Priority	Number of bytes of data transmitted at the priority used by JMS priority 0 messages. Typically this is an accurate measure of the number of bytes of message data transmitted at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

BytesSentAtLowPriorityCount	ClientDetailedStats.BytesSentAtLowPriority	Number of bytes of data transmitted at a low priority. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesSentAtVeryLowPriorityCount	ClientDetailedStats.BytesSentAtVeryLowPriority	Number of bytes of data transmitted at a very low priority. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesSentAtLowestPriorityCount	ClientDetailedStats.BytesSentAtLowestPriority	Number of bytes of data transmitted at the lowest possible priority. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesReceivedAtHighestPriorityCount	ClientDetailedStats.BytesReceivedAtHighestPriority	Number of bytes of data received at the highest possible priority. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesReceivedAtVeryHighPriorityCount	ClientDetailedStats.BytesReceivedAtVeryHighPriority	Number of bytes of data received at a very high priority. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

BytesReceivedAtHighPriorityCount	ClientDetailedStats.BytesReceivedAtHighPriority	Number of bytes of data received at a high priority. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesReceivedAtJMS9PriorityCount	ClientDetailedStats.BytesReceivedAtJMS9Priority	Number of bytes of data received at the priority used by JMS priority 9 messages. Typically this is an accurate measure of the number of bytes of message data received at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesReceivedAtJMS8PriorityCount	ClientDetailedStats.BytesReceivedAtJMS8Priority	Number of bytes of data received at the priority used by JMS priority 8 messages. Typically this is an accurate measure of the number of bytes of message data received at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

BytesReceivedAtJMS7PriorityCount	ClientDetailedStats.BytesReceivedAtJMS7Priority	Number of bytes of data received at the priority used by JMS priority 7 messages. Typically this is an accurate measure of the number of bytes of message data received at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesReceivedAtJMS6PriorityCount	ClientDetailedStats.BytesReceivedAtJMS6Priority	Number of bytes of data received at the priority used by JMS priority 6 messages. Typically this is an accurate measure of the number of bytes of message data received at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesReceivedAtJMS5PriorityCount	ClientDetailedStats.BytesReceivedAtJMS5Priority	Number of bytes of data received at the priority used by JMS priority 5 messages. Typically this is an accurate measure of the number of bytes of message data received at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

BytesReceivedAtJMS4PriorityCount	ClientDetailedStats.BytesReceivedAtJMS4Priority	Number of bytes of data received at the priority used by JMS priority 4 messages. Typically this is an accurate measure of the number of bytes of message data received at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesReceivedAtJMS3PriorityCount	ClientDetailedStats.BytesReceivedAtJMS3Priority	Number of bytes of data received at the priority used by JMS priority 3 messages. Typically this is an accurate measure of the number of bytes of message data received at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesReceivedAtJMS2PriorityCount	ClientDetailedStats.BytesReceivedAtJMS2Priority	Number of bytes of data received at the priority used by JMS priority 2 messages. Typically this is an accurate measure of the number of bytes of message data received at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

BytesReceivedAtJMS1PriorityCount	ClientDetailedStats.BytesReceivedAtJMS1Priority	Number of bytes of data received at the priority used by JMS priority 1 messages. Typically this is an accurate measure of the number of bytes of message data received at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesReceivedAtJMS0PriorityCount	ClientDetailedStats.BytesReceivedAtJMS0Priority	Number of bytes of data received at the priority used by JMS priority 0 messages. Typically this is an accurate measure of the number of bytes of message data received at this priority level. However, from time to time, control transmissions used to negotiate the flow of messages might be transmitted at this priority level.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesReceivedAtLowPriorityCount	ClientDetailedStats.BytesReceivedAtLowPriority	Number of bytes of data received at a low priority. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BytesReceivedAtVeryLowPriorityCount	ClientDetailedStats.BytesReceivedAtVeryLowPriority	Number of bytes of data received at a very low priority. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

BytesReceivedAtLowestPriorityCount	ClientDetailedStats.BytesReceivedAtLowestPriority	Number of bytes of data received at the lowest possible priority. Message data cannot be transmitted with this priority, so typically these bytes of data will comprise control transmissions used to negotiate the flow of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesSentAtJMS9PriorityCount	ClientDetailedStats.MessagesSentAtJMS9Priority	Number of messages transmitted at JMS priority 9.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesSentAtJMS8PriorityCount	ClientDetailedStats.MessagesSentAtJMS8Priority	Number of messages transmitted at JMS priority 8.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesSentAtJMS7PriorityCount	ClientDetailedStats.MessagesSentAtJMS7Priority	Number of messages transmitted at JMS priority 7.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesSentAtJMS6PriorityCount	ClientDetailedStats.MessagesSentAtJMS6Priority	Number of messages transmitted at JMS priority 6.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesSentAtJMS5PriorityCount	ClientDetailedStats.MessagesSentAtJMS5Priority	Number of messages transmitted at JMS priority 5.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesSentAtJMS4PriorityCount	ClientDetailedStats.MessagesSentAtJMS4Priority	Number of messages transmitted at JMS priority 4.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesSentAtJMS3PriorityCount	ClientDetailedStats.MessagesSentAtJMS3Priority	Number of messages transmitted at JMS priority 3.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

MessagesSentAtJMS2PriorityCount	ClientDetailedStats.MessagesSentAtJMS2Priority	Number of messages transmitted at JMS priority 2.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesSentAtJMS1PriorityCount	ClientDetailedStats.MessagesSentAtJMS1Priority	Number of messages transmitted at JMS priority 1.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesSentAtJMS0PriorityCount	ClientDetailedStats.MessagesSentAtJMS0Priority	Number of messages transmitted at JMS priority 0.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesReceivedAtJMS9PriorityCount	ClientDetailedStats.MessagesReceivedAtJMS9Priority	Number of messages received at JMS priority 9.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesReceivedAtJMS8PriorityCount	ClientDetailedStats.MessagesReceivedAtJMS8Priority	Number of messages received at JMS priority 8.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesReceivedAtJMS7PriorityCount	ClientDetailedStats.MessagesReceivedAtJMS7Priority	Number of messages received at JMS priority 7.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesReceivedAtJMS6PriorityCount	ClientDetailedStats.MessagesReceivedAtJMS6Priority	Number of messages received at JMS priority 6.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesReceivedAtJMS5PriorityCount	ClientDetailedStats.MessagesReceivedAtJMS5Priority	Number of messages received at JMS priority 5.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesReceivedAtJMS4PriorityCount	ClientDetailedStats.MessagesReceivedAtJMS4Priority	Number of messages received at JMS priority 4.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Detailed Statistics

MessagesReceivedAtJMS3PriorityCount	ClientDetailedStats.MessagesReceivedAtJMS3Priority	Number of messages received at JMS priority 3.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesReceivedAtJMS2PriorityCount	ClientDetailedStats.MessagesReceivedAtJMS2Priority	Number of messages received at JMS priority 2.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesReceivedAtJMS1PriorityCount	ClientDetailedStats.MessagesReceivedAtJMS1Priority	Number of messages received at JMS priority 1.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesReceivedAtJMS0PriorityCount	ClientDetailedStats.MessagesReceivedAtJMS0Priority	Number of messages received at JMS priority 0.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Standard Statistics

Name	Key	Description	Version	Granularity	Type	Level
ClientsAttachedCount	ClientStats.ClientsAttached	The number of distinct client processes currently network connected to this application server.	6.0 and later	current clients/connections connected to this application server	CountStatistic	Low
APIConnectionsCount	ClientStats.APIConnections	The number of API sessions being used by clients that are currently network connected to this application server. Some of these API connections might be being by internal system processes on behalf of a client.	6.0 and later	current clients/connections connected to this application server	CountStatistic	Low
ErrorsCount	ClientStats.Errors	Communication errors that have occurred and resulted in a network connection to a client being disconnected.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
WritesCount	ClientStats.Writes	Number of write operations used to transmit data to client processes via network connections.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
ReadsCount	ClientStats.Reads	Number of read operations used to receive data from client processes via network connections.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
WritesBlockedCount	ClientStats.WritesBlocked	Number of write operations that could not be completed immediately. This number can be used as an indicator of network congestion when communicating with client processes.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
ReadsBlockedCount	ClientStats.ReadsBlocked	Number of read operations that could not be completed immediately. This number can be used as an indicator of network congestion when communicating with client processes.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MulticastWriteBytesCount	ClientStats.MulticastWriteBytes	Number of bytes transmitted using multicast protocols.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MulticastSendMessageCount	ClientStats.MulticastSendMessage	Number of messages transmitted using multicast protocols.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Clients > Standard Statistics

BufferedWriteBytesCount	ClientStats.BufferedWriteBytes	Number of bytes of data being held pending transmission. Large values might indicate network congestion or clients which are unable to process data fast enough to keep up with the application server.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
BufferedReadBytesCount	ClientStats.BufferedReadBytes	Number of bytes of data that have been received from the network and are held pending further processing. Large values might indicate that the application server is unable to process data fast enough to keep up with the clients attached.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessagesBytesWrittenCount	ClientStats.MessageBytesWritten	Number of bytes of message data sent to client processes over network connections. This does not include data used to negotiate the transmission of messages	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
MessageBytesReadCount	ClientStats.MessageBytesRead	Number of bytes of message data received from client processes over network connections. This does not include data used to negotiate the transmission of messages	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
TotalBytesWrittenCount	ClientStats.TotalBytesWritten	Number of bytes of data sent to client processes. This includes both message data and data used to negotiate the transmission of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low
TotalBytesReadCount	ClientStats.TotalBytesRead	Number of bytes of data received from client processes. This includes both message data and data used to negotiate the transmission of messages.	6.0 and later	All clients connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > Messaging Engines > Standard Statistics

Name	Key	Description	Version	Granularity	Type	Level
MEAttachedCount	MEStats.MEAttached	The number of distinct application server processes hosting messaging engines currently network connected to this application server.	6.0 and later	current applications servers hosting messaging engines/connections connected to this application server.	CountStatistic	Low
APIConnectionsCount	MEStats.APIConnections	The number of sessions being used by messaging engines that are currently network connected to this application server.	6.0 and later	current applications servers hosting messaging engines/connections connected to this application server.	CountStatistic	Low
ErrorsCount	MEStats.Errors	Communication errors that have occurred and resulted in a network connection to a messaging engine being disconnected.	6.0 and later	All messaging engines connected or that have been connected to this application server	CountStatistic	Low
WritesCount	MEStats.Writes	Number of write operations used to transmit data to application server processes hosting messaging engines via network connections.	6.0 and later	All messaging engines connected or that have been connected to this application server	CountStatistic	Low
ReadsCount	MEStats.Reads	Number of read operations used to receive data from application server processes hosting messaging engines via network connections.	6.0 and later	All messaging engines connected or that have been connected to this application server	CountStatistic	Low
WritesBlockedCount	MEStats.WritesBlocked	Number of write operations that could not be completed immediately. This number can be used as an indicator of network congestion when communicating with application server processes hosting messaging engines.	6.0 and later	All messaging engines connected or that have been connected to this application server	CountStatistic	Low
ReadsBlockedCount	MEStats.ReadsBlocked	Number of read operations that could not be completed immediately. This number can be used as an indicator of network congestion when communicating with application server processes hosting messaging engines.	6.0 and later	All messaging engines connected or that have been connected to this application server	CountStatistic	Low

BufferedWriteBytesCount	MEStats.BufferedWriteBytes	Number of bytes of data being held pending transmission. Large values might indicate network congestion or application server processes hosting messaging engines which are unable to process data fast enough to keep up with the application server.	6.0 and later	All messaging engines connected or that have been connected to this application server	CountStatistic	Low
BufferedReadBytesCount	MEStats.BufferedReadBytes	Number of bytes of data that have been received from the network and are held pending further processing. Large values might indicate that the application server is unable to process data fast enough to keep up with the other application server processes hosting messaging engines that it is network attached.	6.0 and later	All messaging engines connected or that have been connected to this application server	CountStatistic	Low
MessagesBytesWrittenCount	MEStats.MessageBytesWritten	Number of bytes of message data sent to application server processes hosting messaging engines over network connections. This does not include data used to negotiate the transmission of messages	6.0 and later	All messaging engines connected or that have been connected to this application server	CountStatistic	Low
MessageBytesReadCount	MEStats.MessageBytesRead	Number of bytes of message data received from application server processes hosting messaging engines over network connections. This does not include data used to negotiate the transmission of messages	6.0 and later	All messaging engines connected or that have been connected to this application server	CountStatistic	Low
TotalBytesWrittenCount	MEStats.TotalBytesWritten	Number of bytes of data sent to application server processes hosting messaging engines.	6.0 and later	All messaging engines connected or that have been connected to this application server	CountStatistic	Low
TotalBytesReadCount	MEStats.TotalBytesRead	Number of bytes of data received from application server processes hosting messaging engines.	6.0 and later	All messaging engines connected or that have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > WMQ Client Links > Standard Statistics

Name	Key	Description	Version	Granularity	Type	Level
BatchesSentCount	MQClientLinkStats.BatchesSent	Number of batches of messages sent to network attached MQJMS clients.	6.0 and later	All WMQ JMS clients that are or have been connected to this application server	CountStatistic	Low
MessagesSentCount	MQClientLinkStats.MessagesSent	Number of messages sent to network attached WMQ JMS clients.	6.0 and later	All WMQ JMS clients that are or have been connected to this application server	CountStatistic	Low
MessagesReceivedCount	MQClientLinkStats.MessagesReceived	Number of messages received from network attached WMQ JMS clients.	6.0 and later	All WMQ JMS clients that are or have been connected to this application server	CountStatistic	Low
BytesSentCount	MQClientLinkStats.BytesSent	Number of bytes of data sent to network attached WMQ JMS clients. This includes bytes of message data as well as bytes of data used to control the flow of messages.	6.0 and later	All WMQ JMS clients that are or have been connected to this application server	CountStatistic	Low
BytesReceivedCount	MQClientLinkStats.BytesReceived	Number of bytes of data received from network attached WMQ JMS clients. This includes bytes of message data as well as bytes of data used to control the flow of messages.	6.0 and later	All WMQ JMS clients that are or have been connected to this application server	CountStatistic	Low
APICallsServicedCount	MQClientLinkStats.APICallsServiced	The number of MQ API call requests serviced on behalf of WMQ JMS clients.	6.0 and later	All WMQ JMS clients that are or have been connected to this application server	CountStatistic	Low
CommsErrorsCount	MQClientLinkStats.CommsErrors	The number of errors that have cause connections to WMQ JMS clients to be dropped.	6.0 and later	All WMQ JMS clients that are or have been connected to this application server	CountStatistic	Low
ClientsAttachedCount	MQClientLinkStats.ClientsAttached	The current number of WMQ JMS clients attached to this application server.	6.0 and later	WMQ JMS clients that are currently attached.	CountStatistic	Low
WritesBlockedCount	MQClientLinkStats.WritesBlocked	Number of write operations that could not be completed immediately. This number can be used as an indicator of network congestion when communicating with WMQ JMS clients.	6.0 and later	All WMQ JMS clients that are or have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > WMQ Client Links > Standard Statistics

ReadsBlockedCount	MQClientLinkStats.ReadsBlocked	Number of read operations that could not be completed immediately. This number can be used as an indicator of network congestion when communicating with WMQ JMS clients.	6.0 and later	All WMQ JMS clients that are or have been connected to this application server	CountStatistic	Low
-------------------	--------------------------------	---	---------------	--	----------------	-----

Performance Modules > SIB Service > SIB Communications > WMQ Links > Standard Statistics

Name	Key	Description	Version	Granularity	Type	Level
BatchesSentCount	MQLinkStats.BatchesSent	Number of batches of messages sent to network attached WMQ Queue Managers.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low
BatchesReceivedCount	MQLinkStats.BatchesReceived	Number of batches of messages received from network attached WMQ Queue Managers.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low
MessagesSentCount	MQLinkStats.MessagesSent	Number of messages sent to network attached WMQ Queue Managers.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low
MessagesReceivedCount	MQLinkStats.MessagesReceived	Number of messages received from network attached WMQ Queue Managers.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low
SenderBytesSentCount	MQLinkStats.SenderBytesSent	Number of bytes of data sent by sender channels to network attached WMQ Queue Managers.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low
SenderBytesReceivedCount	MQLinkStats.SenderBytesReceived	Number of bytes of data received by sender channels from network attached WMQ Queue Managers.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low
ReceiverBytesSentCount	MQLinkStats.ReceiverBytesSent	Number of bytes of data sent by receiver channels to network attached WMQ Queue Managers.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low
ReceiverBytesReceivedCount	MQLinkStats.ReceiverBytesReceived	Number of bytes of data received by receiver channels from network attached WMQ Queue Managers.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low
ShortRetriesCount	MQLinkStats.ShortRetries	Number of short retries. This indicates the number of times channels were disconnected and could not be re-established for short periods of time.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low
LongRetriesCount	MQLinkStats.LongRetries	Number of long retries. This indicates the number of times channels were disconnected and could not be re-established for longer periods of time.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low
CommsErrorsCount	MQLinkStats.CommsErrors	Number of communication errors that resulted in a network connection to a WMQ Queue Manager being disconnected.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low

Performance Modules > SIB Service > SIB Communications > WMQ Links > Standard Statistics

QMAttachedCount	MQLinkStats.QMAttached	Total number of WMQ Queue Managers currently network attached to this application server	6.0 and later	WMQ Queue Managers that are currently attached	CountStatistic	Low
WritesBlockedCount	MQLinkStats.WritesBlocked	Number of write operations that could not be completed immediately. This number can be used as an indicator of network congestion when communicating with WMQ Queue Managers.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low
ReadsBlockedCount	MQLinkStats.ReadsBlocked	Number of read operations that could not be completed immediately. This number can be used as an indicator of network congestion when communicating with WMQ Queue Managers.	6.0 and later	All WMQ Queue Managers that are or have been connected to this application server	CountStatistic	Low

PMI data collection

PMI data collection can occur in three different interfaces, Java Management Extension, Performance Servlet, or PMI client API (deprecated).

The PMI data can be collected using the following interfaces:

- Java Management Extension (JMX) interface (J2EE MBeans and WebSphere Application Server Perf MBean)
- Performance Servlet
- PMI client API (deprecated)

JMX Interface

JMX interface is part of the J2EE specification and the recommended way to gather WebSphere Application Server performance data. PMI data can be gathered from the J2EE managed object MBeans or the WebSphere Application Server PMI Perf MBean. While the J2EE MBeans provide performance data about the specific component, the Perf MBean acts as a gateway to the WebSphere Application Server PMI service, and provides access to the performance data for all the components.

Performance Servlet

Performance Servlet provides a way to use an HTTP request to query the PMI data for the entire WebSphere Application Server administrative domain. Since the servlet provides the performance data through HTTP, issues such as firewalls are trivial to resolve. The performance servlet outputs the PMI data as an XML document.

PMI client API (deprecated)

PMI client API provides a wrapper class to deliver PMI data to a client. This API was introduced in WebSphere Application Server, Version 4.0 and deprecated in V6.0. The PMI client API uses the JMX infrastructure and the Perf MBean to retrieve the PMI data. PMI client provides the data using a WebSphere Application Server-specific data structure that was introduced in V4.0.

Custom PMI API

You can create specific statistics to best meet your monitoring interests by using custom PMI API.

PMI can be extended using the Custom PMI API to create application specific statistics. For example, a stock trading application can use Custom PMI API to create business specific statistics like "number of stock sell transactions" and "number of stock buy transactions".

Note that PMI provides detailed performance data about various runtime and application components. Starting with WebSphere Application Server Version 6.0, PMI offers approximately 180 or more performance statistics. Before creating new statistics, it is important to make sure that the same data is not captured by PMI already.

With WebSphere PMI, application developers can add their own application-specific instrumentation. The Custom PMI API simplifies the process of "PMI enabling" an application by providing an easy to use API. The statistics created via the Custom PMI can be accessed via the standard PMI and JMX interfaces that are used by monitoring tools including the Tivoli Performance Viewer.

PMI instrumentation is based on the J2EE 1.4 standard. As a result, Custom PMI supports all the Statistic types (CountStatistic, TimeStatistic, RangeStatistic, and BoundedRangeStatistic) defined in the JSR-77 Performance Data Framework. Custom PMI does not support user-defined Statistic types.

What you need to know

PMI collects performance data on runtime applications and provides interfaces that allow external applications to monitor the performance data.

With server side PMI, application developers can add their own instrumentation to their applications to help monitor their own predefined performance metrics.

Key features of Custom PMI:

- Create a custom Stats/PMI (Stats is J2EE terminology) module using an XML template.
- Used by the application to instrument code.
- Statistics in the custom Stats module can be accessed via the standard PMI and JMX interfaces that are used by monitoring tools, including the Tivoli Performance Viewer.
- PMI instrumentation is based on the J2EE 1.4 standard. As a result, Custom PMI supports all the Statistic types (CountStatistic, TimeStatistic, RangeStatistic, and BoundedRangeStatistic) defined in the JSR-77 Performance Data Framework.
- Custom PMI does not support user-defined Statistic types.

PMI is for application server performance monitoring, and the data collected by PMI is used to tune the application server resources such as pools, queues and caches etc. Since performance instrumentation and statistics can have considerable impact on the application server performance, it is necessary that every statistic added via Custom PMI is relevant towards solving a performance problem. When the statistic to be added is designed, the issues like the following should be taken into consideration:

- Significance of the statistic with respect to solving performance problems.
- Relevance to tuning or configuring the application.
- Check for avoiding data redundancy and does not need frequent updates.

Custom PMI implementation - an example

The following steps are required to instrument an application using Custom PMI:

1. Define a Stats module template. An XML document is used to define a set of statistics for a given application component. This XML document is used as a template to create the PMI data. The XML document should follow the DTD `com/ibm/websphere/pmi/xml/stats.dtd`
2. Create a Stats object using StatsFactory. The StatsFactory is used to create an instance (StatsInstance) or group (StatsGroup) of the Stats template. The StatsInstance object represents a single instance of the Stats template and contains all the statistics defined in the template. The StatsGroup is a logical collection of similar Stats instances. Custom PMI provides the flexibility to arrange the groups and instances in a tree structure.
3. Instrument the application by updating the Stats object. To instrument, the application should call the Stats module for PMI service to maintain the raw counts. For example, to instrument the *number of sells* processed by the Stock application, create a Stats module with a statistic of type CountStatistic. When a sell transaction is processed, increment the *number of sells* statistic by calling:
`NumSellsCountStatistic.increment ();`

Enabling PMI data collection

Enable PMI data collection to diagnose problems and tune application performance.

Performance Monitoring Infrastructure (PMI) needs to be enabled (by default PMI is enabled) before collecting any performance data. PMI should be enabled before the server starts. If PMI is enabled after the server is started, the server needs to be restarted to start the PMI.

When PMI service is enabled, the monitoring of individual components can be enabled or disabled dynamically. PMI provides four predefined statistic sets that can be used to enable a set of statistics. The following table provides details about the statistic sets. If the predefined statistic sets does not meet your monitoring requirement, the **Custom** option can be used to selectively enable or disable individual statistics.

Statistic set	Description
None	All statistics are disabled.
Basic	Statistics specified in J2EE 1.4, as well as top statistics like CPU usage and live HTTP sessions are enabled. This set is enabled <i>out-of-the-box</i> and provides basic performance data about runtime and application components.
Extended	Basic set plus key statistics from various WebSphere Application Server components like WLM and Dynamic caching are enabled. This set provides detailed performance data about various runtime and application components.
All	All statistics are enabled.
Custom	Enable or disable statistics selectively.

Custom setting

WebSphere Application Server Version 6.0 introduces fine-grained control to enable/disable statistics individually. The fine-grained control is available under the custom statistic set.

Though the Version 5.x monitoring levels {N, L, M, H, X} are deprecated in Version 6.0 and above, the 5.x PMI APIs are supported for backward compatibility. It is possible to use a Version 6.0 or later API to set the monitoring level and a Version 5.0 API to get the monitoring level. A new level 'F' – “fine-grained” is introduced to indicate to the Version 5.x API that the fine-grained or Version 6.x monitoring specification is in effect. This new level 'F' will be returned if a V5.x API is used to get the monitoring level from a server using Version 6.x monitoring specification.

In WebSphere Application Server Version 4.0 and Version 5.0, the statistics were enabled based on a monitoring/instrumentation level. The levels are None, Low, Medium, High and Max {N, L, M, H, X}. Enabling at a given level will include all the statistics at the given level plus counters from levels below the given level. So if you enable the Web Application module at level Medium {M} it enables all the counters at level M, plus all the Low {L} level counters. See “PMI data collection” on page 2273 for more information.

Sequential Update

In order to minimize the monitoring overhead, the updates to CountStatistic, AverageStatistic, and TimeStatistic are not synchronized. Since these statistic types track total and average, the extra accuracy is generally not worth the performance cost. The RangeStatistic and BoundedRangeStatistic are very sensitive, therefore, they are always synchronized. If needed, updates to all the statistic types can be synchronized by checking the **Use sequential update** check box.

Enable PMI using one of the following methods:

- “Enabling PMI using the administrative console”
- “Enabling PMI using the wsadmin tool” on page 2278
- “Enabling the Java virtual machine profiler data” on page 2284

Enabling PMI using the administrative console

When PMI service is enabled, the monitoring of individual components can be enabled or disabled dynamically.

To monitor performance data through the Performance Monitoring Infrastructure (PMI), you must first enable PMI through the administrative console.

1. Open the administrative console.
2. Click **Servers** > **Application Servers** in the console navigation tree.
3. Click *server*.

4. Click the **Configuration** tab.
5. Click **Performance Monitoring Infrastructure** under Performance.
6. Select the **Enable Performance Monitoring Infrastructure (PMI)** check box.
7. Optionally, select the check box **Use sequential update** to enable precise statistic update.
8. Optionally, choose a statistic set that needs to be monitored under **Currently Monitored Statistic Set**.
9. Optionally, click on **Custom** to selectively enable or disable statistics. Choose a component from the left side tree and enable or disable statistics on the right side table. Go back to the main PMI configuration page by clicking the **Performance Monitoring Infrastructure** link.
10. Click **Apply** or **OK**.
11. Click **Save**.
12. Restart the application server. The changes you make will not take effect until you restart the application server.

When in the **Configuration** tab, settings apply after the server is restarted.

Performance Monitoring Infrastructure settings

Use this page to specify settings for performance monitoring, including enabling performance monitoring, selecting the Performance Monitoring Infrastructure (PMI) module and setting monitoring levels.

To view this administrative console page, click **Servers > Application Servers > server > Performance Monitoring Infrastructure (PMI)**.

Enable Performance Monitoring Infrastructure (PMI):

Specifies whether the application server attempts to enable Performance Monitoring Infrastructure (PMI). If an application server is started when the PMI is disabled, you have to restart the server in order to enable it.

Use sequential counter updates:

Specifies whether access to PMI counters (for example, updates to the counters) is sequential. There is some performance overhead associated with enabling sequential update. The default setting is false.

Persist my changes:

Specifies whether changes to the runtime are also persisted for use on subsequent server startups, and not just the current server runtime. The default setting is false.

Selecting the Persist my changes option ensures that the counter settings are retained after you restart the server. This option itself does not remain selected the next time you come to the panel.

Currently monitored statistic set:

Specifies a pre-defined set of Performance Monitoring Infrastructure (PMI) statistics for all components in the server.

As part of fine-grained control feature, WebSphere Application Server provides new statistic sets, which are pre-defined, fixed server-side sets based on the PMI statistic usage scenarios. This enhancement allows a set of statistics to be enabled via a single action or call. The following statistic sets are defined:

None All statistics are disabled.

Basic Provides basic monitoring for application server resources and applications. This includes J2EE components, HTTP session information, CPU usage information, and the top 38 statistics. This is the default setting.

Extended

Provides extended monitoring, including the basic level of monitoring plus workload monitor, performance advisor, and Tivoli resource models. Extended provides key statistics from frequently used WebSphere Application Server components.

All Enables all statistics.

Custom

Provides fine-grained control with the ability to enable and disable individual statistics.

Custom monitoring level

Use this page to enable and disable specific PMI counters for individual PMI statistics.

To view this administrative console page, click **Servers > Application Servers > server > Performance Monitoring Infrastructure (PMI) > Custom**.

Custom monitoring level:

Click on the individual PMI statistic in the list on the left. The counters available for that module appear in the table on the right along with the counter type, a description of the counter, and its current status (Enabled or Disabled).

You can enable or disable each individual counter by selecting the counter and clicking the Enable or Disable button, respectively.

Custom monitoring level:

Click on the individual PMI module in the list on the left. The counters available for that statistic appear in the table on the right along with the counter type, a description of the counter, and its current status (Enabled or Disabled).

You can enable or disable each individual counter by selecting the counter and clicking the Enable or Disable button, respectively.

Note: Enabling or disabling a statistic set that contains subsets will affect the configuration of all the counters contained in the subsets. The parent statistic set that is selected passes down the current configuration set to its subsets, which can disable any counters that were individually selected within specific subsets. For best results, configure the parent statistic first, and then select specific counters within its subsets.

Performance Monitoring Infrastructure collection

Use this page to configure Performance Monitoring Infrastructure (PMI).

To view this administrative console page, click **Monitoring and Tuning > Performance Monitoring Infrastructure (PMI)** .

Name:

Specifies the logical name of the server.

The Name property is read only.

Node:

Specifies the name of the node holding the server.

The Node name property is read only.

Version:

Specifies the version of the WebSphere Application Server product on which the server runs.

The Version property is read only.

Enabling PMI using the wsadmin tool

Use this page to learn how to enable Performance Monitoring Infrastructure using command line instead of the administrative console.

You can use the command line to enable Performance Monitoring Infrastructure (PMI).

1. Enable PMI using the administrative console (see “Enabling PMI using the administrative console” on page 2275). Make sure to restart the application server.
2. Run the **wsadmin** command, as described in Starting the wsadmin scripting client. Using **wsadmin**, you can invoke operations on Perf MBean to obtain the PMI data, set or obtain PMI monitoring levels, and enable data counters.

Note: If PMI data are not enabled yet, you need to first enable PMI data by invoking `setInstrumentationLevel` operation on PerfMBean.

The following operations in Perf MBean can be used in **wsadmin**:

```
/** Get performance data information for stats */
public void getConfig (ObjectName mbean);

/** Returns the current statistic set */
public void getStatisticSet ();

/** Enable PMI data using the pre-defined statistic sets.
    Valid values for the statistic set are "basic", "extended", "all", and "none" */
public void setStatisticSet (String statisticSet);

/** Returns the current custom set specification as a string */
public void getCustomSetString ();

/** Customizing PMI data that is enabled using fine-grained control.
    This method allows to enable or disable statistics selectively.
    The format of the custom set specification string is STATS_NAME=ID1,ID2,ID3 seperated by ':',
    where STATS_NAME and IDs are defined in WS*Stat interfaces in com.ibm.websphere.pmi.stat package.
    Use * to enable all the statistics in the given PMI module. For example, to enable all the statistics
    for JVM and active count, pool size for thread pool use: jvmRuntimeModule=*:threadPoolModule=3,4.
    The string jvmRuntimeModule is the value of the constant WSJVMStats.NAME and threadPoolModule is the
    value of WSThreadPoolStats.NAME.
    */
public void setCustomSetString (String customSpec, Boolean recursive);

/** Get stats for an MBean*/
public void getStatsObject (ObjectName mbean, Boolean recursive);

/** Set instrumentation level using String format.
    This should be used by scripting for an easy String processing.
    The level STR is a list of moduleName=Level connected by ":".
    NOTE: This method is deprecated in Version 6.1
    */
public void setInstrumentationLevel(String levelStr, Boolean recursive);

/** Get instrumentation level in String for all the top level modules.
    This should be used by scripting for an easy String processing.
```

```

    NOTE: This method is deprecated in Version 6.1
    */
public String getInstrumentationLevelString();

/** Return the PMI data in String
    NOTE: This method is deprecated in Version 6.1
    */
public String getStatsString(ObjectName on, Boolean recursive);

/** Return the PMI data in String
    Used for PMI modules/submodules without direct MBean mappings.
    NOTE: This method is deprecated in Version 6.1
    */
public String getStatsString(ObjectName on, String submoduleName, Boolean recursive);

/** Return the submodule names if any for the MBean
    NOTE: This method is deprecated in Version 6.1
    */
public String listStatMemberNames(ObjectName on);

```

If an MBean is a `StatisticProvider`, and if you pass its `ObjectName` to `getStatsObject`, you get the `Statistic` data for that MBean. MBeans with the following MBean types are statistic providers:

- `DynaCache`
- `EJBModule`
- `EntityBean`
- `JDBCProvider`
- `J2CResourceAdapter`
- `JVM`
- `MessageDrivenBean`
- `ORB`
- `Server`
- `SessionManager`
- `StatefulSessionBean`
- `StatelessSessionBean`
- `SystemMetrics`
- `ThreadPool`
- `TransactionService`
- `WebModule`
- `Servlet`
- `WLMApServer`
- `WebServicesService`
- `WSGW`

The following are sample commands in **wsadmin** you can use to obtain PMI data:

Obtain the Perf MBean ObjectName

```

wsadmin>set perfName [$AdminControl completeObjectName type=Perf,*]
wsadmin>set perfOName [$AdminControl makeObjectName $perfName]

```

Invoke getStatisticSet operation

Use this method to find the statistic set that is currently in effect:

```

Wsadmin> $AdminControl invoke $perfName getStatisticSet

```

This method returns one of the following values: `basic`, `extended`, `all`, `none`.

Invoke setStatisticSet operation

Use this method to enable monitoring using a statistic set.

The valid statistic set values are: basic, extended, all, none.

```
Wsadmin> set params [java::new {java.lang.Object[]} 1]
Wsadmin> $params set 0 [java::new java.lang.String extended]
Wsadmin> set sigs [java::new {java.lang.String[]} 1]
Wsadmin> $sigs set 0 java.lang.String
Wsadmin> $AdminControl invoke_jmx $perfOName setStatisticSet
$params $sigs
```

Invoke getConfig operation

Use this method to find information about the statistics for a given component.

```
Wsadmin> set jvmName [$AdminControl completeObjectName type=JVM,*]

Wsadmin> set params [java::new {java.lang.Object[]} 1]
Wsadmin> $params set 0 [java::new javax.management.ObjectName $jvmName]
Wsadmin> set sigs [java::new {java.lang.String[]} 1]
Wsadmin> $sigs set 0 javax.management.ObjectName

Wsadmin> $AdminControl invoke_jmx $perfOName getConfig $params
$sigs
```

This method returns the following:

Stats type=jvmRuntimeModule, Description=The performance data from the Java virtual machine run time.

```
{name=UpTime, ID=4, type=CountStatistic, description=The amount of
time (in seconds) that the Java virtual machine has been running.,
unit=SECOND, level=low, statisticSet=basic, resettable=false,
aggregatable=true}
```

```
{name=UsedMemory, ID=3, type=CountStatistic, description=The amount
of used memory (in KBytes) in the Java virtual machine run time.,
unit=KILOBYTE, level=low,
statisticSet=basic, resettable=false, aggregatable=true}
```

```
{name=FreeMemory, ID=2, type=CountStatistic, description=The free
memory (in KBytes) in the Java virtual machine run time.,
unit=KILOBYTE, level=low, statisticSet=all, resettable=false,
aggregatable=true}
```

```
{name=HeapSize, ID=1, type=BoundedRangeStatistic, description=The
total memory (in KBytes) in the Java virtual machine run time.,
unit=KILOBYTE, level=high, statisticSet=basic, resettable=false,
aggregatable=true}
```

Invoke getCustomSetString operation

This operation provides the current monitoring specification in a string format:

```
Wsadmin> $AdminControl invoke $perfName getCustomSetString
```

The output looks similar to the following:

```
jvmRuntimeModule=4,3,1:systemModule=2,1:threadPoolModule=4,3:thread
PoolModule>HAManager.thread.pool=4,3:threadPoolModule>MessageListenerTh
readPool=4,3:threadPoolModule>ORB.thread.pool=4,3:threadPoolModule>Serv
let.Engine.Transports=4,3:threadPoolModule>TCS_DEFAULT=4,3:transactionM
odule=4,19,16,18,3,7,6,1,14
```

This output indicates that statistic ID's 1, 3, and 4 are enabled in the JVM component. The description of the statistic IDs can be found using the above getConfig operation or using the API documentation. The output contains the current monitoring specification for the entire server. The individual modules are separated by a :, and > is used as a separator within the module.

Invoke setCustomString operation

This operation can be used to enable or disable statistics selectively. In the following command the statistic IDs 1, 2, 3, and 4 are enabled for the JVM module. To enable all the statistic IDs use an asterisk (*).

```
Wsadmin> set params [java::new {java.lang.Object[]} 2]
Wsadmin> $params set 0 [java::new java.lang.String
jvmRuntimeModule=1,2,3,4]
Wsadmin> $params set 1 [java::new java.lang.Boolean false]

Wsadmin> set sigs [java::new {java.lang.String[]} 2]
Wsadmin> $sigs set 0 java.lang.String
Wsadmin> $sigs set 1 java.lang.Boolean

Wsadmin> $AdminControl invoke_jmx $perfOName setCustomSetString
$params $sigs
```

Invoke getStatsObject operation

This operation is used to get the statistics for a given MBean. The following example gets the statistics for the JVM:

```
Wsadmin> set jvmName [$AdminControl completeObjectName type=JVM,*]
Wsadmin> set params [java::new {java.lang.Object[]} 2]
Wsadmin> $params set 0 [java::new javax.management.ObjectName
$jvmName]
Wsadmin> $params set 1 [java::new java.lang.Boolean false]
Wsadmin> set sigs [java::new {java.lang.String[]} 2]
Wsadmin> $sigs set 0 javax.management.ObjectName
Wsadmin> $sigs set 1 java.lang.Boolean
Wsadmin> $AdminControl invoke_jmx $perfOName getStatsObject $params
$sigs

Stats name=jvmRuntimeModule, type=jvmRuntimeModule#
{
  name=HeapSize, ID=1, description=The total memory (in KBytes) in
the Java virtual machine run time., unit=KILOBYTE, type=BoundedRangeStatistic, lowWaterMark=51200,
highWaterMark=263038, current=263038, integral=2.494158617766E12, lowerBound
=51200, upperBound=262144

  name=FreeMemory, ID=2, description=The free memory (in KBytes) in
the Java virtual machine run time., unit=KILOBYTE, type=CountStatistic,
count=53509

  name=UsedMemory, ID=3, description=The amount of used memory (in KBytes) in
the Java virtual machine run time., unit=KILOBYTE,
type=CountStatistic, count=209528

  name=UpTime, ID=4, description=The amount of time (in seconds) that
the Java virtual machine has been running., unit=SECOND,
type=CountStatistic, count=83050
}
```

Invoke getInstrumentationLevelString operation

Use *invoke*, because it has no parameter.

```
wsadmin>$AdminControl invoke $perfName
getInstrumentationLevelString
```

This command returns the following:

```
beanModule=H:cacheModule=H:connectionPoolModule=H:j2cModule=H:jvmRu
ntimeModule=H:orbPerfModule=H:servletSessionsModule=H:systemModule=
H:threadPoolModule=H:transactionModule=H:webAppModule=H
```

Note: You can change the level (n, l, m, h, x) in the above string and then pass it to `setInstrumentationLevel` method.

Invoke `setInstrumentationLevel` operation - enable/disable PMI counters

- `sSet` parameters ("`pmi=l`" is the simple way to set all modules to the low level).

```
wsadmin>set params [java::new {java.lang.Object[]} 2]
wsadmin>$params set 0 [java::new java.lang.String pmi=l]
wsadmin>$params set 1 [java::new java.lang.Boolean true]
```

- Set signatures.

```
wsadmin>set sigs [java::new {java.lang.String[]} 2]
wsadmin>$sigs set 0 java.lang.String
wsadmin>$sigs set 1 java.lang.Boolean
```

- Invoke the method. Use `invoke_jmx`, because it has a parameter.

```
wsadmin>$AdminControl invoke_jmx $perfOName
setInstrumentationLevel $params $sigs
```

This command does not return anything.

Note: The PMI level string can be as simple as `pmi=level` (where level is n, l, m, h, or x), or something like `module1=level1:module2=level2:module3=level3` with the same format shown in the string returned from `getInstrumentationLevelString`.

Invoke `getStatsString(ObjectName, Boolean)` operation

If you know the MBean `ObjectName`, you can invoke the method by passing the right parameters. As an example, JVM MBean is used here.

- Get MBean query string. For example, JVM MBean.

```
wsadmin>set jvmName [$AdminControl completeObjectName
type=JVM,*]
```

- Set parameters.

```
wsadmin>set params [java::new {java.lang.Object[]} 2]
wsadmin>$params set 0 [$AdminControl makeObjectName $jvmName]
wsadmin>$params set 1 [java::new java.lang.Boolean true]
```

- Set signatures.

```
wsadmin>set sigs [java::new {java.lang.String[]} 2]
wsadmin>$sigs set 0 javax.management.ObjectName wsadmin>$sigs
set 1 java.lang.Boolean
```

- Invoke method.

```
wsadmin>$AdminControl invoke_jmx $perfOName getStatsString
$params $sigs
```

This command returns the following:

```
{Description jvmRuntimeModule.desc} {Descriptor {{Node wenjianpc}
{Server server
1} {Module jvmRuntimeModule} {Name jvmRuntimeModule} {Type
MODULE}}} {Level 7} {

ark 100596} {MBean 38140.0} }}}}}

```

Invoke `getStatsString (ObjectName, String, Boolean)` operation

This operation takes an additional String parameter, and it is used for PMI modules that do not have matching MBeans. In this case, the parent MBean is used with a String name representing the PMI module. The String names available in an MBean can be found by invoking `listStatMemberNames`. For example, *beanModule* is a logic module aggregating PMI data over all Enterprise JavaBeans, but there is no MBean for *beanModule*. Therefore, you can pass server MBean ObjectName and a String (*beanModule*) to get PMI data in *beanModule*.

- Get MBean query string. For example, server MBean

```
wsadmin>set mySrvName [$AdminControl completeObjectName
type=Server,name=server1,
node=wenjianpc,*]
```
- Set parameters.

```
wsadmin>set params [java::new {java.lang.Object[]} 3]
wsadmin>$params set 0 [$AdminControl makeObjectName $mySrvName]
wsadmin>$params set 1 [java::new java.lang.String beanModule]
wsadmin>$params set 2 [java::new java.lang.Boolean true]
```
- Set signatures.

```
wsadmin>set sigs [java::new {java.lang.String[]} 3]
wsadmin>$sigs set 0 javax.management.ObjectName
wsadmin>$sigs set 1 java.lang.String
wsadmin>$sigs set 2 java.lang.Boolean
```
- Invoke method.

```
wsadmin>$AdminControl invoke_jmx $perfOName getStatsString
$params $sigs
```

This command returns PMI data in all the Enterprise JavaBeans within the BeanModule hierarchy because the recursive flag is set to true.

Note: This method is used to get stats data for the PMI modules that do not have direct MBean mappings.

Invoke listStatMemberNames operation

- Get MBean queryString. For example, Server.

```
wsadmin>set mySrvName [$AdminControl completeObjectName  
type=Server,name=server1,  
node=wenjianpc,*]
```
- Set parameter.

```
wsadmin>set params [java::new {java.lang.Object[]} 1]  
wsadmin>$params set 0 [$AdminControl makeObjectName  
$mySrvName]
```
- Set signatures.

```
wsadmin>set sigs [java::new {java.lang.String[]} 1]  
wsadmin>$sigs set 0 javax.management.ObjectName  
wsadmin>$AdminControl invoke_jmx $perfOName  
listStatMemberNames $params $sigs
```

This command returns the PMI module and submodule names, which have no direct MBean mapping. The names are separated by a space " ". You can then use the name as the String parameter in getStatsString method. For example:

```
beanModule connectionPoolModule j2cModule servletSessionsModule  
threadPoolModule  
webAppModule
```

Enabling the Java virtual machine profiler data

Use the Java virtual machine profiler to enable the collection of information.

Use the Java Virtual Machine Tool Interface (JVMTI) to collect data about garbage collection and thread states from the JVM that runs the application server. When JVMTI is enabled, a collection of JVMTI-specific statistics can be enabled through the predefined All statistic set or through the use of a Custom statistic set.

To enable JVMTI data reporting for each individual application server:

1. Open the administrative console.
2. Click **Servers** > **Application Servers** in the administrative console navigation tree.
3. Click the application server for the JVM profiler that needs enabling.
4. Click **Java and Process Management** under Server Infrastructure.
5. Click **Process Definition**.
6. Click **Java virtual machine** under Additional properties.
7. Type `-agentlib:pmiJvmtiProfiler` in the **Generic JVM arguments** field.

Note: If the deprecated JVMPi profiler is used in WebSphere Application Server Version 6.1 type `-XrunpmiJvmpiProfiler` in the **Generic JVM arguments** field. For more information, refer to "Java virtual machine profiling" on page 2285.

8. Click **Apply** or **OK**.
9. Click **Save**.
10. Click **Servers** > **Application Servers** in the administrative console navigation tree.
11. Click the application server for the JVM profiler that needs enabling.
12. Click the **Configuration** tab. When in the **Configuration** tab, settings apply when the server is restarted. When in the **Runtime** Tab, settings apply immediately. Performance Monitoring Infrastructure (PMI) can be enabled only in the **Configuration** tab.
13. Click **Performance Monitoring Infrastructure** under Performance.
14. Select the **Enable Performance Monitoring Infrastructure (PMI)** check box.
15. Click **Custom** and select **JVM Runtime** on the left-side tree.

16. Click a JVM profiler group under **JVM Runtime** and enable or disable the statistic on the right-side table. Go back to the main PMI configuration page, by clicking PMI.
17. Click **Apply** or **OK**.
18. Click **Save**.
19. Start the application server, or restart the application server if it is currently running.
20. Refresh the Tivoli Performance Viewer if you are using it. The changes you make will not take affect until you restart the application server.

Java virtual machine profiling

Use Java virtual machine profiling to gather data about your system for performance analysis.

The Java virtual machine Tool Interface (JVMTI) is a native programming interface that provides tools the ability to inspect the state of the Java virtual machine (JVM). This interface is new for the JVM, V1.5. JVMTI replaces the Java virtual machine Profiling Interface (JVMPPI), which is supported in WebSphere Application Server, Version 6.0.2 and earlier. The JVMPPI interface is deprecated as of WebSphere Application Server Version 6.1.

Both interfaces (JVMTI and JVMPPI) provide the ability to collect information about the JVM that runs the application server. The Tivoli Performance Viewer leverages these interfaces to enable more comprehensive performance analysis.

JVMTI is a two-way function call interface between the JVM and an in-process profiler agent. The JVM notifies the profiler agent of various events, for example, garbage collection and thread starts. The profiler agent activates or deactivates specific event notifications that are based on the needs of the profiler. The allocate, move, and free object counters that are provided through the JVMPPI interface are not available through the JVMTI implementation in WebSphere Application Server Version 6.1.

JVMTI supports partial profiling, by enabling you to choose which types of profiling information to collect and to select certain subsets of the time during which the JVM API is active. JVMTI moderately increases the performance impact. Therefore, it is recommended that you use JVMTI monitoring to help diagnose application problems only.

Developing your own monitoring applications

You can use the Performance Monitoring Infrastructure (PMI) interfaces to develop your own applications to collect and display performance information.

There are three such interfaces - a Java Machine Extension (JMX)-based interface, a PMI client interface, and a servlet interface. All three interfaces return the same underlying data.

The JMX interface is accessible through the AdminClient tool as described in “Using the JMX interface to develop your own monitoring application” on page 2306. The PMI client interface is a Java interface. The servlet interface is perhaps the simplest, requiring minimal programming, as the output is XML.

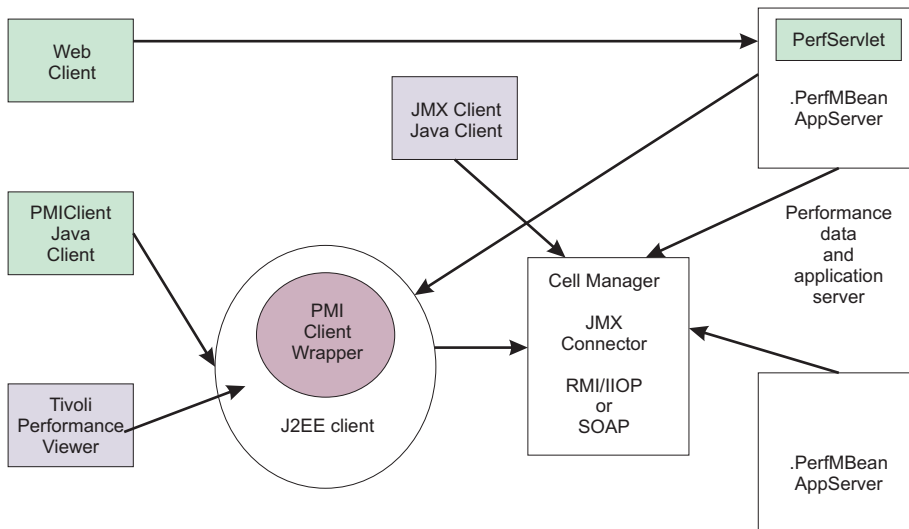

1. “Using PMI client to develop your monitoring application (deprecated)” on page 2287.
2. “Performance servlet (PerfServlet)” on page 2302
3. “Compiling your monitoring applications” on page 2323
4. “Running your new monitoring applications” on page 2323
5. “Using the JMX interface to develop your own monitoring application” on page 2306.
6. “Developing PMI interfaces (Version 4.0) (deprecated)” on page 2322.

PMI client interface (deprecated)

The data provided by the Performance Monitoring Infrastructure (PMI) client interface is documented here.

Access to the PMI client interface data is provided in a hierarchical structure. Descending from the object are node information objects, module information objects, CpdCollection objects and CpdData objects. Using Version 5.0, you will get Stats and Statistic objects. The node and server information objects contain no performance data, only static information.

HTTP

Each time a client retrieves performance data from a server, the data is returned in a subset of this structure; the form of the subset depends on the data retrieved. You can update the entire structure with new data, or update only part of the tree, as needed.

The JMX statistic data model is supported, as well as the existing CPD data model from Version 4.0. When you retrieve performance data using the Version 5.0 PMI client API, you get the Stats object, which includes Statistic objects and optional sub-Stats objects. When you use the Version 4.0 PMI client API to collect performance data, you get the CpdCollection object, which includes the CpdData objects and optional sub-CpdCollection objects.

The following are additional Performance Monitoring Infrastructure (PMI) interfaces:

- BoundaryStatistic
- BoundedRangeStatistic
- CountStatistic
- MBeanStatDescriptor
- MBeanLevelSpec
- New Methods in PmiClient
- RangeStatistic
- Stats
- Statistic
- TimeStatistic

The following PMI interfaces introduced in Version 4.0 are also supported:

- CpdCollection
- CpdData
- CpdEventListener and CpdEvent
- CpdFamily class
- CpdValue
 - CpdLong
 - CpdStat
 - CpdLoad
- PerfDescriptor
- PmiClient class

The CpdLong maps to CountStatistic; CpdStat maps to Time Statistic; CpdCollection maps to Stats; and CpdLoad maps to RangeStatistic and BoundedRangeStatistic.

Note: Version 4.0 PmiClient APIs are supported in this version, however, there are some changes. The data hierarchy is changed in some PMI modules, notably the enterprise bean module and HTTP sessions module. If you have an existing PmiClient application, and you want to run it against Version 5.0, you might have to update the PerfDescriptor(s) based on the new PMI data hierarchy. Also, the getDataName and getDataId methods in PmiClient are changed to be non-static methods in order to support multiple WebSphere Application Server versions. You might have to update your existing application which uses these two methods.

Using PMI client to develop your monitoring application (deprecated)

You can use the Performance Monitoring Infrastructure (PMI) interfaces to develop your own applications to collect and display performance information.

The following is the programming model for Performance Monitoring Infrastructure (PMI) client:

1. Create an instance of PmiClient. This is used for all subsequent method calls.
2. **Optional:** You can create your own MBeans. Refer to Extending the WebSphere Application Server administrative system with custom MBeans.
3. Call the listNodes() and listServers(nodeName) methods to find all the nodes and servers in the WebSphere Application Server domain.
4. Call listMBeans and listStatMembers to get all the available MBeans and MBeanStatDescriptors.
5. Call the getStats method to get the Stats object for the PMI data.
6. **Optional:** The client can also call setStatLevel or getStatLevel to set and get the monitoring level. Use the MBeanLevelSpec objects to set monitoring levels.

Performance Monitoring Infrastructure client (WebSphere Version 4.0)

A Performance Monitoring Infrastructure (PMI) client is an application that receives PMI data from servers and processes this data.

In WebSphere Application Server Version 4.0, PmiClient API takes PerfDescriptor(s) and returns PMI data as a CpdCollection object. Each CpdCollection could contain a list of CpdData, which has a CpdValue of the following types:

- CpdLong
- CpdStat
- CpdLoad

Version 4.0 PmiClient APIs are supported in this version, however, there are some changes. The data hierarchy is changed in some PMI modules, notably the enterprise bean module and HTTP sessions module. If you have an existing PmiClient application, and you want to run it against WebSphere Application Server Version 5.0 or above, you might have to update the PerfDescriptor(s) based on the new PMI data hierarchy. Also, the getDataName and getDataId methods in PmiClient are changed to be non-static methods in order to support multiple WebSphere Application Server versions. You might have to update your existing application which uses these two methods.

Example: Performance Monitoring Infrastructure client (Version 4.0)

The following is a list of example Performance Monitoring Infrastructure (PMI) client code from (Version 4.0):

```
/**
 * This is a sample code to show how to use PmiClient to collect PMI data.
 * You will need to use adminconsole to set instrumentation level (a level other
 * than NONE) first.
 *
 * <p>
```

```

* End-to-end code path in 4.0:
*   PmiTester -> PmiClient -> AdminServer -> appServer
*/

package com.ibm.websphere.pmi;

import com.ibm.websphere.pmi.*;
import com.ibm.websphere.pmi.server.*;
import com.ibm.websphere.pmi.client.*;
import com.ibm.ws.pmi.server.*;
import com.ibm.ws.pmi.perfServer.*;
import com.ibm.ws.pmi.server.modules.*;
import com.ibm.ws.pmi.wire.*;
import java.util.ArrayList;

/**
 * Sample code to use PmiClient API (old API in 4.0) and get CpdData/CpdCollection objects.
 *
 */
public class PmiTester implements PmiConstants {

    /** a test driver:
     * @param args[0] - node name
     * @param args[1] - port number, optional, default is 2809
     * @param args[2] - connector type, default is RMI
     * @param args[3] - version (AE, AEs, WAS50), default is WAS50
     *
     */
    public static void main(String[] args) {
        String hostName = null;
        String portNumber = "2809";
        String connectorType = "RMI";
        String version = "WAS50";

}

for(int j=0; j<serverPds.length; j++) {
    System.out.println("server " + j + ": " + serverPds[j].getName());

    // Option: you can call createPerfLevelSpec and then
    setInstrumentationLevel to set the level
    // for each server if you want. For example, to set all
    the modules to be LEVEL_HIGH for the server j,
    // uncomment the following.
    // PerfLevelSpec[] plds = new PerfLevelSpec[1];
    // plds[0] = pmiCInt.createPerfLevelSpec(null, LEVEL_HIGH);
    // pmiCInt.setInstrumentationLevel(serverPds[j].getNodeName(),
serverPds[j].getServerName(), plds, true);

    // First, list the PerfDescriptor in the server
    PerfDescriptor[] myPds = pmiCInt.listMembers(serverPds[j]);

    // check returned PerfDescriptor
    if(myPds == null) {
        System.out.println("null from listMembers");
        continue;
    }

    // you can add the pds in which you are interested to PerfDescriptorList
    PerfDescriptorList pdList = new PerfDescriptorList();
    for(int i=0; i<myPds.length; i++) {
        // Option 1: you can recursively call listMembers for each myPds
        // and find the one you are interested. You can call
listMembers
        // until individual data level and after that level
you will null from listMembers.
        // e.g., PerfDescriptor[] nextPds = pmiCInt.listMembers(myPds[i]);

        // Option 2: you can filter these pds before adding to pdList
        System.out.println("add to pdList: " + myPds[i].getModuleName());
        pdList.addDescriptor(myPds[i]);
        if( i % 2 == 0)
            pmiCInt.add(myPds[i]);
    }

    // call gets method to get the CpdCollection[] corresponding to pdList
    CpdCollection[] cpdCols = pmiCInt.gets(pdList, true);

    if(cpdCols == null) {
        // check error
        if(pmiCInt.getErrorCode() >0)
            System.out.println(pmiCInt.getErrorMessage());
        continue;
    }

    for(int i=0; i<cpdCols.length; i++) {
        // simple print them
        //System.out.println(cpdCols[i].toString());
    }
}

```

```

        // Or call processCpdCollection to get each data
        processCpdCollection(cpdCols[i], "");
    }

    // Or call gets() method to add the CpdCollection[] for whatever
there by calling pmiCInt.add().
    System.out.println("\n\n\n ---- get data using gets(true) ----- ");
    cpdCols = pmiCInt.gets(true);

    if(cpdCols == null) {

```

Performance servlet (PerfServlet)

The PerfServlet is used for simple end-to-end retrieval of performance data that any tool, provided by either IBM or a third-party vendor, can handle.

The servlet provides a way to use an HTTP request to query the performance metrics for an entire WebSphere Application Server administrative domain. Because the servlet provides the performance data through HTTP, issues such as firewalls are trivial to resolve.

The PerfServlet provides the performance data output as an XML document, as described in the provided document type description (DTD). In the XML structure, the leaves of the structure provide the actual observations of performance data and the paths to the leaves that provide the context.

Starting with version 6.0, the PerfServlet in WebSphere Application Server uses the JMX Perf MBean interface to retrieve the PMI data and outputs an XML document that uses the J2EE 1.4 Performance Data Framework to describe the statistics. The PerfServlet in can also provide an output that is compatible with the PerfServlet 5.0. To provide PerfServlet 5.0 compatible output it uses the PMI client interface.

The performance servlet .ear file PerfServletApp.ear is located in the WAS_HOME/installableApps directory, where WAS_HOME is the installation path for WebSphere Application Server.

The performance servlet is deployed exactly as any other servlet. To use it, follow these steps:

1. Deploy the servlet on a single application server instance within the domain.
2. After the servlet deploys, you can invoke it to retrieve performance data for the entire domain. Invoke the performance servlet by accessing the following default URL:

```
http://hostname/wasPerfTool/servlet/perfservlet
```

The performance servlet provides performance data output as an XML document, as described by the provided document type definition (DTD). The DTD is located inside the PerfServletApp.ear file.

PerfServlet input

The PerfServlet input and output is used for simple end-to-end retrieval of performance data that any tool, provided by either IBM or a third-party vendor, can handle

The PerfServlet is deployed in one of the application server instance within the domain. By default, the PerfServlet collects all of the performance data across a WebSphere Application Server cell. However, it is possible to limit the data returned by the servlet to either a specific node, server, or PMI module:

Node .The servlet can limit the information it provides to a specific host by using the node parameter. For example, to limit the data collection to the node 'rjones', invoke the following URL:

```
http://hostname/wasPerfTool/servlet/perfservlet?node=rjones
```

Server

The servlet can limit the information it provides to a specific server by using the server parameter. For example, in order to limit the data collection to the 'testserver' server on all nodes, invoke the following URL:

```
http://hostname/wasPerfTool/servlet/perfservlet?server=testserver
```

To limit the data collection to the 'testserver' server located on the host 'rjones', invoke the following URL:

```
http://hostname/wasPerfTool/servlet/perfservlet?node=rjones&server=testserver
```

Module

The servlet can limit the information it provides to a specific PMI module by using the module parameter. You can request multiple modules by using the following URL:

```
http://hostname/wasPerfTool/servlet/perfservlet?module=beanModule+jvmRuntimeModule
```

For example, to limit the data collection to the beanModule on all servers and nodes, invoke the following URL:

```
http://hostname/wasPerfTool/servlet/perfservlet?module=beanModule
```

To limit the data collection to the beanModule on the server 'testserver' on the node rjones, invoke the following URL:

```
http://hostname/wasPerfTool/servlet/perfservlet?node=rjones&server=testserver&module=beanModule
```

To find the list of the modules, invoke the PerfServlet help with the following URL:

```
http://hostname/wasPerfTool/servlet/perfservlet?action=help
```

In WebSphere Application Server Network Deployment (ND), the PerfServlet automatically connects to the deployment manager to provide PMI data about the entire cell.

When the performance servlet is first initialized, it retrieves the list of nodes and servers within the domain in which it is deployed. Because the collection of this data is expensive, the performance servlet holds this information as a cached list. If a new node is added to the domain or a new server is started, the performance servlet does not automatically retrieve the information about the newly created element. To force the servlet to refresh its configuration, you must add the refreshConfig parameter to the invocation as follows:

<http://hostname/wasPerfTool/servlet/perfservlet?refreshConfig=true>

You may want to configure other parameters of the performance servlets according to your specific needs. You can define the host, port number, connector type, and a user name and password.

- **Host.** This defines the host name where the server is running. The default value is "localhost." For base installations, use "localhost" or "host" where application server is running. In Network Deployment installations, use the Deployment Manager's host name.

Note: There can be more than one server instance in Network Deployment installations and a performance servlet can be installed in any one of the servers.

- **Port.** This is the port through which the server will connect. The default value is '8880' (SOAP connector port in base installation). In a base installation, use the application server SOAP or RMI connector port. In a Network Deployment installation, use the Deployment Manager's SOAP or RMI port.

Note: The port numbers for SOAP/RMI connector can be configured in the administrative console under **Servers > Application Servers > server_name > End Points.**

- **Connector.** The connector type can be either SOAP or RMI. The default value is SOAP.
- **Username.** If security is enabled provide the user name.
- **Password.** If security is enabled provide the password.

PerfServlet output

The PerfServlet input and output is used for simple end-to-end retrieval of performance data that any tool, provided by either IBM or a third-party vendor, can handle.

The performance servlet .ear file PerfServletApp.ear is located in the WAS_HOME/installableApps directory.

The PerfServlet 6.0 provides output using the J2EE 1.4 Performance Data Framework. By default, the PerfServlet output is in 6.0 format. PerfServlet can provide the output in 5.0 format using the version parameter:

<http://hostname/wasPerfTool/servlet/perfservlet?version=5>

Refer to "PMI data classification" on page 2165 for details about the Performance Data Framework.

PerfServlet 5.0 output details: The following section describes the PerfServlet 5.0 output. There are three types of leaves or output formats within the XML structure: PerfNumericInfo, PerfStatInfo, and PerfLoadInfo.

PerfNumericInfo:

When each invocation of the performance servlet retrieves the performance values from Performance Monitoring Infrastructure (PMI), some of the values are raw counters that record the number of times a specific event occurs during the lifetime of the server. If a performance observation is of the type PerfNumericInfo, the value represents the raw count of the number of times this event has occurred since the server started. This information is important to note because the analysis of a single document of data provided by the performance servlet might not be useful for determining the current load on the system. To determine the load during a specific interval of time, it might be necessary to apply simple statistical formulas to the data in two or more documents provided during this interval.

The PerfNumericInfo type has the following attributes:

- time** Specifies the time when the observation was collected (Java System.currentTimeMillis)
- uid** Specifies the PMI identifier for the observation
- val** Specifies the raw counter value

The following document fragment represents the number of loaded servlets. The path providing the context of the observation is not shown:

```
<numLoadedServlets>
  <PerfNumericData time="988162913175" uid="pmi1" val="132"/>
</numLoadedServlets>
```

PerfStatInfo:

When each invocation of the performance servlet retrieves the performance values from PMI, some of the values are stored as statistical data. Statistical data records the number of occurrences of a specific event, as the PerfNumericInfo type does. In addition, this type has sum of squares, mean, and total for each observation. This value is relative to when the server started.

The PerfStatInfo type has the following attributes:

- time** Specifies the time when the observation was collected (Java System.currentTimeMillis)
- uid** Specifies the PMI identifier for the observation
- num** Specifies the number of observations
- sum_of_squares**
Specifies the sum of the squares of the observations
- total** Specifies the sum of the observations
- mean** Specifies the mean (total number) for this counter

The following fragment represents the response time of an object. The path providing the context of the observation is not shown:

```
<responseTime>
  <PerfStatInfo mean="1211.5" num="5" sum_of_squares="3256265.0"
    time="9917644193057" total="2423.0" uid="pmi13"/>
</responseTime>
```

PerfLoadInfo:

When each invocation of the performance servlet retrieves the performance values from PMI, some of the values are stored as a load. Loads record values as a function of time; they are averages. This value is relative to when the server started.

The PerfLoadInfo type has the following attributes:

- time** Specifies the time when the observation was collected (Java System.currentTimeMillis)
- uid** Specifies the PMI identifier for the observation
- currentValue**
Specifies the current value for this counter
- integral**
Specifies the time-weighted sum
- timeSinceCreate**
Specifies the elapsed time in milliseconds since this data was created in the server
- mean** Specifies time-weighted mean (integral/timeSinceCreate) for this counter

The following fragment represents the number of concurrent requests. The path providing the context of the observation is not shown:

```
<poolSize>
  <PerfLoadInfo currentValue="1.0" integral="534899.0" mean="0.9985028962051592"
    time="991764193057" timeSinceCreate="535701.0" uid="pmi5"/>
</poolSize>
```

Using the JMX interface to develop your own monitoring application

You can use AdminClient API to get Performance Monitoring Infrastructure (PMI) data by using either PerfMBean or individual MBeans.

You can invoke methods on MBeans through the AdminClient Java Management Extension (JMX) interface. You can use AdminClient API to get Performance Monitoring Infrastructure (PMI) data by using either PerfMBean or individual MBeans. See information about using individual MBeans at bottom of this article.

Individual MBeans provide the Stats attribute from which you can get PMI data. The PerfMBean provides extended methods for PMI administration and more efficient ways to access PMI data. To set the PMI module instrumentation level, you must invoke methods on PerfMBean. To query PMI data from multiple MBeans, it is faster to invoke the getStatsArray method in PerfMBean than to get the Stats attribute from multiple individual MBeans. Perf MBean can provide PMI data from multiple MBeans using a single JMX call, but multiple JMX calls have to be made through individual MBeans.

See the topic “Developing an administrative client program” for more information on AdminClient JMX.

After the performance monitoring service is enabled and the application server is started or restarted, a PerfMBean is located in each application server giving access to PMI data. To use PerfMBean:

1. Create an instance of AdminClient. When using AdminClient API, you need to first create an instance of AdminClient by passing the host name, port number and connector type.

The example code is:

```
AdminClient ac = null;
java.util.Properties props = new java.util.Properties();
props.put(AdminClient.CONNECTOR_TYPE, connector);
props.put(AdminClient.CONNECTOR_HOST, host);
props.put(AdminClient.CONNECTOR_PORT, port);
try {
    ac = AdminClientFactory.createAdminClient(props);
}
catch(Exception ex) {
    failed = true;
    new AdminException(ex).printStackTrace();
    System.out.println("getAdminClient: exception");
}
```

2. Use AdminClient to query the MBean ObjectNames Once you get the AdminClient instance, you can call queryNames to get a list of MBean ObjectNames depending on your query string. To get all the ObjectNames, you can use the following example code. If you have a specified query string, you will get a subset of ObjectNames.

```
javax.management.ObjectName on = new javax.management.ObjectName("WebSphere:*");
Set objectNameSet= ac.queryNames(on, null);
// you can check properties like type, name, and process to find a specified ObjectName
```

After you get all the ObjectNames, you can use the following example code to get all the node names:

```

HashSet nodeSet = new HashSet();
for(Iterator i = objectNameSet.iterator(); i.hasNext(); on =
(ObjectName)i.next()) {
    String type = on.getKeyProperty("type");
    if(type != null && type.equals("Server")) {
        nodeSet.add(servers[i].getKeyProperty("node"));
    }
}

```

Note, this will only return nodes that are started. To list running servers on the node, you can either check the node name and type for all the ObjectNames or use the following example code:

```

StringBuffer oNameQuery= new StringBuffer(41);
oNameQuery.append("WebSphere:*");
oNameQuery.append(",type=").append("Server");
oNameQuery.append(",node=").append(mynode);

oSet= ac.queryNames(new ObjectName(oNameQuery.toString()), null);
Iterator i = objectNameSet.iterator ();
while (i.hasNext ()) {
    on=(ObjectName) i.next();
    String process= on[i].getKeyProperty("process");
    serversArrayList.add(process);
}

```

3. Get the PerfMBean ObjectName for the application server from which you want to get PMI data. Use this example code:

```

for(Iterator i = objectNameSet.iterator(); i.hasNext(); on = (ObjectName)i.next()) {
    // First make sure the node name and server name is what you want
    // Second, check if the type is Perf
    String type = on.getKeyProperty("type");
    String node = on.getKeyProperty("node");
    String process= on.getKeyProperty("process");
    if (type.equals("Perf") && node.equals(mynode) &
& server.equals(myserver)) {
        perfOName = on;
    }
}

```

4. Invoke operations on PerfMBean through the AdminClient. Once you get the PerfMBean(s) in the application server from which you want to get PMI data, you can invoke the following operations on the PerfMBean through AdminClient API:

- setStatisticSet: Enable PMI data using the pre-defined statistic sets.
 params[0] = new String[] { com.ibm.websphere.pmi.stat.StatConstants.STATISTIC_SET_EXTENDED};
 signature = new String[] {"java.lang.String"};
 ac.invoke (perfOName, "setStatisticSet", params, signature);
- getStatisticSet: Returns the current statistic set.
 ac.invoke (perfOName, "getStatisticSet", null, null);
- setCustomSetString: Customizing PMI data that is enabled using fine-grained control. This method allows to enable or disable statistics selectively. The format of the custom set specification string is STATS_NAME=ID1,ID2,ID3 separated by ':', where STATS_NAME and IDs are defined in WS*Stat interfaces in com.ibm.websphere.pmi.stat package.
 params[0] = new String (WSJVMSStats.NAME + "=" + WSJVMSStats.HeapSize);
 params[1] = new Boolean (false);
 signature = new String[] {"java.lang.String", "java.lang.Boolean"};
 ac.invoke (perfOName, "setCustomSetString", null, null);
- getCustomSetString: Returns the current custom set specification as a string
 ac.invoke (perfOName, "getCustomSetString", null, null);
- setInstrumentationLevel: set the instrumentation level
 params[0] = new MBeanLevelSpec(objectName, new int[] {WSJVMSStats.HEAPSIZE});
 params[1] = new Boolean(true);

```

        signature= new String[]{ "com.ibm.websphere.pmi.stat.MBeanLevelSpec",
"java.lang.Boolean"};
        ac.invoke(perfOName, "setInstrumentationLevel", params, signature);

- getInstrumentationLevel: get the instrumentation level
    params[0] = objectName;
    params[1] = new Boolean(recursive);
    String[] signature= new String[]{
"javax.management.ObjectName", "java.lang.Boolean"};
    MBeanLevelSpec[] mlss = (MBeanLevelSpec[])ac.invoke(perfOName,
"getInstrumentationLevel", params, signature);

- setInstrumentationLevel: set the instrumentation level (deprecated in V6.0)
    params[0] = new MBeanLevelSpec(objectName, optionalSD, level);
    params[1] = new Boolean(true);
    signature= new String[]{ "com.ibm.websphere.pmi.stat.MBeanLevelSpec",
"java.lang.Boolean"};
    ac.invoke(perfOName, "setInstrumentationLevel", params, signature);

- getInstrumentationLevel: get the instrumentation level (deprecated in V6.0)
    Object[] params = new Object[2];
    params[0] = new MBeanStatDescriptor(objectName, optionalSD);
    params[1] = new Boolean(recursive);
    String[] signature= new String[]{
"com.ibm.websphere.pmi.stat.MBeanStatDescriptor", "java.lang.Boolean"};
    MBeanLevelSpec[] mlss = (MBeanLevelSpec[])ac.invoke(perfOName,
"getInstrumentationLevel", params, signature);

- getConfigs: get PMI static config info for all the MBeans
    configs = (PmiModuleConfig[])ac.invoke(perfOName, "getConfigs", null, null);

- getConfig: get PMI static config info for a specific MBean
    ObjectName[] params = {objectName};
    String[] signature= { "javax.management.ObjectName" };
    config = (PmiModuleConfig)ac.invoke(perfOName, "getConfig", params,
signature);

- getStatsObject: you can use either ObjectName or MBeanStatDescriptor
    Object[] params = new Object[2];
    params[0] = objectName; // either ObjectName or or MBeanStatDescriptor
    params[1] = new Boolean(recursive);
    String[] signature = new String[] { "javax.management.ObjectName",
"java.lang.Boolean"};
    Stats stats = (Stats)ac.invoke(perfOName, "getStatsObject", params,
signature);

```

Note: The returned data only have dynamic information (value and time stamp). See PmiJmxTest.java for additional code to link the configuration information with the returned data.

```

- getStatsArray: you can use either ObjectName or MBeanStatDescriptor
    ObjectName[] onames = new ObjectName[]{objectName1, objectName2};
    Object[] params = new Object[]{onames, new Boolean(true)};
    String[] signature = new String[]{"[Ljavax.management.ObjectName;",
"java.lang.Boolean"};
    Stats[] statsArray = (Stats[])ac.invoke(perfOName, "getStatsArray",
params, signature);

```

Note: The returned data only have dynamic information (value and time stamp). See PmiJmxTest.java for additional code to link the configuration information with the returned data.

```

- listStatMembers: navigate the PMI module trees

    Object[] params = new Object[]{mName};
    String[] signature= new String[]{"javax.management.ObjectName"};
    MBeanStatDescriptor[] msds = (MBeanStatDescriptor[])ac.invoke(perfOName,

```

```
"listStatMembers", params, signature);
```

or,

```
        Object[] params = new Object[]{mbeanSD};
        String[] signature= new String[]
{"com.ibm.websphere.pmi.stat.MBeanStatDescriptor"};
        MBeanStatDescriptor[] msds = (MBeanStatDescriptor[])ac.invoke
(perfOName, "listStatMembers", params, signature);
```

Refer the API documentation for deprecated classes

- **To use an individual MBean:** You need to get the AdminClient instance and the ObjectName for the individual MBean. Then you can simply get the Stats attribute on the MBean.

Example: Administering Java Management Extension-based interface

The page provides example code directly using Java Management Extension (JMX) API. For information on compiling your source code, see "Compiling your monitoring applications."

```
package com.ibm.websphere.pmi;
```

```
import com.ibm.websphere.management.AdminClient;
import com.ibm.websphere.management.AdminClientFactory;
import com.ibm.websphere.management.exception.ConnectorException;
import com.ibm.websphere.management.exception.InvalidAdminClientTypeException;
import com.ibm.websphere.management.exception.*;
```

```
import java.util.*;
import javax.management.*;

    return null;
}
}

```

Developing PMI interfaces (Version 4.0) (deprecated)

You can use the Performance Monitoring Infrastructure (PMI) interfaces to develop your own applications to collect and display performance information.

This section discusses the use of the Performance Monitoring Infrastructure (PMI) client interfaces in applications. The basic steps in the programming model follow:

1. Retrieve an initial collection or snapshot of performance data from the server. A client uses the `CpdCollection` interface to retrieve an initial collection or snapshot from the server. This snapshot, which is called `Snapshot` in this example, is provided in a hierarchical structure as described in data organization and hierarchy, and contains the current values of all performance data collected by the server. The snapshot maintains the same structure throughout the lifetime of the `CpdCollection` instance.

2. Process and display the data as specified. The client processes and displays the data as specified. Processing and display objects, for example, filters and GUIs, can register as CpdEvent listeners to data of interest. The listener works only within the same Java virtual machine (JVM). When the client receives updated data, all listeners are notified.
3. Display the new CpdCollection instance through the hierarchy. When the client receives new or changed data, the client can simply display the new CpdCollection instance through its hierarchy. When it is necessary to update the Snapshot collection, the client can use the update method to update Snapshot with the new data.

```
Snapshot.update(S1);
// ...later...
Snapshot.update(S2);
```

Steps 2 and 3 are repeated through the lifetime of the client.

Compiling your monitoring applications

Use this page to find the JAR files required to compile your Performance Monitoring Infrastructure (PMI).

To compile your Performance Monitoring Infrastructure (PMI) code, you must have the following JAR file in your class path:

- %WAS_HOME%\plugins\com.ibm.ws.runtime_6.1.0.jar

The JAR files listed above are needed to compile the PmiJmxTest example application. If your monitoring applications use APIs in other packages, also include those packages on the class path. If any WebSphere Application Server class is not found with the above set of jars, then you can include all the WebSphere jars using:

```
javac -classpath %WAS_HOME%\plugins\com.ibm.ws.runtime_6.1.0.jar myclass.java
```

Running your new monitoring applications

Use this page to learn about the steps you must follow in order to run monitoring applications.

Follow these steps to run your monitoring applications.

1. You need a WebSphere Application Server installation or WebSphere Application Server J2EE client package to run a PMI application.
2. Use a PMI client API to write your own application.
3. Compile the newly-written PMI application and place it on the class path. (The jar files under %WAS_HOME%\lib and %WAS_HOME%\classes folder will be placed in the class path by the following script.)
4. To run a PMI application you need a WebSphere Application Server runtime environment (the application server installation or a J2EE client package). Using the following script to run the application:

Note: The following is formatted for Windows based systems. You may need to adjust the script depending on your operating system.

```
@echo off
@setlocal

call "%~dp0setupCmdLine.bat"

"%JAVA_HOME%\bin\java" "%CLIENTSAS%" "%CLIENTSOAP%" -DwebsphereV5Statistics=false
-Dwas.install.root="%WAS_HOME%" -Dws.ext.dirs="%WAS_EXT_DIRS%" -classpath "%WAS_CLASSPATH%"
com.ibm.ws.bootstrap.WSLauncher com.ibm.websphere.pmi.PmiJmxTest %*
```

Performance Monitoring Infrastructure client package

Use this page to learn how to use the PmiClient application and JMX connector to communicate to the Perf MBean in an application server.

A Performance Monitoring Infrastructure (PMI) client package provides a PmiClient wrapper class to deliver PMI data to a client. As shown in the following figure, the PmiClient API uses the AdminClient API to communicate to the Perf MBean in an application server.

The PmiClient communicates with the network manager first, retrieving an AdminClient instance to each application server. When the PmiClient receives the instance, it uses it to communicate with the application server directly for performance or level setting changes. Since level settings are persistent through PmiClient, you are only required to set it once, unless you want to change it.

Performance Monitoring Infrastructure and Java Management Extensions

The PmiClient API does not work if the Java Management Extensions (JMX) infrastructure and Perf MBean are not running. If you prefer to use the AdminClient API directly to retrieve PMI data, you still have a dependency on the JMX infrastructure.

When using the PmiClient API, you have to pass the JMX connector protocol and port number to instantiate an object of the PmiClient. Once you get a PmiClient object, you can call its methods to list nodes, servers and MBeans, set the monitoring level, and retrieve PMI data.

The PmiClient API creates an instance of the AdminClient API and delegates your requests to the AdminClient API. The AdminClient API uses the JMX connector to communicate with the Perf MBean in the corresponding server and then returns the data to the PmiClient, which returns the data to the client.

Running your monitoring applications with security enabled

You can opt to run a Performance Monitoring Infrastructure client application with security enabled.

In order to run a Performance Monitoring Infrastructure (PMI) client application with security enabled, you must have %CLIENTSOAP% properties defined on your Java virtual machine command line for a SOAP connector, and %CLIENTSAS% properties defined for a RMI connector. The %CLIENTSOAP% and %CLIENTSAS% properties are defined in the setupCmdLine.bat or setupCmdline.sh files.

- If you are configuring security for a SOAP connector:
 1. Set com.ibm.SOAP.securityEnabled to **True** in the soap.client.props file for the SOAP connector. The soap.client.props property file is located in the *profile_root*/properties directory.
 2. Set com.ibm.SOAP.loginUserId and com.ibm.SOAP.loginPassword as the user ID and password for login.
- If you are configuring security for a RMI connector, set the sas.client.props file or type the user ID and password in the window, if you do not put them in the property file for Remote Method Invocation (RMI) connector. A common mistake is to leave extra spaces at the end of the lines in the property file. Do not leave extra spaces at the end of the lines, especially for the user ID and password lines.

Monitoring performance with Tivoli Performance Viewer (TPV)

Tivoli Performance Viewer (TPV) enables administrators and programmers to monitor the overall health of WebSphere Application Server from within the administrative console.

In Version 4.0, Tivoli Performance Viewer was named the Resource Analyzer. In Version 5.0, TPV is a standalone Java application. In Versions 6.0.x and later, TPV is embedded in the administrative console. From TPV, you can view current activity and summary reports, or log Performance Monitoring Infrastructure (PMI) performance data. TPV provides a simple viewer for the performance data collected by the Performance Monitoring Infrastructure.

By viewing TPV data, administrators can determine which part of the application and configuration settings to change in order to improve performance. For example, you can view the servlet summary reports, enterprise beans, and Enterprise JavaBeans (EJB) methods in order to determine what part of the application to focus on. Then, you can sort these tables to determine which of these resources has the highest response time. Focus on improving the configuration for those application resources taking the longest response time.

1. **Optional:** Adjust the Performance Monitoring Infrastructure (PMI) settings for the servers that you want to monitor. The PMI service is enabled by default with a basic set of counters enabled.
2. Monitor current server activity. You can view real-time data on the current performance activity of a server using TPV in the administrative console.
 - Use the performance advisors to examine various data while your application is running. The performance advisor in TPV provides advice to help tune systems for optimal performance by using collected PMI data.
 - Configure user and logging settings for TPV. These settings may affect the performance of your application server.
 - View summary reports on servlets, Enterprise JavaBeans (EJB) methods, connections pools and thread pools in WebSphere Application Server.
 - View performance modules that provide graphs and of various performance data on system resources such as CPU utilization, on WebSphere pools and queues such as database connection pools, and on customer application data such as servlet response time. In addition to providing a viewer for performance data, TPV enables you to view data for other products or customer applications that have implemented custom PMI.
3. View server performance logs. You can record and view data that has been logged by TPV in the administrative console. Be sure to configure user and logging settings for TPV.
4. Log performance data. You can record real-time data for later retrieval and analysis.

Why use Tivoli Performance Viewer?

Administrators and programmers can monitor the overall health of WebSphere Application Server from within the administrative console by using Tivoli Performance Viewer (TPV).

From TPV, you can view current activity or log Performance Monitoring Infrastructure (PMI) performance data for the following:

- System resources such as CPU utilization
- WebSphere pools and queues such as a database connection pool
- Customer application data such as average servlet response time

You can also view data for other products or customer applications that implement custom PMI by using TPV. For more information on custom PMI, refer to “Enabling PMI data collection” on page 2274.

By viewing PMI data, administrators can determine which part of the application and configuration settings to alter in order to improve performance. For example, in order to determine what part of the application to focus on, you can view the servlet summary report, enterprise beans and Enterprise JavaBeans (EJB) methods, and determine which of these resources has the highest response time. You can then focus on improving the configuration for those application resources with the longest response times.

Tivoli Performance Viewer is used to help manage configuration settings by viewing the various graphs or using the Tivoli Performance Advisor. For example, by looking at the summary chart for thread pools, you

can determine whether the thread pool size needs to be increased or decreased by monitoring the percent (%) usage. After configuration settings are changed based on the data provided, you can determine the effectiveness of the changes. To help with configuration settings, use the Tivoli Performance Advisor. The Advisor assesses various data while your application is running, and provides configuration setting advice to improve performance.

transition: In Version 4.0, Tivoli Performance Viewer was originally named the Resource Analyzer. In Version 5.0, TPV was a standalone Java application. In Versions 6.0.x and later, TPV is embedded in the administrative console.

TPV topologies and performance impacts

The Tivoli Performance Viewer (TPV) enables administrators and programmers to monitor the overall health of WebSphere Application Server from within the administrative console.

The following two topologies exist for the Tivoli Performance Viewer:

- Tivoli Performance Viewer running in a single server environment
- Tivoli Performance Viewer running in a Network Deployment environment

When the Tivoli Performance Viewer is running in a single server environment, the collection and viewing of the data occurs in the same Java virtual machine. Because the collection and viewing of data occurs in the application server, performance may be affected depending on TPV settings. “Viewing Data with the Tivoli Performance Viewer” on page 2330 describes the various TPV settings and their effect on performance.

When the Tivoli Performance Viewer is used in a Network Deployment environment, the data is collected at each of the nodes and stored in memory at the node agent. Data is then viewed from the deployment manager. This architecture enables the monitoring work to be distributed among the nodes. Similar to the single server environment, the various user and logging settings directly influence the extent to which performance is affected.

Related tasks

“Monitoring performance with Tivoli Performance Viewer (TPV)” on page 2324

Tivoli Performance Viewer (TPV) enables administrators and programmers to monitor the overall health of WebSphere Application Server from within the administrative console.

Viewing current performance activity

You can view the current performance activity of a server using the Tivoli Performance Viewer (TPV) in the administrative console.

Once monitoring is enabled, TPV monitors the performance activity of all servers on a node, which can include the following:

- Application servers
- Node agent for the node being monitored

TPV enables administrators and programmers to monitor the current health of WebSphere Application Server. Because the collection and viewing of data occurs in the application server, performance may be affected. To minimize performance impacts, monitor only those servers whose resources need to be optimized.

1. Click **Monitoring and Tuning > Performance Viewer > Current Activity** in the console navigation tree. The TPV current activity collection is displayed.
2. Start monitoring the current activity of a server in either of two ways:
 - Under **Server**, click the name of the server whose activity you want to monitor. Clicking on the name starts the monitoring for the server and displays the activity page for the server.

- Select the check box for the server whose activity you want to monitor, and click **Start Monitoring**. To start monitoring multiple servers at the same time, select the servers and click **Start Monitoring**.

A TPV console panel is displayed, providing a navigation tree on the left and a view of real-time data on the current performance activity of a server on the right.

3. From the navigation tree, select the server activity data that you want to view.

Option	Description
Advisor	Use the Performance Advisor to examine various data while your application is running. The Performance Advisor provides advice to help tune systems for optimal performance and gives recommendations on inefficient settings by using collected PMI data.
Settings	Configure user and logging settings for TPV. These settings can affect the performance of your application server.
Summary Reports	View summary reports on servlets, enterprise beans (EJBs), EJB methods, connections pools and thread pools in WebSphere Application Server.
Performance Modules	View performance modules that provide graphics and charts of various performance data on system resources such as CPU utilization, on WebSphere pools and queues such as database connection pools, and on customer application data such as servlet response time. In addition to providing a viewer for performance data, TPV enables you to view data for other products or customer applications that have implemented custom PMI.

When you finish monitoring a server, select the server and click **Stop Monitoring**. TPV automatically stops monitoring a server if you the browser window is closed or if the user logs out..

Selecting a server and changing monitoring status

Use this page to start and stop monitoring for each server and to select a server for Tivoli Performance Viewer. You can also view the collection status for each server.

To view this administrative console page, click **Monitoring and Tuning > Performance Viewer > Current Activity**.

On this page, you can view the collection status of each server. When the collection status is **Monitored**, Tivoli Performance Monitor is enabled. If the collection status is **Available**, the server is ready to be enabled. If the collection status is **Unavailable, server stopped, PMI not enabled, or nodeagent stopped**, you must restart your server before you can start monitoring. Click on any server or node agent to view the current activity for that server. Lastly, **Performance Data Collection Not Supported** means that the server is not version 6.0.x or later.

Maximum rows: Specifies the maximum number of rows that displays when the collection is large. The rows that are not displayed appear on the next page.

Retain filter criteria: Specifies whether to use the same filter criteria entered in the show filter function to display this page the next time you visit it.

Start monitoring:

Select one or more servers from the list and press Start monitoring to start the Tivoli Performance Monitor for the selected servers.

Stop monitoring:

Select one or more servers from the list and press Stop monitoring to stop the Tivoli Performance Monitor for the selected servers.

Configuring TPV settings

You can configure user and logging settings of the Tivoli Performance Viewer (TPV). Configuring the TPV settings affects the performance of your application server.

TPV monitors the performance activity of all servers on a node.

The data can also be viewed from the deployment manager.

You can configure the activity monitoring of TPV on a per-user basis. Any changes made to TPV settings are only for the server being monitored and only affect the user viewing the data.

You can change the user and log TPV settings in the administrative console.

- Configure the TPV user settings.
 1. Click **Monitoring and Tuning > Performance Viewer > Current Activity > server_name > Settings > User** in the console navigation tree. To see the **User** link on the Tivoli Performance Viewer page, expand the **Settings** node of the TPV navigation tree on the left side of the page. After clicking **User**, the TPV user settings are displayed on the right side of the page.
 2. Change the values as needed for the user settings. The settings are described briefly below and in more detail in the Tivoli Performance Viewer settings.

Refresh Rate	Specifies how frequently TPV collects performance data for a server from the Performance Monitoring Infrastructure (PMI) service provided by that server. The default is 30 seconds. To collect performance data for the server more frequently, set the refresh rate to a smaller number. To collect performance data less frequently, set the refresh rate to a larger number. The allowed range is 5 to 500 seconds.
Buffer Size	Specifies the number of entries to be stored for a server. Data displayed in TPV is stored in a short in-memory buffer. After the buffer is full, each time a new entry is retrieved the oldest entry is discarded. The default buffer size is 40 entries. Supported values are 10, 20, 30, 40, 50, 60, 70, 80, 90 and 100. The larger the buffer size, the more memory is consumed. Thus, specify a buffer size that allows you capture enough monitoring data for analysis without wasting memory storing unneeded data.

View Data As	<p>Specifies how counter values are displayed. Viewing options include the following:</p> <p>Raw Value Displays the absolute value. If the counter represents load data, such as the average number of connections in a database pool, then TPV displays the current value followed by the average. For example, 18 (avg:5).</p> <p>Change in Value Displays the change in the current value from the previous value.</p> <p>Rate of Change Displays the ratio $\text{change}/(T1 - T2)$, where <i>change</i> is the change in the current value from the previous value, <i>T1</i> is the time when the current value was retrieved, and <i>T2</i> is the time when the previous value was retrieved.</p>
---------------------	--

The refresh rate and buffer size settings combine to control how much temporal history you have for the application server. The default values for **Refresh Rate** (30 seconds) and **Buffer Size** (40 entries) provide you with a 20-minute history of the application server's performance. Changing one of these parameters affects the length of the temporal history.

The values you set for **Refresh Rate** and **Buffer Size** depend on your use of TPV. To diagnose a known problem on a test machine, you might poll data more frequently while having a decreased buffer size. To monitor a production server, you might poll data less frequently and specify a buffer size depending on how much history you want. However, TPV is not intended to be a full-time monitoring solution.

3. Click **Apply**.
- Configure the TPV log settings. The log settings control what happens when **Start Logging** is clicked in, for example, a summary report on the performance of a servlet, enterprise bean (EJB), EJB method, connection pool or thread pool.
 1. Click **Monitoring and Tuning > Performance Viewer > Current Activity > server_name > Settings > Log** in the console navigation tree. To see the **Log** link on the Tivoli Performance Viewer page, expand the **Settings** node of the TPV navigation tree on the left side of the page. After clicking **Log**, the TPV log settings are displayed on the right side of the page.
 2. Change the values as needed for the log settings. The settings are described below and in the Tivoli Performance Viewer settings.

Duration	Specifies the length of time, in minutes, that logging continues, unless Stop Logging is clicked first. TPV is not intended as a full-time logging solution.
Maximum File Size	Specifies the maximum size, in megabytes, of a single file. Note that TPV automatically zips log files to save space and this parameter controls the pre-zipped file size and not the post-zipped, which is smaller.
Maximum Number of Historical Files	Specifies the number of files TPV writes before stopping. If TPV reaches the maximum file size before the logging duration ends, it continues logging in another file, up to the maximum. If TPV reaches the maximum number of historical files before the logging duration ends, TPV deletes the oldest historical file and continues logging in a new file. The total amount of data that is stored is constrained by the Maximum File Size and Maximum Number of Historical Files parameters.

File Name	Specifies the name of the log file. The server name and the time at which the log is started is appended to the log name to help users identify a log file.
Log Output Format	Specifies whether TPV writes log files as XML or in a binary format. Binary format is recommended as it provides a smaller log file when uncompressed.

3. Click **Apply**.

Viewing Data with the Tivoli Performance Viewer

Use this page to view and refresh performance data for the selected server, change user and log settings, view summary reports, and information on specific performance modules.

To view this administrative console page, click **Monitoring and Tuning > Performance Viewer > Current Activity > server**.

Click the server name to view the current activity for that server. In this view, the Tivoli Performance Viewer (TPV) has two main parts, which include the navigation panel located beside the administrative console navigation tree, and the data viewing panel located to the right of the Tivoli Performance Viewer navigation panel.

Refresh:

Click **Refresh** to rebuild the navigation tree. Refreshing is helpful when the available Performance Monitoring (PMI) Infrastructure data has changed, and the tree does not reflect those changes.

View Module(s):

Click **View Module** after one or more performance modules are selected in the tree to display the information for these modules in the data viewing panel.

The Data Monitoring panel enables the selection of multiple counters and displays the resulting performance data for the associated resources. It consists of two panels:

- Viewing Counter panel
- Counter Selection panel. If necessary, you can change the scaling factors by editing the default values in the scale field.

Deselect all items:

Select **Deselect all items** to quickly deselect all modules that are selected in the navigation tree.

Navigation tree:

Use the navigation tree to view advisor output, configure TPV, and select PMI modules for viewing.

- Click the **Advisor** node to have the advisor display the data in the viewing panel.
- Expand the **Settings** node to select and configure either the **User** or **Log** settings.
- Expand the **Performance Modules** node to view one or more PMI modules.

Advisor:

Click **Advisor** to examine various data while your application is running. The Performance Advisor provides advice to help tune systems for optimal performance using the PMI data collected.

The first table represents the number of requests per second and the response time in milliseconds for the Web container.

The pie graph displays the CPU activity as a percentage of busy and idle.

The third table displays average thread activity for the different resources, for example, Default, Object Request Broker, and Web container. Activity is expressed as the number of threads or connections busy and idle.

To view detailed information about the advice, select the message you want to view. This view provides additional information about the advice message, severity, description, user action, and detail.

User settings:

Change the values as needed for the following user settings:

Refresh Rate	Specifies how frequently TPV collects performance data for a server from the Performance Monitoring Infrastructure (PMI) service provided by that server. The default is 30 seconds. To collect performance data for the server more frequently, set the refresh rate to a smaller number. To collect performance data less frequently, set the refresh rate to a larger number. The allowed range is 5 to 500 seconds.
Buffer Size	Specifies the amount of data to be stored for a server. Data displayed in TPV is stored in a short in-memory buffer. After the buffer is full, each time a new entry is retrieved the oldest entry is discarded. The default buffer size is 40. Allowed values are 10, 20, 30, 40, 50, 60, 70, 80, 90 and 100. The larger the buffer size, the more memory is consumed. Thus, specify a buffer size that allows you capture enough monitoring data for analysis without wasting memory storing unneeded data.
View Data As	Specifies how counter values are displayed. Viewing options include the following: Raw Value Displays the absolute value. If the counter represents load data, for example, the average number of connections in a database pool, then TPV displays the current value. Change in Value Displays the change in the current value from the previous value. Rate of Change Displays the ratio $change / (T1 - T2)$, where <i>change</i> is the change in the current value from the previous value, <i>T1</i> is the time when the current value was retrieved, and <i>T2</i> is the time when the previous value was retrieved.

Log settings:

The log settings control what happens when **Start Logging** is clicked in, for example, a summary report on the performance of a servlet, enterprise bean (EJB), EJB method, connection pool or thread pool.

Change the value as needed for the following log settings:

Duration	Specifies the length of time, in minutes, that logging continues, unless Stop Logging is clicked first. TPV is not intended as a full-time logging solution.
-----------------	---

Maximum File Size	Specifies the maximum size, in megabytes, of a single file. Note that TPV automatically zips log files to save space and this parameter controls the pre-zipped file size and not the post-zipped, which is smaller.
Maximum Number of Historical Files	Specifies the number of files TPV writes before stopping. If TPV reaches the maximum file size before the logging duration ends, it continues logging in another file, up to the maximum. If TPV reaches the maximum number of historical files before the logging duration ends, TPV deletes the oldest historical file and continues logging in a new file. The total amount of data that is stored is constrained by the Maximum File Size and Maximum Number of Historical Files parameters.
File Name	Specifies the name of the log file. The server name and the time at which the log is started is appended to the log name to help users identify a log file.
Log Output Format	Specifies whether TPV writes log files as XML or in a binary format. Binary format is recommended as it provides a smaller log file when not compressed.

View summary reports:

Summary reports are available for each application server.

Before viewing reports, make sure data counters are enabled and monitoring levels are set properly.

The standard monitoring level enables all reports except the report on Enterprise JavaBeans (EJB) methods. To enable an EJB methods report, adjust the PMI level to include EJB method data.

Tivoli Performance Viewer provides the following summary reports for each application server:

Servlets

The servlet summary lists all servlets that are running in the current application server. Use the servlet summary view to quickly find the most time intensive servlets and the applications that use them, and to determine which servlets are invoked most often. You can sort the summary table by any of the columns.

Tips

- Sort by **Avg Response Time** to find the slowest servlet or JavaServer page (JSP).
- Sort by **Total Requests** to find the servlet or JSP used the most.
- Sort by **Total Time** to find the servlet or JSP with the highest response times.

Enterprise JavaBeans

The Enterprise JavaBeans (EJB) summary lists all enterprise beans running in the server, the amount of time spent in their methods, the number of EJB invocations, and the total time spent in each enterprise bean.

`total_time = number_of_invocations * time_in_methods`

Sort the various columns to find the most expensive enterprise bean. Also, if the PMI counters are enabled for individual EJB methods, select the check box next to the EJB name see statistics for each of the methods.

Tips

- Sort by **Avg Response Time** to find the slowest enterprise bean.
- Sort by **Method Calls** to find the enterprise bean used the most.
- Sort by **Total Time** to find the enterprise bean with the slowest response time.

EJB Methods

The EJB method summary shows statistics for each EJB method. Use the EJB method summary to find the most costly methods of your enterprise beans.

Tips

- Sort by **Avg Response Time** to find the slowest EJB method.
- Sort by **Method Calls** to find the EJB method used the most.
- Sort by **Total Time** to find the EJB method with the slowest response time.

Connection pools

The connection pool summary lists all data source connections that are defined in the application server and shows their usage over time.

Tip

- When the application is experiencing normal to heavy usage, the pools used by that application should be nearly fully utilized. Low utilization means that resources are being wasted by maintaining connections or threads that are never used. Consider the order in which work progresses through the various pools. If the resources near the end of the pipeline are under utilized, it might mean that resources near the front are constrained or that more resources than necessary are allocated near the end of the pipeline.

Thread pools

The thread pool summary shows the usage of all thread pools in the application server over time.

Tip

- When the application is experiencing normal to heavy usage, the pools used by that application should be nearly fully utilized. Low utilization means that resources are being wasted by maintaining connections or threads that are never used. Consider the order in which work progresses through the various pools. If the resources near the end of the pipeline are under utilized, it might mean that resources near the front are constrained or that more resources than necessary are allocated near the end of the pipeline.

Performance module:

View performance modules that provide graphics and charts of various performance data on system resources such as CPU utilization, on WebSphere Application Server pools and queues such as database connection pools, and on customer application data such as servlet response time. In addition to providing a viewer for performance data, TPV enables you to view data for other products or customer applications that have implemented custom PMI.

Each performance module has several counters associated with it. These counters are displayed in a table underneath the data chart or table. Selected counters are displayed in the chart or table. You can add or remove counters from the chart or table by selecting or deselecting the check box next to them. By default, the first three counters for each module are shown.

Tivoli Performance Viewer displays interactive graphics using the Scalable Vector Graphics (SVG) format or non-interactive graphics using the JPG format. The SVG format is recommended because it provides a better user experience and is more processor and memory efficient for the application server.

In the performance module, you view current activity. This is a real time operation where the state of various system resources and their usage is displayed. Unless logging is turned on, data generated in this scenario will not be saved and is unavailable for subsequent viewing and analysis. To monitor behavior and system resources, click **Start Logging**. The user can replay and analyze the file at a later time.

Start Logging/Stop Logging

Use this to start or stop logging performance data. Once you start monitoring for your server, you will be able to view real time operation in the TPV panels.

Reset to Zero

This sets a new baseline using the current counter readings at the instant the button is clicked. Future data points are plotted on the graph relative to their position at the time **Reset to Zero** is clicked. Data points gathered prior to the time **Reset to Zero** is clicked are not displayed, although they are still held in the TPV buffer. If **Undo Reset to Zero** is clicked again, TPV displays all data currently in the buffer from their original baseline, not from the **Reset to Zero** point.

View Table/View Graph

To view the data in a table, click **View Table** on the counter selection table. To toggle back to a chart, click **View Graph**.

Show Legend/Hide Legend

To view the legend for a chart, click **Show Legend**. To hide the legend, click **Hide Legend**.

Clear Buffer

To clear values from the table or chart, click **Clear Buffer** beneath the chart or table. This removes all PMI data.

Unable to view Scalable Vector Graphics on Internet Explorer: If you encounter problems while viewing SVG with your Internet Explorer browser, visit the Adobe SVG website at <http://www.adobe.com/svg/main.html> to test your Adobe SVG Viewer. You can also download the most recent version of the Adobe SVG Viewer, view the release notes, and report any bugs with the Adobe SVG Viewer from this Web site.

Viewing TPV summary reports

The Tivoli Performance Viewer (TPV) provides five different summary reports that make important data quickly and easily accessible. View summary reports to help you find performance bottlenecks in your applications and modules. The TPV summary reports are generated upon request and are not dynamically refreshed.

This article assumes that one or more applications or modules are deployed and running on one or more servers.

In order to prepare a specific summary report, you must enable the minimum level of PMI data collection, or utilize the **custom** level of monitoring and enable specific counters.

Use the administrative console to view TPV summary reports.

1. Click **Monitoring and Tuning > Performance Viewer > Current Activity > server_name > Summary Reports** in the console navigation tree.
2. Select the code artifact or pool for which you want a summary report. Expand the **Summary Reports** node of the TPV navigation tree on the left side of the Tivoli Performance Viewer page to see links for the types of summary reports. After clicking on a link for an artifact or pool, a list of artifacts or pools on the server is displayed on the right side of the page.
3. Select the artifact or pool for which you want to view a summary report.

Types of TPV Summary Reports:

Servlets

The servlet summary lists all servlets that are running in the current application server. Use the servlet summary view to quickly find the most time intensive servlets and the applications that use them, and to determine which servlets are invoked most often. You can sort the summary table by any of the columns.

Tips

- Sort by **Avg Response Time** to find the slowest servlet or JavaServer page (JSP).
- Sort by **Total Requests** to find the servlet or JSP used the most.
- Sort by **Total Time** to find the most costly servlet or JSP.

Enterprise beans

The Enterprise JavaBeans (EJB) summary lists all enterprise beans running in the server, the amount of time spent in their methods, the number of EJB invocations, and the total time spent in each enterprise bean.

```
total_time = number_of_invocations * time_in_methods
```

Sort the various columns to find the most expensive enterprise bean. Also, if the PMI counters are enabled for individual EJB methods, there is a check box next to the EJB name that you can select to see statistics for each of the methods.

Tips

- Sort by **Avg Response Time** to find the slowest enterprise bean.
- Sort by **Method Calls** to find the enterprise bean used the most.
- Sort by **Total Time** to find the most costly enterprise bean.

EJB methods

The EJB method summary shows statistics for each EJB method. Use the EJB method summary to find the most costly methods of your enterprise beans.

Tips

- Sort by **Avg Response Time** to find the slowest EJB method.
- Sort by **Method Calls** to find the EJB method used the most.
- Sort by **Total Time** to find the most costly EJB method.

Connection pools

The connection pool summary lists all data source connections that are defined in the application server and shows their usage over time.

Tip

- When the application is experiencing normal to heavy usage, the pools used by that application should be nearly fully utilized. Low utilization means that resources are being wasted by maintaining connections or threads that are never used. Consider the order in which work progresses through the various pools. If the resources near the end of the pipeline are under utilized, it might mean that resources near the front are constrained or that more resources than necessary are allocated near the end of the pipeline.

Thread Pools

The thread pool summary shows the usage of all thread pools in the application server over time.

Tip

- When the application is experiencing normal to heavy usage, the pools used by that application should be nearly fully utilized. Low utilization means that resources are being wasted by maintaining connections or threads that are never used. Consider the order in which work progresses through the various pools. If the resources near the end of the pipeline are under utilized, it might mean that resources near the front are constrained or that more resources than necessary are allocated near the end of the pipeline.

PMI levels and counters required

In order to view Tivoli Performance Viewer (TPV) summary reports, the minimum PMI level must be enabled. Otherwise, you must use the **custom** monitoring level, and enable the PMI level counters required for the specific report you want to view.

Table 64. Required properties for TPV summary reports

Summary Report	PMI level required	Custom PMI counters required
Servlets	Basic	JDBC Connection Pools.PoolSize JDBC Connection Pools.AllocateCount JDBC Connection Pools.ReturnCount
Enterprise beans	Basic	Thread Pools.PoolSize Thread Pools.ActiveCount
EJB methods	All	Enterprise Beans.MethodCallCount Enterprise Beans.MethodResponseTime
Connection pools	Extended	WSEJBStats.MethodStats.MethodLevelCallCount WSEJBStats.MethodStats.MethodLevelResponseTime
Thread pools	Extended	Web Applications.RequestCount Web Applications.ServiceTime

Related tasks

“Enabling PMI data collection” on page 2274

Enable PMI data collection to diagnose problems and tune application performance.

“Viewing TPV summary reports” on page 2334

The Tivoli Performance Viewer (TPV) provides five different summary reports that make important data quickly and easily accessible. View summary reports to help you find performance bottlenecks in your applications and modules. The TPV summary reports are generated upon request and are not dynamically refreshed.

Viewing PMI data with TPV

You can use the Tivoli Performance Viewer (TPV) to view Performance Monitoring Infrastructure (PMI) data in chart or table form.

TPV monitors the performance activity of all servers on a node. This article assumes that one or more servers have been created and are running on the node, and that PMI is enabled.

TPV displays graphics in either the Scalable Vector Graphics (SVG) format or as a static image in the JPG format. If you do not have the Adobe SVG browser plug-in installed, you are prompted to download and install it. If you select not to install the plug-in (by selecting **Cancel**), TPV displays the static image. Installing the Adobe SVG plug-in is advantageous for several reasons. First, the SVG format provides interactive graphics that provide additional information when you hover your mouse over a point, line, or legend item. The SVG format also enables you to click a point and see details for it. Secondly, using the SVG format provides a performance benefit because the work to display the SVG image is done on the client side. When viewing a static image, the application server must convert the SVG image into a static image, which is a processor and memory intensive operation.

If you experience problems with SVG, see “Problems with Scalable Vector Graphics” on page 2338 for more information.

You view performance modules when your server is experiencing performance problems. For example, a common performance problem occurs when individual sessions are too large. To help view data on a session, you can view the Servlet Session Manager PMI module and monitor the **SessionObjectSize** counter to make sure that **Session Object Size** is not too large.

Performance modules are shown in the TPV current activity settings in the administrative console.

- Select PMI data to view.
 1. Click **Monitoring and Tuning > Performance Viewer > Current Activity > server_name > Performance Modules** in the console navigation tree.
 2. Place a check mark in the check box beside the name of each performance module that you want to view. Expand the tree by clicking + next to a node and shrink it by clicking – next to a node.

If you do not see all the PMI counters you expect, or a PM you are interested in is visible but cannot be selected, PMI is not enabled for that particular counter or for any counter in that PM. Go to the PMI control area of the administrative console and enable PMI for any counters you wish to view, then return to TPV and select those PMs. To view the PMI page, click on **Monitoring and Tuning > Performance Monitoring Infrastructure > server_name**.
 3. Click on **View Modules**. A chart or table providing the requested data is displayed on the right side of the page. Charts are displayed by default.

Each module has several counters associated with it. These counters are displayed in a table underneath the data chart or table. Selected counters are displayed in the chart or table. You can add or remove counters from the chart or table by selecting or deselecting individual counters. By default, the first three counters for each module are shown.

You can select up to 20 counters and display them in the TPV in the **Current Activity** mode. The data from all the PMI counters that are currently enabled in each PM for all active instances of the PM can be recorded and captured in a TPV log file. Refer to “Logging performance data with TPV” on page 2338 for more information on the TPV log file. You can view the TPV log file for a particular time period multiple times, selecting different combinations of up to 20 counters each time. You have the flexibility to observe the relationships among different performance data in a server during a particular period of time.
 4. **Optional:** To remove a module from a chart or table, deselect the check box next to the module and click **View Modules** again.
 5. **Optional:** To view the data in a table, click **View Table** on the counter selection table. To toggle back to a chart, click **View Graph**.
 6. **Optional:** To view the legend for a chart, click **Show Legend**. To hide the legend, click **Hide Legend**.
- Scale the PMI data. You can manually adjust the scale for each counter so that the graph displays meaningful comparisons of different counters.
 1. Find the counter whose scale you want to modify in the table beneath the chart.
 2. Change the value for **Scale** as needed. **Tips:**
 - When the scale is set to 1 the true value of the counter is displayed in the graph.
 - A value greater than 1 indicates that the value is amplified by the factor shown.
 - A value less than 1 indicates that the variable is decreased by the factor shown.

For example, a scale setting of .5 means that the counter is graphed as one-half its actual value. A scale setting of 2 means that the counter is graphed as twice its actual value. Scaling only applies to the graphed values and has no effect on the data displayed when viewing it in table form.
 3. Click **Update**.
- Clear values from tables and charts.
 1. Ensure that one or more modules are selected under **Performance Modules** in the TPV navigation tree
 2. Click **Clear Buffer** beneath the chart or table. The PMI data is removed from a table or chart.
- Reset counters to zero (0).
 1. Ensure that one or more modules are selected under **Performance Modules** in the TPV navigation tree
 2. Click **Reset to Zero** beneath the chart or table. **Reset to Zero** sets a new baseline using the current counter readings at the instant the button is clicked. Future datapoints are plotted on the graph relative to their position at the time **Reset to Zero** is clicked. Datapoints gathered prior to the

time **Reset to Zero** is clicked are not displayed, although they are still held in the TPV buffer. If **Undo Reset to Zero** is clicked again, TPV displays all data recorded from the original baseline, not from the **Reset to Zero** point.

For information on how TPV displays the data, see “Configuring TPV settings” on page 2328.

Problems with Scalable Vector Graphics:

Consult this topic for problems and solutions for Scalable Vector Graphics.

Using TPV without Scalable Vector Graphics (SVG)

When viewing performance data in Tivoli Performance Viewer (TPV) on a browser that does not support Scalable Vector Graphics (SVG) graphics, either using the Adobe SVG plug-in or through native support, complex graphs might take a long time to refresh. Eventually an out of memory error may occur.

When TPV detects a browser that does not support SVG, it uses Apache Batik to transcode the SVG into a binary image format. The transcoding process is highly memory intensive. The complexity of the graph is affected by two things: the TPV buffer size, which dictates how many points are in each line that is drawn, and the number of selected data points, which dictates how many lines are drawn.

To avoid long refresh times or the out of memory errors, use a browser that supports SVG, either with a plug-in, like the Adobe SVG plug-in, or natively, which is included in some Mozilla builds. If this is not possible, keep the graph simple by limiting the size of the buffer and the number of selected data points.

Unable to view Scalable Vector Graphics on Internet Explorer

If you encounter problems while viewing SVG with your Internet Explorer browser, visit the Adobe SVG Zone Web site at <http://www.adobe.com/svg/main.html> to test your Adobe SVG Viewer. You can also download the most recent version of the Adobe SVG Viewer, view the release notes, and report any bugs with the Adobe SVG Viewer from this Web site.

Logging performance data with TPV

The Tivoli Performance Viewer (TPV) provides an easy way to store real-time data for system resources, WebSphere Application Server pools and queues, and applications in log files for later retrieval. You can start and stop logging while viewing current activity for a server, and later replay this data. Logging of performance data captures performance data in windows of time so you can later analyze the data.

This article assumes that one or more servers have been created and are running on the node, and that you have configured the TPV log settings. The log settings may affect performance and are described in detail in “Viewing Data with the Tivoli Performance Viewer” on page 2330. The TPV logging feature is not intended to be a full-time monitoring solution, but instead for selective data recording for subsequent replay and analysis.

You can study the sequence of events that led to a peculiar condition in the application server or node agent. First, enable TPV logging so performance data generated in the application server persists in a log file stored at a specific location. Later, using the replay feature in TPV, view the performance data that was generated in exactly the same chronological order as it was generated in real time, enabling you to analyze a prior sequence of events.

You do not need to know the syntax and format in which log files are generated and stored. Do not edit log files generated by TPV; doing so will irrecoverably corrupt or destroy the performance data stored in the log files.

If monitoring for the node agent is enabled, the log file includes system data from the node agent so that data is available when you replay the log. If monitoring for the node agent is disabled, then that data is not available. By default, TPV starts monitoring the node agent whenever monitoring starts on a server in the node.

You can create and view logs in the administrative console.

- Create logs.
 1. Click **Monitoring and Tuning > Performance Viewer > Current Activity > *server_name* > Settings > Log** in the console navigation tree. To see the **Log** link on the Tivoli Performance Viewer page, expand the **Settings** node of the TPV navigation tree on the left side of the page. After clicking **Log**, the TPV log settings are displayed on the right side of the page.
 2. Click on **Start Logging** when viewing summary reports or performance modules.
 3. When finished, click **Stop Logging**. Once started, logging stops when the logging duration expires, **Stop Logging** is clicked, or the file size and number limits are reached. To adjust the settings, see step 1.

By default, the log files are stored in the *profile_root/logs/tpv* directory on the node on which the server is running. TPV automatically compresses the log file when it finishes writing to it to conserve space. At this point, there must only be a single log file in each .zip file and it must have the same name as the .zip file.

- View logs.
 1. Click **Monitoring and Tuning > Performance Viewer > View Logs** in the console navigation tree.
 2. Select a log file to view using either of the following options:
 - Explicit Path to Log File**
Choose a log file from the machine on which the browser is currently running. Use this option if you have created a log file and transferred it to your system. Click **Browse** to open a file browser on the local machine and select the log file to upload.
 - Server File**
Specify the path of a log file on the server.

In a stand-alone application server environment, type in the path to the log file. The *profile_root\logs\tpv* directory is the default on a Windows system.

In a deployment manager environment, click the **Browse** button next to the input to browse the various nodes and find the log file to view.
 3. Click **View Log**. The log is displayed with log control buttons at the top of the view.
 4. Adjust the log view as needed. Buttons available for log view adjustment are described below. By default, the data replays at the **Refresh Rate** specified in the user settings. You can choose one of the **Fast Forward** modes to play data at rate faster than the refresh rate.

Rewind	Returns to the beginning of the log file.
Stop	Stops the log at its current location.
Play	Begins playing the log from its current location.
Fast Forward	Loads the next data point every three (3) seconds.
Fast Forward 2	Loads ten data points every three (3) seconds.

You can view multiple logs at a time. After a log has been loaded, return to the View Logs panel to see a list of available logs. At this point, you can load another log.

TPV automatically compresses the log file when finishes writing it. The log does not need to be decompressed before viewing it, though TPV can view logs that have been decompressed.

Viewing Data Recorded by the TPV

Use this page to view logged data from Tivoli Performance Viewer.

To view this administrative console page, click **Monitoring and Tuning > Performance Viewer > View logs**.

Explicit path to log file:

Select explicit path to a log file, specify the path name, and click **View log** to display the stored data.

Server file:

Select server file, specify the path name, and click **View log** to display the stored data.

Capturing a RMF workload activity report

Using the Workload Activity Reports, you can observe the measurements in the service and reporting classes.

For more information on RMF workload activity reports and the RMF Monitor III refer to the article “RMF Workload Activity reports and RMF Monitor III.”

The following RMF1 job reads the data from RMF data buffers.

1. Run the RMF Monitor 1 post processor as a batch job which can read the RMF data buffers from memory and produce a report.

The sample job that follows will run the RMF Monitor 1 post processor (You will need to change the time and date parameters.)

```
//RMF1JOB JOB 1,CLASS=A
//RMFPP EXEC PGM=ERBRMFPP,REGION=0M
//MFPMMSGDS DD SYSOUT=*
//SYSIN DD *
SYSOUT(0)
NOSUMMARY
SYSRPTS(WLMGL(SCPER(WSHIGH,WSMED,WSLOW,SYSSTC,OPS_DEF)))
DATE(04172003,04172003) /* <== SET TO MEAS. DATE MMDDYYYY */
RTOD(1430,1500) /* <== SET TO MEAS. TIME OF DAY HHMM*/
DINTV(0002)
/*
//
```

This will take the raw SMF data, in this case the MANE data, and produce the workload activity report as an H output class in SDSF.

2. Using the Workload Activity Reports, observe the measurements in the service and reporting classes. After your measurement run is over, you should reset the SMF parameters to their standard settings with the SET SMF=xx command.

RMF Workload Activity reports and RMF Monitor III

Performance metrics include transaction rates and response times. Resource utilization includes CPU, I/O (channel), and storage utilization.

Transactions/second

This is shown in the AVG, MPL, and AVG ENC fields which is equal to the average number of enclaves in the period in the RMF Monitor I report below.

Response times

The actual response times of the WLM transaction is shown in the TRANS.-TIME SS.TTT' column in the RMF Monitor I report below and are measured in milliseconds. (This also includes time waiting on WLM queue.)

Service Rates

Resource utilization in CPU service units, and Service Units per Sec. The APPL% field shows the number of processor engines (CPs) required to drive the work in the service (report) class.

Controller Regions Example: Here is the report for the WebSphere controller regions which were all assigned a particular reporting class according to the STC classification rules based on the started class jobname. There is only one transaction active in the system, there are no response time figures, and required 37.2% of a processor engine to support its work.

TRANSACTIONS	TRANS.-TIME	SS.TTT	---SERVICE--		--SERVICE RATES--	
AVG 1.00	ACTUAL	0	IOC	0	ABSRPTN	89615
MPL 1.00	EXECUTION	0	CPU	522567	TRX SERV	89615
ENDED 0	QUEUED	0	MSO	10159K	TCB	39.9
END/S 0.00	R/S AFFINITY	0	SRB	61728	SRB	4.7
#SWAPS 0	INELIGIBLE	0	TOT	10743K	RCT	0.0
EXCTD 0	CONVERSION	0	/SEC	89630	IIT	0.0
AVG ENC 0.00	STD DEV	0			HST	0.0
REM ENC 0.00					APPL %	37.2

Servant Regions Example: Here is the report for the WebSphere servant regions which were all assigned a particular reporting class according to the STC classification rules based on the started class jobname. There are only two transactions active in the system (meaning there were two servant regions), there are no response time figures, and they required 10% of a processor engine to support their work.

TRANSACTIONS	TRANS.-TIME	SS.TTT	---SERVICE--		--SERVICE RATES--	
AVG 2.00	ACTUAL	0	IOC	0	ABSRPTN	122075
MPL 2.00	EXECUTION	0	CPU	143957	TRX SERV	122075

WebSphere Transactions (Enclaves) Example: Here is the report for the real WebSphere transaction work which runs as enclaves in this particular reporting class. The average number of these kind of transactions active in the system was 241.52, the average response time was 276 milliseconds, and required 2.129 processor engines to support this work.

TRANSACTIONS	TRANS.-TIME	SS.TTT	---SERVICE--		--SERVICE RATES--

Delays Example: The QMPL field in the following report means that the server was waiting for a Server Region to select work off the WLM queue. Here is a queue delay report which shows that work was delayed 23.5% of the time waiting for the CPU and 12.6% of the time waiting for a servant region:

EX	PERF	AVG	--USING%--		----- EXECUTION DELAYS % -----		
GOAL	VEL	INDX	ADRSP	CPU	I/O	TOTAL	CPU QMPL
40.0%							
ACTUALS	45.3%	.89	13.4	0.1	0.0	36.1	23.5 12.6

Started Class Classification Example: Here is an example of the STC classification rules/panel in WLM which can be used to classify the non-enclave time in the websphere server regions. WebSphere production controller region with a jobname of WSPRODC is assigned a service class of STCCR and reporting class of RCTLREG, production controller region with a jobname of WSPRODC is assigned a service class of STCSR and reporting class of RSRVREG, and testregions (servant and controllers) with a jobname starting with WSTare assigned a service class of STCWSTST and reporting class of RWSTST.

```

Subsystem Type . . . . . : STC
Description . . . . . : All started tasks
-----Qualifier-----
Type      Name      Start
Type      Name      Start
                                DEFAULTS: STCMED  RSTCMED_
1  TNG      WSPRODC  ___      STCCR    RCTLREG_
1  TNG      WSPRODS  ___      STCSR    RSRVREG_
1  TNG      WST*     ___      STCWSTST RWSTST_

```

Third-party performance monitoring and management solutions

Several performance monitoring, problem determination, and management solutions are available that can be used with WebSphere Application Server.

These products use WebSphere Application Server interfaces, including:

- Performance Monitoring Infrastructure (PMI)
- Java Management Extensions (JMX)

See the topic “Performance: Resources for learning” on page 2157 for a link to IBM business partners providing monitoring solutions for WebSphere Application Server.

WLM Delay Monitoring

WebSphere Application Server for z/OS Version 5 uses Workload Manager (WLM) services to report transaction begin-to-end response times and execution delay times.

The WLM data collected by Resource Measurement Facility (RMF) is captured in two phases of the RMF report:

- BTE - the begin-to-end phase applies to requests handled by the controller
- EXE - the execution phase applies to requests handled by the servant

You can use this status information to determine where possible performance bottlenecks are occurring. This feature is available on z/OS V1R2 and above with WLM APAR OW51848 and RMF APAR OW52227.

For details on workload management, see *z/OS MVS Planning: Workload Management*. For details on WLM delay monitoring, refer to *z/OS MVS Programming: Workload Management Services*. Both are available on the z/OS Internet Library Web site.

When a new transaction enters the system, the WebSphere Application Server for z/OS application control region (ACR) starts the classify service. Delays associated with the WebSphere Application Server for z/OS ACR service class are counted separately for the BTE phase and the EXE phase. This support allows WLM to associate a performance block (PB) with an enclave to record delays that occur in the flow of a transaction. The state samples are collected on an ongoing basis and reported as a percentage of average transaction response time. The following table shows the states, their codes, the section of the RMF report where each is reported, the meaning, and suggested response. You can use this information in the RMF report to determine where some of your system’s performance problems may be occurring.

Table 65. WLM delay monitoring states

State	Code	Report	Meaning	Response
ACTIVE	ACTIVE SUB	Both BTE and EXE	WebSphere is actively processing request	
ACTIVE_APPLIC	ACTIVE APPL	Both BTE and EXE	Application is running	Use application monitoring tool to determine the cause of the delay.

Table 65. WLM delay monitoring states (continued)

WAITING TYPE1	TYP1	EXE	EJB collaborator delay	
WAITING TYPE2	TYP2	EXE	Resource manager delay	Call a J2C connector to resource managers such as DB2, IMS, and CICS. Investigate the other resource manager using their monitoring tools.
WAITING TYPE3	TYP3	EXE	Servant called to a different distributed object server using RMI/IIOP	<ol style="list-style-type: none"> 1. Investigate the delay on the other server. The delay might point to session caches. 2. Look for any network problems. 3. Avoid outbound calls.
WAITING TYPE 4	TYP4	BTE	OTS call to RRS. Occurs only in controller when controller is trying to commit a distributed transaction.	<ol style="list-style-type: none"> 1. Investigate the delay on the other server. 2. Look for any network problems. 3. Consider combining application into one server to avoid delay.
WAITING REGIST TO WORKTABLE	WORK	BTE	An indication of contention within the controller while trying to process concurrent requests.	If delay is excessive, consider adding another controller and splitting work off to it.
WAITING OTHER_PRODUCT	OTHER	BTE	Indicates a configuration problem in DNS or TCP/IP	Check to make sure all the DNS servers are running. You might want to look at OPING or ONSLOOKUP.
WAITING DISTRIB	DIST	BTE	Controller as a client went outbound waiting for a response.	<ol style="list-style-type: none"> 1. Investigate the delay on the other server. 2. Look for any network problems. 3. Consider combining application into one server to avoid delay.
WAITING SESS_NETWORK	REMT	BTE	Time spent waiting for a TCP/IP session to be established on the network.	The two session delays should be observable in conjunction with TYP3 delays. Look at TCP/IP configuration.
WAITING SESS_SYSPLEX	SYSP	BTE	Time spent waiting for a TCP/IP session to be established on the sysplex.	The two session delays should be observable in conjunction with TYP3 delays. Look at TCP/IP configuration.
WAITING REGULAR_THREAD	REGT	BTE	Waiting for a thread in the controller. Work is bottlenecked in the controller because it is receiving more requests than it can process.	Split the controller.

Table 65. WLM delay monitoring states (continued)

WAITING SSL_THREAD	SSLT	BTE	Waiting for an SSL thread in the controller. Work is bottlenecked in the controller because it is receiving more requests for SSL handshakes than it can process.	Split controller to increase SSL threads. 1. Increase SSL threads. 2. Look at SSL configuration. 3. Split the controller to increase SSL threads.
WAITING SESS_LOCALMVS	LOCL	BTE	Time spent communicating with a different distributed object server using local optimized communication.	1. Investigate the delay on the other server. 2. Avoid outbound calls.

RMF report examples

The Workload Manager data collected by Resource Measurement Facility (RMF) is captured and displayed in a report.

This section includes several examples of RMF reports with WLM delay monitoring information.

Performance and accounting information for WebSphere Application Server for z/OS

WebSphere Application Server for z/OS relies on WLM services to collect some of the accounting and performance data.

Resource Measurement Facility (RMF) and RMF-written System Management Facility (SMF) records present performance and accounting information to the WebSphere Application Server. In addition, the WebSphere Application Server for z/OS has SMF records that collect additional domain-specific information.

Turn off the SMF records or RMF data using the administrative console and the SMFPRMxx parmlib member if you do not need the information. Use the SMFPRMxx parmlib member to control the detail of the WebSphere Application Server for z/OS SMF records. If you need SMF information, review the SMF records to ensure you are collecting only the record types and details that you need.

Setting up your workload manager goals and filtering criteria is beyond the scope of this section. You can classify work into service classes based on user ID and server name. Classify the control regions as reasonably high-performing system tasks.

Chapter 25. Monitoring application flow

Monitoring, optimizing, and troubleshooting WebSphere Application Server performance can be a challenge. This article gives you a basic strategy for monitoring with an understanding of the application view.

This information includes understanding the application flow that satisfies the end user request. This perspective provides the views of specific servlets that access specific session beans, entity container-managed persistence beans, and a specific database. This perspective is important for the in-depth internal understanding of who is using specific resources. Typically at this stage, you deploy some type of trace through the application, or thread analysis under load condition techniques to isolate areas of the application and particular interactions with the back-end systems that are especially slow under load. In this case, WebSphere Application Server provides request metrics to help trace each individual transaction as it flows through the application server, recording the response time at different stages of the transaction flow (for example, request metrics records the response times for the Web server, the Web container, the Enterprise JavaBeans container, and the back-end database). In addition, several IBM development and monitoring tools that are based on the request metrics technology (for example, Tivoli Monitoring for Transaction Performance) are available to help view the transaction flow.

Why use request metrics?

Request metrics is a tool that enables you to track individual transactions, recording the processing time in each of the major WebSphere Application Server components.

The information that is tracked by request metrics might either be saved to log files for later retrieval and analysis, be sent to Application Response Measurement (ARM) agents, or both.

As a transaction flows through the system, request metrics includes additional information so that the log records from each component can be correlated, building up a complete picture of that transaction. The result looks similar to the following example:

```
HTTP request/trade/scenario -----> 172 ms
Servlet/trade/scenario -----> 130 ms
  EJB TradeEJB.getAccountData -----> 38 ms
    JDBC select -----> 7 ms
```

This transaction flow with associated response times can help you target performance problem areas and debug resource constraint problems. For example, the flow can help determine if a transaction spends most of its time in the Web server plug-in, the Web container, the Enterprise JavaBeans (EJB) container or the back end database. The response time that is collected for each level includes the time spent at that level and the time spent in the lower levels. For example, the response time for the servlet, which is 130

milliseconds, also includes 38 milliseconds from the enterprise beans and Java Database Connectivity. Therefore, 92 ms can be attributed to the servlet process.

Request metrics tracks the response time for a particular transaction. Because request metrics tracks individual transactions, using it imposes some performance implications on the system. However, this function can be mitigated by the use of the request filtering capabilities.

For example, tools can inject synthetic transactions. Request metrics can then track the response time within the WebSphere Application Server environment for those transactions. A synthetic transaction is one that is injected into the system by administrators to take a proactive approach to testing the performance of the system. This information helps administrators tune the performance of the Web site and take corrective actions. Therefore, the information that is provided by request metrics might be used as an alert mechanism to detect when the performance of a particular request type goes beyond acceptable thresholds. The filtering mechanism within request metrics might be used to focus on the specific synthetic transactions and can help optimize performance in this scenario.

When you have the isolated problem areas, use request metrics filtering mechanism to focus specifically on those areas. For example, when you have an isolated problem in a particular servlet or EJB method, use the uniform resource identifier (URI) algorithms or EJB filter to enable the instrumentation only for the servlet or EJB method. This filtering mechanism supports a more focused performance analysis.

Five types of filters are supported:

- Source IP filter
- URI filter
- EJB method name filter
- JMS parameters filter
- Web services parameters filter

When filtering is enabled, only requests that match the filter generate request metrics data, create log records, call the ARM interfaces, or all. You can inject the work into a running system (specifically to generate trace information) to evaluate the performance of specific types of requests in the context of a normal load, ignoring requests from other sources that might be hitting the system.

Note: Filters are only applicable where the request first enters WebSphere Application Server.

- Learn more about request metrics by reviewing detailed explanations in this section.
- Configure and enable request metrics.
- Retrieve performance data and monitor application flow.
- Extend monitoring to track applications that might require additional instrumentation points.

Example: Using request metrics

Use this page to learn how to use request metrics by viewing an example.

In this example, the HitCount servlet and the Increment enterprise bean are deployed on two different application server processes. As shown in the following diagram, the Web container tier and Enterprise JavaBeans (EJB) container tiers are running in two different application servers. To set up such a configuration, install WebSphere Application Server Network Deployment.

Assume that the Web server and the Web container tier both run on machine 192.168.0.1, and the Enterprise JavaBeans (EJB) container tier runs on a second machine 192.168.0.2. The client requests might be sent from a different machine; 192.168.0.3, for example, or other machines.

To illustrate the use of source IP filtering, one source IP filter (192.168.0.3) is defined and enabled. You can trace requests that originate from machine 192.168.0.3 through `http://192.168.0.1/hitcount?selection=EJB&lookup=GBL&trans=CMT`. However, requests that originate from any other machines are not traced because the source IP address is not in the filter list.

By only creating a source IP filter, any requests from that source IP address are effectively traced. This tool is effective for locating performance problems with systems under load. If the normal load originates from other IP addresses, then its requests are not traced. By using the defined source IP address to generate requests, you can see performance bottlenecks at the various hops by comparing the trace records of the loaded system to trace records from a non-loaded run. This ability helps focus tuning efforts to the correct node and process within a complex deployment environment.

Make sure that request metrics is enabled using the administrative console. Also, make sure that the trace level is set to at least hops (writing request traces at process boundaries). Using the configuration previously listed, send a request `http://192.168.0.1/hitcount?selection=EJB&lookup=GBL&trans=CMT` through the HitCount servlet from machine 192.168.0.3.

In this example, at least three trace records are generated:

- A trace record for the Web server plug-in is displayed in the plug-in log file (default location is `plugins_root/logs/web_server_name/http_plugin.log`) on machine 192.168.0.1.
- A trace record for the servlet displays in the application server log file (default location is `profile_root/logs/appserver/SystemOut.log`) on machine 192.168.0.1.
- A trace record for the increment bean method invocation displays in the application server log file (default location is `profile_root/logs/appserver/SystemOut.log`) on machine 192.168.0.2.

The two trace records that are displayed on machine 192.168.0.1 are similar to the following example:

```
PLUGIN:
parent:ver=1,ip=192.168.0.1,time=1016556185102,pid=796,reqid=40,event=0
- current:ver=1,ip=192.168.0.1,time=1016556185102,pid=796,reqid=40,event=1
type=HTTP detail=/hitcount elapsed=90 bytesIn=0 bytesOut=2252

Application server (web container tier)
PMRM0003I: parent:ver=1,ip=192.168.0.1,time=1016556185102,pid=796,reqid=40,event=0
- current:ver=1,ip=192.168.0.1,time=1016556186102,pid=884,reqid=40,event=1
type=URI detail=/hitcount elapsed=60
```

The trace record that is displayed on machine 192.168.0.2 is similar to the following example:

```
PMRM0003I:
parent:ver=1,ip=192.168.0.1,time=1016556186102,pid=884,reqid=40,event=1
-
current:ver=1,ip=192.168.0.2,time=1016556190505,pid=9321,reqid=40,event=1
type=EJB
detail=com.ibm.defaultapplication.Increment.increment elapsed=40
```

Data you can collect with request metrics

Typically, different components of the enterprise application might be hosted across several nodes in a distributed system. For example, the servlets might be hosted on one node, while the enterprise beans on which these servlets depend might be hosted on an entirely different node. When a request comes to a process, the process might send the request to one or more downstream processes, as shown in the following figure:

Trace records might be generated for each process with associated elapsed times for that process. These trace records might be correlated together to build a complete picture of the request flow through the distributed system, similar to the diagram in “Why use request metrics?” on page 2347.

You can view the process response time that is monitored by request metrics through the Application Response Measurement (ARM) interface and system log files. When a request is sent to the application server, request metrics captures response times for the initiating request and any related downstream invocations. Request metrics are instrumented in the following components as the request, for example, transaction, travels through the Web server, Proxy Server and the application server:

- the Web server plug-in which is only available when using the Web server port.
- the Proxy Server, instrumented as servlet and Web services requests.
- the Web container, including servlet and servlet filters.
- the Enterprise JavaBeans (EJB) container.
- Java DataBase Connectivity (JDBC) calls.
- J2EE Connector Architecture (JCA).
- Web services, both on the server and the client side.
- the Java Message Service (JMS) engine.
- Service Integration Bus (SIB).
- Portlet container, including the portlet requests.
- Asynchronous Beans.

Select which components that you want to instrument. For example, if you want instrumentation data only for the Web container and the JMS API, select this data in the administrative console and the detailed instrumentation data is generated only for the components that you select. The edge transactions are traced for the other components that are not specified for instrumentation.

When filtering is enabled, only requests that match the filter generate request metrics data, create log records, or call the ARM interfaces. You can add work into a running system specifically to generate trace information to evaluate the performance of specific types of requests in the context of normal load, ignoring requests from other sources that might affect the system. If the request matches any filter with a trace level greater than None, trace records are generated for that request.

Getting performance data from request metrics

This topic describes how to enable request metrics.

Request metrics is a tool that enables you to track individual transactions, recording the processing time in each of the major WebSphere Application Server components.

You can enable request metrics from the following locations:

- The administrative console. To enable request metrics in the administrative console, refer to the instructions under the Steps for this task section that follows.
- Command line. Java Management Extensions (JMX) interfaces are exposed for enabling request metrics through external tools. For more details on the exposed interfaces, refer to the request metrics API documentation.

To enable request metrics in the administrative console:

1. Open the administrative console.
2. Click **Monitoring and Tuning** > **Request metrics** in the console navigation tree.
3. Verify that **Prepare servers for request metrics collection** check box is selected. If **Prepare servers for request metrics collection** check box is not selected, you will have to select it, save the change, and restart the server.
4. Select All, None, or Custom under **Components to be instrumented** to specify the request metrics components. If you select **Custom**, be sure to select the components you would like to enable.
5. Specify the components that are instrumented by request metrics.
6. Specify how much data to collect.
7. Enable and disable logging.
8. Enable Application Response Measurement (ARM) Agent.
9. Specify which ARM type to use.
10. Specify the name of the ARM transaction factory implementation class.
11. Isolate performance for specific types of requests.
 - a. Add and remove request metrics filters.
12. Click **Apply** or **OK**.
13. Click **Save**.

The request metrics is enabled.

To ensure that the Web server plug-in recognizes the changes you made for the request metrics configuration, follow the steps in “Regenerating the Web server plug-in configuration file” on page 2364, if logging time spent in the Web server.

Request metrics

Use this page to enable request metrics, select the components that are instrumented by request metrics, set trace levels, enable standard logs, enable Application Response Measurement (ARM), specify the type of ARM agent, and specify the ARM transaction factory implementation class name.

To view this administrative console page, click **Monitoring and Tuning** > **Request metrics**.

Prepare Servers for request metrics collection

Turns on the request metrics feature.

When unchecked, the request metrics function is disabled. To enable request metrics, check the box, save the change, and restart the server. When it is checked, the server is ready to enable request metrics and

you will not need to restart the server. Depending on what option is selected under **Components to be instrumented**, request metrics instrumentation will be enabled/disabled in various components.

Note: This selection process differs from the **Enable Request Metrics** check box in WebSphere Application Server Version 6.0x. You now have the option of selecting All, None, or Custom. If you select **Custom**, you must specify which components you would like to enable.

Components to be instrumented

Selects the components that are instrumented by request metrics.

When **None** is selected, no request metrics instrumentation will be enabled. When **All** is selected, request metrics instrumentation will be enabled in all the components listed under **Custom**. When **Custom** is selected, request metrics instrumentation will be enabled in the selected components.

Note: An edge transaction, which is defined as the first transaction that enters the application server without a parent correlator, will always be instrumented even if the corresponding component is disabled for instrumentation.

Trace level

Specifies how much trace data to accumulate for a given transaction. Note that **Trace level** and **Components to be instrumented** work together to control whether or not a request will be instrumented.

Including one of the following values:

None No instrumentation.

Hops Generates instrumentation information on process boundaries only (for example, at the entry and exit points for the Web container).

Generates instrumentation information on process boundaries only (for example, a servlet request coming from a browser or a Web server and a JDBC request going to a database).

Performance_debug

Generates one additional level of instrumentation data, whereas debug generates detailed instrumentation data.

Generates the data at Hops level and the first level of the intra-process servlet and Enterprise JavaBeans (EJB) call (for example, when an inbound servlet forwards to a servlet and an inbound EJB calls another EJB). Other intra-process calls like naming and service integration bus (SIB) are not enabled at this level.

Debug

Provides detailed instrumentation data, including response times for all intra-process servlet and Enterprise JavaBeans (EJB) calls.

Provides detailed instrumentation data, including response times for all intra-process calls.

Note: Requests to servlet filters will only be instrumented at this level.

Standard logs

Enables the request metrics logging feature.

Select this check box to trigger the generation of request metrics logs in the SystemOut.log file.

Note: Since enabling the request metrics logging feature will increase processor usage, it is recommended using this feature together with filters so that only selected requests are instrumented.

Application Response Measurement (ARM) agent

Enables request metrics to call an underlying Application Response Measurement (ARM) agent.

Before enabling ARM, you need to install an ARM agent and configure it to the appropriate classpath and path, following the instructions of the ARM provider.

Specify ARM agent

Specifies the type of ARM agent that you want to use.

The ARM 4.0 agent and Tivoli ARM 2.0 agent are supported.

ARM transaction factory implementation class name

Specifies the ARM transaction factory implementation class name in the package that is supplied by your provider. This field is required when ARM 4.0 agent is selected, but it is not required when Tivoli ARM agent is selected.

In this field, type the name of the ARM transaction factory implementation class that is present in the ARM library. Be sure to follow the instructions of the ARM provider and understand the name of the ARM transaction factory class for the installed ARM agent.

Filters

When filtering is enabled, only requests matching the specified filter will generate request metrics data. Filters exist for source IP address, URI name, EJB method name, JMS parameters, and the WebServices parameters.

Application Response Measurement

Request metrics information might be either saved to the log file for later retrieval and analysis, be sent to Application Response Measurement (ARM) agents, or both. Request metrics provides response time for each of the major WebSphere Application Server components through ARM APIs.

ARM is an Open Group standard. Request metrics helps you to plug in an ARM agent to collect response time measurements.

WebSphere Application Server does not ship an ARM agent. However, it supports the use of agents adhering to ARM 4.0 and ARM 2.0 standards.

You can choose your own ARM implementation providers to obtain the ARM implementation libraries. Follow the instruction from the ARM provider, and ensure that the ARM API Java archive (JAR) files found in the ARM provider are on the class path so that the WebSphere Application Server can load the needed classes. In the case of Tivoli Monitoring Transaction Performance, V5.3, copy the `armjni.jar` and `core_util.jar` files from the Tivoli Monitoring Transaction Performance `<tntp_install_root>/lib` installation root directory to the `app_server_root/lib` directory, which is the WebSphere Application Server installation root directory. If the underlying ARM implementation is ARM 4.0, you need to specify the ARM transaction factory class name. Otherwise, this specification is not required.

See the article “Performance: Resources for learning” on page 2157 for more information about the ARM specifications.

ARM application properties and transaction context data

Request metrics provides build-in instrumentation to monitor transaction flows. The data that is collected by request metrics can be sent to a supported Application Response Measurement (ARM) agent.

ARM application properties

The following tables show the ARM application properties when request metrics initializes an ARM 4.0 agent.

Identity property names	Value
-------------------------	-------

Cell Name	The cell name that the server belongs to.
Version	The version of WebSphere Application Server.

Application Properties	Value
Registered application name	WebSphere:<server_type> The <server_type> can be APPLICATION_SERVER, ONDEMAND_ROUTER, or PROXY_SERVER.
Application group	<server_name>
Application instance	<node_name>.<server_name>

The following code sample displays how WebSphere Application Server creates an ARM application.

```
String serverType; // the server type like APPLICATION_SERVER
String version; // WebSphere version
String sCellName; // the cell name of dMgr
String sAppInstance. // <short_node_name>.<short_server_name>
String sServerInstance; // short server name
String sWasName = "WebSphere:" + serverType;
String[] IDNAMES = new String[]{"Cell Name", "Version"};
ArmIdentityProperties appIdentity = txFactory.newArmIdentityProperties(IDNAMES, new String[]{sCellName,
version}, null);
ArmApplicationDefinition appDef = txFactory.newArmApplicationDefinition( sWasName, appIdentity, null );
ArmApplication app = txFactory.newArmApplication(appDef, sServerInstance, sAppInstance, null );
```

ARM transaction types

You can use the following code sample to create an instance of ARM transaction.

```
String[] contextNames; // the names for the context data like Port, QueryString, URI, EJBName
String tranIdentityName; // the transaction types shown in the following table like URI, EJB.
String appDef; // defined and created in above code snippet under ARM application properties
String app; // defined and created in above code snippet under ARM application properties
ArmIdentityPropertiesTransaction props = armFactory.newArmIdentityPropertiesTransaction( null, null,
contextNames, null );
ArmTransactionDefinition atd = armFactory.newArmTransactionDefinition(appDef, identityName, props, (ArmID)null);
ArmTransaction at = txFactory.newArmTransaction(app, atd );
```

The sections below show all ARM transaction types and their corresponding context names. Some types of transactions are not instrumented unless the trace level is set to DEBUG. In addition, not every transaction is available in all types of servers. All transaction types and context names are case sensitive.

- “Uniform resource identifier (URI)” on page 2355
- “Enterprise Java Bean (EJB)” on page 2355
- “Servlet filter” on page 2355
- “Java Database Connectivity (JDBC)” on page 2356
- “Java Connector Architecture (JCA)” on page 2356
- “Web Services Provider” on page 2356
- “Web Services Requestor” on page 2357
- “Java Message Service (JMS)” on page 2357
- “JMS send and receive” on page 2358
- “SIB send and receive” on page 2358
- “SIB mediation” on page 2358
- “AsyncBeans” on page 2359
- “JNDI” on page 2359

- “Portlet” on page 2359

Uniform resource identifier (URI)

This transaction type is the uniform resource identifier (URI) for servlet and JavaServer Page (JSP) requests. All of the following transaction types and context names are available in all types of servers.

Transaction type: URI	
Context name	Description
Port	The TCP/IP port where the request arrived, specified as a string representation of the decimal value. Example: 9080
QueryString	The portion of the dynamic URI that contains the search parameters of the request in the query segment of the URI string, excluding the question mark (?) character. Example: selection=EJB&lookup=GBL&trans=CMT
URI	The incoming request URI of the servlet and JSP file used. Example: /hitcount

Enterprise Java Bean (EJB)

This EJB transaction type and context names are only available in application servers.

Transaction Type: EJB	
Context name	Description
EJBName	The fully qualified Enterprise Java™ Bean (EJB) class name, followed by method name with a period (.) to connect them. For example, com.mypackge.MyEJBClass.mymethod. Example: com.ibm.defaultapplication.IncrementBean.create
ApplicationName	The Java™ 2 Platform, Enterprise Edition (J2EE) application name that contains the enterprise bean. Example: DefaultApplication
ModuleName	The J2EE module name that contains the enterprise bean. Example: Increment.jar

Servlet filter

The servlet filter transaction type is only available at the DEBUG trace level. For other levels, servlet filters are not instrumented. This transaction type and context names are only available in application servers.

Transaction Type: Servlet filter	
Context name	Description

Transaction Type: Servlet filter	
FilterName	The servlet filter name for the servlet. Example: ALoginFilter

Java Database Connectivity (JDBC)

The JDBC transaction type is only available at the DEBUG trace level. For other levels, JDBC is a block call. This transaction type and context names are only available in application servers.

Transaction type: JDBC	
Context name	Description
ClassName	The interface name for the JDBC call. This name is not the actual class name. Example: java.sql.PreparedStatement
MethodName	The method name for the JDBC call. Example: executeUpdate()

Java Connector Architecture (JCA)

The JCA transaction type is available only at the DEBUG trace level. For other levels, JCA is a block call. This transaction type and context names are only available in application servers.

Transaction type: JCA	
Context name	Description
ClassName	The class name for the JCA call. Example: javax.resource.spi.ManagedConnection
MethodName	The method name for the JCA call. Example: getConnection(Subject, ConnectionRequestInfo)

Web Services Provider

The Web services provider transaction type is for server-side Web services requests. This transaction type and the *WsdlPort* and *Operation* context names are available in all types of servers. The *Transport*, *NameSpace*, and *InputMessage* context names are only available in application servers.

Transaction type: Web Services Provider	
Context name	Description
WsdlPort	The WSDL port name that is associated with the Web service. Example: AccountManager
Operation	The operation name that is associated with the Web service. Example: createNewAccount

Transaction type: Web Services Provider	
Transport	The transport name that is associated with the Web service. Example: http
NameSpace	The name space that is associated with the Web service. Example: http://accountmanager.mycorp.com
InputMessage	The input message name that is associated with the Web service. Example: createNewAccountRequest

Web Services Requestor

The Web services requestor transaction type is available only at DEBUG trace level. For other levels, Web services requestor is a block call. This transaction type and context names are only available in application servers.

Transaction type: Web Services Requestor	
Context name	Description
WsdIIPort	The Web Services Description Language (WSDL) port name that is associated with the Web service. Example: AccountManager
Operation	The operation name that is associated with the Web service. Example: createNewAccount
Transport	The transport name that is associated with the Web service. Example: http
Parameters	The parameters for the Web service request. Example: customerName,addressStreet,addressCity,addressState,addressZip

Java Message Service (JMS)

The JMS transaction type is only for message-driven bean (MDB) scenarios in default messaging, including the System Integration Bus (SIB) layer and MQ. This transaction type and context names are only available in application servers.

Transaction type: JMS	
Context name	Description
DestinationName	The destination queue name or topic name for the Java Message Service (JMS). Example: MyBusiness.Topic.Space
MessageSelector	The message selector for JMS.
Provider	Provider refers to either default messaging, SIB, or MQ. Example: Default Messaging

JMS send and receive

The JMS send and receive transaction type is only available at the DEBUG trace level. For other levels, JMS send and receive is a block call. This transaction type and context names are only available in application servers.

Transaction type: JMS send/receive	
Context name	Description
ClassName	The class name in the JMS provider that makes the call. Example: com.ibm.ws.sib.api.jms.impl.JmsTopicPublisherImpl
MethodName	The method name in the JMS provider that makes the call. Example: sendMessage

SIB send and receive

The SIB send and receive transaction type is only available at the DEBUG trace level. For other levels, SIB send and receive is a block call. This transaction type and context names are only available in application servers.

Transaction type: SIB send/receive.	
Context name	Description
ClassName	The class name in the SIB layer that makes the call. Example: com.ibm.ws.sib.processor.impl.ProducerSessionImpl
MethodName	The method name in the SIB layer that makes the call. Example: send

SIB mediation

The SIB mediation transaction type and context names are only available in application servers.

Transaction type: SIB mediation	
Context name	Description
ClassName	The class name in which the call is made.
MethodName	The method name in which the call is made.
MediationName	The mediation name for the JMS. Example: myMediation
BusName	The service integration bus name for the JMS. Example: thisBusName
DestinationName	The destination name for the JMS. Example: myMessageQueue

AsyncBeans

The AsyncBeans transaction type is for AsyncBeans timers, alerts, and deferred starts. This transaction type and context names are only available in application servers.

Transaction type: AsyncBeans	
Context name	Description
Type	The type of AsyncBeans task. Example: COMMONJ_TIMER
ClassName	The class name that executes the AsyncBeans task. Example: com.mycorp.MyTaskClass

JNDI

The JNDI transaction type is only available at DEBUG trace level. For other trace levels, JNDI calls will not be instrumented. This transaction type and context names are only available in application servers.

Transaction type: JNDI	
Context name	Description
JNDIName	The JNDI lookup name. Example: ejbJndiName

Portlet

The portlet transaction type is and context names are only available in application servers.

Transaction type: Portlet	
Context name	Description
Method	The method of the portlet that is currently utilized, which can be either action or render.
WindowID	The window identifier of the portlet that is currently utilized.
URI	The context path of the current portlet request.

ARM correlators via HTTP and SOAP protocols

For HTTP inbound, WebSphere Application Server checks the case sensitive HTTP header "ARM_CORRELATOR" for the incoming ARM correlator. The application server does not allow the flow of ARM correlators via HTTP outbound.

For SOAP inbound, WebSphere Application Server checks the SOAP header for an element as follows:

- element = "arm_correlator";
- namespace URI = "http://websphere.ibm.com",
- prefix = "reqmetrics";
- actor URI = "reqmetricsURI";

For SOAP outbound, WebSphere Application Server creates a new SOAP header and passes the ARM correlator string as a text node in the header. For example:

- element = "arm_correlator";
- namespace URI = "http://websphere.ibm.com",
- prefix = "reqmetrics";
- actor URI = "reqmetricsURI";

The following is an example SOAP header with an ARM correlator. Note that the ARM correlator must be passed in hex string format of the ARM correlator byte array despite whether HTTP or SOAP protocol is used.

```
<soapenv:Header xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/" xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<reqmetrics:arm_correlator soapenv:actor="reqmetricsURI" xmlns:reqmetrics="http://websphere.ibm.com">
37000000000000000000000000000000
</reqmetrics:arm_correlator>
</soapenv:Header>
```

Isolating performance for specific types of requests

This topic describes how to enable request metrics filters.

Request metrics compares each incoming request to a set of known filters, but you need to enable these filters.

1. Open the administrative console.
2. Click **Monitoring and Tuning** > **Request metrics** in the administrative console navigation tree.
3. Click **Filters**.
4. Click *filter type*.
5. Select the check box in the **Enable** field under the Configuration tab.
6. Click **Apply** or **OK**.
7. Click **Save**. You can enable or disable a filter group. If the group is enabled, you can enable or disable individual filters.

The request metrics filters are enabled according to your configuration. For example, if you enabled source IP, only requests whose source IP matches the one specified in the filter will be instrumented.

Note: Filters will only be checked for edge transactions. An edge transaction is the transaction that first enters an instrumented system. For example, if a servlet calls an Enterprise JavaBean, the servlet is the edge transaction, assuming it is not instrumented at the Web server plug-in, and the URI and SOURCE_IP filters will be checked for the servlet request. However, when the request comes to EJB container, EJB filter will not be checked because it is no longer an edge transaction.

If logging time is spent in the Web server, refer to "Regenerating the Web server plug-in configuration file" on page 2364.

Adding and removing request metrics filters

This topic summarizes how to add and remove request metrics filter.

To add or remove request metrics filters, perform the following steps:

1. Open the administrative console.
2. Click **Monitoring and Tuning** > **Request metrics** in the console navigation tree.
3. Click **Filters**.
4. Choose a filter type.
 - a. Click **Filter values**.

- b. You can edit, add, and delete a filter value. To edit, click a filter value and change its value. To add, click **New** and type in the value and optionally check the **Enable filter** box. To delete, select a filter value and click **Delete**.
5. Click **Apply** or **OK**.
6. Click **Save**.

Adding or removing request metrics filters is complete.

If logging time spent in the Web server, refer to “Regenerating the Web server plug-in configuration file” on page 2364.

Request metrics filters

Use this page to view a list of request metrics filters.

To view this administrative console page, click **Monitoring and Tuning > Request metrics > Filters**.

Maximum rows: Specifies the maximum number of rows that displays when the collection is large. The rows that are not displayed appear on the next page.

Retain filter criteria: Specifies whether to use the same filter criteria entered in the show filter function to display this page the next time you visit it.

Type:

Specifies the type of request metrics filter.

Enable:

Specifies whether this filter is enabled. This option must be enabled to enable the filter values under this filter type.

Request metrics filter settings

Use this page to specify filters that define whether or not trace is enabled for inbound requests. Note that the filters will only be checked for inbound requests. For intra-process and outbound calls, filters will not be checked. If an inbound request passes the relevant filters, the request will be instrumented as it moves through WebSphere Application Server. If an inbound request does not pass the relevant filters, the request will not be instrumented for its entire code path in WebSphere Application Server.

To view this administrative console page, click **Monitoring and Tuning > Request metrics > Filters > filter_type**.

Type:

Specifies the type of request metrics filter.

Enable:

Specifies whether this filter is enabled.

Filter values:

Specifies the value(s) of the request metrics filter type and enablement for the value(s).

Filter values collection

Use this page to specify the values for source IP, URI, Web services, Java Message Service (JMS), or Enterprise JavaBeans (EJB) request metrics filters. When multiple filter values are enabled, a request will pass the filter as long as it matches one of the filter values.

To view this administrative console page, click **Monitoring and Tuning > Request metrics > Filters > filter_type > Filter values**.

Maximum rows: Specifies the maximum number of rows that displays when the collection is large. The rows that are not displayed appear on the next page.

Retain filter criteria: Specifies whether to use the same filter criteria entered in the show filter function to display this page the next time you visit it.

Value:

Specifies a source IP, URI, Web services, JMS, or EJB value based on the type of filter.

For example, for URI filters, the value might be `"/servlet/snoop"`.

Enable filter:

Specifies whether a filter value is enabled.

Filter values settings

Use this page to specify the values for source IP, URI, Web services, Java Message Service (JMS), or Enterprise JavaBeans (EJB) 2method name request metrics filters.

To view this administrative console page, click **Monitoring and Tuning > Request metrics > Filters > filter_type > Filter values > filter_value**.

Value:

Specifies a source IP, URI, Web services, JMS, or EJB value based on the type of filter.

For example, for URI filters, the value can be `/servlet/snoop`. When needed, the wildcard (`*`) can be appended at the end of the value. For example, `/servlet/s*` is a valid URI filter value.

For JMS and Web services filter values, the wildcard can be used at the end of one or more name/value pairs.

Enable filter:

Specifies whether this filter value is enabled.

Specifying how much data to collect

This topic describes how to set the trace level to generate trace records in the administrative console.

Trace level specifies how much trace data to accumulate for a given transaction. You should choose the one of the following values when setting the trace level in the administrative console.

None No instrumentation.

Hops Generates instrumentation information on process boundaries only (for example, a servlet request coming from a browser or a Web server and a JDBC request going to a database).

Performance_debug

Generates the data at Hops level and the first level of the intra-process servlet and Enterprise JavaBeans (EJB) call (for example, when an inbound servlet forwards to a servlet and an inbound EJB calls another EJB). Other intra-process calls like naming and service integration bus (SIB) are not enabled at this level.

Debug

Provides detailed instrumentation data, including response times for all intra-process calls.

Note: Requests to servlet filters will only be instrumented at this level.

1. Open the administrative console.
2. Click **Monitoring and Tuning > Request metrics** in the administrative console navigation tree.
3. Find **Trace level** in the Configuration tab.
4. Select a trace level from the drop down list box. To set the request metrics trace level to generate records, make sure that the trace level is set to a value greater than None.
5. Click **Apply** or **OK**.
6. Click **Save**.

Information will be generated to reflect the trace level you selected.

Regenerate the Web server plug-in configuration file as described in the “Regenerating the Web server plug-in configuration file” on page 2364 file, if logging time is spent in the Web server.

Request metrics trace filters

When request metrics is active, trace filters control which requests get traced. The data is recorded to the system log file or sent through Application Response Measurement (ARM) for real-time and historical analysis.

Incoming HTTP requests

HTTP requests that arrive at WebSphere Application Server might be filtered based on the URI or the IP address or both of the originator of the request.

- **Source IP address filters.** Requests are filtered based on a known IP address. You can specify a mask for an IP address using the asterisk (*). If used, the asterisk must always be the last character of the mask, for example 127.0.0.*, 127.0.*, 127*. For performance reasons, the pattern matches character by character, until either an asterisk is found in the filter, a mismatch occurs, or the filters are found to be an exact match.

Only addresses that are entered in one of the following addressing formats are acceptable as the source IP addresses:

- The IPv4 addressing format:

```
^(\d{1,2}|1\d\d|2[0-4]\d|25[0-5])\.(\d{1,2}|1\d\d|2[0-4]\d|25[0-5])\.(\d{1,2}|1\d\d|2[0-4]\d|25[0-5])\.(\d{1,2}|1\d\d|2[0-4]\d|25[0-5])$
```

- The IPv6 addressing format:

```
^([0-9a-fA-F]*[0-9a-fA-F]*[0-9a-fA-F]*[0-9a-fA-F]*:){1,7}([0-9a-fA-F]*[0-9a-fA-F]*[0-9a-fA-F]*[0-9a-fA-F]*)$
```

- The IPv4 compatible IPv4 addressing format:

```
^([0]*[0]*[0]*[0]*:){1,7}((\d{1,2}|1\d\d|2[0-4]\d|25[0-5])\.(\d{1,2}|1\d\d|2[0-4]\d|25[0-5])\.(\d{1,2}|1\d\d|2[0-4]\d|25[0-5])\.(\d{1,2}|1\d\d|2[0-4]\d|25[0-5]))$
```

- The IPv4MappedIPv6 addressing format:

```
^([0]*[0]*[0]*[0]*:){1,6}([fF][fF][fF][fF]:){1}((\d{1,2}|1\d\d|2[0-4]\d|25[0-5])\.(\d{1,2}|1\d\d|2[0-4]\d|25[0-5])\.(\d{1,2}|1\d\d|2[0-4]\d|25[0-5])\.(\d{1,2}|1\d\d|2[0-4]\d|25[0-5]))$
```

Note: If the client machine is a dual stack machine and its IP address is specified as the source IP address that is filtered by the request metrics filter, you must specify the IPv4 addressing format rather than the IPv6 addressing format. Only if the client machine is a single stack IPv6 machine, can you specify it as the IPv6 addressing format

- **URI filters.** Requests are filtered, based on the URI of the incoming HTTP requests. The rules for pattern matching are the same as for matching source IP address filters.
- **Filter combinations.** If both URI and source IP address filters are active, request metrics requires a match for both filter types. If neither is active, all requests are considered a match.

Incoming enterprise bean requests

Incoming enterprise bean requests

- Requests are filtered based on the full name of the EJB method. As with IP address and URI filters, the asterisk (*) might be used in the mask. If used, the asterisk must always be the last character of a filter pattern.

Because the ability to track the request response times comes with a cost, filtering helps optimize performance when using request metrics.

The Web services filter and the Java Message Service (JMS) filter was added to the WebSphere Application Server, Version 6 product. The filter values for Web services are a combination of a Web Services Description Language (WSDL) port name, operation name, and transport name. The filter value for JMS is the destination name.

Related tasks

“Specifying how much data to collect” on page 2362

This topic describes how to set the trace level to generate trace records in the administrative console.

Regenerating the Web server plug-in configuration file

This topic describes the steps to regenerate the Web server plug-in configuration file after you modify the request metrics configuration.

After modifying the request metrics configuration, you must complete the following steps to regenerate the Web server plug-in configuration file. Regeneration ensures that the Web server plug-in recognizes the changes that you made for the request metrics configuration. If you make multiple changes to request metrics, then regenerate the plug-in configuration files when you complete all the changes.

Important: You must complete this step after you change the request metrics configuration. If you do not, the Web server plug-in might have different request metrics configuration data than the application server. This difference in configuration data might cause inconsistent behaviors for request metrics between the Web server plug-in and the application server.

1. Open the administrative console.
2. Click **Server > Web servers** .
3. Select the *Web server* check box.
4. Click **Generate Plug-in**.

The regeneration of the Web server plug-in configuration file is complete.

Enabling and disabling logging

This topic describes how to enable and disable logging through the administrative console.

You can enable and disable logging through the administrative console to start the generation of request metrics logs in the SystemOut.log file in the following directory:

profile_root/logs/server_name

1. Open the administrative console.

2. Click **Monitoring and Tuning > Request metrics**.
3. Under **Request Metrics Destination**, select the **Standard Logs** check box to enable the logging feature. To disable the logging, clear the **Standard Logs** check box.

The logging feature is enabled. You can view the generated request metrics logs in the SystemOut.log file.

Request metrics performance data

Use this page to learn how to interpret performance data for request metrics in trace record format.

The trace records for request metrics data are output to two log files: the Web server plug-in log file and the application server log file. The default directory for these log files is *plugin_install_root/logs/web_server_name/http_plugin.log* and *install_root/profiles/profile_name/logs/server_name* and the default names are SystemOut.log and http_plugin.log. You might, however, specify these log file names and their locations.

In the WebSphere Application Server log file the trace record format is:

```
PMRM0003I: parent:ver=n,ip=n.n.n.n,time=nnnnnnnnnn,pid=nnnn,reqid=nnnnnn,event=nnnn
-
current:ver=n,ip=n.n.n.n,time=nnnnnnnnnn,pid=nnnn,reqid=nnnnnn,event=nnnn
      type=TTT detail=some_detail_information elapsed=nnnn
```

In the Web server plug-in log file the trace record format is:

```
PLUGIN:
parent:ver=n,ip=n.n.n.n,time=nnnnnnnnnn,pid=nnnn,reqid=nnnnnn,event=nnnn
- current:ver=n,ip=n.n.n.n,time=nnnnnnnnnn,pid=nnnn,reqid=nnnnnn,event=nnnn
      type=TTT detail=some_detail_information elapsed=nnnn bytesIn=nnnn
      bytesOut=nnnn
```

The trace record format is composed of two correlators: a parent correlator and current correlator. The parent correlator represents the upstream request and the current correlator represents the current operation. If the parent and current correlators are the same, then the record represents an operation that occurs as it enters WebSphere Application Server.

To correlate trace records for a particular request, collect records with a message ID of PMRM0003I from the appropriate application server log files and the PLUGIN trace record from the Web server plug-in log file. Records are correlated by matching current correlators to parent correlators. You can create the logical tree by connecting the current correlators of parent trace records to the parent correlators of child records. This tree shows the progression of the request across the server cluster. Refer to “Why use request metrics?” on page 2347 for an example of the transaction flow.

The parent correlator is denoted by the comma separating fields following the keyword, parent:. Likewise, the current correlator is denoted by the comma separating fields following, current:.

The fields of both parent and current correlators are:

- **ver:** The version of the correlator. For convenience, it is duplicated in both the parent and current correlators.
- **ip:** The IP address of the node of the application server that generated the correlator. If the system has multiple IP addresses, request metrics uses one of the IP addresses to identify the system.
- **pid:** The process ID of the application server that generated the correlator.
- **time:** The start time of the application server process that generated the correlator.
- **reqid:** An ID that is assigned to the request by request metrics, unique to the application server process.
- **event:** An event ID that is assigned to differentiate the actual trace events.

Following the parent and current correlators, the metrics data for timed operation are:

- **type:** A code that represents the type of operation being timed. Supported types include HTTP, URI, EJB, JDBC, JMS, COMMONJ_WORK_POOLED, COMMONJ_TIMER, Web services requester, and Web services provider.
- **detail:** Identifies the name of the operation being timed (See the following description of Universal Resource Identifier (URI), HTTP, EJB, JDBC, JMS, asynchronous beans, and Web services.)
- **elapsed:** The measured elapsed time in <units> for this operation, which includes all sub-operations called by this operation. The unit of elapsed time is milliseconds.
- **bytesIn:** The number of bytes from the request that is received by the Web server plug-in.
- **bytesOut:** The number of bytes from the reply that is sent from the Web server plug-in to the client.

The type and detail fields that are described include:

- **HTTP:** The Web server plug-in generates the trace record. The detail is the name of the URI that is used to invoke the request.
- **URI:** The trace record is generated by a Web component. The URI is the name of the URI that is used to invoke the request.
- **EJB:** The fully qualified package and the method name of the enterprise bean.
- **JDBC:** The interface name and method name for that JDBC call.
- **JMS:** JMS includes the particulars of various JMS parameters
- **Asynchronous beans:** The detail specifies the name of the asynchronous beans. Asynchronous beans include two types: COMMONJ_WORK_POOLED and COMMONJ_TIMER.
- **Web services:** Web services include the particulars of various Web services parameters. Web services include two types: Web services requestor and Web services provider.
- **SIB:** Used for instrumentation in service integration bus including message send/receive and mediation.
- **JCA:** J2EE Connector Architecture. The detail specifies the class name in which the JCA call is made.
- **JNDI:** Used for JNDI naming look up. The detail specifies the JNDI name.
- **JMS send and receive:** Generates the trace record by JMS sending and receiving messages.
- **SIB send and receive:** Generates the trace record by SIB sending and receiving messages.

When there are multiple servant regions for an application server, there are multiple SystemOut.log files, one for each servant region. Therefore, request metrics might log the trace records in multiple SystemOut.log files. The servant region that handles a request logs the relevant records in its SystemOut.log files. The pid in the current request metrics correlator is the pid for the corresponding servant region. If the system has multiple IP addresses, the IP in the correlator could be one of them, but it should use the same IP for the same servant region.

This topic describes how to enable and disable logging through the administrative console.

Request metric extension

Certain applications might require additional instrumentation points within the request metrics flow. For example, you might want to understand the response time to a unique back-end system as seen in the following call graph:

```

HTTP request /trade/scenario -----> 172 ms
  Servlet/trade/scenario -----> 130 ms
    Servlet/call to unique back-end system ----->38 ms

```

Request metrics uses a *token* or *correlator* when tracing the flow of each request through the system. To create the call graph above with this instrumentation, you must plug into that flow of the request and issue the appropriate Application Response Measurement (ARM) API for an ARM agent to collect the data and for the ARM vendor to create the call graph.

Request metrics exposes the Correlation Service API for you to plug into the flow of the request. The following example is one of the typical flows that might be followed by an instrumented application to plug into the request metrics flow:

1. Create a new `ArmTransaction` object, which runs various instrumentation calls such as start or stop. The `Correlation Service Arm` wrapper (`PmiRmArmTx`) encapsulates this object before being inserted into the request metrics flow.
2. Populate the `ArmTransaction` object with an appropriate `ArmCorrelator` object. This object encapsulates the actual ARM correlator bytes.
3. Run the start method on the `ArmTransaction` object, marking the beginning of the instrumented method.
4. Instantiate a `PmiRmArmTx` object using the static method on the `PmiRmArmTxFactory` class, and populate it with the `ArmTransaction` object above.
5. Pass the `PmiRmArmTx` object above to the `Correlation Service` by pushing it onto the `Correlation Service` stack using exposed methods on the `PmiRmArmStack` class.
6. Perform the tasks that need to be done by the method being instrumented. The `Correlation Service` takes care of flowing the `ArmTransaction` object as necessary, which eventually results in the call graph view of the transaction times.
7. At the end of the instrumented method, access the `PmiRmArmTx` object from the `Correlation Service` using exposed methods on the `PmiRmArmStack` class, access the `ArmTransaction` object and perform a stop to indicate the end of the transaction.

Example: Using the correlation service interface

Consult this information when utilizing the ARM API with the correlation service as part of a servlet instrumentation.

The `arm40` binaries should be installed in accordance with the installation instructions supplied by the implementation provider. Once this is done, restart the server. This causes trace records to be generated in the `SystemOut.log` file indicating the instantiation of the appropriate ARM implementation.

The following example illustrates one of the typical workflows of using the ARM API in conjunction with the correlation service as part of a servlet instrumentation:

```
public void doGet(HttpServletRequest request, HttpServletResponse response)
    throws ServletException, IOException {

    PmiRmArmTx artrax =
    // The factory detects the currently active ARM implementation (specified by user through
    // admin console) and instantiates an appropriate ARM wrapper object

        PmiRmArmTxFactory.createPmiRmArmTx();
    ArmTransaction at = newArmTx();
    if (null == at)
        out.println("Got a null ArmTransaction");
    ArmCorrelator arc = newArmCorr();
    at.start(arc);
    try {
        artrax.setArmTransaction(at);
        PmiRmArmStack.pushTransaction(artrax);
    } catch (Exception e) {
        System.out.println("Caught 1 exception" + e);
    }

    PmiRmArmTx atxwrp = PmiRmArmStack.peekTransaction();

    if (atxwrp == null)
        out.println("Armtransaction is null");

    //getArmType
    try {
        out.println("ARMTYPE is"+ PmiRmArmTx.getARMTYPE());
    } catch (Exception e) {
        out.println(e);
    }
}
```

```

//getting correlator bytes
try {
    if (null == atxwrp.getCorrelatorBytes())
        out.println("Got a null Correlator");
} catch (Exception e) {
    out.println(e);
}

//blocked/unblocked
long blkid = 0;
try {
    out.println(blkid = atxwrp.blocked());
} catch (Exception e) {
    out.println(e);
}

try {
    out.println(atxwrp.unblocked(blkid));
} catch (Exception e) {
    out.println(e);
}

try {
    atxwrp = PmiRmArmStack.popTransaction();
    ArmTransaction art = (ArmTransaction) atxwrp.getArmTransaction();
    art.stop(ArmConstants.STATUS_GOOD);
} catch (Exception e) {
    out.println(e);
}

}

private ArmTransaction newArmTx() {

    ArmTransactionFactory txFactory = null;
    try {
        String sWasName = "WebSphere";
        String appName = "t23xpimage/t23xpimage/server1";
        String sCellName = appName.substring(0, appName.indexOf("/"));
        String sNodeInstance =
            appName.substring(appName.indexOf("/") + 1, appName.length());
        sNodeInstance = sNodeInstance.replace('/', '.');
        txFactory = (ArmTransactionFactory)
            newObjectInstance("org.opengroup.arm40.sdk.ArmTransactionFactoryImpl");
        ArmApplication app = null; // 149297
        ArmApplicationDefinition appDef = null; //LIDB3207
        appDef = txFactory.newArmApplicationDefinition(sWasName, null, null);
        app = txFactory.newArmApplication(appDef, sCellName, sNodeInstance, null);

        String[] idnames = { "request_type" };
        String[] idvalues = { "URI" };
        String[] ctxnames = { "URI" };
        ArmIdentityPropertiesTransaction props =
            txFactory.newArmIdentityPropertiesTransaction(
                idnames,
                idvalues,
                ctxnames,
                null);
        ArmTransactionDefinition atd =
            txFactory.newArmTransactionDefinition(
                appDef,
                "URI",
                props,
                (ArmID) null);
        ArmTransaction at = txFactory.newArmTransaction(app, atd);
        return at;
    }
}

```

```

} catch (Exception e) {
    System.out.println(e);
    return null;
}

}

private ArmCorrelator newArmCorr() {

    ArmTransactionFactory txFactory = null;
    try {
        String sWasName = "WebSphere";
        String appName = "t23xpimage/t23xpimage/server1";
        txFactory =
            (ArmTransactionFactory) newObjectInstance("org.opengroup.arm40.sdk.ArmTransactionFactoryImpl");

        ArmCorrelator arc =txFactory.newArmCorrelator(
            PmiRmArmStack.peekTransaction().getCorrelatorBytes());
        return arc;
    } catch (Exception e) {
        System.out.println(e);
        return null;
    }

}

```

There are several potential scenarios for using the PmiRmArmStack. This example shows a scenario where code accesses an existing PmiRmArmTx on the stack, extracts the correlator, and calls blocked and unblocked. This is a typical scenario when sending a correlator along an unsupported protocol. In this scenario, the Arm transaction is already on the stack.

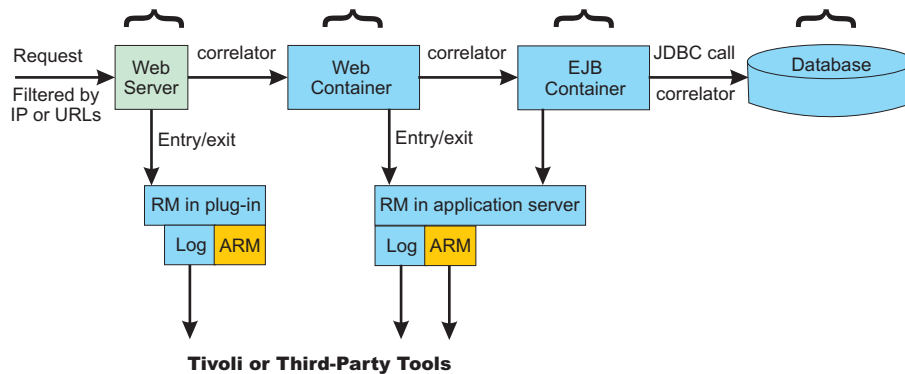

```

1  PmiRmArmTx artrax =
2  PmiRmArmStack.peekTransaction();
3  if( artrax != null )
4      {
5          {
6              try
7              {
8                  byte[] cbytes = artrax.getCorrelatorBytes();
9                  stuffBytesIntoOutboundMessage( msg, cbytes);
10                 long blockedId = 0;
11                 try
12                 {
13                     blockedId = artrax.blocked();
14                 }
15                 catch( NoSuchMethodException nsme )
16                 {
17                     // must not be running ARM4 or eWLM
18                 }
19                 sendMsg( msg );
20             }
21             try
22             {
23                 artrax.blocked( blockedId );
24             }
25             catch( NoSuchMethodException nsme )
26             {
27                 // must not be running ARM4 or eWLM
28             }
29         }
30     }
31     catch( Exception e )
32     {
33         report a problem;
34     }
35 }

```

Differences between Performance Monitoring Infrastructure and request metrics

Performance Monitoring Infrastructure (PMI) provides information about average system resource usage statistics, with no correlation between the data across different WebSphere Application Server components. For example, PMI provides information about average thread pool usage. Request metrics provides data about each individual transaction, correlating this information across the various WebSphere Application Server components to provide an end-to-end picture of the transaction, as shown in the following diagram:

Chapter 26. Troubleshooting deployment

- Select the problem you are having with deploying or installing developed code for WebSphere Application Server.
 - Errors or problems deploying, installing, or promoting applications
 - Class loader exceptions
- To troubleshoot other deployment issues, use the following resources.
 - For current information available from IBM Support on known problems and their resolution, see the IBM Support page.
 - IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.
 - If you do not see a problem that resembles yours, or if the information provided does not solve your problem, see Troubleshooting help from IBM.

Errors or problems deploying, installing, or promoting applications

This topic describes problems that you might encounter when deploying, installing, or promoting applications and suggests ways to resolve the problems.

What kind of problem are you having?

- “I installed my application using the wsadmin tool, but the application does not display under Applications > Enterprise Applications ” on page 2372
- “Unable to save a deployed application” on page 2372
- “I get a java.lang.RuntimeException: Failed_saving_bytes_to_wor_ERROR_ error in the assembly tool, administrative console or the wsadmin tool.” on page 2372
- “WASX7015E error running wsadmin command \$AdminApp installInteractive or \$AdminApp install” on page 2373
- “Data definition language (DDL) generated by an assembly tool throws SQL error on target platform ” on page 2373
- “Error message ADMA0004E: Validation error in task Specifying the Default Datasource for EJB Modules returned when installing application using the administrative console or the wsadmin tool” on page 2373
- “Cannot load resource WEB-INF/ibm-web-bnd.xmi in archive file” on page 2374
- “Error message No valid target is specified in ObjectName anObject for module module_name from installation ” on page 2374
- “addNode -includeapps option does not appear to upload all applications to the deployment manager” on page 2375
- “”Timeout!!!” error displays when attempting to install an enterprise application in the administrative console ” on page 2375
- “I get a NameNotFoundException message when deploying an application that contains an EJB module” on page 2375
- “During application installation, the call to EJB deploy throws an exception” on page 2375
- “I get compilation errors and EJB deploy fails when installing an EJB JAR file generated for Version 5.x or earlier” on page 2375
- “While uploading documents, addNode -includeapps fails with an OutOfMemoryError exception” on page 2376

Check the following first:

- Verify that the logical name that you have specified to appear on the console for your application, enterprise bean module or other resource does not contain invalid characters such as these: - / \ : * ? " < > |.

- If the application was installed using the `wsadmin $AdminApp install` command with the **-local** flag, restart the server or rerun the command without the `-local` flag.

If you do not see a problem that resembles yours, or if the information provided does not solve your problem, check to see if the problem is identified and documented by looking at available online support including hints and tips, technotes, and fixes. If the problem has not been identified, see Troubleshooting help from IBM.

I installed my application using the wsadmin tool, but the application does not display under Applications > Enterprise Applications

The application might be installed but you have not saved the configuration:

1. Verify that the application subdirectory is located under the `app_server_root/installedApps` directory.
2. Run the `$AdminApp list` command and verify that the application is not among those displayed.
 - In the bin directory, run the `wsadmin.bat` or `wsadmin.sh` command.
 - From the `wsadmin` prompt, enter `$AdminApp list` and verify that the problem application is not among the items that display.
3. Reinstall your application using the `wsadmin` tool. Run the `$AdminConfig save` command in the `wsadmin` tool before exiting.

Unable to save a deployed application

If you are unable to save a deployed application, the problem might be that too many files are opened, exceeding the limit of the operating system.

On the SuSE9 or other Linux platform, you can either increase the number of files that can be opened to resolve the problem or you can modify the application to close files with disciplines. To increase the number of files that you can open at the same time, run the following command in the shell before invoking the process that needs to open a number of files:

```
ulimit -n number_of_files
```

Only root has authority to adjust the maximum number of files for each process. Complete the following steps to modify the application to close files with disciplines:

1. After you open a file and complete your work, call the close method of the file to release the file handle back to the operating system.
2. Using the `java.io.FileInputStream` and the `FileOutputStream` classes as examples, you can invoke their close method to release any system resources that are associated with the stream.

I get a java.lang.RuntimeException: Failed saving bytes to wor_ERROR_ error in the assembly tool, administrative console or the wsadmin tool.

If you see this error when attempting to generate deployed code in an assembly tool, installing an application or module in the administrative console, or using the `wsadmin` tool to install an application or module, the file path length of the temporary system file might be exceeded. This situation is typically an issue only on Windows platforms.

To verify this problem, check the `TEMP` and `TMP` environment variables for your system. Long environment variables add path length to the file names accessed by the EJB deployment tool.

To resolve the problem:

1. Stop all WebSphere Application Server processes and close all DOS prompts.
2. Set the `TMP` and `TEMP` environment variables to something short, for example `C:\TMP` and `C:\TEMP`.
3. Reinstall the application.

Otherwise, try rebooting and redeploying or reinstalling the application.

WASX7015E error running wsadmin command \$AdminApp installInteractive or \$AdminApp install

This problem has two possible causes:

- If the full text of the error is similar to:

```
WASX7015E: Exception running command: "$AdminApp installInteractive Documents and Settings/
myUserName/Desktop/MyApp/myapp.ear"; exception information:
com.ibm.bsf.BSFException: error while
eval'ing Jacl expression: can't find method "installInteractive"
with 3 argument(s) for class
"com.ibm.ws.scripting.AdminAppClient"
```

The file and path name are incorrectly specified. In this case, since the path included spaces, it was interpreted as multiple parameters by the wsadmin program.

Enter the path of the .ear file correctly. In this case, by enclosing it in double quotes:

```
$AdminApp installInteractive "Documents and Settings/myUserName/Desktop/MyApps/myapp.ear"
```

- If the full text of the error is similar to:

```
WASX7015E: Exception running command: "$AdminApp installInteractive MyApps\myapp.ear ";
exception information: com.ibm.ws.scripting.ScriptingException: WASX7115E:
Cannot read input file
"WebSphere\AppServer\bin\MyAppsmyapp.ear"
```

The application path is incorrectly specified. In this case, you must use "forward-slash" (/) separators in the path.

Data definition language (DDL) generated by an assembly tool throws SQL error on target platform

If you receive SQL errors in attempting to execute data definition language (DDL) statements generated by an assembly tool on a different platform, for example if you are deploying a container-managed persistence (CMP) enterprise bean designed on Windows onto a UNIX operating system server, try the following actions:

- Browse the DDL statements for dependencies on specific user identifiers and passwords, and correct as necessary.
- Browse the DDL statements for dependencies on specific server names, and correct as necessary.
- Refer to the message reference of the vendor for causes and suggested actions regarding specific SQL errors. For IBM DB2, you can view the message references online at <http://www.ibm.com/cgi-bin/db2www/data/db2/udb/winos2unix/support/index.d2w/report>.

If you receive the following error after executing a DDL file created on the Windows operating system or on operating systems such as AIX or Linux, the problem might come from a difference in file formats:

```
SQL0104N  An unexpected token "CREATE TABLE AGENT (COMM DOUBLE, PERCENT DOUBLE, P"
was found following "      ".  Expected tokens may include: " ".
SQLSTATE=42601
```

To resolve this problem:

- For operating systems other than Linux, edit the DDL in the vi editor, removing the Ctl-M character at the beginning of each line.
- For Linux systems, regenerate the deployment code for the application EAR file on a Linux platform.

Error message ADMA0004E: Validation error in task Specifying the Default Datasource for EJB Modules returned when installing application using the administrative console or the wsadmin tool

If you see the following error when trying to install an application through the administrative console or the wsadmin command prompt:

```
AppDeploymentException: [ADMA0014E: Validation failed.
ADMA0004E: Validation error in task Specifying the Default Datasource for
EJB Modules JNDI name is not
specified for module beanameBean Jar with URI filename.jar,META-INF/ejb-jar.xml.
You have not specified the
data source for each CMP bean belonging to this module. Either specify the data
source for each CMP beans or
specify the default data source for the entire module.]
```

one possible cause is that in WebSphere Application Server version 4.0, it was mandatory to have a data source defined for each CMP bean in each JAR. In versions 5.0 and later releases, you can specify either a data source for a container-managed persistence (CMP) bean or a default data source for all CMP beans in the JAR file. Thus during installation interaction, such as the installation wizard in the administrative console, the data source fields are optional, but the validation performed at the end of the installation checks to see that at least one data source is specified.

To correct this problem, step through the installation again, and specify either a default data source or a data source for each CMP-type enterprise bean. If you are using the wsadmin tool:

- Use the `$AdminApp installInteractive filename` command to receive prompts for data sources during installation, or to provide them in a response file.

Cannot load resource WEB-INF/ibm-web-bnd.xmi in archive file

The Web application tmp.war installs on WebSphere Application Server versions 5.0 and 5.1, but fails on a WebSphere Application Server version 6 server. The application fails to install because the WEB-INF/ibm-web-bnd.xmi file contains xmi tags that the underlying WCCM model no longer recognizes.

The following error messages display:

```
IWAE0007E Could not load resource "WEB-INF/ibm-web-bnd.xmi" in archive "tmp.war"
[2/24/05 14:53:10:297 CST] 000000bc SystemErr      R
AppDeploymentException:
com.ibm.etools.j2ee.commonarchivecore.exception.ResourceLoadException:
IWAE0007E Could not load resource "WEB-INF/ibm-web-bnd.xmi" in archive "tmp.war"
[2/24/05 14:53:10:297 CST] 000000bc SystemErr      R
com.ibm.etools.j2ee.commonarchivecore.exception.ResourceLoadException:
IWAE0007E Could not load resource "WEB-INF/ibm-web-bnd.xmi" in archive "tmp.war"
!Stack_trace_of_nested_exce!
com.ibm.etools.j2ee.exception.WrappedRuntimeException: Exception occurred loading
WEB-INF/ibm-web-bnd.xmi
!Stack_trace_of_nested_exce!
```

To work around this problem, remove the `xmi:type=EJBLocalRef` tag from the `ibm-web-bnd.xmi` file. Removing this tag does not affect the application because the tag was previously used for matching the cross document reference type. The application now works for the WebSphere Application Server v5.1, v6.0, and later releases.

Error message No valid target is specified in ObjectName *anObject* for module *module_name* from installation

This error can occur in a clustered environment if the target cell, node, server or cluster into which the application is to be installed is incorrectly specified. For example, it can occur if the target is misspelled.

To correct this problem, check the target names against the actual WebSphere Application Server topology and reenter them with corrections.

addNode -includeapps option does not appear to upload all applications to the deployment manager

This error can occur when some or all applications on the target node are already uploaded to the deployment manager. The addNode program detects which applications are already installed and does not upload them again.

Use the administrative console to browse the deployment manager configuration and see the applications that are already installed.

"Timeout!!!" error displays when attempting to install an enterprise application in the administrative console

This error can occur if you attempt to install an enterprise application that has not been deployed.

To correct this problem:

- Open the *file_name.ear* file in an assembly tool and then click **Deploy**. This action creates a file with a name like *Deployed_file_name.ear*.
- In the administrative console, install the deployed .ear file.

I get a NameNotFoundException message when deploying an application that contains an EJB module

If you specify that EJB deploy be run during application installation and the installation fails with a NameNotFoundException message, ensure that the input JAR or EAR file does not contain source files. If there are source files in the input JAR or EAR file, the EJB deployment tools runs a rebuild before generating the deployment code.

To work around this problem, either remove the source files or include all dependent classes and resource files on the class path. Otherwise, the source files or the lack of access to dependent classes and resource files might cause problems during rebuilding of your application on the server.

During application installation, the call to EJB deploy throws an exception

When you specify that the EJB deployment tool be run during application installation and if installation fails with the error command line too long, the problem is that the deployment command generated during installation exceeds the character limit for a command line on the Windows platform. This problem occurs only on Windows platforms.

To work around this problem, you can reduce the length of the EAR file name, reduce the length of the JAR file name within the EAR file, reduce the class path or other options specified for deployment, or change the %TEMP% location of the Windows system to make its path shorter.

I get compilation errors and EJB deploy fails when installing an EJB JAR file generated for Version 5.x or earlier

When installing an old application that uses EJB modules that were built to run on WebSphere Application Server Version 5.x or earlier, compilation errors result and EJB deploy fails. The EJB JAR file contains Java source for the old generated code. The old Java source was generated for Version 5.x or before but, when deployed to a WebSphere Application Server Version 6.x product, it is compiled using the Version 6.x run-time JAR files.

To work around this problem, remove all .java files from the application .ear file. After the Java source files are removed, you can deploy the application onto a server successfully.

While uploading documents, addNode -includeapps fails with an OutOfMemoryError exception

This error can occur when you use addNode -includeapps while you are installing applications with large EAR files. To correct this problem:

- If you are using addNode to add a node from the base server, modify the addNode script to include the following parameter:
`-Xmxsize`
- If you are adding a node from the administrative console, increase the *maximumHeapSize* in the Java virtual machine settings of the deployment manager, then restart the deployment manager. See addNode command and Java virtual machine settings for details.

For example, the addNode.bat file that follows sets a maximum heap size of 512 MB on a Windows platform:

```
%JAVA_HOME%\bin\java" -Xmx512m %DEBUG% %WAS_TRACE% %CONSOLE_ENCODING%
%CLIENTSOAP%" %CLIENTSAS%" -classpath" %WAS_CLASSPATH%"
"-Dws.ext.dirs=%WAS_EXT_DIRS%" %USER_INSTALL_PROP%
-Dwas.install.root=%WAS_HOME%" "com.ibm.ws.bootstrap.WSLauncher"
"com.ibm.ws.management.tools.NodeFederationUtility" "%CONFIG_ROOT%" "%WAS_CELL%"
"%WAS_NODE%" %*
```

Troubleshooting testing and first time run problems

Select the problem you are having with testing or the first run of deployed code for WebSphere Application Server:

- “A Web resource does not display” on page 2382.
- “Cannot access a data source” on page 766.
- “Cannot access an enterprise bean from a servlet, a JSP file, a stand-alone program, or another client” on page 230.
- Cannot look up an object hosted by WebSphere Application Server from a servlet, JSP file, or other client.
- Access problems after enabling security.
- Errors after enabling security.
- Errors after configuring or enabling Secure Sockets Layer.
- Errors in messaging.
- .
- Errors connecting to WebSphere MQ and creating WebSphere MQ queue connection factory.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the Must gather documents page for information to gather to send to IBM Support page.

Errors starting an application

Use this information for troubleshooting problems that occur when starting an application.

What kind of error do you see when you start an application?

- “HTTP server and Application Server are working separately, but requests are not passing from HTTP server to Application Server” on page 2377
- “File serving problems” on page 2377
- “Graphics do not appear in the JSP file or servlet output” on page 2378
- “SRVE0026E: [Servlet Error]-[Unable to compile class for JSP file” on page 2378

- “Message like “Message: /jspname.jsp(9,0) Include: Mandatory attribute page missing” appears when attempting to browse JSP file” on page 2379
- “The JSP Batch Compiler fails with the message “Enterprise Application [application name you typed in] not found.”” on page 2379
- “There is a translation problem with non-English browser input” on page 2379
- “Scroll bars do not appear around items in the browser window” on page 2379
- “Error “Page cannot be displayed... server not found or DNS error” appears when attempting to browse a JavaServer Pages (JSP) file using Internet Explorer” on page 2380
- “DeploymentDescriptorLoadException results when starting an application” on page 2380

HTTP server and Application Server are working separately, but requests are not passing from HTTP server to Application Server

If your HTTP server appears to be functioning correctly, and the Application Server also works on its own, but browser requests sent to the HTTP server for pages are not being served, a problem exists in the WebSphere Application Server plug-in.

In this case:

1. Determine whether the HTTP server is attempting to serve the requested resource itself, rather than forwarding it to the WebSphere Application Server.
 - a. Browse the HTTP server access log (*IHS install root/logs/access.log* for IBM HTTP Server). It might indicate that it could not find the file in its own document root directory.
 - b. Browse the plug-in log file as described below.
2. Refresh the `plugin-cfg.xml` file that determines which requests sent to the HTTP server are forwarded to the WebSphere Application Server, and to which Application Server.

Use the console to refresh this file:

 - In the WebSphere Application Server administrative console, expand the Environment tree control.
 - Click **Update WebSphere Plugin**.
 - Stop and restart the HTTP server.
 - Retry the Web request.
3. Browse the `plugin_install_root/logs/web_server_name/http_plugin.log` file for clues to the problem. Make sure the timestamps with the most recent plug-in information stanza, which is printed out when the plug-in is loaded, correspond to the time the Web server started.
4. Turn on plug-in tracing by setting the `LogLevel` attribute in the `plugin-cfg.xml` file to `Trace` and reloading the request. Browse the `plugin_install_root/logs/Web_server_name/http_plugin.log` file. You should be able to see the plug-in attempting to match the request URI with the various URI definitions for the routes in the `plugin-cfg.xml`. Check which rules the plug-in is not matching against and then figure out if you need to add additional ones. If you just recently installed the application you might need to manually regenerate the plug-in configuration to pick up the new URIs related to the new application.

For further details on troubleshooting plug-in-related problems, see Webserver plug-in troubleshooting tips located in the *Administering applications and their environment* PDF book.

File serving problems

If text output appears on your JSP- or servlet-supported Web page, but image files do not:

- Verify that your files are in the right place: the **document root** directory of your Web application WebSphere Application Server follows the J2EE standard, which means that the document root is the `Web_module_name.war` directory of your deployed Web application.

Typically this directory will be found in the `install_root/installedApps/nodename/appname.ear` directory or `install_root/installedApps/nodename/appnameNetwork.ear` directory.

If the files are in a subdirectory of the document root, verify that the reference to the file reflects that. That is, if the invoices.html file is stored in Windows directory *Web_module_name.war\invoices*, then links from other pages in the Web application to display it should read "invoices\invoices.html", not "invoices.html".

- Verify that your Web application is configured to enable file serving (in other words, that it is enabled to display static resources like image and .html files):

1. Edit the **fileServingEnabled** property in the deployed Web application *ibm-web-ext.xml* configuration file.

The file typically is found in the *install_root/config/cells/nodename* or *nodenameNetwork/applications/application_name/deployments/application_name/Web_module_name/web-inf* directory.

Graphics do not appear in the JSP file or servlet output

If text output appears on your JSP- or -servlet-supported Web page, but image files do not:

- Verify that your graphic files are in the right place: the **document root** directory of your Web application. WebSphere Application Server Version 5 follows the J2EE standard, which means that the document root is the *Web_module_name.war* directory of your deployed Web application.

Typically, this directory is found in the *install_root/installedApps/nodename/appname.ear* directory or *install_root/installedApps/nodename/appnameNetwork.ear* directory.

If the graphics files are in a subdirectory of the document root, verify that the reference to the graphic reflects that; for example, if the banner.gif file is stored in Windows directory *Web_module_name.war/images*, the tag to display it should read: ****, not ****.

- Verify that your Web application is configured to enable file serving (that is, display of static resources like image and .html files).

1. Edit the **fileServingEnabled** property in the deployed Web application *ibm-web-ext.xml* configuration file.

The file typically is found in the *install_root/config/cells/nodename* or *nodenameNetwork/applications/application_name/deployments/application_name/Web_module_name/web-inf* directory.

2. After completing the previous step:
 - In the administrative console, expand the **Environment** tree control .
 - Click **Update WebSphere Plugin**.
 - Stop and restart the HTTP server and retry the Web request.

SRVE0026E: [Servlet Error]-[Unable to compile class for JSP file

If this error appears in a browser when trying to access a new or modified .jsp file for the first time, the most likely cause is that the JSP file Java source failed (was incorrect) during the javac compilation phase.

Check the log files for a compiler error message.

Fix the problem in the JSP source file, save the source and request the JSP file again.

If this error occurs when trying to serve a JSP file that was copied from another system where it ran successfully, then there is something different about the new server environment that prevents the JSP file from running. Browse the text of the error for a statement like:

```
Undefined variable or class name: MyClass
```

This error indicates that a supporting class or jar file is not copied to the target server, or is not on the class path. Find the MyClass.class file, and place it on the Web module WEB-INF/classes directory, or place its containing .jar file in the Web module WEB-INF/lib directory.

Verify that the URL used to access the resource is correct by doing the following:

- For a JSP file, html file, or image file: `http://host_name/Web_module_context_root/subdir under doc root, if any/filename.ext`. The document root for a Web application is the `application_name.WAR` directory of the installed application.
- For servlets served by class name, the URL is `http://hostname/Web_module_context_root/servlet/packageName.className`.

Correct the URL in the "from" HTML file, servlet or JSP file. An HREF with no leading slash (/) inherits the calling resource context. For example:

- an HREF in `http://[hostname]/myapp/servlet/MyServlet` to "ServletB" resolves to `"http://hostname/myapp/servlet/ServletB"`
- an HREF in `http://[hostname]/myapp/servlet/MyServlet` to `"servlet/ServletB"` resolves to `"http://hostname/myapp/servlet/servlet/ServletB"` (an error)
- an HREF in `http://[hostname]/myapp/servlet/MyServlet` to `"/ServletB"` resolves to `"http://hostname/ServletB"` (an error, if ServletB requires the same context root as MyServlet)

Message like "Message: /jspname.jsp(9,0) Include: Mandatory attribute page missing" appears when attempting to browse JSP file

It is probable that the JSP file failed during the translation to Java phase. Specifically, a JSP directive, in this case an Include statement, was incorrect or referred to a file that could not be found.

To correct this problem, fix the problem in the JSP source, save the source and request the JSP file again.

The JSP Batch Compiler fails with the message "Enterprise Application [application name you typed in] not found."

It is probable that the full enterprise application path and name, starting with the `.ear` subdirectory that resides in the applications directory is expected as an argument to the `JspBatchCompiler` tool, not just the display name.

For example:

- `"JspBatchCompiler -enterpriseapp.name sampleApp.ear/deployments/sampleApp"` is correct, as opposed to
- `"JspBatchCompiler -enterpriseapp.name sampleApp"`, which is incorrect.

There is a translation problem with non-English browser input

If non-English-character-set browser input cannot be translated after being read by a servlet or JSP file, ensure that the request parameters are encoded according to the expected character set before reading. For example, if the site is Chinese, the target `.jsp` file should have a line:

```
req.setCharacterEncoding("gb2312");
```

before any `req.getParameter` method calls.

This problem affects servlets and `jsp` files ported from earlier versions of WebSphere Application Server, which converted characters automatically based upon the locale of the WebSphere Application Server.

Scroll bars do not appear around items in the browser window

In some browsers, tree or list type items that extend beyond their allotted windows do not have scroll bars to permit viewing of the entire list.

To correct this problem, right-click on the browser window and click **Reload** from the menu.

Error "Page cannot be displayed... server not found or DNS error" appears when attempting to browse a JavaServer Pages (JSP) file using Internet Explorer

This error can occur when an HTTP timeout causes the servant to be brought down and restarted. To correct this problem, increase the ConnectionIOTimeout value:

1. From the administrative console, select **System administration > Deployment manager > Administration Services > Custom Properties**
2. Select ConnectionIOTimeout.
3. Increase the ConnectionIOTimeout value.
4. Click **OK**.

DeploymentDescriptorLoadException results when starting an application

If an application server on which the application is deployed synchronizes configuration with the deployment manager during server startup, then the application might not start and a DeploymentDescriptorLoadException might be written to the server SystemErr.log file. Stop and restart the server, and then try starting the application again.

The application does not start or starts with errors

When an application is not starting or starting with errors, the problem could be from one of various sources.

What kind of error do you see when you start an application?

- A "java.lang.ClassNotFoundException: classname Bean_AdderServiceHome_04f0e027Bean" error occurs
- A "ConnectionFac E J2CA0102E: Invalid EJB component: Cannot use an EJB module with version 1.1 using The Relational Resource Adapter" on page 2381 error occurs
- "NMSV0605E: "A Reference object looked up from the context..." error when starting an application" on page 2381.

If none of these errors match the error you see:

- Browse the log files of the application server for this application looking for clues. By default, these files are: *install_dir/logs/server_name/SystemErr.log* and *SystemOut.log*.
- Look up any error or warning messages in the message reference table by clicking the Reference view and expanding the "Messages" heading.

If you do not see a problem that resembles yours, or if the information provided does not solve your problem, see Troubleshooting help from IBM.

java.lang.ClassNotFoundException: *classname* Bean_AdderServiceHome_04f0e027Bean

An similar exception occurs when you try to start an undeployed application containing enterprise beans, or containing undeployed enterprise bean modules.

To avoid this problem, do the following:

- Use an assembly tool and administrative console to generate deployment code and install the application or Enterprise JavaBeans module onto a server.
 1. Uninstall the application or Enterprise JavaBeans module in the administrative console.
 2. Configure your assembly tool so the target server is a WebSphere Application Server installation such as **WebSphere Application Server v6**. If you do not have access to the target server, you can specify a false location such as *c:\temp*. Specifying a false location enables you to assemble and generate deployment code for the enterprise bean.

3. In the Project Explorer view of an assembly tool, right-click the enterprise bean (Enterprise JavaBeans) in the undeployed .ear file containing the Enterprise JavaBeans module or the standalone undeployed Enterprise JavaBeans JAR file, and click **Deploy**. If your assembly tool can access the WebSphere Application Server target server, deployment code is generated for the Enterprise JavaBeans and the assembly tool attempts to install the application or module onto the target server. If your assembly tool cannot access the WebSphere Application Server target server or the installation fails, use the deployment code that is generated for the next step.
For information on using an assembly tool, refer to *Assembling applications*.
 4. Use the `wsadmin $AdminApp install` command or the administrative console to install the deployed version created by the assembly tool.
- If you use the `wsadmin $AdminApp install` command, uninstall it and then reinstall using the `-EJBDeploy` option. Follow the install command with the `$AdminConfig save` command.

ConnectionFac E J2CA0102E: Invalid EJB component: Cannot use an EJB module with version 1.1 using The Relational Resource Adapter

This error occurs when an enterprise bean developed to the Enterprise JavaBeans 1.1 specification is deployed with a WebSphere Application Server V5 J2C-compliant data source, which is the default data source. By default, persistent enterprise beans created under WebSphere Application Server V4.0's using the Application Assembly Tool fulfill the Enterprise JavaBeans 1.1 specification. To run on WebSphere Application Server V6, these enterprise beans must be associated with a WebSphere Application Server V4.0-type data source.

Either modify the mapping in the application of enterprise beans to associate 1.x container managed persistence (CMP) beans to associate them with a V4.0 data source or delete the existing data source and create a V4.0 data source with the same name.

To modify the mapping in the application of enterprise beans, in the WebSphere Application Server administrative console, select the properties for the problem application and use **map resource references to resources** or **Map data sources for all 1.x CMP beans** to switch the data source the enterprise bean uses. Save the configuration and restart the application.

To delete the existing data source and create a V4.0 data source with the same name:

1. In the administrative console, click **Resources>Manage JDBC Providers>JDBC_provider_name>Data sources**.
2. Delete the data source associated with the Enterprise JavaBeans 1.1 module.
3. Click **Resources>Manage JDBC Providers>JDBC_provider_name>Data sources (Version 4)**.
4. Create the data source for the Enterprise JavaBeans 1.1 module.
5. Save the configuration and restart the application.

NMSV0605E: "A Reference object looked up from the context..." error when starting an application

If the full text of the error is similar to:

```
[7/17/02 15:20:52:093 CDT] 5ae5a5e2 UrlContextHel W NMSV0605E: A Reference object looked up from the context
"java:" with the name "comp/PM/WebSphereCMPConnectionFactory" was sent to the JNDI Naming Manager
and an exception resulted. Reference data follows:
Reference Factory Class Name: com.ibm.ws.naming.util.IndirectJndiLookupObjectFactory
Reference Factory Class Location URLs:
Reference Class Name: java.lang.Object
Type: JndiLookupInfo
Content: JndiLookupInfo: ; jndiName="eis/jdbc/MyDatasource_CMP"; providerURL=""; initialContextFactory=""
```

then the problem might be that the data source intended to support a CMP enterprise bean is not correctly associated with the enterprise bean.

To resolve this problem:

1. Select the **Use this Data Source in container managed persistence (CMP)** check box in the data source "General Properties" panel of the administrative console.
2. Verify that the JNDI Name given in administrative console under **Resources > Manage JDBC Provider > DataSource > JNDI Name** for DataSource matches the JNDI Name given for CMP or BMP Resource Bindings at the time of assembling the application in an assembly tool, or
3. Check the JNDI Name for CMP or BMP resource bindings specified in the code by J2EE Application Developer. Open the deployed .ear folder in an assembly tool, and look for the JNDI Name for your entity beans under CMP or BMP resource bindings. Verify that the names match.

A Web resource does not display

If you are not able to display a resource in your browser, follow these steps:

1. Verify that your HTTP server is healthy by accessing the URL `http://server_name` from a browser and seeing whether the Welcome page appears. This action indicates whether the HTTP server is up and running, regardless of the state of WebSphere Application Server.
2. If the HTTP server Welcome page does not appear, that is, if you get a browser message like page cannot be displayed or something similar, try to diagnose your Web server problem.
3. If the HTTP server appears to function, the Application Server might not be serving the target resource. Try accessing the resource directly through the Application Server instead of through the HTTP server.

If you cannot access the resource directly through the Application Server, Verify that the URL used to access the resource is correct.

If the URL is incorrect and it is created as a link from another JSP file, servlet, or HTML file, try correcting it in the browser URL field and reloading, to confirm that the problem is a malformed URL. Correct the URL in the "from" HTML file, servlet or JSP file.

If the URL appears to be correct, but you cannot access the resource directly through the Application Server, verify the health of the hosting Application Server and Web module:

- a. View the hosting Application Server and Web module in the administrative console to verify that they are up and running.
- b. Copy a simple HTML or JSP file (such as `SimpleJsp.jsp` in the WebSphere Application Server directory structure) to your Web module document root, and try to access it. If successful, the problem is with your resource.

View the logs of your Application Server to find out why your resource cannot be found or served .

4. If you can access the resource directly through the Application Server, but not through an HTTP server, the problem lies with the HTTP plug-in -- the component that communicates between the HTTP server and the WebSphere Application Server.
5. If the JSP file and the servlet output are served, but not static resources such as .html and image files, see the steps for enabling file serving.
6. If some kinds of resources display correctly, but you cannot display a servlet by its class name:
 - Verify that the servlet is in a directory in the Web module class path, such as in the `/Web_module_name.war/WEB-INF/classes` directory.
 - Verify that you specify the full class name of the servlet, including its package name, in the URL.
 - Verify that `/servlet` precedes the class name in the URL. For example, if the root context of a Web module is "myapp", and the servlet is `com.mycom.welcomeServlet`, then the URL reads:
`http://hostname/myapp/servlet/com.mycom.welcomeServlet`
 - For servlets or other resources served by mapped URLs, the URL is `http://hostname/Web module context root/mappedURL`.

Accessing a Web resource through the application server and bypassing the HTTP server

Starting with WebSphere Application Server Version 4.0, you can bypass the HTTP server and access a Web resource through the application server. It is not recommended to serve a production Web site in this way, but it provides a good diagnostic tool when it is not clear whether a problem resides in the HTTP server, WebSphere Application Server, or the HTTP plug-in.

To access a Web resource through the Application Server:

1. Determine the port of the HTTP service in the target application server.
 - a. In the WebSphere administrative console, click **Servers>Manage Application Servers**.
 - b. Select the target server, then under Additional Properties click **Web Container**.
 - c. Under the Additional Properties of the Web container, click **HTTP Transports**. You see the ports listed for virtual hosts served by the application server.
2. Use the HTTP transport port number of the application server to access the resource from a browser. For example, if the port is 9080, the URL is `http://hostname:9080/myAppContext/myJSP.jsp`.
3. If you are still unable to access the resource, verify that the HTTP transport port is in the "Host Alias" list:
 - a. Click **Application Servers > Your_ApplicationServer > Web Container > HTTP Transports** to check the Default virtual host and the HTTP transport ports used by this application server.
 - b. Click **Environment > Manage Virtual Hosts > default host > Host Aliases** to check if the HTTP transport port exists. Add an entry if necessary. For example, if the HTTP port for your application is server is 9080, add a host alias of `*:9082`.

Cannot uninstall an application or remove a node or application server

What kind of problem are you having?

- After uninstalling an application through wsadmin tool, the application continues to run and throws "DocumentIOException"
- The `removeNode` command does not remove the installed application from the deployment manager
- I cannot display the syntax for the `removeNode` command.

If none of these steps fixes your problem:

- Make sure that the application and its Web and EJB modules are in a stopped state before uninstalling.
- If you are uninstalling or installing an application using **wsadmin**, make sure that you are using the **-conntype NONE** option to invoke **wsadmin** and enable local mode. To use the **-conntype NONE** option, stop the hosting application server before uninstalling the application.
- Check to see if the problem has been identified and documented by looking at the available online support (hints and tips, technotes, and fixes).
- If you don't find your problem listed there contact IBM support

After uninstalling application through the wsadmin tool, the application throws "DocumentIOException"

If this exception occurs after the application was uninstalled using wsadmin with the **-conntype NONE** option:

- Restart the server or,
- Rerun the uninstall command without the **-conntype NONE** option.

The `removeNode` command does not remove the installed application from the deployment manager

If the applications were installed indirectly using the **addNode** program with the **-includeapps** option, then `removeNode` will not uninstall them, since they may be in use by other nodes. These applications must be explicitly uninstalled, for example through the administrative console.

I cannot display the syntax for the `removeNode` command

Unlike the `addNode` command, the `removeNode` command is valid with no parameters, so executing it will execute the operation, that is, remove the node, without displaying the command syntax.

To see the valid options for `removeNode`, execute `removeNode -?` or `removeNode -help`.

Chapter 27. Troubleshooting administration

Use this information if you are having problems with administrative functions.

Select the problem you are experiencing.

- I have problems bringing up or using the administrative console.
- I have problems starting or using the **wsadmin** command prompt.
- My Web module or application server dies or hangs.
- I get errors trying to configure and enable security.
- I have problems creating or using HTTP sessions.
- I have problems using tracing, logging, log files, or other troubleshooting features.
- I get errors connecting to the administrative console from a browser.

Administration and administrative console troubleshooting

In WebSphere Application Server products, administrative functions are supported by:

- The application server (such as server1) process
- The deployment manager process in the Network Deployment product

The process must be running to use the administrative console. The **wsadmin** command-line utility has a local mode that you can use to perform some administrative functions, even when the server process is not running.

What kind of problem are you seeing?

- “Server status and messages in the console view are not current”
- “Role-based authorization fails” on page 2386
- “When starting or stopping a server using a wsadmin interactive scripting session, you receive an exception indicating read timed out” on page 2387
- “Problems starting or using the administrative console or wsadmin utility” on page 2387

Server status and messages in the console view are not current

When connecting to an Application Server that uses a Simple Object Access Protocol (SOAP) connection for a long time, the following problems begin to occur:

- Under the status column in the Servers view on an administrative console panel, the status of the server does not refresh.
- Server messages are not updated in the administrative console.
- A decrease of system resources occurs as numerous ports are created and left in the TIME_WAIT state.

This problem persists even after you restart the server or you start another server that uses the SOAP connection port.

The problem occurs because the SOAP connector does not support connection pooling. If the Application Server has many ongoing operations that use the SOAP connector, the Application Server quickly opens and closes many ports. Due to the nature of the underlying TCP/IP protocol, these ports remain in the TIME_WAIT state for some time before the operating system can reclaim them. The number of ports that WebSphere Application Server opens can exceed the limit that the operating system imposes. Under this condition, the opening of additional ports fails through the SOAP connector until the operating system reclaims ports.

Use the following options to work around the problem:

- Increase the operating system limits on the number of ports.

- For WebSphere Application Server Toolkit, the wsadmin utility, or Java applications that use the Java Management Extension (JMX) connectors, switch to the Remote Method Invocation (RMI) connector.
- Wait until few or no ports are in the TIME_WAIT state before performing new operations through WebSphere Application Server Toolkit or the administrative console.

Role-based authorization fails

When you make a Java Management Extension (JMX) call such as `getAttribute`, `setAttribute`, `invoke`, and so on in your application, the caller requires an administrative role with sufficient permissions. The required role depends on the MBean attribute or method that the JMX caller calls and can be one of administrator, configurator, monitor, or operator. If one of the administrative roles is not assigned to the caller, or if the role is assigned, but the caller does not have the required permissions, the application receives a role-based authorization failure, for example:

```
SECJ0305I: Role based authorization check failed for securityname server.domain.name:3890/user.id,
accessId user:server.domain.name:3890/uid=user.id,ou=xxx,dc=yyy,dc=zzz while invoking method
getNodeName on resource Server and module Server.
```

If the caller of the application cannot be assigned one of the administrative roles, the application can log in with one of the roles on behalf of the caller. For example:

```
try
{
    // Create a LoginContext to authenticate a user ID and password.
    javax.security.auth.login.LoginContext
    lc = new javax.security.auth.login.LoginContext("WSLogin",
    new com.ibm.websphere.security.auth.callback.WSCallbackHandlerImpl("adminuser",
    "adminpassword"));

    // perform the login
    lc.login();

    // Get the authenticated subject.
    javax.security.auth.Subject adminSubject = lc.getSubject();

    // Define the action that will take place using the authenticated Subject
    // You can define this action anywhere in the code, the action
    // is reference in the WSSubject.doAs that follows.
    java.security.PrivilegedAction adminAction = new java.security.PrivilegedAction()
    {
        public Object run()
        {
            try
            {
                // Get the WebSphere AdminService.
                AdminService adminservice = AdminServiceFactory.getAdminService();

                // Get the WebSphere Admin Local Server MBean instance.
                ObjectName objectname = adminservice.getLocalServer();

                // Get the Node name.
                String nodeName = (String)adminservice.getAttribute(objectname, "nodeName");

                // Get the Application Server name.
                String serverName = (String)adminservice.getAttribute(objectname, "name");

                // Get the Application Server Process ID.
                String serverPid = (String)adminservice.getAttribute(objectname, "pid");

                // Return a result, for this example, just return the serverPid.
                return serverPid;
            }
            catch (Exception e)
            {
                e.printStackTrace();
            }
        }
    };
}
```

```

    }
    return null;
  }
});

// Invoke an AdminClient resource using the authenticated subject.
// This example demonstrates the action of creating an
// administrative client and returning a String value to use outside
// the doAs block.
String myData = (String)
    com.ibm.websphere.security.auth.WSSubject.doAs(adminSubject, adminAction);

// use "myData" later on....
}
catch (javax.security.auth.login.LoginException e)
{
    e.printStackTrace();
}

```

When starting or stopping a server using a wsadmin interactive scripting session, you receive an exception indicating read timed out

When starting or stopping a server using a wsadmin interactive scripting session, you receive an exception indicating read timed out, for example:

```

WASX7015E: Exception running command: "$AdminControl startServer server1 Node1";
exception information: com.ibm.websphere.management.exception.ConnectorException
org.apache.soap.SOAPException: [SOAPException: faultCode=SOAP-ENV:Client; msg=Read
timed out; targetException=java.net.SocketTimeoutException: Read timed out]

```

This exception occurs because the timeout value is too small. Increase the timeout value specified by the `com.ibm.SOAP.requestTimeout` property in the `soap.client.props` file in the `app_server_root/profiles/profile_name/properties` directory for a single server edition or in the `app_server_root/profiles/profile_name/properties` directory for a network deployment installation. The value you choose depends on a number of factors such as the size and the number of the applications installed on the server, the speed of your machine, and the level of usage of your machine. The default value of the `com.ibm.SOAP.requestTimeout` property is 180 seconds.

Problems starting or using the administrative console or wsadmin utility

If you have problems starting or using the administrative console or wsadmin utility, verify that the supporting server process is started and that it is healthy.

- For the application server process, look at these files:
 - `app_server_root/profiles/profile_name/logs/server_name/startServer.log` for the message that indicates that the server started successfully: `ADMU3000I: Server server1 open for e-business; process id is nnnn..`
 - The server log files for the message that indicates that the server started successfully: `WSVR0001I: Server server open for e-business.`
- For the Network Deployment product, look at these files:
 - `app_server_root/profiles/profile_name/logs/dmgr/startServer.log` for the message that indicates that the server started successfully: `ADMU3000I: Server dmgr open for e-business; process id is nnnn.`
 - The server log files for this message indicating that the server started successfully: `WSVR0001I: Server dmgr open for e-business.`
- For the z/OS product, check the job output.
- Look up any error messages in these files in the message reference table. Select the **Reference** view in the information center navigation, and click **Messages**. A message like `WASX7213I: This scripting client is not connected to a server process when trying to start wsadmin` indicates that either the server process is not running, the host machine where it is running is not accessible, or that the port or server name that the wsadmin utility uses is incorrect.

- Verify that you are using the right port number to communicate with the administrative console or the wsadmin server:
 - Look in the joblogs file.
 - The line ADMC0013I: SOAP connector available at port *nnnn* indicates the port that the server is using to listen for wsadmin functions.
 - The com.ibm.ws.scripting.port property in the *app_server_root/profiles/profile_name/properties/wsadmin.properties* file controls the port used by the wsadmin utility to send requests to the server.
 - If port value is different from the value shown in the SystemOut.log file, either change the port number in the wsadmin.properties file, or specify the correct port number when starting the wsadmin utility by using the -port *port_number* property on the command line.

The com.ibm.ws.scripting.port property in the *app_server_root/profiles/profile_name/properties/wsadmin.properties* file controls the port used by the wsadmin utility to send requests to the server.
 - If the port value is different than the one specified in the Web address for the administrative console, change the Web address in the browser to the correct value. The default value is <http://localhost:9060/ibm/console>.
- Use the **telnet** command to test that the host name where the application server or deployment manager is running, is reachable from the system where the browser or wsadmin program is used. If you can ping the host name, no firewall or connectivity issues exist.
- If the host where the application server or deployment manager is running is remote to the machine from which the client browser or wsadmin command is running, ensure that the appropriate host name parameter is correct. Verify:
 - The host name in the browser Web address for the console.
 - The -host *host name* option of the **wsadmin** command that is used to direct the wsadmin utility to the right server

If none of these steps solves the problem, see if the specific problem you are having is addressed in the Installation completes but the administrative console does not start topic. Check to see if the problem has been identified and documented using the links in the Diagnosing and fixing problems: Resources for learning topic. If you do not see a problem that resembles yours, or if the information provided does not solve your problem, contact IBM support for further assistance.

For current information available from IBM Support on known problems and their resolution, see the following topics on the IBM support page:

- Administrative Console
- Administrative Scripting Tools
- System management

IBM Support has documents that can save you time gathering the information that is needed to resolve this problem. Before opening a PMR, see the following topics on information gathering on the IBM support page:

- Administrative Console
- Administrative Scripting Tools
- System management

Installation completes but the administrative console does not start

This topic discusses problems that you can encounter when you attempt to access the console.

What kind of problem are you having?

- “An Internal Server Error, Page cannot be found, 404, or similar error occurs trying to view the administrative console” on page 2389
- “An Unable to process login. Check user ID and password and try again. error occurs when trying to access the administrative console page” on page 2389

- “The directory paths in the administrative console contain strange characters”

If you can bring up the browser page, but the administrative console behavior is inconsistent, error prone, or unresponsive, try upgrading your browser. Older browsers might not support all the features of the administrative console. For a listing of supported Web browsers, see the Supported hardware and software Web page.

IBM Support has documents and tools that can save you time gathering information needed to resolve problems as described in Troubleshooting help from IBM. Before opening a problem report, see the Support page:

- http://www.ibm.com/software/webservers/appserv/zos_os390/support/

An Internal Server Error, Page cannot be found, 404, or similar error occurs trying to view the administrative console

Here are some steps to try if you are unable to view the administrative console:

- Verify that the application server which supports the administrative console is up and running.
 - For a base configuration, the administrative console is deployed by default on server1. Before viewing the administrative console, you must verify that server1 is running. Do so by issuing the following command on the MVS console to list active processes:

```
D A,L
```

Note: See z/OS MVS System Commands for information on how to use MVS operator commands. Check for the application server procedure name of BB05ACR with the server short name of BB0S001. If it is not running, enter the following command on the MVS console:

```
START appserver_proc_name,JOBNAME=server_short_name,
      ENV=cell_short_name.node_short_name.server_short_name
```

Example:

```
START BB06ACR,JOBNAME=BB0S001,ENV=PLEX1.SY1.BB0S001
```

- For a network deployment configuration, the deployment manager runs the administrative console. For example, to start the deployment manager, you can issue the following command from the MVS console:

```
START BB05DCR,JOBNAME=BB0DMGR,ENV=PLEX1.PLEX1.BB0DMGR
```
- View the joblog or sysprint for the application server or deployment manager to verify that the server supporting the administrative console has started.
- Check the Web address you use to view the console.
- Try to eliminate connection, address and firewall issues by pinging the server machine from a command prompt, using the server name in the URL.

An Unable to process login. Check user ID and password and try again. error occurs when trying to access the administrative console page

This error indicates that security is enabled for WebSphere Application Server, and that the user ID or password supplied is either not valid or not authorized to access the console.

To access the console:

- If you are the administrator, use the ID defined as the security administrative ID. This ID is stored in the WebSphere Application Server security.xml file.

The directory paths in the administrative console contain strange characters

Directory paths that are used for class paths or resources specified in an assembly tool, in configuration files, or elsewhere that contain strange characters when they are viewed in the administrative console might result from the Java run time interpreting a backslash (\) as a control character.

To resolve, make sure you have no back slashes in your class paths. Replace any back slashes with forward slashes.

Errors connecting to the administrative console from a browser

This topic describes problems that you can have when logging into the administrative console from a browser.

Review the following information to resolve your browser problem.

If you are able to bring up the browser page, but the console behavior is inconsistent, error-prone, or unresponsive, try upgrading the browser you are using. Older browsers may not support the administrative console's features. For a listing of supported Web browsers, see the Supported hardware and software Web page.

Check to see if the problem has been identified and documented using the links in Diagnosing and fixing problems: Resources for learning. If you do not see a problem that resembles yours, or if the information provided does not solve your problem, contact IBM support for further assistance.

Check the following list for your problem and how to solve it:

- When a single user that uses multiple instances of the Mozilla browser logs into the administrative console, the first user ID that logs into the administrative console is the current user.
- A user on Mozilla browser Version 1.4 selects a check box on a collection table, presses Enter, and receives an error.
- A user on Mozilla browser Version 1.4 enters an invalid ID or password, presses Enter, and receives an error message

When a single user that uses multiple instances of the Mozilla browser logs into the administrative console, the first user ID that logs into the administrative console is the current user.

When a single user logged into an operating system tries to use multiple instances of the Mozilla browser, the first user ID that logs into the administrative console is the current user. This situation occurs because the browser windows share a single process.

To resolve the problem, do one of the following actions:

- Have single users logged into an operating system use a single instance of the Mozilla browser to log into the administrative console.
- If the operating system allows multiple users on an operating system, have each user log into the operating system with a different user ID and bring up a single instance of the Mozilla browser.

A user on Mozilla browser Version 1.4 selects a check box on a collection table, presses Enter, and receives an error.

A user on Mozilla browser Version 1.4 selects a check box on a collection table, presses Enter, and receives an error.

To resolve the problem, do one of the following actions:

- Explicitly select a button of interest on the administrative console panel instead of pressing Enter.
- Use a later version of a supported Mozilla browser.
- Use a supported version of the Microsoft Internet Explorer browser.

A user on Mozilla browser Version 1.4 enters an invalid ID or password, presses Enter, and receives an error message

A user on Mozilla browser Version 1.4 enters an invalid user ID or password, presses Enter, and receives an error message. Clicking OK fails to refresh the administrative login screen

To resolve the problem, do one of the following actions:

- Use a later version of a supported Mozilla browser.
- Use a supported version of the Microsoft Internet Explorer browser.

Web server plug-in troubleshooting tips

The following topics might help you diagnose problems with the Web server plug-ins.

If you are having problems using a Web server plug-in, try these steps:

- Review the file *plugins_root/logs/web_server_name/http_plugin.log* for clues. Look up any error or warning messages in the message table.
- Review your Web server's error and access logs to see if the Web server is having a problem:
 - IBM HTTP Server and Apache: *access.log* and *error.log*.
 - Domino Web server: *httpd-log* and *httpd-error*.
 - Sun Java System: *access* and *error*.
 - Microsoft IIS: *timedatestamp.log*.

If these files don't reveal the cause of the problem, follow these additional steps.

Plug-in Problem Determination Steps

The plug-in provides very readable tracing which can be beneficial in helping to figure out the problem. By setting the *LogLevel* attribute in the *config/plugin-cfg.xml* file to **Trace**, you can follow the request processing to see what is going wrong. At a high level:

1. The plug-in gets a request.
2. The plug-in checks the routes defined in the *plugin-cfg.xml* file.
3. It finds the server group.
4. It finds the server.
5. It picks the transport protocol, HTTP or HTTPS.
6. It sends the request.
7. It reads the response.
8. It writes it back to the client.

You can see this very clearly by reading through the trace for a single request:

- The first step is to determine if the plug-in has successfully loaded into the Web server.
 - Check to make sure the *http_plugin.log* file has been created.
 - If it has, look in it to see if any error messages indicate some sort of failure that took place during plug-in initialization. If no errors are found look for the following stanza, which indicates that the plug-in started normally. Ensure that the timestamps for the messages correspond to the time you started the Web server:

```
[Thu Jul 11 10:59:15 2002] 000009e 000000b1 - PLUGIN: -----System Information-----
[Thu Jul 11 10:59:15 2002] 000009e 000000b1 - PLUGIN: Bld date: Jul 3 2002, 15:35:09
[Thu Jul 11 10:59:15 2002] 000009e 000000b1 - PLUGIN: Web server: IIS
[Thu Jul 11 10:59:15 2002] 000009e 000000b1 - PLUGIN: Hostname = SWEETTJ05
[Thu Jul 11 10:59:15 2002] 000009e 000000b1 - PLUGIN: OS version 4.0, build 1381, 'Service Pack 6'
[Thu Jul 11 10:59:15 2002] 000009e 000000b1 - PLUGIN: -----
```

- Some common errors are:

lib_security: loadSecurityLibrary: Failed to load gsk library

Either GSKit did not get installed or the wrong version of GSKit got installed. To determine which situation occurred:

If you cannot find the appropriate file, try reinstalling the plug-in with the correct GSKit version to see if this fixes the problem.

ws_transport: transportInitializeSecurity: Keyring wasn't set

The HTTPS transport defined in the configuration file was prematurely terminated and did not contain the Property definitions for the keyring and stashfile. Check your XML syntax for the line number given in the error messages that follow this one to make sure the Transport element contains definitions for the keyring and stashfiles before it is terminated.

- If the http_plugin.log file is not created, check the Web server error log to see if any plug-in related error messages have been logged there that indicate why the plug-in is failing to load. Typical causes of this can include failing to correctly configure the plug-in with the Web server environment. Check the documentation for configuring the Web server that you are using with the Web server plug-in.
- Determine whether there are network connection problems with the plug-in and the various application servers defined in the configuration. Typically you will see the following message when this is the case:

ws_common: webspHEREGetStream: Failed to connect to app server, OS err=%d

Where %d is an OS specific error code related to why the connect() call failed. This can happen for a variety of reasons.

- Ping the machines to make sure they are properly connected to the network. If the machines cannot be pinged, there is no way for the plug-in to contact them. Possible reasons for this problem include:
 - Firewall policies that limit the traffic from the plug-in to the application server.
 - The machines are not on the same network.
- If you are able to ping the machines then the probable cause of the problem is that the port is not active. The port might not be active because the application server or cluster is not started or the application server has gone down for some reason. To verify that this is the problem, you can try to manually telnet into the port that the connect is failing on. If you cannot telnet into the port the application server is not up and that problem needs to be resolved before the plug-in can successfully connect.
- Determine whether other activity on the machines where the servers are installed is impairing the ability of the server to service a request. Check the processor utilization as measured by the task manager, processor ID, or some other outside tool to see if it:
 - Is not what was expected.
 - Is erratic rather than a constant.
 - Shows that a newly added member of the cluster is not being utilized.
 - Shows that a failing member that has been fixed is not being utilized.
- Check the administrative console for server status.

Check the administrative console to ensure that the application servers are started. View the administrative console for error messages.
- In the administrative console, select the problem application server and view its installed applications to verify that they are started.

If none of these steps solves the problem:

- For specific problems that can cause web pages and their contents not to display, see Web resource (JSP file, servlet, html file, image, etc) will not display in the information center.
- Check to see if the problem has been identified and documented using the links in Diagnosing and fixing problems: Resources for learning.
- If you do not see a problem that resembles yours, or if the information provided does not solve your problem, contact IBM support for further assistance.

For current information available from IBM Support on known problems and their resolution, see the following topics on the IBM support page:

- HTTP transport
- HTTP plug-in
- HTTP plug-in remote install

For current information available from IBM Support on known problems and their resolution, see the IBM Support page. You should also refer to this page before opening a PMR because it contains documents that can save you time gathering information needed to resolve a problem.

You might find the following topics on the IBM support page helpful:

- HTTP plug-in
- HTTP plug-in remote install

Cannot restart the Deployment Manager monitoring policy

The Deployment Manager monitoring policy is permanently set to STOPPED and cannot be changed. Therefore, if the Deployment Manager fails it will never be restarted by WebSphere Application Server monitoring.

To correct the problem, use the z/OS Automatic Restart Facility (ARM) to monitor and restart the Deployment Manager. See z/OS Automatic Restart Facility for information on ARM.

Errors setting up multiserver environments

Use this information to troubleshoot problems with setting up multiserver environments.

What kind of problem are you seeing?

- “After creating and starting a cluster, the cluster does not start, and logs show that servers in the cluster are not found” on page 2394
- “One or more nodes do not display in the administrative console” on page 2394
- “The addNode command fails” on page 2394
- “Application files are not present on all nodes” on page 2395
- “After downloading the Network Deployment plug-in to my system, my server does not start” on page 2395
- “In a clustered environment, a server with debug mode enabled does not start” on page 2395

If none of these problem solution descriptions fixes your problem:

1. Browse the logs of the problem deployment manager and applications servers.
 - a. Look up any error messages by selecting the **Reference** view of the information center navigation and expanding **Messages** in the navigation tree.
 - b. If Java exceptions are displayed in the log files, try to determine the actual subcomponent directly involved in the problem by examining the trace stack and looking for a WebSphere Application Server-related class near the top of the stack (names beginning with `com.ibm.websphere` or `com.ibm.ws`) that created the exception. If appropriate, review the steps for troubleshooting the appropriate subcomponent in the Troubleshooting by component: what is not working? topic.
For example, if the exception seems to be created by a class in the `com.ibm.websphere.naming` package, review the Naming services component troubleshooting tips topic.
2. Ensure that all the machines in your configuration have TCP/IP connectivity to each other by running the **ping** command:
 - a. From each physical server to the deployment manager
 - b. From the deployment manager to each physical server
3. Although the problem is occurring in a clustered environment, the actual cause might be indirectly related, or unrelated to clustering. Investigate all relevant possibilities:
 - a. If an enterprise bean on one or more servers is not serving requests, review the “Cannot access an enterprise bean from a servlet, a JSP file, a stand-alone program, or another client” on page 230 and Cannot look up an object hosted by WebSphere Application Server from a servlet, JSP file, or other client topics.
 - b. If problems seem to occur after enabling security, review the Access problems after enabling security topic.

- c. If an application server stops responding to request, or spontaneously fails (its process closes), review the Web module or application server stops processing requests topic.
 - d. If SOAP requests are not served by some servers, review the topic.
 - e. If you have problems installing or deploying an application on servers on one or more nodes, review the “Errors or problems deploying, installing, or promoting applications” on page 2371 topic.
4. If your topology consists of a Windows-based deployment manager with UNIX-based servers, browse any recently-updated `.xml` and `.policy` files on the UNIX-based platform using the vi editor to ensure that Control-M characters are not present in the files. Edit these files using the vi editor on the UNIX-based platform, to avoid inserting these characters.
 5. Check the steps for troubleshooting the workload management component.
 6. Check to see if the problem is identified and documented by looking at available online support (hints and tips, technotes, and fixes).

After creating and starting a cluster, the cluster does not start, and logs show that servers in the cluster are not found

This error can occur when the configuration is not synchronized from the deployment manager to a node. If ***auto synchronization*** is enabled, wait until the synchronization has run. If you are using manual synchronization, explicitly request a synchronization to each node on the cluster.

To determine whether synchronization has occurred, look at the configuration on the node machines using the administrative console and verify that the new cluster members are defined on each node.

One or more nodes do not display in the administrative console

This problem can occur when a basic connectivity problem exists between the deployment manager server and other servers in the topology. Look for the `serverindex.xml` file in the deployment manager directory structure:

- If the problem node does not display in the list, review the steps for adding a node to the cluster.
- If the problem node does display in the list:
 - From the deployment manager server, ping the server name as it displays in the list. If the **ping** command indicates no communication, verify that the host name is correct in the list, correct it if necessary, then restart the deployment manager.
 - If the name that displays in the list is the short name, ping the fully qualified network name. If the corrected name works, update the list, and restart the deployment manager.
 - If the problem server uses Dynamic Host Configuration Protocol (DHCP), try replacing the logical host name with the IP address and restart the deployment manager. If this action resolves the problem, be aware that you must change the `serverindex.xml` file each time the problem server address changes, and potentially each time the problem machine is rebooted. To avoid this problem, consider assigning a static IP address to the server.
- If you still cannot establish communication between the servers, contact your network administrator to resolve the problem, and restart the deployment manager after the problem is corrected.

The addNode command fails

This error can occur when the deployment manager Domain Name Server (DNS) configuration is set up improperly. The default installation on Linux systems uses the loopback address (127.0.0.1) as the default host address. To verify this problem, query the host name of the suspect machine. If the query returns localhost 127.0.0.1, or if the file transfer traces at the node show that the node is trying to upload files to a Web address that includes 127.0.0.1, the node has an incorrect DNS configuration.

To correct this problem, update the `/etc/hosts` file or the name service configuration file, `/etc/nsswitch.conf`, to query the Domain Name Server or Network Information Server (NIS) before searching hosts.

Application files are not present on all nodes

In the WebSphere Application Server Network Deployment environment, application binary files are transferred to the individual nodes where applications are supported as part of the node synchronization operation. During node synchronization, application files are only propagated if their deployment descriptors specify `enableDistribution=true`. This flag is specified as part of the application installation procedure in the administrative console, and is stored as a property in the `app_server_root/config/cells/cell_name/applications/application_name/deployment.xml` file.

To confirm this problem, check to see whether the `enableDistribution` flag is set. If it is already set to `true`, ensure that the target node is configured to run auto file synchronization.

If both of these settings are correct and the problem persists, manually perform a synchronization. If the application files still do not display in the installation directory, use the `EARExpander` tool in `app_server_root/bin` directory to expand the EAR file from the repository to the installation destination. On remote nodes, the repository displays in the `config/cells/cell_name/applications/application_name.ear/` directory.

After downloading the Network Deployment plug-in to my system, my server does not start

If you experience this situation, the most likely cause is that the transport paths in the plug-in must be modified to work in your environment. See the [Example: Manually editing transport settings in the server.xml file](#) topic for information on how to modify these settings.

In a clustered environment, a server with debug mode enabled does not start

This problem occurs when the following three conditions exist:

- Multiple server processes are configured to run on the same node
- More than one server has debug mode enabled
- The debug arguments for more than one of the servers are left at the default values, so that more than one server in the node is trying to use the same debug port (port number 7777).

The server does not start because multiple servers processes running on the same physical host machine with debug enabled cannot use the same debug port.

To correct this problem, for each server:

1. On the administrative console click **Server > Application servers > server_name > Java and Process Management > Process Definition > Java Virtual Machine**.
2. Update the debug argument so that the address of the debug port (`address=port number`) is unique for each server process.

Workload management component troubleshooting tips

If the workload management component is not properly distributing the workload across servers in multi-node configuration, use the following options to isolate the problem.

- Ensure that the workload is distributed across clustered servers
- Resolve any problems with the multiserver Deployment Manager environment setup
- “Eliminate environment or configuration issues”
- “Resolve problem or contact IBM support” on page 2396

Eliminate environment or configuration issues

Determine if the servers are capable of serving the applications for which they have been enabled. Identify the cluster that has the problem.

- Are there network connection problems with the members of the cluster or the administrative servers, for example deployment manager or node agents?
 - If so, ping the machines to ensure that they are properly connected to the network.
- Is there other activity on the machines where the servers are installed that is impacting the servers ability to service a request? For example, check the processor utilization as measured by the task manager, processor ID, or some other outside tool to see if:
 - It is not what is expected, or is erratic rather than constant.
 - It shows that a newly added, installed, or upgraded member of the cluster is not being utilized.
- Are all of the application servers you started on each node running, or are some stopped?
- Are the applications installed and operating?
- If the problem relates to distributing workload across container-managed persistence (CMP) or bean-managed persistence (BMP) enterprise beans, have you configured the supporting JDBC providers and “Data sources” on page 557 JDBC data source on each server? For problems relating to data access, review the topic “Cannot access a data source” on page 766.

If you are experiencing workload management problems related to HTTP requests, such as HTTP requests not being served by all members of the cluster, be aware that the HTTP plug-in balances the load across all servers that are defined in the PrimaryServers list if affinity has not been established. If you do not have a PrimaryServers list defined then the plug-in load balances across all servers that are defined in the cluster if affinity has not been established. If affinity has been established, the plug-in should go directly to that server for all requests.

For workload management problems relating to enterprise bean requests, such as enterprise bean requests not getting served by all members of a cluster:

- Are the weights set to the allowed values?
 - For the cluster in question, log onto the administrative console and:
 1. Select **Servers > Clusters**.
 2. Select your cluster from the list.
 3. Select **Cluster members**.
 4. For each server in the cluster, click on *server_name* and note the assigned weight of the server.
 - Ensure that the weights are within the valid range of 0-20. If a server has a weight of 0, no requests are routed to it. Weights greater than 20 are treated as 0.

The remainder of this article deals with enterprise bean workload balancing only. For more help on diagnosing problems in distributing Web (HTTP) requests, view the topics “Web server plug-in troubleshooting tips” on page 2391 and “A Web resource does not display” on page 2382.

Resolve problem or contact IBM support

If the client logs indicate an error in WLM, collect the following information and contact IBM support.

- A detailed description of your environment.
- A description of the symptoms.
- The server log files for all servers in the cluster.
- A description of what the client is attempting to do, and a description of the client. For example, 1 thread, multiple threads, servlet, J2EE client, etc.

If none of these steps solves the problem, check to see if the problem has been identified and documented using the links in Diagnosing and fixing problems: Resources for learning. If you do not see a problem that resembles yours, or if the information provided does not solve your problem, contact IBM support for further assistance.

If you do not find your problem listed there, contact IBM Support.

Workload is not getting distributed

This information might help you diagnose the trouble if you are having a workload distribution problem.

What kind of problem are you seeing?

- “HTTP requests are not distributed to all servers”
- “Enterprise bean requests are not distributed to all servers” on page 2398
- “A failing server still receives enterprise bean requests (failover is not completed)” on page 2398
- “Stopped or hung servers do not share the workload after being restored” on page 2398

If none of these problem solution descriptions fix your problem:

1. Browse the JVM logs of the problem deployment manager and application servers:
 - a. Look up any error messages by selecting the **Reference** view of the information center navigation and expanding **Messages** in the navigation tree.
 - b. If Java exceptions appear in the log files, try to determine the actual subcomponent that is directly involved in the problem by examining the trace stack and looking for a WebSphere Application Server-related class near the top of the stack (names beginning with com.ibm.websphere or com.ibm.ws) that created the exception. If appropriate, review the steps for troubleshooting the appropriate subcomponent under the Troubleshooting by component: what is not working? topic.
For example, if the exception appears to have been thrown by a class in the com.ibm.websphere.naming package, review the Naming Services Component troubleshooting tips topic.
2. Ensure that all the machines in your configuration have TCP/IP connectivity to each other by running the **ping** command:
 - a. From each physical server to the deployment manager
 - b. From the deployment manager to each physical server
3. Although the problem is happening in a clustered environment, the actual cause might be only indirectly related, or unrelated, to clustering. Investigate all relevant possibilities:
 - a. If an enterprise bean on one or more servers is not serving requests, review the Cannot access an enterprise bean from a servlet, JSP, stand-alone program, or other client and Cannot access an object hosted by WebSphere Application Server from a servlet, JSP file, or other client topics.
 - b. If problems seem to appear after enabling security, review the Errors or access problems after enabling security topic.
 - c. If an application server stops responding to requests, or spontaneously dies (its process closes), review the Web module or application server dies or hangs topic.
 - d. If SOAP requests are not being served by some or all servers, review the Errors returned to client trying to send a SOAP request topic.
4. Check to see if the problem is identified and documented by looking at available online support (hints and tips, technotes, and fixes).

HTTP requests are not distributed to all servers

If HTTP requests are not being distributed to all servers:

- Check your Primary Servers list. The plug-in load balances across all servers that are defined in the Primary Servers list, if affinity has not been established. If you do not have a Primary Servers list defined, the plug-in load balances across all servers defined in the cluster, if affinity has not been established. In the case where affinity has been established, the plug-in should go directly to that server, for all requests within the same HTTP session.
- If some servers are servicing requests and one or more others are not, try accessing a problem server directly to verify that it works, apart from workload management issues. If that does not work:
 - Use the administrative console to ensure that the affected server is running.
 - See the article “A Web resource does not display” on page 2382 for more information.
- See the article HTTP plug-in component troubleshooting tips for more information.

Enterprise bean requests are not distributed to all servers

If a client cannot reach a server in a cluster thought to be reachable, a server might be marked unusable, or is down. To verify this:

- Use the administrative console to verify that the server is started. Try starting it, or if started, stop and restart it.
- Browse the administrative console and verify that the node that runs the server having the problem appears. If it does not:
 - Review the steps for adding a node to a cluster.
 - Review the steps in the section *One or more nodes do not show up in the administrative console*.
- If possible, try accessing the enterprise bean directly on the problem server to see if there is a problem with TCP/IP connectivity, application server health, or other problem not related to workload management. If this fails, review the topic *Cannot access enterprise bean from a servlet, JSP, stand-alone program , or other client*.

A failing server still receives enterprise bean requests (failover is not completed)

Some possible causes of this problem are:

- The client might have been in a transaction with an enterprise bean on the server that went down. Check the JVM logs of the application server hosting the problem enterprise bean instance. If a request is returned with **CORBA SystemException COMM_FAILURE org.omg.CORBA.completion_status.COMPLETED_MAYBE**, this might be working as designed. The design is to let this particular exception flow back to the client, since the transaction might have completed. Failing over this request to another server could result in this request being serviced twice.
- If the requests sent to the servers come back to the client with any other exceptions consistently, it might be that no servers are available.

Stopped or hung servers do not share the workload after being restored

This error occurs when the servers that were unavailable are not recognized by the Workload Management component after they are restored. There is an *unusable* interval determined by the property `com.ibm.websphere.wlm.unusable.interval` during which the workload manager waits to send to a server that has been marked unusable. By default this is 5 minutes.

You can confirm that this is the problem by ensuring that servers that were down are now up and capable of servicing requests. Then wait for the unusable interval to elapse before checking to determine whether failover occurs.

Problems starting or using the wsadmin command

Use this information if you are having problems starting or using the wsadmin tool.

What kind of problem are you having?

- WASX7016E, WASX7017E, or WASX7209I: Jython scripting language error
- "WASX7023E: Error creating "SOAP" connection to host" or similar error trying to launch wsadmin command line utility.
- "com.ibm.bsf.BSFException: error while evaluating Jacl expression: no such method "<command name>" in class com.ibm.ws.scripting.AdminConfigClient" returned from wsadmin command.
- WASX7022E returned from running "wsadmin -c ..." command, indicating invalid command.
- com.ibm.ws.scripting.ScriptingException: WASX7025E: String "" is malformed; cannot create ObjectName.
- WASX701E: Exception received while running file "*scriptName.jacl*"; exception information: com.ibm.bsf.BSFException: error while evaluating Jacl expression: missing close-bracket
- Unexpected error CWSIV0806E in WebSphere log following deletion of an outbound service
- Separator exception
- Enabling authentication in the file transfer service

- The format of "\$AdminConfig list" output has changed for V6.0
- You are not prompted for user ID and password after applying V6.0.2 service if you use an existing 6.0 profile
- Required ports not defined when a new V5.0/V5.1 server is created
- When running the \$AdminApp searchJNDIReferences command with the Java Naming and Directory Interface (JNDI) name of a message destination, the message destination reference is not returned
- AWXJR0006E: Exception received when configuring JACC provider for the Tivoli Access Manager
- WASX7017E: Exception received while running file "<application stopping script>"; exception information: javax.management.MBeanException com.ibm.ws.exception.RuntimeWarning: Application <appname> not started

If you do not see your problem here:

- If you are not able to enter wsadmin command mode, try running **wsadmin -c "\\$Help wsadmin"** for help in verifying that you are entering the command correctly.
- If you can get the wsadmin command prompt, enter **\$Help help** to verify that you are using specific commands correctly.
- wsadmin commands are a superset of Jacl (Java Command Language), which is in turn a Java-based implementation of the Tcl command language. For details on Jacl syntax beyond wsadmin commands, refer to the Tcl developers' site, <http://www.tcl.tk>. For specific details relating to the Java implementation of Tcl, refer to <http://www.tcl.tk/software/java>.
- Browse the *install_dir/profiles/profile_name/logs/wsadmin.traceout* file for clues.
 - Keep in mind that wsadmin.traceout is refreshed (existing log records are deleted) whenever a new wsadmin session is started.
 - If the error returned by wsadmin does not seem to apply to the command you entered, for example, you receive WASX7023E, stating that a connection could not be created to host "myhost," but you did not specify "-host myhost" on the command line, examine the properties files used by wsadmin to determine what properties are specified. If you do not know what properties files were loaded, look for the WASX7326I messages in the wsadmin.traceout file; there will be one of these messages for each properties file loaded.

WASX7016E, WASX7017E, or WASX7209I: Jython scripting language error

The following errors may occur when you run this Jython script:

Jython script

```
"profile_root/bin/wsadmin.sh -lang jython -profile profile_name -host host_name -f
script_file.py"
```

Error Messages

```
WASX7209I: Connected to process "server1" on node
node_name using SOAP connector; The type of process is:
UnManagedProcess
```

```
WASX7016E: Exception received while reading file
"script_file.py"; exception information:
sun.io.MalformedInputException
```

```
WASX7017E: Exception received while running file
"script_file.py"; exception information:
com.ibm.bsf.BSFException: exception from Jython: Traceback
(innermost last): File "<string>" line 89, in ? NameError: log
```

These errors can occur because there are UTF-8 characters in the file that are not valid. The default codepage for RHEL 3 is UTF-8 (en_US.UTF-8). When doing a text file read through Java™ code, the program assumes all characters are UTF-8 encoded. There might be one or more characters in the file that are not part of the UTF-8 specification, causing the load to fail. An easy way to determine if a character that is not valid is causing the error is to enter export LANG=C and run the script again. If you determine that the problem is a character that is not valid:

1. Open a new text reader on the file.
2. Read it one character at a time.
3. Print the character that is not valid.
4. When you press the back characters, you get the exception and will then know which of the characters is causing the error.
5. Remove any characters that are not valid, then run the script again

"WASX7023E: Error creating "SOAP" connection to host" or similar error trying to launch wsadmin command line utility

By default, the wsadmin utility attempts to connect to an application server at startup. This is because some commands act upon running application servers. This error indicates that no connection could be established.

To resolve this problem:

- If you are not sure whether an application server is running, start it by entering **startserver.sh server short name** from the command prompt. If the server is already running, you will see an error similar to "ADMU3027E: An instance of the server is already running".
- If you are running a z/OS configuration, you will first need to start the deployment manager by issuing the following command from a command prompt on the MVS console:

```
START dmgr_proc_name,JOBNAME=server_short_name,
      ENV=cell_short_name.node_short_name.server_short_name
```

Note: This command must be entered on a single line. It is split here for display purposes.

Then you can launch wsadmin immediately to connect to the deployment manager, or start a node and application server to connect to.

- If an application server is running and you still get this error:
 - If you are running remotely (that is, on a different machine from the one running WebSphere Application Server), you must use the **-host hostname** option to the wsadmin command to direct wsadmin to the right physical server.
 - If you are using the **-host** option, try pinging the server machine from the command line from the machine on which you are trying to launch wsadmin to verify there are no issues of connectivity such as firewalls.
 - verify that you are using the right port number to connect to the WebSphere Application Server process:
 - If you are not specifying a port number (using the **-port** option) when you start the wsadmin tool, the wsadmin tool uses the default port specified in *install_dir/profiles/profile_name/properties/wsadmin.properties* file, property name=**com.ibm.ws.scripting.port** (default value =8879).
 - The port that wsadmin should send on depends on the server process wsadmin is trying to connect to.

For a single-server installation, wsadmin attempts to connect to the application server process by default. To verify the port number:

- Look in the file *profile_root/config/cells/node_name/nodes/node_name/serverindex.xml* for a tag containing the property **serverType="APPLICATION_SERVER"**.
- Look for an entry within that tag with the property **endPointName="SOAP_CONNECTOR_ADDRESS"**.
- Look for a **port** property within that tag. This is the port wsadmin should send on.

In a Network Deployment installation, wsadmin launched from the bin directory on the Network Deployment installation attempts to send requests to the deployment manager by default. To verify the port number:

- Get the hostname of the node on which the Deployment Manager is installed.
- Using that hostname, look in *profile_root/config/cells/cell_name/nodes/node_name/serverindex.xml* file for a tag containing the property **serverType="DEPLOYMENT_MANAGER"**.

- Within that tag, look for an entry with a property `endPointName="SOAP_CONNECTOR_ADDRESS"`.
- Within that tag, look for a "port" property. This is the port that the wsadmin tool should send on.

"com.ibm.bsf.BSFException: error while eval'ing Jacl expression: no such method *command name* in class com.ibm.ws.scripting.AdminConfigClient" returned from wsadmin command.

This error is usually caused by a misspelled command name. Use the `$AdminConfig help` command to get information about what commands are available. Note that command names are case-sensitive.

WASX7022E returned from running "wsadmin -c ..." command, indicating invalid command

If the command following `-c` appears to be valid, the problem may be caused by the shell attempting to do variable substitution. Variable substitution can occur on Unix System Services if `wsadmin -c` invokes a command that is enclosed in double quotes and includes dollar signs. To confirm that this is the problem, check the command to see if it contains an unescaped dollar sign, for example: `wsadmin -c "$AdminApp install"`.

To correct this problem, escape the dollar sign with a backslash. For example: `wsadmin -c "\$AdminApp install ..."`.

Note: When the command is enclosed in single quotes, the shell does not attempt to do variable substitution. Therefore, you do not need to escape the dollar sign. Example: `wsadmin.sh -c '$AdminApp install ...'`

com.ibm.ws.scripting.ScriptingException: WASX7025E: String "" is malformed; cannot create ObjectName

One possible cause of this error is that an empty string was specified for an object name. This can happen if you use one scripting statement to create an object name and the next statement to use that name, perhaps in an "invoke" or "getAttribute" command, but you don't check to see if the first statement really returned an object name. For example (the following samples use basic Jacl commands in addition to the wsadmin Jacl extensions to make a sample script):

```
#let's misspell "Server"
set serverName [$AdminControl queryNames type=Srever,*]
$AdminControl getAttributes $serverName
```

To correct this error, make sure that object name strings have values before using them. For example:

```
set serverName[$AdminControl queryNames node=mynode,type=Server,name=server1,*]
if {$serverName == ""} {puts "queryNames returned empty - check query argument"}
else {$AdminControl getAttributes $serverName}
```

For details on Jacl syntax beyond wsadmin commands, refer to the Tcl developers' site, <http://www.tcl.tk>.

WASX701E: Exception received while running file "*scriptName.jacl*"; exception information: com.ibm.bsf.BSFException: error while evaluating Jacl expression: missing close-bracket

This error is caused by a mix-up between the code page that the scripting client expects to see and the code page in which the Jacl script was written.

To fix this problem, set the `-Dscript.encoding=script codepage` option in the `wsadmin.sh` or `wsadmin.bat` file to the code page of the Jacl script. The following guideline will help you to determine the code page of the script:

- If the script was written in the OMVS interface using the OEDIT editor, the code page is IBM-037. In this case, set the option to the following: `-Dscript.encoding=Cp037`
- If the script was written in a telnet session to the OMVS interface using the VI editor, the code page is IBM-1047. In this case, set the option to the following: `-Dscript.encoding=Cp1047`
- If the script was written on a personal computer, or any other ASCII machine, and was transferred to the host as a text file, the code page is IBM-1047. In this case, set the option to the following: `-Dscript.encoding=Cp1047`
- If the script was written on a personal computer, or any other ASCII machine, and transferred to the host in binary format, the code page is ISO-8859-1 (ASCII). In this case, you do not need to set the option because the default is ASCII. You should review other possible reasons for this error.

Unexpected error CWSIV0806E in WebSphere log following deletion of an outbound service

This error occurs when an exception is issued for destination `MPOutBoundServicePortDestination`, on messaging engine `trueliesNode01.server1-FVTSIBus01`, on bus `FVTSIBus01`, for endpoint activation:

```
com.ibm.websphere.sib.exception.SINotPossibleInCurrentConfigurationException: CWSIP0111E: The destination with name MPOutBoundServicePortDestination is being deleted on messaging engine {1}.
```

You can ignore this error; it is benign.

Separator exception

You must use forward slashes (/) as your path separator. Backward slashes (\) will not work.

Enabling authentication in the file transfer service

In WebSphere Application Server Network Deployment Version 5.0.1 or later, the file transfer service was enhanced to provide role-based authentication. Two versions of the file transfer Web application were provided. By default, the version that does not authenticate its caller is installed. This default supports compatibility between the WebSphere Application Server Network Deployment, Version 5.0 and Version 5.0.1 or later. Turning the file transfer authentication on is recommended to prevent unauthorized use of the file transfer application. However, if you have any Version 5.0 clients in your WebSphere Application Server Network Deployment environment, they will not be able to communicate with the secured file transfer application if global security is turned on.

In WebSphere Application Server Version 6.x, mixed cells are supported and file transfer has become a system application. If all of the nodes in the cell are of Version 5.0.1 or later, you can activate authentication in the file transfer service by redeploying the file transfer application at the deployment manager. The compatible version is shipped in the `${app_server_root}/systemApps/filetransfer.ear` directory. The secured version is provided in the `${app_server_root}/systemApps/filetransferSecured.ear` directory.

Also in WebSphere Application Server Version 6.x, the file transfer service is also supported for WebSphere Application Server and WebSphere Application Server Express as long as the node is not federated into a managed cell. If this node becomes federated, it will make use of the deployment manager file transfer.

A wsadmin Jacl script is provided to help you redeploy file transfer. The script is `redeployFileTransfer.jacl` and you can find it in the `${app_server_root}/bin` directory. After the deployment manager and all the nodes are at Version 5.0.1 or later, you can deploy the secured file transfer service by running the script. The syntax for running the script from the bin directory includes the following:

```
wsadmin -profile redeployFileTransfer.jacl -c "fileTransferAuthenticationXxx
cell_name node_name server_name
```

where "Xxx" is "On" or "Off".

For example, when running the script to enable use of the filetransferSecured.ear, the syntax is similar to the following example:

```
wsadmin -profile redeployFileTransfer.jacl -c  
"fileTransferAuthenticationOn managedCell managedCellManager dmgr"
```

or

```
wsadmin -profile redeployFileTransfer.jacl -c  
"fileTransferAuthenticationOn baseCell base server1"
```

If you want to go back to run the file transfer service without authentication, you can run the script as shown in the following example:

```
wsadmin -profile redeployFileTransfer.jacl -c  
"fileTransferAuthenticationOff managedCell managedCellManager dmgr"
```

or

```
wsadmin -profile redeployFileTransfer.jacl -c  
"fileTransferAuthenticationOff baseNodeCell baseNode server1"
```

The format of "\$AdminConfig list" output has changed for V6.0

If you have a script that parses the output of \$AdminConfig list, such as \$AdminConfig list Node, you might receive errors, such as "Node not found." Scripts should not parse the output of \$AdminConfig; however, if you have a script that does this parsing, it must be updated for WebSphere Application Server V6.0 to reflect changes to the output format.

You are not prompted for user ID and password after applying V6.0.2 service if you use an existing 6.0 profile

If security is enabled, executing a .bat file requires a user ID and password. On V6.0.2, a new feature is introduced to prompt you for a user ID and password if they are not supplied in the command line. However, this feature is not available for profiles that were created at the 6.0 level.

Property files for profiles created at the V6.0 level are not updated after applying the V6.0.2 refresh pack.

There are two solutions to this problem:

1. Create a new profile after applying the V6.0.2 service. This new profile contains all the updated property files and you will then be prompted for a user ID and password.
2. If you want to keep the existing V6.0 profile and use the new prompt feature, you must manually update three files:
 - for *app_server_root/properties/soap.client.props*, add the following line:
com.ibm.SOAP.loginSource=prompt
 - for *app_server_root/properties/wsjaas_client.conf*, add the following lines:
WSAdminClientLogin {
 com.ibm.ws.security.common.auth.module.proxy.WSLoginModuleProxy required del
 egate=com.ibm.ws.security.common.auth.module.WSAdminClientLoginModuleImpl;
};
 - for *app_server_root/bin/setupCmdLine.bat* add the following line:
SET JAASSOAP=-Djava.security.auth.login.config=*app_server_root/properties/*
wsjaas_client.conf

Required ports not defined when a new V5.0/V5.1 server is created

Required ports not defined when a new V5.0/V5.1 server is created

You create a new V5.0 or V5.1 server using a default template in a mixed cell environment, and all of the required ports are not defined for the newly created server.

Add the following two entries to the `serverindex.xml` directory in the deployment manager profile: `profile_root/config/templates/servertypes/APPLICATION_SERVER/serverindex.xml` directory:

- ```
<serverEntries xmi:id="ServerEntry_3" serverName="default_5X"
serverType="APPLICATION_SERVER">
 <specialEndpoints xmi:id="NamedEndPoint_25" endPointName="BOOTSTRAP_ADDRESS">
 <endPoint xmi:id="EndPoint_25" host="$(node.host.name)" port="2809"/>
 </specialEndpoints>
 <specialEndpoints xmi:id="NamedEndPoint_26" endPointName="SOAP_CONNECTOR_ADDRESS">
 <endPoint xmi:id="EndPoint_26" host="$(node.host.name)" port="8880"/>
 </specialEndpoints>
 <specialEndpoints xmi:id="NamedEndPoint_27" endPointName="SAS_SSL_
SERVERAUTH_LISTENER_ADDRESS">
 <endPoint xmi:id="EndPoint_27" host="$(node.host.name)" port="0"/>
 </specialEndpoints>
 <specialEndpoints xmi:id="NamedEndPoint_28" endPointName="CSIV2_
SSL_SERVERAUTH_LISTENER_ADDRESS">
 <endPoint xmi:id="EndPoint_28" host="$(node.host.name)" port="0"/>
 </specialEndpoints>
 <specialEndpoints xmi:id="NamedEndPoint_29" endPointName="CSIV2_
SSL_MUTUALAUTH_LISTENER_ADDRESS">
 <endPoint xmi:id="EndPoint_29" host="$(node.host.name)" port="0"/>
 </specialEndpoints>
</serverEntries>
```
- ```
<serverEntries xmi:id="ServerEntry_4" serverDisplayName="default
ZOS_5X" serverName="defaultZOS_5X" serverType="APPLICATION_SERVER"
serverUniqueId="BB80B67909190083000000DC0010200209390F08">
  <specialEndpoints xmi:id="NamedEndPoint_31" endPointName="BOOTSTRAP_ADDRESS">
    <endPoint xmi:id="EndPoint_31" host="$(node.host.name)" port="2809"/>
  </specialEndpoints>
  <specialEndpoints xmi:id="NamedEndPoint_32" endPointName="SOAP_CONNECTOR_ADDRESS">
    <endPoint xmi:id="EndPoint_32" host="$(node.host.name)" port="8880"/>
  </specialEndpoints>
  <specialEndpoints xmi:id="NamedEndPoint_33" endPointName="ORB_SSL_LISTENER_ADDRESS">
    <endPoint xmi:id="EndPoint_33" host="*" port="0"/>
  </specialEndpoints>
  <specialEndpoints xmi:id="NamedEndPoint_34" endPointName="ORB_LISTENER_ADDRESS">
    <endPoint xmi:id="EndPoint_34" host="*" port="0"/>
  </specialEndpoints>
</serverEntries>
```

The xmi:ids must all be unique within this file.

When running the `$AdminApp searchJNDIReferences` command with the Java Naming and Directory Interface (JNDI) name of a message destination, the message destination reference is not returned

This problem occurs when the command `$AdminApp searchJNDIReferences` is run with the JNDI name of a message destination. The command cannot collect the message destination reference that is defined in the application deployment descriptor. The message destination that you configured for the application server is defined with a message destination link on not one element, but two: both a message-driven bean (MDB) and a message destination reference.

Currently there is no workaround for this problem. The `$AdminApp searchJNDIReferences` command cannot return a reference for a message destination that is defined on two elements.

AWXJR0006E: Exception received when configuring JACC provider for the Tivoli Access Manager

This problem occurs when you attempt to configure a JACC provider for the Tivoli Access Manager using the wsadmin tool in a deployment manager environment with or without nodes added. You enter a deployment manager node name, for example, t54Manager, instead of an asterisk (*) for all nodes. The wsadmin command finishes successfully but when you try to add a new node and start the node, or start an existing node, you receive an error in the nodeagent SystemOut.log file similar to the following:

```
[12/7/05 17:09:51:266 CST] 0000000a SystemOut      0 AWXJR0006E   The file,
C:\cc_was602\WebSphere\AppServer\profiles\AppSrv01\etc\tam\amwas.t54Node01_.amjacc.pr
operties, was not found.
[12/7/05 17:09:51:266 CST] 0000000a distSecurityC E   SECJ0391E: Error when setting
the Policy object to the providers policy implementation {0}. The exception is
{1}.
[12/7/05 17:09:51:281 CST] 0000000a distSecurityC E   SECJ0324E: Error during Java
2 Security and Dynamic Policy initialization.
```

To workaroud this problem, unconfigure the existing Tivoli Access Manager configuration and configure it again using an asterisk (*) for the node name, for example:

```
wsadmin.bat -user wsadmin -password pw1 -f enableTAM.jacl "*" TAMHostName:7135"
TAMHostName:7136:1" "cn=wsadmin,o=ibm,c=us" "o=ibm,c=us" "sec_master"
sec_master pw1 "9990:9999"
```

WASX7017E: Exception received while running file "<application stopping script>"; exception information: javax.management.MBeanException com.ibm.ws.exception.RuntimeWarning: Application <appname> not started

While using scripting, this error is issued when you stop an application that is already stopped or start an application that is already running.

Problems using tracing, logging or other troubleshooting features

Use this information if you are having problems using tracing, logging or other troubleshooting tools.

What kind of problem are you having?

- Netscape browser fails when trying to enable a component trace.

Netscape browser fails when trying to enable a component trace

On systems using AIX, the Netscape browser fails when you try to enable trace on a component.

To work around this problem, do one of the following:

- Disable JavaScript on the browser and continue setting trace.
- Administer the AIX server from a remote machine running another browser and operating system.
- Change the trace manually in the *server.xml* file.

Timeout condition resolutions

This file gives an overview of how to resolve timeout conditions

In such a complex environment as WebSphere Application Server for z/OS, timeouts might occur for many different reasons. Although you can alter timeout values, you should not do so until you understand why the timeout occurs. Depending on the timeout condition, you might be able to permanently fix the timeout condition by doing some system or application tuning. For example, if the diagnostic data indicates throughput problems, you can alter the number of server regions, the number of threads within each server region, or the use of replicated servers.

Generally speaking, increasing the timeout values should be your last resort, or only a temporary action taken to prevent multiple timeout-abend dumps from causing system performance problems. If you increase timeout values without properly diagnosing the timeout condition, the only results you might see are less frequent abends and dumps for the same timeout condition, or slower system or application performance.

Timer overview

This file gives an overview of understanding timers

Timers define a limit to the amount of time required for a specific operation to complete. When the timer begins its countdown depends on type of operation it controls. The timers that WebSphere Application Server for z/OS uses can be classified into the general types described later in this article; the specific timers themselves are described in Controlling behavior through timeout values. Most of the timers have a default value that defines a reasonable limit for the particular operation to complete. When the timer pops (that is, reaches the time limit), WebSphere Application Server for z/OS takes one of the following actions:

- Sends a minor code to the client for timers that pop before the client request is dispatched to a servant region.
- Abnormally ends the servant region with an EC3 ABEND for timers that pop while the client request is being processed by an application component running in the servant region. All threads in the abending servant region will be terminated.

WebSphere terminates the servant region to prevent the application from tying up resources, thus causing other requests to start backing up. Once the servant is terminated, WLM starts a new servant to take its place and continue processing requests from the controller.

Note: The total transaction lifetime timeout and the maximum transaction timeout have grace periods beyond the timeout value specified of about four minutes that must be reached before an ABEND occurs.

Different types of timers might be counting down simultaneously, because the operations they control might overlap to a certain degree. For example, suppose the application server receives an IIO client request that will be processed by an application component that uses transaction support. In this case, both of the following WebSphere timers can be counting down simultaneously:

- `control_region_wlm_dispatch_timeout`, which limits both the amount of time a client request waits on the WLM queue, as well as the time required for the application component to process the request; and
- `transaction_defaultTimeout`, which limits the amount of time the controller will wait for a transaction to be either committed or rolled back.

These timers overlap only for the time during which the application's transaction is being processed. To determine which timer cause the error, you can use the symptoms- specific minor codes or EC3 ABEND reason codes.

General types of timers and the operations they control

General type	Timer processing	Timeout symptoms
Input	Input timers define limits for receiving a complete request; the countdown starts when a connection to the J2EE server is established. The communication protocol (HTTP, HTTPS) determines the timer used for the request.	The session is closed.

General type	Timer processing	Timeout symptoms
Session	Session timers define limits for the use of session connections. These timers start the countdown as soon as a session becomes idle.	The session is closed.
WLM dispatch	Dispatch timers control how long a complete client request waits to be dispatched in a servant region for processing. The countdown starts when the controller places the request on the WLM queue. Depending on the specific timer, the time limit can include not only wait time on the WLM queue, but also the time required for processing a response to the client request.	Message BBOO0232W and an EC3 ABEND in the servant (region), with one of these accompanying reason codes: 04130003 04130004 04130006
Transaction	Transaction timers define how long: <ul style="list-style-type: none"> An application or controller will wait for one transaction to complete. The countdown starts when the container starts a transaction on behalf of the application component. A controller will attempt to recover in-doubt transactions during peer restart and recovery mode. 	<ul style="list-style-type: none"> Message BBOT0003W or BBOO0232W An EC3 ABEND in the servant (region), with one of these accompanying reason codes: 04130002 04130005
Output	Output timers define how long a controller will wait to receive output for a client request. The countdown starts when the client request is dispatched to the servant region for processing. The communication protocol (HTTP, HTTPS) determines the timer used for the request.	Message BBOO0232W and an EC3 ABEND in the servant (region), with reason code 04130007

Guidelines for analyzing diagnostic data for timeout conditions

This file gives an overview of how to enable and use the System Management Facilities (SMF) to collect and record system and job-related information.

The following guidelines provide instructions for finding diagnostic data in an SVC dump that can help you determine what timeout condition occurred:

- Find the task with the EC3 abend:
 - Format the TCB summary for the servant that was timed out by entering the following command:

```
ip summ format asid(x' address ')
```

where *address* is the address space ID of the servant.

Find the TCB that had the EC3 completion code. Ignore any EC3 completion code on the "main" thread which is the 4th TCB listed in the summary format (the 1st one after the 3 MVS TCBs). The WebSphere main thread is the one that is waiting in BBO_BOA::impl_is_ready. No application requests are ever dispatched on this thread, therefore there is nothing to timeout. During timeout processing the main thread for the server region is also abended with EC3 as a mechanism of bringing the address space down. Thus the reason why the EC3 completion code may appear on the main thread. This is never the cause of a timeout though, only a result of timeout processing.

2. If there is no EC3 completion code in the TCB summary, look in systrace. Format the systrace in GMT time since the other timestamps you'll be comparing it to are in GMT time. To format in GMT time, enter the following command::

```
ip systrace all time(gmt)
```

You may not see the EC3 abend in systrace either as systrace can cover a small amount of time.

3. You can also try looking in ip verbx mtrace or in syslog to see when the EC3 abend occurred. You'll need this time to determine the 'end' time of the request which is the GMT time the timeout value was reached.
- Determine what timeout values are in effect by checking the reason code associated with the EC3 abend.

Reason code	Explanation
04130002	The controller issued an ABTERM for this servant region because a transaction timeout occurred. Code under dispatch could have been in a tight loop.
04130003	The controller issued an ABTERM for this servant region because it was hung trying to move a controller request into the servant region. The target request was timed out, but the servant was currently copying the request. The controller checked the servant for progress at regular intervals, before taking action by issuing an ABTERM.
04130004	The controller issued a ABTERM for this servant region because the WLM queue timeout occurred. Code under dispatch could have been in a tight loop.
04130005	The controller issued an ABTERM for this servant region because a transaction timeout occurred. The transaction has timed out, but no current request associated with the transaction was found. The servant associated with the transaction will be terminated.
04130006	A controller thread encountered a problem while processing a request. The request has been queued to WLM and associated with a servant region. The termination of the associated servant region is needed to complete cleanup for the request.
04130007	The controller issued a ABTERM for this servant region because the HTTP OUTPUT timeout occurred. Code under dispatch could have been in a tight loop.

- Find the method name to determine if it was

```
httpRequest
```

```
,
```

```
httpsRequest
```

or

```
DispatchbyURI
```

or some other method.

If the request is not specifically a request that came through the HTTP or HTTPS transport handlers, the

```
protocol_http_output_timeout
```

(HTTP) and

```
protocol_https_timeout_output
```

(HTTPS) timeout values will not be a factor. In other words, when the request is a DispatchbyURI

method, the request is received through the RMI/IIOP protocol, so the protocol_http

* variables have no affect.

- Obtain the callback stack for the request, using the IPCS verbexit LEDATA, with the CEEDUMP or NTHREADS option.

Timeout conditions - possible causes and fixes

This file lists common timer variables and tools for monitoring these timeout conditions

The timer that expires first might not indicate the actual problem that needs to be fixed. To properly diagnose timeout conditions, you should know all of the timer values that might be in effect for a particular servant region.

General type of timer	Possible causes	Possible solutions
Input	The client sent only part of the data and was delayed in sending the rest.	The application on the client side may want to consider having retry logic in place if it does receive a timeout minor code in return.
Session	The session is idle through lack of use.	If you consider losing idle sessions to be a problem, increase the values of the persistent-session timeouts, or use the session more frequently.
WLM dispatch	<p>No threads are free to pick up the request because of one of the following conditions:</p> <ul style="list-style-type: none"> • The threads are all busy processing requests. • The currently executing threads are waiting for a response from DB2, WebSphere MQ, another server, and so on. In this case, look for messages indicating contention for resources; for example, on the z/OS console, you might see messages about DB2 deadlocks. <p>In either case, the request times out waiting in the WLM queue to be dispatched in a servant (region).</p>	<p>The case where the threads are all busy processing requests could indicate one of the following conditions:</p> <ul style="list-style-type: none"> • The number of servant regions that WLM may start is set too low. To set this value, on the administrative console select Servers >Application Servers >server_name >Server Instance. Click on Multiple Instances Enabled and specify a value for Maximum Number of Instances. • The number of threads allowed within a servant region is set too low. The number is controlled by the Isolation Policy setting in Administrative console or WebSphere variable: <i>server_region_workload_profile</i> • You need to replicate servers to handle the amount of incoming work. <p>All of these conditions indicate that performance tuning might be necessary.</p>

General type of timer	Possible causes	Possible solutions
Transaction	Possible causes of transaction timeouts include: <ul style="list-style-type: none"> • The same as those for WLM dispatch timeouts, or • Delays that prevent the transaction coordinator from committing or rolling back a transaction within the allotted time. 	See the possible solutions for WLM dispatch timeouts. In addition, you can look for messages indicating contention for resources that are involved in the transaction that timed out.
Output	Possible causes of output timeouts are the same as those for WLM dispatch (dispatch is for IOP, output is for HTTP).	See the possible solutions for WLM dispatch timeouts. In addition, you can use the WebSphere variable <code>protocol_accept_http_work_after_min_srs=1</code> to prevent the HTTP transport handler from dispatching requests until WLM starts a minimum number of servant regions.

Guidelines for altering timeout values

This file lists common timer variables and tools for monitoring these timeout conditions

Generally speaking, increasing the timeout values should be your last resort, or only a temporary action taken to prevent multiple timeout-abend dumps from causing system performance problems. If you increase timeout values without properly diagnosing the timeout condition, the only results you might see are less frequent abends and dumps for the same timeout condition, or slower system or application performance.

For information on how to set values for these timer variables, and how these variables map to internal variables, see Controlling behavior through timeout values

Common timer variables and tools for monitoring these timeout conditions

WebSphere variable and its relationship, if any, to other timers	How to monitor processing for this type of timeout condition:	If you want to adjust the value, consider the following:
WLM timeout For HTTP work and Scalable Messaging Support, the WLM timer is not set and only the ConnectionResponseTimeout is in effect (covering the entire dispatch window)	SMF provides data on WLM queue time	How long work takes to get to a servant depends on the number of servants that WLM starts, how many you let it start, how many service classes the work is spread across, how much work you're getting, and so on.
ConnectionIOTimeout None.	This behavior is not easily monitored. Turning on a trace point would indicate whether a client failed because of this input timeout setting, but tracing has performance consequences.	<ul style="list-style-type: none"> • How long are you willing to allow a control region worker thread to be blocked while it is waiting for a message? • How big are incoming HTTP requests? The larger they are, the longer it might take to get the whole request through the network.
ConnectionResponseTimeout If the application component starts transactions, then the transaction timers also might be involved.	This behavior is not easily monitored, but the controller will terminate the servant (region) with abend EC3 for this timeout condition.	<ul style="list-style-type: none"> • How long are you willing to let a client hang waiting for a response? • How long are you willing to let a thread in a servant (region) be tied up working on a response before concluding that the request has taken too long? • If you have multiple application threads in the servant (region), all of them will be terminated when only one of them times out. This loss of work might make you want to allow these time outs to occur less frequently.
ConnectionKeepAliveTimeout None. All the other timers relate to work processing, whereas this one relates to what happens when there is no work.	None.	How much time passes between requests vs. how much does it cost to establish a new session. You would want to keep idle sessions around for a while to avoid the startup cost of a new session, but don't want to keep them forever as resource usage accumulation will eventually be a problem.

WebSphere variable and its relationship, if any, to other timers	How to monitor processing for this type of timeout condition:	If you want to adjust the value, consider the following:
Request Timeout (ORB Service) None. This variable is a client-side timeout, and IIOp only.	None, other than to observe the timeouts occurring on the client side.	How long are you willing to let the client wait?
ORB listener keep alive ORB SSL listener keep alive None. These variables relate to session activity during idle periods and only for IIOp, so these timers do not interact with the ConnectionKeepAliveTimeout timer.	You should read TCP/IP APAR PQ18618 for information about the SOCK_TCP_KEEPALIVE values and their consequences.	Is it useful to have idle sessions timeout? They normally don't which can consume resources. However, detecting a timeout requires network traffic between TCP/IP stacks. Creating traffic on otherwise idle sessions may have network consequences you don't want.
Total Transaction Lifetime Timeout This variable can be overridden by applications up to the maximum indicated by the Maximum Transaction Timeout variable, which limits the amount of time an application can set for its transactions to complete. Output timers also might cause work to time out, but the transaction timers and output timers are not aware of each other.	The controller issues message BBOT0003W to indicate a timeout condition, and terminates the servant (region) with abend EC3 reason codes 04130002 or 04130005.	<ul style="list-style-type: none"> • How long are you willing to let a client hang waiting for a response? • How long are you willing to let a thread in a servant (region) be tied up working on a response before concluding that the request has taken too long? • If you have multiple application threads in the servant (region), all of them will be terminated when only one of them times out. This loss of work might make you want to allow these time-outs to occur less frequently.
Maximum Transaction Timeout If set, this variable limits the amount of time an application can set for its transactions to complete. If the Maximum Transaction Timeout variable is not set, application transactions are controlled by the time limit set on the Total Transaction Lifetime Timeout variable.	None.	Same considerations as for transaction_defaultTimeout
transaction_recoveryTimeout None	None.	Locks are held while one controller (region) waits for other controllers that are required to resolve in-doubt transactions. How long can you afford to have these resources held?

Appendix. Directory conventions

References in the product information to *app_server_root*, *profile_root*, and other directories imply specific directory locations. This topic describes the conventions in use for WebSphere Application Server for z/OS.

smpe_root

Refers to the root directory for product code installed with SMP/E.

The corresponding product variable is `smpe.install.root`.

The default is `/usr/lpp/zWebSphere/V6R1`.

configuration_root

Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

The `configuration_root` contains the various `app_server_root` directories and certain symbolic links associated with them. Each different `configuration_root` normally requires its own cataloged procedures under z/OS.

The default is `/WebSphere/V6R1`.

app_server_root

Refers to the top directory for a WebSphere Application Server node.

The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own `app_server_root`. Before Version 6.0 of the product information, this was referred to as the "WAS_HOME" directory. Corresponding product variables are `was.install.root` and `WAS_HOME`.

The default varies based on node type. Common defaults are `configuration_root/Appserver` and `configuration_root/DeploymentManager`.

profile_root

Refers to the home directory for a particular instantiated WebSphere Application Server profile.

Corresponding product variables are `server.root` and `user.install.root`.

In general, this is the same as `app_server_root/profiles/profile_name`. On z/OS, this will be always be `app_server_root/profiles/default` because only the profile name "default" is used in WebSphere Application Server for z/OS.
